67.4.3 LPUART clocks

The simplified block diagram given in Figure 825 shows two fully independent clock domains:

- The lpuart_pclk clock domain
  The lpuart_pclk clock signal feeds the peripheral bus interface. It must be active when accesses to the LPUART registers are required.
- The lpuart_ker_ck kernel clock domain
  The lpuart_ker_ck is the LPUART clock source. It is independent of the lpuart_pclk and delivered by the RCC. So, the LPUART registers can be written/read even when the lpuart_ker_ck is stopped.
  When the dual clock domain feature is not supported, the lpuart_ker_ck is the same as the lpuart_pclk clock.
  There is no constraint between lpuart_pclk and lpuart_ker_ck: lpuart_ker_ck can be faster or slower than lpuart_pclk, with no more limitation than the ability for the software to manage the communication fast enough.

67.4.4 LPUART character description

The word length can be set to 7 or 8 or 9 bits, by programming the M bits (M0: bit 12 and M1: bit 28) in the LPUART_CR1 register (see Figure 801).

- 7-bit character length: M[1:0] = '10
- 8-bit character length: M[1:0] = 00
- 9-bit character length: M[1:0] = 01

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

An Idle character is interpreted as an entire frame of “1”s. (The number of “1” ‘s includes the number of stop bits).

A Break character is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator. The transmission and reception clocks are generated when the enable bit is set for the transmitter and receiver, respectively.

The details of each block is given below.

67.4.5 LPUART FIFOs and thresholds

The LPUART can operate in FIFO mode.

The LPUART comes with a Transmit FIFO (TXFIFO) and a Receive FIFO (RXFIFO). The FIFO mode is enabled by setting FIFOEN bit (bit 29) in LPUART_CR1 register.

Since 9 bits the maximum data word length is 9 bits, the TXFIFO is 9-bits wide. However the RXFIFO default width is 12 bits. This is due to the fact that the receiver does not only store the data in the FIFO, but also the error flags associated to each character (Parity error, Noise error and Framing error flags).

Note: The received data is stored in the RXFIFO together with the corresponding flags. However, only the data are read when reading the RDR.

The status flags are available in the LPUART_ISR register.

It is possible to define the TXFIFO and RXFIFO levels at which the Tx and RX interrupts are triggered. These thresholds are programmed through RXFTCFG and TXFTCFG bitfields in LPUART_CR3 control register.

In this case:

- The Rx interrupt is generated when the number of received data in the RXFIFO reaches the threshold programmed in the RXFTCFG bitfields.
  In this case, the RXF flag is set in the LPUART_ISR register. This means that RXFTCFG data have been received: 1 data in LPUART_RDR and (RXFTCFG - 1) data in the RXFIFO. As an example, when the RXFTCFG is programmed to ‘101, the RXF flag is set when a number of data corresponding to the FIFO size has been received: FIFO size - 1 data in the RXFIFO and 1 data in the LPUART_RDR. As a result, the next received data does not set the overrun flag.

- The Tx interrupt is generated when the number of empty locations in the TXFIFO reaches the threshold programmed in the TXFTCFG bitfields.

67.4.6 LPUART transmitter

The transmitter can send data words of either 7 or 8 or 9 bits, depending on the M bit status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin.

Character transmission

During an LPUART transmission, data shifts out least significant bit first (default configuration) on the TX pin. In this mode, the LPUART_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see Figure 825).

When FIFO mode is enabled, the data written to the LPUART_TDR register are queued in the TXFIFO.

Every character is preceded by a start bit which corresponds to a low logic level for one bit period. The character is terminated by a configurable number of stop bits.

The number of stop bits can be 1 or 2.
**Note:** The TE bit must be set before writing the data to be transmitted to the LPUART_TDR. The TE bit must not be reset during data transmission. Resetting the TE bit during the transmission corrupts the data on the TX pin as the baud rate counters is frozen. The current data being transmitted are lost.

An idle frame is sent after the TE bit is enabled.

**Configurable stop bits**

The number of stop bits to be transmitted with every character can be programmed in LPUART_CR2 (bits 13,12).

- **1 stop bit:** This is the default value of number of stop bits.
- **2 Stop bits:** This is supported by normal LPUART, Single-wire and Modem modes.

An idle frame transmission includes the stop bits.

A break transmission is 10 low bits (when M[1:0] = 00) or 11 low bits (when M[1:0] = 01) or 9 low bits (when M[1:0] = 10) followed by 2 stop bits. It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

**Figure 827. Configurable stop bits**

![Configurable stop bits diagram](MS31885V1)

**Character transmission procedure**

To transmit a character, follow the sequence below:

1. Program the M bits in LPUART_CR1 to define the word length.
2. Select the desired baud rate using the LPUART_BRR register.
3. Program the number of stop bits in LPUART_CR2.
4. Enable the LPUART by writing the UE bit in LPUART_CR1 register to 1.
5. Select DMA enable (DMAT) in LPUART_CR3 if Multi buffer Communication is to take place. Configure the DMA register as explained in Section 67.4.13: Continuous communication using DMA and LPUART.
6. Set the TE bit in LPUART_CR1 to send an idle frame as first transmission.
7. Write the data to send in the LPUART_TDR register. Repeat this operation for each data to be transmitted in case of single buffer.
   - When FIFO mode is disabled, writing a data in the LPUART_TDR clears the TXE flag.
   - When FIFO mode is enabled, writing a data in the LPUART_TDR adds one data to the TXFIFO. Write operations to the LPUART_TDR are performed when TXFNF flag is set. This flag remains set until the TXFIFO is full.

8. When the last data is written to the LPUART_TDR register, wait until TC=1. This indicates that the transmission of the last frame is complete.
   - When FIFO mode is disabled, this indicates that the transmission of the last frame is complete.
   - When FIFO mode is enabled, this indicates that both TXFIFO and shift register are empty.
   This check is required to avoid corrupting the last transmission when the LPUART is disabled or enters Halt mode.

Single byte communication

- When FIFO mode disabled:
  Writing to the transmit data register always clears the TXE bit. The TXE flag is set by hardware to indicate that:
    - the data have been moved from the LPUART_TDR register to the shift register and data transmission has started;
    - the LPUART_TDR register is empty;
    - the next data can be written to the LPUART_TDR register without overwriting the previous data.
  The TXE flag generates an interrupt if the TXEIE bit is set.
  When a transmission is ongoing, a write instruction to the LPUART_TDR register stores the data in the TDR register, which is copied to the shift register at the end of the current transmission.
  When no transmission is ongoing, a write instruction to the LPUART_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

- When FIFO mode is enabled, the TXFNF (TXFIFO Not Full) flag is set by hardware to indicate that:
  - the TXFIFO is not full;
  - the LPUART_TDR register is empty;
  - the next data can be written to the LPUART_TDR register without overwriting the previous data. When a transmission is ongoing, a write operation to the
LPUART_TDR register stores the data in the TXFIFO. Data are copied from the TXFIFO to the shift register at the end of the current transmission.

When the TXFIFO is not full, the TXFNF flag stays at 1 even after a write in LPUART_TDR. It is cleared when the TXFIFO is full. This flag generates an interrupt if TXFNEIE bit is set.

Alternatively, interrupts can be generated and data can be written to the TXFIFO when the TXFIFO threshold is reached. In this case, the CPU can write a block of data defined by the programmed threshold.

If a frame is transmitted (after the stop bit) and the TXE flag (TXFE is case of FIFO mode) is set, the TC bit goes high. An interrupt is generated if the TCIE bit is set in the LPUART_CR1 register.

After writing the last data in the LPUART_TDR register, it is mandatory to wait for TC=1 before disabling the LPUART or causing the microcontroller to enter the low-power mode (see Figure 828: TC/TXE behavior when transmitting).

**Figure 828. TC/TXE behavior when transmitting**

---

**Note:** When FIFO management is enabled, the TXFNF flag is used for data transmission.

**Break characters**

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bits (see Figure 826).

If a 1 is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The LPUART inserts a logic 1 signal (STOP) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

When the SBKRQ bit is set, the break character is sent at the end of the current transmission.
When FIFO mode is enabled, sending the break character has priority on sending data even if the TXFIFO is full.

**Idle characters**

Setting the TE bit drives the LPUART to send an idle frame before the first data frame.

### 67.4.7 LPUART receiver

The LPUART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the LPUART_CR1 register.

**Start bit detection**

In the LPUART, the start bit is detected when a falling edge occurs on the Rx line, followed by a sample taken in the middle of the start bit to confirm that it is still 0. If the start sample is at 1, then the noise error flag (NE) is set, then the start bit is discarded and the receiver waits for a new start bit. Else, the receiver continues to sample all incoming bits normally.

**Character reception**

During an LPUART reception, data are shifted in least significant bit first (default configuration) through the RX pin. In this mode, the LPUART_RDR register consists of a buffer (RDR) between the internal bus and the received shift register.

**Character reception procedure**

To receive a character, follow the sequence below:

1. Program the M bits in LPUART_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register LPUART_BRR.
3. Program the number of stop bits in LPUART_CR2.
4. Enable the LPUART by writing the UE bit in LPUART_CR1 register to 1.
5. Select DMA enable (DMAR) in LPUART_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in Section 67.4.13: Continuous communication using DMA and LPUART.
6. Set the RE bit LPUART_CR1. This enables the receiver which begins searching for a start bit.

When a character is received

- When FIFO mode is disabled, the RXNE bit is set. It indicates that the content of the shift register is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags).
- When FIFO mode is enabled, the RXFNE bit is set indicating that the RXFIFO is not empty. Reading the LPUART_RDR returns the oldest data entered in the RXFIFO.
When a data is received, it is stored in the RXFIFO, together with the corresponding error bits.

- An interrupt is generated if the RXNEIE (RXFNEIE in case of FIFO mode) bit is set.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception.
- In Multibuffer communication mode:
  - When FIFO mode is disabled, the RXNE flag is set after every byte received and is cleared by the DMA read of the Receive Data Register.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every DMA request, a data is retrieved from the RXFIFO. DMA request is triggered by RXFIFO is not empty i.e. there is a data in the RXFIFO to be read.
- In Single-buffer mode:
  - When FIFO mode is disabled, clearing the RXNE flag is done by performing a software read from the LPUART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register. The RXNE bit must be cleared before the end of the reception of the next character to avoid an overrun error.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every read operation from the LPUART_RDR register, a data is retrieved from the RXFIFO. When the RXFIFO is empty, the RXFNE flag is cleared. The RXFNE flag can also be cleared by writing 1 to the RXFRQ bit in the LPUART_RQR register. When the RXFIFO is full, the first entry in the RXFIFO must be read before the end of the reception of the next character to avoid an overrun error. The RXFNE flag generates an interrupt if the RXFNEIE bit is set. Alternatively, interrupts can be generated and data can be read from RXFIFO when the RXFIFO threshold is reached. In this case, the CPU can read a block of data defined by the programmed threshold.

**Break character**

When a break character is received, the USART handles it as a framing error.

**Idle character**

When an idle frame is detected, it is handled in the same way as a data character reception except that an interrupt is generated if the IDLEIE bit is set.
Overrun error

- **FIFO mode disabled**
  
  An overrun error occurs when a character is received when RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared. The RXNE flag is set after every byte received.

  An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:
  - the ORE bit is set;
  - the RDR content is not lost. The previous data is available when a read to LPUART_RDR is performed.;
  - the shift register is overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXNEIE bit or EIE bit is set.

- **FIFO mode enabled**
  
  An overrun error occurs when the shift register is ready to be transferred when the receive FIFO is full.

  Data can not be transferred from the shift register to the LPUART_RDR register until there is one free location in the RXFIFO. The RXFNE flag is set when the RXFIFO is not empty.

  An overrun error occurs if the RXFIFO is full and the shift register is ready to be transferred. When an overrun error occurs:
  - the ORE bit is set;
  - the first entry in the RXFIFO is not lost. It is available when a read to LPUART_RDR is performed.
  - the shift register is overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXFNEIE bit or EIE bit is set.

The ORE bit is reset by setting the ORECF bit in the ICR register.

*Note:*

The ORE bit, when set, indicates that at least 1 data has been lost. T

When the FIFO mode is disabled, there are two possibilities

- if RXNE=1, then the last valid data is stored in the receive register (RDR) and can be read,
- if RXNE=0, then the last valid data has already been read and there is nothing left to be read in the RDR. This case can occur when the last valid data is read in the RDR at the same time as the new (and lost) data is received.

Selecting the clock source

The choice of the clock source is done through the Clock Control system (see *Section Reset and clock controller (RCC)*). The clock source must be selected through the UE bit, before enabling the LPUART.

The clock source must be selected according to two criteria:

- Possible use of the LPUART in low-power mode
- Communication speed.

The clock source frequency is lpuart_ker_ck.
When the dual clock domain and the wake-up from low-power mode features are supported, the `lpuart_ker_ck` clock source can be configured in the RCC (see Section Reset and clock controller (RCC)). Otherwise, the `lpuart_ker_ck` is the same as `lpuart_pclk`.

The `lpuart_ker_ck` can be divided by a programmable factor in the LPUART\_PRES register.

**Figure 829. lpuart_ker_ck clock divider block diagram**

Some `lpuart_ker_ck` sources enable the LPUART to receive data while the MCU is in low-power mode. Depending on the received data and Wake-up mode selection, the LPUART wakes up the MCU, when needed, in order to transfer the received data by software reading the LPUART\_RDR register or by DMA.

For the other clock sources, the system must be active to enable LPUART communications.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver samples each incoming bit as close as possible to the middle of the bit-period. Only a single sample is taken of each of the incoming bits.

*Note:* *There is no noise detection for data.*

**Framing error**

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:
- the FE bit is set by hardware;
- the invalid data is transferred from the Shift register to the LPUART\_RDR register.
- no interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multibuffer communication, an interrupt is issued if the EIE bit is set in the LPUART\_CR3 register.

The FE bit is reset by writing 1 to the FECF in the LPUART\_ICR register.
Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of LPUART_CR2: it can be either 1 or 2 in Normal mode.

- **1 stop bit**: sampling for 1 stop bit is done on the 8th, 9th and 10th samples.
- **2 stop bits**: sampling for the 2 stop bits is done in the middle of the second stop bit. The RXNE and FE flags are set just after this sample i.e. during the second stop bit. The first stop bit is not checked for framing error.

### 67.4.8 LPUART baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the value programmed in the LPUART_BRR register.

\[
\text{Tx/Rx baud} = \frac{256 \times \text{lpuart\_ker\_ck\_pres}}{\text{LPUARTDIV}}
\]

LPUARTDIV is defined in the LPUART_BRR register.

**Note:** The baud counters are updated to the new value in the baud registers after a write operation to LPUART_BRR. Hence the baud rate register value must not be changed during communication.

*It is forbidden to write values lower than 0x300 in the LPUART_BRR register.*

\(f_{CK}\) must range from 3 x baud rate to 4096 x baud rate.

The maximum baud rate that can be reached when the LPUART clock source is the LSE, is 9600 bauds. Higher baud rates can be reached when the LPUART is clocked by clock sources different from the LSE clock. For example, if the LPUART clock source frequency is 100 MHz, the maximum baud rate that can be reached is about 33 Mbauds.

</table>
67.4.9 Tolerance of the LPUART receiver to clock deviation

The asynchronous receiver of the LPUART works correctly only if the total clock system deviation is less than the tolerance of the LPUART receiver. The causes which contribute to the total deviation are:

- \( DTRA \): deviation due to the transmitter error (which also includes the deviation of the transmitter’s local oscillator)
- \( DQUANT \): error due to the baud rate quantization of the receiver
- \( DREC \): deviation of the receiver local oscillator
- \( DTCL \): deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

\[
DTRA + DQUANT + DREC + DTCL + DWU < \text{LPUART receiver tolerance}
\]

where

\[
DWU = \frac{t_{WUPUART}}{11 \times T\text{bit}}
\]

when \( M[1:0] = 01 \):

\[
DWU = \frac{t_{WUPUART}}{10 \times T\text{bit}}
\]

when \( M[1:0] = 00 \):

\[
DWU = \frac{t_{WUPUART}}{9 \times T\text{bit}}
\]

\( t_{WUPUART} \) is the time between the detection of the start bit falling edge and the instant when the clock (requested by the peripheral) is ready and reaching the peripheral, and the regulator is ready.

The LPUART receiver can receive data correctly at up to the maximum tolerated deviation specified in Table 685:

- Number of Stop bits defined through STOP[1:0] bits in the LPUART_CR2 register
- LPUART_BRR register value.

Note: The data specified in Table 685 may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M bits = 00 (11-bit times when M = '01 or 9- bit times when M = '10).

67.4.10 LPUART multiprocessor communication

It is possible to perform LPUART multiprocessor communications (with several LPUARTs connected in a network). For instance one of the LPUARTs can be the master, with its TX output connected to the RX inputs of the other LPUARTs. The others are slaves, with their respective TX outputs are logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations it is often desirable that only the intended message recipient actively receives the full message contents, thus reducing redundant LPUART service overhead for all non addressed receivers.

The non addressed devices can be placed in Mute mode by means of the muting function. To use the Mute mode feature, the MME bit must be set in the LPUART_CR1 register.

Note: When FIFO management is enabled and MME is already set, MME bit must not be cleared and then set again quickly (within two lpuart_ker_ck cycles), otherwise Mute mode might remain active.

When the Mute mode is enabled:

• none of the reception status bits can be set;
• all the receive interrupts are inhibited;
• the RWU bit in LPUART_ISR register is set to 1. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the LPUART_RQR register, under certain conditions.

The LPUART can enter or exit from Mute mode using one of two methods, depending on the WAKE bit in the LPUART_CR1 register:

• Idle Line detection if the WAKE bit is reset,
• Address mark detection if the WAKE bit is set.

Idle line detection (WAKE=0)

The LPUART enters Mute mode when the MMRQ bit is written to 1 and the RWU is automatically set.

The LPUART wakes up when an Idle frame is detected. The RWU bit is then cleared by hardware but the IDLE bit is not set in the LPUART_ISR register. An example of Mute mode behavior using Idle line detection is given in Figure 830.
Figure 830. Mute mode using Idle line detection

<table>
<thead>
<tr>
<th>RX</th>

<th>Data 2</th>
<th>Data 3</th>
<th>Data 4</th>
<th>IDLE</th>
<th>Data 5</th>
<th>Data 6</th>
</tr>
</thead>
</table>

| RWU | Mute mode | Normal mode |

MMRQ written to 1
Idle frame detected

Note: If the MMRQ is set while the IDLE character has already elapsed, Mute mode is not entered (RWU is not set).

If the LPUART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

4-bit/7-bit address mark detection (WAKE=1)

In this mode, bytes are recognized as addresses if their MSB is a 1 otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the LPUART_CR2 register.

Note: In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The LPUART enters Mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the LPUART enters Mute mode.

The LPUART also enters Mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case.

The LPUART exits from Mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE/RXFNE bit is set for the address character since the RWU bit has been cleared.

Note: When FIFO management is enabled, when MMRQ bit is set while the receiver is sampling the last bit of a data, this data may be received before effectively entering in Mute mode.

An example of Mute mode behavior using address mark detection is given in Figure 831.
67.4.11 LPUART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the LPUART_CR1 register. Depending on the frame length defined by the M bits, the possible LPUART frame formats are as listed in Table 686.

<table>
<thead>

<td>SB</td>
</tr>
</tbody>
</table>

2. In the data register, the PB is always taking the MSB position (8th or 7th, depending on the M bit value).

Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame which is made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101, and 4 bits are set, then the parity bit is equal to 0 if even parity is selected (PS bit in LPUART_CR1 = 0).

Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101 and 4 bits set, then the parity bit is equal to 1 if odd parity is selected (PS bit in LPUART_CR1 = 1).
Parity checking in reception

If the parity check fails, the PE flag is set in the LPUART_ISR register and an interrupt is generated if PEIE is set in the LPUART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the LPUART_ICR register.

Parity generation in transmission

If the PCE bit is set in LPUART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).

67.4.12 LPUART single-wire Half-duplex communication

Single-wire Half-duplex mode is selected by setting the HDSEL bit in the LPUART_CR3 register.

The LPUART can be configured to follow a Single-wire Half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in LPUART_CR3.

As soon as HDSEL is written to 1:
- The TX and RX lines are internally connected.
- The RX pin is no longer used
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal LPUART mode. Any conflict on the line must be managed by software (for instance by using a centralized arbiter). In particular, the transmission is never blocked by hardware and continues as soon as data is written in the data register while the TE bit is set.

Note: In LPUART communications, in the case of 1-stop bit configuration, the RXNE flag is set in the middle of the stop bit.

67.4.13 Continuous communication using DMA and LPUART

The LPUART is capable of performing continuous communication using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

Note: Refer to Section 66.4: USART implementation on page 2747 to determine if the DMA mode is supported. If DMA is not supported, use the LPUSRT as explained in Section 66.5.7. To perform continuous communication. When FIFO is disabled, clear the TXE/ RXNE flags in the LPUART_ISR register.

Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the LPUART_CR3 register. Data are loaded from an SRAM area configured using the DMA peripheral (refer to Section Direct memory access controller) to the LPUART_TDR register whenever the TXE flag (TXFNF flag if FIFO mode is enabled) is set. To map a DMA channel for LPUART transmission, use the following procedure (x denotes the channel number):
1. Write the LPUART_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE (or TXFNF if FIFO mode is enabled) event.

2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the LPUART_TDR register from this memory area after each TXE (or TXFNF if FIFO mode is enabled) event.

3. Configure the total number of bytes to be transferred to the DMA control register.

4. Configure the channel priority in the DMA register.

5. Configure DMA interrupt generation after half/full transfer as required by the application.

6. Clear the TC flag in the LPUART_ISR register by setting the TCCF bit in the LPUART_ICR register.

7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In Transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the TC flag can be monitored to make sure that the LPUART communication is complete. This is required to avoid corrupting the last transmission before disabling the LPUART or entering low-power mode. Software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.

Note: The DMAT bit must not be cleared before the DMA end of transfer.

Figure 832. Transmission using DMA
Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in LPUART_CR3 register. Data are loaded from the LPUART_RDR register to a SRAM area configured using the DMA peripheral (refer to section Direct memory access controller (DMA)) whenever a data byte is received. To map a DMA channel for LPUART reception, use the following procedure:

1. Write the LPUART_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE (RXFNE in case FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from LPUART_RDR to this memory area after each RXNE (RXFNE in case FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register.
5. Configure interrupt generation after half/full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

Note: The DMAR bit must not be cleared before the DMA end of transfer.

Figure 833. Reception using DMA

Error flagging and interrupt generation in multibuffer communication

If any error occurs during a transaction in Multibuffer communication mode, the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE (RXFNE in case FIFO mode is enabled) in single byte reception, there is a separate error flag interrupt.
enable bit (EIE bit in the LPUART_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

### 67.4.14 RS232 Hardware flow control and RS485 Driver Enable

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The Figure 834 shows how to connect 2 devices in this mode:

**Figure 834. Hardware flow control between 2 LPUARTs**

RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits respectively to 1 (in the LPUART_CR3 register).

**RS232 RTS flow control**

If the RTS flow control is enabled (RTSE=1), then RTS is deasserted (tied low) as long as the LPUART receiver is ready to receive a new data. When the receive register is full, RTS is asserted, indicating that the transmission is expected to stop at the end of the current frame. Figure 835 shows an example of communication with RTS flow control enabled.

**Figure 835. RS232 RTS flow control**

*Note:* When FIFO mode is enabled, RTS is asserted only when RXFIFO is full.
RS232 CTS flow control

If the CTS flow control is enabled (CTSE = 1), then the transmitter checks the CTS input before transmitting the next frame. If CTS is deasserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE/TXFE=0), else the transmission does not occur. When CTS is asserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE = 1, the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the LPUART_CR3 register is set. Figure 836 shows an example of communication with CTS flow control enabled.

**Figure 836. RS232 CTS flow control**

![Diagram showing CTS flow control](image)

**Note:** For correct behavior, CTS must be deasserted at least 3 LPUART clock source periods before the end of the current character. In addition it must be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.

RS485 driver enable

The driver enable feature is enabled by setting bit DEM in the LPUART_CR3 control register. This enables activating the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the start bit. It is programmed using the DEAT [4:0] bitfields in the LPUART_CR1 control register. The de-assertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bitfields in the LPUART_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the LPUART_CR3 control register.
The LPUART DEAT and DEDT are expressed in LPUART clock source (fCK) cycles:
- The Driver enable assertion time equals
  - \((1 + (\text{DEAT} \times P)) \times f_{\text{CK}}, \text{if } P \neq 0\)
  - \((1 + \text{DEAT}) \times f_{\text{CK}}, \text{if } P = 0\)
- The Driver enable de-assertion time equals
  - \((1 + (\text{DEDT} \times P)) \times f_{\text{CK}}, \text{if } P \neq 0\)
  - \((1 + \text{DEDT}) \times f_{\text{CK}}, \text{if } P = 0\)

where \(P = \text{BRR}[20:11]\)

### 67.4.15 LPUART Autonomous mode

The LPUART peripheral can be functional in Stop mode thanks to the Autonomous mode. This mode can also be used in Run and Sleep mode. The UESM bit must be set prior to entering low-power mode.

The APB clock is requested by the peripheral each time the LPUART status needs to be updated. Once the LPUART receives the kernel and APB clocks, it generates either an interrupt or a DMA request, depending on the peripheral configuration.

If an interrupt is generated, the device wakes up from Stop mode. If no interrupt is generated, the device remains in Stop mode but the APB clock is still available for the LPUART and all the autonomous peripherals enabled in the reset and clock controller (RCC). If DMA requests are enabled, the data are directly transferred to/from the SRAM thanks to the DMA while the product remains in Stop mode.

### Transmission mode

In transmission, the APB clock is requested only when the TE bit is set and in the following cases:
- If the FIFO mode is enabled, the APB clock is requested when
  - the TxFIFO is empty (TXFE = 1) and the corresponding interrupt is enabled (TXFEIE = 1)
  - the TxFIFO threshold is reached (TXFT = 1) and the corresponding interrupt is enabled (TXFTIE = 1)
  - the TxFIFO is not full (TXFNF = 1) and the corresponding interrupt or DMA is enabled (TXFNFIE = 1 or DMAT = 1)
- If the FIFO mode is disabled, the APB clock is requested as soon as data are transferred to the shift register. The DMA or associated interrupt must be enabled.

The TE bit is set by hardware if an asynchronous trigger is detected.

A transmission is automatically launched when an asynchronous trigger is detected in Run, Sleep or Stop mode. The trigger is selected through the TRIGSEL bit in the LPUART_AUTOCR register. It sets the TE bit in the LPUART_CR1 register and generates an APB clock request to enable the transfer. The APB clock is requested until the transmission completes and the TE bit is cleared by hardware when the programmed number of data to be transmitted (TDN bits field in the LPUART_AUTOCR register) is reached. In this case, the TC flag is set when the number of data to be transmitted is reached and the last byte is transmitted.
Reception mode

- If the FIFO mode is enabled, the APB clock is requested when
  - the RxFIFO is full (RXFF = 1) and the corresponding interrupt is enabled (RXFFIE = 1)
  - the RxFIFO threshold is reached (RXFT = 1) and the corresponding interrupt is enabled (RXFTIE = 1)
  - the RxFIFO is not empty (RXFNE = 1) and the corresponding interrupt or DMA is enabled (RXFNEIE = 1)
- If the FIFO mode is disabled, the APB clock is requested when the LPUART finishes sampling data and it is ready to be written in the LPUART_RDR. The DMA or the associated interrupt must be enabled.

Note: The APB clock is requested in Reception mode when an overrun error occurs (ORE = 1). The EIE bit must be set to enable the generation an interrupt and waking up the MCU, and the OVRDIS bit must remain cleared. The APB clock request is kept until the interrupt flag is cleared.

In Reception mode, the APB clock is requested when a Parity/Noise/Framing error occurs and the DMA is used for reception. The APB clock request is kept until the interrupt flag is cleared.

Determining the maximum LPUART baud rate that enables to correctly wake up the MCU from low-power mode

The maximum baud rate that enables to correctly wake up the MCU from low-power mode depends on the wake-up time parameter (refer to the device datasheet) and on the LPUART receiver tolerance (see Section 67.4.9: Tolerance of the LPUART receiver to clock deviation).

Let us take the example of OVER8 = 0, M bits = 01, ONEBIT = 0 and BRR [3:0] = 0000.

In these conditions, according to Table 685: Tolerance of the LPUART receiver, the LPUART receiver tolerance equals 3.41%.

\[
D_{WU\text{max}} = \frac{t_{WULPUART}}{11 \times T_{\text{bit Min}}} \\
T_{\text{bit Min}} = \frac{t_{WULPUART}}{11 \times D_{WU\text{max}}} \\
\text{where } t_{WULPUART} \text{ is the wake-up time from low-power mode.}
\]

If we consider the ideal case where DTRA, DQUANT, DREC and DTCL parameters are at 0%, the maximum value of DWU is 3.41%. In reality, we need to consider at least the lpuart_ker_ck inaccuracy.

For example, if HSI is used as lpuart_ker_ck, and the HSI inaccuracy is of 1%, then we obtain:

\[
t_{WULPUART} = 3 \mu s \text{ (values provided only as examples; for correct values, refer to the device datasheet).} \\
D_{WU\text{max}} = 3.41\% - 1\% = 2.41\% \\
T_{\text{bit min}} = 3 \mu s / (11 \times 2.41\%) = 11.32 \mu s.
\]

As a result, the maximum baud rate that enables to wake up correctly from low-power mode is: \(1/11.32 \mu s = 88.36 \text{ kbauds}\).
67.5 LPUART in low-power modes

Table 687. Effect of low-power modes on the LPUART

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. LPUART interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>

</table>

1. The LPUART can wake up the device from Stop mode only if the peripheral instance supports the Wake-up from Stop mode feature. Refer to Section 67.3: LPUART implementation for the list of supported Stop modes.
2. RXFF flag is asserted if the LPUART receives \( n+1 \) data (\( n \) being the RXFIFO size): \( n \) data in the RXFIFO and 1 data in LPUART_RDR. In Stop mode, LPUART_RDR is not clocked. As a result, this register is not written and once \( n \) data are received and written in the RXFIFO, the RXFF interrupt is asserted (RXFF flag is not set).

3. Parity/Noise/Framing error interrupts enable waking up from Stop modes when the DMA is used.

4. When OVRDIS = 0.

5. The DMA must be used when the FIFO mode is enabled.

### 67.7 LPUART registers

Refer to Section 1.2 on page 126 for a list of abbreviations used in register descriptions. The peripheral registers have to be accessed by words (32 bits).

### 67.7.1 LPUART control register 1 (LPUART_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

Bit 28  M1: Word length
This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.
M[1:0] = 00: 1 Start bit, 8 Data bits, n Stop bit
M[1:0] = 01: 1 Start bit, 9 Data bits, n Stop bit
M[1:0] = 10: 1 Start bit, 7 Data bits, n Stop bit
This bit can only be written when the LPUART is disabled (UE=0).

Note: In 7-bit data length mode, the Smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.

Bits 27:26  Reserved, must be kept at reset value.

Bits 25:21  DEAT[4:0]: Driver Enable assertion time
This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in lpuart_ker_ck clock cycles. For more details, refer Section 66.5.21: RS232 Hardware flow control and RS485 Driver Enable.
This bitfield can only be written when the LPUART is disabled (UE=0).

Bits 20:16  DEDT[4:0]: Driver Enable deassertion time
This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in lpuart_ker_ck clock cycles. For more details, refer Section 67.4.14: RS232 Hardware flow control and RS485 Driver Enable.
If the LPUART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 15  Reserved, must be kept at reset value.

Bit 14  CMIE: Character match interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated when the CMF bit is set in the LPUART_ISR register.

Bit 13  MME: Mute mode enable
This bit activates the Mute mode function of the LPUART. When set, the LPUART can switch between the active and Mute modes, as defined by the WAKE bit. It is set and cleared by software.
0: Receiver in Active mode permanently
1: Receiver can switch between Mute mode and Active mode.

Bit 12  M0: Word length
This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).
This bit can only be written when the LPUART is disabled (UE=0).

Bit 11  WAKE: Receiver wake-up method
This bit determines the LPUART wake-up method from Mute mode. It is set or cleared by software.
0: Idle line
1: Address mark
This bitfield can only be written when the LPUART is disabled (UE=0).
Bit 10  **PCE:** Parity control enable
This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).
0: Parity control disabled
1: Parity control enabled
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 9  **PS:** Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.
0: Even parity
1: Odd parity
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 8  **PEIE:** PE interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever PE=1 in the LPUART_ISR register

Bit 7  **TXFNFIE:** TXFIFO not full interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever TXFN =1 in the LPUART_ISR register

Bit 6  **TCIE:** Transmission complete interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever TC=1 in the LPUART_ISR register

Bit 5  **RXFNEIE:** RXFIFO not empty interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever ORE=1 or RXFNE=1 in the LPUART_ISR register

Bit 4  **IDLEIE:** IDLE interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever IDLE=1 in the LPUART_ISR register

Bit 3  **TE:** Transmitter enable
This bit enables the transmitter. When the Autonomous mode is not used, TE bit is set and cleared by software. When the Autonomous mode is used, TE bit becomes a status bit, which is set and cleared by hardware.
0: Transmitter is disabled
1: Transmitter is enabled

**Note:** During transmission, a low pulse on the TE bit (0 followed by 1) sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to 1. To ensure the required duration, the software can poll the TEACK bit in the USART_ISR register.

In Smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.
### LPUART control register 1 [alternate] (LPUART_CR1)

**Address offset:** 0x00  
**Reset value:** 0x0000 0000

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

#### FIFO mode disabled

RM0456 Low-power universal asynchronous receiver transmitter (LPUART)

Bits 31:30  Reserved, must be kept at reset value.

Bit 29 **FIFOEN**: FIFO mode enable
   This bit is set and cleared by software.
   0: FIFO mode is disabled.
   1: FIFO mode is enabled.

Bit 28 **M1**: Word length
   This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.
   \( M[1:0] = 00 \): 1 Start bit, 8 Data bits, n Stop bit
   \( M[1:0] = 01 \): 1 Start bit, 9 Data bits, n Stop bit
   \( M[1:0] = 10 \): 1 Start bit, 7 Data bits, n Stop bit
   This bit can only be written when the LPUART is disabled (UE=0).

Note: In 7-bit data length mode, the Smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.

Bits 27:26  Reserved, must be kept at reset value.

Bits 25:21 **DEAT[4:0]**: Driver Enable assertion time
   This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in lpuart_ker_ck clock cycles. For more details, refer Section 66.5.21: RS232 Hardware flow control and RS485 Driver Enable.
   This bitfield can only be written when the LPUART is disabled (UE=0).

Bits 20:16 **DEDT[4:0]**: Driver Enable deassertion time
   This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in lpuart_ker_ck clock cycles. For more details, refer Section 67.4.14: RS232 Hardware flow control and RS485 Driver Enable.
   If the LPUART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.
   This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 15  Reserved, must be kept at reset value.

Bit 14 **CMIE**: Character match interrupt enable
   This bit is set and cleared by software.
   0: Interrupt is inhibited
   1: A LPUART interrupt is generated when the CMF bit is set in the LPUART_ISR register.

Bit 13 **MME**: Mute mode enable
   This bit activates the Mute mode function of the LPUART. When set, the LPUART can switch between the active and Mute modes, as defined by the WAKE bit. It is set and cleared by software.
   0: Receiver in Active mode permanently
   1: Receiver can switch between Mute mode and Active mode.

Bit 12 **M0**: Word length
   This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).
   This bit can only be written when the LPUART is disabled (UE=0).
Bit 11 **WAKE**: Receiver wake-up method
This bit determines the LPUART wake-up method from Mute mode. It is set or cleared by software.
0: Idle line
1: Address mark
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 10 **PCE**: Parity control enable
This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).
0: Parity control disabled
1: Parity control enabled
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 9 **PS**: Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.
0: Even parity
1: Odd parity
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 8 **PEIE**: PE interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever PE=1 in the LPUART_ISR register

Bit 7 **TXEIE**: Transmit data register empty
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever TXE =1 in the LPUART_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever TC=1 in the LPUART_ISR register

Bit 5 **RXNEIE**: Receive data register not empty
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever ORE=1 or RXNE=1 in the LPUART_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever IDLE=1 in the LPUART_ISR register
Bit 3 TE: Transmitter enable
This bit enables the transmitter. When the Autonomous mode is disabled, TE bit is set and cleared by software. When the Autonomous mode is enabled, TE bit becomes a status bit, which is set and cleared by hardware.
0: Transmitter is disabled
1: Transmitter is enabled

Note: During transmission, a low pulse on the TE bit (0 followed by 1) sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to 1. To ensure the required duration, the software can poll the TEACK bit in the LPUART_ISR register.
In Smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.

Bit 2 RE: Receiver enable
This bit enables the receiver. It is set and cleared by software.
0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1 UESM: LPUART enable in low-power mode
When this bit is cleared, the LPUART cannot request its kernel clock and is not functional in low-power mode.
When this bit is set, the LPUART can wake up the MCU from low-power mode.
This bit is set and cleared by software.
0: LPUART not functional in low-power mode.
1: LPUART functional in low-power mode.

Note: The UESM bit must be set at the initialization phase.
If the LPUART does not support the Wake-up from low-power mode, this bit is reserved and must be kept at reset value. Refer to Section 67.3: LPUART implementation on page 2833.

Bit 0 UE: LPUART enable
When this bit is cleared, the LPUART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the LPUART is kept, but all the status flags, in the LPUART_ISR are reset. This bit is set and cleared by software.
0: LPUART prescaler and outputs disabled, low-power mode
1: LPUART enabled

Note: To enter low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the LPUART_ISR to be set before resetting the UE bit.
The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.
## LPUART control register 2 (LPUART_CR2)

### Bits 31:24 **ADD[7:0]**: Address of the LPUART node

These bits give the address of the LPUART node in Mute mode or a character code to be recognized in low-power or Run mode:

- In Mute mode: they are used in multiprocessor communication to wake up from Mute mode with 4-bit/7-bit address mark detection. The MSB of the character sent by the transmitter must be equal to 1. In 4-bit address mark detection, only ADD[3:0] bits are used.
- In low-power mode: they are used for wake up from low-power mode on character match. When a character, received during low-power mode, corresponds to the character programmed through ADD[7:0] bitfield, the CMF flag is set and wakes up the device from low-power mode if the corresponding interrupt is enabled by setting CMIE bit.
- In Run mode with Mute mode inactive (for example, end-of-block detection in ModBus protocol): the whole received character (8 bits) is compared to ADD[7:0] value and CMF flag is set on match. An interrupt is generated if the CMIE bit is set.

These bits can only be written when the reception is disabled (RE = 0) or when the USART is disabled (UE = 0).

### Bits 23:20 Reserved, must be kept at reset value.

**Bit 19** **MSBFIRST**: Most significant bit first  
This bit is set and cleared by software.

0: data is transmitted/received with data bit 0 first, following the start bit.
1: data is transmitted/received with the MSB (bit 7/8) first, following the start bit.

This bitfield can only be written when the LPUART is disabled (UE=0).

**Bit 18** **DATAINV**: Binary data inversion  
This bit is set and cleared by software.

0: Logical data from the data register are send/received in positive/direct logic. (1=H, 0=L)
1: Logical data from the data register are send/received in negative/inverse logic. (1=L, 0=H). The parity bit is also inverted.

This bitfield can only be written when the LPUART is disabled (UE=0).

**Bit 17** **TXINV**: TX pin active level inversion  
This bit is set and cleared by software.

0: TX pin signal works using the standard logic levels (VDD =1/idle, Gnd=0/mark)
1: TX pin signal values are inverted. ((VDD =0/mark, Gnd=1/idle).

This enables the use of an external inverter on the TX line.

This bitfield can only be written when the LPUART is disabled (UE=0).
Bit 16 **RXINV**: RX pin active level inversion
This bit is set and cleared by software.
0: RX pin signal works using the standard logic levels ($V_{DD} = 1/\text{idle}, Gnd=0/\text{mark}$)
1: RX pin signal values are inverted. ($(V_{DD} = 0/\text{mark}, Gnd=1/\text{idle}$).
This enables the use of an external inverter on the RX line.
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 15 **SWAP**: Swap TX/RX pins
This bit is set and cleared by software.
0: TX/RX pins are used as defined in standard pinout
1: The TX and RX pins functions are swapped. This enables to work in the case of a cross-wired connection to another UART.
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 14 Reserved, must be kept at reset value.

Bits 13:12 **STOP[1:0]**: STOP bits
These bits are used for programming the stop bits.
00: 1 stop bit
01: Reserved.
10: 2 stop bits
11: Reserved
This bitfield can only be written when the LPUART is disabled (UE=0).

Bits 11:5 Reserved, must be kept at reset value.

Bit 4 **ADDM7**: 7-bit Address Detection/4-bit Address Detection
This bit is for selection between 4-bit address detection or 7-bit address detection.
0: 4-bit address detection
1: 7-bit address detection (in 8-bit data mode)
This bit can only be written when the LPUART is disabled (UE=0)

Note: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address ($ADD[5:0]$ and $ADD[7:0]$) respectively.

Bits 3:0 Reserved, must be kept at reset value.

**67.7.4 LPUART control register 3 (LPUART_CR3)**
Address offset: 0x08
Reset value: 0x0000 0000

Bits 31:29 **TXFTCFG[2:0]**: TXFIFO threshold configuration
- 000: TXFIFO reaches 1/8 of its depth.
- 001: TXFIFO reaches 1/4 of its depth.
- 110: TXFIFO reaches 1/2 of its depth.
- 100: TXFIFO reaches 7/8 of its depth.
- 101: TXFIFO becomes empty.
- Remaining combinations: Reserved.

Bit 28 **RXFTIE**: RXFIFO threshold interrupt enable
- This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated when Receive FIFO reaches the threshold programmed in RXFTCFG.

Bits 27:25 **RXFTCFG[2:0]**: Receive FIFO threshold configuration
- 000: Receive FIFO reaches 1/8 of its depth.
- 001: Receive FIFO reaches 1/4 of its depth.
- 110: Receive FIFO reaches 1/2 of its depth.
- 011: Receive FIFO reaches 3/4 of its depth.
- 100: Receive FIFO reaches 7/8 of its depth.
- 101: Receive FIFO becomes full.
- Remaining combinations: Reserved.

Bit 24 Reserved, must be kept at reset value.

Bit 23 **TXFTIE**: TXFIFO threshold interrupt enable
- This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: A LPUART interrupt is generated when TXFIFO reaches the threshold programmed in TXFTCFG.

Bits 22:16 Reserved, must be kept at reset value.

Bit 15 **DEP**: Driver enable polarity selection
- 0: DE signal is active high.
- 1: DE signal is active low.
- This bit can only be written when the LPUART is disabled (UE=0).

Bit 14 **DEM**: Driver enable mode
- This bit enables the user to activate the external transceiver control, through the DE signal.
- 0: DE function is disabled.
- 1: DE function is enabled. The DE signal is output on the RTS pin.
- This bit can only be written when the LPUART is disabled (UE=0).

Bit 13 **DDRE**: DMA Disable on Reception Error
- 0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data is transferred.
- 1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE before clearing the error flag.
- This bit can only be written when the LPUART is disabled (UE=0).

*Note: The reception errors are: parity error, framing error or noise error.*
Bit 12 **OVRDIS**: Overrun Disable
- This bit is used to disable the receive overrun detection.
  - 0: Overrun Error Flag, ORE is set when received data is not read before receiving new data.
  - 1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set, the ORE flag is not set and the new received data overwrites the previous content of the LPUART_RDR register.
- This bit can only be written when the LPUART is disabled (UE=0).

*Note: This control bit enables checking the communication flow w/o reading the data.*

Bit 11 **Reserved, must be kept at reset value.**

Bit 10 **CTSE**: CTS interrupt enable
- 0: Interrupt is inhibited
- 1: An interrupt is generated whenever CTSIF=1 in the LPUART_ISR register

Bit 9 **CTSE**: CTS enable
- 0: CTS hardware flow control disabled
- 1: CTS mode enabled, data is only transmitted when the CTS input is deasserted (tied to 0).
  - If the CTS input is asserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while CTS is asserted, the transmission is postponed until CTS is deasserted.
  - This bit can only be written when the LPUART is disabled (UE=0)

Bit 8 **RTSE**: RTS enable
- 0: RTS hardware flow control disabled
- 1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted.
- The RTS output is deasserted (pulled to 0) when data can be received.
  - This bit can only be written when the LPUART is disabled (UE=0).

Bit 7 **DMAT**: DMA enable transmitter
- This bit is set/reset by software
- 0: DMA mode is enabled for transmission
- 1: DMA mode is disabled for transmission

Bit 6 **DMAR**: DMA enable receiver
- This bit is set/reset by software
- 0: DMA mode is enabled for reception
- 1: DMA mode is disabled for reception

Bits 5:4 **Reserved, must be kept at reset value.**

Bit 3 **HDSEL**: Half-duplex selection
- Selection of Single-wire Half-duplex mode
- 0: Half-duplex mode is not selected
- 1: Half-duplex mode is selected
  - This bit can only be written when the LPUART is disabled (UE=0).

Bits 2:1 **Reserved, must be kept at reset value.**

Bit 0 **EIE**: Error interrupt enable
- Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error or noise flag (FE=1 or ORE=1 or NE=1 in the LPUART_ISR register).
- 0: Interrupt is inhibited
- 1: An interrupt is generated when FE=1 or ORE=1 or NE=1 in the LPUART_ISR register.
67.7.5 LPUART baud rate register (LPUART_BRR)

This register can only be written when the LPUART is disabled (UE=0). It may be automatically updated by hardware in auto baud rate detection mode.

Address offset: 0x0C

Reset value: 0x0000 0000

Note: It is forbidden to write values lower than 0x300 in the LPUART_BRR register. Provided that LPUART_BRR must be ≥ 0x300 and LPUART_BRR is 20 bits, a care must be taken when generating high baud rates using high fck values. fck must be in the range [3 x baud rate..4096 x baud rate].

67.7.6 LPUART request register (LPUART_RQR)

Address offset: 0x18

Reset value: 0x0000 0000

Note: In FIFO mode, the TXFNF flag is reset during the flush request until TxFIFO is empty in order to ensure that no data are written in the data register.

Bit 4 TXFRQ: Transmit data flush request

This bit is used when FIFO mode is enabled. TXFRQ bit is set to flush the whole FIFO. This sets the flag TXFE (TXFIFO empty, bit 23 in the LPUART_ISR register).

Note: In FIFO mode, the TXFNF flag is reset during the flush request until TxFIFO is empty in order to ensure that no data are written in the data register.

Bit 3 RXFRQ: Receive data flush request

Writing 1 to this bit clears the RXNE flag. This enables discarding the received data without reading it, and avoid an overrun condition.
Bit 2 **MMRQ**: Mute mode request  
Writing 1 to this bit puts the LPUART in Mute mode and resets the RWU flag.

Bit 1 **SBKRQ**: Send break request  
Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available.  
**Note**: If the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software must wait for the TXE flag assertion before setting the SBKRQ bit.

Bit 0 Reserved, must be kept at reset value.

### 67.7.7 LPUART interrupt and status register (LPUART_ISR)

Address offset: 0x1C  
Reset value: 0x0080 00C0  
The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

#### FIFO mode enabled

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **TXFT**: TXFIFO threshold flag  
This bit is set by hardware when the TXFIFO reaches the threshold programmed in TXFTCFG in LPUART_CR3 register i.e. the TXFIFO contains TXFTCFG empty locations. An interrupt is generated if the TXFTIE bit =1 (bit 31) in the LPUART_CR3 register.  
0: TXFIFO does not reach the programmed threshold.  
1: TXFIFO reached the programmed threshold.

Bit 26 **RXFT**: RXFIFO threshold flag  
This bit is set by hardware when the RXFIFO reaches the threshold programmed in RXFTCFG in LPUART_CR3 register i.e. the Receive FIFO contains RXFTCFG data. An interrupt is generated if the RXFTIE bit =1 (bit 27) in the LPUART_CR3 register.  
0: Receive FIFO does not reach the programmed threshold.  
1: Receive FIFO reached the programmed threshold.

Bit 25 Reserved, must be kept at reset value.

Bit 24 **RXFF**: RXFIFO Full  
This bit is set by hardware when the number of received data corresponds to RXFIFO size + 1 (RXFIFO full + 1 data in the LPUART_RDR register. An interrupt is generated if the RXFFIE bit =1 in the LPUART_CR1 register.  
0: RXFIFO is not Full.  
1: RXFIFO is Full.
<table>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>23</td>
<td><strong>TXFE</strong>: TXFIFO Empty</td>
<td>This bit is set by hardware when TXFIFO is Empty. When the TXFIFO contains at least one data, this flag is cleared. The TXFE flag can also be set by writing 1 to the bit TXFRQ (bit 4) in the LPUART_RQR register. An interrupt is generated if the TXFEIE bit =1 (bit 30) in the LPUART_CR1 register. 0: TXFIFO is not empty. 1: TXFIFO is empty.</td>
</tr>
<tr>
<td>22</td>
<td><strong>REACK</strong>: Receive enable acknowledge flag</td>
<td>This bit is set/reset by hardware, when the Receive Enable value is taken into account by the LPUART. It can be used to verify that the LPUART is ready for reception before entering low-power mode. <em>Note</em>: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.</td>
</tr>
<tr>
<td>21</td>
<td><strong>TEACK</strong>: Transmit enable acknowledge flag</td>
<td>This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the LPUART. It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the LPUART_CR1 register, in order to respect the TE=0 minimum period.</td>
</tr>
<tr>
<td>20</td>
<td>Reserved, must be kept at reset value.</td>
<td></td>
</tr>
<tr>
<td>19</td>
<td><strong>RWU</strong>: Receiver wake-up from Mute mode</td>
<td>This bit indicates if the LPUART is in Mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the LPUART_CR1 register. When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the LPUART_RQR register. 0: Receiver in Active mode 1: Receiver in Mute mode <em>Note</em>: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.</td>
</tr>
<tr>
<td>18</td>
<td><strong>SBKF</strong>: Send break flag</td>
<td>This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRFQ bit in the LPUART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission. 0: No break character transmitted 1: Break character transmitted</td>
</tr>
<tr>
<td>17</td>
<td><strong>CMF</strong>: Character match flag</td>
<td>This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the LPUART_ICR register. An interrupt is generated if CMIE=1 in the LPUART_CR1 register. 0: No Character match detected 1: Character match detected</td>
</tr>
<tr>
<td>16</td>
<td><strong>BUSY</strong>: Busy flag</td>
<td>This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not). 0: LPUART is idle (no reception) 1: Reception on going</td>
</tr>
<tr>
<td>15:11</td>
<td>Reserved, must be kept at reset value.</td>
<td></td>
</tr>
</tbody>
</table>
Bit 10  **CTS**: CTS flag  
This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.  
0: CTS line set  
1: CTS line reset  
*Note*: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 9  **CTSIF**: CTS interrupt flag  
This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the LPUART_ICR register.  
An interrupt is generated if CTSIE=1 in the LPUART_CR3 register.  
0: No change occurred on the CTS status line  
1: A change occurred on the CTS status line  
*Note*: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bit 7  **TXFNF**: TXFIFO not full  
TXFNF is set by hardware when TXFIFO is not full, and so data can be written in the LPUART_TDR. Every write in the LPUART_TDR places the data in the TXFIFO. This flag remains set until the TXFIFO is full. When the TXFIFO is full, this flag is cleared indicating that data cannot be written into the LPUART_TDR.  
The TXFNF is kept reset during the flush request until TXFIFO is empty. After sending the flush request (by setting TXFRQ bit), the flag TXFNF must be checked prior to writing in TXFIFO (TXFNF and TXFE are set at the same time).  
An interrupt is generated if the TXFNFIE bit =1 in the LPUART_CR1 register.  
0: Data register is full/Transmit FIFO is full.  
1: Data register/Transmit FIFO is not full.  
*Note*: This bit is used during single buffer transmission.

Bit 6  **TC**: Transmission complete  
This bit indicates that the last data written in the LPUART_TDR has been transmitted out of the shift register. The TC flag behaves as follows:  
- When TDN = 0, the TC flag is set when the transmission of a frame containing data is complete and when TXFE is set.  
- When TDN is equal to the number of data in the TXFIFO, the TC flag is set when TXFIFO is empty and TDN is reached.  
- When TDN is greater than the number of data in the TXFIFO, TC remains cleared until the TXFIFO is filled again to reach the programmed number of data to be transferred.  
- When TDN is less than the number of data in the TXFIFO, TC is set when TDN is reached even if the TXFIFO is not empty.  
An interrupt is generated if TCIE=1 in the LPUART_CR1 register.  
TC bit is cleared by software by writing 1 to the TCCF in the LPUART_ICR register or by writing to the LPUART_TDR register.
Bit 5 **RXFNE**: RXFIFO not empty
RXFNE bit is set by hardware when the RXFIFO is not empty, and so data can be read from the LPUART_RDR register. Every read of the LPUART_RDR frees a location in the RXFIFO. It is cleared when the RXFIFO is empty.

The RXFNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register.

An interrupt is generated if RXFNEIE=1 in the LPUART_CR1 register.

- 0: Data is not received
- 1: Received data is ready to be read

Bit 4 **IDLE**: Idle line detected
This bit is set by hardware when an Idle line is detected. An interrupt is generated if IDLEIE=1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the LPUART_ICR register.

- 0: No Idle line is detected
- 1: Idle line is detected

*Note:* The **IDLE** bit is not set again until the **RXFNE** bit has been set (i.e. a new idle line occurs).

If Mute mode is enabled (MME=1), IDLE is set if the LPUART is not mute (RWU=0), whatever the Mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.

Bit 3 **ORE**: Overrun error
This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the LPUART_RDR register while RXFF = 1. It is cleared by a software, writing 1 to the ORECF, in the LPUART_ICR register.

An interrupt is generated if RXFNEIE=1 in the LPUART_CR1 register, or EIE = 1 in the LPUART_CR3 register.

- 1: Overrun error is detected

*Note:* When this bit is set, the LPUART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the **ORE** flag is set during multi buffer communication if the EIE bit is set.

This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the LPUART_CR3 register.
**Bit 2 NE:** Start bit noise detection flag

This bit is set by hardware when noise is detected on the start bit of a received frame. It is cleared by software, writing 1 to the NFCF bit in the LPUART_ICR register.

0: No noise is detected
1: Noise is detected

*Note:* This bit does not generate an interrupt as it appears at the same time as the RXFNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

This error is associated with the character in the LPUART_RDR.

**Bit 1 FE:** Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the LPUART_ICR register.

When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).

An interrupt is generated if EIE = 1 in the LPUART_CR3 register.

0: No Framing error is detected
1: Framing error or break character is detected

*Note:* This error is associated with the character in the LPUART_RDR.

**Bit 0 PE:** Parity error

This bit is set by hardware when a parity error occurs in Reception mode. It is cleared by software, writing 1 to the PECF in the LPUART_ICR register.

An interrupt is generated if PEIE = 1 in the LPUART_CR1 register.

0: No parity error
1: Parity error

*Note:* This error is associated with the character in the LPUART_RDR.

### 67.7.8 LPUART interrupt and status register [alternate] (LPUART_ISR)

Address offset: 0x1C

Reset value: 0x0000 00C0

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

**FIFO mode disabled**

**Note:** This error is associated with the character in the LPUART_RDR.
Bits 31:23  Reserved, must be kept at reset value.

Bit 22  **REACK**: Receive enable acknowledge flag  
This bit is set/reset by hardware, when the Receive Enable value is taken into account by the LPUART.  
It can be used to verify that the LPUART is ready for reception before entering low-power mode.  

*Note:* If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.

Bit 21  **TEACK**: Transmit enable acknowledge flag  
This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the LPUART.  
It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the LPUART_CR1 register, in order to respect the TE=0 minimum period.

Bit 20  Reserved, must be kept at reset value.

Bit 19  **RWU**: Receiver wake-up from Mute mode  
This bit indicates if the LPUART is in Mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the LPUART_CR1 register.  
When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the LPUART_RQR register.  
0: Receiver in Active mode  
1: Receiver in Mute mode  

*Note:* If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.

Bit 18  **SBKF**: Send break flag  
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the LPUART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.  
0: No break character transmitted  
1: Break character transmitted

Bit 17  **CMF**: Character match flag  
This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the LPUART_ICR register.  
An interrupt is generated if CMIE=1in the LPUART_CR1 register.  
0: No Character match detected  
1: Character match detected

Bit 16  **BUSY**: Busy flag  
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).  
0: LPUART is idle (no reception)  
1: Reception on going

Bits 15:11  Reserved, must be kept at reset value.
Bit 10 **CTS**: CTS flag
This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.
0: CTS line set
1: CTS line reset

*Note:* If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 9 **CTSIF**: CTS interrupt flag
This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the LPUART_ICR register.
An interrupt is generated if CTSIE=1 in the LPUART_CR3 register.
0: No change occurred on the CTS status line
1: A change occurred on the CTS status line

*Note:* If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **TXE**: Transmit data register empty
TXE is set by hardware when the content of the LPUART_TDR register has been transferred into the shift register. It is cleared by a write to the LPUART_TDR register.
An interrupt is generated if the TXEIE bit =1 in the LPUART_CR1 register.
0: Data register is full/Transmit FIFO is full.
1: Data register/Transmit FIFO is not full.

*Note:* This bit is used during single buffer transmission.

Bit 6 **TC**: Transmission complete
This bit indicates that the last data written in the USART_TDR has been transmitted out of the shift register. The TC flag is set when the transmission of a frame containing data is complete and when TXE is set.
An interrupt is generated if TCIE=1 in the LPUART_CR1 register.
TC bit is cleared by software by writing 1 to the TCCF in the USART_ICR register or by writing to the USART_TDR register.

Bit 5 **RXNE**: Read data register not empty
RXNE bit is set by hardware when the content of the LPUART_RDR shift register has been transferred to the LPUART_RDR register. It is cleared by a read to the LPUART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register.
The RXFNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register.
An interrupt is generated if RXNEIE=1 in the LPUART_CR1 register.
0: Data is not received
1: Received data is ready to be read.

Bit 4 **IDLE**: Idle line detected
This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE=1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the LPUART_ICR register.
0: No Idle line is detected
1: Idle line is detected

*Note:* The IDLE bit is not set again until the RXNE bit has been set (i.e. a new idle line occurs).

*If Mute mode is enabled (MME=1), IDLE is set if the LPUART is not mute (RWU=0), whatever the Mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.*

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **RDR[8:0]**: Receive data value

- Contains the received data character.
- The RDR register provides the parallel interface between the input shift register and the internal bus (see Figure 825).
- When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.
67.7.11 LPUART transmit data register (LPUART_TDR)

Address offset: 0x28
Reset value: 0x0000 0000

</table>

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 TDR[8:0]: Transmit data value

- Contains the data character to be transmitted.
- The TDR register provides the parallel interface between the internal bus and the output shift register (see Figure 825).
- When transmitting with the parity enabled (PCE bit set to 1 in the LPUART_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

Note: This register must be written only when TXE/TXFN=1.

67.7.12 LPUART prescaler register (LPUART_PRESC)

This register can only be written when the LPUART is disabled (UE=0).

Address offset: 0x2C
Reset value: 0x0000 0000

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **PRESCALER[3:0]**: Clock prescaler
   The LPUART input clock can be divided by a prescaler:
   - 0000: input clock not divided
   - 0001: input clock divided by 2
   - 0010: input clock divided by 4
   - 0011: input clock divided by 6
   - 0100: input clock divided by 8
   - 0101: input clock divided by 10
   - 0110: input clock divided by 12
   - 0111: input clock divided by 16
   - 1000: input clock divided by 32
   - 1001: input clock divided by 64
   - 1010: input clock divided by 128
   - 1011: input clock divided by 256
   Remaining combinations: Reserved.

   **Note:** When **PRESCALER** is programmed with a value different of the allowed ones, programmed prescaler value is equal to 1011 i.e. input clock divided by 256.

| 31:23 | Reserved, must be kept at reset value.
| 22:19 | **TRIGSEL[3:0]**: Trigger selection bits
   Refer to Section : Description LPUART interconnections.
   This bitfield can be written only when the UE bit is cleared in LPUART_CR1 register.
   - 0000: lpuart_trg0 selected
   - 0001: lpuart_trg1 selected
   ...
   - 1111: lpuart_trg15 selected

   **Note:** This bitfield can be written only when the UE bit of LPUART_CR1 register is cleared.

Bit 18  **IDLEDIS**: Idle frame transmission disable bit after enabling the transmitter
   - 0: Idle frame sent after enabling the transmitter (TE = 1 in LPUART_CR1)
   - 1: Idle frame not sent after enabling the transmitter

   **Note:** This bitfield can be written only when the UE bit of LPUART_CR1 register is cleared.
Bit 17 **TRIGEN**: Trigger enable bit
- 0: Trigger disabled
- 1: Trigger enabled

*Note: This bitfield can be written only when the UE bit of LPUART_CR1 register is cleared. When a trigger is detected, TE is set to 1 in LPUART_CR1 and the data transfer is launched.*

Bit 16 **TRIGPOL**: Trigger polarity bit
- 0: Trigger active on rising edge
- 1: Trigger active on falling edge

Bits 15:0 **TDN[15:0]**: TDC transmission data number
This bitfield enables the programming of the number of data to be transmitted. It can be written only when UE is cleared in LPUART_CR1.

Refer to Section 2.3 for the register boundary addresses.
68 Serial peripheral interface (SPI)

68.1 Introduction

The serial peripheral interface (SPI) can be used to communicate with external devices while using the specific synchronous protocol. The SPI protocol supports half-duplex, full-duplex and simplex synchronous, serial communication with external devices. The interface can be configured as master or slave and is capable of operating in multi slave or multi master configurations. The device configured as master provides communication clock (SCK) to the slave device. The Slave select (SS) and ready (RDY) signals can be applied optionally just to setup communication with concrete slave and to assure it handles the data flow properly. The Motorola data format is used by default, but some other specific modes are supported as well.

68.2 SPI main features

- Full-duplex synchronous transfers on three lines
- Half-duplex synchronous transfer on two lines (with bidirectional data line)
- Simplex synchronous transfers on two lines (with unidirectional data line)
- From 4- up to 32-bit data size selection or fixed to 8-bit multiples
- Multi master or multi slave mode capability
- Dual clock domain, the peripheral kernel clock is independent from the APB bus clock
- Baud rate prescaler up to kernel frequency/2 or bypass from RCC in Master mode
- Protection of configuration and setting
- Hardware or software management of SS for both master and slave
- Adjustable minimum delays between data and between SS and data flow
- Configurable SS signal polarity and timing, MISO x MOSI swap capability
- Programmable clock polarity and phase
- Programmable data order with MSB-first or LSB-first shifting
- Programmable number of data within a transaction to control SS and CRC
- Dedicated transmission and reception flags with interrupt capability
- SPI Motorola and TI formats support
- Hardware CRC feature can verify integrity of the communication at the end of transaction by:
  - Adding CRC value in Tx mode
  - Automatic CRC error checking for Rx mode
- Error detection with interrupt capability in case of data overrun, CRC error, data underrun, the mode fault and frame error, depending upon the operating mode
- Two multiples of 8-bit embedded Rx and Tx FIFOs (FIFO size depends on instance)
- Configurable FIFO thresholds (data packing)
- Capability to handle data streams by system DMA controller
- Configurable behavior for slave underrun condition (support of cascaded circular buffers)
• Autonomous functionality in Stop modes (handling of the transaction flow and required clock distribution) with wake-up from Stop capability
• Optional status pin RDY signalizing the slave device ready to handle the data flow

68.3 SPI implementation

Table 690 describes the SPI implementation. The instances are applied either with a full set or a limited set of features.

Table 690. SPI features

Note: For detailed information about instances capabilities to exit from Stop and Standby modes refer to Table 696: SPI wake-up and interrupt requests and Table 100: Functionalities depending on the working mode.
68.4 SPI functional description

68.4.1 SPI block diagram

The SPI enables a synchronous, serial communication between the MCU and external devices. The application software can manage the communication by polling the status flag or using a dedicated SPI interrupt. The main SPI elements and their interactions are shown in Figure 837.

The simplified scheme of Figure 837 shows three fully independent clock domains:
- the spi_pclk clock domain
- the spi_ker_ck kernel clock domain
- the serial interface clock domain

All the control and status signals between these domains are strictly synchronized. There is no specific constraint concerning the frequency ratio between these clock signals. The user has to consider a ratio compatible with the data flow speed to avoid data underrun or overrun events.
The **spi_pclk** clock signal feeds the peripheral bus interface. It must be active when accesses to the SPI registers are required.

The SPI working in Slave mode handles a data flow using the serial interface clock derived from the external SCK signal provided by the external master SPI device. This is why the SPI slave is able to receive and send data even when the **spi_pclk** and **spi_ker_ck** clock signals are inactive. As a consequence, a specific slave logic working within the serial interface clock domain needs some additional traffic to be setup correctly (for example when underrun or overrun is evaluated, see Section 68.5.2 for details). This cannot be done when the bus becomes idle. In some cases the slave even requires the clock generator working (see Section 68.5.1).

When the SPI works as master, it needs **spi_ker_ck** kernel clock coming from RCC active during communication to feed the serial interface clock via the clock generator where it can be divided by prescaler or bypassed optionally. The signal is then provided to slaves via the SCK pin and internally to the serial interface domain of the master.

### 68.4.2 SPI pins and internal signals

Up to five I/O pins are dedicated to SPI communication with external devices.

- **MISO**: master in / slave out data. In the general case, this pin is used to transmit data in Slave mode and receive data in Master mode.
- **MOSI**: master out / slave in data. In the general case, this pin is used to transmit data in Master mode and receive data in Slave mode.
- **SCK**: serial clock output pin for SPI masters and input pin for SPI slaves.
- **SS**: slave select pin. Depending on the SPI and SS settings, this pin can be used to either:
  - select an individual slave device for communication
  - synchronize the data frame, or
  - detect a conflict between multiple masters
  See Section 68.4.7 for details.
- **RDY**: optional status pin signaling slave FIFO occupancies and so the slave availability to continue the transaction without any risk of data flow corruption. It can be checked by master to control temporal suspension of the ongoing communication.

The SPI bus enables the communication between one master device and one or more slave devices. The bus consists of at least two wires: one for the clock signal and the other for synchronous data transfer. Other signals are optional and can be added depending on the data exchange between SPI nodes and their communication control management.

Refer to **Table 691** and **Table 692** for the list of SPI input / output pins and internal signals.

1. This connection is not present in STM32U535/545 since COMP2 is not available.
68.4.3 SPI communication general aspects

The SPI allows the MCU to communicate using different configurations, depending on the device targeted and the application requirements. These configurations use 2 or 3 wires (with software SS management) or 3 or 4 wires (with hardware SS management). The communication is always initiated and controlled by the master. The master provides a clock signal on the SCK line and selects or synchronizes slave(s) for communication by SS line when it is managed by hardware. The data between the master and the slave flow on the MOSI and/or MISO lines.

68.4.4 Communications between one master and one slave

The communication flow may use one of 3 possible modes: the full-duplex (3 wires) mode, half-duplex (2 wires) mode or the simplex (2 wires) mode. The SS signal is optional in single master-slave configuration and is often not connected between the two communication nodes. Nevertheless, the SS signal can be helpful in this configuration to synchronize the data flow and it is used by default for some specific SPI modes (for example the TI mode).

The next optional RDY signal can help to assure correct management of all the transacted data at slave side.

**Full-duplex communication**

By default, the SPI is configured for full-duplex communication (bits COMM[1:0] = 00 in the SPI_CFG2 register). In this configuration, the shift registers of the master and slave are
linked using two unidirectional lines between the MOSI and the MISO pins. During the SPI communication, the data are shifted synchronously on the SCK clock edges provided by the master. The master transmits the data to be sent to the slave via the MOSI line and receives data from the slave via the MISO line simultaneously. When the data frame transfer is complete (all the bits are shifted) the information between the master and slave is exchanged.

**Figure 838. Full-duplex single master/ single slave application**

1. To apply SS pins interconnection is not mandatory to make the SPI interface working (see Section 68.4.7 for details).
2. RDY signal provided by slave can be read by master optionally.

**Half-duplex communication**

The SPI can communicate in half-duplex mode by setting \( \text{COMM}[1:0] = 11 \) in the SPI_CFG2 register. In this configuration, one single cross connection line is used to link the shift registers of the master and slave together. During this communication, the data are synchronously shifted between the shift registers on the SCK clock edge in the transfer direction selected reciprocally by both master and slave with the HDDIR bit in their SPI_CR1 registers. Note that the SPI must be disabled when changing direction of the communication. In this configuration, the MISO pin at master and the MOSI pin at slave are free for other application uses and act as GPIOs.

**Figure 839. Half-duplex single master/ single slave application**

1. To apply SS pins interconnection is not mandatory to make the SPI interface working (see Section 68.4.7 for details).
2. In this configuration, the MISO pin at master and MOSI pin at slave can be used as GPIOs.

3. A critical situation can happen when the communication direction is not changed synchronously between two nodes working in bidirectional mode. The new transmitter accesses the common data line while the former transmitter still keeps an opposite value on the line (the value depends on the SPI configuration and communicated data). The nodes can conflict temporarily with opposite output levels on the line until the former transmitter changes its data direction setting. It is suggested to insert a serial resistance between MISO and MOSI pins in this mode to protect the conflicting outputs and limit the current flow between them.

4. RDY signal provided by slave can be read by master optionally.

**Simplex communications**

The SPI can communicate in simplex mode by setting the SPI in transmit-only or in receive-only using the COMM[1:0] field in the SPI_CFG2 register. In this configuration, only one line is used for the transfer between the shift registers of the master and slave. The remaining MISO or MOSI pins pair is not used for communication and can be used as standard GPIOs.

- **Transmit-only mode: COMM[1:0] = 01**
  
  The master in transmit-only mode generates the clock as long as there are data available in the TxFIFO and the master transfer is ongoing.
  
  The slave in transmit-only mode sends data as long as it receives a clock on the SCK pin and the SS pin (or software managed internal signal) is active (see Section 68.4.7).

- **Receive-only mode: COMM[1:0] = 10**
  
  In Master mode, the MOSI output is disabled and may be used as GPIO. The clock signal is generated continuously as long as the SPI is enabled and the CSTART bit in the SPI_CR1 register is set. The clock is stopped either by software explicitly requesting this by setting the CSUSP bit in the SPI_CR1 register or automatically when the RxFIFO is full, when the MASRX bit in the SPI_CR1 is set.
  
  In slave configuration, the MISO output is disabled and the pin can be used as a GPIO. The slave continues to receive data from the MOSI pin while its slave select signal is active (see Section 68.4.7).

**Note:** In whatever Master and Slave modes, the data pin dedicated for transmission can be replaced by the data pin dedicated for reception and vice versa by changing the IOSWP bit value in the SPI_CFG2 register (This bit may only be modified when the SPI is disabled). Any simplex communication can be replaced by a variant of the half duplex communication with a constant setting of the transaction direction (bidirectional mode is enabled, while the HDDIR bit is never changed) or by full duplex control when unused data line and corresponding data flow is ignored.
1. SS pins interconnection is not mandatory to make the SPI interface working (see Section 68.4.7).
2. In this configuration, both the MISO pins can be used as GPIOs.
3. RDY signal provided by slave can be read by master optionally.

### 68.4.5 Standard multislave communication

In a configuration with two or more independent slaves, the master uses a star topology with dedicated GPIO pins to manage the chip select lines for each slave separately (see Figure 841). The master must select one of the slaves individually by pulling low the GPIO connected to the slave SS input (only one slave can control data on common MISO line at a given time). When this is done, a communication between the master and the selected slave is established. Except the simplicity, the advantage of this topology is that a specific SPI configuration can be applied for each slave as all the communication sessions are performed separately just within single master-slave pair. Optionally, when there is no need to read any information from slaves, the master can transmit the same information to the multiple slaves.
Figure 841. Master and three independent slaves connected in star topology

1. Master single SS pin hardware output functionality cannot support this topology (to be replaced by set of GPIOs under SW control) and user should avoid SPI AF setting at the pin (see Section 68.4.7 for details).

2. If the application cannot assure that no more than a single SS active signal is provided by the master at a given time, it is better to configure MISO pins into open-drain configuration with an external pull up on the MISO line to prevent conflicts between interconnected outputs of the slaves. Else, a push-pull configuration can be applied without extra resistor (see I/O alternate function input/output (GPIO) section).

3. RDY signals can be read by master from the slaves optionally.

68.4.6 Multimaster communication

Unless the SPI bus is not designed primarily for a multimaster capability, it is possible to use a built-in feature that detects a potential conflict between two nodes trying to master the bus at the same time. For this detection, the SS pin is used configured in hardware input mode. The connection of more than two SPI nodes working in this mode is impossible, as only one node can apply its output on a common data line at a given time.

When the nodes are not active, both stay in Slave mode by default. When a node wants to take control on the bus, it switches itself into Master mode and applies active level on the slave select input of the other node via the dedicated GPIO pin. After the session is
completed, the active slave select signal is released and the node mastering the bus temporary returns back to passive Slave mode waiting for a next session to start.

If both nodes raise their mastering request at the same time, a bus conflict event appears (see mode fault MODF event). The user can apply some simple arbitration process (for example postpone next attempt by predefined different time-outs applied in both nodes).

**Figure 842. Multimaster application**

1. The SS pin is configured at hardware input mode at both nodes. Its active level enables the MISO line output control as passive node is configured as a slave.
2. The RDY signal is not used in this communication.

### 68.4.7 Slave select (SS) pin management

In Slave mode, the SS works as a standard 'chip select' input and lets the slave communicate with the master. In Master mode, the SS can be used either as an output or an input. As an input it can prevent a multi master bus collision, and as an output it can drive a slave select signal of a single slave. The SS signal can be managed internally (software management of the SS input) or externally when both the SS input and output are associated with the SS pin (hardware SS management). The user can configure which level of this input/output external signal (present on the SS pin) is considered as active one by the SSIOP bit setting. SS level is considered as active if it is equal to SSIOP.

The hardware or software slave select management can be set using the SSM bit in the SPI_CFG2 register:

- **Software SS management (SSM = 1)**: in this configuration, slave select information is driven internally by the SSI bit value in the register SPI_CR1. The external SS pin is free for other application uses (as GPIO or other alternate function).
- **Hardware SS management (SSM = 0)**: in this case, there are two possible configurations. The configuration used depends on the SS output configuration (SSOE bit in register SPI_CFG2).
  - **SS output enable (SSOE = 1)**: this configuration is only used when the MCU is set as master. The SS pin is managed by the hardware. The functionality is tied to CSTART and EOT control. As a consequence, the master must apply proper TSIZE>0 setting to control the SS output correctly. Even if SPI AF is not applied at the SS pin (it can be used as a standard GPIO then), keep anyway SSOE = 1 to
assure default SS input level and prevent any mode fault evaluation at input of the master SS internal logic applicable at a multimaster topology exclusively.

a) When SSOM = 0 and SP = 000, the SS signal is driven to the active level as soon as the master transfer starts (CSTART = 1) and it is kept active until its EOT flag is set or the transmission is suspended.

b) When SP = 001, a pulse is generated as defined by the TI mode.

c) When SSOM = 1, SP = 000 and MIDI > 1 the SS is pulsed inactive between data frames, and kept inactive for a number of SPI clock periods defined by the MIDI value decremented by one (1 to 14).

d) SS input is forced to non active state internally at master to prevent its any mode fault.

– SS output disable (SSM = 0, SSOE = 0):

a) if the micro-controller is acting as the master on the bus, this configuration allows multi master capability. If the SS pin is pulled into an active level in this mode, the SPI enters Master mode fault state and the SPI device is automatically reconfigured in Slave mode (MASTER = 0).

b) In Slave mode, the SS pin works as a standard ‘chip select’ input and the slave is selected while the SS line is at its active level.

Note: The purpose of automatic switching into Slave mode at mode fault condition is to avoid the possible conflicts on data and clock line. As the SPE is automatically reset in this condition, both Rx and Tx FIFOs are flushed and current data is lost.

When the SPI slave is enabled in the hardware SS management mode, all the traffic is ignored even in case of the SS is found at active level. They are ignored until the slave detects a start of the SS signal (transition from non-active to active level) just synchronizing the slave with the master. This is because the hardware management mode cannot be used when the external SS pin is fixed. There is no such protection in the SS software management. Then the SSI bit must be changed when there is no traffic on the bus and the SCK signal is at idle state level between transfers exclusively in this case.
When the hardware output SS control is applied (SSM = 0, SSOE = 1), by configuration of the MIDI[3:0] and MSSI[3:0] bitfields, the user can control the timing of the SS signal between data frames and can insert an extra delay at the beginning of every transaction (to separate the SS and clock starts). This can be useful when the slave needs to slow down the flow to obtain sufficient room for correct data handling (see Figure 844).

Additionally, bit SSOM = 1 setting invokes specific mode which interleaves pulses between data frames if there is a sufficient space to provide them (MIDI[3:0] must be set greater than one SPI period). Some configuration examples are shown in Figure 845.
Figure 845. SS interleaving pulses between data (SSOE = 1, SSOM = 1, SSM = 0)
2. SS interleaves between data when MIDI[3:0] > 1 wide of the interleaving pulse is always one SCK period less then gap provided between frames (defined by MIDI parameter). If MIDI is set the frames are separated by single SCK period but no interleaving pulse appears on SS.

68.4.8 Ready pin (RDY) management

The status of the slave capability to handle data, can be checked on the RDY pin. By default, a low level indicates that the slave is not ready for transaction. The reason can be that slave's TxFIFO is empty, RxFIFO full or the SPI is disabled. An active level of the signal can be selected by the RDIOP bit. If the master continues or starts to communicate with the slave when it indicates a not ready status, the transaction fails great probably.

The logic to control the RDY output is rather complex, tied closely with TSIZE and DSIZE settings. The RDY reaction is more pessimistic and sensitive to TxFIFO becoming nearly empty and/or RxFIFO nearly full during a frame transaction. This pessimistic logic is suppressed at the end of a transaction only when RDY stays active, despite TxFIFO becomes fully empty and/or RxFIFO becomes fully occupied. The target is to prevent any data corruption and inform master in time that it is necessary to suspend the transaction temporarily till the next transacted data can be processed safely again. When RDY signal input is enabled at master side, master suspends the communication once the slave indicates not ready status. This prevents the master to complete transaction of an ongoing frame which just empties slave's TxFIFO or full fills its RxFIFO till a next data is written and/or read there (despite the frame still can be completed without any constraint). It can make a problem if TSIZE = 0 configuration is applied at slave because slave then never evaluates end of transaction (which suppresses the not ready status just when the last data is sent). Then the user has to release the RxFIFO and/or write additional (even dummy) data to TxFIFO by software at slave side to release the not RDY signal, unblock ST master and so enable it to continue at the communication suspended at middle of a frame occasionally.

When RDY is not used by the master, it must be disabled (RDIOM = 0). Then an internal logic of the master simulates the slave status always ready. In this case, the RDIOP bit setting has no meaning.

Due to synchronization between clock domains and evaluation of the RDY logic on both master and slave sides, the RDY pin feature is not reliable and cannot be used when the size of data frames is configured shorter than 8-bit.

68.4.9 Communication formats

During SPI communication, receive and transmit operations are performed simultaneously. The serial clock (SCK) synchronizes the shifting and sampling of the information on the data lines. The communication format depends on the clock phase, the clock polarity and the data frame format. To be able to communicate together, the master and slave devices must follow the same communication format and be synchronized correctly.

Clock phase and polarity controls

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits in the SPI_CFG2 register. The CPOL (clock polarity) bit controls the idle state value of the clock when no data are being transferred. This bit affects both Master and Slave modes. If CPOL is reset, the SCK pin has a low-level idle state. If CPOL is set, the SCK pin has a high-level idle state.
If the CPHA bit is set, the second edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is reset, rising edge if the CPOL bit is set). Data are latched on each occurrence of this clock transition type. If the CPHA bit is reset, the first edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is set, rising edge if the CPOL bit is reset). Data are latched on each occurrence of this clock transition type.

The combination of the CPOL (clock polarity) and CPHA (clock phase) bits selects the data capture clock edges (dotted lines in Figure 846).

Figure 846, shows an SPI full-duplex transfer with the four combinations of the CPHA and CPOL bits.

Note: Prior to changing the CPOL/CPHA bits the SPI must be disabled by resetting the SPE bit.
The idle state of SCK must correspond to the polarity selected in the SPI_CFG2 register (by pulling the SCK pin up if CPOL = 1 or pulling it down if CPOL = 0).

Figure 846. Data clock timing diagram

1. The order of data bits depends on LSBFRST bit setting.
Data frame format

The SPI shift register can be set up to shift out MSB-first or LSB-first, depending on the value of the LSBFRST bit in SPI_CFG2 register.

At instance with full feature set, the data frame size is chosen by using the DSIZE[4:0] bits at SPI_CFG1 register. It can be set from 4-bit up to 32-bit length and the setting applies for both transmission and reception. When the SPI_TXDR/SPI_RXDR registers are accessed, data frames are always right-aligned into either a byte (if the data fit into a byte), a half-word or a word (see Figure 847).

If the access is a multiple of the configured data size, data packing is applied automatically. During communication, only bits within the data frame are clocked and transferred.

Figure 847. Data alignment when data size is not equal to 8-, 16- or 32-bit

Note: The minimum data length is 4 bits. If a data length of less than 4 bits is selected, it is forced to an 4-bit data frame size.

At the instance with limited set of features, data size is fixed to multiply 8-bit up to maximum data length (depends on instance) in according to DSIZE[4:3] bits value. If the SPI_TXDR or SPI_RXDR are accessed by wider access (a multiply of the configured the data size), data packing is applied automatically.

68.4.10 Configuring the SPI

The configuration procedure is almost the same for the master and the slave. For specific mode setups, follow the dedicated chapters. When a standard communication must be initialized, perform these steps:

1. Write the proper GPIO registers: configure GPIO alternate functions at MOSI, MISO, SCK, SS and RDY pins if applied.
2. Write into the SPI_CFG1 and SPI_CFG2 registers and set up proper values of all 'not reserved' bits and bitfields, prior SPI is enabled, with the following exceptions:
   a) The SSOM, MASRX, SSOE, RDIOM, MBR[2:0], BPASS, MID[3:0], MSSI[3:0] bits are taken into account in Master mode only, the MSSI[3:0] bits take effect when the SSOE bit is set, the RDIOP bit takes no effect when the RDIOM bit is not set in Master mode. When slave is configured at TI mode, MBR[2:0] setting is considered, too.
   b) UDRCFG is taken into account in Slave mode only.
   c) CRCSIZE[4:0] is required if CRCEN is set.
d) \text{CPOL, CPHA, LSBFRST, SSOM, SSOE, SSIOP, SSM, RDIOP, RDIOM, MSSI and MIDI are not required in TI mode.}

e) Once the AFCNTR bit is set in the SPI_CFG2 register, all the SPI outputs start to be propagated onto the associated GPIO pins regardless the peripheral enable. So any later configuration changes of the SPI_CFG1 and SPI_CFG2 registers can affect the level of signals on these pins.

3. Write to the SPI_CR2 register to select the length of the transfer, if it is not known TSIZE must be programmed to zero.

4. Write to SPI_CRCPOLY and into TCRCINI, RCRCINI and CRC33_17 bits at the SPI_CR1 register to configure the CRC polynomial and CRC calculation if needed.

5. Configure DMA streams dedicated for the SPI Tx and Rx in DMA registers if the DMA streams are used (see chapter Communication using DMA).

6. Configure SSI, HDDIR and MASRX at SPI_CR1 register if required.

7. Program the IOLOCK bit in the SPI_CFG1 register if the configuration protection is required (for safety).

68.4.11 Enabling the SPI

It is recommended to configure and enable the SPI slave before the master sends the clock. But there is no impact if the configuration and enabling procedure is done while a traffic is ongoing on the bus, assuming that the SS signal is managed by hardware at slave or kept inactive by slave’s software when the software management of the SS signal is applied (see Section 68.4.7). The data register of the slave transmitter should contain data to be sent before the master starts its clocking. The SCK signal must be settled to the idle state level corresponding to the selected polarity, before the SPI slave is selected by SS, else the following transaction may be desynchronized.

When the SPI slave is enabled at the hardware SS management mode, all the traffics are ignored even in case of the SS is found at active level. They are ignored until the slave detects a start of the SS signal (its transition from non-active to active level) just synchronizing the slave with the master. This is why the hardware management mode cannot be used when external SS pin is fixed. There is no such protection at the SS software management. In this case, the SSI bit must be changed when there is no traffic on the bus and the SCK signal is at idle state level between transfers exclusively in this case.

The master in full duplex (or in any transmit-only mode) starts to communicate when the SPI is enabled, the CSTART bit is set and the TxFIFO is not empty, or with the next write to TxFIFO.

In any master receive-only mode, the master starts to communicate and the clock starts running after the SPI is enabled and the CSTART bit is set.

For handling DMA, see Section 68.4.15.

68.4.12 SPI data transmission and reception procedures

The setting of data communication format follows the basic principle that sure number of data with a flexible size must be transferred within a session (transaction) while, optionally, the data handling can be cumulated effectively into a single access of the SPI data registers (data packing) or even grouped into a sequence of such services if data is collected at consistent bigger data packets. The data handling services are based upon FIFO packet occupancy events. This is why the complete data packet must be serviced exclusively upon a dedicated packet flag.
To understand better the next detailed content of this section, the user should capture the configuration impact and meaning of the following items at first:

**Data size (DSIZE)** - defines data frame (sets the number of bits at single data frame).

**FIFO threshold (FTHLV)** - defines data packet, sets the number of data frames at single data packet and so the occurrence of the packet occupancy events to handle SPI data registers either by software or by DMA.

**Data access** – a way how to handle the SPI data register content when the transfer data between the application and the SPI FIFOs upon a packet event. It depends on the packet size configuration. Optionally, multiply data can be handled effectively by a single access of the register (by data packing) or by sequence of such accesses (when servicing a bigger data packet).

**FIFO size** – capacity or space to absorb available data. It depends on the data size and the internal hardware efficiency how the data is compressed and organized within this space. The FTHLV setting must respect the FIFO capacity to store two data packets at least.

**Transaction size (TSIZE)** – defines total number of data frames involved at a transaction session overall possibly covered by several data packet services. There is no need to align this number with the packet size (handling of a last not aligned data packet is supported if TSIZE is programmed properly).

**Data handling via RxFIFO and TxFIFO**

All SPI data transactions pass through the embedded FIFOs organized by bytes (N x 8-bit). The size of the FIFOs (N) is dependent on the product and the peripheral instance. This enables the SPI to work in a continuous flow, and prevents overruns when the data frame size is short or the interrupt/DMA latency is too long. Each direction has its own FIFO called TxFIFO and RxFIFO, respectively.

The handling of the FIFOs content is based on servicing data packet events exclusively raised by dedicated FIFO packet occupancy flags (TXP, RXP or DXP). The flags occurrence depends on the data exchange mode (duplex, simplex), the data frame size (number of bits in the frame) and how data are organized at data packets. The frequency of the packet events can be decreased significantly when data are organized into packets via defining the FIFOs threshold. Several data frames grouped at packet can be then handled effectively based on a single FIFO occupancy packet event either by a single SPI data register access or their sequence what consumes less system performance. The user can control the access type by casting the data register address to force a concrete CPU instruction applied for the register read or write. The access then can be 8-bit, 16-bit or 32-bit but single data frame must be always accessed at least. It is crucial to keep the setting of the packet size (FTHVL) and the data size (DSIZE) always balanced with the applied data registers access (no matter if a single access or their sequence is applied) just to apply and complete service of a single data packet upon its event. This principle, occurrence and clearing capabilities of the FIFO occupancy flags are common no matter if DMA, interrupt, or polling is applied.

A read access to the SPI_RXDR register returns the oldest value stored in the RxFIFO that has not been read yet. A write access to the SPI_TXDR stores the written data in the TxFIFO at the end of a send queue.

A read access to the SPI_RXDR register must be managed by the RXP event. This flag is set by hardware when at least one complete data packet (defined as receiver threshold by FTHLV[3:0] bits at the SPI_CFG1 register) is available at the reception FIFO while reception is active. The RXP is cleared as soon as less data than complete single packet is available in the RxFIFO, when reading SPI_RXDR by software or by DMA.
The RXP triggers an interrupt if the RXPIE bit is set and/or a DMA request if the RXDMAEN bit is set.

Upon setting of the RXP flag, the application performs the due number of SPI data register reads to download the content of one data packet. Once a complete data packet is downloaded, the application software or DMA checks the RXP value to see if other packets are pending into the receive FIFO and, if so, downloads them packet by packet until the RXP reads 0. RxFIFO can store up to \( N \) data frames (for frame size \( \leq 8\)-bit), \( N/2 \) data frames (for \( 8\)-bit \( < \) frame \( \leq 16\)-bit), \( N/3 \) data frames (for \( 16\)-bit \( < \) frame \( \leq 24\)-bit) or \( N/4 \) data frames (if data frame \( > 24\)-bit) where \( N \) is the size of the FIFO in bytes.

At the end of a reception, it may happen that some data are still available in the RxFIFO, without reaching the FTHLV level, thus the RXP is not set. In this case, the number of remaining RX data frames in the FIFO is indicated by RXWNE and RXPLVL fields in the SPI_SR register. It happens when the number of the last data received in a transfer cannot fully accomplish the configured packet size; in case the transfer size and the packet size are not aligned. Nevertheless the application software can still perform the standard number of reads from the RxFIFO used for the previous complete data packets without drawbacks: only the consistent data (completed data frames) are popped from the RxFIFO while redundant reads (or any uncompleted data) are reading 0. Thanks to that, the application software can treat all the data in a transfer in the same way, and is off-loaded to foresee the reception of the last data in a transfer and to calculate the due number of reads to be popped from RxFIFO.

In a similar way, the write access of a data frame to be transmitted is managed by the TXP event. This flag is set by hardware when there is enough space for the application to push at least one complete data packet (defined at FTHLV[3:0] bits at SPI_CFG1 register) into the transmission FIFO while transmission is active. The TXP is cleared as soon as the TxFIFO is filled by software and/or by the DMA. The space currently available for any next complete data packet is lost. This can lead to oscillations of the TXP signal when data are released out from the TxFIFO while a new packet is stored frame by frame. Any write to the TxFIFO is ignored when there is no sufficient room to store at least a single data frame (TXP event is not respected), when TXTF is set or when the SPI is disabled.

The TXP triggers an interrupt if the TXPIE bit is set and/or with a DMA request if the TXDMAEN bit is set. The TXPIE mask is cleared by hardware when the TXTF flag is set.

Upon setting of the TXP flag, the application performs the due number of SPI data register writes to upload the content of one entire data packet. Once new complete data packet is uploaded, the application software or DMA checks the TXP value to see if other packets can be pushed into the TxFIFO and, if so, uploads them packet by packet until TXP reads 0.

The number of last data in a transfer can be shorter than the configured packet size in the case when the transfer size and the packet size are not aligned. Nevertheless the application software can still perform the standard number of data register writes used for the previous packets without drawbacks: only the consistent data are pushed into the TxFIFO while redundant writes are discarded. Thanks to that, the application software can treat all the data in a transfer in the same way and is off-loaded to foresee the transmission of the last data in a transfer and from calculating the due number of writes to push the last data into TxFIFO. Just for the last data case, the TXP event is asserted by SPI once there is enough space into TxFIFO to store remaining data to complete current transfer.

Both TXP and RXP events can be polled or handled by interrupts. The DXP bit can be monitored as a common TXP and RXP event at full-duplex mode.
Upon setting of the DXP flag the application performs the due number of writes to the SPI data register to upload the content of one entire data packet for transmission, followed by the same number of reads from the SPI data register to download the content of one data packet. Once one data packet is uploaded and one is downloaded, the application software or DMA checks the DXP value to see if other packets can be pushed and popped in sequence and, if so, uploads/downloads them packet by packet until DXP reads 0.

The DXP triggers an interrupt if the DXPIE bit is set. The DXPIE mask is cleared by hardware when the TXTF flag is set.

The DXP is useful in full-duplex communication in order to optimize performance in data uploading/downloading, and reducing the number of interrupts or DMA sequences required to support an SPI transfer thus minimizing the request for CPU bandwidth and system power especially when SPI is operated in Stop mode.

When relay on the DXP interrupt exclusively, the user must consider the drawback of such a simplification when TXP and RXP events are serviced by common procedures because the TXP services are delayed by purpose in this case. This is due to fact that the TXP events precedes the reception RXP ones normally to allow the TXP servicing prior transaction of the last frame fully emptying the TxFIFO else master cannot provide a continuous SCK clock flow and the slave can even face an underrun condition. The possible solution is to prefill the TxFIFO by few data packets ahead prior the session starts and to handle all the data received after the TXTF event by EOT exclusively at the end of the transaction (as TXTF suppresses the DXP interrupts at the end of the transaction). In case of CRC computation is enabled, the user must calculate with additional space to accommodate the CRC frame at RxFIFO when relying on EOT exclusively at the end of transaction.

Another way to manage the data exchange is to use DMA (see Section 68.4.15).

If the next data is received when the RxFIFO is full, an overrun event occurs (see description of OVR flag in Section 68.5.2). An overrun event can be polled or handled by an interrupt.

This may happen in Slave mode or in a master receive mode when MASRX = 0. If MASRX bit is set at a master receiver, the generated clock stops automatically when the RxFIFO is full, therefore overrun is prevented.

Both RxFIFO and TxFIFO content is kept flushed and cannot be accessed when SPI is disabled (SPE = 0).

**Transaction handling**

A few data frames can be passed at single sequence to complete a message. The user can handle a number of data within a message thanks to the value stored into TSIZE. In principle, the transaction of a message starts when the SPI is enabled by setting CSTART bit and finishes when the total number of required data is transacted. The end of transaction controls the CRC and the hardware SS management when applied. To restart the internal state machine properly, SPI is strongly suggested to be disabled and re-enabled before next transaction starts despite its setting is not changed.

If TSIZE is kept at zero while CSTART is set, an endless transaction is initialized (no control of transfer size is applied). During an endless transaction, the number of transacted data aligned with FIFOs threshold is supported exclusively. If the number of data (or its grouping into packets) is unpredictable, the user must keep the FIFO threshold setting (packet size) at single data (FTHLV = 0) to assure that each data frame raises its own packet event to be serviced by the application or DMA. The transaction can be suspended at any time thanks.
to CSUSP which clears the CSTART bit. SPI must be always disabled after such software suspension and re-enabled before the next transaction starts.

When the transmission is enabled, a sequence begins and continues while any data is present in the TxFIFO of the master. The clock signal is provided permanently by the master until TxFIFO becomes empty, then it stops, waiting for additional data.

In receive-only modes, half-duplex (COMM[1:0] = 11, HDDIR = 0) or simplex (COMM[1:0] = 10) modes, the master starts the sequence when the SPI is enabled and the transaction is released by setting the CSTART bit. The clock signal is provided by the master and it does not stop until either SPI or receive-only mode is disabled/suspended by the master. The master receives data frames permanently up to this moment. The reception can be suspended either by software control, writing 1 to the CSUSP bit in the SPI_CR1 register, or automatically when MASRX = 1 and RxFIFO becomes full or upon the RDY status if this signal is applied (see Section 68.4.8). The reception is automatically stopped also when the number of frames programmed in TSIZE has been completed.

In order to disable the master receive-only mode, the SPI must first be suspended. When the SPI is suspended, the current frame is completed, before changing the configuration.

**Caution:** If the SPE bit is cleared in Master mode, while the reception is ongoing without any suspending, the clock is stopped without completing the current frame, and the RxFIFO is flushed.

While the master can provide all the transactions in continuous mode (SCK signal is continuous) it must respect the slave capability to handle data flow and its content at anytime. If the slave features the RDY signal option, the master can monitor the RDY signal issued by the slave, to control the communication flow. If the RDY pin is not used, the slave is considered always ready for communication with the master.

When necessary, the master must slow down the communication and provide either a slower clock or separate frames or data sessions with sufficient delays by MIDI[3:0] bits setting or provide an initial delay by setting MSSI[1:0], which postpones any transaction start to give slave sufficient room for preparing data. Be aware data from the slave are always transacted and processed by the master even if the slave cannot prepare it correctly in time. It is preferable for the slave to use DMA, especially when data frames are short, FIFO is accessed by bytes and the SPI bus rate is high.

In order to add some software control on the SPI communication flow from a slave transmitter node, a specific value written in the SPI_UDRDR (SPI Underrun Data Register) may be used. On slave side, when TxFIFO becomes empty, this value is sent out automatically as next data and may be interpreted by software on the master receiver side (either simply dropped or interpreted as a XOFF like command, in order to suspend the master receiver by software).

In the multislave star topology, only a single slave only can be enabled for output data at a given time. The slave just selected for the communication with the master needs to detect a change of its SS input into active level before communication with the master starts. In a single slave system it is not necessary to control the slave with SS, but it is often better to provide the pulse here too, to synchronize the slave with the beginning of each data sequence. The SS can be managed by both software and hardware (Section 68.4.7).

### 68.4.13 Disabling the SPI

To disable the SPI, it is mandatory to follow the disable procedures described in this paragraph.
In the Master mode, it is important to do this before the system enters a low-power mode when the peripheral clock is stopped, otherwise, ongoing transactions may be corrupted.

In Slave mode, the SPI communication can continue when the \texttt{spi\_pclk} and \texttt{spi\_ker\_ck} clocks are stopped, without interruption, until any end of communication or data service request condition is reached. The \texttt{spi\_pclk} can generally be stopped by setting the system into Stop mode. Refer to the RCC section for further information.

The master in full-duplex or transmit-only mode can finish any transaction when it stops providing data for transmission. In this case, the clock stops after the last data transaction. TXC flag can be polled (or interrupt enabled with EOTIE = 1) in order to wait for the last data frame to be sent.

When the master is in any receive-only mode, in order to stop the peripheral, the SPI communication must first be suspended, by setting the CSUSP bit to 1.

The data received but not read remain stored in RxFIFO when the SPI is suspended.

After such a software suspension, SPI must be always disabled to restart the internal state machine properly.

When SPI is disabled, RxFIFO is flushed. To prevent losing unread data, the user must ensure that RxFIFO is empty when disabling the SPI, by reading all remaining data (as indicated by the RXP, RXWNE and RXPLVL fields in the SPI\_SR register).

The standard disable procedure is based on polling EOT and/or TXC status to check if a transmission session is (fully) completed. This check can be done in specific cases, too, when it is necessary to identify the end of ongoing transactions, for example:

- When the master handles SS signal by a GPIO not related to SPI (for example at case of multislave star topology) and it has to provide proper end of SS pulse for slave, or
- When transaction streams from DMA or FIFO are completed while the last data frame or CRC frame transaction is still ongoing in the peripheral bus.

When TSIZE>0, EOT and TXC signals are equal so polling of EOT is reliable at whatever SPI communication mode to check end of the bus activity. When TSIZE = 0, the user has to check TXC, SUSP or FIFO occupancy flags in accord with the applied SPI mode and the way of the data flow termination.

The correct disable procedure in Master mode, except when receive-only mode is used, is:

1. Wait until TXC = 1 and/or EOT = 1 (no more data to transmit and last data frame sent). When CRC is used, it is sent automatically after the last data in the block is processed. TXC/EOT is set when CRC frame is completed in this case. When a transmission is suspended the software has to wait till CSTART bit is cleared.
2. Read all RxFIFO data (until RXWNE = 0 and RXPLVL = 00).
3. Disable the SPI (SPE = 0).

The correct disable procedure for master receive-only modes is:

1. Wait on EOT or break the receive flow by suspending SPI (CSUSP = 1).
2. Wait until SUSP = 1 (the last data frame is processed) if receive flow is suspended.
3. Read all RxFIFO data (until RXWNE = 0 and RXPLVL = 00).
4. Disable the SPI (SPE = 0).

In Slave mode, any on going data are lost when disabling the SPI.
Controlling the I/Os

As soon as the SPI is disabled, the associated and enabled AF outputs can still be driven by the device depending on the AFCNTR setting. When active output control is applied (AFCNTR = 1) and SPI is just been disabled (SPE = 0), the enabled outputs associated with SPI control signals (like SS and SCK at master and RDY at slave) can toggle immediately to inactive level (according to SSIOP and CPOL settings at master and RDIOP at slave respectively). The data line output (MOSI at master and MISO at slave) can instead change its level immediately at dependency on the actual TxFIFO content with the effect of potentially making invalid and no more guaranteed the value of the latest transacted bit on the bus. If necessary, the user has to take care about proper data hold time at the data line and avoid any eventual fast SPI disable just after the last data transaction is completed.

Note: Despite stability of the latest bit is guaranteed by design during the sampling edge of the clock, some devices can require even extension of this data bit stability interval during the sampling. It can be done for example by inserting small software delay between EOT event occurrence and SPI disable action.

68.4.14 Data packing

From user point of view there are two ways of data packing which can overlay each other:

- Type of access when data are written to TxFIFO or read from Rx FIFO
  Multiple data can be pushed or fetched effectively by single access if data size is multiplied less than the access performed upon SPI_TXDR or SPI_RXDR registers.
- Number of data to be handled during the single software service
  It is convenient to group data into packets and cumulate the FIFO services overall the data packet content exclusively instead of handling data frame by frame separately.
  The user can define packets by FIFO threshold settings. Then all the FIFO occupancy events are related to that threshold level while required services are signaled by proper flags with interrupt and/or wake up capabilities.

When the data frame size fits into one byte (less than or equal to 8 bits), the data packing is used automatically when any read or write 16-bit or 32-bit access is performed on the SPI_RXDR/SPI_TXDR register. The multiple data frame pattern is handled in parallel in this case. At first, the SPI operates using the pattern stored in the LSB of the accessed word, then with the other data stored in the MSB.

Figure 848 provides an example of data packing mode sequence handling at full feature set instance. While DSIZE[4:0] is configured to 4-bit there, two or four data frames are written in the TxFIFO after the single 16-bit or 32-bit access the SPI_TXDR register of the transmitter. When the data frame size is between 9-bit and 16-bit, data packing is used automatically when a 32-bit access is done. Least significant half-word is used first. (regardless of the LSBFRST value)

This sequence can generate two or four RXP events in the receiver if the Rx FIFO threshold is set frame (and data is read on a frame basis, unpacked), or it can generate a single RXP event if the FTHLV[3:0] field in the SPI_CFG1 register is programmed to a multiple of the frames to be read in a packed mode (16-bit or 32-bit read access).

The data are aligned in accordance with Figure 847. The valid bits are performed on the bus exclusively. Unused bits are not cared at transmitter while padded by zeros at receiver.

When short data frames (< 8-bit or < 16-bit) are used together with a larger data access mode (16-bit or 32-bit), the FTHLV value must be programmed as a multiple of the number
of frames/data access (multiple of 4 if 32-bit access is used to up to 8-bit frames or multiple of 2 if 16-bit access is used to up to 8-bit frames or 32-bit access to up to 16-bit frames.).

The RxFIFO threshold setting must always be higher or equal at least than the following read access size, as spurious extra data would be read otherwise.

The FIFO data access less than the configured data size is forbidden. One complete data frame must be always accessed at minimum.

A specific problem appears if an incomplete data packet is available at FIFO: less than threshold set at FTHLV bits.

There are two ways of dealing with this problem:

A. without using TSIZE field

On transmitter side, writing the last data frame of any odd sequence with an 8-bit/16-bit access to SPI_TXDR is enough.

On receiver side, the remaining data may be read by any access. Any extra data read are padded with zeros. Polling the RXWNE and RXPLVL may be used to detect when the RX data are available in the RxFIFO. (A time out may be used at system level in order to detect the polling)

B. using the TSIZE field

On transmitter side, the transaction is stopped by the master when it faces EOT event.

In reception, the RXP flag is not set when EOT is set. In the case when the number of data to be received (TSIZE) is not a multiple of packet size, the number of remaining data is indicated by the RXWNE and RXPLVL fields in the SPI_SR register. The remaining data can be read by any access. Any extra read is padded by zeros.

Figure 848. Packing data in FIFO for transmission and reception at full feature set instance

1. DSIZE[4:0] is configured to 4-bit, data is right aligned, valid bits are performed only on the bus, their order depends on LSBFRST, if it is set, the order is reversed at all the data frames.

68.4.15 Communication using DMA (direct memory addressing)

To operate at its maximum speed and to facilitate the data register read/write process required to avoid overrun, the SPI features a DMA capability, which implements a simple request/acknowledge protocol.
A DMA access is requested when the TXDMAEN or RXDMAEN enable bits in the SPI_CFG1 register are set. Separate requests must be issued to the Tx and Rx buffers to fulfill service of the defined packet.

- In transmission, a series of DMA requests is triggered each time TXP is set to 1. The DMA then performs series of writes to the SPI_TXDR register.
- In reception, a series of DMA requests is triggered each time RXP is set to 1. The DMA then performs series of reads from the SPI_RXDR register. When EOT is set at the end of transaction and last data packet is incomplete then DMA request is activated automatically in according with RXWNE and RXPLVL[1:0] setting to read rest of data.

If the SPI is programmed in receive-only mode, UDR is never set.

If the SPI is programmed in a transmit mode, TXP and UDR can be eventually set at slave side, because transmit data may not be available. In this case, some data are sent on the TX line according with the UDR management selection.

When the SPI is used at a simplex mode, the user must enable the adequate DMA channel only while keeping the complementary unused channel disabled.

If the SPI is programmed in transmit-only mode, RXP and OVR are never set.

If the SPI is programmed in full-duplex mode, RXP and OVR are eventually set, because received data are not read.

In transmission mode, when the DMA or the user has written all the data to be transmitted (the TXTF flag is set at SPI_SR register), the EOT (or TXC at case TSIZE = 0) flag can be monitored to ensure that the SPI communication is complete. This is required to avoid corrupting the last transmission before disabling the SPI or before disabling the spi_pclk in Master mode. The software must first wait until EOT = 1 and/or TXC = 1.

When starting communication using DMA, to prevent DMA channel management raising error events, these steps must be followed in order:

1. Enable DMA Rx buffer in the RXDMAEN bit in the SPI_CFG1 register, if DMA Rx is used.
2. Enable DMA requests for Tx and Rx in DMA registers, if the DMA is used.
3. Enable DMA Tx buffer in the TXDMAEN bit in the SPI_CFG1 register, if DMA Tx is used.
4. Enable the SPI by setting the SPE bit.

To close communication it is mandatory to follow these steps in order:

1. Disable DMA request for Tx and Rx in the DMA registers, if the DMA issued.
2. Disable the SPI by following the SPI disable procedure.
3. Disable DMA Tx and Rx buffers by clearing the TXDMAEN and RXDMAEN bits in the SPI_CFG1 register, if DMA Tx and/or DMA Rx are used.

Data packing with DMA

If the transfers are managed by DMA (TXDMAEN and RXDMAEN set in the SPI_CFG1 register) the packing mode is enabled/disabled automatically depending on the PSIZE value configured for SPI TX and the SPI RX DMA channel.

If the DMA channel PSIZE value is equal to 16-bit and the SPI data size is less than or equal to 8-bit, then the packing mode is enabled. Similarly, If the DMA channel PSIZE value is equal to 32-bit and the SPI data size is less than or equal to 16-bit, then the packing mode is
enabled. The DMA then automatically manages the write operations to the SPI_TXDR register.

Regardless data packing mode is used and the number of data to transfer is not a multiple of the DMA data size (16-bit or 32-bit) while the frame size is smaller, DMA completes the transfer automatically in according with the TSIZE field setting.

Alternatively, last data frames may be written by software, in the single/unpacked mode.

To configure any DMA data access less than the configured data size is forbidden. One complete data frame must be always accessed at minimum.

68.4.16 Autonomous mode

The SPI is capable to handle and initialize transactions autonomously requiring no specific system execution interaction till the ongoing transaction ends. Such autonomous transactions can be handled not only in Run or Sleep modes but even in Stop mode when the SPI logic is able to provide temporary clock requests addressed to the reset and clock controller (RCC) to ensure clocking of those SPI domains just necessary for handling the data flow between the memory and the peripheral interface at dependency in the SPI mode.

In Stop mode, the APB clock is requested by the peripheral each time the SPI registers need to be updated based on specific traffic events (mainly TXP and RXP). The required clock is provided by RCC if SPI autonomous mode is enabled at the RCC configuration and the SPI is clocked by an internal oscillator available in Stop mode.

Interrupts or DMA requests are then generated, depending on the SPI configuration. If no interrupt is enabled, the device remains in Stop mode. If DMA requests are enabled, the data are directly transferred to/from the SRAM thanks to the DMA while the device remains in Stop mode. If an enabled interrupt occurs, the device wakes up from Stop mode.

*Note:* The peripheral clock request stays pending till flag with enabled interrupt stays set. This is why it is important to service these pending requests and clear their flag as soon as possible at system sensitive to the low-power consumption especially and the application must acknowledge all pending interrupts events before switching the SPI to low-power mode.

Slave mode

When the SPI is configured as a standard slave and device is at Stop mode, the SPI kernel clock and the SPI APB clock are not provided permanently. All the data flow between the SPI interface and associated FIFOs is handled by an external SCK clock provided by outer master device within the serial interface clock domain. APB clock temporal requests are then based upon specific traffic events at dependency on the SPI configuration. As slave never initializes a transaction, there is no need to synchronize any transaction start in this mode.

*Note:* The peripheral clock request stays pending till flag with enabled interrupt stays set. This is why it is important to service these pending requests and clear their flag as soon as possible at system sensitive to the low-power consumption especially and the application must acknowledge all pending interrupts events before switching the SPI to low-power mode.

Master mode

The SPI operating in Master mode provides the SCK signal for outer slaves until the transaction is completed. The SCK signal is derived from the SPI clock generator running within the kernel clock domain fed from RCC upon kernel clock request provided by the SPI
when the device is in Stop mode. Temporal requests for APB clock are then based upon specific traffic events, depending upon the SPI configuration. The SPI master always initializes a transaction.

To minimize consumption in Stop mode, it is suggested to combine communication starts triggered by hardware (TRIGEN bit set in the SPI_AUTOCR register) and transfers of predefined data size (FSIZE > 0 in the SPI CR2 register). This ensures that any APB clock request is suppressed between EOT handling and the next trigger event.

A transaction starts once the CSTART bit is set. In case of master transmitter, the TxFIFO must be filled by data, too. The CSTART bit can be written either by software or by hardware when a synchronous trigger is detected at Run, Sleep or Stop mode. The trigger source is selected by the TRIGSEL bits and enabled by the TRIGEN bit in the SPI_AUTOCR register. When the enabled trigger is detected, the transfer starts and continues by handling data till the EOT event or the transaction suspension. When the TRIGEN bit is changed, the user must prevent any trigger event occurrence. If the user cannot prevent that, the TRIGEN bit must be written while the SPI is disabled otherwise the peripheral behavior is not guaranteed.

### 68.5 SPI specific modes and control

#### 68.5.1 TI mode

With a specific SP[2:0] bit field setting of the SPI_CFG2 register, the SPI can be configured compliant with the TI protocol. The SCK and SS signals polarity, phase and flow as well as the bits order are fixed so the setting of CPOL, CPHA, LSBFRST, SSOM, SSOE, SSIOP, SSM, RDIOP, RDIOM, MSSI and MIDI is not required when the SPI is in TI mode configuration. The SS signal synchronizes the protocol by pulses over the LSB data bit as it is shown in [Figure 849](#).

![Figure 849. TI mode transfer](#)

In Slave mode, the clock generator is used to define time when the slave output at MISO pin becomes to HiZ when the current transaction finishes. The master baud rate setting (MBR[2:0] at SPI_CFG1) is applied and any baud rate can be used to determine this moment with optimal flexibility. The delay for the MISO signal to become HiZ (TRELEASE) depends on internal re-synchronization, too, which takes next additional 2-4 periods of the clock signal feeding the generator. It is given by formula:
If the slave detects misplaced SS pulse during data transaction the TIFRE flag is set.

### 68.5.2 SPI error flags

An SPI interrupt is generated if one of the following error flags is set and interrupt is enabled by setting the corresponding Interrupt Enable bit.

**Overrun flag (OVR)**

An overrun condition occurs when data are received by a master or slave and the RxFIFO has not enough space to store these received data. This can happen if the software or the DMA did not have enough time to read the previously received data (stored in the RxFIFO).

When an overrun condition occurs, the OVR flag is set and the newly received value does not overwrite the previous one in the RxFIFO. The newly received value is discarded and all data transmitted subsequently are lost. OVR flag triggers an interrupt if OVRIE bit is set.

Clearing the OVR bit is done by a writing 1 to the OVRC bit in the SPI_IFCR. To prevent any next overrun event the clearing should be done after RxFIFO is emptied by software reads. It is suggested to release the RxFIFO space as much as possible, this means to read out all the available data packets based on RXP flag indication.

In Master mode, the user can prevent the RxFIFO overrun by automatic communication suspend (MASRX bit).

**Underrun flag (UDR)**

In a slave-transmitting mode, the underrun condition is captured internally by hardware if no data is available for transmission in the slave TxFIFO commonly. The UDR flag setting is then propagated into the status register by hardware (see note below). UDR triggers an interrupt if the UDRIE bit is set.

Underrun detection logic and system behavior depends on the UDRCFG bit. When an underrun is detected by slave, it can provide out either a constant pattern stored by the user at the UDRDR register or the data received previously from the master. When the first configuration (UDRCFG = 0) is applied, the underrun condition is evaluated whenever master starts to communicate a new data frame while TxFIFO is empty. Then single additional dummy (accidental) data is always inserted between last valid data and constant pattern defined at the UDRDR register (see Figure 850). Assuming that TxFIFO is not empty when master starts the communication, the underrun condition is evaluated just once the FIFO becomes empty during the next data flow. Valid data from TxFIFO is then upended by the lastly received data immediately.

The standard transmission is re-enabled once the software clears the UDR flag and this clearing is propagated into SPI logic by hardware. The user should write some data into TxFIFO prior clearing the UDR flag to prevent any next underrun condition occurrence capture.

The data transacted by slave is unpredictable especially when the transaction starts or continues while TxFIFO is empty and underrun condition is either not yet captured or just cleared. Typically, this is the case when SPI is just enabled or when a transaction with a defined size just starts. First bits can be corrupted in this case, as well, when slave software
writes first data into the empty TxFIFO too close prior the data transaction starts (propagation of the data into TxFIFO takes few APB clock cycles).

**Figure 850. Optional configurations of slave detecting underrun condition**

- **UDRCFG=0**
  - SCK
  - MOSI: Di1, Di2, Di3
  - MISO: DO1, Dummy, [UDRDR]
  - TxFIFO occupancy: 1 0
  - UDR: UDR propagation latency

- **UDRCFG=1**
  - SCK
  - MOSI: Di1, Di2, Di3
  - MISO: DO1, Di1, Di2
  - TxFIFO occupancy: 1 0
  - UDR: UDR propagation latency

**Note:** The hardware propagation of an UDR event needs additional traffic on the bus. It always takes few extra SPI clock cycles after the event happens (both underrun captured by hardware and cleared by software). If clearing of the UDR flag by software is applied close to the end of data frame transaction or when SCK line is at idle in between the frames, next extra underrun pattern is sent initially by slave prior the valid data from TxFIFO becomes transacted again. The user can prevent this by SPI disable/enable action between sessions to restart the underrun logic and so initiate the next session by the valid data.

**Mode fault (MODF)**

Mode fault occurs when the master device has its internal SS signal (SS pin in SS hardware mode, or SSI bit in SS software mode) pulled low. This automatically affects the SPI interface in the following ways:

- The MODF bit is set and the SPI interrupt is triggered if the MODFIE bit is set.
- The SPE bit is forced to zero till MODF bit is set. This disables SPI and blocks all the peripheral outputs except the MODF interrupt request if enabled.
- The MASTER bit is cleared, thus forcing the device into Slave mode.

MODF is cleared by writing 1 to the MODFC bit in the SPI_IFCR.
To avoid any multiple slave conflicts in a system comprising several MCUs, the SS pin must be pulled to its non-active level before re-enabling the SPI, by setting the SPE bit.

As a security, hardware does not allow the SPE bit to be set while the MODF bit is set. In a slave device the MODF bit cannot be set except as the result of a previous multi master conflict.

A correct software procedure when master overtakes the bus at multi master system should be the following one:

- Switch into Master mode while SSOE = 0 (potential conflict can appear when another master occupies the bus. MODF is raised in this case, preventing any next node switching into Master mode)
- Put GPIO pin dedicated for another master SS control into active level
- Perform data transaction
- Put GPIO pin dedicated for another master SS control into non active level
- Switch back to Slave mode

**CRC error (CRCE)**

This flag is used to verify the validity of the value received when the CRCEN bit in the SPI_CFG1 register is set. The CRCE flag in the SPI_SR register is set if the value received in the shift register does not match the receiver SPI_RXCRC value, after the last data is received (as defined by TSIZE). The CRCE flag triggers an interrupt if CRCEIE bit is set. Clearing the bit CRCE is done by a writing 1 to the CRCEC bit in the SPI_IFCR.

**TI mode frame format error (TIFRE)**

A TI mode frame format error is detected when an SS pulse occurs during an ongoing communication when the SPI is operating in Slave mode and configured to conform to the TI mode protocol. When this error occurs, the TIFRE flag is set in the SPI_SR register. The SPI is not disabled when an error occurs, the SS pulse is ignored, and the SPI waits for the next SS pulse before starting a new transfer. The data may be corrupted since the error detection may result in the loss of few data frames.

The TIFRE flag is cleared by writing 1 to the TIFREC bit in the SPI_IFCR. If the TIFREIE bit is set, an interrupt is generated on the SS error detection. As data consistency is no longer guaranteed, communication should be re-initiated by software between master and slave.

### 68.5.3 CRC computation

Two separate 33-bit or two separate 17-bit CRC calculators are implemented to check the reliability of transmitted and received data. For instances with full feature set, the SPI offers CRC polynomial length from 5 to 33 bits when maximum data size is 32-bit and from 9 to 17 bits for the peripheral instances with data size limited to 16 bits. For instances with limited set of features, the CRC polynomial length can be set either to 9 or 17 only when data size is limited to 16 bit and optionally to 33 when data size is extended to 32-bit. The length of the polynomial is defined by the most significant bit of the value stored at the CRCPOLY register. It must be set greater than data frame length defined at DSIZE field. When
maximum data size is applied, the CRC33_17 bit must be set additionally to define the most significant bit of the polynomial string while keep its size always greater than data. The CRCSIZE field in the SPI_CFG1 then defines how many the most significant bits from CRC calculation registers are transacted and compared as CRC frame. It is defined independently from the data frame length, but it must be either equal or an integer multiple of the data frame size while its size cannot exceed the maximum data size of the instance.

To fully benefit from the CRC calculation capability, the polynomial length setting must correspond to the CRC pattern size, else the bits unused at the calculation are transacted and expected all zero at the end of the CRC pattern if its size is set greater then the polynomial length.

**CRC principle**

The CRC calculation is enabled by setting the CRCEN bit in the SPI_CFG1 register before the SPI is enabled (SPE = 1). The CRC value is then calculated using the CRC polynomial defined by the CRCPOLY register and CRC33_17 bit. When SPI is enabled, the CRC polynomial can be changed but only in case when there is no traffic on the bus.

The CRC computation is done, bit by bit, on the sampling clock edge defined by the CPHA and CPOL bits in the SPI_CR1 register. The calculated CRC value is checked automatically at the end of the data block defined by the SPI_CR2 register exclusively.

When a mismatch is detected between the CRC calculated internally on the received data and the CRC received from the transmitter, a CRCE flag is set to indicate a data corruption error. The right procedure for handling the CRC depends on the SPI configuration and the chosen transfer management.

**CRC transfer management**

Communication starts and continues normally until the last data frame must be sent or received in the SPI_DR register.

The length of the transfer must be defined by TSIZE. When the desired number of data is transacted, the TXCRC is transmitted and the data received on the line are compared to the RXCRC value.

No matter what is the CRCSIZE configuration, TSIZE cannot be set neither to 0xFFFF at full feature set instance nor to 0x3FF value at limited feature one if CRC is enabled.

In transmission, the CRC computation is frozen during CRC transaction and the TXCRC are transmitted, in a frame of length equal to the CRCSIZE field value.

In reception, the RXCRC is also frozen when desired number of data is transacted. Information to be compared with the RXCRC register content is then received in a frame of length equal to the CRCSIZE value.

Once the CRC frame is completed, an automatic check is performed comparing the received CRC value and the value calculated in the SPI_RXCRC register. The software has to check the CRCE flag in the SPI_SR register to determine if the data transfers were corrupted or not. Software clears the CRCE flag by writing 1 to the CRCEC.

The user takes no care about any flushing redundant CRC information, it is done automatically.
Reseting the SPI_TXCRC and SPI_RXCRC values

The SPI_TXCRC and SPI_RXCRC values are initialized automatically when new data is sampled after a CRC phase. This allows the use of DMA circular mode in order to transfer data without any interruption (several data blocks covered by intermediate CRC checking phases). Initialization patterns for receiver and transmitter can be configured either to zero or to all ones in dependency on setting bits TCRCINI and RCRCINI at SPI_CR1 register.

The CRC values are reset when the SPI is disabled.

68.6 SPI low-power modes

The SPI supports autonomous operation down to Stop mode, refer to Section 68.4.16: Autonomous mode.

Table 695. Effect of low-power modes on the SPI

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. SPI interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop(^{(1)})</td>
<td>The SPI registers content is kept. If the autonomous mode is enabled at RCC configuration and SPI is clocked by an internal oscillator available in Stop mode, transfers are functional. The DMA requests are functional and the interrupts in these modes cause the device to exit Stop mode.</td>
</tr>
<tr>
<td>Standby(^{(1)})</td>
<td>The SPI instance not functional when this mode is powered down and must be reinitialized after exiting Standby mode. The SPI instance capable to work in this mode features DMA requests and wake-up capabilities.</td>
</tr>
</tbody>
</table>

1. Refer to Section 68.3: SPI implementation for information about wake-up from Stop mode support per instance as well as Standby mode availability. If an instance is not functional in a Stop mode, it must be disabled before entering this Stop mode.

68.7 SPI interrupts

Table 696 gives an overview of the SPI events capable to generate interrupts if enabled. Some of them feature wake up from Low-power mode capability, additionally. Most of them can be enabled and disabled independently while using specific interrupt enable control bits. The flags associated with the events are cleared by specific methods. Refer to description of SPI registers for more details about the event flags. When SPI is disabled, all the pending interrupt requests are blocked to prevent their propagation into the interrupt services, except the MODF interrupt request.
## Table 696. SPI wake-up and interrupt requests

<tr>
<td></td>
<td>TxFIFO transmission complete (TxFIFO empty)</td>
<td>TXC(3)</td>
<td></td>
<td>TXC cleared by hardware when a transmission activity starts on the bus</td>
<td>No</td>
</tr>
</tbody>
</table>

1. All the interrupt events are capable to wake up system from Sleep mode at each instance. For detailed information about instances capabilities to exit from concrete Stop and Standby mode refer to ‘functionalities depending on the working mode’ table.

2. Refer to Section 68.3: SPI implementation for information about Standby mode availability.

3. The TXC flag behavior depends on the TSIZE setting. When TSIZE>0, the flag fully follows the EOT one including its clearing by EOTC.

| rw | rw | rw | rw | rw | rw | w  | rs | rw |

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
Bits 31:17  Reserved, must be kept at reset value.

Bit 16  **IOLOCK**: locking the AF configuration of associated I/Os
This bit can be set by software only when SPI is disabled (SPE = 0). It is cleared by hardware exclusively whenever the SPE bit is changed from 1 to 0, either by hardware or software.  
0: AF configuration is not locked  
1: AF configuration is locked  
When this bit is set, SPI_CFG2 register content cannot be modified. This bit is write-protected when SPI is enabled (SPE = 1).

Bit 15  **TCRCINI**: CRC calculation initialization pattern control for transmitter  
0: all zero pattern is applied  
1: all ones pattern is applied

Bit 14  **RCRCINI**: CRC calculation initialization pattern control for receiver  
0: All zero pattern is applied  
1: All ones pattern is applied

Bit 13  **CRC33_17**: 32-bit CRC polynomial configuration  
0: Full size (33-bit or 17-bit) CRC polynomial is not used  
1: Full size (33-bit or 17-bit) CRC polynomial is used

Bit 12  **SSI**: internal SS signal input level  
This bit has an effect only when the SSM bit is set. The value of this bit is forced onto the peripheral SS input internally and the I/O value of the SS pin is ignored.

Bit 11  **HDDIR**: Rx/Tx direction at Half-duplex mode  
In Half-Duplex configuration the HDDIR bit establishes the Rx/Tx direction of the data transfer. This bit is ignored in Full-Duplex or any Simplex configuration.  
0: SPI is receiver  
1: SPI is transmitter

Bit 10  **CSUSP**: master suspend request  
This bit reads as zero.  
In Master mode, when this bit is set by software, the CSTART bit is reset at the end of the current frame and communication is suspended. The user has to check SUSP flag to check end of the frame transaction.  
The Master mode communication must be suspended (using this bit or keeping TXDR empty) before going to Low-power mode.  
After software suspension, SUSP flag must be cleared and SPI disabled and re-enabled before the next transaction starts.

Bit 9  **CSTART**: master transfer start  
This bit can be set by software if SPI is enabled only to start an SPI communication. It is cleared by hardware when end of transfer (EOT) flag is set or when a transaction suspend request is accepted.  
0: master transfer is at idle  
1: master transfer is ongoing or temporary suspended by automatic suspend  
In SPI mode, the bit is taken into account at master mode only. If transmission is enabled, communication starts or continues only if any data is available in the transmission FIFO.
Bit 8 **MASRX**: master automatic suspension in Receive mode

This bit is set and cleared by software to control continuous SPI transfer in master receiver mode and automatic management in order to avoid overrun condition.

0: SPI flow/clock generation is continuous, regardless of overrun condition. (data are lost)
1: SPI flow is suspended temporary on RxFIFO full condition, before reaching overrun condition. The SUSP flag is set when the SPI communication is suspended.

When SPI communication is suspended by hardware automatically, it may happen that few bits of next frame are already clocked out due to internal synchronization delay.

This is why, the automatic suspension is not quite reliable when size of data drops below 8 bits. In this case, a safe suspension can be achieved by combination with delay inserted between data frames applied when MIDI parameter keeps a non zero value; sum of data size and the interleaved SPI cycles should always produce interval at length of 8 SPI clock periods at minimum. After software clearing of the SUSP bit, the communication resumes and continues by subsequent bits transaction without any next constraint. Prior the SUSP bit is cleared, the user must release the RxFIFO space as much as possible by reading out all the data packets available at RxFIFO based on the RXP flag indication to prevent any subsequent suspension.

Bits 7:1  Reserved, must be kept at reset value.

Bit 0 **SPE**: serial peripheral enable

This bit is set by and cleared by software.

0: Serial peripheral disabled.
1: Serial peripheral enabled

When SPE = 1, SPI data transfer is enabled, SPI_CFG1 and SPI_CFG2 configuration registers, CRCPOLY, UDRDR, part of SPI_AUTOCR register and IOLOCK bit in the SPI_CR1 register are write protected. They can be changed only when SPE = 0.

When SPE = 0 any SPI operation is stopped and disabled, all the pending requests of the events with enabled interrupt are blocked except the MODF interrupt request (but their pending still propagates the request of the spi_plck clock), the SS output is deactivated at master, the RDY signal keeps not ready status at slave, the internal state machine is reseted, all the FIFOs content is flushed, CRC calculation initialized, receive data register is read zero. SPE is cleared and cannot be set when MODF error flag is active.

<td>CRC calculation disabled</td>
</tr>
<tr>
<td>1</td>
<td>CRC calculation enabled</td>
</tr>
</tbody>
</table>

| Bit 21 | Reserved, must be kept at reset value. |
Bits 20:16 **CRCSIZE[4:0]**: length of CRC frame to be transacted and compared

Most significant bits are taken into account from polynomial calculation when CRC result is transacted or compared. The length of the polynomial is not affected by this setting.

- 00000: reserved
- 00001: reserved
- 00010: reserved
- 00011: 4-bits
- 00100: 5-bits
- 00101: 6-bits
- 00110: 7-bits
- 00111: 8-bits
- ....
- 11101: 30-bits
- 11110: 31-bits
- 11111: 32-bits

The value must be set equal or multiply of data size (DSIZE[4:0]). Its maximum size corresponds to DSIZE maximum at the instance.

*Note: The most significant bit at CRCSIZE bit field is reserved at the peripheral instances where data size is limited to 16-bit.*

Bit 15 **TXDMAEN**: Tx DMA stream enable

- 0: Tx DMA disabled
- 1: Tx DMA enabled

Bit 14 **RXDMAEN**: Rx DMA stream enable

- 0: Rx-DMA disabled
- 1: Rx-DMA enabled

Bits 13:10 Reserved, must be kept at reset value.
Bit 9 **UDRCFG**: behavior of slave transmitter at underrun condition

0: slave sends a constant pattern defined by the user at the SPI_UDRDR register
1: Slave repeats lastly received data from master. When slave is configured at transmit only mode (COMM[1:0] = 01), all zeros pattern is repeated.

For more details see Figure 850: **Optional configurations of slave detecting underrun condition**.

Bits 8:5 **FTHLV[3:0]**: FIFO threshold level

Defines number of data frames at single data packet. Size of the packet should not exceed 1/2 of FIFO space.

- 0000: 1-data
- 0001: 2-data
- 0010: 3-data
- 0011: 4-data
- 0100: 5-data
- 0101: 6-data
- 0110: 7-data
- 0111: 8-data
- 1000: 9-data
- 1001: 10-data
- 1010: 11-data
- 1011: 12-data
- 1100: 13-data
- 1101: 14-data
- 1110: 15-data
- 1111: 16-data

SPI interface is more efficient if configured packet sizes are aligned with data register access parallelism:
- If SPI data register is accessed as a 16-bit register and DSIZE ≤ 8 bit, better to select FTHLV = 2, 4, 6.
- If SPI data register is accessed as a 32-bit register and DSIZE > 8 bit, better to select FTHLV = 2, 4, 6, while if DSIZE ≤ 8 bit, better to select FTHLV = 4, 8, 12.

*Note: FTHLV[3:2] bits are reserved at instances with limited set of features*
Bits 4:0 **DSIZE[4:0]**: number of bits in at single SPI data frame

- 00000: not used
- 00001: not used
- 00010: not used
- 00011: 4 bits
- 00100: 5 bits
- 00101: 6 bits
- 00110: 7 bits
- 00111: 8 bits
- ...
- 11101: 30 bits
- 11110: 31 bits
- 11111: 32 bits

*Note:* Maximum data size can be limited up to 16-bits at some instances. At instances with limited set of features, DSIZE[2:0] bits are reserved and must be kept at reset state. DSIZE[4:3] bits then control next settings of data size:

- 00xxx: 8-bits
- 01xxx: 16-bits
- 10xxx: 24-bits
- 11xxx: 32-bits.

### 68.8.4 SPI configuration register 2 (SPI_CFG2)

Address offset: 0x0C

Reset value: 0x0000 0000

The content of this register is write protected when SPI is enabled or IOLOCK bit is set at SPI_CR1 register.

RM0456 Rev 5 2927/3637
Bit 31  **AFCNTR**: alternate function GPIOs control
This bit is taken into account when SPE = 0 only
0: The peripheral takes no control of GPIOs while it is disabled
1: The peripheral keeps always control of all associated GPIOs
When SPI must be disabled temporarily for a specific configuration reason (for example CRC reset, CPHA or HDDIR change) setting this bit prevents any glitches on the associated outputs configured at alternate function mode by keeping them forced at state corresponding the current SPI configuration.

Bit 30  **SSOM**: SS output management in Master mode
This bit is taken into account in Master mode when SSOE is enabled. It allows the SS output to be configured between two consecutive data transfers.
0: SS is kept at active level till data transfer is completed, it becomes inactive with EOT flag
1: SPI data frames are interleaved with SS non active pulses when MIDI[3:0]>1

Bit 29  **SSOE**: SS output enable
This bit is taken into account in Master mode only
0: SS output is disabled and the SPI can work in multilaster configuration
1: SS output is enabled. The SPI cannot work in a multilaster environment. It forces the SS pin at inactive level after the transfer is completed or SPI is disabled with respect to SSOM, MIDI, MSSI, SSIOP bits setting

Bit 28  **SSIOP**: SS input/output polarity
0: low level is active for SS signal
1: high level is active for SS signal

Bit 27  Reserved, must be kept at reset value.

Bit 26  **SSM**: software management of SS signal input
0: SS input value is determined by the SS PAD
1: SS input value is determined by the SSI bit
When master uses hardware SS output (SSM = 0 and SSOE = 1) the SS signal input is forced to not active state internally to prevent master mode fault error.

Bit 25  **CPOL**: clock polarity
0: SCK signal is at 0 when idle
1: SCK signal is at 1 when idle

Bit 24  **CPHA**: clock phase
0: the first clock transition is the first data capture edge
1: the second clock transition is the first data capture edge

Bit 23  **LSBFRST**: data frame format
0: MSB transmitted first
1: LSB transmitted first

Bit 22  **MASTER**: SPI Master
0: SPI Slave
1: SPI Master

Bits 21:19  **SP[2:0]**: serial protocol
000: SPI Motorola
001: SPI TI
others: reserved, must not be used
Bits 18:17 **COMM[1:0]**: SPI Communication Mode
- 00: full-duplex
- 01: simplex transmitter
- 10: simplex receiver
- 11: half-duplex

Bit 16 Reserved, must be kept at reset value.

Bit 15 **IOSWP**: swap functionality of MISO and MOSI pins
- 0: no swap
- 1: MOSI and MISO are swapped
  When this bit is set, the function of MISO and MOSI pins alternate functions are inverted.
  Original MISO pin becomes MOSI and original MOSI pin becomes MISO.

Bit 14 **RDIOP**: RDY signal input/output polarity
- 0: high level of the signal means the slave is ready for communication
- 1: low level of the signal means the slave is ready for communication

Bit 13 **RDIOM**: RDY signal input/output management
- 0: RDY signal is defined internally fixed as permanently active (RDIOP setting has no effect)
- 1: RDY signal is overtaken from alternate function input (at master case) or output (at slave case) of the dedicated pin (RDIOP setting takes effect)

*Note:* When DSIZE at the SPI_CFG1 register is configured shorter than 8-bit, the RDIOM bit must be kept at zero.

Bits 12:8 Reserved, must be kept at reset value.

Bits 7:4 **MIDI[3:0]**: master Inter-Data Idleness
Specifies minimum time delay (expressed in SPI clock cycles periods) inserted between two consecutive data frames in Master mode.
- 0000: no delay
- 0001: 1 clock cycle period delay
- ...
- 1111: 15 clock cycle periods delay

*Note:* This feature is not supported in TI mode.

Bits 3:0 **MSSI[3:0]**: Master SS Idleness
Specifies an extra delay, expressed in number of SPI clock cycle periods, inserted additionally between active edge of SS opening a session and the beginning of the first data frame of the session in Master mode when SSOE is enabled.
- 0000: no extra delay
- 0001: 1 clock cycle period delay added
- ...
- 1111: 15 clock cycle periods delay added

*Note:* This feature is not supported in TI mode.
To include the delay, the SPI must be disabled and re-enabled between sessions.
## 68.8.5 SPI interrupt enable register (SPI_IER)

**Bits 31:10** Reserved, must be kept at reset value.

- **Bit 9** **MODFIE**: mode Fault interrupt enable  
  0: MODF interrupt disabled  
  1: MODF interrupt enabled

- **Bit 8** **TIFREIE**: TIFRE interrupt enable  
  0: TIFRE interrupt disabled  
  1: TIFRE interrupt enabled

- **Bit 7** **CRCEIE**: CRC error interrupt enable  
  0: CRC interrupt disabled  
  1: CRC interrupt enabled

- **Bit 6** **OVRIE**: OVR interrupt enable  
  0: OVR interrupt disabled  
  1: OVR interrupt enabled

- **Bit 5** **UDRIE**: UDR interrupt enable  
  0: UDR interrupt disabled  
  1: UDR interrupt enabled

- **Bit 4** **TXTFIE**: TXTFIE interrupt enable  
  0: TXTF interrupt disabled  
  1: TXTF interrupt enabled

- **Bit 3** **EOTIE**: EOT, SUSP and TXC interrupt enable  
  0: EOT/SUSP/TXC interrupt disabled  
  1: EOT/SUSP/TXC interrupt enabled

- **Bit 2** **DXPIE**: DXP interrupt enabled  
  DXPIE is set by software and cleared by TXTF flag set event.  
  0: DXP interrupt disabled  
  1: DXP interrupt enabled

- **Bit 1** **TXPIE**: TXP interrupt enable  
  TXPIE is set by software and cleared by TXTF flag set event.  
  0: TXP interrupt disabled  
  1: TXP interrupt enabled

- **Bit 0** **RXPIE**: RXP interrupt enable  
  0: RXP interrupt disabled  
  1: RXP interrupt enabled
68.8.6 SPI status register (SPI_SR)

Address offset: 0x14
Reset value: 0x0000 1002

All the flags of this register are not cleared automatically when the SPI is re-enabled. They require specific clearing access exclusively via the flag clearing register as noted in the bits descriptions below.

<table>
<thead>
<tr>
<th>Bit 31:16</th>
<th>CTSIZE[15:0]</th>
<th>number of data frames remaining in current TSIZE session</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>The value is not quite reliable when traffic is ongoing on bus or during autonomous operation in low-power mode.</td>
</tr>
<tr>
<td>Note:</td>
<td>CTSIZE[15:0] bits are not available in instances with limited set of features.</td>
<td></td>
</tr>
</tbody>
</table>

Bit 15 RXWNE: RxFIFO word not empty
0: less than four bytes of RxFIFO space is occupied by data
1: at least four bytes of RxFIFO space is occupied by data

Note: This bit value does not depend on DSIZE setting and keeps together with RXPLVL[1:0] information about RxFIFO occupancy by residual data.

Bits 14:13 RXPLVL[1:0]: RxFIFO packing level
When RXWNE = 0 and data size is set up to 16-bit, the value gives number of remaining data frames persisting at RxFIFO.
00: no next frame is available at RxFIFO
01: 1 frame is available
10: 2 frames are available*
11: 3 frames are available*

Note: (*): Possible value when data size is set up to 8-bit only.
When data size is greater than 16-bit, these bits are always read as 00. In that consequence, the single data frame received at the FIFO cannot be detected neither by RWNE nor by RXPLVL bits if data size is set from 17 to 24 bits. The user must then apply other methods to detect the number of data received, such as monitor the EOT event when TSIZE > 0 or RXP events when FTHLV = 0.

Bit 12 TXC: TxFIFO transmission complete
The flag behavior depends on TSIZE setting.
When TSIZE = 0, the TXC is changed by hardware exclusively and it raises each time the TxFIFO becomes empty and there is no activity on the bus.
If TSIZE ≠ 0 there is no specific reason to monitor TXC as it just copies the EOT flag value including its software clearing. The TXC generates an interrupt when EOTIE is set.
This flag is set when SPI is reset or disabled.
0: current data transaction is still ongoing, data is available in TxFIFO or last frame transmission is on going.
1: last TxFIFO frame transmission complete
Bit 11 **SUSP**: suspension status

In Master mode, SUSP is set by hardware either as soon as the current frame is completed after CSUSP request is done or at master automatic suspend receive mode (MASRX bit is set at SPI_CR1 register) on RxFIFO full condition.

SUSP generates an interrupt when EOTIE is set.

This bit must be cleared prior SPI is disabled and this is done by writing 1 to SUSPC bit of SPI_IFCR exclusively.

0: SPI not suspended (Master mode active or other mode).
1: Master mode is suspended (current frame completed).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **MODF**: mode fault

0: no mode fault

1: mode fault detected.

When MODF is set, SPE and IOLOCK bits of SPI_CR1 register are reset and setting SPE again is blocked until MODF is cleared.

This bit is cleared by writing 1 to MODFC bit of SPI_IFCR exclusively.

Bit 8 **TIFRE**: TI frame format error

0: no TI Frame Error

1: TI frame error detected

This bit is cleared by writing 1 to TIFREC bit of SPI_IFCR exclusively.

Bit 7 **CRCE**: CRC error

0: no CRC error

1: CRC error detected

This bit is cleared when SPI is re-enabled or by writing 1 to CRCEC bit of SPI_IFCR optionally.

Bit 6 **OVR**: overrun

0: no overrun

1: overrun detected

This bit is cleared when SPI is re-enabled or by writing 1 to OVRC bit of SPI_IFCR optionally.

Bit 5 **UDR**: underrun

0: no underrun

1: underrun detected

This bit is cleared when SPI is re-enabled or by writing 1 to UDRC bit of SPI_IFCR optionally.

**Note**: In SPI mode, the UDR flag applies to Slave mode only.

Bit 4 **TXTF**: transmission transfer filled

0: upload of TxFIFO is ongoing or not started

1: TxFIFO upload is finished

TXTF is set by hardware as soon as all of the data packets in a transfer have been submitted for transmission by application software or DMA, that is when TSIZE number of data have been pushed into the TxFIFO.

This bit is cleared by software write 1 to TXTFC bit of SPI_IFCR exclusively.

TXTF flag triggers an interrupt if TXTFIE bit is set.

TXTF setting clears the TXPIE and DXPIE masks so to off-load application software from calculating when to disable TXP and DXP interrupts.
Bit 3  **EOT**: end of transfer
EOT is set by hardware as soon as a full transfer is complete, that is when SPI is re-enabled or when TSIZE number of data have been transmitted and/or received on the SPI. EOT is cleared when SPI is re-enabled or by writing 1 to EOTC bit of SPI_IFCR optionally. EOT flag triggers an interrupt if EOTIE bit is set.
If DXF flag is used until TXTF flag is set and DXPIE is cleared, EOT can be used to download the last packets contained into RxFIFO in one-shot.
0: transfer is ongoing or not started
1: transfer complete
In master, EOT event terminates the data transaction and handles SS output optionally. When CRC is applied, the EOT event is extended over the CRC frame transaction.
To restart the internal state machine properly, SPI is strongly suggested to be disabled and re-enabled before next transaction starts despite its setting is not changed.

Bit 2  **DXP**: duplex packet
0: TxFIFO is Full and/or RxFIFO is Empty
1: both TxFIFO has space for write and RxFIFO contains for read a single packet at least
DXP flag is set whenever both TXP and RXP flags are set regardless SPI mode.

Bit 1  **TXP**: Tx-packet space available
0: not enough free space at TxFIFO to host next data packet
1: enough free space at TxFIFO to host at least one data packet
TXP flag can be changed only by hardware. Its value depends on the physical size of the FIFO and its threshold (FTHLV[3:0]), data frame size (FSIZE[4:0] in SPI mode), and actual communication flow. If the data packet is stored by performing consecutive write operations to SPI_TXDR, TXP flag must be checked again once a complete data packet is stored at TxFIFO. TXP is set despite SPI TxFIFO becomes inaccessible when SPI is reset or disabled.

Bit 0  **RXP**: Rx-packet available
0: RxFIFO is empty or an incomplete data packet is received
1: RxFIFO contains at least one data packet
The flag is changed by hardware. It monitors the total number of data currently available at RxFIFO if SPI is enabled. RXP value depends on the FIFO threshold (FTHLV[3:0]), data frame size (FSIZE[4:0] in SPI mode), and actual communication flow. If the data packet is read by performing consecutive read operations from SPI_RXDR, RXP flag must be checked again once a complete data packet is read out from RxFIFO.

</tbody>
</table>

Bits 31:0 **TXDR[31:0]**: transmit data register

The register serves as an interface with Tx_FIFO. A write to it accesses Tx_FIFO.

*Note: data is always right-aligned. Unused bits are ignored when writing to the register, and read as zero when the register is read.*

*Note: DR can be accessed byte-wise (8-bit access): in this case only one data-byte is written by single access.

halfword-wise (16 bit access) in this case 2 data-bytes or 1 halfword-data can be written by single access.

word-wise (32 bit access). In this case 4 data-bytes or 2 halfword-data or word-data can be written by single access.

Write access of this register less than the configured data size is forbidden.

**STI**
68.8.11 SPI polynomial register (SPI_CRCPOLY)

Address offset: 0x40
Reset value: 0x0000 0107

The content of this register is write protected when SPI is enabled.

 Bits 31:0 CRCPOLY[31:0]: CRC polynomial register

This register contains the polynomial for the CRC calculation.

The default 9-bit polynomial setting 0x107 corresponds to default 8-bit setting of DSIZE. It is compatible with setting 0x07 used in other ST products with fixed length of the polynomial string, where the most significant bit of the string is always kept hidden.

Length of the polynomial is given by the most significant bit of the value stored in this register. It must be set greater than DSIZE. CRC33_17 bit must be set additionally with CRCPOLY register when DSIZE is configured to maximum 32-bit or 16-bit size and CRC is enabled (to keep polynomial length greater than data size).

Note: CRCPOLY[31:16] bits are reserved at instances with data size limited to 16-bit. There is no constrain when 32-bit access is applied at these addresses. Reserved bits 31-16 are always read zero while any write to them is ignored.

68.8.12 SPI transmitter CRC register (SPI_TXCRC)

Address offset: 0x44
Reset value: 0x0000 0000

Bits 31:0 TXCRC[31:0]: receive data register

The register serves as an interface with RxFIFO. When it is read, RxFIFO is accessed.

Note: data is always right-aligned. Unused bits are read as zero when the register is read.

Writing to the register is ignored.

Note: DR can be accessed byte-wise (8-bit access): in this case only one data-byte is read by single access

halfword-wise (16 bit access) in this case 2 data-bytes or 1 halfword-data can be read by single access

word-wise (32 bit access). In this case 4 data-bytes or 2 halfword-data or word-data can be read by single access.

Read access of this register less than the configured data size is forbidden.
Bits 31:0 **TXCRC[31:0]**: CRC register for transmitter

When CRC calculation is enabled, the TXCRC[31:0] bits contain the computed CRC value of the subsequently transmitted bytes. CRC calculation is initialized when the CRCEN bit of SPI_CR1 is set or when a data block is transacted completely. The CRC is calculated serially using the polynomial programmed in the SPI_CRCPOLY register.

The number of bits considered at calculation depends on SPI_CRCPOLY register and CRCSIZE bits settings at SPI_CFG1 register.

**Note:** A read to this register when the communication is ongoing may return an incorrect value.

**Note:** TXCRC[31-16] bits are reserved at instances with data size limited to 16-bit. There is no constrain when 32-bit access is applied at these addresses. Reserved bits 31-16 are always read zero while any write to them is ignored.

**Note:** The configuration of CRCSIZE bit field is not taken into account when the content of this register is read by software. No masking is applied for unused bits in this case.

### 68.8.13 SPI receiver CRC register (SPI_RXCRC)

**RXCRC[31:16]**

**RXCRC[15:0]**

Bits 31:0 **RXCRC[31:0]**: CRC register for receiver

When CRC calculation is enabled, the RXCRC[31:0] bits contain the computed CRC value of the subsequently received bytes. CRC calculation is initialized when the CRCEN bit of SPI_CR1 is set or when a data block is transacted completely. The CRC is calculated serially using the polynomial programmed in the SPI_CRCPOLY register.

The number of bits considered at calculation depends on SPI_CRCPOLY register and CRCSIZE bits settings at SPI_CFG1 register.

**Note:** A read to this register when the communication is ongoing may return an incorrect value.

**Note:** RXCRC[31-16] bits are reserved at the peripheral instances with data size limited to 16-bit. There is no constrain when 32-bit access is applied at these addresses. Reserved bits 31-16 are always read zero while any write to them is ignored.

**Note:** The configuration of CRCSIZE bit field is not taken into account when the content of this register is read by software. No masking is applied for unused bits in this case.
68.8.14 SPI underrun data register (SPI_UDRDR)

Address offset: 0x4C
Reset value: 0x0000 0000

The content of this register is write protected when SPI is enabled.

</tbody>
</table>

UDRDR[31:16]

Bits 31:0 UDRDR[31:0]: data at slave underrun condition

The register is taken into account in Slave mode and at underrun condition only. The number of bits considered depends on DSIZE bit settings of the SPI_CFG1 register. Underrun condition handling depends on setting UDRCFG bit at SPI_CFG1 register.

Note: UDRDR[31-16] bits are reserved at the peripheral instances with data size limited to 16-bit. There is no constraint when 32-bit access is applied at these addresses. Reserved bits 31-16 are always read zero while any write to them is ignored.

68.8.15 SPI register map

Table 697. SPI register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x00   | SPI_CR1       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|       |               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x04   | SPI_CR2       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|       |               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x08   | SPI_CFG1      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|       |               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

|        | Reset value   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |     |

1. The bitfield is reserved for instances with limited set of features and it must be kept at reset value. For more details, refer to the concrete register description in Section 68.8: SPI registers.

2. The bits 31-16 are reserved for the peripheral instances with data size limited to 16-bit. There is no constrain when the 32-bit access is applied at these addresses. The bits 31-16, when reserved, are always read to zero while any write to them is ignored.

Refer to Section 2.3 for the register boundary addresses.
69 Serial audio interface (SAI)

69.1 Introduction

The SAI interface (serial audio interface) offers a wide set of audio protocols due to its flexibility and wide range of configurations. Many stereo or mono audio applications may be targeted. I2S standards, LSB or MSB-justified, PCM/DSP, TDM, and AC’97 protocols may be addressed for example. SPDIF output is offered when the audio block is configured as a transmitter.

To bring this level of flexibility and reconfigurability, the SAI contains two independent audio subblocks. Each block has its own clock generator and I/O line controller.

The SAI works in master or slave configuration. The audio subblocks are either receiver or transmitter and work synchronously or not (with respect to the other one).

The SAI can be connected with other SAIs to work synchronously.

69.2 SAI main features

- Two independent audio subblocks which can be transmitters or receivers with their respective FIFO.
- 8-word integrated FIFOs for each audio subblock.
- Synchronous or asynchronous mode between the audio subblocks.
- Possible synchronization between multiple SAIs.
- Master or slave configuration independent for both audio subblocks.
- Clock generator for each audio block to target independent audio frequency sampling when both audio subblocks are configured in master mode.
- Data size configurable: 8-, 10-, 16-, 20-, 24-, 32-bit.
- Audio protocol: I2S, LSB or MSB-justified, PCM/DSP, TDM, AC’97
- PDM interface, supporting up to 4 microphone pairs
- SPDIF output available if required.
- Up to 16 slots available with configurable size.
- Number of bits by frame can be configurable.
- Frame synchronization active level configurable (offset, bit length, level).
- First active bit position in the slot is configurable.
- LSB first or MSB first for data transfer.
- Mute mode.
- Stereo/Mono audio frame capability.
- Communication clock strobing edge configurable (SCK).
- Error flags with associated interrupts if enabled respectively.
  - Overrun and underrun detection,
  - Anticipated frame synchronization signal detection in slave mode,
  - Late frame synchronization signal detection in slave mode,
  - Codec not ready for the AC’97 mode in reception.
• Interrupt sources when enabled:
  – Errors,
  – FIFO requests.
• 2-channel DMA interface.

69.4 SAI functional description

69.4.1 SAI block diagram

*Figure 851* shows the SAI block diagram while *Table 699* and *Table 700* list SAI internal and external signals.
The SAI is mainly composed of two audio subblocks with their own clock generator. Each audio block integrates a 32-bit shift register controlled by their own functional state machine. Data are stored or read from the dedicated FIFO. FIFO may be accessed by the CPU, or by DMA in order to leave the CPU free during the communication. Each audio block is independent. They can be synchronous with each other.

An I/O line controller manages a set of 4 dedicated pins (SD, SCK, FS, MCLK) for a given audio block in the SAI. Some of these pins can be shared if the two subblocks are declared as synchronous to leave some free to be used as general purpose I/Os. The MCLK pin can be output, or not, depending on the application, the decoder requirement and whether the audio block is configured as the master.

If one SAI is configured to operate synchronously with another one, even more I/Os can be freed (except for pins SD_x).

The functional state machine can be configured to address a wide range of audio protocols. Some registers are present to set-up the desired protocols (audio frame waveform generator).

The audio subblock can be a transmitter or receiver, in master or slave mode. The master mode means the SCK_x bit clock and the frame synchronization signal are generated from the SAI, whereas in slave mode, they come from another external or internal master. There is a particular case for which the FS signal direction is not directly linked to the master or slave mode definition. In AC'97 protocol, it is an SAI output even if the SAI (link controller) is set-up to consume the SCK clock (and so to be in Slave mode).

1. These signals might not be available for all SAI instances. Refer to Section 69.3: SAI implementation for details.
69.4.2 SAI pins and internal signals

\(^1\) These signals might not be available in all SAI instances. Refer to Section 69.3: SAI implementation for details.

69.4.3 Main SAI modes

Each audio subblock of the SAI can be configured to be master or slave via MODE bits in the SAI_xCR1 register of the selected audio block.

**Master mode**

In master mode, the SAI delivers the timing signals to the external connected device:
- The bit clock and the frame synchronization are output on pin SCK_x and FS_x, respectively.
- If needed, the SAI can also generate a master clock on MCLK_x pin.

Both SCK_x, FS_x and MCLK_x are configured as outputs.
Slave mode

The SAI expects to receive timing signals from an external device.

- If the SAI subblock is configured in asynchronous mode, then SCK_x and FS_x pins are configured as inputs.
- If the SAI subblock is configured to operate synchronously with another SAI interface or with the second audio subblock, the corresponding SCK_x and FS_x pins are left free to be used as general purpose I/Os.

In slave mode, MCLK_x pin is not used and can be assigned to another function.

It is recommended to enable the slave device before enabling the master.

Configuring and enabling SAI modes

Each audio subblock can be independently defined as a transmitter or receiver through the MODE bit in the SAI_xCR1 register of the corresponding audio block. As a result, SAI_SD_x pin is respectively configured as an output or an input.

Two master audio blocks in the same SAI can be configured with two different MCLK and SCK clock frequencies. In this case they have to be configured in asynchronous mode.

Each of the audio blocks in the SAI are enabled by SAIEN bit in the SAI_xCR1 register. As soon as this bit is active, the transmitter or the receiver is sensitive to the activity on the clock line, data line and synchronization line in slave mode.

In master TX mode, enabling the audio block immediately generates the bit clock for the external slaves even if there is no data in the FIFO. However FS signal generation is conditioned by the presence of data in the FIFO. After the FIFO receives the first data to transmit, this data is output to external slaves. If there is no data to transmit in the FIFO, 0 values are then sent in the audio frame with an underrun flag generation.

In slave mode, the audio frame starts when the audio block is enabled and when a start of frame is detected.

In Slave TX mode, no underrun event is possible on the first frame after the audio block is enabled, because the mandatory operating sequence in this case is:
1. Write into the SAI_xDR (by software or by DMA).
2. Wait until the FIFO threshold (FLH) flag is different from 0b000 (FIFO empty).
3. Enable the audio block in slave transmitter mode.

69.4.4 SAI synchronization mode

There are two levels of synchronization, either at audio subblock level or at SAI level.

Internal synchronization

An audio subblock can be configured to operate synchronously with the second audio subblock in the same SAI. In this case, the bit clock and the frame synchronization signals are shared to reduce the number of external pins used for the communication. The audio block configured in synchronous mode sees its own SCK_x, FS_x, and MCLK_x pins released back as GPIOs while the audio block configured in asynchronous mode is the one for which FS_x and SCK_x ad MCLK_x I/O pins are relevant (if the audio block is considered as master).
Typically, the audio block in synchronous mode can be used to configure the SAI in full duplex mode. One of the two audio blocks can be configured as a master and the other as slave, or both as slaves with one asynchronous block (corresponding SYNCEN[1:0] bits set to 00 in SAI_xCR1) and one synchronous block (corresponding SYNCEN[1:0] bits set to 01 in the SAI_xCR1).

**Note:** Due to internal resynchronization stages, PCLK APB frequency must be higher than twice the bit rate clock frequency.

### External synchronization

The audio subblocks can also be configured to operate synchronously with another SAI. This can be done as follow:

1. The SAI, which is configured as the source from which the other SAI is synchronized, has to define which of its audio subblock is supposed to provide the FS and SCK signals to other SAI. This is done by programming SYNCOUT[1:0] bits.
2. The SAI which receives the synchronization signals, has to select which SAI provides the synchronization by setting the proper value on SYNCIN[1:0] bits. For each of the two SAI audio subblocks, the user must then specify if it operates synchronously with the other SAI via the SYNCEN bit.

**Note:** SYNCIN[1:0] and SYNCOUT[1:0] bits are located into the SAI_GCR register, and SYNCEN bits into SAI_xCR1 register.

If both audio subblocks in a given SAI need to be synchronized with another SAI, it is possible to choose one of the following configurations:

- Configure each audio block to be synchronous with another SAI block through the SYNCEN[1:0] bits.
- Configure one audio block to be synchronous with another SAI through the SYNCEN[1:0] bits. The other audio block is then configured as synchronous with the second SAI audio block through SYNCEN[1:0] bits.

The following table shows how to select the proper synchronization signal depending on the SAI block used. For example SAI2 can select the synchronization from SAI1 by setting SAI2 SYNCIN to 0. If SAI1 wants to select the synchronization coming from SAI2, SAI1 SYNCIN must be set to 1. Positions noted as ‘Reserved’ must not be used.

### 69.4.5 Audio data size

The audio frame can target different data sizes by configuring bit DS[2:0] in the SAI_xCR1 register. The data sizes may be 8, 10, 16, 20, 24 or 32 bits. During the transfer, either the MSB or the LSB of the data are sent first, depending on the configuration of bit LSBFIRST in the SAI_xCR1 register.
69.4.6 Frame synchronization

The FS signal acts as the Frame synchronization signal in the audio frame (start of frame). The shape of this signal is completely configurable in order to target the different audio protocols with their own specificities concerning this Frame synchronization behavior. This reconfigurability is done using register SAI_xFRCR. Figure 852 illustrates this flexibility.

**Figure 852. Audio frame**

In AC’97 mode or in SPDIF mode (bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01 in the SAI_xCR1 register), the frame synchronization shape is forced to match the AC’97 protocol. The SAI_xFRCR register value is ignored.

Each audio block is independent and consequently each one requires a specific configuration.

**Frame length**

- **Master mode**
  
  The audio frame length can be configured to up to 256 bit clock cycles, by setting FRL[7:0] field in the SAI_xFRCR register.

  If the frame length is greater than the number of declared slots for the frame, the remaining bits to transmit is extended to 0 or the SD line is released to Hi-z depending the state of bit TRIS in the SAI_xCR2 register (refer to FS signal role). In reception mode, the remaining bit is ignored.

  If bit NODIV is cleared, (FRL+1) must be equal to a power of 2, from 8 to 256, to ensure that an audio frame contains an integer number of MCLK pulses per bit clock cycle.

  If bit NODIV is set, the (FRL+1) field can take any value from 8 to 256. Refer to *Section 69.4.8: SAI clock generator*.

- **Slave mode**

  The audio frame length is mainly used to specify to the slave the number of bit clock cycles per audio frame sent by the external master. It is used mainly to detect from the master any anticipated or late occurrence of the Frame synchronization signal during an ongoing audio frame. In this case an error is generated. For more details refer to *Section 69.4.14: Error flags*.

  In slave mode, there are no constraints on the FRL[7:0] configuration in the SAI_xFRCR register.

  The number of bits in the frame is equal to FRL[7:0] + 1.

  The minimum number of bits to transfer in an audio frame is 8.
Frame synchronization polarity

FSPOL bit in the SAI_xFRCR register sets the active polarity of the FS pin from which a frame is started. The start of frame is edge sensitive.

In slave mode, the audio block waits for a valid frame to start transmitting or receiving. Start of frame is synchronized to this signal. It is effective only if the start of frame is not detected during an ongoing communication and assimilated to an anticipated start of frame (refer to Section 69.4.14: Error flags).

In master mode, the frame synchronization is sent continuously each time an audio frame is complete until the SAIEN bit in the SAI_xCR1 register is cleared. If no data are present in the FIFO at the end of the previous audio frame, an underrun condition is managed as described in Section 69.4.14: Error flags, but the audio communication flow is not interrupted.

Frame synchronization active level length

The FSALL[6:0] bits of the SAI_xFRCR register enable the configuration of the length of the active level of the Frame synchronization signal. The length can be set from 1 to 128 bit clock cycles.

As an example, the active length can be half of the frame length in I2S, LSB or MSB-justified modes, or one-bit wide for PCM/DSP or TDM.

Frame synchronization offset

Depending on the audio protocol targeted in the application, the Frame synchronization signal can be asserted when transmitting the last bit or the first bit of the audio frame (this is the case in I2S standard protocol and in MSB-justified protocol, respectively). FSOFF bit in the SAI_xFRCR register enables to choose one of the two configurations.

FS signal role

The FS signal can have a different meaning depending on the FS function. FSDEF bit in the SAI_xFRCR register selects which meaning it has:

- 0: start of frame, like for instance the PCM/DSP, TDM, AC’97, audio protocols,
- 1: start of frame and channel side identification within the audio frame like for the I2S, the MSB or LSB-justified protocols.

When the FS signal is considered as a start of frame and channel side identification within the frame, the number of declared slots must be considered to be half the number for the left channel and half the number for the right channel. If the number of bit clock cycles on half audio frame is greater than the number of slots dedicated to a channel side, and TRIS = 0, 0 is sent for transmission for the remaining bit clock cycles in the SAI_xCR2 register. Otherwise if TRIS = 1, the SD line is released to HI-Z. In reception mode, the remaining bit clock cycles are not considered until the channel side changes.
The frame length must be even.

1. The frame length must be even.

If FSDEF bit in SAI_xFRCR is kept clear, so FS signal is equivalent to a start of frame, and if the number of slots defined in NBSLOT[3:0] in SAI_xSLOTR multiplied by the number of bits by slot configured in SLOTSZ[1:0] in SAI_xSLOTR is less than the frame size (bit FRL[7:0] in the SAI_xFRCR register), then:

- if TRIS = 0 in the SAI_xCR2 register, the remaining bit after the last slot is forced to 0 until the end of frame in case of transmitter,
- if TRIS = 1, the line is released to HI-Z during the transfer of these remaining bits. In reception mode, these bits are discarded.
The FS signal is not used when the audio block in transmitter mode is configured to get the SPDIF output on the SD line. The corresponding FS I/O is released and left free for other purposes.

69.4.7 Slot configuration

The slot is the basic element in the audio frame. The number of slots in the audio frame is equal to NBSLOT[3:0] + 1.

The maximum number of slots per audio frame is fixed at 16.

For AC'97 protocol or SPDIF (when bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01), the number of slots is automatically set to target the protocol specification, and the value of NBSLOT[3:0] is ignored.

Each slot can be defined as a valid slot, or not, by setting SLOTEN[15:0] bits of the SAI_xSLOTR register.

When an invalid slot is transferred, the SD data line is either forced to 0 or released to HI-z depending on TRIS bit configuration (refer to Output data line management on an inactive slot) in transmitter mode. In receiver mode, the received value from the end of this slot is ignored. Consequently, there is no FIFO access and so no request to read or write the FIFO linked to this inactive slot status.

The slot size is also configurable as shown in Figure 855. The size of the slots is selected by setting SLOTSZ[1:0] bits in the SAI_xSLOT register. The size is applied identically for each slot in an audio frame.
It is possible to choose the position of the first data bit to transfer within the slots. This offset is configured by FBOFF[4:0] bits in the SAI_xSLOTR register. 0 values are injected in transmitter mode from the beginning of the slot until this offset position is reached. In reception, the bit in the offset phase is ignored. This feature targets the LSB justified protocol (if the offset is equal to the slot size minus the data size).

Figure 856. First bit offset

It is mandatory to respect the following conditions to avoid bad SAI behavior:

- FBOFF ≤ (SLOTSZ - DS),
- DS ≤ SLOTSZ,
- NBSLOT x SLOTSZ ≤ FRL (frame length),

The number of slots must be even when bit FSDEF in the SAI_xFRCR register is set.

In AC'97 and SPDIF protocol (bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01), the slot size is automatically set as defined in Section 69.4.11: AC'97 link controller.
69.4.8 SAI clock generator

Each audio block has its own clock generator. The clock generator builds the master clock (MCLK_x) and bit clock (SCK_x) signals from the sai_x_ker_ck. The sai_x_ker_ck clock is delivered by the clock controller of the product (RCC).

Generation of the master clock (MCLK_x)

The clock generator provides the master clock (MCLK_x) when the audio block is defined as Master or Slave. The master clock is generated as soon as the MCKEN bit is set to 1 even if the SAIEN bit for the corresponding block is set to 0. This feature can be useful if the MCLK_x clock is used as system clock for an external audio device, since it enables the generation of the MCLK_x before activating the audio stream.

To generate a master clock on MCLK_x output before transferring the audio samples, the user application has to follow the sequence below:

1. Check that SAIEN = 0.
2. Program the MCKDIV[5:0] divider to the required value.
3. Set the MCKEN bit to 1.
4. Later, the application can configure other parts of the SAI, and sets the SAIEN bit to 1 to start the transfer of audio samples.

To avoid disturbances on the clock generated on MCLK_x output, the following operations are not recommended:

- Changing MCKDIV when MCKEN = 1
- Setting MCKEN to 0 if the SAIEN = 1

The SAI guarantees that there is no spurs on MCLK_x output when the MCLK_x is switched ON and OFF via MCKEN bit (with SAIEN = 0).

*Table 702* shows MCLK_x activation conditions.

</tr>
</tbody>
</table>

*Note:* MCLK_x can also be generated in AC’97 mode, when MCLKEN is set to 1.
Generation of the bit clock (SCK_x)

The clock generator provides the bit clock (SCK_x) when the audio block is defined as Master. The frame synchronization (FS_x) is also derived from the signals provided by the clock generator.

In Slave mode, the value of NODIV and OSR fields are ignored, and the SCK_x clock is not generated.

The bit clock strobing edge of SCK_x can be configured through the CKSTR fields, which is functional both in master and slave mode.

*Figure 857* illustrates the architecture of the audio block clock generator.

![Figure 857. Audio block clock generator overview](image.png)

The NODIV bit must be used to force the ratio between the master clock (MCLK_x) and the frame synchronization (FS_x) frequency to 256 or 512.

- If NODIV is set to 0, the frequency ratio between the frame synchronization and the master clock is fixed to 512 or 256, according to OSR value, but the frame length must be a power of 2. More details are given hereafter.
- If NODIV is set to 1, the application can adjust the frequency of the bit clock (SCK_x) via MCKDIV. In addition there is no restriction on the frame length value as long as the frame length is bigger or equal to 8 (i.e. FRL[7:0] > 6). The frame synchronization frequency depends on MCKDIV and frame length (FRL[7:0]). In that case, the frequency of the MCLK_x is equal to the SCK_x.

The NODIV, MCKEN, SAIEN, OVR, CKSTR and MCKDIV[5:0] bits belong to the SAI_xCR1 register, while FRL[7:0] belongs to SAI_xFRCR.
Clock generator programming when NODIV = 0

In that case, MCLK_x frequency is:

- \( F_{MCLK_x} = 256 \times F_{FS_x} \) if OSR = 0
- \( F_{MCLK_x} = 512 \times F_{FS_x} \) if OSR = 1

When MCKDIV is different from 0, MCLK_x frequency is given by the formula below:

\[
F_{MCLK_x} = \frac{F_{sai_x_ker_ck}}{MCKDIV}
\]

The frame synchronization frequency is given by:

\[
F_{FS_x} = \frac{F_{sai_x_ker_ck}}{MCKDIV \times (OSR + 1) \times 256}
\]

The bit clock frequency (SCK_x) is given by the following formula:

\[
F_{SCK_x} = \frac{F_{sai_x_ker_ck} \times (FRL + 1)}{MCKDIV \times (OSR + 1) \times 256}
\]

Note: When NODIV is equal to 0, \((FRL+1)\) must be a power of two. In addition, \((FRL+1)\) must range between 8 and 256. \((FRL+1)\) represents the number of bit clock in the audio frame.

When MCKDIV division ratio is odd, the MCLK duty cycle is not 50%. The bit clock signal (SCK_x) can also have a duty cycle different from 50% if MCKDIV is odd, if OSR is equal to 0, and if \((FRL+1) = 2^8\).

It is recommended, to program MCKDIV to an even value or to big values (higher than 10).

Note that MCKDIV = 0 gives the same result as MCKDIV = 1.

Clock generator programming when NODIV = 1

When MCKDIV is different from 0, the frequency of the bit clock (SCK_x) is given in the formula below:

\[
F_{SCK_x} = F_{MCLK_x} = \frac{F_{sai_x_ker_ck}}{MCKDIV}
\]

The frequency of the frame synchronization (FS_x) is given by the following formula:

\[
F_{FS_x} = \frac{F_{sai_x_ker_ck}}{(FRL + 1) \times MCKDIV}
\]

Note: When NODIV is set to 1, \((FRL+1)\) can take any values from 8 to 256.

Note that MCKDIV = 0 gives the same result as MCKDIV = 1.
Clock generator programming examples

1. N is an integer value between 3 and 8.

69.4.9 Internal FIFOs

Each audio block in the SAI has its own FIFO. Depending if the block is defined to be a transmitter or a receiver, the FIFO can be written or read, respectively. There is therefore only one FIFO request linked to FREQ bit in the SAI_xSR register.

An interrupt is generated if FREQIE bit is enabled in the SAI_xIM register. This depends on:

- FIFO threshold setting (FLVL bits in SAI_xCR2)
- Communication direction (transmitter or receiver). Refer to Interrupt generation in transmitter mode and Interrupt generation in reception mode.

Interrupt generation in transmitter mode

The interrupt generation depends on the FIFO configuration in transmitter mode:

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO empty (FTH[2:0] set to 0b000), an interrupt is generated (FREQ bit set by hardware to 1 in SAI_xSR register) if no data are available in SAI_xDR register (FLVL[2:0] bits in SAI_xSR is less than 001b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO is no more empty (FLVL[2:0] bits in SAI_xSR are different from 0b000) i.e one or more data are stored in the FIFO.
- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO quarter full (FTH[2:0] set to 001b), an interrupt is generated (FREQ bit set by hardware to 1 in SAI_xSR register) if less than a quarter of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are less than 0b010). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when at least a quarter of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are higher or equal to 0b010).
- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO half full (FTH[2:0] set to 0b010), an interrupt is generated (FREQ bit set by hardware to 1 in
SAI_xSR register) if less than half of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are less than 011b). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when at least half of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are higher or equal to 011b).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO three quarter full (FTH[2:0] set to 011b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if less than three quarters of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are less than 0b100). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when at least three quarters of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are higher or equal to 0b100).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO full (FTH[2:0] set to 0b100), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if the FIFO is not full (FLVL[2:0] bits in SAI_xSR is less than 101b). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO is full (FLVL[2:0] bits in SAI_xSR is equal to 101b value).

**Interrupt generation in reception mode**

The interrupt generation depends on the FIFO configuration in reception mode:

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO empty (FTH[2:0] set to 0b000), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least one data is available in SAI_xDR register (FLVL[2:0] bits in SAI_xSR is higher or equal to 001b). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO becomes empty (FLVL[2:0] bits in SAI_xSR is equal to 0b000) i.e no data are stored in FIFO.

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO quarter full (FTH[2:0] set to 001b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least one quarter of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR is higher or equal to 0b010). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when less than a quarter of the FIFO data locations become available (FLVL[2:0] bits in SAI_xSR is less than 0b010).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO half full (FTH[2:0] set to 0b010 value), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least half of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR is higher or equal to 011b). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when less than half of the FIFO data locations become available (FLVL[2:0] bits in SAI_xSR is less than 011b).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO three quarter full (FTH[2:0] set to 011b value), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least three quarters of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR is higher or equal to 0b100). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO has less than three quarters of the FIFO data locations available (FLVL[2:0] bits in SAI_xSR is less than 0b100).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO full (FTH[2:0] set to 0b100), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if the FIFO is full (FLVL[2:0] bits in SAI_xSR is equal to 101b). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO is not full (FLVL[2:0] bits in SAI_xSR is less than 101b).
Like interrupt generation, the SAI can use the DMA if DMAEN bit in the SAI_xCR1 register is set. The FREQ bit assertion mechanism is the same as the interrupt generation mechanism described above for FREQIE.

Each FIFO is an 8-word FIFO. Each read or write operation from/to the FIFO targets one word FIFO location whatever the access size. Each FIFO word contains one audio slot. FIFO pointers are incremented by one word after each access to the SAI_xDR register.

Data must be right aligned when it is written in the SAI_xDR.

Data received are right aligned in the SAI_xDR.

The FIFO pointers can be reinitialized when the SAI is disabled by setting bit FFLUSH in the SAI_xCR2 register. If FFLUSH is set when the SAI is enabled the data present in the FIFO are lost automatically.

### 69.4.10 PDM interface

The PDM (Pulse Density Modulation) interface is provided in order to support digital microphones. Up to 4 digital microphone pairs can be connected in parallel. Depending on product implementation, less microphones can be supported (refer to Section 69.3: SAI implementation).

*Figure 858* shows a typical connection of a digital microphone pair via a PDM interface. Both microphones share the same bitstream clock and data line. Thanks to a configuration pin (LR), a microphone can provide valid data on SAI_CK[m] rising edge while the other provides valid data on SAI_CK[m] falling edge (m being the number of clock lines).

*Figure 858. PDM typical connection and timing*

- n refers to the number of data lines and p to the number of microphone pairs.

The PDM function is intended to be used in conjunction with SAI_A subblock configured in TDM master mode. It cannot be used with SAI_B subblock. The PDM interface uses the timing signals provided by the TDM interface of SAI_A and adapts them to generate a bitstream clock (SAI_CK[m]).
The data processing sequence into the PDM is the following:

1. The PDM interface builds the bitstream clock from the bit clock received from the TDM interface of SAI_A.
2. The bitstream data received from the microphones (SAI_D[n]) are de-interleaved and go through a 7-bit delay line in order to fine-tune the delay of each microphone with the accuracy of the bitstream clock.
3. The shift registers translate each serial bitstream into bytes.
4. The last operation consists in shifting-out the resulting bytes to SAI_A via the serial data line of the TDM interface.

*Figure 859* hereafter shows the block diagram of PDM interface, with a detailed view of a de-interleaver.

**Note:** The PDM interface does not embed the decimation filter required to build-up the PCM audio samples from the bitstream. It is up to the application software to perform this operation.

The PDM interface can be enabled through the PDMEN bit in SAI_PDMCR register. However the PDM interface must be enabled prior to enabling SAI_A block.

To reduce the memory footprint, the user can select the amount of microphones the application needs. This can be done through MICNBR[1:0] bits. It is possible to select

---

1. n refers to the number of data lines and p to the number of microphone pairs.
2. These signals might not be available in all SAI instances. Refer to *Section 69.3: SAI implementation* for details.
between 2, 4, 6 or 8 microphones. For example, if the application is using 3 microphones, the user has to select 4.

**Enabling the PDM interface**

To enable the PDM interface, follow the sequence below:

1. Configure SAI_A in TDM master mode (see Table 704).
2. Configure the PDM interface as follows:
   a) Define the number of digital microphones via MICNBR.
   b) Enable the bitstream clock needed in the application by setting the corresponding bits on CKEN to 1.
3. Enable the PDM interface, via PDMEN bit.
4. Enable the SAI_A.

**Note:** Once the PDM interface and SAI_A are enabled, the first 2 TDMA frames received on SAI_ADR are invalid and must be dropped.

**Start-up sequence**

*Figure 860* shows the start-up sequence: Once the PDM interface is enabled, it waits for the frame synchronization event prior to starting the acquisition of the microphone samples. After 8 SAI_CK clock periods, a data byte coming from each microphone is available, and transferred to the SAI, via the TDM interface.

*Figure 860. Start-up sequence*

**SAI_ADR data format**

The arrangement of the data coming from the microphone into the SAI_ADR register depends on the following parameters:

- The amount of microphones
- The slot width selected
- LSBFIRST bit.

The slot width defines the amount of significant bits into each word available into the SAI_ADR.
When a slot width of 32 bits is selected, each data available into the SAI_ADR contains 32 useful bits. This reduces the amount of words stored into the memory. However the counterpart is that the software has to perform some operations to de-interleave the data of each microphone.

In the other hand, when the slot width is set to 8 bits, each data available into the SAI_ADR contain 8 useful bits. This increases the amount of words stored into the memory. However, it offers the advantage to avoid extra processing since each word contains information from one microphone.

**SAI_ADR data format example**

- **32-bit slot width** (DS = 0b111 and SLOTSZ = 0). Refer to *Figure 861*.
  - For an 8 microphone configuration, two consecutive words read from the SAI_ADR register contain a data byte from each microphone.
  - For a 4 microphones configuration, each word read from the SAI_ADR register contains a data byte from each microphone.

*Figure 861. SAI_ADR format in TDM, 32-bit slot width*

- **16-bit slot width** (DS = 0b100 and SLOTSZ = 0). Refer to *Figure 862*.
  - For an 8 microphone configuration, four consecutive words read from the SAI_ADR register contain a data byte from each microphone. Note that the 16-bit data of SAI_ADR are right aligned.
  - For 4 or 2 microphone configuration, the SAI behavior is similar to 8-microphone configurations. Up to 2 words of 16 bits are required to acquire a byte from 4 microphones and a single word for 2 microphones.
Using a 8-bit slot width (DS = 0b010 and SLOTSZ = 0). Refer to Figure 863.

For an 8 microphone configuration, 8 consecutive words read from the SAI_ADR register contain a byte of data from each microphone. Note that the 8-bit data of SAI_ADR are right aligned.

For 4 or 2 microphone configuration, the SAI behavior is similar to 8 microphone configurations. Up to 4 words of 8 bits are required to acquire a byte from 4 microphones and 2 words from 2 microphones.

**TDM configuration for PDM interface**

SAI_A TDM interface is internally connected to the PDM interface to get the microphone samples. The user application must configure the PDM interface as shown in Table 704 to ensure a good connection with the PDM interface.

Adjusting the bitstream clock rate

To properly program the SAI TDM interface, the user application must take into account the settings given in Table 704, and follow the below sequence:

1. Adjust the bit clock frequency \( F_{\text{SCK_A}} \) according to the required frequency for the PDM bitstream clock, using the following formula:

\[
F_{\text{SCK_A}} = F_{\text{PDM_CK}} \times (\text{MICNBR} + 1) \times 2
\]

MICNBR can be 0,1,2 or 3 (0 = 2 microphones, see Section 69.6.18)

2. Set the frame length \( F_{\text{RL}} \) using the following formula

\[
F_{\text{RL}} = (16 \times (\text{MICNBR} + 1)) - 1
\]

3. Configure the slot size \( \text{DS} \) to a multiple of \( F_{\text{RL}} + 1 \).

Adjusting the delay lines

When the PDM interface is enabled, the application can adjust on-the-fly the delay cells of each microphone input via SAI_PDMDLY register.

The new delays values become effective after two TDM frames.
69.4.11 AC’97 link controller

The SAI is able to work as an AC’97 link controller. In this protocol:

- The slot number and the slot size are fixed.
- The frame synchronization signal is perfectly defined and has a fixed shape.

To select this protocol, set PRT CFG[1:0] bits in the SAI_xCR1 register to 10. When AC’97 mode is selected, only data sizes of 16 or 20 bits can be used, otherwise the SAI behavior is not guaranteed.

- NBSLOT[3:0] and SLOTSZ[1:0] bits are consequently ignored.
- The number of slots is fixed to 13 slots. The first one is 16-bit wide and all the others are 20-bit wide (data slots).
- FBOFF[4:0] bits in the SAI_xSLOTR register are ignored.
- The SAI_xFRCCR register is ignored.
- The MCLK is not used.

The FS signal from the block defined as asynchronous is configured automatically as an output, since the AC’97 controller link drives the FS signal whatever the master or slave configuration.

*Figure 864 shows an AC’97 audio frame structure.*

**Figure 864. AC’97 audio frame**

![AC'97 audio frame](image)

**Note:** In AC’97 protocol, bit 2 of the tag is reserved (always 0), so bit 2 of the TAG is forced to 0 level whatever the value written in the SAI FIFO.

For more details about tag representation, refer to the AC’97 protocol standard.

One SAI can be used to target an AC’97 point-to-point communication.

Using two SAIs (for devices featuring two embedded SAIs) enables the control of three external AC’97 decoders as illustrated in *Figure 865.*

In SAI1, the audio block A must be declared as asynchronous master transmitter whereas the audio block B is defined to be slave receiver and internally synchronous to the audio block A.

The SAI2 is configured for audio block A and B both synchronous with the external SAI1 in slave receiver mode.
In receiver mode, the SAI acting as an AC’97 link controller requires no FIFO request and so no data storage in the FIFO when the Codec ready bit in the slot 0 is decoded low. If bit CNRDYIE is enabled in the SAI_xIM register, flag CNRDY is set in the SAI_xSR register and an interrupt is generated. This flag is dedicated to the AC’97 protocol.

Clock generator programming in AC’97 mode

In AC’97 mode, the frame length is fixed at 256 bits, and its frequency must be set to 48 kHz. The formulas given in Section 69.4.8: SAI clock generator must be used with FRL = 255, in order to generate the proper frame rate ($F_{FS,x}$).
69.4.12  SPDIF output

The SPDIF interface is available in transmitter mode only. It supports the audio IEC60958. To select SPDIF mode, set PRTCFG[1:0] bit to 01 in the SAI_xCR1 register.

For SPDIF protocol:
- Only SD data line is enabled.
- FS, SCK, MCLK I/Os pins are left free.
- MODE[1] bit is forced to 0 to select the master mode in order to enable the clock generator of the SAI and manage the data rate on the SD line.
- The data size is forced to 24 bits. The value set in DS[2:0] bits in the SAI_xCR1 register is ignored.
- The clock generator must be configured to define the symbol-rate, knowing that the bit clock must be twice the symbol-rate. The data is coded in Manchester protocol.
- The SAI_xFRCR and SAI_xSLOTR registers are ignored. The SAI is configured internally to match the SPDIF protocol requirements as shown in Figure 866.

Figure 866. SPDIF format

A SPDIF block contains 192 frames. Each frame is composed of two 32-bit sub-frames, generally one for the left channel and one for the right channel. Each sub-frame is composed of a SOPD pattern (4-bit) to specify if the sub-frame is the start of a block (and so is identifying a channel A) or if it is identifying a channel A somewhere in the block, or if it is referring to channel B (see Table 706). The next 28 bits of channel information are composed of 24 bits data + 4 status bits.
The data stored in SAI_xDR has to be filled as follows:

- SAI_xDR[26:24] contain the Channel status, User and Validity bits.
- SAI_xDR[23:0] contain the 24-bit data for the considered channel.

If the data size is 20 bits, then data must be mapped on SAI_xDR[23:4].

If the data size is 16 bits, then data must be mapped on SAI_xDR[23:8].

SAI_xDR[23] always represents the MSB.

**Note:** The transfer is performed always with LSB first.

The SAI first sends the adequate preamble for each sub-frame in a block. The SAI_xDR is then sent on the SD line (manchester coded). The SAI ends the sub-frame by transferring the Parity bit calculated as described in Table 707.

The underrun is the only error flag available in the SAI_xSR register for SPDIF mode since the SAI can only operate in transmitter mode. As a result, the following sequence must be
executed to recover from an underrun error detected via the underrun interrupt or the underrun status bit:

1. Disable the DMA stream (via the DMA peripheral) if the DMA is used.
2. Disable the SAI and check that the peripheral is physically disabled by polling the SAIEN bit in SAI_xCR1 register.
3. Clear the COVRUNDR flag in the SAI_xCLRFR register.
4. Flush the FIFO by setting the FFLUSH bit in SAI_xCR2.
   The software needs to point to the address of the future data corresponding to a start of new block (data for preamble B). If the DMA is used, the DMA source base address pointer must be updated accordingly.
5. Enable again the DMA stream (DMA peripheral) if the DMA used to manage data transfers according to the new source base address.
6. Enable again the SAI by setting SAIEN bit in SAI_xCR1 register.

Clock generator programming in SPDIF generator mode

For the SPDIF generator, the SAI provides a bit clock twice faster as the symbol-rate. The table hereafter shows usual examples of symbol rates with respect to the audio sampling rate.

<table>
<thead>
<tr>
<th>Audio sampling frequencies (F_S)</th>
<th>Symbol-rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>44.1 kHz</td>
<td>2.8224 MHz</td>
</tr>
<tr>
<td>48 kHz</td>
<td>3.072 MHz</td>
</tr>
<tr>
<td>96 kHz</td>
<td>6.144 MHz</td>
</tr>
<tr>
<td>192 kHz</td>
<td>12.288 MHz</td>
</tr>
</tbody>
</table>

More generally, the relationship between the audio sampling frequency \(F_S\) and the bit clock rate \(F_{SCK_x}\) is given by the formula:

\[
F_S = \frac{F_{SCK_x}}{128}
\]

The bit clock rate is obtained as follows:

\[
F_{SCK_x} = \frac{F_{\text{sai}_x}_{\text{Ker,ck}}}{MCKDIV}
\]

Note: The above formulas are valid only if NODIV is set to 1 in SAI_ACR1 register.
69.4.13 Specific features

The SAI interface embeds specific features which can be useful depending on the audio protocol selected. These functions are accessible through specific bits of the SAI_xCR2 register.

Mute mode

The mute mode can be used when the audio subblock is a transmitter or a receiver.

Audio subblock in transmission mode

In transmitter mode, the mute mode can be selected at anytime. The mute mode is active for entire audio frames. The MUTE bit in the SAI_xCR2 register enables the mute mode when it is set during an ongoing frame.

The mute mode bit is strobed only at the end of the frame. If it is set at this time, the mute mode is active at the beginning of the new audio frame and for a complete frame, until the next end of frame. The bit is then strobed to determine if the next frame is still a mute frame.

If the number of slots set through NBSLOT[3:0] bits in the SAI_xSLOTR register is lower than or equal to 2, it is possible to specify if the value sent in mute mode is 0 or if it is the last value of each slot. The selection is done via MUTEVAL bit in the SAI_xCR2 register.

If the number of slots set in NBSLOT[3:0] bits in the SAI_xSLOTR register is greater than 2, MUTEVAL bit in the SAI_xCR2 is meaningless as 0 values are sent on each bit on each slot.

The FIFO pointers are still incremented in mute mode. This means that data present in the FIFO and for which the mute mode is requested are discarded.

Audio subblock in reception mode

In reception mode, it is possible to detect a mute mode sent from the external transmitter when all the declared and valid slots of the audio frame receive 0 for a given consecutive number of audio frames (MUTECNT[5:0] bits in the SAI_xCR2 register).

When the number of MUTE frames is detected, the MUTEDET flag in the SAI_xSR register is set and an interrupt can be generated if MUTEDETIE bit is set in SAI_xCR2.

The mute frame counter is cleared when the audio subblock is disabled or when a valid slot receives at least one data in an audio frame. The interrupt is generated just once, when the counter reaches the value specified in MUTECNT[5:0] bits. The interrupt event is then reinitialized when the counter is cleared.

Note: The mute mode is not available for SPDIF audio blocks.

Mono/stereo mode

In transmitter mode, the mono mode can be addressed, without any data preprocessing in memory, assuming the number of slots is equal to 2 (NBSLOT[3:0] = 0001 in SAI_xSLOTR). In this case, the access time to and from the FIFO is reduced by 2 since the data for slot 0 is duplicated into data slot 1.

To enable the mono mode,
1. Set MONO bit to 1 in the SAI_xCR1 register.
2. Set NBSLOT to 1 and SLOTEN to 3 in SAI_xSLOTR.
In reception mode, the MONO bit can be set and is meaningful only if the number of slots is equal to 2 as in transmitter mode. When it is set, only slot 0 data are stored in the FIFO. The data belonging to slot 1 are discarded since, in this case, it is supposed to be the same as the previous slot. If the data flow in reception mode is a real stereo audio flow with a distinct and different left and right data, the MONO bit is meaningless. The conversion from the output stereo file to the equivalent mono file is done by software.

Compingding mode

Telecommunication applications can require to process the data to be transmitted or received using a data companding algorithm.

Depending on the COMP[1:0] bits in the SAI_xCR2 register (used only when Free protocol mode is selected), the application software can choose to process or not the data before sending it on SD serial output line (compression) or to expand the data after the reception on SD serial input line (expansion) as illustrated in Figure 868. The two companding modes supported are the µ-Law and the A-Law log which are a part of the CCITT G.711 recommendation.

The companding standard used in the United States and Japan is the µ-Law. It supports 14 bits of dynamic range (COMP[1:0] = 10 in the SAI_xCR2 register).

The European companding standard is A-Law and supports 13 bits of dynamic range (COMP[1:0] = 11 in the SAI_xCR2 register).

Both µ-Law or A-Law companding standard can be computed based on 1’s complement or 2’s complement representation depending on the CPL bit setting in the SAI_xCR2 register.

In µ-Law and A-Law standards, data are coded as 8 bits with MSB alignment. Companded data are always 8-bit wide. For this reason, DS[2:0] bits in the SAI_xCR1 register are forced to 010 when the SAI audio block is enabled (SAIEN bit = 1 in the SAI_xCR1 register) and when one of these two companding modes selected through the COMP[1:0] bits.

If no companding processing is required, COMP[1:0] bits must be kept clear.
Expansion and compression mode are automatically selected through the SAI_xCR2:

- If the SAI audio block is configured to be a transmitter, and if the COMP[1] bit is set in the SAI_xCR2 register, the compression mode is applied.
- If the SAI audio block is declared as a receiver, the expansion algorithm is applied.

### Output data line management on an inactive slot

In transmitter mode, it is possible to choose the behavior of the SD line output when an inactive slot is sent on the data line (via TRIS bit).

- Either the SAI forces 0 on the SD output line when an inactive slot is transmitted, or
- The line is released in HI-z state at the end of the last bit of data transferred, to release the line for other transmitters connected to this node.

It is important to note that the two transmitters cannot attempt to drive the same SD output pin simultaneously, which may result in a short circuit. To ensure a gap between transmissions, if the data is lower than 32-bit, the data can be extended to 32-bit by setting bit SLOTSZ[1:0] = 10 in the SAI_xSLOTR register. The SD output pin is then tri-stated at the end of the LSB of the active slot (during the padding to 0 phase to extend the data to 32-bit) if the following slot is declared inactive.

In addition, if the number of slots multiplied by the slot size is lower than the frame length, the SD output line is tri-stated when the padding to 0 is done to complete the audio frame. *Figure 869* illustrates these behaviors.
When the selected audio protocol uses the FS signal as a start of frame and a channel side identification (bit FSDEF = 1 in the SAI_xFRCR register), the tristate mode is managed according to Figure 870 (where bit TRIS in the SAI_xCR1 register = 1, and FSDEF=1, and half frame length is higher than number of slots/2, and NBSLOT=6).
If the TRIS bit in the SAI_xCR2 register is cleared, all the High impedance states on the SD output line on Figure 869 and Figure 870 are replaced by a drive with a value of 0.

69.4.14 Error flags

The SAI implements the following error flags:
- FIFO overrun/underrun
- Anticipated frame synchronization detection
- Late frame synchronization detection
- Codec not ready (AC'97 exclusively)
- Wrong clock configuration in master mode.

FIFO overrun/underrun (OVRUDR)

The FIFO overrun/underrun bit is called OVRUDR in the SAI_xSR register.

The overrun or underrun errors share the same bit since an audio block can be either receiver or transmitter and each audio block in a given SAI has its own SAI_xSR register.

Overrun

When the audio block is configured as receiver, an overrun condition may appear if data are received in an audio frame when the FIFO is full and not able to store the received data. In this case, the received data are lost, the flag OVRUDR in the SAI_xSR register is set and an interrupt is generated if OVRUDRIE bit is set in the SAI_xIM register. The slot number, from which the overrun occurs, is stored internally. No more data are stored into the FIFO until it becomes free to store new data. When the FIFO has at least one data free, the SAI audio block receiver stores new data (from new audio frame) from the slot number which was stored internally when the overrun condition was detected. This avoids data slot de-alignment in the destination memory (refer to Figure 871).

The OVRUDR flag is cleared when COVRUDR bit is set in the SAI_xCLRFR register.
Figure 871. Overrun detection error

Underrun

An underrun may occur when the audio block in the SAI is a transmitter and the FIFO is empty when data need to be transmitted. If an underrun is detected, the slot number for which the event occurs is stored and MUTE value (00) is sent until the FIFO is ready to transmit the data corresponding to the slot for which the underrun was detected (refer to Figure 872). This avoids desynchronization between the memory pointer and the slot in the audio frame.

The underrun event sets the OVRUDR flag in the SAI_xSR register and an interrupt is generated if the OVRUDRIE bit is set in the SAI_xIM register. To clear this flag, set COVRUDR bit in the SAI_xCLRFR register.

The underrun event can occur when the audio subblock is configured as master or slave.

Figure 872. FIFO underrun event
Anticipated frame synchronization detection (AFSDET)

The AFSDET flag is used only in slave mode. It is never asserted in master mode. It indicates that a frame synchronization (FS) has been detected earlier than expected since the frame length, the frame polarity, the frame offset are defined and known.

Anticipated frame detection sets the AFSDET flag in the SAI_xSR register.

This detection has no effect on the current audio frame which is not sensitive to the anticipated FS. This means that “parasitic” events on signal FS are flagged without any perturbation of the current audio frame.

An interrupt is generated if the AFSDETIE bit is set in the SAI_xIM register. To clear the AFSDET flag, CAFSDET bit must be set in the SAI_xCLRFR register.

To resynchronize with the master after an anticipated frame detection error, four steps are required:

1. Disable the SAI block by resetting SAIEN bit in SAI_xCR1 register. To make sure the SAI is disabled, read back the SAIEN bit and check it is set to 0.
2. Flush the FIFO via FFLUS bit in SAI_xCR2 register.
3. Enable again the SAI peripheral (SAIEN bit set to 1).
4. The SAI block waits for the assertion on FS to restart the synchronization with master.

Note: The AFSDET flag is not asserted in AC’97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the FS signal is not used.

Late frame synchronization detection

The LFSDET flag in the SAI_xSR register can be set only when the SAI audio block operates as a slave. The frame length, the frame polarity and the frame offset configuration are known in register SAI_xFRCR.

If the external master does not send the FS signal at the expecting time thus generating the signal too late, the LFSDET flag is set and an interrupt is generated if LFSDETIE bit is set in the SAI_xIM register.

The LFSDET flag is cleared when CLFSDET bit is set in the SAI_xCLRFR register.

The late frame synchronization detection flag is set when the corresponding error is detected. The SAI needs to be resynchronized with the master (see sequence described in Anticipated frame synchronization detection (AFSDET)).

In a noisy environment, glitches on the SCK clock may be wrongly detected by the audio block state machine and shift the SAI data at a wrong frame position. This event can be detected by the SAI and reported as a late frame synchronization detection error.

There is no corruption if the external master is not managing the audio data frame transfer in continuous mode, which must not be the case in most applications. In this case, the LFSDET flag is set.

Note: The LFSDET flag is not asserted in AC’97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the signal FS is not used by the protocol.
Codec not ready (CNRDY AC'97)

The CNRDY flag in the SAI_xSR register is relevant only if the SAI audio block is configured to operate in AC'97 mode (PRTCFG[1:0] = 10 in the SAI_xCR1 register). If CNRDYIE bit is set in the SAI_xIM register, an interrupt is generated when the CNRDY flag is set.

CNRDY is asserted when the Codec is not ready to communicate during the reception of the TAG 0 (slot0) of the AC'97 audio frame. In this case, no data are automatically stored into the FIFO since the Codec is not ready, until the TAG 0 indicates that the Codec is ready. All the active slots defined in the SAI_xSLOTTR register are captured when the Codec is ready.

To clear CNRDY flag, CCNRDY bit must be set in the SAI_xCLRFR register.

Wrong clock configuration in master mode (with NODIV = 0)

When the audio block operates as a master (MODE[1] = 0) and NODIV bit is equal to 0, the WCKCFG flag is set as soon as the SAI is enabled if the following conditions are met:

- (FRL+1) is not a power of 2, and
- (FRL+1) is not between 8 and 256.

MODE, NODIV, and SAIEN bits belong to SAI_xCR1 register and FRL to SAI_xFRCR register.

If WCKCFGIE bit is set, an interrupt is generated when WCKCFG flag is set in the SAI_xSR register. To clear this flag, set CWCKCFG bit in the SAI_xCLRFR register.

When WCKCFG bit is set, the audio block is automatically disabled, thus performing a hardware clear of SAIEN bit.

69.4.15 Disabling the SAI

The SAI audio block can be disabled at any moment by clearing SAIEN bit in the SAI_xCR1 register. All the already started frames are automatically completed before the SAI is stops working. SAIEN bit remains High until the SAI is completely switched-off at the end of the current audio frame transfer.

If an audio block in the SAI operates synchronously with the other one, the one which is the master must be disabled first.

69.4.16 SAI DMA interface

To free the CPU and to optimize bus bandwidth, each SAI audio block has an independent DMA interface to read/write from/to the SAI_xDR register (to access the internal FIFO). There is one DMA channel per audio subblock supporting basic DMA request/acknowledge protocol.

To configure the audio subblock for DMA transfer, set DMAEN bit in the SAI_xCR1 register. The DMA request is managed directly by the FIFO controller depending on the FIFO threshold level (for more details refer to Section 69.4.9: Internal FIFOs). DMA transfer direction is linked to the SAI audio subblock configuration:

- If the audio block operates as a transmitter, the audio block FIFO controller outputs a DMA request to load the FIFO with data written in the SAI_xDR register.
- If the audio block is operates as a receiver, the DMA request is related to read operations from the SAI_xDR register.
Follow the sequence below to configure the SAI interface in DMA mode:
1. Configure SAI and FIFO threshold levels to specify when the DMA request is launched.
2. Configure SAI DMA channel.
3. Enable the DMA.
4. Enable the SAI interface.

*Note:* Before configuring the SAI block, the SAI DMA channel must be disabled.

### 69.5 SAI interrupts

The SAI supports 7 interrupt sources as shown in Table 709.

Follow the sequence below to enable an interrupt:
1. Disable SAI interrupt.
2. Configure SAI.
3. Configure SAI interrupt source.
4. Enable SAI.

69.6 SAI registers

The peripheral registers have to be accessed by words (32 bits).

69.6.1 SAI global configuration register (SAI_GCR)

Address offset: 0x00
Reset value: 0x0000 0000

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 **SYNCOUT[1:0]**: Synchronization outputs

These bits are set and cleared by software.
- 00: No synchronization output signals. SYNCOUT[1:0] must be configured as “No synchronization output signals” when audio block is configured as SPDIF
- 01: Block A used for further synchronization for others SAI
- 10: Block B used for further synchronization for others SAI
- 11: Reserved. These bits must be set when both audio blocks (A and B) are disabled.

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **SYNCIN[1:0]**: Synchronization inputs

These bits are set and cleared by software.
Refer to Table 701: External synchronization selection for information on how to program this field.
These bits must be set when both audio blocks (A and B) are disabled.
They are meaningful if one of the two audio blocks is defined to operate in synchronous mode with an external SAI (SYNCEN[1:0] = 10 in SAI_ACR1 or in SAI_BCR1 registers).
69.6.2 SAI configuration register 1 (SAI_ACR1)

Address offset: 0x004
Reset value: 0x0000 0040

| Bit 31:28 Reserved, must be kept at reset value. |
| Bit 27 **MCKEN**: Master clock generation enable |
| 0: The master clock is not generated |
| 1: The master clock is generated independently of SAIEN bit |
| Bit 26 **OSR**: Oversampling ratio for master clock |
| This bit is meaningful only when NODIV bit is set to 0. |
| 0: Master clock frequency = F_FS x 256 |
| 1: Master clock frequency = F_FS x 512 |
| Bits 25:20 **MCKDIV[5:0]**: Master clock divider |
| These bits are set and cleared by software. |
| 000000: Divides by 1 the kernel clock input (sai_x_ker_ck). |
| Otherwise, The master clock frequency is calculated according to the formula given in Section 69.4.8: SAI clock generator. |
| These bits have no meaning when the audio block is slave. |
| They have to be configured when the audio block is disabled. |
| Bit 19 **NODIV**: No divider |
| This bit is set and cleared by software. |
| 0: the ratio between the Master clock generator and frame synchronization is fixed to 256 or 512 |
| 1: the ratio between the Master clock generator and frame synchronization depends on FRL[7:0] |
| Bit 18 Reserved, must be kept at reset value. |
| Bit 17 **DMAEN**: DMA enable |
| This bit is set and cleared by software. |
| 0: DMA disabled |
| 1: DMA enabled |

*Note: Since the audio block defaults to operate as a transmitter after reset, the MODE[1:0] bits must be configured before setting DMAEN to avoid a DMA request in receiver mode.*
Bit 16 **SAIEN**: Audio block enable

This bit is set by software.

To switch off the audio block, the application software must program this bit to 0 and poll the bit till it reads back 0, meaning that the block is completely disabled. Before setting this bit to 1, check that it is set to 0, otherwise the enable command is not taken into account.

This bit enables to control the state of the SAI audio block. If it is disabled when an audio frame transfer is ongoing, the ongoing transfer completes and the cell is fully disabled at the end of this audio frame transfer.

0: SAI audio block disabled
1: SAI audio block enabled.

*Note:* When the SAI block (A or B) is configured in master mode, the clock must be present on the SAI block input before setting SAIEN bit.

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OUTDRIV**: Output drive

This bit is set and cleared by software.

0: Audio block output driven when SAIEN is set
1: Audio block output driven immediately after the setting of this bit.

*Note:* This bit has to be set before enabling the audio block and after the audio block configuration.

Bit 12 **MONO**: Mono mode

This bit is set and cleared by software. It is meaningful only when the number of slots is equal to 2.

When the mono mode is selected, slot 0 data are duplicated on slot 1 when the audio block operates as a transmitter. In reception mode, the slot1 is discarded and only the data received from slot 0 are stored. Refer to Section: Mono/stereo mode for more details.

0: Stereo mode
1: Mono mode.

Bits 11:10 **SYNCEN[1:0]**: Synchronization enable

These bits are set and cleared by software. They must be configured when the audio subblock is disabled.

00: audio subblock in asynchronous mode.
01: audio subblock is synchronous with the other internal audio subblock. In this case, the audio subblock must be configured in slave mode.
10: audio subblock is synchronous with an external SAI embedded peripheral. In this case the audio subblock must be configured in Slave mode.
11: Reserved

*Note:* The audio subblock must be configured as asynchronous when SPDIF mode is enabled.

Bit 9 **CKSTR**: Clock strobing edge

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in SPDIF audio protocol.

0: Signals generated by the SAI change on SCK rising edge, while signals received by the SAI are sampled on the SCK falling edge.
1: Signals generated by the SAI change on SCK falling edge, while signals received by the SAI are sampled on the SCK rising edge.

Bit 8 **LSBFIRST**: Least significant bit first

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in AC’97 audio protocol since AC’97 data are always transferred with the MSB first. This bit has no meaning in SPDIF audio protocol since in SPDIF data are always transferred with LSB first.

0: Data are transferred with MSB first
1: Data are transferred with LSB first
**Bits 7:5** DS[2:0]: Data size

These bits are set and cleared by software. These bits are ignored when the SPDIF protocols are selected (bit PRTCFG[1:0]), because the frame and the data size are fixed in such case. When the companding mode is selected through COMP[1:0] bits, DS[1:0] are ignored since the data size is fixed to 8 bits by the algorithm.

These bits must be configured when the audio block is disabled.

- 000: Reserved
- 001: Reserved
- 010: 8 bits
- 011: 10 bits
- 100: 16 bits
- 101: 20 bits
- 110: 24 bits
- 111: 32 bits

**Bit 4** Reserved, must be kept at reset value.

**Bits 3:2** PRTCFG[1:0]: Protocol configuration

These bits are set and cleared by software. These bits have to be configured when the audio block is disabled.

- 00: Free protocol. Free protocol enables to use the powerful configuration of the audio block to address a specific audio protocol (such as I2S, LSB/MSB justified, TDM, PCM/DSP...) by setting most of the configuration register bits as well as frame configuration register.
- 01: SPDIF protocol
- 10: AC’97 protocol
- 11: Reserved

**Bits 1:0** MODE[1:0]: SAIx audio block mode

These bits are set and cleared by software. They must be configured when SAIx audio block is disabled.

- 00: Master transmitter
- 01: Master receiver
- 10: Slave transmitter
- 11: Slave receiver

*Note: When the audio block is configured in SPDIF mode, the master transmitter mode is forced (MODE[1:0] = 00).*

---

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **MCKEN**: Master clock generation enable
- 0: The master clock is not generated
- 1: The master clock is generated independently of SAIEN bit

Bit 26 **OSR**: Oversampling ratio for master clock
- This bit is meaningful only when NODIV bit is set to 0.
  - 0: Master clock frequency = $F_{FS} \times 256$
  - 1: Master clock frequency = $F_{FS} \times 512$

Bits 25:20 **MCKDIV[5:0]**: Master clock divider
- These bits are set and cleared by software.
  - 000000: Divides by 1 the kernel clock input ($sai_x_ker_ck$).
  - Otherwise, The master clock frequency is calculated according to the formula given in Section 69.4.8: SAI clock generator.
- These bits have no meaning when the audio block is slave.
- They have to be configured when the audio block is disabled.

Bit 19 **NODIV**: No divider
- This bit is set and cleared by software.
  - 0: the ratio between the Master clock generator and frame synchronization is fixed to 256 or 512
  - 1: the ratio between the Master clock generator and frame synchronization depends on FRL[7:0]

Bit 18 Reserved, must be kept at reset value.

Bit 17 **DMAEN**: DMA enable
- This bit is set and cleared by software.
  - 0: DMA disabled
  - 1: DMA enabled
- *Note*: Since the audio block defaults to operate as a transmitter after reset, the **MODE[1:0]** bits must be configured before setting **DMAEN** to avoid a DMA request in receiver mode.

Bit 16 **SAIEN**: Audio block enable
- This bit is set by software.
  - To switch off the audio block, the application software must program this bit to 0 and poll the bit till it reads back 0, meaning that the block is completely disabled. Before setting this bit to 1, check that it is set to 0, otherwise the enable command is not taken into account.
  - This bit enables to control the state of the SAI audio block. If it is disabled when an audio frame transfer is ongoing, the ongoing transfer completes and the cell is fully disabled at the end of this audio frame transfer.
  - 0: SAI audio block disabled
  - 1: SAI audio block enabled.
  - *Note*: When the SAI block (A or B) is configured in master mode, the clock must be present on the SAI block input before setting SAIEN bit.

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OUTDRIV**: Output drive
- This bit is set and cleared by software.
  - 0: Audio block output driven when SAIEN is set
  - 1: Audio block output driven immediately after the setting of this bit.
  - *Note*: This bit has to be set before enabling the audio block and after the audio block configuration.
Bit 12 **MONO**: Mono mode

This bit is set and cleared by software. It is meaningful only when the number of slots is equal to 2. When the mono mode is selected, slot 0 data are duplicated on slot 1 when the audio block operates as a transmitter. In reception mode, the slot1 is discarded and only the data received from slot 0 are stored. Refer to Section : Mono/stereo mode for more details.

0: Stereo mode
1: Mono mode.

Bits 11:10 **SYNCEN[1:0]**: Synchronization enable

These bits are set and cleared by software. They must be configured when the audio subblock is disabled.

00: audio subblock in asynchronous mode.
01: audio subblock is synchronous with the other internal audio subblock. In this case, the audio subblock must be configured in slave mode
10: audio subblock is synchronous with an external SAI embedded peripheral. In this case the audio subblock must be configured in Slave mode.
11: Reserved

*Note: The audio subblock must be configured as asynchronous when SPDIF mode is enabled.*

Bit 9 **CKSTR**: Clock strobing edge

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in SPDIF audio protocol.

0: Signals generated by the SAI change on SCK rising edge, while signals received by the SAI are sampled on the SCK falling edge.
1: Signals generated by the SAI change on SCK falling edge, while signals received by the SAI are sampled on the SCK rising edge.

Bit 8 **LSBFIRST**: Least significant bit first

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in AC’97 audio protocol since AC’97 data are always transferred with the MSB first. This bit has no meaning in SPDIF audio protocol since in SPDIF data are always transferred with LSB first.

0: Data are transferred with MSB first
1: Data are transferred with LSB first

Bits 7:5 **DS[2:0]**: Data size

These bits are set and cleared by software. These bits are ignored when the SPDIF protocols are selected (bit PRTCFG[1:0]), because the frame and the data size are fixed in such case. When the companding mode is selected through COMP[1:0] bits, DS[1:0] are ignored since the data size is fixed to 8 bits by the algorithm.

These bits must be configured when the audio block is disabled.

000: Reserved
001: Reserved
010: 8 bits
011: 10 bits
100: 16 bits
101: 20 bits
110: 24 bits
111: 32 bits
Bit 4 Reserved, must be kept at reset value.

**Bits 3:2 PRTCFG[1:0]: Protocol configuration**

These bits are set and cleared by software. These bits have to be configured when the audio block is disabled.

00: Free protocol. Free protocol enables to use the powerful configuration of the audio block to address a specific audio protocol (such as I2S, LSB/MSB justified, TDM, PCM/DSP...) by setting most of the configuration register bits as well as frame configuration register.

01: SPDIF protocol
10: AC'97 protocol
11: Reserved

**Bits 1:0 MODE[1:0]: SAIx audio block mode**

These bits are set and cleared by software. They must be configured when SAIx audio block is disabled.

00: Master transmitter
01: Master receiver
10: Slave transmitter
11: Slave receiver

*Note: When the audio block is configured in SPDIF mode, the master transmitter mode is forced (MODE[1:0] = 00). In Master transmitter mode, the audio block starts generating the FS and the clocks immediately.*

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:14  COMP[1:0]: Comping mode.
These bits are set and cleared by software. The μ-Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that is used depends on CPL bit.
The data expansion or data compression are determined by the state of bit MODE[0].
The data compression is applied if the audio block is configured as a transmitter.
The data expansion is automatically applied when the audio block is configured as a receiver.
Refer to Section : Comping mode for more details.
00: No companding algorithm
01: Reserved.
10: μ-Law algorithm
11: A-Law algorithm

Note:  Comping mode is applicable only when Free protocol mode is selected.

Bit 13  CPL: Complement bit.
This bit is set and cleared by software.
It defines the type of complement to be used for companding mode
0: 1’s complement representation.
1: 2’s complement representation.

Note:  This bit has effect only when the companding mode is μ-Law algorithm or A-Law algorithm.

Bits 12:7  MUTECNT[5:0]: Mute counter.
These bits are set and cleared by software. They are used only in reception mode.
The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag MUTEDET is set and an interrupt is generated if bit MUTEDETIE is set.
Refer to Section : Mute mode for more details.

Bit 6  MUTEVAL: Mute value.
This bit is set and cleared by software. It must be written before enabling the audio block: SAIEN.
This bit is meaningful only when the audio block operates as a transmitter, the number of slots is lower or equal to 2 and the MUTE bit is set.
If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0, whatever the value of MUTEVAL.
if the number of slot is lower or equal to 2 and MUTEVAL = 1, the MUTE value transmitted for each slot is the one sent during the previous frame.
Refer to Section : Mute mode for more details.
0: Bit value 0 is sent during the mute mode.
1: Last values are sent during the mute mode.

Note:  This bit is meaningless and must not be used for SPDIF audio blocks.

Bit 5  MUTE: Mute.
This bit is set and cleared by software. It is meaningful only when the audio block operates as a transmitter. The MUTE value is linked to value of MUTEVAL if the number of slots is lower or equal to 2, or equal to 0 if it is greater than 2.
Refer to Section : Mute mode for more details.
0: No mute mode.
1: Mute mode enabled.

Note:  This bit is meaningless and must not be used for SPDIF audio blocks.

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:14  **COMP[1:0]**: Comanding mode.
- These bits are set and cleared by software. The μ-Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that is used depends on CPL bit.
- The data expansion or data compression are determined by the state of bit MODE[0].
- The data compression is applied if the audio block is configured as a transmitter.
- The data expansion is automatically applied when the audio block is configured as a receiver.
- Refer to Section : Comanding mode for more details.
  00: No companding algorithm
  01: Reserved.
  10: μ-Law algorithm
  11: A-Law algorithm

**Note:** Comanding mode is applicable only when Free protocol mode is selected.

Bit 13  **CPL**: Complement bit.
- This bit is set and cleared by software.
- It defines the type of complement to be used for companding mode
  0: 1’s complement representation.
  1: 2’s complement representation.

**Note:** This bit has effect only when the companding mode is μ-Law algorithm or A-Law algorithm.

Bits 12:7  **MUTECNT[5:0]**: Mute counter.
- These bits are set and cleared by software. They are used only in reception mode.
- The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag MUTEDET is set and an interrupt is generated if bit MUTEDETIE is set.
- Refer to Section : Mute mode for more details.

Bit 6  **MUTEVAL**: Mute value.
- This bit is set and cleared by software. It must be written before enabling the audio block: SAIEN.
- This bit is meaningful only when the audio block operates as a transmitter, the number of slots is lower or equal to 2 and the MUTE bit is set.
- If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0, whatever the value of MUTEVAL.
- If the number of slot is lower or equal to 2 and MUTEVAL = 1, the MUTE value transmitted for each slot is the one sent during the previous frame.
- Refer to Section : Mute mode for more details.
  0: Bit value 0 is sent during the mute mode.
  1: Last values are sent during the mute mode.

**Note:** This bit is meaningless and must not be used for SPDIF audio blocks.

Bit 5  **MUTE**: Mute.
- This bit is set and cleared by software. It is meaningful only when the audio block operates as a transmitter. The MUTE value is linked to value of MUTEVAL if the number of slots is lower or equal to 2, or equal to 0 if it is greater than 2.
- Refer to Section : Mute mode for more details.
  0: No mute mode.
  1: Mute mode enabled.

**Note:** This bit is meaningless and must not be used for SPDIF audio blocks.
Bit 4 **TRIS**: Tristate management on data line.
This bit is set and cleared by software. It is meaningful only if the audio block is configured as a transmitter. This bit is not used when the audio block is configured in SPDIF mode. It must be configured when SAI is disabled.
Refer to *Section: Output data line management on an inactive slot* for more details.
0: SD output line is still driven by the SAI when a slot is inactive.
1: SD output line is released (HI-Z) at the end of the last data bit of the last active slot if the next one is inactive.

Bit 3 **FFLUSH**: FIFO flush.
This bit is set by software. It is always read as 0. This bit must be configured when the SAI is disabled.
0: No FIFO flush.
1: FIFO flush. Programming this bit to 1 triggers the FIFO Flush. All the internal FIFO pointers (read and write) are cleared. In this case data still present in the FIFO are lost (no more transmission or received data lost). Before flushing, SAI DMA stream/interrupt must be disabled.

Bits 2:0 **FTH[2:0]**: FIFO threshold.
This bit is set and cleared by software.
000: FIFO empty
001: ¼ FIFO
010: ½ FIFO
011: ¾ FIFO
100: FIFO full
101: Reserved
110: Reserved
111: Reserved

### 69.6.6 SAI frame configuration register (SAI_AFRCR)

Address offset: 0x00C
Reset value: 0x0000 0007

*Note:* *This register has no meaning in AC’97 and SPDIF audio protocol.*
Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **FSOFF**: Frame synchronization offset.
This bit is set and cleared by software. It is meaningless and is not used in AC'97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.
- 0: FS is asserted on the first bit of the slot 0.
- 1: FS is asserted one bit before the first bit of the slot 0.

Bit 17 **FSPOL**: Frame synchronization polarity.
This bit is set and cleared by software. It is used to configure the level of the start of frame on the FS signal. It is meaningless and is not used in AC'97 or SPDIF audio block configuration.
- 0: FS is active low (falling edge)
- 1: FS is active high (rising edge)

Bit 16 **FSDEF**: Frame synchronization definition.
This bit is set and cleared by software.
- 0: FS signal is a start frame signal
- 1: FS signal is a start of frame signal + channel side identification
When the bit is set, the number of slots defined in the SAI_xSLOTR register has to be even. It means that half of this number of slots are dedicated to the left channel and the other slots for the right channel (e.g.: this bit has to be set for I2S or MSB/LSB-justified protocols...).
This bit is meaningless and is not used in AC'97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **FSALL[6:0]**: Frame synchronization active level length.
These bits are set and cleared by software. They specify the length in number of bit clock (SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame.
These bits are meaningless and are not used in AC'97 or SPDIF audio block configuration.
They must be configured when the audio block is disabled.

Bits 7:0 **FRL[7:0]**: Frame length.
These bits are set and cleared by software. They define the audio frame length expressed in number of SCK clock cycles: the number of bits in the frame is equal to FRL[7:0] + 1.
The minimum number of bits to transfer in an audio frame must be equal to 8, otherwise the audio block behaves in an unexpected way. This is the case when the data size is 8 bits and only one slot 0 is defined in NBSLOT[4:0] of SAI_xSLOTR register (NBSLOT[3:0] = 0000).
In master mode, if the master clock (available on MCLK_x pin) is used, the frame length must be aligned with a number equal to a power of 2, ranging from 8 to 256. When the master clock is not used (NODIV = 1), it is recommended to program the frame length to an value ranging from 8 to 256. These bits are meaningless and are not used in AC'97 or SPDIF audio block configuration. They must be configured when the audio block is disabled.
69.6.7  **SAI frame configuration register (SAI_BFRCR)**

*Address offset: 0x02C*

*Reset value: 0x0000 0007*

**Note:**  *This register has no meaning in AC'97 and SPDIF audio protocol*

Bits 31:19  Reserved, must be kept at reset value.

**Bit 18  FSOFF**: Frame synchronization offset.

- This bit is set and cleared by software. It is meaningless and is not used in AC'97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.
- 0: FS is asserted on the first bit of the slot 0.
- 1: FS is asserted one bit before the first bit of the slot 0.

**Bit 17  FSPOL**: Frame synchronization polarity.

- This bit is set and cleared by software. It is used to configure the level of the start of frame on the FS signal. It is meaningless and is not used in AC'97 or SPDIF audio block configuration.
- This bit must be configured when the audio block is disabled.
- 0: FS is active low (falling edge)
- 1: FS is active high (rising edge)

**Bit 16  FSDEF**: Frame synchronization definition.

- This bit is set and cleared by software.
- 0: FS signal is a start frame signal
- 1: FS signal is a start of frame signal + channel side identification

When the bit is set, the number of slots defined in the SAI_xSLOTR register has to be even. It means that half of this number of slots is dedicated to the left channel and the other slots for the right channel (e.g: this bit has to be set for I2S or MSB/LSB-justified protocols...).

This bit is meaningless and is not used in AC'97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.
Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **FSALL[6:0]**: Frame synchronization active level length.
   These bits are set and cleared by software. They specify the length in number of bit clock (SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame.
   These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration.
   They must be configured when the audio block is disabled.

Bits 7:0 **FRL[7:0]**: Frame length.
   These bits are set and cleared by software. They define the audio frame length expressed in number of SCK clock cycles: the number of bits in the frame is equal to FRL[7:0] + 1.
   The minimum number of bits to transfer in an audio frame must be equal to 8, otherwise the audio block behaves in an unexpected way. This is the case when the data size is 8 bits and only one slot 0 is defined in NBSLOT[4:0] of SAI-xsLOTR register (NBSLOT[3:0] = 0000).
   In master mode, if the master clock (available on MCLK_x pin) is used, the frame length must be aligned with a number equal to a power of 2, ranging from 8 to 256. When the master clock is not used (NODIV = 1), it is recommended to program the frame length to an value ranging from 8 to 256.
   These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration.

### 69.6.8 SAI slot register (SAI_ASLOTR)

Address offset: 0x010
Reset value: 0x0000 0000

**Note:** This register has no meaning in AC’97 and SPDIF audio protocol.

Bits 31:16 **SlotEN[15:0]**: Slot enable.
   These bits are set and cleared by software.
   Each SlotEN bit corresponds to a slot position from 0 to 15 (maximum 16 slots).
   0: Inactive slot.
   1: Active slot.
   The slot must be enabled when the audio block is disabled.
   They are ignored in AC’97 or SPDIF mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **NBSLOT[3:0]**: Number of slots in an audio frame.
   These bits are set and cleared by software.
   The value set in this bitfield represents the number of slots + 1 in the audio frame (including the number of inactive slots). The maximum number of slots is 16.
   The number of slots must be even if FSDEF bit in the SAI_xFRCR register is set.
   The number of slots must be configured when the audio block is disabled.
   They are ignored in AC’97 or SPDIF mode.
Bits 7.6 **SLOTSZ[1:0]**: Slot size

This bits is set and cleared by software.

The slot size must be higher or equal to the data size. If this condition is not respected, the behavior of the SAI is undetermined.

Refer to Output data line management on an inactive slot for information on how to drive SD line.

These bits must be set when the audio block is disabled.

They are ignored in AC’97 or SPDIF mode.

- **00**: The slot size is equivalent to the data size (specified in DS[3:0] in the SAI_xCR1 register).
- **01**: 16-bit
- **10**: 32-bit
- **11**: Reserved

Bit 5 Reserved, must be kept at reset value.

Bits 4.0 **FBOFF[4:0]**: First bit offset

These bits are set and cleared by software.

The value set in this bitfield defines the position of the first data transfer bit in the slot. It represents an offset value. In transmission mode, the bits outside the data field are forced to 0. In reception mode, the extra received bits are discarded.

These bits must be set when the audio block is disabled.

They are ignored in AC’97 or SPDIF mode.

### 69.6.9 SAI slot register (SAI_BSLOTR)

**Address offset**: 0x030

**Reset value**: 0x0000 0000

**Note**: This register has no meaning in AC’97 and SPDIF audio protocol.
31:16 **SLOTEN[15:0]**: Slot enable.
   These bits are set and cleared by software.
   Each SLOTEN bit corresponds to a slot position from 0 to 15 (maximum 16 slots).
   0: Inactive slot.
   1: Active slot.
   The slot must be enabled when the audio block is disabled.
   They are ignored in AC'97 or SPDIF mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **NBSLOT[3:0]**: Number of slots in an audio frame.
   These bits are set and cleared by software.
   The value set in this bitfield represents the number of slots + 1 in the audio frame (including the number of inactive slots).
   The maximum number of slots is 16.
   The number of slots must be even if FSDEF bit in the SAI_xFRCR register is set.
   They must be set when the audio block is disabled.
   They are ignored in AC'97 or SPDIF mode.

Bits 7:6 **SLOTSZ[1:0]**: Slot size
   This bits is set and cleared by software.
   The slot size must be higher or equal to the data size. If this condition is not respected, the behavior of the SAI is undetermined.
   Refer to Output data line management on an inactive slot for information on how to drive SD line.
   These bits must be set when the audio block is disabled.
   They are ignored in AC'97 or SPDIF mode.

   00: The slot size is equivalent to the data size (specified in DS[3:0] in the SAI_xCR1 register).
   01: 16-bit
   10: 32-bit
   11: Reserved

Bits 5 Reserved, must be kept at reset value.

Bits 4:0 **FBOFF[4:0]**: First bit offset
   These bits are set and cleared by software.
   The value set in this bitfield defines the position of the first data transfer bit in the slot. It represents an offset value. In transmission mode, the bits outside the data field are forced to 0. In reception mode, the extra received bits are discarded.
   These bits must be set when the audio block is disabled.
   They are ignored in AC'97 or SPDIF mode.

### 69.6.10 SAI interrupt mask register (SAI_AIM)

Address offset: 0x014
Reset value: 0x0000 0000
Bits 31:7  Reserved, must be kept at reset value.

Bit 6  **LFSDETIE**: Late frame synchronization detection interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the LFSDET bit is set in the SAI_xSR register.
This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

Bit 5  **AFSDETIE**: Anticipated frame synchronization detection interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the AFSDET bit in the SAI_xSR register is set.
This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

Bit 4  **CNRDYIE**: Codec not ready interrupt enable (AC'97).
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC'97 frame if the
Codec connected to this line is ready or not. If it is not ready, the CNRDY flag in the SAI_xSR
register is set and an interrupt is generated.
This bit has a meaning only if the AC'97 mode is selected through PRTCFG[1:0] bits and the audio
block is operates as a receiver.

Bit 3  **FREQIE**: FIFO request interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the FREQ bit in the SAI_xSR register is set.
Since the audio block defaults to operate as a transmitter after reset, the MODE bit must be
configured before setting FREQIE to avoid a parasitic interrupt in receiver mode.

Bit 2  **WCKCFGIE**: Wrong clock configuration interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and
NODIV = 0.
It generates an interrupt if the WCKCFG flag in the SAI_xSR register is set.
*Note: This bit is used only in Free protocol mode and is meaningless in other modes.*

Bit 1  **MUTEDETIE**: Mute detection interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI_xSR register is set.
This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0  **OVRUDRIE**: Overrun/underrun interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI_xSR register is set.
### 69.6.11 SAI interrupt mask register (SAI_BIM)

</tbody>
</table>
Bit 2 **WCKCFGIE**: Wrong clock configuration interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and NODIV = 0.
It generates an interrupt if the WCKCFG flag in the SAI_xSR register is set.
*Note: This bit is used only in Free protocol mode and is meaningless in other modes.*

Bit 1 **MUTEDETIE**: Mute detection interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI_xSR register is set.
This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0 **OVRUDR**: Overrun/underrun interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI_xSR register is set.

</table>

- **FLVL[2:0]**: FIFO level threshold.
  - This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).
  - 000: FIFO empty (transmitter and receiver modes)
  - 001: FIFO ≤ ¼ but not empty (transmitter mode), FIFO < ¼ but not empty (receiver mode)
  - 010: ¼ < FIFO ≤ ½ (transmitter mode), ¼ ≤ FIFO < ½ (receiver mode)
  - 011: ½ < FIFO ≤ ¾ (transmitter mode), ½ ≤ FIFO < ¾ (receiver mode)
  - 100: ¾ < FIFO but not full (transmitter mode), ¾ ≤ FIFO but not full (receiver mode)
  - 101: FIFO full (transmitter and receiver modes)
  - Others: Reserved

- **Bits 15:7**: Reserved, must be kept at reset value.
Bit 6 **LFSDET**: Late frame synchronization detection.

This bit is read only.

0: No error.

1: Frame synchronization signal is not present at the right time.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC'97 or SPDIF mode.

It can generate an interrupt if LFSDETIE bit is set in the SAI_xIM register.

This flag is cleared when the software sets bit CLFSDET in SAI_xCLRFR register.

Bit 5 **AFSDET**: Anticipated frame synchronization detection.

This bit is read only.

0: No error.

1: Frame synchronization signal is detected earlier than expected.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC'97 or SPDIF mode.

It can generate an interrupt if AFSDETIE bit is set in SAI_xIM register.

This flag is cleared when the software sets CAFSDET bit in SAI_xCLRFR register.

Bit 4 **CNRDY**: Codec not ready.

This bit is read only.

0: External AC’97 Codec is ready

1: External AC’97 Codec is not ready

This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register and configured in receiver mode.

It can generate an interrupt if CNRDYIE bit is set in SAI_xIM register.

This flag is cleared when the software sets CCNRDY bit in SAI_xCLRFR register.

Bit 3 **FREQ**: FIFO request.

This bit is read only.

0: No FIFO request.

1: FIFO request to read or to write the SAI_xDR.

The request depends on the audio block configuration:

- If the block is configured in transmission mode, the FIFO request is related to a write request operation in the SAI_xDR.
- If the block configured in reception, the FIFO request related to a read request operation from the SAI_xDR.

This flag can generate an interrupt if FREQIE bit is set in SAI_xIM register.
Bit 2 **WCKCFG**: Wrong clock configuration flag.
This bit is read only.
0: Clock configuration is correct
1: Clock configuration does not respect the rule concerning the frame length specification defined in 
*Section 69.4.6: Frame synchronization* (configuration of FRL[7:0] bit in the SAI_xFRCR register)
This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NODIV = 0.
It can generate an interrupt if WCKCFGIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CWCKCFG bit in SAI_xCLRFR register.

Bit 1 **MUTEDET**: Mute detection.
This bit is read only.
0: No MUTE detection on the SD input line
1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frame
This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a consecutive number of audio frames (set in the MUTECNT bit in the SAI_xCR2 register).
It can generate an interrupt if MUTEDETIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CMUTEDET in the SAI_xCLRFR register.

Bit 0 **OVRUDR**: Overrun / underrun.
This bit is read only.
0: No overrun/underrun error.
1: Overrun/underrun error detection.
The overrun and underrun conditions can occur only when the audio block is configured as a receiver and a transmitter, respectively.
It can generate an interrupt if OVRUDRIE bit is set in SAI_xIM register.
This flag is cleared when the software sets COVRUDR bit in SAI_xCLRFR register.

<td>r</td>
<td>r</td>
</tr>
</tbody>
</table>
Bits 31:19  Reserved, must be kept at reset value.

Bits 18:16  **FLVL[2:0]**: FIFO level threshold.
This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).
- 000: FIFO empty (transmitter and receiver modes)
- 001: FIFO ≤ ¼ but not empty (transmitter mode), FIFO < ¼ but not empty (receiver mode)
- 010: ¼ < FIFO ≤ ½ (transmitter mode), ¼ ≤ FIFO < ½ (receiver mode)
- 011: ½ < FIFO ≤ ¾ (transmitter mode), ½ ≤ FIFO < ¾ (receiver mode)
- 100: ¾ < FIFO but not full (transmitter mode), ¾ ≤ FIFO but not full (receiver mode)
- 101: FIFO full (transmitter and receiver modes)
Others: Reserved

Bits 15:7  Reserved, must be kept at reset value.

Bit 6  **LFSDET**: Late frame synchronization detection.
This bit is read only.
- 0: No error.
- 1: Frame synchronization signal is not present at the right time.
This flag can be set only if the audio block is configured in slave mode.
It is not used in AC’97 or SPDIF mode.
It can generate an interrupt if LFSDETIE bit is set in the SAI_xIM register.
This flag is cleared when the software sets bit CLFSDET in SAI_xCLRFR register

Bit 5  **AFSDET**: Anticipated frame synchronization detection.
This bit is read only.
- 0: No error.
- 1: Frame synchronization signal is detected earlier than expected.
This flag can be set only if the audio block is configured in slave mode.
It is not used in AC’97 or SPDIF mode.
It can generate an interrupt if AFSDETIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CAFSDET bit in SAI_xCLRFR register.

Bit 4  **CNRDY**: Codec not ready.
This bit is read only.
- 0: External AC’97 Codec is ready
- 1: External AC’97 Codec is not ready
This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register and configured in receiver mode.
It can generate an interrupt if CNRDYIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CCNRDY bit in SAI_xCLRFR register.

Bit 3  **FREQ**: FIFO request.
This bit is read only.
- 0: No FIFO request.
- 1: FIFO request to read or to write the SAI_xDR.
The request depends on the audio block configuration:
  - If the block is configured in transmission mode, the FIFO request is related to a write request operation in the SAI_xDR.
  - If the block configured in reception, the FIFO request related to a read request operation from the SAI_xDR.
This flag can generate an interrupt if FREQIE bit is set in SAI_xIM register.
Bit 2 **WCKCFG**: Wrong clock configuration flag.

- This bit is read only.
- 0: Clock configuration is correct
- 1: Clock configuration does not respect the rule concerning the frame length specification defined in Section 69.4.6: Frame synchronization (configuration of FRL[7:0] bit in the SAI_xFRCR register)

This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NODIV = 0. It can generate an interrupt if WCKCFGIE bit is set in SAI_xIM register.

This flag is cleared when the software sets CWCKCFG bit in SAI_xCLRFR register.

Bit 1 **MUTEDET**: Mute detection.

- This bit is read only.
- 0: No MUTE detection on the SD input line
- 1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frames

This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a consecutive number of audio frames (set in the MUTECNT bit in the SAI_xCR2 register). It can generate an interrupt if MUTEDETIE bit is set in SAI_xIM register.

This flag is cleared when the software sets CMUTEDET in the SAI_xCLRFR register.

Bit 0 **OVRUDR**: Overrun / underrun.

- This bit is read only.
- 0: No overrun/underrun error.
- 1: Overrun/underrun error detection.

The overrun and underrun conditions can occur only when the audio block is configured as a receiver and a transmitter, respectively. It can generate an interrupt if OVRUDRIE bit is set in SAI_xIM register.

This flag is cleared when the software sets COVRUDR bit in SAI_xCLRFR register.

### 69.6.14 SAI clear flag register (SAI_ACLRFR)

- **CLFSDET**: Clear flag synchronization
- **CAFSDT**: Clear audio format synchronization
- **CCNRDY**: Clear clock recovery
- **CWCKCFG**: Clear wrong clock configuration
- **CMUTEDET**: Clear mute detection
- **COVRUDR**: Clear overrun/underrun error

www
Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CLFSDET**: Clear late frame synchronization detection flag.
- This bit is write only.
- Programming this bit to 1 clears the LFSDET flag in the SAI_xSR register.
- This bit is not used in AC’97 or SPDIFF mode.
- Reading this bit always returns the value 0.

Bit 5 **CAFSDET**: Clear anticipated frame synchronization detection flag.
- This bit is write only.
- Programming this bit to 1 clears the AFSDET flag in the SAI_xSR register.
- It is not used in AC’97 or SPDIFF mode.
- Reading this bit always returns the value 0.

Bit 4 **CCNRDY**: Clear Codec not ready flag.
- This bit is write only.
- Programming this bit to 1 clears the CNRDY flag in the SAI_xSR register.
- This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register.
- Reading this bit always returns the value 0.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CWCKCFG**: Clear wrong clock configuration flag.
- This bit is write only.
- Programming this bit to 1 clears the WCKCFG flag in the SAI_xSR register.
- This bit is used only when the audio block is set as master (MODE[1] = 0) and NODIV = 0 in the SAI_xCR1 register.
- Reading this bit always returns the value 0.

Bit 1 **CMUTEDET**: Mute detection flag.
- This bit is write only.
- Programming this bit to 1 clears the MUTEDET flag in the SAI_xSR register.
- Reading this bit always returns the value 0.

Bit 0 **COVRUDR**: Clear overrun / underrun.
- This bit is write only.
- Programming this bit to 1 clears the OVRUDR flag in the SAI_xSR register.
- Reading this bit always returns the value 0.

      |        | SAI_CK4 might not be available for all SAI instances. Refer to Section 69.3: SAI implementation for details. |
Bit 10 **CKEN3**: Clock enable of bitstream clock number 3
This bit is set and cleared by software.
0: SAI_CK3 clock disabled
1: SAI_CK3 clock enabled
*Note:* It is not recommended to configure this bit when PDMEN = 1.
SAI_CK3 might not be available for all SAI instances. Refer to Section 69.3: SAI implementation for details.

Bit 9 **CKEN2**: Clock enable of bitstream clock number 2
This bit is set and cleared by software.
0: SAI_CK2 clock disabled
1: SAI_CK2 clock enabled
*Note:* It is not recommended to configure this bit when PDMEN = 1.
SAI_CK2 might not be available for all SAI instances. Refer to Section 69.3: SAI implementation for details.

Bit 8 **CKEN1**: Clock enable of bitstream clock number 1
This bit is set and cleared by software.
0: SAI_CK1 clock disabled
1: SAI_CK1 clock enabled
*Note:* It is not recommended to configure this bit when PDMEN = 1.
SAI_CK1 might not be available for all SAI instances. Refer to Section 69.3: SAI implementation for details.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **MICNBR[1:0]**: Number of microphones
This bit is set and cleared by software.
00: Configuration with 2 microphones
01: Configuration with 4 microphones
10: Configuration with 6 microphones
11: Configuration with 8 microphones
*Note:* It is not recommended to configure this field when PDMEN = 1.*
The complete set of data lines might not be available for all SAI instances. Refer to Section 69.3: SAI implementation for details.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **PDMEN**: PDM enable
This bit is set and cleared by software. This bit enables to control the state of the PDM interface block.
Make sure that the SAI is already operating in TDM master mode before enabling the PDM interface.
0: PDM interface disabled
1: PDM interface enabled

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **DLYM4R[2:0]**: Delay line for second microphone of **pair 4**

This bit is set and cleared by software.

000: No delay

001: Delay of 1 $T_{SAI\_CK}$ period

010: Delay of 2 $T_{SAI\_CK}$ periods

... 111: Delay of 7 $T_{SAI\_CK}$ periods

This field can be changed on-the-fly.

*Note:* This field can be used only if D4 line is available. Refer to [Section 69.3: SAI implementation](#) to check if it is available.

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **DLYM4L[2:0]**: Delay line for first microphone of pair 4

This bit is set and cleared by software.

000: No delay

001: Delay of 1 $T_{SAI\_CK}$ period

010: Delay of 2 $T_{SAI\_CK}$ periods

... 111: Delay of 7 $T_{SAI\_CK}$ periods

This field can be changed on-the-fly.

*Note:* This field can be used only if D4 line is available. Refer to [Section 69.3: SAI implementation](#) to check if it is available.

Bit 23 Reserved, must be kept at reset value.
Bits 22:20 **DLYM3R[2:0]**: Delay line for second microphone of pair 3
This bit is set and cleared by software.
000: No delay
001: Delay of 1 $T_{SAI\_CK}$ period
010: Delay of 2 $T_{SAI\_CK}$ periods
...
111: Delay of 7 $T_{SAI\_CK}$ periods
This field can be changed on-the-fly.
*Note: This field can be used only if D3 line is available. Refer to Section 69.3: SAI implementation to check if it is available.*

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **DLYM3L[2:0]**: Delay line for first microphone of pair 3
This bit is set and cleared by software.
000: No delay
001: Delay of 1 $T_{SAI\_CK}$ period
010: Delay of 2 $T_{SAI\_CK}$ periods
...
111: Delay of 7 $T_{SAI\_CK}$ periods
This field can be changed on-the-fly.
*Note: This field can be used only if D3 line is available. Refer to Section 69.3: SAI implementation to check if it is available.*

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **DLYM2R[2:0]**: Delay line for second microphone of pair 2
This bit is set and cleared by software.
000: No delay
001: Delay of 1 $T_{SAI\_CK}$ period
010: Delay of 2 $T_{SAI\_CK}$ periods
...
111: Delay of 7 $T_{SAI\_CK}$ periods
This field can be changed on-the-fly.
*Note: This field can be used only if D2 line is available. Refer to Section 69.3: SAI implementation to check if it is available.*

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **DLYM2L[2:0]**: Delay line for first microphone of pair 2
This bit is set and cleared by software.
000: No delay
001: Delay of 1 $T_{SAI\_CK}$ period
010: Delay of 2 $T_{SAI\_CK}$ periods
...
111: Delay of 7 $T_{SAI\_CK}$ periods
This field can be changed on-the-fly.
*Note: This field can be used only if D2 line is available. Refer to Section 69.3: SAI implementation to check if it is available.*

Bit 7 Reserved, must be kept at reset value.
Bits 6:4 **DLYM1R[2:0]**: Delay line adjust for second microphone of pair 1
This bit is set and cleared by software.
000: No delay
001: Delay of 1 T\_SAL\_CK period
010: Delay of 2 T\_SAL\_CK periods
...
111: Delay of 7 T\_SAL\_CK periods

This field can be changed on-the-fly.
*Note:* This field can be used only if D1 line is available. Refer to Section 69.3: SAI implementation to check if it is available.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **DLYM1L[2:0]**: Delay line adjust for first microphone of pair 1
This bit is set and cleared by software.
000: No delay
001: Delay of 1 T\_SAL\_CK period
010: Delay of 2 T\_SAL\_CK periods
...
111: Delay of 7 T\_SAL\_CK periods

This field can be changed on-the-fly.
*Note:* This field can be used only if D1 line is available. Refer to Section 69.3: SAI implementation to check if it is available.

70 FD controller area network (FDCAN)

70.1 Introduction

The controller area network (CAN) subsystem (see Figure 873) consists of one CAN module, a shared message RAM and a configuration block. Refer to the memory map for the base address of each of these parts.

The modules (FDCAN) are compliant with ISO 11898-1: 2015 (CAN protocol specification version 2.0 part A, B) and CAN FD protocol specification version 1.0.

A 0.8-Kbyte message RAM per FDCAN instance implements filters, receive FIFOs, transmit event FIFOs and transmit FIFOs.

The CAN subsystem I/O signals and pins are detailed, respectively, in Table 711 and Figure 873.

70.2 FDCAN main features

- Conform with CAN protocol version 2.0 part A, B and ISO 11898-1: 2015, -4
- CAN FD with maximum 64 Data bytes supported
- CAN error logging
- AUTOSAR and J1939 support
- Improved acceptance filtering
- Two receive FIFOs of three payloads each (up to 64 bytes per payload)
- Separate signaling on reception of high priority messages
- Configurable Transmit FIFO / queue of three payload (up to 64 bytes per payload)
- Transmit event FIFO
- Programmable loop-back test mode
- Maskable module interrupts
- Two clock domains: APB bus interface and CAN core kernel clock
- Power down support
70.3 FDCAN functional description

Figure 874. FDCAN block diagram

Dual interrupt lines

The FDCAN peripheral provides two interrupt lines, fdcan_intr0_it and fdcan_intr1_it. By programming EINT0 and EINT1 bits in FDCAN_IIE register, the interrupt lines can be separately enabled or disabled.

CAN core

The CAN core contains the protocol controller and receive / transmit shift registers. It handles all ISO 11898-1:2015 protocol functions and supports both 11-bit and 29-bit identifiers.

Sync

The Sync block synchronizes signals from the APB clock domain to the CAN kernel clock domain and vice versa.
Tx handler

Controls the message transfer from the Message RAM to the CAN core. A maximum of three Tx buffers is available for transmission. Tx buffer can be used as Tx FIFO or a Tx queue. Tx event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported.

Rx handler

Controls the transfer of received messages from the CAN core to the external Message RAM. The Rx handler supports two receive FIFOs, for storage of all messages that have passed acceptance filtering. An Rx timestamp is stored together with each message. Up to 28 filters can be defined for 11-bit IDs, up to 8 filters for 29-bit IDs.

APB interface

Connects the FDCAN to the APB bus for configuration registers, controller configuration and RAM access.

Message RAM interface

Connects the FDCAN access to an external 1-Kbyte Message RAM through a RAM controller / arbiter.

70.3.1 Bit timing

The bit timing logic monitors the serial bus-line and performs sampling and adjustment of the sample point by synchronizing on the start-bit edge and resynchronizing on the following edges.

As shown in Figure 875, its operation may be explained simply by splitting the bit time in three segments, as follows:

- Synchronization segment (SYNC_SEG): a bit change is expected to occur within this time segment, having a fixed length of one time quantum (1 x tq).
- Bit segment 1 (BS1): defines the location of the sample point. It includes the PROP_SEG and PHASE_SEG1 of the CAN standard. Its duration is programmable between 1 and 16 time quanta, but may be automatically lengthened to compensate for positive phase drifts due to differences in the frequency of various nodes of the network.
- Bit segment 2 (BS2): defines the location of the transmit point. It represents the PHASE_SEG2 of the CAN standard, its duration is programmable between one and eight time quanta, but may also be automatically shortened to compensate for negative phase drifts.
The baud rate is the inverse of bit time (baud rate = 1 / bit time), which, in turn, is the sum of three components. Figure 875 indicates that bit time = t_{SyncSeg} + t_{BS1} + t_{BS2}, where:

- for the nominal bit time
  - \( t_q = (FDCAN\_NBTP\_NBRP[8:0] + 1) \times t_{fdcan\_tq\_clk} \)
  - \( t_{SyncSeg} = 1 \times t_q \)
  - \( t_{BS1} = t_q \times (FDCAN\_NBTP\_NTSEG1[7:0] + 1) \)
  - \( t_{BS2} = t_q \times (FDCAN\_NBTP\_NTSEG2[6:0] + 1) \)

- for the data bit time
  - \( t_q = (FDCAN\_DBTP\_DBRP[4:0] + 1) \times t_{fdcan\_tq\_clk} \)
  - \( t_{SyncSeg} = 1 \times t_q \)
  - \( t_{BS1} = t_q \times (FDCAN\_DBTP\_DTSEG1[4:0] + 1) \)
  - \( t_{BS2} = t_q \times (FDCAN\_DBTP\_DTSEG2[3:0] + 1) \)

The (Re)Synchronization jump width (SJW) defines an upper bound for the amount of lengthening or shortening of the bit segments. It is programmable between one and four time quanta.

A valid edge is defined as the first transition in a bit time from dominant to recessive bus level, provided the controller itself does not send a recessive bit.

If a valid edge is detected in BS1 instead of SYNCSEG, BS1 is extended by up to SJW so that the sample point is delayed.

Conversely, if a valid edge is detected in BS2 instead of SYNCSEG, BS2 is shortened by up to SJW so that the transmit point is moved earlier.

As a safeguard against programming errors, the configuration of the Bit timing register is only possible while the device is in Standby mode. Registers FDCAN_DBTP and FDCAN_NBTP (dedicated, respectively, to data and nominal bit timing) are only accessible when CCCR.CCE and CCCR.INIT are set.

**Note:** For a detailed description of the CAN bit timing and resynchronization mechanism refer to the ISO 11898-1 standard.

### 70.3.2 Operating modes

#### Configuration

Access to IP version, hardware and input clock divider configuration. When the clock divider is set to 0, the primary input clock is used as it is.
Software initialization

Software initialization is started by setting INIT bit in FDCAN_CCCR register, either by software or by a hardware reset, or by going Bus_Off. While INIT bit in FDCAN_CCCR register is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus output FDCAN_TX is recessive (high). The EML (error management logic) counters are unchanged. Setting INIT bit in FDCAN_CCCR does not change any configuration register. Clearing INIT bit in FDCAN_CCCR finishes the software initialization. Afterwards the bit stream processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the FDCAN configuration registers is only enabled when both INIT bit in FDCAN_CCCR register and CCE bit in FDCAN_CCCR register are set.

CCE bit in FDCAN_CCCR register can only be set/cleared while INIT bit in FDCAN_CCCR is set. CCE bit in FDCAN_CCCR register is automatically cleared when INIT bit in FDCAN_CCCR is cleared.

The following registers are reset when CCE bit in FDCAN_CCCR register is set:
- FDCAN_HPMS - High priority message status
- FDCAN_RXF0S - Rx FIFO 0 status
- FDCAN_RXF1S - Rx FIFO 1 status
- FDCAN_TXFQS - Tx FIFO/Queue status
- FDCAN_TXBRP - Tx buffer request pending
- FDCAN_TXBTO - Tx buffer transmission occurred
- FDCAN_TXBCF - Tx buffer cancellation finished
- FDCAN_TXEFS - Tx event FIFO status

The timeout counter value TOC bit in FDCAN_TOCV register is preset to the value configured by TOP bit in FDCAN_TOCC register when CCE bit in FDCAN_CCCR is set.

In addition the state machines of the Tx Handler and Rx handler are held in idle state while CCE bit in FDCAN_CCCR is set.

The following registers can be written only when CCE bit in FDCAN_CCCR register is cleared:
- TXBAR - Tx buffer add request
- TXBCR - Tx buffer cancellation request

TEST bit in FDCAN_CCCR and MON bit in FDCAN_CCCR can only be set by software while both INIT bit in CCCR and CCE bit in CCCR register are set. Both bits may be reset at any time. DAR bit in FDCAN_CCCR can only be set/cleared while both INIT bit in FDCAN_CCCR and CCE bit in FDCAN_CCCR are set.

Normal operation

The FDCAN default operating mode after hardware reset is event-driven CAN communication. TT Operation Mode is not supported.

Once the FDCAN is initialized and INIT bit in FDCAN_CCCR register is cleared, the FDCAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC are stored into the Rx FIFO 0 or Rx FIFO 1.
For messages to be transmitted, Tx FIFO or Tx queue can be initialized or updated. Automated transmission on reception of remote frames is not supported.

**CAN FD operation**

There are two variants in the FDCAN protocol:

1. Long frame mode (LFM), where the data field of a CAN frame may be longer than eight bytes
2. Fast frame mode (FFM), where control field, data field, and CRC field of a CAN frame are transmitted with a higher bit rate compared to the beginning and to the end of the frame

Fast Frame Mode can be used in combination with Long Frame Mode.

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers are decoded as FDF bit: FDF recessive signifies a CAN FD frame, while FDF dominant signifies a classic CAN frame.

In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bit rate inside this CAN FD frame is switched. A CAN FD bit rate switch is signified by res dominant and BRS recessive. The coding of res recessive is reserved for future expansion of the protocol. In case the FDCAN receives a frame with FDF recessive and res recessive, it signals a Protocol exception event by setting bit PSR.PXE. When Protocol exception handling is enabled (CCCR.PXHD = 0), this causes the operation state to change from Receiver (PSR.ACT = 10) to Integrating (PSR.ACT = 00) at the next sample point. In case Protocol exception Handling is disabled (CCCR.PXHD = 1), the FDCAN treats a recessive res bit as a form error and responds with an error frame.

CAN FD operation is enabled by programming CCCR.FDOE. In case CCCR.FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a classic CAN frame is transmitted can be configured via bit FDF in the respective Tx buffer element. With CCCR.FDOE = 0, received frames are interpreted as classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if bit FDF of a Tx buffer element is set. CCCR.FDOE and CCCR.BRSE can only be changed while CCCR.INIT and CCCR.CCE are both set.

With CCCR.FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format. With CCCR.FDOE = 1 and CCCR.BRSE = 0, only bit FDF of a Tx buffer element is evaluated. With CCCR.FDOE = 1 and CCCR.BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.
A mode change during CAN operation is recommended only under the following conditions:

- The failure rate in the CAN FD data phase is significantly higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN partial networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming is completed. Then all nodes switch back to Classic CAN communication.

In the FDCAN format, the coding of the DLC differs from the one of the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15 (that in standard CAN all code a data field of 8 bytes) are coded according to Table 712.

<table>
<thead>
<tr>
<th>DLC</th>
<th>9</th>
<th>10</th>
<th>11</th>
<th>12</th>
<th>13</th>
<th>14</th>
<th>15</th>

<td>12</td>
<td>16</td>
<td>20</td>
<td>24</td>
<td>32</td>
<td>48</td>
<td>64</td>
</tr>
</tbody>
</table>

In CAN FD Fast frames, the bit timing is switched inside the frame, after the BRS (bit rate switch) bit, if this bit is recessive. Before the BRS bit, in the FDCAN arbitration phase, the standard CAN bit timing is used as defined by the Bit timing and prescaler register BTP. In the following FDCAN data phase, the fast CAN bit timing is used as defined by the Fast bit timing and prescaler register FBTP. The bit timing is switched back from the fast timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the FDCAN kernel clock frequency. For example, with a FDCAN kernel clock frequency of 20 MHz and the shortest configurable bit time of four time quanta (tq), the bit rate in the data phase is 5 Mbit/s.

In both data frame formats (CAN FD long frames and CAN FD fast frames), the value of bit ESI (error status indicator) is determined by the transmitter error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant. In CAN FD remote frames the ESI bit is always transmitted dominant, independent of the transmitter error state. The data length code of CAN FD remote frames is transmitted as 0.

In case a FDCAN Tx buffer is configured for FDCAN transmission with DLC > 8, the first eight bytes are transmitted as configured in the Tx buffer while the remaining part of the data field is padded with 0xCC. When the FDCAN receives a FDCAN frame with DLC > 8, the first eight bytes of that frame are stored into the matching Rx FIFO. The remaining bytes are discarded.

**Transceiver delay compensation**

During the data phase of a FDCAN transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via pin FDCAN_TX the protocol controller receives the transmitted data from its local CAN transceiver via pin FDCAN_RX. The received data is delayed by the CAN transceiver loop delay. If this delay is
greater than TSEG1 (time segment before sample point), a bit error is detected. Without transceiver delay compensation, the bit rate in the data phase of a FDCAN frame is limited by the transceivers loop delay.

The FDCAN implements a delay compensation mechanism to compensate the CAN transceiver loop delay, thereby enabling transmission with higher bit rates during the FDCAN data phase independent of the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the secondary sample point (SSP). If a bit error is detected, the transmitter reacts on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the new ISO11898-1. It is enabled by setting bit DBTP.TDC.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the FDCAN transmit output pin FDCAN_TX through the transceiver to the receive input pin FDCAN_RX plus the transmitter delay compensation offset as configured by TDCR.TDCO. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (e.g. half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of mtq (minimum time quantum, that is one period of fdcan_tq_ck clock).

PSR.TDCV shows the actual transmitter delay compensation value. PSR.TDCV is cleared when CCCR.INIT is set and is updated at each transmission of an FD frame while DBTP.TDC is set.

The following boundary conditions have to be considered for the transmitter delay compensation implemented in the FDCAN:

- The sum of the measured delay from FDCAN_Tx to FDCAN_Rx and the configured transmitter delay compensation offset TDCR.TDCO has to be lower than 6 bit times in the data phase.
- The sum of the measured delay from FDCAN_TX to FDCAN_RX and the configured transmitter delay compensation offset TDCR.TDCO has to be lower than or equal to 127 mtq. If the sum exceeds this value, the maximum value (127 mtq) is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, which stops checking received bits at the SSPs.

If transmitter delay compensation is enabled by programming DBTP.TDC = 1, the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input pin FDCAN_TX of the transmitter. The resolution of this measurement is one mtq.
To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit (resulting in a too early SSP position), the use of a transmitter delay compensation filter window can be enabled by programming TDCR.TDCF. This defines a minimum value for the SSP position. Dominant edges on FDCAN_RX, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least TDCR.TDCF and FDCAN_RX is low.

**Restricted operation mode**

In Restricted operation mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters (ECR.REC, ECR.TEC) are frozen while error logging (ECR.CEL) is active. The software can set the FDCAN into Restricted operation mode by setting bit CCCR.ASM. The bit can only be set by software when both CCCR.CCE and CCCR.INIT are set to 1. The bit can be cleared by software at any time.

Restricted operation mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted operation mode the software has to reset CCCR.ASM.

The Restricted operation mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted operation mode after it has received a valid frame.

**Note:** The Restricted operation mode must not be combined with the Loop back mode (internal or external).
Bus monitoring mode

The FDCAN is set in Bus monitoring mode by setting CCCR.MON bit. In Bus monitoring mode (for more details refer to ISO11898-1, 10.12 Bus monitoring), the FDCAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus. If the FDCAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the FDCAN can monitor it, even if the CAN bus remains in recessive state. In Bus monitoring mode the TXBRP register is held in reset state.

The Bus monitoring mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. Figure 877 shows the connection of FDCAN_TX and FDCAN_RX signals to the FDCAN in Bus monitoring mode.

Figure 877. Pin control in Bus monitoring mode

Disabled automatic retransmission (DAR) mode

According to the CAN specification (see ISO11898-1, 6.3.3 Recovery Management), the FDCAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled.

Frame transmission in DAR mode

In DAR mode all transmissions are automatically canceled after they have been started on the CAN bus. A Tx buffer Tx Request Pending bit TXBRP.TRPx is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, or has been aborted due to lost arbitration, or when an error has occurred during frame transmission.
- Successful transmission
  - Corresponding Tx buffer transmission occurred bit TXBTO[TOx] set
  - Corresponding Tx buffer cancellation finished bit TXBCF[CFx] not set
- Successful transmission in spite of cancellation
  - Corresponding Tx buffer transmission occurred bit TXBTO[TOx] set
  - Corresponding Tx buffer cancellation finished bit TXBCF[CFx] set
- Arbitration loss or frame transmission disturbed
  - Corresponding Tx buffer transmission occurred bit TXBTO[TOx] not set
  - Corresponding Tx buffer cancellation finished bit TXBCF[CFx] set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

**Power down (Sleep mode)**

The FDCAN can be set into power down mode controlled by clock stop request input via CC control register CCCR[CSR]. As long as the clock stop request is active, bit CCCR[CSR] is read as 1.

When all pending transmission requests have completed, the FDCAN waits until bus idle state is detected. Then the FDCAN sets then CCCR[INIT] to 1 to prevent any further CAN transfers. Now the FDCAN acknowledges that it is ready for power down by setting CCCR[CSA] to 1. In this state, before the clocks are switched off, further register accesses can be made. A write access to CCCR[INIT] has no effect. Now the module clock inputs may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting CC control register flag CCCR.CSR. The FDCAN acknowledges this by resetting CCCR[CSA]. Afterwards, the application can restart CAN communication by resetting bit CCCR[INIT].

**Test modes**

To enable write access to *FDCAN test register (FDCAN_TEST)*, bit CCCR.TEST must be set to 1, thus enabling the configuration of test modes and functions.

Four output functions are available for the CAN transmit pin FDCAN_TX by programming TEST.TX. In addition to its default function (the serial data output) it can drive the CAN Sample Point signal to monitor the FDCAN bit timing and it can drive constant dominant or recessive values. The actual value at pin FDCAN_RX can be read from TEST.RX. Both functions can be used to check the CAN bus physical layer.

Due to the synchronization mechanism between CAN kernel clock and APB clock domain, there may be a delay of several APB clock periods between writing to TEST.TX until the new configuration is visible at FDCAN_TX output pin. This applies also when reading FDCAN_RX input pin via TEST.RX.

*Note:* Test modes must be used for production tests or self test only. The software control for FDCAN_TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.
External loop back mode

The FDCAN can be set in External loop back mode by programming TEST.LBCK to 1. In Loop Back mode, the FDCAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into Rx FIFOs. Figure 878 shows the connection of transmit and receive signals FDCAN_TX and FDCAN_RX to the FDCAN in External loop back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the FDCAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data / remote frame) in Loop back mode. In this mode the FDCAN performs an internal feedback from its transmit output to its receive input. The actual value of the FDCAN_RX input pin is disregarded by the FDCAN. The transmitted messages can be monitored at the FDCAN_TX transmit pin.

Internal loop back mode

Internal loop back mode is entered by programming bits TEST.LBCK and CCCR.MON to 1. This mode can be used for a “Hot selftest”, meaning the FDCAN can be tested without affecting a running CAN system connected to the FDCAN_TX and FDCAN_RX pins. In this mode, FDCAN_RX pin is disconnected from the FDCAN and FDCAN_TX pin is held recessive. Figure 878 shows the connection of FDCAN_TX and FDCAN_RX pins to the FDCAN in case of Internal loop back mode.

External loop back mode

Internal loop back mode

Timestamp generation

For timestamp generation the FDCAN supplies a 16-bit wrap-around counter. A prescaler TSCC.TCP can be configured to clock the counter in multiples of CAN bit times (1 ... 16). The counter is readable via TSCV[TCV]. A write access to register TSCV resets the counter to 0. When the timestamp counter wraps around interrupt flag IR[TSW] is set.

On start of frame reception/transmission the counter value is captured and stored into the timestamp section of a Rx FIFO (RXTS[15:0]) or Tx event FIFO (TXTS[15:0]) element.

By programming bit TSCC.TSS, a 16-bit timestamp can be used.
**Debug mode behavior**

In debug mode the set / reset on read feature is automatically disabled during the debugger register access, and enabled during normal MCU operation.

**Timeout counter**

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx event FIFO the FDCAN supplies a 16-bit timeout counter. It operates as downcounter and uses the same prescaler controlled by TSCC[TCP] as the Timestamp Counter. The timeout counter is configured via register TOCC. The actual counter value can be read from TOCV[TOC]. The timeout counter can only be started while CCCR[INIT] = 0. It is stopped when CCCR[INIT] = 1, e.g. when the FDCAN enters Bus_Off state.

The operation mode is selected by TOCC[TOS]. When operating in Continuous mode, the counter starts when CCCR[INIT] is reset. A write to TOCV presets the counter to the value configured by TOCC[TOP] and continues downcounting.

When the timeout counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Downcounting is started when the first FIFO element is stored. Writing to TOCV has no effect.

When the counter reaches 0, interrupt flag IR[TOO] is set. In Continuous mode, the counter is immediately restarted at TOCC[TOP].

*Note:* The clock signal for the timeout counter is derived from the CAN core sample point signal. Therefore the point in time where the timeout counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN core. If the baud rate switch feature in FDCAN is used, the timeout counter is clocked differently in arbitration and data fields.

**70.3.3 Message RAM**

The Message RAM has a 32-bit width, and the FDCAN module is configured to allocate up to 212 words in it. It is not necessary to configure each of the sections shown in Figure 879.
When the FDCAN addresses the Message RAM, it addresses 32-bit words (aligned), not a single byte. The RAM addresses are 32-bit words, i.e. only bits 15 to 2 are evaluated, the two least significant bits are ignored.

In case of multiple instances the RAM start address for the FDCANn is computed by end address + 4 of FDCANn-1, and the FDCANn end address is computed by FDCANn start address + 0x0350 - 4.

As an example, for two instances:
- FDCAN1:
  - start address 0x0000
  - end address 0x034C (as in Figure 879)
- FDCAN2:
  - start address = 0x034C (FDCAN1 end address) + 4 = 0x0350
  - end address = 0x0350 (FDCAN2 start address) + 0x0350 - 4 = 0x069C.

**Rx handling**

The Rx handler controls the acceptance filtering, the transfer of received messages to Rx to one of the two Rx FIFOs, as well as the Rx FIFO Put and Get Indexes.

**Acceptance filter**

The FDCAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and another for extended identifiers. These filters can be assigned to Rx FIFO 0 or Rx FIFO 1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. Following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
  - range filter (from - to)
  - filter for one or two dedicated IDs
  - classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled/disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration (RXGFC)
- Extended ID AND Mask (XIDAM)

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Reject received frame
- Set High priority message interrupt flag IR[HPM]
- Set High priority message interrupt flag IR[HPM] and store received frame in FIFO 0 or FIFO 1.
Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx FIFO has been found, the Message Handler starts writing the received message data in 32-bit portions to the matching Rx FIFO. If the CAN protocol controller has detected an error condition (e.g. CRC error), this message is discarded with the following impact:

- **Rx FIFO**
  Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see PSR.LEC and PSR.DLEC. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in **Rx FIFO overwrite mode** have to be considered.

**Note:** When an accepted message is written to one of the two Rx FIFOs, the unmodified received identifier is stored independently from the used filter(s). The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

**Range filter**

The filter matches for all received frames with Message IDs in the range defined by SF1ID/SF2ID and EF1ID/EF2ID.

There are two possibilities when range filtering is used together with extended frames:

- **EFT = 00:** The Message ID of received frames is AND-ed with the Extended ID AND Mask (XIDAM) before the range filter is applied
- **EFT = 11:** The Extended ID AND Mask (XIDAM) is not used for range filtering

**Filter for dedicated IDs**

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SF1ID = SF2ID and EF1ID = EF2ID.

**Classic bit mask filter**

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SF1ID/EF1ID is used as Message ID filter, while SF2ID/EF2ID is used as filter mask.

A 0 bit at the filter mask masks out the corresponding bit position of the configured ID filter, e.g. the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering.

In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are 0, all Message IDs match.

**Standard message ID filtering**

*Figure 880* shows the flow for standard message ID (11-bit Identifier) filtering. The standard message ID filter element is described in **Section 70.3.8**.

Controlled by the Global filter configuration (RXGFC) message ID, Remote transmission request bit (RTR), and the Identifier extension bit (IDE) of received frames are compared against the list of configured filter elements.

  - RXGFC[ANFS[1]] = 1
  - RXGFC[ANFS[1]] = 0
- Accept non-matching frames
- RXGFC[ANFS[1]] = 1
  - Yes: Discard frame
  - No: Append to target FIFO
- RXGFC[ANFS[1]] = 0
  - Yes: Target FIFO full
  - No: Append to target FIFO
**Extended message ID filtering**

*Figure 881* shows the flow for extended message ID (29-bit Identifier) filtering. The Extended Message ID filter element is described in *Section 70.3.9*.

Controlled by the Global filter configuration RXGFC and the Extended ID filter Configuration RXGFC message ID, Remote transmission request bit (RTR), and the Identifier extension bit (IDE) of received frames are compared against the list of configured filter elements.

*Figure 881. Extended Message ID filter path*

The Extended ID AND Mask (XIDAM) is AND-ed with the received identifier before the filter list is executed.
Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can hold up to three elements each.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1, see Acceptance filter. The Rx FIFO element is described in Section 70.3.5.

When an Rx FIFO full condition is signaled by IR[RFnF], no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. In case a message is received while the corresponding Rx FIFO is full, this message is discarded and interrupt flag IR[RFnL] is set.

When reading from an Rx FIFO, Rx FIFO Get Index RXFnS[FnGI] + FIFO Element Size has to be added to the corresponding Rx FIFO start address [FnSA].

Rx FIFO blocking mode

The Rx FIFO blocking mode is configured by RXGFC.FnOM = 0. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (RXFnS.FnPI = RXFnS.FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signaled by RXFnS.FnF = 1. In addition interrupt flag IR.RFnF is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signaled by RXFnS.RFnL = 1. In addition interrupt flag IR.RFnL is set.

Rx FIFO overwrite mode

The Rx FIFO overwrite mode is configured by RXGFC.FnOM = 1.

When an Rx FIFO full condition (RXFnS.FnPI = RXFnS.FnGI) is signaled by RXFnS.FnF = 1, the next message accepted for the FIFO overwrites the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signaled, reading of the Rx FIFO elements must start at least at get index + 1. This is because it can happen that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO.

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index RXFnA.FnA. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (RXFnS.FnF = 0).

Tx handling

The Tx Handler handles transmission requests for the Tx FIFO, and the Tx queue. It controls the transfer of transmit messages to the CAN core, the Put and Get Indices, and the Tx event FIFO. Up to three Tx buffers can be set up for message transmission. The CAN
message data field is configured to 64 bytes, Tx FIFO allocates eighteen 32-bit words for storage of a Tx element.

Note: AUTOSAR requires at least three Tx queue buffers and support of transmit cancellation.

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx buffer with lowest Message ID) when the Tx buffer Request Pending register TXBRP is updated, or when a transmission has been started.

Transmit pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority must be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If, as an example, CAN ECU-1 has the feature enabled and is requested by its application software to transmit four messages, it waits, after the first successful message transmission, for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The feature is controlled by TXP bit in CCCR register. If the bit is set, the FDCAN, each time it has successfully transmitted a message, pauses for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is disabled (CCCR.TXP = 0).

This feature looses up burst transmissions coming from a single node and it protects against "babbling idiot" scenarios where the application program erroneously requests too many transmissions.

Tx FIFO

Tx FIFO operation is configured by programming TXBC[TFQM] to 0. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index TXFQS[TFGI]. After each transmission the Get Index is incremented cyclically until the Tx
FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx buffers in the order these messages have been written to the Tx FIFO. The FDCAN calculates the Tx FIFO Free Level TXFQS[TFFL] as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS[TFQF]= 1) is signaled. In this case no further messages must be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing 1 to the TXBAR bit related to the Tx buffer referenced by the Tx FIFO Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx buffers starting with the Put Index. The transmissions are then requested via TXBAR. The Put Index is then cyclically incremented by n. The number of requested Tx buffers must not exceed the number of free Tx buffers as indicated by the Tx FIFO Free Level.

When a transmission request for the Tx buffer referenced by the Get Index is canceled, the Get Index is incremented to the next Tx buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates eighteen 32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx FIFO buffer is calculated by adding four times the Put Index TXFQS[TFQPI] (0 … 2) to the Tx buffer Start Address TBSA.

**Tx queue**

Tx queue operation is configured by programming TXBC[TFQM] to 1. Messages stored in the Tx queue are transmitted starting with the message with the lowest Message ID (highest priority).

In case of mixing of standard and extended Message IDs, the standard Message IDs are compared to bits [28:18] of extended Message IDs.

In case that multiple queue buffers are configured with the same Message ID, the queue buffer with the lowest buffer number is transmitted first.

New messages have to be written to the Tx buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request cyclically increments the Put Index to the next free Tx buffer. In case that the Tx queue is full (TXFQS[TFQF] = 1), the Put Index is not valid and no further message must be written to the Tx queue until at least one of the requested messages has been sent out or a pending transmission request has been canceled.

The application may use register TXBRP instead of the Put Index and may place messages to any Tx buffer without pending transmission request.

A Tx queue buffer allocates eighteen 32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx queue buffer is calculated by adding four times the Tx queue Put Index TXFQS[TFQPI] (0 … 2) to the Tx buffer Start Address TBSA.
Transmit cancellation

The FDCAN supports transmit cancellation. To cancel a requested transmission from a Tx queue buffer the Host has to write a 1 to the corresponding bit position (= number of Tx buffer) of register TXBCR. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of register TXBCF to 1.

In case a transmit cancellation is requested while a transmission from a Tx buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

Note: In case a pending transmission is canceled immediately before it has been started, there is a short time window where no transmission is started even if another message is pending in the node. This may enable another node to transmit a message that may have a priority lower than that of the second message in the node.

Tx event handling

To support Tx event handling the FDCAN has implemented a Tx event FIFO. After the FDCAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx event FIFO element. To link a Tx event to a Tx event FIFO element, the Message Marker from the transmitted Tx buffer is copied into the Tx event FIFO element.

The Tx event FIFO is configured to three elements. The Tx event FIFO element is described in Tx FIFO.

The purpose of the Tx event FIFO is to decouple handling transmit status information from transmit message handling i.e. a Tx buffer holds only the message to be transmitted, while the transmit status is stored separately in the Tx event FIFO. This has the advantage, especially when operating a dynamically managed transmit queue, that a Tx buffer can be used for a new message immediately after successful transmission. There is no need to save transmit status information from a Tx buffer before overwriting that Tx buffer.

When a Tx event FIFO full condition is signaled by IR[TEFF], no further elements are written to the Tx event FIFO until at least one element has been read out and the Tx event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx event FIFO is full, this event is discarded and interrupt flag IR[TEFL] is set.

When reading from the Tx event FIFO, two times the Tx event FIFO Get Index TXEFS[EFGI] has to be added to the Tx event FIFO start address EFSA.

70.3.4 FIFO acknowledge handling

The Get Indices of Rx FIFO 0, Rx FIFO 1, and the Tx event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index, see Section 70.4.23 and Section 70.4.25. Writing to the FIFO acknowledge index sets the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

1. When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.

2. When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFO Get Index.
Due to the fact that the CPU has free access to the FDCAN Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a high priority message from one of the two Rx FIFOs. In this case the FIFO Acknowledge Index must not be written because this would set the Get Index to a wrong position and also alters the FIFO Fill Level. In this case some of the older FIFO elements would be lost.

**Note:** The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The FDCAN does not check for erroneous values.

### 70.3.5 FDCAN Rx FIFO element

Two Rx FIFOs are configured in the Message RAM. Each Rx FIFO section can be configured to store up to three received messages. The structure of an Rx FIFO element is described in **Table 714**, the description is provided in **Table 715**.

### 70.3.6 FDCAN Tx buffer element

The Tx buffers section (three elements) can be configured to hold Tx FIFO or Tx queue. The Tx Handler distinguishes between Tx FIFO and Tx queue using the Tx buffer configuration FDCAN_TXBC.TFQM. The element size is configured for storage of CAN FD messages with up to 64 bytes data.

| Tn Bits 7:0 DBm-3[7:0] | Data byte m-3 |

1. The ESI bit of the transmit buffer is OR-ed with the error passive flag to decide the value of the ESI bit in the transmitted FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node always transmits the ESI bit recessive.
70.3.7 FDCAN Tx event FIFO element

Each element stores information about transmitted messages. By reading the Tx event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx event FIFO can be obtained from register TXEFS.

Table 718. Tx event FIFO element

0 - 8: Frame with 0-8 Data bytes transmitted  
9 - 15: Frame with 8 Data bytes transmitted |
| E1 Bits 15:0 TXTS[15:0] | Tx Timestamp  
Timestamp counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP]. |

70.3.8 FDCAN Standard message ID filter element

Up to 28 filter elements can be configured for 11-bit standard IDs. When accessing a Standard message ID filter element, its address is the Filter list standard start address FLSSA plus the index of the filter element (0 … 27).

Table 720. Standard message ID filter element

<table>
<thead>
<tr>
<th>Bit</th>
<th>31</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>

</thead>
</table>

Table 721. Standard message ID filter element field description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Bit 31:30 SFT[1:0](1) | Standard filter type  
– 00: Range filter from SFID1 to SFID2  
– 01: Dual ID filter for SFID1 or SFID2  
– 10: Classic filter: SFID1 = filter, SFID2 = mask  
– 11: Filter element disabled |
| Bit 29:27 SFEC[2:0] | Standard filter element configuration  
All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = 100, 101 or 110 a match sets interrupt flag IR.HPM and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match.  
– 000: Disable filter element  
– 001: Store in Rx FIFO 0 if filter matches  
– 010: Store in Rx FIFO 1 if filter matches  
– 011: Reject ID if filter matches  
– 100: Set priority if filter matches  
– 101: Set priority and store in FIFO 0 if filter matches  
– 110: Set priority and store in FIFO 1 if filter matches  
– 111: Not used |
| Bits 26:16 SFID1[10:0] | Standard filter ID 1  
First ID of standard ID filter element. |
| Bits 10:0 SFID2[10:0] | Standard filter ID 2  
Second ID of standard ID filter element. |
1. With SFT = 11 the filter element is disabled and the acceptance filtering continues (same behavior as with SFEC = 000).

**Note:** In case a reserved value is configured, the filter element is considered disabled.

### 70.3.9 FDCAN Extended message ID filter element

Up to 8 filters element can be configured for 29-bit extended IDs. When accessing an Extended message ID filter element, its address is the Filter list extended start address FLESA plus two times the index of the filter element (0 … 7).

#### Table 722. Extended message ID filter element

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| F0 Bits 31:29 EFEC[2:0] | Extended filter element configuration  
All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = 100, 101 or 110 a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match.  
– 000: Disable filter element  
– 001: Store in Rx FIFO 0 if filter matches  
– 010: Store in Rx FIFO 1 if filter matches  
– 011: Reject ID if filter matches  
– 100: Set priority if filter matches  
– 101: Set priority and store in FIFO 0 if filter matches  
– 110: Set priority and store in FIFO 1 if filter matches  
– 111: Not used |
| F1 Bits 28:0 EFID1[28:0] | Extended filter ID 1  
First ID of extended ID filter element.  
When filtering for Rx FIFO, this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism. |
| F1 Bits 31:30 EFT[1:0] | Extended filter type  
– 00: Range filter from EF1ID to EF2ID (EF2ID >= EF1ID)  
– 01: Dual ID filter for EF1ID or EF2ID  
– 10: Classic filter: EF1ID = filter, EF2ID = mask  
– 11: Range filter from EF1ID to EF2ID (EF2ID >= EF1ID), XIDAM mask not applied |
| F1 Bit 29 | Not used |
| F1 Bits 28:0 EFID2[28:0] | Extended filter ID 2  
Second ID of extended ID filter element. |
70.4 FDCAN registers

70.4.1 FDCAN core release register (FDCAN_CREL)

Address offset: 0x0000
Reset value: 0x3214 1218

<table>
<thead>
<tr>
<th>Bits 31:28</th>

</tr>
</tbody>
</table>

Note: The register read must give the reset value to ensure no endianness issue.
### 70.4.3 FDCAN data bit timing and prescaler register (FDCAN_DBTP)

Address offset: 0x000C

Reset value: 0x0000 0A33

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN time quantum may be programmed in the range of 1 to 32 FDCAN clock periods. \( t_q = (DBRP + 1) \) FDCAN clock period.

DTSEG1 is the sum of Prop_Seg and Phase_Seg1. DTSEG2 is Phase_Seg2. Therefore the length of the bit time is (programmed values) \( [DTSEG1 + DTSEG2 + 3] t_q \) or (functional values) \([\text{Sync}_\text{Seg} + \text{Prop}_\text{Seg} + \text{Phase}_\text{Seg1} + \text{Phase}_\text{Seg2}] t_q\).

The Information Processing Time (IPT) is 0, meaning the data for the next bit is available at the first clock edge after the sample point.

</tbody>
</table>

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TDC**: Transceiver delay compensation

0: Transceiver delay compensation disabled

1: Transceiver delay compensation enabled

Bits 22:21 Reserved, must be kept at reset value.

Bits 20:16 **DBRP[4:0]**: Data bit rate prescaler

The value by which the oscillator frequency is divided to generate the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 31. The hardware interpreters this value as the value programmed plus 1.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DTSEG1[4:0]**: Data time segment before sample point

Valid values are 0 to 31. The value used by the hardware is the one programmed, incremented by 1, i.e. \( t_{BS1} = (\text{DTSEG1} + 1) \times t_q \).

Bits 7:4 **DTSEG2[3:0]**: Data time segment after sample point

Valid values are 0 to 15. The value used by the hardware is the one programmed, incremented by 1, i.e. \( t_{BS2} = (\text{DTSEG2} + 1) \times t_q \).

Bits 3:0 **DSJW[3:0]**: Synchronization jump width

Valid values are 0 to 15. The value used by the hardware is the one programmed, incremented by 1: \( t_{SJW} = (\text{DSJW} + 1) \times t_q \).

**Note:** With an FDCAN clock of 8 MHz, the reset value 0x00000A33 configures the FDCAN for a fast bitrate of 500 kbit/s.

**Note:** The data phase bit rate must be higher to or equal to the nominal bit rate.
## 70.4.4 FDCAN test register (FDCAN_TEST)

Write access to the this register is enable by setting bit CCCR[TEST] to 1. All register functions are set to their reset values when bit CCCR[TEST] is reset.

Loop Back mode and software control of Tx pin FDCANx_TX are hardware test modes. Programming TX differently from 00 may disturb the message transfer on the CAN bus.

### Address offset: 0x0010

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 RX: Receive pin
- Monitors the actual value of pin FDCANx_RX
  - 0: The CAN bus is dominant (FDCANx_RX = 0)
  - 1: The CAN bus is recessive (FDCANx_RX = 1)

Bits 6:5 TX[1:0]: Control of transmit pin
- 00: Reset value, FDCANx_TX TX is controlled by the CAN core, updated at the end of the CAN bit time
- 01: Sample point can be monitored at pin FDCANx_TX
- 10: Dominant (0) level at pin FDCANx_TX
- 11: Recessive (1) level at FDCANx_TX

Bit 4 LBCK: Loop back mode
- 0: Reset value, Loop Back mode is disabled
- 1: Loop Back mode is enabled (see Power down (Sleep mode))

Bits 3:0 Reserved, must be kept at reset value.
70.4.5 **FDCAN RAM watchdog register (FDCAN_RWD)**

The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access starts the Message RAM Watchdog Counter with the value configured by the RWD[WDC] bits.

The counter is reloaded with RWD[WDC] bits when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to 0, the counter stops and interrupt flag IR[WDI] bit is set. The RAM Watchdog Counter is clocked by the fdcan_pclk clock.

Address offset: 0x0014

Reset value: 0x0000 0000

<table>

</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **WDV[7:0]**: Watchdog value
- Actual message RAM watchdog counter value.

Bits 7:0 **WDC[7:0]**: Watchdog configuration
- Start value of the message RAM watchdog counter. With the reset value of 00, the counter is disabled.
- These are protected write (P) bits, write access is possible only when the bit 1 [CCE] and bit 0 [INIT] of FDCAN_CCCR register are set to 1.

70.4.6 **FDCAN CC control register (FDCAN_CCCR)**

Address offset: 0x0018

Reset value: 0x0000 0001

For details about setting and resetting of single bits, see *Software initialization*.

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</th>

<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **NISO**: Non ISO operation
- If this bit is set, the FDCAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0.
  - 0: CAN FD frame format according to ISO11898-1
  - 1: CAN FD frame format according to Bosch CAN FD Specification V1.0
Bit 14 **TXP:**
- If this bit is set, the FDCAN pauses for two CAN bit times before starting the next transmission after successfully transmitting a frame.
- 0: disabled
- 1: enabled

Bit 13 **EFBI:** Edge filtering during bus integration
- 0: Edge filtering disabled
- 1: Two consecutive dominant tq required to detect an edge for hard synchronization

Bit 12 **PXHD:** Protocol exception handling disable
- 0: Protocol exception handling enabled
- 1: Protocol exception handling disabled

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **BRSE:** FDCAN bit rate switching
- 0: Bit rate switching for transmissions disabled
- 1: Bit rate switching for transmissions enabled

Bit 8 **FDOE:** FD operation enable
- 0: FD operation disabled
- 1: FD operation enabled

Bit 7 **TEST:** Test mode enable
- 0: Normal operation, register TEST holds reset values
- 1: Test Mode, write access to register TEST enabled

Bit 6 **DAR:** Disable automatic retransmission
- 0: Automatic retransmission of messages not transmitted successfully enabled
- 1: Automatic retransmission disabled

Bit 5 **MON:** Bus monitoring mode
- Bit MON can only be set by software when both CCE and INIT are set to 1. The bit can be reset by the Host at any time.
- 0: Bus monitoring mode disabled
- 1: Bus monitoring mode enabled

Bit 4 **CSR:** Clock stop request
- 0: No clock stop requested
- 1: Clock stop requested. When clock stop is requested, first INIT and then CSA is set after all pending transfer requests have been completed and the CAN bus reached idle.

Bit 3 **CSA:** Clock stop acknowledge
- 0: No clock stop acknowledged
- 1: FDCAN may be set in power down by stopping APB clock and kernel clock.
Bit 2  **ASM**: ASM restricted operation mode
The restricted operation mode is intended for applications that adapt themselves to different
CAN bit rates. The application tests different bit rates and leaves the Restricted operation
Mode after it has received a valid frame. In the optional Restricted operation Mode the node
is able to transmit and receive data and remote frames and it gives acknowledge to valid
frames, but it does not send active error frames or overload frames. In case of an error
condition or overload condition, it does not send dominant bits, instead it waits for the
occurrence of bus idle condition to resynchronize itself to the CAN communication. The error
counters are not incremented. Bit ASM can only be set by software when both CCE and INIT
are set to 1. The bit can be reset by the software at any time.
0: Normal CAN operation
1: Restricted operation Mode active

Bit 1  **CCE**: Configuration change enable
0: The CPU has no write access to the protected configuration registers.
1: The CPU has write access to the protected configuration registers (while CCCR.INIT = 1).

Bit 0  **INIT**: Initialization
0: Normal operation
1: Initialization started

**Note:**  *Due to the synchronization mechanism between the two clock domains, there may be a
delay until the value written to INIT can be read back. Therefore the programmer has to
assure that the previous value written to INIT has been accepted by reading INIT before
setting INIT to a new value.*

### 70.4.7 FDCAN nominal bit timing and prescaler register (FDCAN_NBTP)

**Address offset:** 0x001C

**Reset value:** 0x0600 0A03

This register is only writable if bits CCCR[CCE] and CCCR[INIT] are set. The CAN bit time
may be programmed in the range of 4 to 81 tq. The CAN time quantum may be programmed
in the range of [1 … 1024] FDCAN kernel clock periods.

\[ tq = (BRP + 1) \text{ FDCAN clock period fdcan_clk} \]

NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2. Therefore the
length of the bit time is (programmed values) \([NTSEG1 + NTSEG2 + 3]\) tq or (functional
values) \([\text{Sync}_\text{Seg} + \text{Prop}_\text{Seg} + \text{Phase}_\text{Seg1} + \text{Phase}_\text{Seg2}]\) tq.

The Information Processing Time (IPT) is 0, meaning the data for the next bit is available at
the first clock edge after the sample point.

3044/3637  RM0456 Rev 5
Bits 31:25 **NSJW[6:0]**: Nominal (re)synchronization jump width
Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that the used value is the one programmed incremented by one.
These are protected write (P) bits, write access is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bits 24:16 **NBRP[8:0]**: Bit rate prescaler
Value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values are 0 to 511. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
These are protected write (P) bits, write access is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bits 15:8 **NTSEG1[7:0]**: Nominal time segment before sample point
Valid values are 0 to 255. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
These are protected write (P) bits, write access is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **NTSEG2[6:0]**: Nominal time segment after sample point
Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.

**Note:** With a CAN kernel clock of 48 MHz, the reset value of 0x06000A03 configures the FDCAN for a bit rate of 3 Mbit/s.

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **TCP[3:0]**: Timestamp counter prescaler
Configures the timestamp and timeout counters time unit in multiples of CAN bit times [1 … 16].
The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
In CAN FD mode the internal timestamp counter TCP does not provide a constant time base due to the different CAN bit times between arbitration phase and data phase. Thus CAN FD requires an external counter for timestamp generation (TSS = 10).
These are protected write (P) bits, write access is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bits 15:2 Reserved, must be kept at reset value.
70.4.9  **FDCAN timestamp counter value register (FDCAN_TSCV)**

Bits 1:0  **TSS[1:0]:** Timestamp select  
00: Timestamp counter value always 0x0000  
01: Timestamp counter value incremented according to TCP  
10: External timestamp counter from TIM3 value (tim3_cnt[0:15])  
11: Same as 00.  
These are protected write (P) bits, write access is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.  

Note: A “wrap around” is a change of the Timestamp Counter value from non-0 to 0 that is not caused by write access to TSCV.

70.4.10  **FDCAN timeout counter configuration register (FDCAN_TOCC)**

Address offset: 0x0028  
Reset value: 0xFFFF 0000

<td>0</td>
</tr>
</tbody>
</table>

Bits 15:0  **TSC[15:0]:** Timestamp counter  
The internal/external timestamp counter value is captured on start of frame (both Rx and Tx).  
When TSCC[TSS] = 01, the timestamp counter is incremented in multiples of CAN bit times [1 … 16] depending on the configuration of TSCC[TCP]. A wrap around sets interrupt flag IR[TSW]. Write access resets the counter to 0.  
When TSCC.TSS = 10, TSC reflects the external timestamp counter value. A write access has no impact.  

Note: A “wrap around” is a change of the Timestamp Counter value from non-0 to 0 that is not caused by write access to TSCV.

Bits 31:16  Reserved, must be kept at reset value.  

Bits 15:3  **TOP[15:0]:** Timeout period  
Start value of the timeout counter (down-counter). Configures the timeout period.  

Bits 15:3  Reserved, must be kept at reset value.
Bits 2:1 TOS[1:0]: Timeout select
When operating in Continuous mode, a write to TOCV presets the counter to the value configured by TOCC[TOP] and continues down-counting. When the timeout counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored.

00: Continuous operation
01: Timeout controlled by Tx event FIFO
10: Timeout controlled by Rx FIFO 0
11: Timeout controlled by Rx FIFO 1

These are protected write (P) bits, write access is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bit 0 ETOC: Timeout counter enable
0: Timeout counter disabled
1: Timeout counter enabled

This is a protected write (P) bit, write access is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

For more details see Timeout counter.

CEL[7:0]

rc_r rc_r rc_r rc_r rc_r rc_r rc_r rc_r

RP REC[6:0] TEC[7:0]
Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 CEL[7:0]: CAN error logging
The counter is incremented each time when a CAN protocol error causes the transmit error counter or the receive error counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag IR[ELO].
Access type is RX: reset on read.

Bit 15 RP: Receive error passive
0: The receive error counter is below the error passive level of 128.
1: The receive error counter has reached the error passive level of 128.

Bits 14:8 REC[6:0]: Receive error counter
Actual state of the receive error counter, values between 0 and 127.

Bits 7:0 TEC[7:0]: Transmit error counter
Actual state of the transmit error counter, values between 0 and 255.
When CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.

</tbody>
</table>

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 TDCV[6:0]: Transmitter delay compensation value
Position of the secondary sample point, defined by the sum of the measured delay from FDCAN_TX to FDCAN_RX and TDCR.TDCO. The SSP position is, in the data phase, the number of minimum time quanta (mtq) between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq.

Bit 15 Reserved, must be kept at reset value.

Bit 14 PXE: Protocol exception event
0: No protocol exception event occurred since last read access
1: Protocol exception event occurred

Bit 13 REDL: Received FDCAN message
This bit is set independent of acceptance filtering.
0: Since this bit was reset by the CPU, no FDCAN message has been received.
1: Message in FDCAN format with EDL flag set has been received.
Access type is RX: reset on read.
Bit 12 **RBRS**: BRS flag of last received FDCAN message

This bit is set together with REDL, independent of acceptance filtering.

0: Last received FDCAN message did not have its BRS flag set.
1: Last received FDCAN message had its BRS flag set.
Access type is RX: reset on read.

Bit 11 **RESI**: ESI flag of last received FDCAN message

This bit is set together with REDL, independent of acceptance filtering.

0: Last received FDCAN message did not have its ESI flag set.
1: Last received FDCAN message had its ESI flag set.
Access type is RX: reset on read.

Bits 10:8 **DLEC[2:0]**: Data last error code

Type of last error that occurred in the data phase of a FDCAN format frame with its BRS flag set. Coding is the same as for LEC. This field is cleared to 0 when a FDCAN format frame with its BRS flag set has been transferred (reception or transmission) without error.
Access type is RS: set on read.

Bit 7 **BO**: Bus_Off status

0: The FDCAN is not Bus_Off.
1: The FDCAN is in Bus_Off state.

Bit 6 **EW**: Warning Sstatus

0: Both error counters are below the Error_Warning limit of 96.
1: At least one of error counter has reached the Error_Warning limit of 96.

Bit 5 **EP**: Error passive

0: The FDCAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected.
1: The FDCAN is in the Error_Passive state.

Bits 4:3 **ACT[1:0]**: Activity

Monitors the module’s CAN communication state.

00: Synchronizing: node is synchronizing on CAN communication.
01: Idle: node is neither receiver nor transmitter.
10: Receiver: node is operating as receiver.
11: Transmitter: node is operating as transmitter.
Bits 2:0  **LEC[2:0]: Last error code**

The LEC indicates the type of the last error to occur on the CAN bus. This field is cleared to 0 when a message has been transferred (reception or transmission) without error.

000: No Error: No error occurred since LEC has been reset by successful reception or transmission.
001: Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.
010: Form Error: A fixed format part of a received frame has the wrong format.
011: AckError: The message transmitted by the FDCAN was not acknowledged by another node.
100: Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value 1), but the monitored bus value was dominant.
101: Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value 0), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).
110: CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data.
111: NoChange: Any read access to the Protocol status register re-initializes the LEC to ‘7’. When the LEC shows the value ‘7’, no CAN bus event was detected since the last CPU read access to the Protocol status register.

Access type is RS: set on read.

**Note:** When a frame in FDCAN format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) is shown in FLEC instead of LEC. An error in a fixed stuff bit of a FDCAN CRC sequence is shown as a Form Error, not Stuff Error.

**Note:** The Bus_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT]. If the device goes Bus_Off, it sets CCCR.INIT of its own, stopping all bus activities. Once CCCR[INIT] has been cleared by the CPU, the device then waits for 129 occurrences of Bus Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters are reset. During the waiting time after the reset of CCCR[INIT], each time a sequence of 11 recessive bits has been monitored, a Bit0 Error code is written to PSR[LEC], enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR[REC] is used to count these sequences.

### 70.4.14 FDCAN transmitter delay compensation register (FDCAN_TDCR)

Access type is RS: set on read.
Bits 31:15 Reserved, must be kept at reset value.

Bits 14:8 **TDCO[6:0]**: Transmitter delay compensation offset  
Offset value defining the distance between the measured delay from FDCAN_TX to FDCAN_RX and the secondary sample point. Valid values are 0 to 127 mtq.  
These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **TDCF[6:0]**: Transmitter delay compensation filter window length  
Defines the minimum value for the SSP position, dominant edges on FDCAN_RX that would result in an earlier SSP position are ignored for transmitter delay measurements.  
These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

### 70.4.15 FDCAN interrupt register (FDCAN_IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position.

Writing a 0 has no effect. A hard reset clears the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signaled.

Bits 31:24 Reserved, must be kept at reset value.

**Bit 23 ARA**: Access to reserved address  
0: No access to reserved address occurred  
1: Access to reserved address occurred

**Bit 22 PED**: Protocol error in data phase (data bit time is used)  
0: No protocol error in data phase  
1: Protocol error in data phase detected (PSR.DLEC different from 0,7)

**Bit 21 PEA**: Protocol error in arbitration phase (nominal bit time is used)  
0: No protocol error in arbitration phase  
1: Protocol error in arbitration phase detected (PSR.LEC different from 0,7)

**Bit 20 WDI**: Watchdog interrupt  
0: No message RAM watchdog event occurred  
1: Message RAM watchdog event due to missing READY
Bit 19 **BO**: Bus_Off status
   0: Bus_Off status unchanged
   1: Bus_Off status changed

Bit 18 **EW**: Warning status
   0: Error_Warning status unchanged
   1: Error_Warning status changed

Bit 17 **EP**: Error passive
   0: Error_Passive status unchanged
   1: Error_Passive status changed

Bit 16 **ELO**: Error logging overflow
   0: CAN error logging counter did not overflow.
   1: Overflow of CAN error logging counter occurred.

Bit 15 **TOO**: Timeout occurred
   0: No timeout
   1: Timeout reached

Bit 14 **MRAF**: Message RAM access failure
   The flag is set when the Rx handler:
   i. has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx handler starts processing of the following message.
   ii. was unable to write a message to the message RAM. In this case message storage is aborted.
   In both cases the FIFO put index is not updated. The partly stored message is overwritten when the next message is stored to this location.
   The flag is also set when the Tx Handler was not able to read a message from the Message RAM in time. In this case message transmission is aborted. In case of a Tx Handler access failure the FDCAN is switched into Restricted operation Mode (see Restricted operation mode). To leave Restricted operation Mode, the Host CPU has to reset CCCR.ASM.
   0: No Message RAM access failure occurred
   1: Message RAM access failure occurred

Bit 13 **TSW**: Timestamp wraparound
   0: No timestamp counter wrap-around
   1: Timestamp counter wrapped around

Bit 12 **TEFL**: Tx event FIFO element lost
   0: No Tx event FIFO element lost
   1: Tx event FIFO element lost

Bit 11 **TEFF**: Tx event FIFO full
   0: Tx event FIFO Not full
   1: Tx event FIFO full

Bit 10 **TEFN**: Tx event FIFO New Entry
   0: Tx event FIFO unchanged
   1: Tx handler wrote Tx event FIFO element.

Bit 9 **TFE**: Tx FIFO empty
   0: Tx FIFO non-empty
   1: Tx FIFO empty
The settings in the interrupt enable register determine which status changes in the interrupt register are signaled on an interrupt line.

### 70.4.17 FDCAN interrupt line select register (FDCAN_ILS)

This register assigns an interrupt generated by a specific group of interrupt flag from the Interrupt register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via ILE[EINT0] and ILE[EINT1].

Address offset: 0x0058
Reset value: 0x0000 0000

Bits 31:2  Reserved, must be kept at reset value.

Bit 1  **EINT1**: Enable interrupt line 1
   0: Interrupt line fdcan_intr0_it disabled
   1: Interrupt line fdcan_intr0_it enabled

Bit 0  **EINT0**: Enable interrupt line 0
   0: Interrupt line fdcan_intr1_it disabled
   1: Interrupt line fdcan_intr1_it enabled
### 70.4.19 FDCAN global filter configuration register (FDCAN_RXGFC)

Global settings for Message ID filtering. The Global Filter Configuration controls the filter path for standard and extended messages as described in Figure 880 and Figure 881.

Address offset: 0x0080

Reset value: 0x0000 0000

| Bits 31:28 | Reserved, must be kept at reset value. |
| Bits 27:24 | **LSE[3:0]**: List size extended  
  0: No extended message ID filter  
  1 to 8: Number of extended message ID filter elements  
  >8: Values greater than 8 are interpreted as 8.  
  These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1. |
| Bits 23:21 | Reserved, must be kept at reset value. |
| Bits 20:16 | **LSS[4:0]**: List size standard  
  0: No standard message ID filter  
  1 to 28: Number of standard message ID filter elements  
  >28: Values greater than 28 are interpreted as 28.  
  These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1. |
| Bits 15:10 | Reserved, must be kept at reset value. |
| Bit 9 | **F0OM**: FIFO 0 operation mode (overwrite or blocking)  
  This is protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1. |
| Bit 8 | **F1OM**: FIFO 1 operation mode (overwrite or blocking)  
  This is a protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1. |
| Bits 7:6 | Reserved, must be kept at reset value. |
| Bits 5:4 | **ANFS[1:0]**: Accept Non-matching frames standard  
  Defines how received messages with 11-bit IDs that do not match any element of the filter list are treated.  
  00: Accept in Rx FIFO 0  
  01: Accept in Rx FIFO 1  
  10: Reject  
  11: Reject  
  These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1. |
Bits 3:2 ANFE[1:0]: Accept non-matching frames extended
Defines how received messages with 29-bit IDs that do not match any element of the filter list are treated.
00: Accept in Rx FIFO 0
01: Accept in Rx FIFO 1
10: Reject
11: Reject
These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bit 1 RRFS: Reject remote frames standard
0: Filter remote frames with 11-bit standard IDs
1: Reject all remote frames with 11-bit standard IDs
These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bit 0 RRFE: Reject remote frames extended
0: Filter remote frames with 29-bit standard IDs
1: Reject all remote frames with 29-bit standard IDs
These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

70.4.20 FDCAN extended ID and mask register (FDCAN_XIDAM)
Address offset: 0x0084
Reset value: 0x1FFF FFFF

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:0 EIDM[28:0]: Extended ID mask
For acceptance filtering of extended frames the Extended ID AND Mask is AND-ed with the Message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set to 1 the mask is not active.
These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.
70.4.21 FDCAN high-priority message status register (FDCAN_HPMC)

This register is updated every time a Message ID filter element configured to generate a priority event match. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

Address offset: 0x0088
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 FLST: Filter list
Indicates the filter list of the matching filter element.
0: Standard filter list
1: Extended filter list

Bits 14:13 Reserved, must be kept at reset value.

Bits 12:8 FIDX[4:0]: Filter index
Index of matching filter element. Range is 0 to RXGFC[LSS] - 1 or RXGFC[LSE] - 1.

Bits 7:6 MSI[1:0]: Message storage indicator
00: No FIFO selected
01: FIFO overrun
10: Message stored in FIFO 0
11: Message stored in FIFO 1

Bits 5:3 Reserved, must be kept at reset value.

Bits 2:0 BIDX[2:0]: Buffer index
Index of Rx FIFO element to which the message was stored. Only valid when MSI[1] = 1.

70.4.22 FDCAN Rx FIFO 0 status register (FDCAN_RXF0S)

Address offset: 0x0090
Reset value: 0x0000 0000

Bits 31:26 Reserved, must be kept at reset value.
Bit 25 **RF0L**: Rx FIFO 0 message lost  
This bit is a copy of interrupt flag IR[RF0L]. When IR[RF0L] is reset, this bit is also reset.  
0: No Rx FIFO 0 message lost  
1: Rx FIFO 0 message lost, also set after write attempt to Rx FIFO 0 of size 0

Bit 24 **F0F**: Rx FIFO 0 full  
0: Rx FIFO 0 not full  
1: Rx FIFO 0 full

Bits 23:18 Reserved, must be kept at reset value.

Bits 17:16 **F0PI[1:0]**: Rx FIFO 0 put index  
Rx FIFO 0 write index pointer, range 0 to 2.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **F0GI[1:0]**: Rx FIFO 0 get index  
Rx FIFO 0 read index pointer, range 0 to 2.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **F0FL[3:0]**: Rx FIFO 0 fill level  
Number of elements stored in Rx FIFO 0, range 0 to 3.

### 70.4.23 CAN Rx FIFO 0 acknowledge register (FDCAN_RXF0A)

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **F0AI[2:0]**: Rx FIFO 0 acknowledge index  
After the Host has read a message or a sequence of messages from Rx FIFO 0 it has to write the buffer index of the last element read from Rx FIFO 0 to F0AI. This sets the Rx FIFO 0 get index RXF0S[F0GI] to F0AI + 1 and update the FIFO 0 fill level RXF0S[F0FL].

</table>

Bits 31:3  Reserved, must be kept at reset value.

Bits 2:0  **F1AI[2:0]**: Rx FIFO 1 acknowledge index
   After the Host has read a message or a sequence of messages from Rx FIFO 1 it has to write the buffer index of the last element read from Rx FIFO 1 to F1AI. This sets the Rx FIFO 1 get index RXF1S[F1GI] to F1AI + 1 and update the FIFO 1 Fill Level RXF1S[F1FL].
70.4.26  FDCAN Tx buffer configuration register (FDCAN_TXBC)

Address offset: 0x00C0
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:25  Reserved, must be kept at reset value.

Bit 24  TFQM: Tx FIFO/queue mode
0: Tx FIFO operation
1: Tx queue operation.

Bits 23:0  Reserved, must be kept at reset value.

70.4.27  FDCAN Tx FIFO/queue status register (FDCAN_TXFQS)

The Tx FIFO/Queue status is related to the pending Tx requests listed in register TXBRP. Therefore the effect of Add/Cancellation requests may be delayed due to a running Tx scan (TXBRP not yet updated).

Address offset: 0x00C4
Reset value: 0x0000 0003

<td>Number of consecutive free Tx FIFO elements starting from TFGI, range 0 to 3. Read as 0 when Tx queue operation is configured (TXBC[TFQM] = 1).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bits 31:3</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 2:0</td>
<td><strong>TRP[2:0]</strong>: Transmission request pending</td>
</tr>
<tr>
<td></td>
<td>Each Tx buffer has its own transmission request pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been canceled via register TXBCR.</td>
</tr>
<tr>
<td></td>
<td>After a TXBRP bit has been set, a Tx scan is started to check for the pending Tx request with the highest priority (Tx buffer with lowest Message ID).</td>
</tr>
<tr>
<td></td>
<td>A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset.</td>
</tr>
<tr>
<td></td>
<td>After a cancellation has been requested, a finished cancellation is signaled via TXBCF after successful transmission together with the corresponding TXBTO bit when the transmission has not yet been started at the point of cancellation when the transmission has been aborted due to lost arbitration when an error occurred during frame transmission</td>
</tr>
<tr>
<td></td>
<td>In DAR mode all transmissions are automatically canceled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions.</td>
</tr>
<tr>
<td></td>
<td>0: No transmission request pending</td>
</tr>
<tr>
<td></td>
<td>1: Transmission request pending</td>
</tr>
</tbody>
</table>

**Note:** TXBRP bits set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx buffer, this Add Request is canceled immediately, the corresponding TXBRP bit is reset.
### 70.4.29 FDCAN Tx buffer add request register (FDCAN_TXBAR)

Address offset: 0x00CC  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>rw</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bits 2:0</th>
<th>AR[2:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No transmission request added</td>
</tr>
<tr>
<td>1</td>
<td>Transmission requested added</td>
</tr>
</tbody>
</table>

**Note:** If an add request is applied for a Tx buffer with pending transmission request (corresponding TXBRP bit already set), the request is ignored.

### 70.4.30 FDCAN Tx buffer cancellation request register (FDCAN_TXBCR)

Address offset: 0x00D0  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>rw</td>

<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **TO[2:0]**: Transmission occurred.

Each Tx buffer has its own TO bit. The bits are set when the corresponding TXBRP bit is cleared after a successful transmission. The bits are reset when a new transmission is requested by writing a 1 to the corresponding bit of register TXBAR.

0: No transmission occurred  
1: Transmission occurred

### 70.4.32 FDCAN Tx buffer cancellation finished register (FDCAN_TXBCF)

Address offset: 0x00D8  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>

<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **CF[2:0]**: Cancellation finished

Each Tx buffer has its own CF bit. The bits are set when the corresponding TXBRP bit is cleared after a cancellation was requested via TXBCR. In case the corresponding TXBRP bit was not set at the point of cancellation, CF is set immediately. The bits are reset when a new transmission is requested by writing a 1 to the corresponding bit of register TXBAR.

0: No transmit buffer cancellation  
1: Transmit buffer cancellation finished
### 70.4.33  FDCAN Tx buffer transmission interrupt enable register (FDCAN_TXBTIE)

Address offset: 0x00DC  
Reset value: 0x0000 0000

---

**STMicroelectronics**

RM0456 Rev 5  
3067/3637
70.4.37  FDCAN CFG clock divider register (FDCAN_CKDIV)

Address offset: 0x0100  
Reset value: 0x0000 0000

| Bits 31:4 | Reserved, must be kept at reset value. |
| Bits 3:0 | PDIV[3:0]: input clock divider |
| The APB clock can be divided prior to be used by the CAN sub system. The rate must be computed using the divider output clock. |
| 0000: Divide by 1 |
| 0001: Divide by 2 |
| 0010: Divide by 4 |
| 0011: Divide by 6 |
| 0100: Divide by 8 |
| 0101: Divide by 10 |
| 0110: Divide by 12 |
| 0111: Divide by 14 |
| 1000: Divide by 16 |
| 1001: Divide by 18 |
| 1010: Divide by 20 |
| 1011: Divide by 22 |
| 1100: Divide by 24 |
| 1101: Divide by 26 |
| 1110: Divide by 28 |
| 1111: Divide by 30 |

These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

70.4.38  FDCAN register map

| Offset  | Register         | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|---------|------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x0000  | FDCAN_CREL       | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 1  | 1  | 0  | 1  | 0  | 1  | 0  | 0  | 1  | 1  | 0  | 1  | 1  | 1  | 1  | 1  | 0  | 0  | 0  | 0  | 1  | 0  |

These values correspond to the reset values of the registers.
Table 724. FDCAN register map and reset values (1) (continued)

71 Universal serial bus full-speed host/device interface (USB)

This section applies to STM32U535/545 devices only.

71.1 Introduction

The USB peripheral implements an interface between a full-speed USB 2.0 bus and the APB2 bus.

USB suspend/resume are supported, which permits to stop the device clocks for low-power consumption.

71.2 USB main features

- USB specification version 2.0 full-speed compliant
- Supports both Host and Device modes
- Configurable number of endpoints from 1 to 8
- Dedicated packet buffer memory (SRAM) of 2048 bytes
- Cyclic redundancy check (CRC) generation/checking, Non-return-to-zero Inverted (NRZI) encoding/decoding and bit-stuffing
- Isochronous transfers support
- Double-buffered bulk/isochronous endpoint/channel support
- USB Suspend/Resume operations
- Frame locked clock pulse generation
- USB 2.0 Link Power Management support (Device mode only)
- Battery Charging Specification Revision 1.2 support (Device mode only)
- USB connect / disconnect capability (controllable embedded pull-up resistor on USB_DP line)

General description and Device mode functionality

The USB peripheral provides a USB-compliant connection between the function implemented by the microcontroller and an external USB function which can be a host PC but also a USB Device. Data transfer between the external USB host or device and the system memory occurs through a dedicated packet buffer memory accessed directly by the USB peripheral. This dedicated memory size is 2048 bytes, and up to 16 mono-directional or 8 bidirectional endpoints can be used. The USB peripheral interfaces with the external USB Host or Device, detecting token packets, handling data transmission/reception, and processing handshake packets as required by the USB standard. Transaction formatting is performed by the hardware, including CRC generation and checking.

Each endpoint/channel is associated with a buffer description block indicating where the endpoint/channel-related memory area is located, how large it is or how many bytes must be transmitted. When a token for a valid function/endpoint pair is recognized by the USB peripheral, the related data transfer (if required and if the endpoint/channel is configured) takes place. The data buffered by the USB peripheral are loaded in an internal 16-bit register and memory access to the dedicated buffer is performed. When all the data have been transferred, if needed, the proper handshake packet over the USB is generated or expected according to the direction of the transfer.

At the end of the transaction, an endpoint/channel-specific interrupt is generated, reading status registers and/or using different interrupt response routines. The microcontroller can determine:

- which endpoint/channel has to be served,
- which type of transaction took place, if errors occurred (bit stuffing, format, CRC, protocol, missing ACK, over/underrun, etc.).

Special support is offered to isochronous transfers and high throughput bulk transfers, implementing a double buffer usage, which permits to always have an available buffer for the USB peripheral while the microcontroller uses the other one.

A special bit THR512 in register USB_ISTR allows notification of 512 bytes being received in (or transmitted from) the buffer. This bit must be used for long ISO packets (from 512 to 1023 bytes) as it facilitates early start or read/write of data. In this way, the first 512 bytes can be handled by software while avoiding use of double buffer mode. This bit works when only one ISO endpoint is configured.

The unit can be placed in low-power mode (SUSPEND mode), by writing in the control register, whenever required. At this time, all static power dissipation is avoided, and the USB clock can be slowed down or stopped. The detection of activity at the USB inputs, while in low-power mode, wakes the device up asynchronously. A special interrupt source can be connected directly to a wake-up line to permit the system to immediately restart the normal clock generation and/or support direct clock start/stop.

Host mode and specific functionality

A single bit, HOST, in register USB_CNTR permits Host mode to be activated. Host mode functionality permits the USB to talk to a remote peripheral. Supported functionality is aligned to Device mode and uses the same register structures to manage the buffers. The same number of endpoints can be supported in Host mode, however in Host mode the terminology “channel” is preferred, as each channel is in reality a combination of the connected device and the endpoint on that device. The basic mechanisms for packet transmission and reception are the same as those supported in Device mode.
When operating in Host mode, the USB is in charge of the bus and in order to do this must issue transaction requests corresponding to active periodic and non-periodic endpoints. A host frame scheduler assures efficient use of the frame. Connection to hubs is supported. Connection to low speed devices is supported, both with a direct connection and through a hub.

Double-buffered mode, as previously described in Device mode, is also supported in Host mode, in both bulk and isochronous channels. The THR512 functionality is also supported (but as in Device mode) only for ISO traffic.

Note: Unlike in Device mode, where there is a detection of battery charging capability (in order to facilitate fast charging), there is no integrated support in Host mode to present battery charging capability (CDP or DCP cases in the standard), the host port is always presented as a default standard data port (SDP).

Note: For LPM (link power management) this feature is not supported in Host mode.

71.4.1 Description of USB blocks used in both Device and Host modes

The USB peripheral implements all the features related to USB interfacing, which include the following blocks:

- USB physical interface (USB PHY): this block is maintaining the electrical interface to an external USB host. It contains the differential analog transceiver itself, controllable embedded pull-up resistor (connected to USB_DP line) and support for battery charging detection (BCD), multiplexed on same USB_DP and USB_DM lines. The output enable control signal of the analog transceiver (active low) is provided externally on USB_NOE. It can be used to drive some activity LED or to provide information about the actual communication direction to some other circuitry.

- Serial interface engine (SIE): the functions of this block include: synchronization pattern recognition, bit-stuffing, CRC generation and checking, PID verification/generation, and handshake evaluation. It must interface with the USB transceivers and uses the virtual buffers provided by the packet buffer interface for local data storage. This unit also generates signals according to USB peripheral events, such as start of frame (SOF), USB_Reset, data errors etc. and to endpoint related events like end of transmission or correct reception of a packet; these signals are then used to generate interrupts.

- Timer: this block generates a start-of-frame locked clock pulse and detects a global suspend (from the host) when no traffic has been received for 3 ms.

- Packet buffer interface: this block manages the local memory implementing a set of buffers in a flexible way, both for transmission and reception. It can choose the proper buffer according to requests coming from the SIE and locate them in the memory addresses pointed by the endpoint/channel registers. It increments the address after each exchanged byte until the end of packet, keeping track of the number of exchanged bytes and preventing the buffer to overrun the maximum capacity.
• Endpoint/channel-related registers: each endpoint/channel has an associated register containing the endpoint/channel type and its current status. For mono-directional/single-buffer endpoints, a single register can be used to implement two distinct endpoints. The number of registers is 8, allowing up to 16 mono-directional/single-buffer or up to 7 double-buffer endpoints in any combination. For example the USB peripheral can be programmed to have 4 double buffer endpoints and 8 single-buffer/mono-directional endpoints.

• Control registers: these are the registers containing information about the status of the whole USB peripheral and used to force some USB events, such as resume and power-down.

• Interrupt registers: these contain the interrupt masks and a record of the events. They can be used to inquire an interrupt reason, the interrupt status or to clear the status of a pending interrupt.

Note: * Endpoint/channel 0 is always used for control transfer in single-buffer mode.

The USB peripheral is connected to the APB2 bus through an APB2 interface, containing the following blocks:

• Packet memory: this is the local memory that physically contains the packet buffers. It can be used by the packet buffer interface, which creates the data structure and can be accessed directly by the application software. The size of the packet memory is 2048 bytes, structured as 512 words of 32 bits.

• Arbiter: this block accepts memory requests coming from the APB2 bus and from the USB interface. It resolves the conflicts by giving priority to APB2 accesses, while always reserving half of the memory bandwidth to complete all USB transfers. This time-duplex scheme implements a virtual dual-port SRAM that allows memory access, while an USB transaction is happening. Multiword APB2 transfers of any length are also allowed by this scheme.

• Register mapper: this block collects the various byte-wide and bit-wide registers of the USB peripheral in a structured 32-bit wide word set addressed by the APB2.

• APB2 wrapper: this provides an interface to the APB2 for the memory and register. It also maps the whole USB peripheral in the APB2 address space.

• Interrupt mapper: this block is used to select how the possible USB events can generate interrupts and map them to the NVIC.

71.4.2 Description of host frame scheduler (HFS) specific to Host mode

The host frame scheduler is the hardware machine in charge to submit host channel requests on the bus according to the USB priority order and bandwidth access rules.

Host channels are divided in two categories:

– Periodic channels: isochronous and interrupt traffic types. With guaranteed bandwidth access.
– Non-periodic channels: bulk and control traffic types. With best effort service.

The host frame scheduler organizes the full-speed frame in 3 sequential windows

– Periodic service window
– Non-periodic service window
– Black security window

At the start of a new frame the host scheduler:
1. First considers all periodic channels which were active (STAT bits VALID) at the start of frame
2. Executes single round of service of periodic channels, the periodic service window, in hardware priority order from CH#1 to CH#8. For bidirectional channels it executes the OUT direction first
3. When the periodic round is finished, HFS closes the periodic service window and stops servicing periodic traffic even if some periodic channel was re-enabled or some new channel was enabled after the SOF.
4. Starts servicing all non-periodic channels which are currently active (STAT bits VALID) in hardware priority order from CH#1 to CH#8. For bidirectional channels it executes the OUT direction first.
5. Executes multiple round-robin service cycles of non-periodic channels until almost the end of frame
6. Non periodic traffic can be requested at any time and is serviced by HFS with best effort latency, with the exception of a black security window at the end of the frame where new injected requests are directly postponed to the next frame to avoid babbles. This is also true for pending transactions which have not been serviced ahead of the security window.

71.5 Programming considerations for Device and Host modes

In the following sections, the expected interactions between the USB peripheral and the application program are described, in order to ease application software development.

71.5.1 Generic USB Device programming

This part describes the main tasks required of the application software in order to obtain USB compliant behavior. The actions related to the most general USB events are taken into account and paragraphs are dedicated to the special cases of double-buffered endpoints and isochronous transfers. Apart from system reset, an action is always initiated by the USB peripheral, driven by one of the USB events described below.

71.5.2 System and power-on reset

Upon system and power-on reset, the first operation the application software must perform is to provide all required clock signals to the USB peripheral and subsequently de-assert its reset signal so to be able to access its registers. The whole initialization sequence is hereafter described.

As a first step application software needs to activate register macrocell clock and de-assert macrocell specific reset signal using related control bits provided by device clock management logic.

After that, the analog part of the device related to the USB transceiver must be switched on using the PDWN bit in CNTR register, which requires a special handling. This bit is intended to switch on the internal voltage references that supply the port transceiver. This circuit has a defined startup time (t_{STARTUP} specified in the datasheet) during which the behavior of the USB transceiver is not defined. It is thus necessary to wait this time, after setting the PDWN bit in the CNTR register, before removing the reset condition on the USB part (by clearing the USBRST bit in the CNTR register). Clearing the ISTR register removes any spurious pending interrupt before any other macrocell operation is enabled.
At system reset, the microcontroller must initialize all required registers and the packet buffer description table, to make the USB peripheral able to properly generate interrupts and data transfers. All registers not specific to any endpoint/channel must be initialized according to the needs of application software (choice of enabled interrupts, chosen address of packet buffers, etc.). Then the process continues as for the USB reset case (see further paragraph).

**USB bus reset (RST_DCON interrupt) in Device mode**

When this event occurs, the USB peripheral is put in the same conditions it is left by the system reset after the initialization described in the previous paragraph: communication is disabled in all endpoint registers (the USB peripheral does not respond to any packet). As a response to the USB reset event, the USB function must be enabled, having as USB address 0, implementing only the default control endpoint (endpoint address is 0 too). This is accomplished by setting the enable function (EF) bit of the USB_DADDR register and initializing the CHEP0R register and its related packet buffers accordingly. During USB enumeration process, the host assigns a unique address to this device, which must be written in the ADD[6:0] bits of the USB_DADDR register, and configures any other necessary endpoint.

When a RST_DCON interrupt is received, the application software is responsible to enable again the default endpoint of USB function 0 within 10 ms from the end of the reset sequence which triggered the interrupt.

**USB bus reset in Host mode**

In Host mode a bus reset is activated by setting the USBRST bit of the USB_CNTR register. It must subsequently be cleared by software once the minimum active reset time from the standard has been respected.

**Structure and usage of packet buffers**

Each bidirectional endpoint may receive or transmit data over the bus. The received data is stored in a dedicated memory buffer reserved for that endpoint, while another memory buffer contains the data to be transmitted by the endpoint. Access to this memory is performed by the packet buffer interface block, which delivers a memory access request and waits for its acknowledgment. Since the packet buffer memory has also to be accessed by the microcontroller, an arbitration logic takes care of the access conflicts, using half APB2 cycle for microcontroller access and the remaining half for the USB peripheral access. In this way, both agents can operate as if the packet memory would be a dual-port SRAM, without being aware of any conflict even when the microcontroller is performing back-to-back accesses. The USB peripheral logic uses a dedicated clock. The frequency of this dedicated clock is fixed by the requirements of the USB standard at 48 MHz, and this can be different from the clock used for the interface to the APB2 bus. Different clock configurations are possible where the APB2 clock frequency can be higher or lower than the USB peripheral one.

*Note:* Due to USB data rate and packet memory interface requirements, the APB2 clock must have a minimum frequency of 12 MHz to avoid data overrun/underrun problems.

Each endpoint is associated with two packet buffers (usually one for transmission and the other one for reception). Buffers can be placed anywhere inside the packet memory because their location and size is specified in a buffer description table, which is also located in the packet memory. Each table entry is associated to an endpoint register and it is composed of two 32-bit words so that table start address must always be aligned to an 8-
byte boundary. Buffer descriptor table entries are described in Section 71.6.2: Buffer descriptor table. If an endpoint is unidirectional and it is neither an isochronous nor a double-buffered bulk, only one packet buffer is required (the one related to the supported transfer direction). Other table locations related to unsupported transfer directions or unused endpoints, are available to the user. Isochronous and double-buffered bulk endpoints have special handling of packet buffers (Refer to Section 71.5.5: Isochronous transfers in Device mode and Section 71.5.3: Double-buffered endpoints and usage in Device mode respectively). The relationship between buffer description table entries and packet buffer areas is depicted in Figure 883.

For Host mode different sections explain the buffer usage model, notably Section 71.5.6: Isochronous transfers in Host mode and Section 71.5.4: Double buffered channels: usage in Host mode.

Figure 883. Packet buffer areas with examples of buffer description table locations

Each packet buffer is used either during reception or transmission starting from the bottom. The USB peripheral never changes the contents of memory locations adjacent to the allocated memory buffers; if a packet bigger than the allocated buffer length is received (buffer overrun condition) the data is copied to the memory only up to the last available location.
Endpoint initialization

The first step to initialize an endpoint is to write appropriate values to the ADDRn_TX/ADDRn_RX fields in the CHEP_TXBD_n and CHEP_RXBD_n registers (in SRAM) so that the USB peripheral finds the data to be transmitted already available and the data to be received can be buffered. The UTYPE bits in the USB_CHEPnR register must be set according to the endpoint type, eventually using the EPKIND bit to enable any special required feature. On the transmit side, the endpoint must be enabled using the STATTX bits in the USB_CHEPnR register and COUNTn_TX must be initialized. For reception, STATRX bits must be set to enable reception and COUNTn_RX must be written with the allocated buffer size using the BLSIZE and NUM_BLOCK fields. Unidirectional endpoints, except isochronous and double-buffered bulk endpoints, need to initialize only bits and registers related to the supported direction. Once the transmission and/or reception are enabled, register USB_CHEPnR and locations ADDRn_TX/ADDRn_RX, COUNTn_TX/COUNTn_RX (respectively), must not be modified by the application software, as the hardware can change their value on the fly. When the data transfer operation is completed, notified by a CTR interrupt event, they can be accessed again to re-enable a new operation.

Data transmission in Device mode (IN packets)

When receiving an IN token packet, if the received address matches a configured and valid endpoint, the USB peripheral accesses the contents of CHEP_TXBD_n (fields ADDRn_TX and COUNTn_TX) inside the buffer descriptor table entry related to the addressed endpoint. The content of these locations is stored in its internal 16-bit registers ADDR and COUNT (not accessible by software). The packet memory is accessed again to read the first byte to be transmitted (refer to Structure and usage of packet buffers on page 3078) and the USB peripheral starts sending a DATA0 or DATA1 PID according to USB_CHEPnR bit DTOGTX. When the PID is completed, the first byte, read from buffer memory, is loaded into the output shift register to be transmitted on the USB bus. After the last data byte is transmitted, the computed CRC is sent. If the addressed endpoint is not valid, a NAK or STALL handshake packet is sent instead of the data packet, according to STATTX bits in the USB_CHEPnR register.

The ADDRn_TX field in the internal register CHEP_TXBD_n is used as a pointer to the current buffer memory location while COUNT is used to count the number of remaining bytes to be transmitted. Each half-word read from the packet buffer memory is transmitted over the USB bus starting from the least significant byte. Transmission buffer memory is read starting from the address pointed by ADDRn_TX for COUNTn_TX/4 words. If a transmitted packet is composed of an odd number of bytes, only the lower half of the last half-word accessed is used.

On receiving the ACK receipt by the host, the USB_CHEPnR register is updated in the following way: DTOGTX bit is toggled, the endpoint is made invalid by setting STATTX = 10 (NAK) and bit VTTX is set. The application software must first identify the endpoint, which is requesting microcontroller attention by examining the IDN and DIR bits in the USBISTR register. Servicing of the VTTX event starts, clearing the interrupt bit; the application software then prepares another buffer full of data to be sent, updates the COUNTn_TX table location with the number of bytes to be transmitted during the next transfer, and finally sets STATTX to 11 (VALID) to re-enable transmission. While the STATTX bits are equal to 10 (NAK), any IN request addressed to that endpoint is NAKed, indicating a flow control condition: the USB host retries the transaction until it succeeds. It is mandatory to execute the sequence of operations in the above mentioned order to avoid losing the notification of a second IN transaction addressed to the same endpoint immediately following the one which triggered the CTR interrupt.
Data transmission in Host mode (OUT packets)

Data transmission in Host mode follows the same general principles as Device mode. The main differences are due to the protocol. For example the host initiates the transmission whereas the device responds to the incoming token.

ADDRn_TX must be set to the location in the packet memory reserved for the packet for transmission. The contents of an OUT packet are then written to that address in the packet memory and COUNTn_TX must be updated (when necessary) to indicate the number of bytes in the packet.

DEVADDR must be written for the correct endpoint and then STATTX must be set to 11 (VALID) in order to trigger the transmit. The transmission is then scheduled by the HFS.

After a successful transmission the CTR interrupt (correct transfer) is triggered. By examining IDN and DIR bits, the corresponding channel and direction is understood. On the indicated channel, the STATTX field now has transitioned to DISABLE. In the case of a NAK being received (when the peripheral is not ready) STATTX is now in NAK. In the case of a STALL response, STATTX is in STALL. In this last case, the bus must be reset.

On receiving the ACK receipt by the device, the USB_CHEPnR register is updated in the following way: DTOGTX bit is toggled.

An error condition is signaled via the bits VTTX and ERR_TX in the case of:
- No handshake being received in time
- False EOP
- Bit stuffing error
- Invalid handshake PID

Data reception in Device mode (OUT and SETUP packets)

These two tokens are handled by the USB peripheral more or less in the same way; the differences in the handling of SETUP packets are detailed in the following paragraph about control transfers. When receiving an OUT/SETUP PID, if the address matches a valid endpoint, the USB peripheral accesses the contents of the ADDRn_RX and COUNTn_RX fields inside the buffer descriptor table entry related to the addressed endpoint. The content of the ADDRn_RX field is stored directly in its internal register ADDR. Internal register COUNT is now reset and the values of BLSIZE and NUM_BLOCK bit fields, which are read within USB_CHEP_RXBD_n content, are used to initialize BUF_COUNT, an internal 16-bit counter, which is used to check the buffer overrun condition (all these internal registers are not accessible by software). Data bytes subsequently received by the USB peripheral are packed in half-words (the first byte received is stored as least significant byte) and then transferred to the packet buffer starting from the address contained in the internal ADDR register while BUF_COUNT is decremented and COUNT is incremented at each byte transfer. When the end of DATA packet is detected, the correctness of the received CRC is tested and only if no errors occurred during the reception, an ACK handshake packet is sent back to the transmitting host.

In case of wrong CRC or other kinds of errors (bit-stuff violations, frame errors, etc.), data bytes are still copied in the packet memory buffer, at least until the error detection point, but the ACK packet is not sent and the ERR bit in USB_ISTR register is set. However, there is usually no software action required in this case: the USB peripheral recovers from reception errors and remains ready for the next transaction to come. If the addressed endpoint is not valid, a NAK or STALL handshake packet is sent instead of the ACK, according to bits
STATRX in the USB_CHEPnR register, and no data is written in the reception memory buffers.

Reception memory buffer locations are written starting from the address contained in the ADDRn_RX for a number of bytes corresponding to the received data packet length, or up to the last allocated memory location, as defined by BLSIZE and NUM_BLOCK, whichever comes first. In this way, the USB peripheral never writes beyond the end of the allocated reception memory buffer area. If the length of the data packet payload (actual number of bytes used by the application) is greater than the allocated buffer, the USB peripheral detects a buffer overrun condition. In this case, a STALL handshake is sent instead of the usual ACK to notify the problem to the host, no interrupt is generated and the transaction is considered failed.

When the transaction is completed correctly, by sending the ACK handshake packet, the internal COUNT register is copied back in the COUNTn_RX location inside the buffer description table entry, leaving unaffected BLSIZE and NUM_BLOCK fields, which normally do not require to be re-written, and the USB_CHEPnR register is updated in the following way: DTOGRX bit is toggled, the endpoint is made invalid by setting STATRX = 10 (NAK) and bit VTRX is set. If the transaction has failed due to errors or buffer overrun condition, none of the previously listed actions take place. The application software must first identify the endpoint, which is requesting microcontroller attention by examining the IDN and DIR bits in the USB_INSTR register. The VTRX event is serviced by first determining the transaction type (SETUP bit in the USB_CHEPnR register); the application software must clear the interrupt flag bit and get the number of received bytes reading the COUNTn_RX location inside the buffer description table entry related to the endpoint being processed. After the received data is processed, the application software must set the STATRX bits to 11 (VALID) in the USB_CHEPnR, enabling further transactions. While the STATRX bits are equal to 10 (NAK), any OUT request addressed to that endpoint is NAKed, indicating a flow control condition: the USB host retries the transaction until it succeeds. It is mandatory to execute the sequence of operations in the above mentioned order to avoid losing the notification of a second OUT transaction addressed to the same endpoint following immediately the one which triggered the CTR interrupt.

Data reception in Host mode (IN packets)

Data reception in Host mode follows the same general principles as Device mode. The main differences are again due to the protocol. In the device, data can be received or not, depending on readiness after previous operations, whereas the host only requests receive data when it is ready and able to store them.

ADDRn_TX must be set to the location in the packet memory reserved for the packet for transmission. The contents received in the data phase response to the IN token packet are then written to that address in the packet memory and COUNTn_TX gets updated by hardware during this process to indicate the number of bytes in the packet.

DEVADDR must be written for the correct endpoint and then STATRX must be set to VALID in order to trigger the reception. The reception is then scheduled by the HFS.

After a successful reception the interrupt CTR (correct transfer) is triggered. By examining IDN and DIR bits, the corresponding channel and direction is understood. On the indicated channel, the STATRX field now has transitioned to DISABLE. In the case of a NAK being received (when the peripheral is not ready) STATRX now is in NAK. In the case of a STALL
response, STATRX is in STALL. In this last case, the bus must be reset. During an IN packet an error condition is signaled via the bits VTRX and ERR_RX in case of:

- False EOP
- Bit stuffing error
- Wrong CRC

**Control transfers in Device mode**

Control transfers are made of a SETUP transaction, followed by zero or more data stages, all of the same direction, followed by a status stage (a zero-byte transfer in the opposite direction). SETUP transactions are handled by control endpoints only and are very similar to OUT ones (data reception) except that the values of DTOGTX and DTOGRX bits of the addressed endpoint registers are set to 1 and 0 respectively, to initialize the control transfer, and both STATTX and STATRX are set to 10 (NAK) to let software decide if subsequent transactions must be IN or OUT depending on the SETUP contents. A control endpoint must check SETUP bit in the USB_CHEPnR register at each VTRX event to distinguish normal OUT transactions from SETUP ones. A USB Device can determine the number and direction of data stages by interpreting the data transferred in the SETUP stage, and is required to STALL the transaction in the case of errors. To do so, at all data stages before the last, the unused direction must be set to STALL, so that, if the host reverses the transfer direction too soon, it gets a STALL as a status stage.

While enabling the last data stage, the opposite direction must be set to NAK, so that, if the host reverses the transfer direction (to perform the status stage) immediately, it is kept waiting for the completion of the control operation. If the control operation completes successfully, the software changes NAK to VALID, otherwise to STALL. At the same time, if the status stage is an OUT, the STATUS_OUT (EPKIND in the USB_CHEPnR register) bit must be set, so that an error is generated if a status transaction is performed with non-zero data. When the status transaction is serviced, the application clears the STATUS_OUT bit and sets STATRX to VALID (to accept a new command) and STATTX to NAK (to delay a possible status stage immediately following the next setup).

Since the USB specification states that a SETUP packet cannot be answered with a handshake different from ACK, eventually aborting a previously issued command to start the new one, the USB logic does not permit a control endpoint to answer with a NAK or STALL packet to a SETUP token received from the host.

When the STATRX bits are set to 01 (STALL) or 10 (NAK) and a SETUP token is received, the USB accepts the data, performing the required data transfers and sends back an ACK handshake. If that endpoint has a previously issued VTRX request not yet acknowledged by the application (for example VTRX bit is still set from a previously completed reception), the USB discards the SETUP transaction and does not answer with any handshake packet regardless of its state, simulating a reception error and forcing the host to send the SETUP token again. This is done to avoid losing the notification of a SETUP transaction addressed to the same endpoint immediately following the transaction, which triggered the VTRX interrupt.

**Control transfers in Host mode**

Control transfers are made of a SETUP transaction, followed by zero or more data stages, all of the same direction, followed by a status stage (a zero-byte transfer in the opposite direction). SETUP transactions are handled by control endpoints only. A control endpoint must set the SETUP bit in the USB_CHEPnR register. The values of DTOGTX and DTOGRX bits of the addressed endpoint registers are set to 0. Depending on whether it is a
control write or control read then STATTX or STATRX are set to 11 (ACTIVE) in order to trigger the control transfer via the host frame scheduler.

On receiving a CTR interrupt the channel (device address and endpoint) can be determined by examining IDN and DIR bits. Devices are expected to NAK every control unless the packet is corrupted in which case they do not acknowledge. The situation is reflected in the value of STATTX.

In the case of an error condition the ERR bit gets set. One possible case is where a CRC error is seen at the device, in this case no ACK is returned to the host. The host sees no ACK and after an appropriate delay this generates a timeout error with ERR_TX set (which can generate an interrupt).

### 71.5.3 Double-buffered endpoints and usage in Device mode

All different endpoint types defined by the USB standard represent different traffic models, and describe the typical requirements of different kind of data transfer operations. When large portions of data are to be transferred between the host PC and the USB function, the bulk endpoint type is the most suited model. This is because the host schedules bulk transactions so as to fill all the available bandwidth in the frame, maximizing the actual transfer rate as long as the USB function is ready to handle a bulk transaction addressed to it. If the USB function is still busy with the previous transaction when the next one arrives, it answers with a NAK handshake and the host PC issues the same transaction again until the USB function is ready to handle it, reducing the actual transfer rate due to the bandwidth occupied by re-transmissions. For this reason, a dedicated feature called ‘double-buffering’ can be used with bulk endpoints.

When ‘double-buffering’ is activated, data toggle sequencing is used to select, which buffer is to be used by the USB peripheral to perform the required data transfers, using both ‘transmission’ and ‘reception’ packet memory areas to manage buffer swapping on each successful transaction in order to always have a complete buffer to be used by the application, while the USB peripheral fills the other one. For example, during an OUT transaction directed to a ‘reception’ double-buffered bulk endpoint, while one buffer is being filled with new data coming from the USB host, the other one is available for the microcontroller software usage (the same would happen with a ‘transmission’ double-buffered bulk endpoint and an IN transaction).

Since the swapped buffer management requires the usage of all 4 buffer description table locations hosting the address pointer and the length of the allocated memory buffers, the USB_CHEPnR registers used to implement double-buffered bulk endpoints are forced to be used as unidirectional ones. Therefore, only one STAT bit pair must be set at a value different from 00 (DISABLED): STATRX if the double-buffered bulk endpoint is enabled for reception, STATTX if the double-buffered bulk endpoint is enabled for transmission. In case it is required to have double-buffered bulk endpoints enabled both for reception and transmission, two USB_CHEPnR registers must be used.

To exploit the double-buffering feature and reach the highest possible transfer rate, the endpoint flow control structure, described in previous chapters, has to be modified, in order to switch the endpoint status to NAK only when a buffer conflict occurs between the USB peripheral and application software, instead of doing it at the end of each successful transaction. The memory buffer which is currently being used by the USB peripheral is defined by the DTOG bit related to the endpoint direction: DTOGRX (bit 14 of USB_CHEPnR register) for ‘reception’ double-buffered bulk endpoints or DTOGTX (bit 6 of USB_CHEPnR register) for ‘transmission’ double-buffered bulk endpoints. To implement the new flow control scheme, the USB peripheral must know which packet buffer is currently in
use by the application software, so to be aware of any conflict. Since in the USB_CHEPnR register, there are two DTOG bits but only one is used by USB peripheral for data and buffer sequencing (due to the unidirectional constraint required by double-buffering feature) the other one can be used by the application software to show which buffer it is currently using. This new buffer flag is called SW_BUF. In the following table the correspondence between USB_CHEPnR register bits and DTOG/SW_BUF definition is explained, for the cases of ‘transmission’ and ‘reception’ double-buffered bulk endpoints.

Table 726. Double-buffering buffer flag definition

<table>
<thead>
<tr>
<th>Buffer flag</th>
<th>‘Transmission’ endpoint</th>
<th>‘Reception’ endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>DTOG</td>
<td>DTOGTX (USB_CHEPnR bit 6)</td>
<td>DTOGRX (USB_CHEPnR bit 14)</td>
</tr>
<tr>
<td>SW_BUF</td>
<td>USB_CHEPnR bit 14</td>
<td>USB_CHEPnR bit 6</td>
</tr>
</tbody>
</table>

The memory buffer which is currently being used by the USB peripheral is defined by DTOG buffer flag, while the buffer currently in use by application software is identified by SW_BUF buffer flag. The relationship between the buffer flag value and the used packet buffer is the same in both cases, and it is listed in the following table.

Table 727. Bulk double-buffering memory buffers usage (Device mode)

<table>
<thead>
<tr>

<td>None (1)</td>
<td>Buffer description table locations.</td>
</tr>
</tbody>
</table>
Double-buffering feature for a bulk endpoint is activated by:

- Writing UTYPE bit field at 00 in its USB_CHEPnR register, to define the endpoint as a bulk, and
- Setting EPKIND bit at 1 (DBL_BUF), in the same register.

The application software is responsible for DTOG and SW_BUF bits initialization according to the first buffer to be used; this has to be done considering the special toggle-only property that these two bits have. The end of the first transaction occurring after having set DBL_BUF, triggers the special flow control of double-buffered bulk endpoints, which is used for all other transactions addressed to this endpoint until DBL_BUF remain set. At the end of each transaction the VTRX or VTTX bit of the addressed endpoint USB_CHEPnR register is set, depending on the enabled direction. At the same time, the affected DTOG bit in the USB_CHEPnR register is hardware toggled making the USB peripheral buffer swapping completely software independent. Unlike common transactions, and the first one after DBL_BUF setting, STAT bit pair is not affected by the transaction termination and its value remains 11 (VALID). However, as the token packet of a new transaction is received, the actual endpoint status is masked as 10 (NAK) when a buffer conflict between the USB peripheral and the application software is detected (this condition is identified by DTOG and SW_BUF having the same value, see Table 727 on page 3085). The application software responds to the CTR event notification by clearing the interrupt flag and starting any required handling of the completed transaction. When the application packet buffer usage is over, the software toggles the SW_BUF bit, writing 1 to it, to notify the USB peripheral about the availability of that buffer. In this way, the number of NAKed transactions is limited only by the application elaboration time of a transaction data: if the elaboration time is shorter than the time required to complete a transaction on the USB bus, no re-transmissions due to flow control takes place and the actual transfer rate is limited only by the host PC.

The application software can always override the special flow control implemented for double-buffered bulk endpoints, writing an explicit status different from 11 (VALID) into the STAT bit pair of the related USB_CHEPnR register. In this case, the USB peripheral always uses the programmed endpoint status, regardless of the buffer usage condition.

71.5.4 Double buffered channels: usage in Host mode

In Host mode the underlying transmit and receive methods for double buffered channels are the same as those described for Device mode.

Similar to the Device mode table, a new table below Table 728: Bulk double-buffering memory buffers usage (Host mode) shows the programming settings for OUT and IN tokens.
The USB standard supports full speed peripherals requiring a fixed and accurate data production/consume frequency, defining this kind of traffic as ‘isochronous’. Typical examples of this data are: audio samples, compressed video streams, and in general any sort of sampled data having strict requirements for the accuracy of delivered frequency. When an endpoint is defined to be ‘isochronous’ during the enumeration phase, the host allocates in the frame the required bandwidth and delivers exactly one IN or OUT packet each frame, depending on endpoint direction. To limit the bandwidth requirements, no re-transmission of failed transactions is possible for isochronous traffic; this leads to the fact that an isochronous transaction does not have a handshake phase and no ACK packet is expected or sent after the data packet. For the same reason, isochronous transfers do not support data toggle sequencing and always use DATA0 PID to start any data packet.

The isochronous behavior for an endpoint is selected by setting the UTYPE bits at 10 in its USB_CHEPnR register; since there is no handshake phase the only legal values for the STATRX/STATTX bit pairs are 00 (DISABLED) and 11 (VALID), any other value produces results not compliant to USB standard. Isochronous endpoints implement double-buffering.
to ease application software development, using both ‘transmission’ and ‘reception’ packet memory areas to manage buffer swapping on each successful transaction in order to have always a complete buffer to be used by the application, while the USB peripheral fills the other.

The memory buffer which is currently used by the USB peripheral is defined by the DTOG bit related to the endpoint direction (DTOGRX for ‘reception’ isochronous endpoints, DTOGTX for ‘transmission’ isochronous endpoints, both in the related USB_CHEPnR register) according to Table 729.

<table>
<thead>
<tr>
<th>Endpoint Type</th>
<th>DTOG bit value</th>
<th>Packet buffer used by the USB peripheral</th>
<th>Packet buffer used by the application software</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transmit (IN)</td>
<td>0</td>
<td>USB_CHEP_TXRXBD_0 (ADDR_TX / COUNT_TX)</td>
<td>USB_CHEP_RXTXBD_0 (ADDR_TX / COUNT_TX)</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>USB_CHEP_RXTXBD_0 (ADDR_TX / COUNT_TX)</td>
<td>USB_CHEP_TXRXBD_0 (ADDR_TX / COUNT_TX)</td>
</tr>
<tr>
<td>Receive (OUT)</td>
<td>0</td>
<td>USB_CHEP_RXTXBD_0 (ADDR_RX / COUNT_RX)</td>
<td>USB_CHEP_TXRXBD_0 (ADDR_RX / COUNT_RX)</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>USB_CHEP_TXRXBD_0 (ADDR_RX / COUNT_RX)</td>
<td>USB_CHEP_RXTXBD_0 (ADDR_RX / COUNT_RX)</td>
</tr>
</tbody>
</table>

As it happens with double-buffered bulk endpoints, the USB_CHEPnR registers used to implement isochronous endpoints are forced to be used as unidirectional ones. In case it is required to have isochronous endpoints enabled both for reception and transmission, two USB_CHEPnR registers must be used.

The application software is responsible for the DTOG bit initialization according to the first buffer to be used; this has to be done considering the special toggle-only property that these two bits have. At the end of each transaction, the VTRX or VTTX bit of the addressed endpoint USB_CHEPnR register is set, depending on the enabled direction. At the same time, the affected DTOG bit in the USB_CHEPnR register is hardware toggled making buffer swapping completely software independent. STAT bit pair is not affected by transaction completion; since no flow control is possible for isochronous transfers due to the lack of handshake phase, the endpoint remains always 11 (VALID). CRC errors or buffer-overrun conditions occurring during isochronous OUT transfers are anyway considered as correct transactions and they always trigger a VTRX event. However, CRC errors set the ERR bit in the USB_ISTR register anyway, in order to notify the software of the possible data corruption.

### 71.5.6 Isochronous transfers in Host mode

From the host point of view isochronous packets are issued or requested one by frame by the host frame scheduler. There is no NAK/ACK protocol and no resend of data or token.
The mechanism is based on a table very similar to that for Device mode. See Table 730 below to understand the relationship between the DTOG bit buffers and the buffer usage.

### Table 730. Isochronous memory buffers usage

<table>
<thead>
<tr>
<th>Endpoint Type</th>

</tr>
<tr>
<td></td>
<td></td>
<td>Buffer description table locations.</td>
<td>Buffer description table locations.</td>
</tr>
</tbody>
</table>

The isochronous behavior for an endpoint is selected by setting the UTYPE bits at 10 in its USB_CHEPnR register; since there is no handshake phase the only legal values for the STATRX/STATTX bit pairs are 00 (DISABLED) and 11 (VALID).

Just as in Device mode, the mechanism allows automatic toggle of the DTOG bit. Note that in Host mode, at the same time as this toggle, the STATTX or STATRX of the completed buffer is automatically set to DISABLED, permitting the future buffer to be accessed before re-enabling it by setting it to 11 (VALID).

### 71.5.7 Suspend/resume events

The USB standard defines a special peripheral state, called SUSPEND, in which the average current drawn from the USB bus must not be greater than 2.5 mA. This requirement is of fundamental importance for bus-powered devices, while self-powered devices are not required to comply to this strict power consumption constraint. In suspend mode, the host PC sends the notification by not sending any traffic on the USB bus for more than 3 ms: since a SOF packet must be sent every 1 ms during normal operations, the USB peripheral detects the lack of 3 consecutive SOF packets as a suspend request from the host PC and set the SUSP bit to 1 in USB_ISTR register, causing an interrupt if enabled. Once the device is suspended, its normal operation can be restored by a so called RESUME sequence, which can be started from the host PC or directly from the peripheral itself, but it is always terminated by the host PC. The suspended USB peripheral must be anyway able to detect a RESET sequence, reacting to this event as a normal USB reset event.

The actual procedure used to suspend the USB peripheral is device dependent since according to the device composition, different actions may be required to reduce the total consumption.
A brief description of a typical suspend procedure is provided below, focused on the USB-related aspects of the application software routine responding to the SUSP notification of the USB peripheral:

1. Set the SUSPEN bit in the USB_CNTR register to 1. This action activates the suspend mode within the USB peripheral. As soon as the suspend mode is activated, the check on SOF reception is disabled to avoid any further SUSP interrupts being issued while the USB is suspended.

2. Remove or reduce any static power consumption in blocks different from the USB peripheral.

3. Set SUSPRDY bit in USB_CNTR register to 1 to remove static power consumption in the analog USB transceivers but keeping them able to detect resume activity.

4. Optionally turn off external oscillator and device PLL to stop any activity inside the device.

When an USB event occurs while the device is in SUSPEND mode, the RESUME procedure must be invoked to restore nominal clocks and regain normal USB behavior. Particular care must be taken to insure that this process does not take more than 10 ms when the wakening event is an USB reset sequence (see “Universal Serial Bus Specification” for more details). The start of a resume or reset sequence, while the USB peripheral is suspended, clears the SUSPRDY bit in USB_CNTR register asynchronously. Even if this event can trigger a WKUP interrupt if enabled, the use of an interrupt response routine must be carefully evaluated because of the long latency due to system clock restart; to have the shorter latency before re-activating the nominal clock it is suggested to put the resume procedure just after the end of the suspend one, so its code is immediately executed as soon as the system clock restarts. To prevent ESD discharges or any other kind of noise from waking-up the system (the exit from suspend mode is an asynchronous event), a suitable analog filter on data line status is activated during suspend; the filter width is about 70 ns.

The following is a list of actions a resume procedure must address:

1. Optionally turn on external oscillator and/or device PLL.

2. Clear SUSPEN bit of USB_CNTR register.

3. If the resume triggering event has to be identified, bits RXDP and RXDM in the USB_FNR register can be used according to Table 731, which also lists the intended software action in all the cases. If required, the end of resume or reset sequence can be detected monitoring the status of the above mentioned bits by checking when they reach the “10” configuration, which represent the idle bus state; moreover at the end of a reset sequence the RST_DCON bit in USB_ISTR register is set to 1, issuing an interrupt if enabled, which must be handled as usual.
A device may require to exit from suspend mode as an answer to particular events not directly related to the USB protocol (for example a mouse movement wakes up the whole system). In this case, the resume sequence can be started by setting the L2RES bit in the USB_CNTR register to 1 and resetting it to 0 after an interval between 1 ms and 15 ms (this interval can be timed using ESOF interrupts, occurring with a 1 ms period when the system clock is running at nominal frequency). Once the L2RES bit is clear, the resume sequence is completed by the host PC and its end can be monitored again using the RXDP and RXDM bits in the USB_FNR register.

Note: The L2RES bit must be anyway used only after the USB peripheral has been put in suspend mode, setting the SUSPEN bit in USB_CNTR register to 1.

### Suspend and resume in Host mode

The basics of the suspend and resume mechanism has been described in the previous section.

From the host stand-point, suspend is entered by writing the SUSPEN bit in USB_CNTR. When suspend entry is confirmed, SUSPRDY (also in USB_CNTR) is set.

Once in suspend, and when the application want to resume the bus, this can be done by setting the L2RES bit in USB_CNTR to 1.

Below in Table 732, the different actions recommended after a wake-up event are indicated. According to the different line states after a wake-up event, the interpretation of the event and the suggested behavior are shown. Note that, this table here is somewhat expanded when compared to the previously shown device table, as the host may encounter both full speed and low speed devices which use different line states for both suspend and resume.

71.6 USB and USB SRAM registers

The USB peripheral registers can be divided into the following groups:
- Common registers: interrupt and control registers
- endpoint/channel registers: endpoint/channel configuration and status

The USB SRAM registers cover:
- Buffer descriptor table: location of packet memory used to locate data buffers (see Section 2.3: Memory organization to find USB SRAM base address).

All register addresses are expressed as offsets with respect to the USB peripheral registers base address, except the buffer descriptor table locations, which starts at the USB SRAM base address.

Refer to Section 1.2 on page 126 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

71.6.1 Common registers

These registers affect the general behavior of the USB peripheral defining operating mode, interrupt handling, device address and giving access to the current frame number updated by the host PC.

USB control register (USB_CNTR)

Address offset: 0x40
Reset value: 0x0000 0003

Bit 15 **CTRM**: Correct transfer interrupt mask
0: Correct transfer (CTR) interrupt disabled.
1: CTR interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 14 **PMAOVRM**: Packet memory area over / underrun interrupt mask
0: PMAOVR interrupt disabled.
1: PMAOVR interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 13 **ERRM**: Error interrupt mask
0: ERR interrupt disabled.
1: ERR interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 12 **WKUPM**: Wake-up interrupt mask
0: WKUP interrupt disabled.
1: WKUP interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 11 **SUSPM**: Suspend mode interrupt mask
0: Suspend mode request (SUSP) interrupt disabled.
1: SUSP interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 10 **RST_DCONM**: USB reset request (Device mode) or device connect/disconnect (Host mode) interrupt mask
0: RESET interrupt disabled.
1: RESET interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 9 **SOFM**: Start of frame interrupt mask
0: SOF interrupt disabled.
1: SOF interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 8 **ESOFM**: Expected start of frame interrupt mask
0: Expected start of frame (ESOF) interrupt disabled.
1: ESOF interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 7 **L1REQM**: LPM L1 state request interrupt mask
0: LPM L1 state request (L1REQ) interrupt disabled.
1: L1REQ interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **L1RES**: L1 remote wake-up / resume driver
  – Device mode
  Software sets this bit to send a LPM L1 50 µs remote wake-up signaling to the host. After the signaling ends, this bit is cleared by hardware.
0: No effect
1: Send 50 µs remote-wake-up signaling to host
Bit 4 **L2RES**: L2 remote wake-up / resume driver

- **Device mode**
  
  The microcontroller can set this bit to send remote wake-up signaling to the host. It must be activated, according to USB specifications, for no less than 1 ms and no more than 15 ms after which the host PC is ready to drive the resume sequence up to its end.

- **Host mode**
  
  Software sets this bit to send resume signaling to the device.
  
  Software clears this bit to send end of resume to device and restart SOF generation.
  
  In the context of remote wake up, this bit is to be set following the WAKEUP interrupt.

  - 0: No effect
  - 1: Send L2 resume signaling to device

Bit 3 **SUSPEN**: Suspend state enable

- **Condition: Device mode**
  
  Software can set this bit when the SUSP interrupt is received, which is issued when no traffic is received by the USB peripheral for 3 ms. Software can also set this bit when the L1REQ interrupt is received with positive acknowledge sent.
  
  As soon as the suspend state is propagated internally all device activity is stopped, USB clock is gated, USB transceiver is set into low power mode and the SUSPRDY bit is set by hardware. In the case that device application wants to pursue more aggressive power saving by stopping the USB clock source and by moving the microcontroller to stop mode, as in the case of bus powered device application, it must first wait few cycles to see the SUSPRDY = 1 acknowledge the suspend request.

  This bit is cleared by hardware simultaneous with the WAKEUP flag set.

  - 0: No effect
  - 1: Enter L1/L2 suspend

- **Condition: Host mode**
  
  Software can set this bit when host application has nothing scheduled for the next frames and wants to enter long term power saving. When set, it stops immediately SOF generation and any other host activity, gates the USB clock and sets the transceiver in low power mode. If any USB transaction is on-going at the time SUSPEN is set, suspend is entered at the end of the current transaction.
  
  As soon as suspend state is propagated internally and gets effective the SUSPRDY bit is set. In the case that host application wants to pursue more aggressive power saving by stopping the USB clock source and by moving the microcontroller to STOP mode, it must first wait few cycles to see SUSPRDY=1 acknowledge to the suspend request.

  This bit is cleared by hardware simultaneous with the WAKEUP flag set.

  - 0: No effect
  - 1: Enter L1/L2 suspend

Bit 2 **SUSPRDY**: Suspend state effective

- This bit is set by hardware as soon as the suspend state entered through the SUSPEN control gets internally effective. In this state USB activity is suspended, USB clock is gated, transceiver is set in low power mode by disabling the differential receiver. Only asynchronous wake-up logic and single ended receiver is kept alive to detect remote wake-up or resume events.

  Software must poll this bit to confirm it to be set before any STOP mode entry.

  This bit is cleared by hardware simultaneously to the WAKEUP flag being set.

  - 0: Normal operation
  - 1: Suspend state
USB interrupt status register (USB_ISTR)

Address offset: 0x44
Reset value: 0x0000 0000

This register contains the status of all the interrupt sources permitting application software to determine which events caused an interrupt request.

The upper part of this register contains single bits, each of them representing a specific event. These bits are set by the hardware when the related event occurs; if the corresponding bit in the USB_CNTR register is set, a generic interrupt request is generated. The interrupt routine, examining each bit, performs all necessary actions, and finally it clears the serviced bits. If any of them is not cleared, the interrupt is considered to be still pending, and the interrupt line is kept high again. If several bits are set simultaneously, only a single interrupt is generated.

Endpoint/channel transaction completion can be handled in a different way to reduce interrupt response latency. The CTR bit is set by the hardware as soon as an endpoint/channel successfully completes a transaction, generating a generic interrupt request if the corresponding bit in USB_CNTR is set. An endpoint/channel dedicated interrupt condition is activated independently from the CTRM bit in the USB_CNTR register. Both interrupt conditions remain active until software clears the pending bit in the corresponding USB_CHEPnR register (the CTR bit is actually a read only bit). For endpoint/channel-related interrupts, the software can use the direction of transaction (DIR) and IDN read-only bits to identify which endpoint/channel made the last interrupt request and called the corresponding interrupt service routine.

The user can choose the relative priority of simultaneously pending USB_ISTR events by specifying the order in which software checks USB_ISTR bits in an interrupt service routine. Only the bits related to events, which are serviced, are cleared. At the end of the service routine, another interrupt is requested, to service the remaining conditions.

Bit 1  **PDWN**: Power down

This bit is used to completely switch off all USB-related analog parts if it is required to completely disable the USB peripheral for any reason. When this bit is set, the USB peripheral is disconnected from the transceivers and it cannot be used.

0: Exit power down
1: Enter power down mode

Bit 0  **USBRST**: USB Reset

- **Condition: Device mode**

  Software can set this bit to reset the USB core, exactly as it happens when receiving a RESET signaling on the USB. The USB peripheral, in response to a RESET, resets its internal protocol state machine. Reception and transmission are disabled until the RST_DCON bit is cleared. All configuration registers do not reset: the microcontroller must explicitly clear these registers (this is to ensure that the RST_DCON interrupt can be safely delivered, and any transaction immediately followed by a RESET can be completed). The function address and endpoint registers are reset by an USB reset event.

  0: No effect
  1: USB core is under reset

- **Condition: Host mode**

  Software sets this bit to drive USB reset state on the bus and initialize the device. USB reset terminates as soon as this bit is cleared by software.

  0: No effect
  1: USB reset driven
To avoid spurious clearing of some bits, it is recommended to clear them with a load instruction where all bits which must not be altered are written with 1, and all bits to be cleared are written with 0 (these bits can only be cleared by software). Read-modify-write cycles must be avoided because between the read and the write operations another bit can be set by the hardware and the next write clears it before the device has the time to service the event.

Bit 31  Reserved, must be kept at reset value.

Bit 30  **LS_DCON**: Low speed device connected
- **Host mode**: This bit is set by hardware when an LS device connection is detected. Device connection is signaled after LS J-state is sampled for 22 consecutive cycles of the USB clock (48 MHz) from the unconnected state.

Bit 29  **DCON_STAT**: Device connection status
- **Host mode**: This bit contains information about device connection status. It is set by hardware when a LS/FS device is attached to the host while it is reset when the device is disconnected.
  - 0: No device connected
  - 1: FS or LS device connected to the host

Bits 28:18  Reserved, must be kept at reset value.

Bit 17  **DDISC**: Device connection
- **Host mode**: This bit is set when a device connection is detected. This bit is read/write but only 0 can be written and writing 1 has no effect.

Bit 16  **THR512**: 512 byte threshold interrupt
This bit is set to 1 by the hardware when 512 bytes have been transmitted or received during isochronous transfers. This bit is read/write but only 0 can be written and writing 1 has no effect. Note that no information is available to indicate the associated channel/endpoint, however in practice only one ISO endpoint/channel with such large packets can be supported, so that channel.

Bit 15  **CTR**: Completed transfer in host mode
This bit is set by the hardware to indicate that an endpoint/channel has successfully completed a transaction; using DIR and IDN bits software can determine which endpoint/channel requested the interrupt. This bit is read-only.
Bit 14 **PMAOVR**: Packet memory area over / underrun

This bit is set if the microcontroller has not been able to respond in time to an USB memory request. The USB peripheral handles this event in the following way: During reception an ACK handshake packet is not sent, during transmission a bit-stuff error is forced on the transmitted stream; in both cases the host retries the transaction. The PMAOVR interrupt must never occur during normal operations. Since the failed transaction is retried by the host, the application software has the chance to speed-up device operations during this interrupt handling, to be ready for the next transaction retry; however this does not happen during isochronous transfers (no isochronous transaction is anyway retried) leading to a loss of data in this case. This bit is read/write but only 0 can be written and writing 1 has no effect.

Bit 13 **ERR**: Error

This flag is set whenever one of the errors listed below has occurred:
- **NANS**: No ANSwer. The timeout for a host response has expired.
- **CRC**: Cyclic redundancy check error. One of the received CRCs, either in the token or in the data, was wrong.
- **BST**: Bit stuffing error. A bit stuffing error was detected anywhere in the PID, data, and/or CRC.
- **FVIO**: Framing format violation. A non-standard frame was received (EOP not in the right place, wrong token sequence, etc.).

The USB software can usually ignore errors, since the USB peripheral and the PC host manage retransmission in case of errors in a fully transparent way. This interrupt can be useful during the software development phase, or to monitor the quality of transmission over the USB bus, to flag possible problems to the user (for example loose connector, too noisy environment, broken conductor in the USB cable and so on). This bit is read/write but only 0 can be written and writing 1 has no effect.

Bit 12 **WKUP**: Wake-up

This bit is set to 1 by the hardware when, during suspend mode, activity is detected that wakes up the USB peripheral. This event asynchronously clears the SUSPRDY bit in the CTLR register and activates the USB_WAKEUP line, which can be used to notify the rest of the device (for example wake-up unit) about the start of the resume process. This bit is read/write but only 0 can be written and writing 1 has no effect.

Bit 11 **SUSP**: Suspend mode request

- **Device mode**
  
  This bit is set by the hardware when no traffic has been received for 3 ms, indicating a suspend mode request from the USB bus. The suspend condition check is enabled immediately after any USB reset and it is disabled by the hardware when the suspend mode is active (SUSPEN=1) until the end of resume sequence. This bit is read/write but only 0 can be written and writing 1 has no effect.

Bit 10 **RST_DCON**: USB reset request (Device mode) or device connect/disconnect (Host mode)

- **Device mode**
  
  This bit is set by hardware when an USB reset is released by the host and the bus returns to idle. USB reset state is internally detected after the sampling of 60 consecutive SE0 cycles.

- **Host mode**
  
  This bit is set by hardware when device connection or device disconnection is detected. Device connection is signaled after J state is sampled for 22 cycles consecutively from unconnected state. Device disconnection is signaled after SE0 state is seen for 22 bit times consecutively from connected state.
Bit 9  **SOF:** Start of frame
This bit signals the beginning of a new USB frame and it is set when a SOF packet arrives through the USB bus. The interrupt service routine may monitor the SOF events to have a 1 ms synchronization event to the USB host and to safely read the USB_FNR register which is updated at the SOF packet reception (this can be useful for isochronous applications). This bit is read/write but only 0 can be written and writing 1 has no effect.

Bit 8  **ESOF:** Expected start of frame
  – Device mode
This bit is set by the hardware when an SOF packet is expected but not received. The host sends an SOF packet each 1 ms, but if the device does not receive it properly, the suspend timer issues this interrupt. If three consecutive ESOF interrupts are generated (for example three SOF packets are lost) without any traffic occurring in between, a SUSP interrupt is generated. This bit is set even when the missing SOF packets occur while the suspend timer is not yet locked. This bit is read/write but only 0 can be written and writing 1 has no effect.

Bit 7  **L1REQ:** LPM L1 state request
  – Device mode
This bit is set by the hardware when LPM command to enter the L1 state is successfully received and acknowledged. This bit is read/write but only 0 can be written and writing 1 has no effect.

Bits 6:5 Reserved, must be kept at reset value.

Bit 4  **DIR:** Direction of transaction
This bit is written by the hardware according to the direction of the successful transaction, which generated the interrupt request.
If DIR bit = 0, VTTX bit is set in the USB_CHEPnR register related to the interrupting endpoint. The interrupting transaction is of IN type (data transmitted by the USB peripheral to the host PC).
If DIR bit = 1, VTRX bit or both VTTX/VTRX are set in the USB_CHEPnR register related to the interrupting endpoint. The interrupting transaction is of OUT type (data received by the USB peripheral from the host PC) or two pending transactions are waiting to be processed. This information can be used by the application software to access the USB_CHEPnR bits related to the triggering transaction since it represents the direction having the interrupt pending. This bit is read-only.

Bits 3:0  **IDN[3:0]:** Device Endpoint / host channel identification number
These bits are written by the hardware according to the host channel or device endpoint number, which generated the interrupt request. If several endpoint/channel transactions are pending, the hardware writes the identification number related to the endpoint/channel having the highest priority defined in the following way: two levels are defined, in order of priority: isochronous and double-buffered bulk channels/endpoints are considered first and then the others are examined. If more than one endpoint/channel from the same set is requesting an interrupt, the IDN bits in USB_ISTR register are assigned according to the lowest requesting register, CHEP0R having the highest priority followed by CHEP1R and so on. The application software can assign a register to each endpoint/channel according to this priority scheme, so as to order the concurring endpoint/channel requests in a suitable way. These bits are read only.
USB frame number register (USB_FNR)

Address offset: 0x48
Reset value: 0x0000 0XXX (where X is undefined)

RXDP   RXDM   LCK   LSOF[1:0]   FN[10:0]
| r | r | r | r | r | r | r | r | r | r | r | r | r |

Bits 31:16  Reserved, must be kept at reset value.

Bit 15  **RXDP**: Receive data + line status
This bit can be used to observe the status of received data plus upstream port data line. It can be used during end-of-suspend routines to help determining the wake-up event.

Bit 14  **RXDM**: Receive data - line status
This bit can be used to observe the status of received data minus upstream port data line. It can be used during end-of-suspend routines to help determining the wake-up event.

Bit 13  **LCK**: Locked
- **Device mode**
  This bit is set by the hardware when at least two consecutive SOF packets have been received after the end of an USB reset condition or after the end of an USB resume sequence. Once locked, the frame timer remains in this state until an USB reset or USB suspend event occurs.

Bits 12:11  **LSOF[1:0]**: Lost SOF
- **Device mode**
  These bits are written by the hardware when an ESOF interrupt is generated, counting the number of consecutive SOF packets lost. At the reception of an SOF packet, these bits are cleared.

Bits 10:0  **FN[10:0]**: Frame number
This bit field contains the 11-bits frame number contained in the last received SOF packet. The frame number is incremented for every frame sent by the host and it is useful for isochronous transfers. This bit field is updated on the generation of an SOF interrupt.

3100/3637  RM0456 Rev 5
Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **EF:** Enable function
This bit is set by the software to enable the USB Device. The address of this device is contained in the following ADD[6:0] bits. If this bit is at 0 no transactions are handled, irrespective of the settings of USB_CHEPnR registers.

Bits 6:0 **ADD[6:0]:** Device address
- **Device mode**
  These bits contain the USB function address assigned by the host PC during the enumeration process. Both this field and the endpoint/channel address (EA) field in the associated USB_CHEPnR register must match with the information contained in a USB token in order to handle a transaction to the required endpoint.
- **Host mode**
  These bits contain the address transmitted with the LPM transaction

**LPM control and status register (USB_LPMCSR)**

</table>

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **BESL[3:0]:** BESL value
- **Device mode**
  These bits contain the BESL value received with last ACKed LPM Token

Bit 3 **REMWAKE:** bRemoteWake value
- **Device mode**
  This bit contains the bRemoteWake value received with last ACKed LPM Token

Bit 2 Reserved, must be kept at reset value.

Bit 1 **LPMACK:** LPM token acknowledge enable
- **Device mode:**
  0: the valid LPM token is NYET.
  1: the valid LPM token is ACK.
  The NYET/ACK is returned only on a successful LPM transaction:
  No errors in both the EXT token and the LPM token (else ERROR)
  A valid bLinkState = 0001B (L1) is received (else STALL)

Bit 0 **LPMEN:** LPM support enable
- **Device mode**
  This bit is set by the software to enable the LPM support within the USB Device. If this bit is at 0 no LPM transactions are handled.
Battery charging detector (USB_BCDR)

Address offset: 0x58
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **DPPU_DPD**: DP pull-up / DPDM pull-down

- Device mode
  This bit is set by software to enable the embedded pull-up on DP line. Clearing it to 0 can be used to signal disconnect to the host when needed by the user software.

- Host mode
  This bit is set by software to enable the embedded pull-down on DP and DM lines.

Bits 14:8 Reserved, must be kept at reset value.

Bit 7 **PS2DET**: DM pull-up detection status

- Device mode
  This bit is active only during PD and gives the result of comparison between DM voltage level and $V_{L_GC}$ threshold. In normal situation, the DM level must be below this threshold. If it is above, it means that the DM is externally pulled high. This can be caused by connection to a PS2 port (which pulls-up both DP and DM lines) or to some proprietary charger not following the BCD specification.
  0: Normal port detected (connected to SDP, ACA, CDP or DCP).
  1: PS2 port or proprietary charger detected.

Bit 6 **SDET**: Secondary detection (SD) status

- Device mode
  This bit gives the result of SD.
  0: CDP detected.
  1: DCP detected.

Bit 5 **PDET**: Primary detection (PD) status

- Device mode
  This bit gives the result of PD.
  0: no BCD support detected (connected to SDP or proprietary device).
  1: BCD support detected (connected to ACA, CDP or DCP).

Bit 4 **DCDET**: Data contact detection (DCD) status

- Device mode
  This bit gives the result of DCD.
  0: data lines contact not detected.
  1: data lines contact detected.
Bit 3 **SDEN**: Secondary detection (SD) mode enable  
- Device mode  
  This bit is set by the software to put the BCD into SD mode. Only one detection mode (DCD, PD, SD or OFF) must be selected to work correctly.

Bit 2 **PDEN**: Primary detection (PD) mode enable  
- Device mode  
  This bit is set by the software to put the BCD into PD mode. Only one detection mode (DCD, PD, SD or OFF) must be selected to work correctly.

Bit 1 **DCDEN**: Data contact detection (DCD) mode enable  
- Device mode  
  This bit is set by the software to put the BCD into DCD mode. Only one detection mode (DCD, PD, SD or OFF) must be selected to work correctly.

Bit 0 **BCDEN**: Battery charging detector (BCD) enable  
- Device mode  
  This bit is set by the software to enable the BCD support within the USB Device. When enabled, the USB PHY is fully controlled by BCD and cannot be used for normal communication. Once the BCD discovery is finished, the BCD must be placed in OFF mode by clearing this bit to 0 in order to allow the normal USB operation.

### Host channel-specific/device endpoint-specific registers

The number of these registers varies according to the number of endpoints or host channels that the USB peripheral is designed to handle. The USB peripheral supports up to 8 bidirectional endpoints or host channels. Each USB Device must support a control endpoint/channel whose address (EA bits) must be set to 0. The USB peripheral behaves in an undefined way if multiple endpoints are enabled having the same endpoint/channel number value. For each endpoint, an USB_CHEPnR register is available to store the endpoint/channel specific information.

#### USB endpoint/channel n register (USB_CHEPnR)

Address offset: 0x00 + 0x4 * n, (n = 0 to 7)  
Reset value: 0x0000 0000  

They are also reset when an USB reset is received from the USB bus or forced through bit USBRST in the CTRL register, except the VTRX and VTTX bits, which are kept unchanged to avoid missing a correct packet notification immediately followed by an USB reset event. Each endpoint/channel has its USB_CHEPnR register where n is the endpoint/channel identifier.

Read-modify-write cycles on these registers must be avoided because between the read and the write operations some bits can be set by the hardware and the next write would modify them before the CPU has the time to detect the change. For this purpose, all bits affected by this problem have an ‘invariant’ value that must be used whenever their modification is not required. It is recommended to modify these registers with a load instruction where all the bits, which can be modified only by the hardware, are written with their ‘invariant’ value.
Bit 31  Reserved, must be kept at reset value.

Bits 30:29  **THREE_ERR_RX[1:0]**: Three errors for an IN transaction

- Host mode
  
  This bit is set by the hardware when 3 consecutive transaction errors occurred on the USB bus for an IN transaction. THREE_ERR_RX is not generated for isochronous transactions. The software can only clear this bit.
  
  Coding of the received error:
  
  00: Less than 3 errors received.
  
  01: More than 3 errors received, last error is timeout error.
  
  10: More than 3 errors received, last error is data error (CRC error).
  
  11: More than 3 errors received, last error is protocol error (invalid PID, false EOP, bitstuffing error, SYNC error).

Bits 28:27  **THREE_ERR_TX[1:0]**: Three errors for an OUT or SETUP transaction

- Host mode
  
  This bit is set by the hardware when 3 consecutive transaction errors occurred on the USB bus for an OUT transaction. THREE_ERR_TX is not generated for isochronous transactions. The software can only clear this bit.
  
  Coding of the received error:
  
  00: Less than 3 errors received.
  
  01: More than 3 errors received, last error is timeout error.
  
  10: More than 3 errors received, last error is data error (CRC error).
  
  11: More than 3 errors received, last error is protocol error (invalid PID, false EOP, bitstuffing error, SYNC error).

Bit 26  **ERR_RX**: Received error for an IN transaction

- Host mode
  
  This bit is set by the hardware when an error (for example no answer by the device, CRC error, bit stuffing error, framing format violation, etc.) has occurred during an IN transaction on this channel. The software can only clear this bit. If the ERRM bit in USB_CNTR register is set, a generic interrupt condition is generated together with the channel related flag, which is always activated.

Bit 25  **ERR_TX**: Received error for an OUT/SETUP transaction

- Host mode
  
  This bit is set by the hardware when an error (for example no answer by the device, CRC error, bit stuffing error, framing format violation, etc.) has occurred during an OUT or SETUP transaction on this channel. The software can only clear this bit. If the ERRM bit in USB_CNTR register is set, a generic interrupt condition is generated together with the channel related flag, which is always activated.
Bit 24 **LS_EP**: Low speed endpoint – host with HUB only
   Host mode
   This bit is set by the software to send an LS transaction to the corresponding endpoint.
   0: Full speed endpoint
   1: Low speed endpoint

Bit 23 **NAK**:  
   Host mode
   This bit is set by the hardware when a device responds with a NAK. Software can use this bit to monitor the number of NAKs received from a device.

Bits 22:16 **DEVADDR[6:0]**:  
   Host mode
   Device address assigned to the endpoint during the enumeration process.

Bit 15 **VTRX**: USB valid transaction received  
   Device mode
   This bit is set by the hardware when an OUT/SETUP transaction is successfully completed on this endpoint; the software can only clear this bit. If the CTRM bit in USB_CNTR register is set accordingly, a generic interrupt condition is generated together with the endpoint related interrupt condition, which is always activated. The type of occurred transaction, OUT or SETUP, can be determined from the SETUP bit described below.
   A transaction ended with a NAK or STALL handshake does not set this bit, since no data is actually transferred, as in the case of protocol errors or data toggle mismatches.
   This bit is read/write but only 0 can be written, writing 1 has no effect.
   Host mode
   This bit is set by the hardware when an IN transaction is successfully completed on this channel. The software can only clear this bit. If the CTRM bit in USB_CNTR register is set a generic interrupt condition is generated together with the channel related flag, which is always activated.

   - A transaction ended with a NAK sets this bit and NAK answer is reported to application reading the NAK state from the STATRX field of this register. One NAKed transaction keeps pending and is automatically retried by the host at the next frame, or the host can immediately retry by resetting STATRX state to VALID.

   - A transaction ended by STALL handshake sets this bit and the STALL answer is reported to application reading the STALL state from the STATRX field of this register. Host application must consequently disable the channel and re-enumerate.

   - A transaction ended with ACK handshake sets this bit
     If double buffering is disabled, ACK answer is reported by application reading the DISABLE state from the STATRX field of this register. Host application must read received data from USBRAM and re-arm the channel by writing VALID to the STATRX field of this register.
     If double buffering is enabled, ACK answer is reported by application reading VALID state from the STATRX field of this register. Host application must read received data from USBRAM and toggle the DTOGTX bit of this register.

   - A transaction ended with error sets this bit.
     Errors can be seen via the bits ERR_RX (host mode only).

   This bit is read/write but only 0 can be written, writing 1 has no effect.
Bit 14 **DTOGRX**: Data Toggle, for reception transfers

If the endpoint/channel is not isochronous, this bit contains the expected value of the data toggle bit (0 = DATA0, 1 = DATA1) for the next data packet to be received. Hardware toggles this bit, when the ACK handshake is sent following a data packet reception having a matching data PID value; if the endpoint is defined as a control one, hardware clears this bit at the reception of a SETUP PID received from host (in device mode), while it sets this bit to 1 when SETUP transaction is acknowledged by device (in host mode).

If the endpoint/channel is using the double-buffering feature this bit is used to support packet buffer swapping too (Refer to Section 71.5.3: Double-buffered endpoints and usage in Device mode).

If the endpoint/channel is isochronous, this bit is used only to support packet buffer swapping for data transmission since no data toggling is used for this kind of channels/endpoints and only DATA0 packet are transmitted (Refer to Section 71.5.5: Isochronous transfers in Device mode). Hardware toggles this bit just after the end of data packet reception, since no handshake is used for isochronous transfers.

This bit can also be toggled by the software to initialize its value (mandatory when the endpoint is not a control one) or to force specific data toggle/packet buffer usage. When the application software writes 0, the value of DTOGRX remains unchanged, while writing 1 makes the bit value toggle. This bit is read/write but it can be only toggled by writing 1.
Bits 13:12 **STATRX[1:0]**: Status bits, for reception transfers

- **Device mode**

  These bits contain information about the endpoint status, which are listed in **Table 733: Reception status encoding on page 3110**. These bits can be toggled by software to initialize their value. When the application software writes 0, the value remains unchanged, while writing 1 makes the bit value to toggle. Hardware sets the STATRX bits to NAK when a correct transfer has occurred (VTRX = 1) corresponding to a OUT or SETUP (control only) transaction addressed to this endpoint, so the software has the time to elaborate the received data before it acknowledges a new transaction.

  Double-buffered bulk endpoints implement a special transaction flow control, which control the status based upon buffer availability condition (Refer to **Section 71.5.3: Double-buffered endpoints and usage in Device mode**).

  If the endpoint is defined as isochronous, its status can be only "VALID" or "DISABLED", so that the hardware cannot change the status of the endpoint after a successful transaction. If the software sets the STATRX bits to 'STALL' or 'NAK' for an isochronous endpoint, the USB peripheral behavior is not defined. These bits are read/write but they can be only toggled by writing 1.

- **Host mode**

  These bits are the host application controls to start, retry, or abort host transactions driven by the channel.

  These bits also contain information about the device answer to the last IN channel transaction and report the current status of the channel according to the following STATRX table of states:

  - **DISABLE**
    
    DISABLE value is reported in case of ACK acknowledge is received on a single-buffer channel. When in DISABLE state the channel is unused or not active waiting for application to restart it by writing VALID. Application can reset a VALID channel to DISABLE to abort a transaction. In this case the transaction is immediately removed from the host execution list. If the aborted transaction was already under execution it is regularly terminated on the USB but the relative VTRX interrupt is not generated.

  - **VALID**
    
    A host channel is actively trying to submit USB transaction to device only when in VALID state. VALID state can be set by software or automatically by hardware on a NAKED channel at the start of a new frame. When set to VALID, an host channel enters the host execution queue and waits permission from the host frame scheduler to submit its configured transaction.

    VALID value is also reported in case of ACK acknowledge is received on a double-buffered channel. In this case the channel remains active on the alternate buffer while application needs to read the current buffer and toggle DTOGTX. In case software is late in reading and the alternate buffer is not ready, the host channel is automatically suspended transparently to the application. The suspended double buffered channel is re-activated as soon as delay is recovered and DTOGTX is toggled.

  - **NAK**
    
    NAK value is reported in case of NAK acknowledge received. When in NAK state the channel is suspended and does not try to transmit. NAK state is moved to VALID by hardware at the start of the next frame, or software can change it to immediately retry transmission by writing it to VALID, or can disable it and abort the transaction by writing DISABLE.

  - **STALL**
    
    STALL value is reported in case of STALL acknowledge received. When in STALL state the channel behaves as disabled. Application must not retry transmission but reset the USB and re.enumerate.
Bit 11 **SETUP:** Setup transaction completed
  
  - **Device mode**
    
    This bit is read-only and it is set by the hardware when the last completed transaction is a SETUP. This bit changes its value only for control endpoints. It must be examined, in the case of a successful receive transaction (VTRX event), to determine the type of transaction occurred. To protect the interrupt service routine from the changes in SETUP bits due to next incoming tokens, this bit is kept frozen while VTRX bit is at 1; its state changes when VTRX is at 0. This bit is read-only.
  
  - **Host mode**
    
    This bit is set by the software to send a SETUP transaction on a control endpoint. This bit changes its value only for control endpoints. It is cleared by hardware when the SETUP transaction is acknowledged and VTTX interrupt generated.

Bits 10:9 **UTYPE[1:0]:** USB type of transaction
  
  These bits configure the behavior of this endpoint/channel as described in Table 734:

  **Endpoint/channel type encoding.** Channel0/Endpoint0 must always be a control endpoint/channel and each USB function must have at least one control endpoint/channel which has address 0, but there may be other control channels/endpoints if required. Only control channels/endpoints handle SETUP transactions, which are ignored by endpoints of other kinds. SETUP transactions cannot be answered with NAK or STALL. If a control endpoint/channel is defined as NAK, the USB peripheral does not answer, simulating a receive error, in the receive direction when a SETUP transaction is received. If the control endpoint/channel is defined as STALL in the receive direction, then the SETUP packet is accepted anyway, transferring data and issuing the CTR interrupt. The reception of OUT transactions is handled in the normal way, even if the endpoint/channel is a control one. Bulk and interrupt endpoints have very similar behavior and they differ only in the special feature available using the EPKIND configuration bit.

  The usage of isochronous channels/endpoints is explained in Section 71.5.5: Isochronous transfers in Device mode.

Bit 8 **EPKIND:** endpoint/channel kind
  
  The meaning of this bit depends on the endpoint/channel type configured by the UTYPE bits. Table 735 summarizes the different meanings.

  **DBL_BUF:** This bit is set by the software to enable the double-buffering feature for this bulk endpoint. The usage of double-buffered bulk endpoints is explained in Section 71.5.3: Double-buffered endpoints and usage in Device mode.

  **STATUS_OUT:** This bit is set by the software to indicate that a status out transaction is expected: in this case all OUT transactions containing more than zero data bytes are answered 'STALL' instead of 'ACK'. This bit may be used to improve the robustness of the application to protocol errors during control transfers and its usage is intended for control endpoints only. When STATUS_OUT is reset, OUT transactions can have any number of bytes, as required.

Bit 7 **VTTX:** Valid USB transaction transmitted
  
  - **Device mode**
    
    This bit is set by the hardware when an IN transaction is successfully completed on this endpoint; the software can only clear this bit. If the CTRM bit in the USB_CNTR register is set accordingly, a generic interrupt condition is generated together with the endpoint related interrupt condition, which is always activated.

    A transaction ended with a NAK or STALL handshake does not set this bit, since no data is actually transferred, as in the case of protocol errors or data toggle mismatches.

    This bit is read/write but only 0 can be written.
  
  - **Host mode**
    
    Same as VTRX behavior but for USB OUT and SETUP transactions.
Bit 6 **DTOGTX**: Data toggle, for transmission transfers

If the endpoint/channel is non-isochronous, this bit contains the required value of the data toggle bit (0 = DATA0, 1 = DATA1) for the next data packet to be transmitted. Hardware toggles this bit when the ACK handshake is received from the USB host, following a data packet transmission. If the endpoint/channel is defined as a control one, hardware sets this bit to 1 at the reception of a SETUP PID addressed to this endpoint (in device mode) or when a SETUP transaction is acknowledged by the device (in host mode).

If the endpoint/channel is using the double buffer feature, this bit is used to support packet buffer swapping too (Refer to Section 71.5.3: Double-buffered endpoints and usage in Device mode).

If the endpoint/channel is isochronous, this bit is used to support packet buffer swapping since no data toggling is used for this sort of endpoints and only DATA0 packet are transmitted (refer to Section 71.5.5: Isochronous transfers in Device mode). Hardware toggles this bit just after the end of data packet transmission, since no handshake is used for isochronous transfers.

This bit can also be toggled by the software to initialize its value (mandatory when the endpoint/channel is not a control one) or to force a specific data toggle/packet buffer usage. When the application software writes 0, the value of DTOGTX remains unchanged, while writing 1 makes the bit value to toggle. This bit is read/write but it can only be toggled by writing 1.

Bits 5:4 **STATTX[1:0]**: Status bits, for transmission transfers

– **Device mode**

These bits contain the information about the endpoint status, listed in Table 736. These bits can be toggled by the software to initialize their value. When the application software writes 0, the value remains unchanged, while writing 1 makes the bit value to toggle. Hardware sets the STATTX bits to NAK, when a correct transfer has occurred (VTTX = 1) corresponding to a IN or SETUP (control only) transaction addressed to this channel/endpoint. It then waits for the software to prepare the next set of data to be transmitted.

Double-buffered bulk endpoints implement a special transaction flow control, which controls the status based on buffer availability condition (Refer to Section 71.5.3: Double-buffered endpoints and usage in Device mode).

If the endpoint is defined as isochronous, its status can only be "VALID" or "DISABLED". Therefore, the hardware cannot change the status of the channel/endpoint/channel after a successful transaction. If the software sets the STATTX bits to ‘STALL’ or ‘NAK’ for an isochronous channel/endpoint, the USB peripheral behavior is not defined. These bits are read/write but they can only be toggled by writing 1.

– **Host mode**

The STATTX bits contain the information about the channel status. Refer to Table 736 for the full descriptions (“Host mode” descriptions). Whereas in Device mode, these bits contain the status that are given out on the following transaction, in Host mode they capture the status last received from the device. If a NAK is received, STATTX contains the value indicating NAK.

Bits 3:0 **EA[3:0]**: endpoint/channel address

– **Device mode**

Software must write in this field the 4-bit address used to identify the transactions directed to this endpoint. A value must be written before enabling the corresponding endpoint.

– **Host mode**

Software must write in this field the 4-bit address used to identify the channel addressed by the host transaction.

71.6.2 Buffer descriptor table

Note: The buffer descriptor table is located inside the packet buffer memory in the separate "USB SRAM" address space.

Although the buffer descriptor table is located inside the packet buffer memory ("USB SRAM" area), its entries can be considered as additional registers used to configure the location and size of the packet buffers used to exchange data between the USB macro cell and the device.

The first packet memory location is located at USB SRAM base address. The buffer descriptor table entry associated with the USB_CHEPnR registers is described below. The memory must be addressed using Word (32-bit) accesses.

A thorough explanation of packet buffers and the buffer descriptor table usage can be found in Structure and usage of packet buffers on page 3078.

Channel/endpoint transmit buffer descriptor n (USB_CHEP_TXRXBD_n)

Address offset: n*8

This register description applies when corresponding CHEPnR register does not program the use of double buffering working in receive mode (otherwise refer to following register description).

| Bits 31:26 | Reserved, must be kept at reset value. |
| Bits 25:16 | COUNT_TX[9:0]: Transmission byte count |
| Bits 15:0  | ADDR_TX[15:0]: Transmission buffer address |

Channel/endpoint receive buffer descriptor n [alternate] (USB_CHEP_TXRXBD_n)

Address offset: n*8

This register description applies when corresponding CHEPnR register programs the use of double buffering and activates receive buffers (otherwise refer to previous register description).

This table location is used to store two different values, both required during packet reception. The most significant bits contains the definition of allocated buffer size, to allow buffer overflow detection, while the least significant part of this location is written back by the USB peripheral at the end of reception to give the actual number of received bytes. Due to
the restrictions on the number of available bits, buffer size is represented using the number of allocated memory blocks, where block size can be selected to choose the trade-off between fine-granularity/small-buffer and coarse-granularity/large-buffer. The size of allocated buffer is a part of the endpoint/channel descriptor and it is normally defined during the enumeration process according to its maxPacketSize parameter value (see “Universal Serial Bus Specification”).

Channel/endpoint receive buffer descriptor n
(USB_CHEP_RXTXBD_n)

Address offset: n*8 + 4

This register description applies when corresponding CHEPnR register does not program use of double buffering in the transmit mode (otherwise refer to following register description).

This table location is used to store two different values, both required during packet reception. The most significant bits contains the definition of allocated buffer size, to allow buffer overflow detection, while the least significant part of this location is written back by the USB peripheral at the end of reception to give the actual number of received bytes. Due to the restrictions on the number of available bits, buffer size is represented using the number of allocated memory blocks, where block size can be selected to choose the trade-off between fine-granularity/small-buffer and coarse-granularity/large-buffer. The size of allocated buffer is a part of the endpoint/channel descriptor and it is normally defined during the enumeration process according to its maxPacketSize parameter value (see “Universal Serial Bus Specification”).

</tr>
</tbody>
</table>
Bit 31  **BLSIZE**: Block size

This bit selects the size of memory block used to define the allocated buffer area.

- If BLSIZE = 0, the memory block is 2-byte large, which is the minimum block allowed in a half-word wide memory. With this block size the allocated buffer size ranges from 2 to 62 bytes.
- If BLSIZE = 1, the memory block is 32-byte large, which permits to reach the maximum packet length defined by USB specifications. With this block size the allocated buffer size theoretically ranges from 32 to 1024 bytes, which is the longest packet size allowed by USB standard specifications. However, the applicable size is limited by the available buffer memory.

Bits 30:26  **NUM_BLOCK[4:0]**: Number of blocks

These bits define the number of memory blocks allocated to this packet buffer. The actual amount of allocated memory depends on the BLSIZE value as illustrated in Table 737.

Bits 25:16  **COUNT_RX[9:0]**: Reception byte count

These bits contain the number of bytes received by the endpoint/channel associated with the USB_CHEPnR register during the last OUT/SETUP transaction addressed to it.

Bits 15:0  **ADDR_RX[15:0]**: Reception buffer address

These bits point to the starting address of the packet buffer, which contains the data received by the endpoint/channel associated with the USB_CHEPnR register at the next OUT/SETUP token addressed to it. Bits 1 and 0 must always be written as “00” since packet memory is word wide and all packet buffers must be word aligned.

**Channel/endpoint transmit buffer descriptor n [alternate] (USB_CHEP_RXTXBD_n)**

Address offset: n*8 + 4

This register description applies when corresponding CHEPnR register programs use of double buffering and activates transmit buffers (otherwise refer to previous register description).

Bits 31:26  **COUNT_TX[9:0]**: Transmission byte count

These bits contain the number of bytes to be transmitted by the endpoint/channel associated with the USB_CHEPnR register at the next IN token addressed to it.

Bits 15:0  **ADDR_TX[15:0]**: Transmission buffer address

These bits point to the starting address of the packet buffer containing data to be transmitted by the endpoint/channel associated with the USB_CHEPnR register at the next IN token addressed to it. Bits 1 and 0 must always be written as “00” since packet memory is word wide and all packet buffers must be word aligned.
### 71.6.3 USB register map

The table below provides the USB register map and reset values.

**Table 738. USB register map and reset values**

| Offset | Register  | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|--------|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x00   | USB_CHEP0R|  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |

Refer to Section 2.3 on page 139 for the register boundary addresses.
72 USB on-the-go full-speed (OTG_FS)

This section applies to STM32U575/585 devices only.

72.1 Introduction

Portions Copyright (c) Synopsys, Inc. All rights reserved. Used with permission.

This section presents the architecture and the programming model of the OTG_FS controller.

The following acronyms are used throughout the section:

- FS Full-speed
- LS Low-speed
- MAC Media access controller
- OTG On-the-go
- PFC Packet FIFO controller
- PHY Physical layer
- USB Universal serial bus
- UTMI USB 2.0 Transceiver Macrocell interface (UTMI)
- LPM Link power management
- BCD Battery charging detector
- HNP Host negotiation protocol
- SRP Session request protocol

References are made to the following documents:

- USB On-The-Go Supplement, Revision 2.0
- Universal Serial Bus Revision 2.0 Specification
- USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007
- Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007
- Battery Charging Specification, Revision 1.2

The USB OTG is a dual-role device (DRD) controller that supports both device and host functions and is fully compliant with the On-The-Go Supplement to the USB 2.0 Specification. It can also be configured as a host-only or device-only controller, fully compliant with the USB 2.0 Specification. OTG_FS supports the speeds defined in the Table 739: OTG_FS speeds supported below. The USB OTG supports both HNP and SRP. The only external device required is a charge pump for $V_{BUS}$ in OTG mode.

72.2 OTG_FS main features

The main features can be divided into three categories: general, host-mode and device-mode features.

72.2.1 General features

The OTG_FS interface general features are the following:

- It is USB-IF certified to the Universal Serial Bus Specification Rev 2.0
- OTG_FS supports the following PHY interface:
  - An on-chip full-speed PHY
- It includes full support (PHY) for the optional On-The-Go (OTG) protocol detailed in the On-The-Go Supplement Rev 2.0 specification
  - Integrated support for A-B device identification (ID line)
  - Integrated support for host Negotiation protocol (HNP) and session request protocol (SRP)
  - It allows host to turn VBUS off to conserve battery power in OTG applications
  - It supports OTG monitoring of VBUS levels with internal comparators
  - It supports dynamic host-peripheral switch of role
- It is software-configurable to operate as:
  - SRP capable USB FS Peripheral (B-device)
  - SRP capable USB FS/LS host (A-device)
  - USB On-The-Go Full-Speed Dual Role device
- It supports FS SOF and LS Keep-alives with
  - SOF pulse PAD connectivity
  - SOF pulse internal connection to timer (TIMx)
  - Configurable framing period
  - Configurable end of frame interrupt
- It includes power saving features such as system stop during USB suspend, switch-off of clock domains internal to the digital core, PHY and DFIFO power management.
- It features a dedicated RAM of 1.25 Kbytes with advanced FIFO control:
  - Configurable partitioning of RAM space into different FIFOs for flexible and efficient use of RAM
  - Each FIFO can hold multiple packets
  - Dynamic memory allocation
  - Configurable FIFO sizes that are not powers of 2 to allow the use of contiguous memory locations
- It guarantees max USB bandwidth for up to one frame (1 ms) without system intervention.
- It supports charging port detection as described in Battery Charging Specification Revision 1.2.
72.2.2 Host-mode features

The OTG_FS interface main features and requirements in host-mode are the following:

- External charge pump for $V_{BUS}$ voltage generation.
- Up to 12 host channels (pipes): each channel is dynamically reconfigurable to allocate any type of USB transfer.
- Built-in hardware scheduler holding:
  - Up to 12 interrupt plus isochronous transfer requests in the periodic hardware queue
  - Up to 12 control plus bulk transfer requests in the non-periodic hardware queue
- Management of a shared Rx FIFO, a periodic Tx FIFO and a nonperiodic Tx FIFO for efficient usage of the USB data RAM.

72.2.3 Peripheral-mode features

The OTG_FS interface main features in peripheral-mode are the following:

- 1 bidirectional control endpoint0
- 5 IN endpoints (EPs) configurable to support bulk, interrupt or isochronous transfers
- 5 OUT endpoints configurable to support bulk, interrupt or isochronous transfers
- Management of a shared Rx FIFO and a Tx-OUT FIFO for efficient usage of the USB data RAM
- Management of up to 6 dedicated Tx-IN FIFOs (one for each active IN EP) to put less load on the application
- Support for the soft disconnect feature.

The USB OTG_FS receives the 48 MHz clock from the reset and clock controller (RCC). This clock is used for driving the 48 MHz domain at full-speed (12 Mbit/s) and must be enabled prior to configuring the OTG core.

The CPU reads and writes from/to the OTG core registers through the AHB peripheral bus. It is informed of USB events through the single USB OTG interrupt line described in Section 72.13: OTG_FS interrupts.

The CPU submits data over the USB by writing 32-bit words to dedicated OTG locations (push registers). The data are then automatically stored into Tx-data FIFOs configured within the USB data RAM. There is one Tx FIFO push register for each in-endpoint (peripheral mode) or out-channel (host mode).

The CPU receives the data from the USB by reading 32-bit words from dedicated OTG addresses (pop registers). The data are then automatically retrieved from a shared Rx FIFO configured within the 1.25-Kbyte USB data RAM. There is one Rx FIFO pop register for each out-endpoint or in-channel.

The USB protocol layer is driven by the serial interface engine (SIE) and serialized over the USB by the transceiver module within the on-chip physical layer (PHY).

Caution: To guarantee a correct operation for the USB OTG FS peripheral, the AHB frequency must be higher than 14.2 MHz.

### Embedded full-speed OTG PHY connected to OTG_FS

The embedded full-speed OTG PHY is controlled by the OTG FS core and conveys USB control & data signals through the full-speed subset of the UTMI+ Bus (UTMIFS). It provides the physical support to USB connectivity.

The full-speed OTG PHY includes the following components:

- **FS/LS transceiver module** used by both host and device. It directly drives transmission and reception on the single-ended USB lines.

- **DP/DM integrated pull-up and pull-down resistors** controlled by the OTG_FS core depending on the current role of the device. As a peripheral, it enables the DP pull-up resistor to signal full-speed peripheral connections as soon as \( V_{BUS} \) is sensed to be at a valid level (B-session valid). In host mode, pull-down resistors are enabled on both DP/DM. Pull-up and pull-down resistors are dynamically switched when the role of the device is changed via the host negotiation protocol (HNP).

- **Pull-up/pull-down resistor ECN circuit.** The DP pull-up consists of two resistors controlled separately from the OTG_FS as per the resistor Engineering Change Notice applied to USB Rev2.0. The dynamic trimming of the DP pull-up strength allows for better noise rejection and Tx/Rx signal quality.

72.4.5 OTG detections

Additionally the OTG_FS uses the following functions:

- integrated ID pull-up resistor used to sample the ID line for A/B device identification.
- $V_{BUS}$ sensing comparators with hysteresis used to detect $V_{BUS}$ valid, A-B session valid and session-end voltage thresholds. They are used to drive the session request protocol (SRP), detect valid startup and end-of-session conditions, and constantly monitor the $V_{BUS}$ supply during USB operations.

72.5 OTG_FS dual role device (DRD)

Figure 885. OTG_FS A-B device connection

1. External voltage regulator only needed when building a VBUS powered device.
2. STMP2141STR needed only if the application has to support a VBUS powered device. A basic power switch can be used if 5 V are available on the application board.

72.5.1 ID line detection

The host or peripheral (the default) role is assumed depending on the ID input pin. The ID line status is determined on plugging in the USB cable, depending on whether a MicroA or MicroB plug is connected to the micro-AB receptacle.

- If the B-side of the USB cable is connected with a floating ID wire, the integrated pull-up resistor detects a high ID level and the default peripheral role is confirmed. In this configuration the OTG_FS complies with the standard FSM described in section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.
- If the A-side of the USB cable is connected with a grounded ID, the OTG_FS issues an ID line status change interrupt (CIDSCHG bit in OTG_GINTSTS) for host software initialization, and automatically switches to the host role. In this configuration the OTG_FS complies with the standard FSM described by section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.
72.5.2 HNP dual role device

The HNP capable bit in the Global USB configuration register (HNPCAP bit in OTG_GUSBCFG) enables the OTG_FS core to dynamically change its role from A-host to A-peripheral and vice-versa, or from B-Peripheral to B-host and vice-versa according to the host negotiation protocol (HNP). The current device status can be read by the combined values of the connector ID status bit in the Global OTG control and status register (CIDSTS bit in OTG_GOTGCTL) and the current mode of operation bit in the global interrupt and status register (CMOD bit in OTG_GINTSTS).

The HNP program model is described in detail in Section 72.16: OTG_FS programming model.

72.5.3 SRP dual role device

The SRP capable bit in the global USB configuration register (SRPCAP bit in OTG_GUSBCFG) enables the OTG_FS core to switch off the generation of VBUS for the A-device to save power. Note that the A-device is always in charge of driving VBUS regardless of the host or peripheral role of the OTG_FS.

The SRP A/B-device program model is described in detail in Section 72.16: OTG_FS programming model.

72.6 OTG_FS as a USB peripheral

This section gives the functional description of the OTG_FS in the USB peripheral mode. The OTG_FS works as an USB peripheral in the following circumstances:

- OTG B-Peripheral
  - OTG B-device default state if B-side of USB cable is plugged in
- OTG A-Peripheral
  - OTG A-device state after the HNP switches the OTG_FS to its peripheral role
- B-device
  - If the ID line is present, functional and connected to the B-side of the USB cable, and the HNP-capable bit in the Global USB Configuration register (HNPCAP bit in OTG_GUSBCFG) is cleared.
- Peripheral only (see Figure 886: OTG_FS peripheral-only connection)
  - The force device mode bit (FDMOD) in the Section 72.15.4: OTG USB configuration register (OTG_GUSBCFG) is set to 1, forcing the OTG_FS core to work as an USB peripheral-only. In this case, the ID line is ignored even if it is present on the USB connector.

Note: To build a bus-powered device implementation in case of the B-device or peripheral-only configuration, an external regulator has to be added, that generates the necessary power-supply from VBUS.
1. Use a regulator to build a bus-powered device.

### 72.6.1 SRP-capable peripheral

The SRP capable bit in the Global USB configuration register (SRPCAP bit in OTG_GUSBCFG) enables the OTG_FS to support the session request protocol (SRP). In this way, it allows the remote A-device to save power by switching off VBUS while the USB session is suspended.

The SRP peripheral mode program model is described in detail in the B-device session request protocol section.

### 72.6.2 Peripheral states

#### Powered state

The VBUS input detects the B-session valid voltage by which the USB peripheral is allowed to enter the powered state (see USB2.0 section 9.1). The OTG_FS then automatically connects the DP pull-up resistor to signal full-speed device connection to the host and generates the session request interrupt (SRQINT bit in OTG_GINTSTS) to notify the powered state.

The VBUS input also ensures that valid VBUS levels are supplied by the host during USB operations. If a drop in VBUS below B-session valid happens to be detected (for instance because of a power disturbance or if the host port has been switched off), the OTG_FS automatically disconnects and the session end detected (SEDET bit in OTG_GOTGINT) interrupt is generated to notify that the OTG_FS has exited the powered state.

In the powered state, the OTG_FS expects to receive some reset signaling from the host. No other USB operation is possible. When a reset signaling is received the reset detected interrupt (USBRST in OTG_GINTSTS) is generated. When the reset signaling is complete, the enumeration done interrupt (ENUMDNE bit in OTG_GINTSTS) is generated and the OTG_FS enters the Default state.
Soft disconnect

The powered state can be exited by software with the soft disconnect feature. The DP pull-up resistor is removed by setting the soft disconnect bit in the device control register (SDIS bit in OTG_DCTL), causing a device disconnect detection interrupt on the host side even though the USB cable was not really removed from the host port.

Default state

In the Default state the OTG_FS expects to receive a SET_ADDRESS command from the host. No other USB operation is possible. When a valid SET_ADDRESS command is decoded on the USB, the application writes the corresponding number into the device address field in the device configuration register (DAD bit in OTG_DCFG). The OTG_FS then enters the address state and is ready to answer host transactions at the configured USB address.

Suspended state

The OTG_FS peripheral constantly monitors the USB activity. After counting 3 ms of USB idleness, the early suspend interrupt (ESUSP bit in OTG_GINTSTS) is issued, and confirmed 3 ms later, if appropriate, by the suspend interrupt (USBSUSP bit in OTG_GINTSTS). The device suspend bit is then automatically set in the device status register (SUSPSTS bit in OTG_DSTS) and the OTG_FS enters the suspended state.

The suspended state may optionally be exited by the device itself. In this case the application sets the remote wake-up signaling bit in the device control register (RWUSIG bit in OTG_DCTL) and clears it after 1 to 15 ms.

When a resume signaling is detected from the host, the resume interrupt (WKUPINT bit in OTG_GINTSTS) is generated and the device suspend bit is automatically cleared.

72.6.3 Peripheral endpoints

The OTG_FS core instantiates the following USB endpoints:

- Control endpoint 0:
  - Bidirectional and handles control messages only
  - Separate set of registers to handle in and out transactions
  - Proper control (OTG_DIEPCTL0/OTG_DOEPCTL0), transfer configuration (OTG_DIEPTSIZ0/OTG_DOEPTSIZ0), and status-interrupt (OTG_DIEPINT0/OTG_DOEPINT0) registers. The available set of bits inside the control and transfer size registers slightly differs from that of other endpoints

- 5 IN endpoints
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has proper control (OTG_DIEPCTLx), transfer configuration (OTG_DIEPTSIZx), and status-interrupt (OTG_DIEPINTx) registers
  - The device IN endpoints common interrupt mask register (OTG_DIEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the IN endpoints (EP0 included)
  - Support for incomplete isochronous IN transfer interrupt (ISOIXFR bit in OTG_GINTSTS), asserted when there is at least one isochronous IN endpoint on
which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG_GINTSTS/EOPF).

- **5 OUT endpoints**
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has a proper control (OTG_DOEPCTLx), transfer configuration (OTG_DOEPTSIZx) and status-interrupt (OTG_DOEPINTx) register
  - Device OUT endpoints common interrupt mask register (OTG_DOEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the OUT endpoints (EP0 included)
  - Support for incomplete isochronous OUT transfer interrupt (INCOMPISOOUT bit in OTG_GINTSTS), asserted when there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG_GINTSTS/EOPF).

**Endpoint control**

- The following endpoint controls are available to the application through the device endpoint-x IN/OUT control register (OTG_DIEPCTLx/OTG_DOEPCTLx):
  - Endpoint enable/disable
  - Endpoint activate in current configuration
  - Program USB transfer type (isochronous, bulk, interrupt)
  - Program supported packet size
  - Program Tx FIFO number associated with the IN endpoint
  - Program the expected or transmitted data0/data1 PID (bulk/interrupt only)
  - Program the even/odd frame during which the transaction is received or transmitted (isochronous only)
  - Optionally program the NAK bit to always negative-acknowledge the host regardless of the FIFO status
  - Optionally program the STALL bit to always stall host tokens to that endpoint
  - Optionally program the SNOOP mode for OUT endpoint not to check the CRC field of received data

**Endpoint transfer**

The device endpoint-x transfer size registers (OTG_DIEPTSIZx/OTG_DOEPTSIZx) allow the application to program the transfer size parameters and read the transfer status. Programming must be done before setting the endpoint enable bit in the endpoint control register. Once the endpoint is enabled, these fields are read-only as the OTG_FS core updates them with the current transfer status.

The following transfer parameters can be programmed:

- Transfer size in bytes
- Number of packets that constitute the overall transfer size

**Endpoint status/interrupt**

The device endpoint-x interrupt registers (OTG_DIEPINTx/OTG_DOPEPINTx) indicate the status of an endpoint with respect to USB- and AHB-related events. The application must read these registers when the OUT endpoint interrupt bit or the IN endpoint interrupt bit in
the core interrupt register (OEPINT bit in OTG_GINTSTS or IEPINT bit in OTG_GINTSTS, respectively) is set. Before the application can read these registers, it must first read the device all endpoints interrupt (OTG_DAINT) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.

The peripheral core provides the following status checks and interrupt generation:

- Transfer completed interrupt, indicating that data transfer was completed on both the application (AHB) and USB sides
- Setup stage has been done (control-out only)
- Associated transmit FIFO is half or completely empty (in endpoints)
- NAK acknowledge has been transmitted to the host (isochronous-in only)
- IN token received when Tx FIFO was empty (bulk-in/interrupt-in only)
- Out token received when endpoint was not yet enabled
- Babble error condition has been detected
- Endpoint disable by application is effective
- Endpoint NAK by application is effective (isochronous-in only)
- More than 3 back-to-back setup packets were received (control-out only)
- Timeout condition detected (control-in only)
- Isochronous out packet has been dropped, without generating an interrupt

### 72.7 OTG_FS as a USB host

This section gives the functional description of the OTG_FS in the USB host mode. The OTG_FS works as a USB host in the following circumstances:

- **OTG A-host**
  - OTG A-device default state when the A-side of the USB cable is plugged in
- **OTG B-host**
  - OTG B-device after HNP switching to the host role
- **A-device**
  - If the ID line is present, functional and connected to the A-side of the USB cable, and the HNP-capable bit is cleared in the Global USB Configuration register (HNPCAP bit in OTG_GUSBCFG). Integrated pull-down resistors are automatically set on the DP/DM lines.
- **Host only**
  - The force host mode bit (FHMOD) in the OTG USB configuration register (OTG_GUSBCFG) forces the OTG_FS core to work as a USB host-only. In this case, the ID line is ignored even if present on the USB connector. Integrated pull-down resistors are automatically set on the DP/DM lines.

**Note:** On-chip 5 V VBUS generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch must be added externally to drive the 5 V VBUS line. The external charge pump can be driven by any GPIO output. This is required for the OTG A-host, A-device and host-only configurations.
1. \( V_{DD} \) range is between 2 V and 3.6 V.

### 72.7.1 SRP-capable host

SRP support is available through the SRP capable bit in the global USB configuration register (SRPCAP bit in OTG_GUSBCFG). With the SRP feature enabled, the host can save power by switching off the VBUS power while the USB session is suspended.

The SRP host mode program model is described in detail in the A-device session request protocol section.

### 72.7.2 USB host states

#### Host port power

On-chip 5 V VBUS generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch, must be added externally to drive the 5 V VBUS line. The external charge pump can be driven by any GPIO output or via an I²C interface connected to an external PMIC (power management IC). When the application decides to power on VBUS, it must also set the port power bit in the host port control and status register (PPWR bit in OTG_HPRT).

#### VBUS valid

When HNP or SRP is enabled the VBUS sensing pin must be connected to VBUS. The VBUS input ensures that valid VBUS levels are supplied by the charge pump during USB operations. Any unforeseen VBUS voltage drop below the VBUS valid threshold (4.4 V) leads to an OTG interrupt triggered by the session end detected bit (SEDET bit in OTG_GOTGINT). The application is then required to remove the VBUS power and clear the port power bit.

When HNP and SRP are both disabled, the VBUS sensing pin does not need to be connected to VBUS.

The charge pump overcurrent flag can also be used to prevent electrical damage. Connect the overcurrent flag output from the charge pump to any GPIO input and configure it to generate a port interrupt on the active level. The overcurrent ISR must promptly disable the VBUS generation and clear the port power bit.
**Host detection of a peripheral connection**

If SRP or HNP are enabled, even if USB peripherals or B-devices can be attached at any time, the OTG_FS does not detect any bus connection until VBUS is no longer sensed at a valid level (5 V). When VBUS is at a valid level and a remote B-device is attached, the OTG_FS core issues a host port interrupt triggered by the device connected bit in the host port control and status register (PCDET bit in OTG_HPRT).

When HNP and SRP are both disabled, USB peripherals or B-device are detected as soon as they are connected. The OTG_FS core issues a host port interrupt triggered by the device connected bit in the host port control and status (PCDET bit in OTG_HPRT).

**Host detection of peripheral a disconnection**

The peripheral disconnection event triggers the disconnect detected interrupt (DISCINT bit in OTG_GINTSTS).

**Host enumeration**

After detecting a peripheral connection the host must start the enumeration process by sending USB reset and configuration commands to the new peripheral.

Before starting to drive a USB reset, the application waits for the OTG interrupt triggered by the debounce done bit (DBCDNE bit in OTG_GOTGINT), which indicates that the bus is stable again after the electrical debounce caused by the attachment of a pull-up resistor on DP (FS) or DM (LS).

The application drives a USB reset signaling (single-ended zero) over the USB by keeping the port reset bit set in the host port control and status register (PRST bit in OTG_HPRT) for a minimum of 10 ms and a maximum of 20 ms. The application takes care of the timing count and then of clearing the port reset bit.

Once the USB reset sequence has completed, the host port interrupt is triggered by the port enable/disable change bit (PENCHNG bit in OTG_HPRT). This informs the application that the speed of the enumerated peripheral can be read from the port speed field in the host port control and status register (PSPD bit in OTG_HPRT) and that the host is starting to drive SOFs (FS) or Keep alives (LS). The host is now ready to complete the peripheral enumeration by sending peripheral configuration commands.

**Host suspend**

The application decides to suspend the USB activity by setting the port suspend bit in the host port control and status register (PSUSP bit in OTG_HPRT). The OTG_FS core stops sending SOFs and enters the suspended state.

The suspended state can be optionally exited on the remote device’s initiative (remote wake-up). In this case the remote wake-up interrupt (WKUPINT bit in OTG_GINTSTS) is generated upon detection of a remote wake-up signaling, the port resume bit in the host port control and status register (PRES bit in OTG_HPRT) self-sets, and resume signaling is automatically driven over the USB. The application must time the resume window and then clear the port resume bit to exit the suspended state and restart the SOF.

If the suspended state is exited on the host initiative, the application must set the port resume bit to start resume signaling on the host port, time the resume window and finally clear the port resume bit.
72.7.3 Host channels

The OTG_FS core instantiates 12 host channels. Each host channel supports an USB host transfer (USB pipe). The host is not able to support more than 12 transfer requests at the same time. If more than 12 transfer requests are pending from the application, the host controller driver (HCD) must re-allocate channels when they become available from previous duty, that is, after receiving the transfer completed and channel halted interrupts.

Each host channel can be configured to support in/out and any type of periodic/nonperiodic transaction. Each host channel makes use of proper control (OTG_HCCHARx), transfer configuration (OTG_HCTSIZx) and status/interrupt (OTG_HCINTx) registers with associated mask (OTG_HCINTMSKx) registers.

Host channel control

- The following host channel controls are available to the application through the host channel-x characteristics register (OTG_HCCHARx):
  - Channel enable/disable
  - Program the FS/LS speed of target USB peripheral
  - Program the address of target USB peripheral
  - Program the endpoint number of target USB peripheral
  - Program the transfer IN/OUT direction
  - Program the USB transfer type (control, bulk, interrupt, isochronous)
  - Program the maximum packet size (MPS)
  - Program the periodic transfer to be executed during odd/even frames

Host channel transfer

The host channel transfer size registers (OTG_HCTSIZx) allow the application to program the transfer size parameters, and read the transfer status. Programming must be done before setting the channel enable bit in the host channel characteristics register. Once the endpoint is enabled the packet count field is read-only as the OTG_FS core updates it according to the current transfer status.

- The following transfer parameters can be programmed:
  - transfer size in bytes
  - number of packets making up the overall transfer size
  - initial data PID

Host channel status/interrupt

The host channel-x interrupt register (OTG_HCINTx) indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read these register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG_GINTSTS) is set. Before the application can read these registers, it must first read the host all channels interrupt (OTG_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_HAINT and OTG_GINTSTS registers.
The mask bits for each interrupt source of each channel are also available in the OTG_HCINTMSKx register.

- The host core provides the following status checks and interrupt generation:
  - Transfer completed interrupt, indicating that the data transfer is complete on both the application (AHB) and USB sides
  - Channel has stopped due to transfer completed, USB transaction error or disable command from the application
  - Associated transmit FIFO is half or completely empty (IN endpoints)
  - ACK response received
  - NAK response received
  - STALL response received
  - USB transaction error due to CRC failure, timeout, bit stuff error, false EOP
  - Babble error
  - frame overrun
  - data toggle error

72.7.4 Host scheduler

The host core features a built-in hardware scheduler which is able to autonomously re-order and manage the USB transaction requests posted by the application. At the beginning of each frame the host executes the periodic (isochronous and interrupt) transactions first, followed by the nonperiodic (control and bulk) transactions to achieve the higher level of priority granted to the isochronous and interrupt transfer types by the USB specification.

The host processes the USB transactions through request queues (one for periodic and one for nonperiodic). Each request queue can hold up to 8 entries. Each entry represents a pending transaction request from the application, and holds the IN or OUT channel number along with other information to perform a transaction on the USB. The order in which the requests are written to the queue determines the sequence of the transactions on the USB interface.

At the beginning of each frame, the host processes the periodic request queue first, followed by the nonperiodic request queue. The host issues an incomplete periodic transfer interrupt (IPXFR bit in OTG_GINTSTS) if an isochronous or interrupt transaction scheduled for the current frame is still pending at the end of the current frame. The OTG_FS core is fully responsible for the management of the periodic and nonperiodic request queues. The periodic transmit FIFO and queue status register (OTG_HPTXSTS) and nonperiodic transmit FIFO and queue status register (OTG_HNPTXSTS) are read-only registers which can be used by the application to read the status of each request queue. They contain:

- The number of free entries currently available in the periodic (nonperiodic) request queue (8 max)
- Free space currently available in the periodic (nonperiodic) Tx FIFO (out-transactions)
- IN/OUT token, host channel number and other status information.

As request queues can hold a maximum of 8 entries each, the application can push to schedule host transactions in advance with respect to the moment they physically reach the SB for a maximum of 8 pending periodic transactions plus 8 pending non-periodic transactions.

To post a transaction request to the host scheduler (queue) the application must check that there is at least 1 entry available in the periodic (nonperiodic) request queue by reading the
PTXQSAV bits in the OTG_HNPTXSTS register or NPTQXSAV bits in the OTG_HNPTXSTS register.

72.8 OTG_FS SOF trigger

**Figure 888. SOF connectivity (SOF trigger output to TIM and ITR1 connection)**

The OTG_FS core provides means to monitor, track and configure SOF framing in the host and peripheral, as well as an SOF pulse output connectivity feature.

Such utilities are especially useful for adaptive audio clock generation techniques, where the audio peripheral needs to synchronize to the isochronous stream provided by the PC, or the host needs to trim its framing rate according to the requirements of the audio peripheral.

72.8.1 Host SOFs

In host mode the number of PHY clocks occurring between the generation of two consecutive SOF (FS) or Keep-alive (LS) tokens is programmable in the host frame interval register (HFIR), thus providing application control over the SOF framing period. An interrupt is generated at any start of frame (SOF bit in OTG_GINTSTS). The current frame number and the time remaining until the next SOF are tracked in the host frame number register (HFNUM).

A SOF pulse signal, is generated at any SOF starting token and with a width of 20 HCLK cycles. The SOF pulse is also internally connected to the input trigger of the timer, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.

72.8.2 Peripheral SOFs

In device mode, the start of frame interrupt is generated each time an SOF token is received on the USB (SOF bit in OTG_GINTSTS). The corresponding frame number can be read from the device status register (FNSOF bit in OTG_DSTS). A SOF pulse signal with a width of 20 HCLK cycles is also generated. The SOF pulse signal is also internally connected to the TIM input trigger, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.
The end of periodic frame interrupt (OTG_GINTSTS/EOPF) is used to notify the application when 80%, 85%, 90% or 95% of the time frame interval elapsed depending on the periodic frame interval field in the device configuration register (PFIVL bit in OTG_DCFG). This feature can be used to determine if all of the isochronous traffic for that frame is complete.

### 72.9 OTG_FS low-power modes

*Table 743* below defines the STM32 low power modes and their compatibility with the OTG.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
<th>USB compatibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run</td>
<td>MCU fully active</td>
<td>Required when USB not in suspend state</td>
</tr>
<tr>
<td>Sleep</td>
<td>USB suspend exit causes the device to exit Sleep mode. Peripheral registers content is kept.</td>
<td>Available while USB is in suspend state</td>
</tr>
<tr>
<td>Stop</td>
<td>USB suspend exit causes the device to exit Stop mode. Peripheral registers content is kept(^1).</td>
<td>Available while USB is in suspend state</td>
</tr>
<tr>
<td>Standby</td>
<td>Powered-down. The peripheral must be reinitialized after exiting Standby mode.</td>
<td>Not compatible with USB applications</td>
</tr>
</tbody>
</table>

\(^1\) Within Stop mode there are different possible settings. Some restrictions may also exist, refer to *Section 10: Power control (PWR)* to understand which (if any) restrictions apply when using OTG.

The following bits and procedures reduce power consumption.

The power consumption of the OTG PHY is controlled by two or three bits in the general core configuration register, depending on OTG revision supported.

- **PHY power down (OTG_GCCFG/PWRDWN)**
  - It switches on/off the full-speed transceiver module of the PHY. It must be preliminarily set to allow any USB operation
- **V\(_{\text{BUS}}\) detection enable (OTG_GCCFG/VBDEN)**
  - It switches on/off the V\(_{\text{BUS}}\) sensing comparators associated with OTG operations

Power reduction techniques are available while in the USB suspended state, when the USB session is not yet valid or the device is disconnected.

- **Stop PHY clock (STPPCLK bit in OTG_PCGCCTL)**
  - When setting the stop PHY clock bit in the clock gating control register, most of the 48 MHz clock domain internal to the OTG core is switched off by clock gating. The dynamic power consumption due to the USB clock switching activity is cut even if the 48 MHz clock input is kept running by the application
  - Most of the transceiver is also disabled, and only the part in charge of detecting the asynchronous resume or remote wake-up event is kept alive.
- **Gate HCLK (GATEHCLK bit in OTG_PCGCCTL)**
  - When setting the Gate HCLK bit in the clock gating control register, most of the system clock domain internal to the OTG_FS core is switched off by clock gating. Only the register read and write interface is kept alive. The dynamic power consumption due to
the USB clock switching activity is cut even if the system clock is kept running by the application for other purposes.

- **USB system stop**
  When the OTG_FS is in the USB suspended state, the application may decide to drastically reduce the overall power consumption by a complete shut down of all the clock sources in the system. USB System Stop is activated by first setting the Stop PHY clock bit and then configuring the system deep sleep mode in the power control system module (PWR).
  The OTG_FS core automatically reactivates both system and USB clocks by asynchronous detection of remote wake-up (as an host) or resume (as a device) signaling on the USB.

To save dynamic power, the USB data FIFO is clocked only when accessed by the OTG_FS core.

### 72.10 OTG_FS Dynamic update of the OTG_HFIR register

The USB core embeds a dynamic trimming capability of SOF framing period in host mode allowing to synchronize an external device with the SOF frames.

When the OTG_HFIR register is changed within a current SOF frame, the SOF period correction is applied in the next frame as described in Figure 889.

For a dynamic update, it is required to set RLDCTRL=1.

**Figure 889. Updating OTG_HFIR dynamically (RLDCTRL = 1)**

![Frame timer](ai18440b)

### 72.11 OTG_FS data FIFOs

The USB system features 1.25 Kbytes of dedicated RAM with a sophisticated FIFO control mechanism. The packet FIFO controller module in the OTG_FS core organizes RAM space into Tx FIFOs into which the application pushes the data to be temporarily stored before the USB transmission, and into a single Rx FIFO where the data received from the USB are temporarily stored before retrieval (popped) by the application. The number of instructed FIFOs and how these are organized inside the RAM depends on the device’s role. In peripheral mode an additional Tx FIFO is instructed for each active IN endpoint. Any FIFO size is software configured to better meet the application requirements.
### 72.11.1 Peripheral FIFO architecture

#### Figure 890. Device-mode FIFO address mapping and AHB FIFO access mapping

**Peripheral Rx FIFO**

The OTG peripheral uses a single receive FIFO that receives the data directed to all OUT endpoints. Received packets are stacked back-to-back until free space is available in the Rx FIFO. The status of the received packet (which contains the OUT endpoint destination number, the byte count, the data PID and the validity of the received data) is also stored by the core on top of the data payload. When no more space is available, host transactions are NACKed and an interrupt is received on the addressed endpoint. The size of the receive FIFO is configured in the receive FIFO size register (OTG_GRXFSIZ).

The single receive FIFO architecture makes it more efficient for the USB peripheral to fill in the receive RAM buffer:

- All OUT endpoints share the same RAM buffer (shared FIFO)
- The OTG_FS core can fill in the receive FIFO up to the limit for any host sequence of OUT tokens

The application keeps receiving the Rx FIFO non-empty interrupt (RXFLVL bit in OTG_GINTSTS) as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register (OTG_GRXSTSP) and finally pops data off the receive FIFO by reading from the endpoint-related pop address.
Peripheral Tx FIFOs

The core has a dedicated FIFO for each IN endpoint. The application configures FIFO sizes by writing the endpoint 0 transmit FIFO size register (OTG_DIEPTXF0) for IN endpoint0 and the device IN endpoint transmit FIFOx registers (OTG_DIEPTXFx) for IN endpoint-x.

72.11.2 Host FIFO architecture

![Host-mode FIFO address mapping and AHB FIFO access mapping](image)

Host Rx FIFO

The host uses one receiver FIFO for all periodic and nonperiodic transactions. The FIFO is used as a receive buffer to hold the received data (payload of the received packet) from the USB until it is transferred to the system memory. Packets received from any remote IN endpoint are stacked back-to-back until free space is available. The status of each received packet with the host channel destination, byte count, data PID and validity of the received data are also stored into the FIFO. The size of the receive FIFO is configured in the receive FIFO size register (OTG_GRXFSIZ).

The single receive FIFO architecture makes it highly efficient for the USB host to fill in the receive data buffer:

- All IN configured host channels share the same RAM buffer (shared FIFO)
- The OTG_FS core can fill in the receive FIFO up to the limit for any sequence of IN tokens driven by the host software

The application receives the Rx FIFO not-empty interrupt as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register and finally pops the data off the receive FIFO.
**Host Tx FIFOs**

The host uses one transmit FIFO for all non-periodic (control and bulk) OUT transactions and one transmit FIFO for all periodic (isochronous and interrupt) OUT transactions. FIFOs are used as transmit buffers to hold the data (payload of the transmit packet) to be transmitted over the USB. The size of the periodic (nonperiodic) Tx FIFO is configured in the host periodic (nonperiodic) transmit FIFO size OTG_HPTXFSIZ / OTG_HNPTXFSIZ) register.

The two Tx FIFO implementation derives from the higher priority granted to the periodic type of traffic over the USB frame. At the beginning of each frame, the built-in host scheduler processes the periodic request queue first, followed by the nonperiodic request queue.

The two transmit FIFO architecture provides the USB host with separate optimization for periodic and nonperiodic transmit data buffer management:

- All host channels configured to support periodic (nonperiodic) transactions in the OUT direction share the same RAM buffer (shared FIFOs)
- The OTG_FS core can fill in the periodic (nonperiodic) transmit FIFO up to the limit for any sequence of OUT tokens driven by the host software

The OTG_FS core issues the periodic Tx FIFO empty interrupt (PTXFE bit in OTG_GINTSTS) as long as the periodic Tx FIFO is half or completely empty, depending on the value of the periodic Tx FIFO empty level bit in the AHB configuration register (PTXFELVL bit in OTG_GAHBCFG). The application can push the transmission data in advance as long as free space is available in both the periodic Tx FIFO and the periodic request queue. The host periodic transmit FIFO and queue status register (OTG_HPTXSTS) can be read to know how much space is available in both.

The OTG_FS core issues the non periodic Tx FIFO empty interrupt (NPTXFE bit in OTG_GINTSTS) as long as the nonperiodic Tx FIFO is half or completely empty depending on the non periodic Tx FIFO empty level bit in the AHB configuration register (TXFELVL bit in OTG_GAHBCFG). The application can push the transmission data as long as free space is available in both the nonperiodic Tx FIFO and nonperiodic request queue. The host nonperiodic transmit FIFO and queue status register (OTG_HNPTXSTS) can be read to know how much space is available in both.

**72.11.3 FIFO RAM allocation**

**Device mode**

**Receive FIFO RAM allocation:** the application must allocate RAM for SETUP packets:

- 10 locations must be reserved in the receive FIFO to receive SETUP packets on control endpoint. The core does not use these locations, which are reserved for SETUP packets, to write any other data.
- One location is to be allocated for Global OUT NAK.
- Status information is written to the FIFO along with each received packet. Therefore, a minimum space of \([(\text{largest packet size} / 4) + 1]\) must be allocated to receive packets. If multiple isochronous endpoints are enabled, then at least two \([(\text{largest packet size} / 4) + 1\)] spaces must be allocated to receive back-to-back packets. Typically, two \([(\text{largest packet size} / 4) + 1\)] spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.
- Along with the last packet for each endpoint, transfer complete status information is also pushed to the FIFO. One location for each OUT endpoint is recommended.
Device RxFIFO =

\[(5 \times \text{number of control endpoints} + 8) + ((\text{largest USB packet used} / 4) + 1 \text{ for status information}) + (2 \times \text{number of OUT endpoints}) + 1 \text{ for Global NAK}\]

Example: The MPS is 1,024 bytes for a periodic USB packet and 512 bytes for a non-periodic USB packet. There are three OUT endpoints, three IN endpoints, one control endpoint, and three host channels.

Device RxFIFO = \[(5 \times 1 + 8) + ((1,024 / 4) + 1) + (2 \times 4) + 1 = 279\]

Transmit FIFO RAM allocation: the minimum RAM space required for each IN endpoint Transmit FIFO is the maximum packet size for that particular IN endpoint.

Note: More space allocated in the transmit IN endpoint FIFO results in better performance on the USB.

**Host mode**

Receive FIFO RAM allocation:

Status information is written to the FIFO along with each received packet. Therefore, a minimum space of \((\text{largest packet size} / 4) + 1\) must be allocated to receive packets. If multiple isochronous channels are enabled, then at least two \((\text{largest packet size} / 4) + 1\) spaces must be allocated to receive back-to-back packets. Typically, two \((\text{largest packet size} / 4) + 1\) spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.

Along with the last packet in the host channel, transfer complete status information is also pushed to the FIFO. So one location must be allocated for this.

Host RxFIFO = \((\text{largest USB packet used} / 4) + 1 \text{ for status information} + 1 \text{ transfer complete}\)

Example: Host RxFIFO = \((1,024 / 4) + 1 = 258\)

Transmit FIFO RAM allocation:

The minimum amount of RAM required for the host Non-periodic Transmit FIFO is the largest maximum packet size among all supported non-periodic OUT channels. Typically, two largest packet sizes worth of space is recommended, so that when the current packet is under transfer to the USB, the CPU can get the next packet.

Non-Periodic TxFIFO = \(\text{largest non-periodic USB packet used} / 4\)

Example: Non-Periodic TxFIFO = \((512 / 4) = 128\)

The minimum amount of RAM required for host periodic Transmit FIFO is the largest maximum packet size out of all the supported periodic OUT channels. If there is at least one isochronous OUT endpoint, then the space must be at least two times the maximum packet size of that channel.

Host Periodic TxFIFO = \(\text{largest periodic USB packet used} / 4\)

Example: Host Periodic TxFIFO = \((1,024 / 4) = 256\)

Note: More space allocated in the Transmit Non-periodic FIFO results in better performance on the USB.
72.12 OTG_FS system performance

Best USB and system performance is achieved owing to the large RAM buffers, the highly configurable FIFO sizes, the quick 32-bit FIFO access through AHB push/pop registers and, especially, the advanced FIFO control mechanism. Indeed, this mechanism allows the OTG_FS to fill in the available RAM space at best regardless of the current USB sequence. With these features:

- The application gains good margins to calibrate its intervention in order to optimize the CPU bandwidth usage:
  - It can accumulate large amounts of transmission data in advance compared to when they are effectively sent over the USB
  - It benefits of a large time margin to download data from the single receive FIFO
- The USB core is able to maintain its full operating rate, that is to provide maximum full-speed bandwidth with a great margin of autonomy versus application intervention:
  - It has a large reserve of transmission data at its disposal to autonomously manage the sending of data over the USB
  - It has a lot of empty space available in the receive buffer to autonomously fill it in with the data coming from the USB

As the OTG_FS core is able to fill in the 1.25-Kbyte RAM buffer very efficiently, and as 1.25-Kbyte of transmit/receive data is more than enough to cover a full speed frame, the USB system is able to withstand the maximum full-speed data rate for up to one USB frame (1 ms) without any CPU intervention.

72.13 OTG_FS interrupts

When the OTG_FS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

*Figure 892* shows the interrupt hierarchy.
1. OTG_FS_WKUP becomes active (high state) when resume condition occurs during L1 SLEEP or L2 SUSPEND states.
72.14 **OTG_FS control and status registers**

By reading from and writing to the control and status registers (CSRs) through the AHB slave interface, the application controls the OTG_FS controller. These registers are 32 bits wide, and the addresses are 32-bit block aligned. The OTG_FS registers must be accessed by words (32 bits).

CSRs are classified as follows:
- Core global registers
- Host-mode registers
- Host global registers
- Host port CSRs
- Host channel-specific registers
- Device-mode registers
- Device global registers
- Device endpoint-specific registers
- Power and clock-gating registers
- Data FIFO (DFIFO) access registers

Only the core global, power and clock-gating, data FIFO access, and host port control and status registers can be accessed in both host and device modes. When the OTG_FS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

### 72.14.1 CSR memory map

The host and device mode registers occupy different addresses. All registers are implemented in the AHB clock domain.

#### Global CSR map

These registers are available in both host and device modes.

<table>

Data FIFO (DFIFO) access register map

These registers, available in both host and device modes, are used to read or write the FIFO space for a specific endpoint or a channel, in a given direction. If a host channel is of type IN, the FIFO can only be read on the channel. Similarly, if a host channel is of type OUT, the FIFO can only be written on the channel.

72.15 OTG_FS registers

These registers are available in both host and device modes, and do not need to be reprogrammed when switching between these modes.

Bit values in the register descriptions are expressed in binary unless otherwise specified.
72.15.1 OTG control and status register (OTG_GOTGCTL)

Address offset: 0x000
Reset value: 0x0001 0000

The OTG_GOTGCTL register controls the behavior and reflects the status of the OTG function of the core.

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **CURMOD**: Current mode of operation
- Indicates the current mode (host or device).
  - 0: Device mode
  - 1: Host mode

Bit 20 **OTGVER**: OTG version
- Selects the OTG revision.
  - 0: OTG Version 1.3. OTG1.3 is obsolete for new product development.
  - 1: OTG Version 2.0. In this version the core supports only data line pulsing for SRP.

Bit 19 **BSVLD**: B-session valid
- Indicates the device mode transceiver status.
  - 0: B-session is not valid.
  - 1: B-session is valid.
- In OTG mode, the user can use this bit to determine if the device is connected or disconnected.
  
  **Note**: Only accessible in device mode.

Bit 18 **ASVLD**: A-session valid
- Indicates the host mode transceiver status.
  - 0: A-session is not valid
  - 1: A-session is valid
  
  **Note**: Only accessible in host mode.

Bit 17 **DBCT**: Long/short debounce time
- Indicates the debounce time of a detected connection.
  - 0: Long debounce time, used for physical connections (100 ms + 2.5 µs)
  - 1: Short debounce time, used for soft connections (2.5 µs)
  
  **Note**: Only accessible in host mode.

Bit 16 **CIDSTS**: Connector ID status
- Indicates the connector ID status on a connect event.
  - 0: The OTG_FS controller is in A-device mode
  - 1: The OTG_FS controller is in B-device mode
  
  **Note**: Accessible in both device and host modes.
Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **EHEN**: Embedded host enable
It is used to select between OTG A device state machine and embedded host state machine.
0: OTG A device state machine is selected
1: Embedded host state machine is selected

Bit 11 **DHNPEN**: Device HNP enabled
The application sets this bit when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host.
0: HNP is not enabled in the application
1: HNP is enabled in the application
*Note: Only accessible in device mode.*

Bit 10 **HSHNPEN**: host set HNP enable
The application sets this bit when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) on the connected device.
0: Host Set HNP is not enabled
1: Host Set HNP is enabled
*Note: Only accessible in host mode.*

Bit 9 **HNPRQ**: HNP request
The application sets this bit to initiate an HNP request to the connected USB host. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG_GOTGINT register (HNSSCHG bit in OTG_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.
0: No HNP request
1: HNP request
*Note: Only accessible in device mode.*

Bit 8 **HNGSCS**: Host negotiation success
The core sets this bit when host negotiation is successful. The core clears this bit when the HNP request (HNPRQ) bit in this register is set.
0: Host negotiation failure
1: Host negotiation success
*Note: Only accessible in device mode.*

Bit 7 **BVALOVAL**: B-peripheral session valid override value.
This bit is used to set override value for Bvalid signal when BVALOEN bit is set.
0: Bvalid value is '0' when BVALOEN = 1
1: Bvalid value is '1' when BVALOEN = 1
*Note: Only accessible in device mode.*

Bit 6 **BVALOEN**: B-peripheral session valid override enable.
This bit is used to enable/disable the software to override the Bvalid signal using the BVALOVAL bit.
0: Override is disabled and Bvalid signal from the respective PHY selected is used internally by the core
1: Internally Bvalid received from the PHY is overridden with BVALOVAL bit value
*Note: Only accessible in device mode.*

Bit 5 **AVALOVAL**: A-peripheral session valid override value.
This bit is used to set override value for Avalid signal when AVALOEN bit is set.
0: Avalid value is '0' when AVALOEN = 1
1: Avalid value is '1' when AVALOEN = 1
*Note: Only accessible in host mode.*
Bit 4 **AVALOEN**: A-peripheral session valid override enable.

This bit is used to enable/disable the software to override the Avalid signal using the AVALOVAL bit.

0: Override is disabled and Avalid signal from the respective PHY selected is used internally by the core.
1: Internally Avalid received from the PHY is overridden with AVALOVAL bit value.

*Note: Only accessible in host mode.*

Bit 3 **VBVALOVAL**: $V_{BUS}$ valid override value.

This bit is used to set override value for vbusvalid signal when VBVALOEN bit is set.

0: vbusvalid value is '0' when VBVALOEN = 1
1: vbusvalid value is '1' when VBVALOEN = 1

*Note: Only accessible in host mode.*

Bit 2 **VBVALOEN**: $V_{BUS}$ valid override enable.

This bit is used to enable/disable the software to override the vbusvalid signal using the VBVALOVAL bit.

0: Override is disabled and vbusvalid signal from the respective PHY selected is used internally by the core.
1: Internally vbusvalid received from the PHY is overridden with VBVALOVAL bit value.

*Note: Only accessible in host mode.*

Bit 1 **SRQ**: Session request

The application sets this bit to initiate a session request on the USB. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG_GOTGINT register (HNSSCHG bit in OTG_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.

If the user uses the USB 1.1 full-speed serial transceiver interface to initiate the session request, the application must wait until $V_{BUS}$ discharges to 0.2 V, after the B-session valid bit in this register (BSVLD bit in OTG_GOTGCTL) is cleared.

0: No session request
1: Session request

*Note: Only accessible in device mode.*

Bit 0 **SRQSCS**: Session request success

The core sets this bit when a session request initiation is successful.

0: Session request failure
1: Session request success

*Note: Only accessible in device mode.*
72.15.2 OTG interrupt register (OTG_GOTGINT)

Address offset: 0x04
Reset value: 0x0000 0000

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

| Bit 31:20 | Reserved, must be kept at reset value. |
| Bit 19   | **DBCDNE**: Debounce done |
| The core sets this bit when the debounce is completed after the device connect. The application can start driving USB reset after seeing this interrupt. This bit is only valid when the HNP Capable or SRP Capable bit is set in the OTG_GUSBCFG register (HNPCAP bit or SRPCAP bit in OTG_GUSBCFG, respectively). |
| Note: Only accessible in host mode. |
| Bit 18   | **ADTOCHG**: A-device timeout change |
| The core sets this bit to indicate that the A-device has timed out while waiting for the B-device to connect. |
| Note: Accessible in both device and host modes. |
| Bit 17   | **HNGDET**: Host negotiation detected |
| The core sets this bit when it detects a host negotiation request on the USB. |
| Note: Accessible in both device and host modes. |
| Bits 16:10 | Reserved, must be kept at reset value. |
| Bit 9    | **HNSSCHG**: Host negotiation success status change |
| The core sets this bit on the success or failure of a USB host negotiation request. The application must read the host negotiation success bit of the OTG_GOTGCTL register (HNGSCS bit in OTG_GOTGCTL) to check for success or failure. |
| Note: Accessible in both device and host modes. |
| Bits 7:3 | Reserved, must be kept at reset value. |
| Bit 8    | **SRSSCHG**: Session request success status change |
| The core sets this bit on the success or failure of a session request. The application must read the session request success bit in the OTG_GOTGCTL register (SRQSCS bit in OTG_GOTGCTL) to check for success or failure. |
| Note: Accessible in both device and host modes. |
| Bit 2    | **SEDET**: Session end detected |
| The core sets this bit to indicate that the level of the voltage on VBUS is no longer valid for a B-Peripheral session when VBUS < 0.8 V. |
| Note: Accessible in both device and host modes. |
| Bits 1:0 | Reserved, must be kept at reset value. |
72.15.3 OTG AHB configuration register (OTG_GAHBCFG)

Address offset: 0x008
Reset value: 0x0000 0000

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

| Bit 31-9 | Reserved, must be kept at reset value.
| Bit 8   | PTXFELVL: Periodic Tx FIFO empty level
|         | Indicates when the periodic Tx FIFO empty interrupt bit in the OTG_GINTSTS register (PTXFE bit in OTG_GINTSTS) is triggered.
|         | 0: PTXFE (in OTG_GINTSTS) interrupt indicates that the Periodic Tx FIFO is half empty
|         | 1: PTXFE (in OTG_GINTSTS) interrupt indicates that the Periodic Tx FIFO is completely empty
| Note:   | Only accessible in host mode.
| Bit 7   | TXFELVL: Tx FIFO empty level
|         | In device mode, this bit indicates when IN endpoint Transmit FIFO empty interrupt (TXFE in OTG_DIEPINTx) is triggered:
|         | 0: The TXFE (in OTG_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is half empty
|         | 1: The TXFE (in OTG_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is completely empty
|         | In host mode, this bit indicates when the nonperiodic Tx FIFO empty interrupt (NPTXFE bit in OTG_GINTSTS) is triggered:
|         | 0: The NPTXFE (in OTG_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is half empty
|         | 1: The NPTXFE (in OTG_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is completely empty
| Bits 6:1 | Reserved, must be kept at reset value.
| Bit 0 GINTMSK: Global interrupt mask
|         | The application uses this bit to mask or unmask the interrupt line assertion to itself.
|         | Irrespective of this bit’s setting, the interrupt status registers are updated by the core.
|         | 0: Mask the interrupt assertion to the application.
|         | 1: Unmask the interrupt assertion to the application.
| Note:   | Accessible in both device and host modes.
**72.15.4 OTG USB configuration register (OTG_GUSBCFG)**

Address offset: 0x0C

Reset value: 0x0000 1440

This register can be used to configure the core after power-on or a changing to host mode or device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

Bit 31: Reserved, must be kept at reset value.

Bit 30 **FDMOD**: Force device mode

- Writing a 1 to this bit, forces the core to device mode irrespective of the OTG_ID input pin.
- 0: Normal mode
- 1: Force device mode

After setting the force bit, the application must wait at least 25 ms before the change takes effect.

*Note: Accessible in both device and host modes.*

Bit 29 **FHM0D**: Force host mode

- Writing a 1 to this bit, forces the core to host mode irrespective of the OTG_ID input pin.
- 0: Normal mode
- 1: Force host mode

After setting the force bit, the application must wait at least 25 ms before the change takes effect.

*Note: Accessible in both device and host modes.*

Bits 28:26 Reserved, must be kept at reset value.

Bits 25:23 Reserved, must be kept at reset value.

Bit 22 Reserved, must be kept at reset value.

Bits 21:16 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bits 13:10 **TRDT[3:0]**: USB turnaround time

These bits are used to set the turnaround time in PHY clocks. They must be configured according to Table 749: TRDT values, depending on the application AHB frequency. Higher TRDT values allow stretching the USB response time to IN tokens in order to compensate for longer AHB read access latency to the data FIFO.

*Note: Only accessible in device mode.*
Bit 9 **HNPCAP**: HNP-capable

The application uses this bit to control the OTG_FS controller’s HNP capabilities.

0: HNP capability is not enabled.
1: HNP capability is enabled.

*Note:* Accessible in both device and host modes.

Bit 8 **SRPCAP**: SRP-capable

The application uses this bit to control the OTG_FS controller’s SRP capabilities. If the core operates as a non-SRP-capable B-device, it cannot request the connected A-device (host) to activate VBUS and start a session.

0: SRP capability is not enabled.
1: SRP capability is enabled.

*Note:* Accessible in both device and host modes.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **PHYSEL**: Full Speed serial transceiver mode select

This bit is always 1 with read-only access.

Bit 5 Reserved, must be kept at reset value.

Bit 4 Reserved, must be kept at reset value.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **TOCAL[2:0]**: FS timeout calibration

The number of PHY clocks that the application programs in this field is added to the full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the line state condition can vary from one PHY to another.

The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock is 0.25 bit times.

Bit 31 **AHBIDL**: AHB master idle
Indicates that the AHB master state machine is in the Idle condition.

*Note*: Accessible in both device and host modes.

Bits 30:11 Reserved, must be kept at reset value.

Bits 10:6 **TXFNUM[4:0]**: Tx FIFO number
This is the FIFO number that must be flushed using the Tx FIFO Flush bit. This field must not be changed until the core clears the Tx FIFO Flush bit.

- 00000: Non-periodic Tx FIFO flush in host mode
- 00001: Periodic Tx FIFO flush in host mode
- 00010: Tx FIFO 1 flush in device mode
- 00100: Tx FIFO 2 flush in device mode
- 01000: Tx FIFO 3 flush in device mode
- 01100: Tx FIFO 4 flush in device mode
- 10000: Flush all the transmit FIFOs in device or host mode.

*Note*: Accessible in both device and host modes.

Bit 5 **TXFFLSH**: Tx FIFO flush
This bit selectively flushes a single or all transmit FIFOs, but cannot do so if the core is in the midst of a transaction.

The application must write this bit only after checking that the core is neither writing to the Tx FIFO nor reading from the Tx FIFO. Verify using these registers:

Read—NAK Effective interrupt ensures the core is not reading from the FIFO
Write—AHBIDL bit in OTG_GRSTCTL ensures the core is not writing anything to the FIFO

Flushing is normally recommended when FIFOs are reconfigured. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower clock of phy_clk or hclk.

*Note*: Accessible in both device and host modes.
Bit 4 **RXFFLSH**: Rx FIFO flush

The application can flush the entire Rx FIFO using this bit, but must first ensure that the core is not in the middle of a transaction.

The application must only write to this bit after checking that the core is neither reading from the Rx FIFO nor writing to the Rx FIFO.

The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear.

*Note: Accessible in both device and host modes.*

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FCRST**: Host frame counter reset

The application writes this bit to reset the frame number counter inside the core. When the frame counter is reset, the subsequent SOF sent out by the core has a frame number of 0.

When application writes '1' to the bit, it might not be able to read back the value as it gets cleared by the core in a few clock cycles.

*Note: Only accessible in host mode.*

Bit 1 **PSRST**: Partial soft reset

Resets the internal state machines but keeps the enumeration info. Can be used to recover some specific PHY errors.

*Note: Accessible in both device and host modes.*

Bit 0 **CSRST**: Core soft reset

Resets the HCLK and PHY clock domains as follows:

- Clears the interrupts and all the CSR register bits except for the following bits:
  - GATEHCLK bit in OTG_PCGCCTL
  - STPPCLK bit in OTG_PCGCCTL
  - FSLSPCS bits in OTG_HCFG
  - DSPD bit in OTG_DCFG
  - SDIS bit in OTG_DCTL
  - OTG_GCCFG register

All module state machines (except for the AHB slave unit) are reset to the Idle state, and all the transmit FIFOs and the receive FIFO are flushed.

Any transactions on the AHB Master are terminated as soon as possible, after completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately.

The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit has been cleared, the software must wait at least 3 PHY clocks before accessing the PHY domain (synchronization delay). The software must also check that bit 31 in this register is set to 1 (AHB Master is Idle) before starting any operation.

Typically, the software reset is used during software development and also when the user dynamically changes the PHY selection bits in the above listed USB configuration registers.

When the user changes the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.

*Note: Accessible in both device and host modes.*
72.15.6 OTG core interrupt register (OTG_GINTSTS)

Address offset: 0x014
Reset value: 0x0400 0020

This register interrupts the application for system-level events in the current mode (device mode or host mode).

Some of the bits in this register are valid only in host mode, while others are valid in device mode only. This register also indicates the current mode. To clear the interrupt status bits of the rc_w1 type, the application must write 1 into the bit.

The FIFO status interrupts are read-only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the OTG_GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

<table>
<thead>
<tr>

</tr>
<tr>
<td>28</td>
<td>CIDSCHG: Connector ID status change</td>
<td>Both device and host modes</td>
</tr>
</tbody>
</table>

**Bit 31 WKUPINT:** Resume/remote wake-up detected interrupt
- Wake-up interrupt during suspend(L2) or LPM(L1) state.
  - During suspend(L2): In device mode, this interrupt is asserted when a resume is detected on the USB. In host mode, this interrupt is asserted when a remote wake-up is detected on the USB.
  - During LPM(L1): This interrupt is asserted for either host initiated resume or device initiated remote wake-up on USB.

*Note: Accessible in both device and host modes.*

**Bit 30 SRQINT:** Session request/new session detected interrupt
In host mode, this interrupt is asserted when a session request is detected from the device. In device mode, this interrupt is asserted when VBUS is in the valid range for a B-peripheral device. Accessible in both device and host modes.

**Bit 29 DISCINT:** Disconnect detected interrupt
Asserted when a device disconnect is detected.

*Note: Only accessible in host mode.*

**Bit 28 CIDSCHG:** Connector ID status change
The core sets this bit when there is a change in connector ID status.

*Note: Accessible in both device and host modes.*
Bit 27  **LPMINT**: LPM interrupt
In device mode, this interrupt is asserted when the device receives an LPM transaction and responds with a non-ERRORed response.
In host mode, this interrupt is asserted when the device responds to an LPM transaction with a non-ERRORed response or when the host core has completed LPM transactions for the programmed number of times (RETRYCNT bit in OTG_GLPMCFG).
This field is valid only if the LPMEN bit in OTG_GLPMCFG is set to 1.

Bit 26  **PTXFE**: Periodic Tx FIFO empty
Asserted when the periodic transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the periodic request queue. The half or completely empty status is determined by the periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (PTXFELVL bit in OTG_GAHBCFG).
*Note: Only accessible in host mode.*

Bit 25  **HCINT**: Host channels interrupt
The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in host mode). The application must read the OTG_HAINT register to determine the exact number of the channel on which the interrupt occurred, and then read the corresponding OTG_HCINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the OTG_HCINTx register to clear this bit.
*Note: Only accessible in host mode.*

Bit 24  **HPRTINT**: Host port interrupt
The core sets this bit to indicate a change in port status of one of the OTG_FS controller ports in host mode. The application must read the OTG_HPRT register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_HPRT register to clear this bit.
*Note: Only accessible in host mode.*

Bit 23  **RSTDET**: Reset detected interrupt
In device mode, this interrupt is asserted when a reset is detected on the USB in partial power-down mode when the device is in suspend.
*Note: Only accessible in device mode.*

Bit 22  Reserved, must be kept at reset value.

Bit 21  **IPXFR**: Incomplete periodic transfer
In host mode, the core sets this interrupt bit when there are incomplete periodic transactions still pending, which are scheduled for the current frame.

**INCOMPISOOUT**: Incomplete isochronous OUT transfer
In device mode, the core sets this interrupt to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

Bit 20  **IISOIXFR**: Incomplete isochronous IN transfer
The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.
*Note: Only accessible in device mode.*
Bit 19  **OEPINT**: OUT endpoint interrupt
The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of
the core (in device mode). The application must read the OTG_DAINT register to determine
the exact number of the OUT endpoint on which the interrupt occurred, and then read the
corresponding OTG_DOEPINTx register to determine the exact cause of the interrupt. The
application must clear the appropriate status bit in the corresponding OTG_DOEPINTx
register to clear this bit.

*Note: Only accessible in device mode.*

Bit 18  **IEPINT**: IN endpoint interrupt
The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the
core (in device mode). The application must read the OTG_DAINT register to determine the
exact number of the IN endpoint on which the interrupt occurred, and then read the
corresponding OTG_DIEPINTx register to determine the exact cause of the interrupt. The
application must clear the appropriate status bit in the corresponding OTG_DIEPINTx
register to clear this bit.

*Note: Only accessible in device mode.*

Bits 17:16 Reserved, must be kept at reset value.

Bit 15  **EOPF**: End of periodic frame interrupt
Indicates that the period specified in the periodic frame interval field of the OTG_DCFG
register (PFIVL bit in OTG_DCFG) has been reached in the current frame.

*Note: Only accessible in device mode.*

Bit 14  **ISOODRP**: Isochronous OUT packet dropped interrupt
The core sets this bit when it fails to write an isochronous OUT packet into the Rx FIFO
because the Rx FIFO does not have enough space to accommodate a maximum size
packet for the isochronous OUT endpoint.

*Note: Only accessible in device mode.*

Bit 13  **ENUMDNE**: Enumeration done
The core sets this bit to indicate that speed enumeration is complete. The application must
read the OTG_DSTS register to obtain the enumerated speed.

*Note: Only accessible in device mode.*

Bit 12  **USBRST**: USB reset
The core sets this bit to indicate that a reset is detected on the USB.

*Note: Only accessible in device mode.*

Bit 11  **USBSUSP**: USB suspend
The core sets this bit to indicate that a suspend was detected on the USB. The core enters
the suspended state when there is no activity on the data lines for an extended period of
time.

*Note: Only accessible in device mode.*

Bit 10  **ESUSP**: Early suspend
The core sets this bit to indicate that an Idle state has been detected on the USB for 3 ms.

*Note: Only accessible in device mode.*

Bits 9:8 Reserved, must be kept at reset value.

Bit 7  **GONAKEFF**: Global OUT NAK effective
Indicates that the Set global OUT NAK bit in the OTG_DCTL register (SGONAK bit in
OTG_DCTL), set by the application, has taken effect in the core. This bit can be cleared by
writing the Clear global OUT NAK bit in the OTG_DCTL register (CGONAK bit in
OTG_DCTL).

*Note: Only accessible in device mode.*
Bit 6 **GINAKEFF**: Global IN non-periodic NAK effective
- Indicates that the Set global non-periodic IN NAK bit in the OTG_DCTL register (SGINAK bit in OTG_DCTL), set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. This bit can be cleared by clearing the Clear global non-periodic IN NAK bit in the OTG_DCTL register (CGINAK bit in OTG_DCTL).
- This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit.

*Note:* Only accessible in device mode.

Bit 5 **NPTXFE**: Non-periodic Tx FIFO empty
- This interrupt is asserted when the non-periodic Tx FIFO is either half or completely empty, and there is space for at least one entry to be written to the non-periodic transmit request queue. The half or completely empty status is determined by the non-periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (TXFELVL bit in OTG_GAHBCFG).

*Note:* Accessible in host mode only.

Bit 4 **RXFLVL**: Rx FIFO non-empty
- Indicates that there is at least one packet pending to be read from the Rx FIFO.

*Note:* Accessible in both host and device modes.

Bit 3 **SOF**: Start of frame
- In host mode, the core sets this bit to indicate that an SOF (FS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt.
- In device mode, in the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the OTG_DSTS register to get the current frame number. This interrupt is seen only when the core is operating in FS.

*Note:* This register may return ‘1’ if read immediately after power on reset. If the register bit reads ‘1’ immediately after power on reset it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit.

*Note:* Accessible in both host and device modes.

Bit 2 **OTGINT**: OTG interrupt
- The core sets this bit to indicate an OTG protocol event. The application must read the OTG interrupt status (OTG_GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_GOTGINT register to clear this bit.

*Note:* Accessible in both host and device modes.

Bit 1 **MMIS**: Mode mismatch interrupt
- The core sets this bit when the application is trying to access:
  - A host mode register, when the core is operating in device mode
  - A device mode register, when the core is operating in host mode
- The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core.

*Note:* Accessible in both host and device modes.

Bit 0 **CMOD**: Current mode of operation
- Indicates the current mode.
  0: Device mode
  1: Host mode

*Note:* Accessible in both host and device modes.
### 72.15.7 OTG interrupt mask register (OTG_GINTMSK)

Address offset: 0x018  
Reset value: 0x0000 0000

This register works with the core interrupt register to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the core interrupt (OTG_GINTSTS) register bit corresponding to that interrupt is still set.

| **Note**: Accessible in both device and host modes. |
| Bit 0 | Reserved, must be kept at reset value. |
## 72.15.8 OTG receive status debug read register (OTG_GRXSTSR)

Address offset for read: 0x01C

Reset value: 0x0000 0000

This description is for register OTG_GRXSTSR in Device mode.

A read to the receive status debug read register returns the contents of the top of the receive FIFO.

The core ignores the receive status read when the receive FIFO is empty and returns a value of 0x0000 0000.

72.15.9 OTG receive status debug read [alternate] (OTG_GRXSTSR)

Address offset for read: 0x01C
Reset value: 0x0000 0000

This description is for register OTG_GRXSTSR in Host mode.

A read to the receive status debug read register returns the contents of the top of the receive FIFO.

The core ignores the receive status read when the receive FIFO is empty and returns a value of 0x0000 0000.

| Bits 31:21 | Reserved, must be kept at reset value. |
| Bits 20:17 | PKTSTS[3:0]: Packet status |
|           | Indicates the status of the received packet |
|           | 0010: IN data packet received |
|           | 0011: IN transfer completed (triggers an interrupt) |
|           | 0101: Data toggle error (triggers an interrupt) |
|           | 0111: Channel halted (triggers an interrupt) |
|           | Others: Reserved |
| Bits 16:15 | DPID[1:0]: Data PID |
|           | Indicates the data PID of the received packet |
|           | 00: DATA0 |
|           | 10: DATA1 |
| Bits 14:4 | BCNT[10:0]: Byte count |
|           | Indicates the byte count of the received IN data packet. |
| Bits 3:0  | CHNUM[3:0]: Channel number |
|           | Indicates the channel number to which the current received packet belongs. |
72.15.10 OTG status read and pop registers (OTG_GRXSTSP)

Address offset for pop: 0x020
Reset value: 0x0000 0000

This description is for register OTG_GRXSTSP in Device mode.

Similarly to OTG_GRXSTSR (receive status debug read register) where a read returns the contents of the top of the receive FIFO, a read to OTG_GRXSTSP (receive status read and pop register) additionally pops the top data entry out of the Rx FIFO.

The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x0000 0000. The application must only pop the receive status FIFO when the receive FIFO non-empty bit of the core interrupt register (RXFLVL bit in OTG_GINTSTS) is asserted.

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **STSPHST**: Status phase start
Indicates the start of the status phase for a control write transfer. This bit is set along with the OUT transfer completed PKTSTS pattern.

Bits 26:25 Reserved, must be kept at reset value.

Bits 24:21 **FRMNUM[3:0]**: Frame number
This is the least significant 4 bits of the frame number in which the packet is received on the USB. This field is supported only when isochronous OUT endpoints are supported.

Bits 20:17 **PKTSTS[3:0]**: Packet status
Indicates the status of the received packet
0001: Global OUT NAK (triggers an interrupt)
0010: OUT data packet received
0011: OUT transfer completed (triggers an interrupt)
0100: SETUP transaction completed (triggers an interrupt)
0110: SETUP data packet received
Others: Reserved

Bits 16:15 **DPID[1:0]**: Data PID
Indicates the data PID of the received OUT data packet
00: DATA0
10: DATA1

Bits 14:4 **BCNT[10:0]**: Byte count
Indicates the byte count of the received data packet.

Bits 3:0 **EPNUM[3:0]**: Endpoint number
Indicates the endpoint number to which the current received packet belongs.
### 72.15.11 OTG status read and pop registers [alternate] (OTG_GRXSTSP)

Address offset for pop: 0x020  
Reset value: 0x0000 0000

This description is for register OTG_GRXSTSP in Host mode.

Similarly to OTG_GRXSTSR (receive status debug read register) where a read returns the contents of the top of the receive FIFO, a read to OTG_GRXSTSP (receive status read and pop register) additionally pops the top data entry out of the Rx FIFO.

The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x0000 0000. The application must only pop the receive status FIFO when the receive FIFO non-empty bit of the core interrupt register (RXFLVL bit in OTG_GINTSTS) is asserted.

Host mode

Bits 31:16 NPTXFD[15:0]: Non-periodic Tx FIFO depth
This value is in terms of 32-bit words.
Minimum value is 16
Programmed values must respect the available FIFO memory allocation and must not exceed the power-on value.

Bits 15:0 NPTXFSA[15:0]: Non-periodic transmit RAM start address
This field configures the memory start address for non-periodic transmit FIFO RAM.
Device mode

Bits 31:16  **TX0FD**: Endpoint 0 Tx FIFO depth
   This value is in terms of 32-bit words.
   Minimum value is 16
   Programmed values must respect the available FIFO memory allocation and must not exceed the power-on value.

Bits 15:0  **TX0FSA**: Endpoint 0 transmit RAM start address
   This field configures the memory start address for the endpoint 0 transmit FIFO RAM.

### 72.15.14 OTG non-periodic transmit FIFO/queue status register (OTG_HNPTXSTS)

Address offset: 0x02C
Reset value: 0x0008 0200

*Note:*  *In device mode, this register is not valid.*

This read-only register contains the free space information for the non-periodic Tx FIFO and the non-periodic transmit request queue.

Bit 31  Reserved, must be kept at reset value.

Bits 30:24  **NPTXQTOP[6:0]**: Top of the non-periodic transmit request queue

Entry in the non-periodic Tx request queue that is currently being processed by the MAC.

- Bits 30:27: Channel/endpoint number
- Bits 26:25:
  - 00: IN/OUT token
  - 01: Zero-length transmit packet (device IN/host OUT)
  - 11: Channel halt command
- Bit 24: Terminate (last entry for selected channel/endpoint)

Bits 23:16  **NPTQXSAV[7:0]**: Non-periodic transmit request queue space available

Indicates the amount of free space available in the non-periodic transmit request queue.
This queue holds both IN and OUT requests.

- 0: Non-periodic transmit request queue is full
- 1: 1 location available
- 2: locations available
- n: n locations available (0 ≤ n ≤ 8)

Others: Reserved

Bits 15:0  **NPTXFSAV[15:0]**: Non-periodic Tx FIFO space available

Indicates the amount of free space available in the non-periodic Tx FIFO.
Values are in terms of 32-bit words.

- 0: Non-periodic Tx FIFO is full
- 1: 1 word available
- 2: 2 words available
- n: n words available (where 0 ≤ n ≤ 512)

Others: Reserved

</tr>
</tbody>
</table>
Bits 31:22  Reserved, must be kept at reset value.

Bit 21  **VBDEN**: USB VBUS detection enable
        Enables $V_{BUS}$ sensing comparators to detect $V_{BUS}$ valid levels on the $V_{BUS}$ PAD for USB host and device operation. If HNP and/or SRP support is enabled, $V_{BUS}$ comparators are automatically enabled independently of VBDEN value.
        0 = $V_{BUS}$ detection disabled
        1 = $V_{BUS}$ detection enabled

Bit 20  **SDEN**: Secondary detection (SD) mode enable
        This bit is set by the software to put the BCD into SD mode. Only one detection mode (DCD, PD, SD or OFF) must be selected to work correctly

Bit 19  **PDEN**: Primary detection (PD) mode enable
        This bit is set by the software to put the BCD into PD mode. Only one detection mode (DCD, PD, SD or OFF) must be selected to work correctly.

Bit 18  **DCDEN**: Data contact detection (DCD) mode enable
        This bit is set by the software to put the BCD into DCD mode. Only one detection mode (DCD, PD, SD or OFF) must be selected to work correctly.

Bit 17  **BCDEN**: Battery charging detector (BCD) enable
        This bit is set by the software to enable the BCD support within the USB device. When enabled, the USB PHY is fully controlled by BCD and cannot be used for normal communication. Once the BCD discovery is finished, the BCD must be placed in OFF mode by clearing this bit to '0' in order to allow the normal USB operation.

Bit 16  **PWRDWN**: Power down control of FS PHY
        Used to activate the FS PHY in transmission/reception. When reset, the PHY is kept in power-down. When set, the BCD function must be off (BCDEN=0).
        0 = USB FS PHY disabled
        1 = USB FS PHY enabled

Bits 15:4  Reserved, must be kept at reset value.

Bit 3  **PS2DET**: DM pull-up detection status
        This bit is active only during PD and gives the result of comparison between DM voltage level and VLGC threshold. In normal situation, the DM level must be below this threshold. If it is above, it means that the DM is externally pulled high. This can be caused by connection to a PS2 port (which pulls-up both DP and DM lines) or to some proprietary charger not following the BCD specification.
        0: Normal port detected (connected to SDP, CDP or DCP)
        1: PS2 port or proprietary charger detected

Bit 2  **SDET**: Secondary detection (SD) status
        This bit gives the result of SD.
        0: CDP detected
        1: DCP detected

Bit 1  **PDET**: Primary detection (PD) status
        This bit gives the result of PD.
        0: no BCD support detected (connected to SDP or proprietary device).
        1: BCD support detected (connected to CDP or DCP).

Bit 0  **DCDET**: Data contact detection (DCD) status
        This bit gives the result of DCD.
        0: data lines contact not detected
        1: data lines contact detected
### 72.15.16 OTG core ID register (OTG_CID)

</tbody>
</table>

Bits 31:29 Reserved, must be kept at reset value.

**Bit 28 ENBESL**: Enable best effort service latency  
This bit enables the BESL feature as defined in the LPM errata:  
0: The core works as described in the following document:  
*USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007*  
1: The core works as described in the LPM Errata:  
*Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007*  
**Note**: Only the updated behavior (described in LPM Errata) is considered in this document and so the ENBESL bit must be set to ‘1’ by application SW.

Bits 27:25 **LPMRCNTSTS[2:0]**: LPM retry count status  
Number of LPM host retries still remaining to be transmitted for the current LPM sequence.  
**Note**: Accessible only in host mode.
Bit 24 **SNDLPM**: Send LPM transaction
   When the application software sets this bit, an LPM transaction containing two tokens, EXT and LPM is sent. The hardware clears this bit once a valid response (STALL, NYET, or ACK) is received from the device or the core has finished transmitting the programmed number of LPM retries.
   
   **Note**: This bit must be set only when the host is connected to a local port.
   **Note**: Accessible only in host mode.

Bits 23:21 **LPMRCNT[2:0]**: LPM retry count
   When the device gives an ERROR response, this is the number of additional LPM retries that the host performs until a valid device response (STALL, NYET, or ACK) is received.
   
   **Note**: Accessible only in host mode.

Bits 20:17 **LPMCHIDX[3:0]**: LPM Channel Index
   The channel number on which the LPM transaction has to be applied while sending an LPM transaction to the local device. Based on the LPM channel index, the core automatically inserts the device address and endpoint number programmed in the corresponding channel into the LPM transaction.
   
   **Note**: Accessible only in host mode.

Bit 16 **L1RSMOK**: Sleep state resume OK
   Indicates that the device or host can start resume from Sleep state. This bit is valid in LPM sleep (L1) state. It is set in sleep mode after a delay of 50 μs ($T_{L1Residency}$).
   
   This bit is reset when SLPSTS is 0.
   - 1: The application or host can start resume from Sleep state
   - 0: The application or host cannot start resume from Sleep state

Bit 15 **SLPSTS**: Port sleep status
   **Device mode**:
   This bit is set as long as a Sleep condition is present on the USB bus. The core enters the Sleep state when an ACK response is sent to an LPM transaction and the $T_{L1TokenRetry}$ timer has expired. To stop the PHY clock, the application must set the STPPCLK bit in OTG_PCGCCTL, which asserts the PHY suspend input signal.
   
   The application must rely on SLPSTS and not ACK in LPMRSP to confirm transition into sleep.
   
   The core comes out of sleep:
   - When there is any activity on the USB line state
   - When the application writes to the RWUSIG bit in OTG_DCTL or when the application resets or soft-disconnects the device.

   **Host mode**:
   The host transitions to Sleep (L1) state as a side-effect of a successful LPM transaction by the core to the local port with ACK response from the device. The read value of this bit reflects the current Sleep status of the port.
   
   The core clears this bit after:
   - The core detects a remote L1 wake-up signal,
   - The application sets the PRST bit or the PRES bit in the OTG_HPRT register, or
   - The application sets the L1Resume/ remote wake-up detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT bit in OTG_GINTSTS, respectively).
   
   0: Core not in L1
   1: Core in L1
Bits 14:13  **LPMRSP[1:0]**: LPM response

**Device mode:**
The response of the core to LPM transaction received is reflected in these two bits.

**Host mode:**
Handshake response received from local device for LPM transaction
- 11: ACK
- 10: NYET
- 01: STALL
- 00: ERROR (No handshake response)

Bit 12  **L1DSEN**: L1 deep sleep enable

Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit must be set to '1' by application SW in all the cases.

Bits 11:8  **BESLTHRS[3:0]**: BESL threshold

**Device mode:**
The core puts the PHY into deep low power mode in L1 when BESL value is greater than or equal to the value defined in this field BESL_Thres[3:0].

**Host mode:**
The core puts the PHY into deep low power mode in L1. BESLTHRS[3:0] specifies the time for which resume signaling is to be reflected by host (T_{L1HubDrvResume2}) on the USB bus when it detects device initiated resume.

BESLTHRS must not be programmed with a value greater than 1100b in host mode, because this exceeds maximum T_{L1HubDrvResume2}.

**Thres[3:0] host mode resume signaling time (μs):**
- 0000: 75
- 0001: 100
- 0010: 150
- 0011: 250
- 0100: 350
- 0101: 450
- 0110: 950
- All other values: reserved

Bit 7  **L1SSEN**: L1 Shallow Sleep enable

Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit must be set to '1' by application SW in all the cases.

Bit 6  **REMWAKE**: bRemoteWake value

**Host mode:**
The value of remote wake up to be sent in the wIndex field of LPM transaction.

**Device mode (read-only):**
This field is updated with the received LPM token bRemoteWake bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.
Bits 5:2 **BESL[3:0]**: Best effort service latency

**Host mode:**
The value of BESL to be sent in an LPM transaction. This value is also used to initiate resume for a duration $T_{\text{LHubDrvResume1}}$ for host initiated resume.

**Device mode (read-only):**
This field is updated with the received LPM token BESL bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.

**BESL[3:0]T_{\text{BESL}} (\mu s)**

</tbody>
</table>

Bit 1 **LPMACK**: LPM token acknowledge enable

Handshake response to LPM token preprogrammed by device application software.

1: ACK

Even though ACK is preprogrammed, the core device responds with ACK only on successful LPM transaction. The LPM transaction is successful if:

- No PID/CRC5 errors in either EXT token or LPM token (else ERROR)
- Valid bLinkState = 0001B (L1) received in LPM transaction (else STALL)
- No data pending in transmit queue (else NYET).

0: NYET

The preprogrammed software bit is over-ridden for response to LPM token when:

- The received bLinkState is not L1 (STALL response), or
- An error is detected in either of the LPM token packets because of corruption (ERROR response).

*Note: Accessible only in device mode.*

Bit 0 **LPMEN**: LPM support enable

The application uses this bit to control the OTG_FS core LPM capabilities.

If the core operates as a non-LPM-capable host, it cannot request the connected device or hub to activate LPM mode.

If the core operates as a non-LPM-capable device, it cannot respond to any LPM transactions.

0: LPM capability is not enabled
1: LPM capability is enabled

  - This field contains the memory start address for IN endpoint transmit FIFOx. The address must be aligned with a 32-bit memory location.
72.15.20 Host-mode registers

Bit values in the register descriptions are expressed in binary unless otherwise specified. Host-mode registers affect the operation of the core in the host mode. Host mode registers must not be accessed in device mode, as the results are undefined. Host mode registers can be categorized as follows:

72.15.21 OTG host configuration register (OTG_HCFG)

Address offset: 0x400
Reset value: 0x0000 0000

This register configures the core after power-on. Do not make changes to this register after initializing the host.

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>

<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FSLSS**: FS- and LS-only support

The application uses this bit to control the core’s enumeration speed. Using this bit, the application can make the core enumerate as an FS host, even if the connected device supports HS traffic. Do not make changes to this field after initial programming.

1: FS/LS-only, even if the connected device can support HS (read-only).

Bits 1:0 **FSLSPCS[1:0]**: FS/LS PHY clock select

When the core is in FS host mode

01: PHY clock is running at 48 MHz
Others: Reserved

When the core is in LS host mode

00: Reserved

01: Select 48 MHz PHY clock frequency

10: Select 6 MHz PHY clock frequency

11: Reserved

Note: The FSLSPCS must be set on a connection event according to the speed of the connected device (after changing this bit, a software reset must be performed).
72.15.22 OTG host frame interval register (OTG_HFIR)

Address offset: 0x404
Reset value: 0x0000 EA60

This register stores the frame interval information for the current speed to which the OTG_FS controller has enumerated.

<table>
<thead>
<tr>
<th>31</th>

<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **RLDCTRL**: Reload control

This bit allows dynamic reloading of the HFIR register during run time.

- 0: The HFIR cannot be reloaded dynamically
- 1: The HFIR can be dynamically reloaded during run time.

This bit needs to be programmed during initial configuration and its value must not be changed during run time.

**Caution:** RLDCTRL = 0 is not recommended.

Bits 15:0 **FRIVL[15:0]**: Frame interval

The value that the application programs to this field, specifies the interval between two consecutive SOFs (FS) or Keep-Alive tokens (LS). This field contains the number of PHY clocks that constitute the required frame interval. The application can write a value to this register only after the port enable bit of the host port control and status register (PENA bit in OTG_HPRT) has been set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS/LS PHY clock select field of the host configuration register (FSLSPCS in OTG_HCFG). Do not change the value of this field after the initial configuration, unless the RLDCTRL bit is set. In such case, the FRIVL is reloaded with each SOF event.

- Frame interval = 1 ms × (FRIVL - 1)
72.15.23 OTG host frame number/frame time remaining register (OTG_HNUM)

Address offset: 0x408
Reset value: 0x0000 3FFF

This register indicates the current frame number. It also indicates the time remaining (in terms of the number of PHY clocks) in the current frame.

<table>
<thead>
<tr>
<th>Bits 31:16</th>
<th>FTREM[15:0]: Frame time remaining</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Indicates the amount of time remaining in the current frame, in terms of PHY clocks. This field decrements on each PHY clock. When it reaches zero, this field is reloaded with the value in the Frame interval register and a new SOF is transmitted on the USB.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bits 15:0</th>
<th>FRNUM[15:0]: Frame number</th>
</tr>
</thead>
<tbody>
<tr>
<td>This field increments when a new SOF is transmitted on the USB, and is cleared to 0 when it reaches 0x3FFF.</td>
<td></td>
</tr>
</tbody>
</table>

72.15.24 OTG_Host periodic transmit FIFO/queue status register (OTG_HPTXSTS)

Address offset: 0x410
Reset value: 0x0008 0100

This read-only register contains the free space information for the periodic Tx FIFO and the periodic transmit request queue.
Bits 31:24  **PTXQTOP[7:0]**: Top of the periodic transmit request queue

This indicates the entry in the periodic Tx request queue that is currently being processed by the MAC.

This register is used for debugging.

- Bit 31: Odd/Even frame
  - 0: send in even frame
  - 1: send in odd frame

- Bits 30:27: Channel/endpoint number

- Bits 26:25: Type
  - 00: IN/OUT
  - 01: Zero-length packet
  - 11: Disable channel command

- Bit 24: Terminate (last entry for the selected channel/endpoint)

Bits 23:16  **PTXQSAV[7:0]**: Periodic transmit request queue space available

Indicates the number of free locations available to be written in the periodic transmit request queue. This queue holds both IN and OUT requests.

- 00: Periodic transmit request queue is full
- 01: 1 location available
- 10: 2 locations available
- bxn: n locations available (0 ≤ n ≤ 8)

Others: Reserved

Bits 15:0  **PTXFSAVL[15:0]**: Periodic transmit data FIFO space available

Indicates the number of free locations available to be written to in the periodic Tx FIFO.

Values are in terms of 32-bit words

- 0000: Periodic Tx FIFO is full
- 0001: 1 word available
- 0010: 2 words available
- bxn: n words available (where 0 ≤ n ≤ PTXFD)

Others: Reserved

### 72.15.25  OTG host all channels interrupt register (OTG_HAINT)

Address offset: 0x414

Reset value: 0x0000 0000

When a significant event occurs on a channel, the host all channels interrupt register interrupts the application using the host channels interrupt bit of the core interrupt register (HCINT bit in OTG_GINTSTS). This is shown in Figure 892. There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding host channel-x interrupt register.

72.15.26 OTG host all channels interrupt mask register (OTG_HAINTMSK)

Address offset: 0x418
Reset value: 0x0000 0000

The host all channel interrupt mask register works with the host all channel interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 HAINT[15:0]: Channel interrupts
One bit per channel: Bit 0 for Channel 0, bit 15 for Channel 15
72.15.27 OTG host port control and status register (OTG_HPRT)

Address offset: 0x440
Reset value: 0x0000 0000

This register is available only in host mode. Currently, the OTG host supports only one port.

A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. It is shown in Figure 892. The rc_w1 bits in this register can trigger an interrupt to the application through the host port interrupt bit of the core interrupt register (HPRTINT bit in OTG_GINTSTS). On a port interrupt, the application must read this register and clear the bit that caused the interrupt. For the rc_w1 bits, the application must write a 1 to the bit to clear the interrupt.

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:17 **PSPD[1:0]:** Port speed
Indicates the speed of the device attached to this port.
01: Full speed
10: Low speed
11: Reserved

Bits 16:13 **PTCTL[3:0]:** Port test control
The application writes a nonzero value to this field to put the port into a Test mode, and the corresponding pattern is signaled on the port.
0000: Test mode disabled
0001: Test_J mode
0010: Test_K mode
0011: Test_SE0_NAK mode
0100: Test_Packet mode
0101: Test_Force_Enable
Others: Reserved

Bit 12 **PPWR:** Port power
The application uses this field to control power to this port, and the core clears this bit on an overcurrent condition.
0: Power off
1: Power on

Bits 11:10 **PLSTS[1:0]:** Port line status
Indicates the current logic level USB data lines
Bit 10: Logic level of OTG_DP
Bit 11: Logic level of OTG_DM

Bit 9 Reserved, must be kept at reset value.
Bit 8  **PRST**: Port reset
When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete.
0: Port not in reset
1: Port in reset
The application must leave this bit set for a minimum duration of at least 10 ms to start a reset on the port. The application can leave it set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by the USB standard.
High speed: 50 ms
Full speed/Low speed: 10 ms

Bit 7  **PSUSP**: Port suspend
The application sets this bit to put this port in suspend mode. The core only stops sending SOFs when this is set. To stop the PHY clock, the application must set the port clock stop bit, which asserts the suspend input pin of the PHY.
The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wake-up signal is detected or the application sets the port reset bit or port resume bit in this register or the resume/remote wake-up detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT in OTG_GINTSTS, respectively).
0: Port not in suspend mode
1: Port in suspend mode

Bit 6  **PRES**: Port resume
The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit.
If the core detects a USB remote wake-up sequence, as indicated by the port resume/remote wake-up detected interrupt bit of the core interrupt register (WKUPINT bit in OTG_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently driving resume signaling.
0: No resume driven
1: Resume driven
When LPM is enabled and the core is in L1 state, the behavior of this bit is as follows:
1. The application sets this bit to drive resume signaling on the port.
2. The core continues to drive the resume signal until a predetermined time specified in BESLTHRS[3:0] field of OTG_GLPMCFG register.
3. If the core detects a USB remote wake-up sequence, as indicated by the port L1Resume/Remote L1Wakeupt detected interrupt bit of the core interrupt register (WKUPINT in OTG_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit at the end of resume. This bit can be set or cleared by both the core and the application. This bit is cleared by the core even if there is no device connected to the host.

Bit 5  **POCCHNG**: Port overcurrent change
The core sets this bit when the status of the port overcurrent active bit (bit 4) in this register changes.

Bit 4  **POCA**: Port overcurrent active
Indicates the overcurrent condition of the port.
0: No overcurrent condition
1: Overcurrent condition

Bit 3  **PENCHNG**: Port enable/disable change
The core sets this bit when the status of the port enable bit 2 in this register changes.
Bit 2 **PENA**: Port enable
A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot set this bit by a register write. It can only clear it to disable the port. This bit does not trigger any interrupt to the application.
0: Port disabled
1: Port enabled

Bit 1 **PCDET**: Port connect detected
The core sets this bit when a device connection is detected to trigger an interrupt to the application using the host port interrupt bit in the core interrupt register (HPRTINT bit in OTG_GINTSTS). The application must write a 1 to this bit to clear the interrupt.

Bit 0 **PCSTS**: Port connect status
0: No device is attached to the port
1: A device is attached to the port

### 72.15.28 OTG host channel x characteristics register (OTG_HCCHARx)

**Address offset**: 0x500 + 0x20 * x, (x = 0 to 11)

**Reset value**: 0x0000 0000

**Bit 31** **CHENA**: Channel enable
This field is set by the application and cleared by the OTG host.
0: Channel disabled
1: Channel enabled

**Bit 30** **CHDIS**: Channel disable
The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the Channel disabled interrupt before treating the channel as disabled.

**Bit 29** **ODDFRM**: Odd frame
This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd frame. This field is applicable for only periodic (isochronous and interrupt) transactions.
0: Even frame
1: Odd frame

**Bits 28:22** **DAD[6:0]**: Device address
This field selects the specific device serving as the data source or sink.
Bits 21:20 **MCNT[1:0]**: Multicount
This field indicates to the host the number of transactions that must be executed per frame for this periodic endpoint. For non-periodic transfers, this field is not used
00: Reserved. This field yields undefined results
01: 1 transaction
10: 2 transactions per frame to be issued for this endpoint
11: 3 transactions per frame to be issued for this endpoint

*Note: This field must be set to at least 01.*

Bits 19:18 **EPTYP[1:0]**: Endpoint type
Indicates the transfer type selected.
00: Control
01: Isochronous
10: Bulk
11: Interrupt

Bit 17 **LSDEV**: Low-speed device
This field is set by the application to indicate that this channel is communicating to a low-speed device.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **EPDIR**: Endpoint direction
Indicates whether the transaction is IN or OUT.
0: OUT
1: IN

Bits 14:11 **EPNUM[3:0]**: Endpoint number
Indicates the endpoint number on the device serving as the data source or sink.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size
Indicates the maximum packet size of the associated endpoint.

### 72.15.29 OTG host channel x interrupt register (OTG_HCINTx)

**Address offset:** 0x508 + 0x20 * x, (x = 0 to 11)

**Reset value:** 0x0000 0000

This register indicates the status of a channel with respect to USB- and AHB-related events. It is shown in Figure 892. The application must read this register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG_GINTSTS) is set. Before the application can read this register, it must first read the host all channels interrupt (OTG_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_HAINT and OTG_GINTSTS registers.

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **DTERR**: Data toggle error.

Bit 9 **FRMOR**: Frame overrun.

Bit 8 **BBERR**: Babble error.

Bit 7 **TXERR**: Transaction error.

  Indicates one of the following errors occurred on the USB.
  CRC check failure
  Timeout
  Bit stuff error
  False EOP

Bit 6 Reserved, must be kept at reset value.

Bit 5 **ACK**: ACK response received/transmitted interrupt.

Bit 4 **NAK**: NAK response received interrupt.

Bit 3 **STALL**: STALL response received interrupt.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CHH**: Channel halted.

  Indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application.

Bit 0 **XFRC**: Transfer completed.

  Transfer completed normally without any errors.

72.15.30 **OTG host channel x interrupt mask register (OTG_HCINTMSKx)**

Address offset: 0x50C + 0x20 * x, (x = 0 to 11)

Reset value: 0x0000 0000

This register reflects the mask for each channel status described in the previous section.

</tbody>
</table>

XFRSIZ[15:0]
Bit 31  **DOPNG:** Do Ping

This bit is used only for OUT transfers. Setting this field to 1 directs the host to do PING protocol.

*Note:* Do not set this bit for IN transfers. If this bit is set for IN transfers, it disables the channel.

Bits 30:29  **D PID[1:0]:** Data PID

The application programs this field with the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer.

00: DATA0
10: DATA1
11: SETUP (control) / reserved (non-control)

Bits 28:19  **PKTCNT[9:0]:** Packet count

This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN).

The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion.

Bits 18:0  **XFRSIZ[18:0]:** Transfer size

For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).

### 72.15.32 Device-mode registers

These registers must be programmed every time the core changes to device mode.

### 72.15.33 OTG device configuration register (OTG_DCFG)

Address offset: 0x800

Reset value: 0x0220 0000

This register configures the core in device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.
Bits 31:16  Reserved, must be kept at reset value.

Bit 15  ERRATIM: Erratic error interrupt mask
1: Mask early suspend interrupt on erratic error
0: Early suspend interrupt is generated on erratic error

Bit 14  Reserved, must be kept at reset value.

Bit 13  Reserved, must be kept at reset value.

Bits 12:11  PFIVL[1:0]: Periodic frame interval
Indicates the time within a frame at which the application must be notified using the end of periodic frame interrupt. This can be used to determine if all the isochronous traffic for that frame is complete.
00: 80% of the frame interval
01: 85% of the frame interval
10: 90% of the frame interval
11: 95% of the frame interval

Bits 10:4  DAD[6:0]: Device address
The application must program this field after every SetAddress control command.

Bit 3  Reserved, must be kept at reset value.

Bit 2  NZLSOHKS: Non-zero-length status OUT handshake
The application can use this field to select the handshake the core sends on receiving a nonzero-length data packet during the OUT transaction of a control transfer’s status stage.
1: Send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application.
0: Send the received OUT packet to the application (zero-length or nonzero-length) and send a handshake based on the NAK and STALL bits for the endpoint in the device endpoint control register.

Bits 1:0  DSPD[1:0]: Device speed
Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected.
00: Reserved
01: Reserved
10: Reserved
11: Full speed (USB 1.1 transceiver clock is 48 MHz)

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **DEVLNSTS[1:0]:** Device line status
Indicates the current logic level USB data lines.
- Bit [23]: Logic level of D+
- Bit [22]: Logic level of D-

Bits 21:8 **FNSOF[13:0]:** Frame number of the received SOF

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **EERR:** Erratic error
The core sets this bit to report any erratic errors.
Due to erratic errors, the OTG_FS controller goes into suspended state and an interrupt is generated to the application with Early suspend bit of the OTG_GINTSTS register (ESUSP bit in OTG_GINTSTS). If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover.

Bits 2:1 **ENUMSPD[1:0]:** Enumerated speed
Indicates the speed at which the OTG_FS controller has come up after speed detection through a chirp sequence.
- 11: Full speed using embedded FS PHY
- Others: reserved

Bit 0 **SUSPSTS:** Suspend status
In device mode, this bit is set as long as a suspend condition is detected on the USB. The core enters the suspended state when there is no activity on the USB data lines for a period of 3 ms. The core comes out of the suspend:
- When there is an activity on the USB data lines
- When the application writes to the remote wake-up signaling bit in the OTG_DCTL register (RWUSIG bit in OTG_DCTL).
# 72.15.36 OTG device IN endpoint common interrupt mask register (OTG_DIEPMSK)

Address offset: 0x810

Reset value: 0x0000 0000

This register works with each of the OTG_DIEPINTx registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the OTG_DIEPINTx register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

### 72.15.37 OTG device OUT endpoint common interrupt mask register (OTG_DOEPMSK)

Address offset: 0x814  
Reset value: 0x0000 0000  

This register works with each of the OTG_DOEPINTx registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the OTG_DOEPINTx register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

### 72.15.38 OTG device all endpoints interrupt register (OTG_DAINT)

Address offset: 0x818
Reset value: 0x0000 0000

When a significant event occurs on an endpoint, a OTG_DAINT register interrupts the application using the device OUT endpoints interrupt bit or device IN endpoints interrupt bit of the OTG_GINTSTS register (OEPINT or IEPINT in OTG_GINTSTS, respectively). There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding device endpoint-x interrupt register (OTG_DIEPINTx/OTG_DOEPINTx).

Bits 31:16 **OEPINT[15:0]**: OUT endpoint interrupt bits
- One bit per OUT endpoint:
  - Bit 16 for OUT endpoint 0, bit 19 for OUT endpoint 3.

Bits 15:0 **IEPINT[15:0]**: IN endpoint interrupt bits
- One bit per IN endpoint:
  - Bit 0 for IN endpoint 0, bit 3 for endpoint 3.
72.15.39  OTG all endpoints interrupt mask register (OTG_DAINTMSK)

Address offset: 0x81C
Reset value: 0x0000 0000

The OTG_DAINTMSK register works with the device endpoint interrupt register to interrupt the application when an event occurs on a device endpoint. However, the OTG_DAINT register bit corresponding to that interrupt is still set.

</table>

**Bit 31 EPENA:** Endpoint enable
The application sets this bit to start transmitting data on the endpoint 0.
The core clears this bit before setting any of the following interrupts on this endpoint:
- Endpoint disabled
- Transfer completed

**Bit 30 EPDIS:** Endpoint disable
The application sets this bit to stop transmitting data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

**Bits 29:28** Reserved, must be kept at reset value.

**Bit 27 SNAK:** Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for an endpoint after a SETUP packet is received on that endpoint.

**Bit 26 CNAK:** Clear NAK
A write to this bit clears the NAK bit for the endpoint.

**Bits 25:22 TXFNUM[3:0]:** Tx FIFO number
This value is set to the FIFO number that is assigned to IN endpoint 0.
Bit 21  **STALL**: STALL handshake
The application can only set this bit, and the core clears it when a SETUP token is received for this endpoint. If a NAK bit, a Global IN NAK or Global OUT NAK is set along with this bit, the STALL bit takes priority.

Bit 20  Reserved, must be kept at reset value.

Bits 19:18  **EPTYP[1:0]**: Endpoint type
Hardcoded to ‘00’ for control.

Bit 17  **NAKSTS**: NAK status
Indicates the following:
0: The core is transmitting non-NAK handshakes based on the FIFO status
1: The core is transmitting NAK handshakes on this endpoint.
When this bit is set, either by the application or core, the core stops transmitting data, even if there are data available in the Tx FIFO. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16  Reserved, must be kept at reset value.

Bit 15  **USBAEP**: USB active endpoint
This bit is always set to 1, indicating that control endpoint 0 is always active in all configurations and interfaces.

Bits 14:2  Reserved, must be kept at reset value.

Bits 1:0  **MPSIZ[1:0]**: Maximum packet size
The application must program this field with the maximum packet size for the current logical endpoint.
00: 64 bytes
01: 32 bytes
10: 16 bytes
11: 8 bytes

**72.15.44  OTG device IN endpoint x control register (OTG_DIEPCTLx)**

Address offset: 0x900 + 0x20 * x, (x = 1 to 5)
Reset value: 0x0000 0000

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.
Bit 31 EPENA: Endpoint enable
The application sets this bit to start transmitting data on an endpoint.
The core clears this bit before setting any of the following interrupts on this endpoint:
– SETUP phase done
– Endpoint disabled
– Transfer completed

Bit 30 EPDIS: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before
the transfer for that endpoint is complete. The application must wait for the endpoint
disabled interrupt before treating the endpoint as disabled. The core clears this bit before
setting the endpoint disabled interrupt. The application must set this bit only if endpoint
enable is already set for this endpoint.

Bit 29 SODDFRM: Set odd frame
Applies to isochronous IN and OUT endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.

Bit 28 SD0PID: Set DATA0 PID
Applies to interrupt/bulk IN endpoints only.
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.

Bit 27 SNAK: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an
endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt,
or after a SETUP is received on the endpoint.

Bit 26 CNAK: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 TXFNUM[3:0]: Tx FIFO number
These bits specify the FIFO number associated with this endpoint. Each active IN endpoint
must be programmed to a separate FIFO number.
This field is valid only for IN endpoints.

Bit 21 STALL: STALL handshake
Applies to non-control, non-isochronous IN endpoints only (access type is rw).
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK
bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority.
Only the application can clear this bit, never the core.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 EPTYP[1:0]: Endpoint type
This is the transfer type supported by this logical endpoint.
00: Control
01: Isochronous
10: Bulk
11: Interrupt
Bit 17 **NAKSTS**: NAK status
   It indicates the following:
   0: The core is transmitting non-NAK handshakes based on the FIFO status.
   1: The core is transmitting NAK handshakes on this endpoint.
   When either the application or the core sets this bit:
   For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there are data available in the Tx FIFO.
   For isochronous IN endpoints: The core sends out a zero-length data packet, even if there are data available in the Tx FIFO.
   Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 **EONUM**: Even/odd frame
   Applies to isochronous IN endpoints only.
   Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.
   0: Even frame
   1: Odd frame

**DPID**: Endpoint data PID
   Applies to interrupt/bulk IN endpoints only.
   Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.
   0: DATA0
   1: DATA1

Bit 15 **USBAYEP**: USB active endpoint
   Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size
   The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.
72.15.45 OTG device IN endpoint x interrupt register (OTG_DIEPINTx)

Address offset: 0x908 + 0x20 * x, (x = 0 to 5)

Reset value: 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in Figure 892. The application must read this register when the IN endpoints interrupt bit of the core interrupt register (IEPINT in OTG_GINTSTS) is set. Before the application can read this register, it must first read the device all endpoints interrupt (OTG_DAINT) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.

</tbody>
</table>

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 NAK: NAK input
The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 Reserved, must be kept at reset value.

Bit 11 PKTDRPSTS: Packet dropped status
This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt.

Bit 10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bit 7 TXFE: Transmit FIFO empty
This interrupt is asserted when the Tx FIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the Tx FIFO Empty Level bit in the OTG_GAHBCFG register (TXFELVL bit in OTG_GAHBCFG).

Bit 6 INEPNE: IN endpoint NAK effective
This bit can be cleared when the application clears the IN endpoint NAK by writing to the CNAK bit in OTG_DIEPCTLx. This interrupt indicates that the core has sampled the NAK bit set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.
Bit 5 **INEPNM**: IN token received with EP mismatch
Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 4 **ITTXFE**: IN token received when Tx FIFO is empty
Indicates that an IN token was received when the associated Tx FIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 3 **TOC**: Timeout condition
Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **EPDISD**: Endpoint disabled interrupt
This bit indicates that the endpoint is disabled per the application’s request.

Bit 0 **XFRC**: Transfer completed interrupt
This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.

---

### 72.15.46 OTG device IN endpoint 0 transfer size register (OTG_DIEPTSIZ0)

**Address offset**: 0x910  
**Reset value**: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the device control endpoint 0 control registers (EPENA in OTG_DIEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–3.

**Bits 31:21**: Reserved, must be kept at reset value.
Bits 20:19 **PKTCNT[1:0]:** Packet count
Indicates the total number of USB packets that constitute the transfer size amount of data for endpoint 0.
This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:7 **Reserved, must be kept at reset value.**

Bits 6:0 **XFRSZ[6:0]:** Transfer size
Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

### 72.15.47 OTG device IN endpoint transmit FIFO status register
(OTG_DTXFSTSx)

Address offset: 0x918 + 0x20 * x, (x = 0 to 5)
Reset value: 0x0000 0200

This read-only register contains the free space information for the device IN endpoint Tx FIFO.

</table>

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **MCNT[1:0]:** Multi count

For periodic IN endpoints, this field indicates the number of packets that must be transmitted per frame on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints.

01: 1 packet
10: 2 packets
11: 3 packets

Bits 28:19 **PKTCNT[9:0]:** Packet count

Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.

This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:0 **XFRSIZ[18:0]:** Transfer size

This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet from the external memory is written to the Tx FIFO.
72.15.49  **OTG device control OUT endpoint 0 control register (OTG_DOEPCTL0)**

Address offset: 0xB00

Reset value: 0x0000 8000

This section describes the OTG_DOEPCTL0 register. Nonzero control endpoints use registers for endpoints 1–3.

<table>

</thead>
</table>
|       | The application cannot disable control OUT endpoint 0.  

| Bit 29:28 | Reserved, must be kept at reset value. |
| Bit 27 | SNAK: Set NAK |
| A write to this bit sets the NAK bit for the endpoint.  
| Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit on a transfer completed interrupt, or after a SETUP is received on the endpoint. |

| Bit 26 | CNAK: Clear NAK |
| A write to this bit clears the NAK bit for the endpoint. |

| Bit 25:22 | Reserved, must be kept at reset value. |
| Bit 21 | STALL: STALL handshake |
| The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake. |

| Bit 20 | SNPM: Snoop mode |
| This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. |

| Bit 19:18 | EPTYP[1:0]: Endpoint type |
| Hardcoded to 2'b00 for control. |
**USB on-the-go full-speed (OTG_FS)**

**Bit 17 NAKSTS: NAK status**

Indicates the following:

0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit, the core stops receiving data, even if there is space in the Rx FIFO to accommodate the incoming packet. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

**Bit 16 Reserved, must be kept at reset value.**

**Bit 15 USBAEP: USB active endpoint**

This bit is always set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces.

**Bits 14:2 Reserved, must be kept at reset value.**

**Bits 1:0 MPSIZ[1:0]: Maximum packet size**

The maximum packet size for control OUT endpoint 0 is the same as what is programmed in control IN endpoint 0.

- 00: 64 bytes
- 01: 32 bytes
- 10: 16 bytes
- 11: 8 bytes

**72.15.50 OTG device OUT endpoint x interrupt register (OTG_DOEPINTx)**

Address offset: 0xB08 + 0x20 * x, (x = 0 to 5)

Reset value: 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in Figure 892. The application must read this register when the OUT endpoints interrupt bit of the OTG_GINTSTS register (OEPINT bit in OTG_GINTSTS) is set. Before the application can read this register, it must first read the OTG_DAINT register to get the exact endpoint number for the OTG_DOEPINTx register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.

**Bits 31:14 Reserved, must be kept at reset value.**

**Bit 13 NAK: NAK input**

The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

**Bit 12 BERR: Babble error interrupt**

The core generates this interrupt when babble is received for the endpoint.
Bits 11:10  Reserved, must be kept at reset value.
Bit 9   Reserved, must be kept at reset value.
Bit 8   Reserved, must be kept at reset value.
Bit 7   Reserved, must be kept at reset value.
Bit 6   Reserved, must be kept at reset value.
Bit 5   STSPHSRX: Status phase received for control write
This interrupt is valid only for control OUT endpoints. This interrupt is generated only after
OTG_FS has transferred all the data that the host has sent during the data phase of a
control write transfer, to the system memory buffer. The interrupt indicates to the application
that the host has switched from data phase to the status phase of a control write transfer.
The application can use this interrupt to ACK or STALL the status phase, after it has
decoded the data phase.
Bit 4   OTEPDIS: OUT token received when endpoint disabled
Applies only to control OUT endpoints.
Indicates that an OUT token was received when the endpoint was not yet enabled. This
interrupt is asserted on the endpoint for which the OUT token was received.
Bit 3   STUP: SETUP phase done
Applies to control OUT endpoint only. Indicates that the SETUP phase for the control
endpoint is complete and no more back-to-back SETUP packets were received for the
current control transfer. On this interrupt, the application can decode the received SETUP
data packet.
Bit 2   Reserved, must be kept at reset value.
Bit 1   EPDISD: Endpoint disabled interrupt
This bit indicates that the endpoint is disabled per the application’s request.
Bit 0   XFRC: Transfer completed interrupt
This field indicates that the programmed transfer is complete on the AHB as well as on the
USB, for this endpoint.
72.15.51  OTG device OUT endpoint 0 transfer size register
(OTG_DOEPTSIZ0)

Address offset: 0xB10
Reset value: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is
enabled using the endpoint enable bit in the OTG_DOEPCTL0 registers (EPENA bit in
OTG_DOEPCTL0), the core modifies this register. The application can only read this
register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–5.

</table>

Bit 31  Reserved, must be kept at reset value.

Bits 30:29  **STUPCNT[1:0]:** SETUP packet count
This field specifies the number of back-to-back SETUP data packets the endpoint can
receive.
01: 1 packet
10: 2 packets
11: 3 packets

Bits 28:20  Reserved, must be kept at reset value.

Bit 19  **PKTCNT:** Packet count
This field is decremented to zero after a packet is written into the Rx FIFO.

Bits 18:7  Reserved, must be kept at reset value.

Bits 6:0  **XFRSIZ[6:0]:** Transfer size
Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only
after it has exhausted the transfer size amount of data. The transfer size can be set to the
maximum packet size of the endpoint, to be interrupted at the end of each packet.
The core decrements this field every time a packet is read from the Rx FIFO and written to
the external memory.
72.15.52 OTG device OUT endpoint x control register (OTG_DOEPCTLx)

Address offset: 0xB00 + 0x20 * x, (x = 1 to 5)
Reset value: 0x0000 0000

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

### Bit 31 EPENA: Endpoint enable
Applies to IN and OUT endpoints.
The application sets this bit to start transmitting data on an endpoint.
The core clears this bit before setting any of the following interrupts on this endpoint:
– SETUP phase done
– Endpoint disabled
– Transfer completed

### Bit 30 EPDIS: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

### Bit 29 SD1PID: Set DATA1 PID
Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the endpoint data PID (DPID) field in this register to DATA1.

### Bit 28 SD0PID: Set DATA0 PID
Applies to interrupt/bulk OUT endpoints only.
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.

### Bit 27 SNAK: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.
Bit 26 **CNAK**: Clear NAK  
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

**Bit 21** **STALL**: STALL handshake  
Applies to non-control, non-isochronous OUT endpoints only (access type is rw).  
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK  
bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes  
priority. Only the application can clear this bit, never the core.  
Applies to control endpoints only (access type is rs).  
The application can only set this bit, and the core clears it, when a SETUP token is received  
for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit,  
the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to  
SETUP data packets with an ACK handshake.

**Bit 20** **SNPM**: Snoop mode  
This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check  
the correctness of OUT packets before transferring them to application memory.

**Bits 19:18** **EPTYP[1:0]**: Endpoint type  
This is the transfer type supported by this logical endpoint.  
00: Control  
01: Isochronous  
10: Bulk  
11: Interrupt

**Bit 17** **NAKSTS**: NAK status  
Indicates the following:  
0: The core is transmitting non-NAK handshakes based on the FIFO status.  
1: The core is transmitting NAK handshakes on this endpoint.  
When either the application or the core sets this bit:  
The core stops receiving any data on an OUT endpoint, even if there is space in the Rx  
FIFO to accommodate the incoming packet.  
Irrespective of this bit’s setting, the core always responds to SETUP data packets with an  
ACK handshake.

**Bit 16** **EONUM**: Even/odd frame  
Applies to isochronous IN and OUT endpoints only.  
Indicates the frame number in which the core transmits/receives isochronous data for this  
endpoint. The application must program the even/odd frame number in which it intends to  
transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM  
fields in this register.  
0: Even frame  
1: Odd frame

**DPID**: Endpoint data PID  
Applies to interrupt/bulk OUT endpoints only.  
Contains the PID of the packet to be received or transmitted on this endpoint. The  
application must program the PID of the first packet to be received or transmitted on this  
endpoint, after the endpoint is activated. The application uses the SD0PID register field to  
program either DATA0 or DATA1 PID.  
0: DATA0  
1: DATA1
Bit 15 **USBAEP**: USB active endpoint
Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size
The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

**72.15.53 OTG device OUT endpoint x transfer size register (OTG_DOEPTSIZx)**

Address offset: 0xB10 + 0x20 * x, (x = 1 to 5)
Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using endpoint enable bit of the OTG_DOEPCTLx registers (EPENA bit in OTG_DOEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Bits 31:8 Reserved, must be kept at reset value.

- **Bit 7 SUSP**: Deep Sleep
  This bit indicates that the PHY is in Deep Sleep when in L1 state.

- **Bit 6 PHYSLEEP**: PHY in Sleep
  This bit indicates that the PHY is in the Sleep state.
Bit 5 **ENL1GTG**: Enable sleep clock gating
When this bit is set, core internal clock gating is enabled in Sleep state if the core cannot assert utmi_11_suspend_n. When this bit is not set, the PHY clock is not gated in Sleep state.

Bit 4 **PHYSUSP**: PHY suspended
Indicates that the PHY has been suspended. This bit is updated once the PHY is suspended after the application has set the STPPCLK bit.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **GATEHCLK**: Gate HCLK
The application sets this bit to gate HCLK to modules other than the AHB Slave and Master and wake-up logic when the USB is suspended or the session is not valid. The application clears this bit when the USB is resumed or a new session starts.

Bit 0 **STPPCLK**: Stop PHY clock
The application sets this bit to stop the PHY clock when the USB is suspended, the session is not valid, or the device is disconnected. The application clears this bit when the USB is resumed or a new session starts.

Refer to Section 2.3 on page 139 for the register boundary addresses.
72.16 OTG_FS programming model

72.16.1 Core initialization

The application must perform the core initialization sequence. If the cable is connected during power-up, the current mode of operation bit in the OTG_GINTSTS (CMOD bit in OTG_GINTSTS) reflects the mode. The OTG_FS controller enters host mode when an “A” plug is connected or device mode when a “B” plug is connected.

This section explains the initialization of the OTG_FS controller after power-on. The application must follow the initialization sequence irrespective of host or device mode operation. All core global registers are initialized according to the core’s configuration:

1. Program the following fields in the OTG_GAHBCFG register:
   – Global interrupt mask bit GINTMSK = 1
   – Rx FIFO non-empty (RXFLVL bit in OTG_GINTSTS)
   – Periodic Tx FIFO empty level
2. Program the following fields in the OTG_GUSBCFG register:
   – HNP capable bit
   – SRP capable bit
   – OTG_FS timeout calibration field
   – USB turnaround time field
3. The software must unmask the following bits in the OTG_GINTMSK register:
   OTG interrupt mask
   Mode mismatch interrupt mask
4. The software can read the CMOD bit in OTG_GINTSTS to determine whether the OTG_FS controller is operating in host or device mode.
72.16.2 Host initialization

To initialize the core as host, the application must perform the following steps:

1. Program the HPRTINT in the OTG_GINTMSK register to unmask
2. Program the OTG_HCFG register to select full-speed host
3. Program the PPWR bit in OTG_HPRT to 1. This drives $V_{BUS}$ on the USB.
4. Wait for the PCDET interrupt in OTG_HPRT0. This indicates that a device is connecting to the port.
5. Program the PRST bit in OTG_HPRT to 1. This starts the reset process.
6. Wait at least 10 ms for the reset process to complete.
7. Program the PRST bit in OTG_HPRT to 0.
8. Wait for the PENCHNG interrupt in OTG_HPRT.
9. Read the PSPD bit in OTG_HPRT to get the enumerated speed.
10. Program the FSLSPCS field in the OTG_HCFG register following the speed of the device detected in step 9. If FSLSPCS has been changed a port reset must be performed.
11. Program the OTG_GRXFSIZ register to select the size of the receive FIFO.
12. Program the OTG_HNPTXFSIZ register to select the size and the start address of the Non-periodic transmit FIFO for non-periodic transactions.
13. Program the OTG_HPTXFSIZ register to select the size and start address of the periodic transmit FIFO for periodic transactions.

To communicate with devices, the system software must initialize and enable at least one channel.

72.16.3 Device initialization

The application must perform the following steps to initialize the core as a device on power-up or after a mode change from host to device.

1. Program the following fields in the OTG_DCFG register:
   - Device speed
   - Non-zero-length status OUT handshake
   - Periodic Frame Interval
2. Clear the DCTL.SDIS bit. The core issues a connect after this bit is cleared.
3. Program the OTG_GINTMSK register to unmask the following interrupts:
   - USB reset
   - Enumeration done
   - Early suspend
   - USB suspend
   - SOF
4. Wait for the USBRST interrupt in OTG_GINTSTS. It indicates that a reset has been detected on the USB that lasts for about 10 ms on receiving this interrupt.
5. Wait for the ENUMDNE interrupt in OTG_GINTSTS. This interrupt indicates the end of reset on the USB. On receiving this interrupt, the application must read the OTG_DSTS
register to determine the enumeration speed and perform the steps listed in \textit{Endpoint initialization on enumeration completion on page 3247}.

At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0.

\subsection*{72.16.4 Host programming model}

\subsubsection*{Channel initialization}

The application must initialize one or more channels before it can communicate with connected devices. To initialize and enable a channel, the application must perform the following steps:

1. Program the \texttt{OTG\_GINTMSK} register to unmask the following:

2. Channel interrupt
   
   - Non-periodic transmit FIFO empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
   
   - Non-periodic transmit FIFO half-empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).

3. Program the \texttt{OTG\_HINTMSK} register to unmask the selected channels' interrupts.

4. Program the \texttt{OTG\_HCINTMSK} register to unmask the transaction-related interrupts of interest given in the host channel interrupt register.

5. Program the selected channel's \texttt{OTG\_HTSIZEx} register with the total transfer size, in bytes, and the expected number of packets, including short packets. The application must program the PID field with the initial data PID (to be used on the first OUT transaction or to be expected from the first IN transaction).

6. Program the \texttt{OTG\_HCCHARx} register of the selected channel with the device's endpoint characteristics, such as type, speed, direction, and so forth. (The channel can be enabled by setting the channel enable bit to 1 only when the application is ready to transmit or receive any packet).

\subsubsection*{Halting a channel}

The application can disable any channel by programming the \texttt{OTG\_HCCHARx} register with the CHDIS and CHENA bits set to 1. This enables the \texttt{OTG\_FS} host to flush the posted requests (if any) and generates a channel halted interrupt. The application must wait for the CHH interrupt in \texttt{OTG\_HCINTx} before reallocating the channel for other transactions. The \texttt{OTG\_FS} host does not interrupt the transaction that has already been started on the USB.

Before disabling a channel, the application must ensure that there is at least one free space available in the non-periodic request queue (when disabling a non-periodic channel) or the periodic request queue (when disabling a periodic channel). The application can simply flush the posted requests when the request queue is full (before disabling the channel), by programming the \texttt{OTG\_HCCHARx} register with the CHDIS bit set to 1 which automatically clears the CHENA bit to 0.

The application is expected to disable a channel on any of the following conditions:
1. When an STALL, TXERR, BBERR or DTERR interrupt in OTG_HCINTx is received for an IN or OUT channel. The application must be able to receive other interrupts (DTERR, Nak, data, TXERR) for the same channel before receiving the halt.

2. When a DISCINT (disconnect device) interrupt in OTG_GINTSTS is received. (The application is expected to disable all enabled channels).

3. When the application aborts a transfer before normal completion.

**Operational model**

The application must initialize a channel before communicating to the connected device. This section explains the sequence of operation to be performed for different types of USB transactions.

- **Writing the transmit FIFO**
  The OTG_FS host automatically writes an entry (OUT request) to the periodic/non-periodic request queue, along with the last 32-bit word write of a packet. The application must ensure that at least one free space is available in the periodic/non-periodic request queue before starting to write to the transmit FIFO. The application must always write to the transmit FIFO in 32-bit words. If the packet size is non-32-bit word aligned, the application must use padding. The OTG_FS host determines the actual packet size based on the programmed maximum packet size and transfer size.

- **Reading the receive FIFO**
  The application must ignore all packet statuses other than IN data packet (bx0010).

**Figure 893. Transmit FIFO write task**

![Diagram of Transmit FIFO write task](image-url)
• **Bulk and control OUT/SETUP transactions**

A typical bulk or control OUT/SETUP pipelined transaction-level operation is shown in Figure 895. See channel 1 (ch_1). Two bulk OUT packets are transmitted. A control SETUP transaction operates in the same way but has only one packet. The assumptions are:

– The application is attempting to send two maximum-packet-size packets (transfer size = 1,024 bytes).
– The non-periodic transmit FIFO can hold two packets (128 bytes for FS).
– The non-periodic request queue depth = 4.

• **Normal bulk and control OUT/SETUP operations**

The sequence of operations in (channel 1) is as follows:

1. Initialize channel 1
2. Write the first packet for channel 1
3. Along with the last word write, the core writes an entry to the non-periodic request queue
4. As soon as the non-periodic queue becomes non-empty, the core attempts to send an OUT token in the current frame
5. Write the second (last) packet for channel 1
6. The core generates the XFRC interrupt as soon as the last transaction is completed successfully
7. In response to the XFRC interrupt, de-allocate the channel for other transfers
8. Handling non-ACK responses
Figure 895. Normal bulk/control OUT/SETUP

1. The grayed elements are not relevant in the context of this figure.
The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions is shown in the following code samples.

- **Interrupt service routine for bulk/control OUT/SETUP and bulk/control IN transactions**
  
  a) Bulk/control OUT/SETUP

  Unmask (NAK/TXERR/STALL/XFRC)

  if (XFRC)
  {
    Reset Error Count
    Mask ACK
    De-allocate Channel
  }

  else if (STALL)
  {
    Transfer Done = 1
    Unmask CHH
    Disable Channel
  }

  else if (NAK or TXERR )
  {
    Rewind Buffer Pointers
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
      Increment Error Count
      Unmask ACK
    }
  }  

  else
  {
    Reset Error Count
  }

  else if (CHH)
  {
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
      De-allocate Channel
    }
  }  

  else
  {
    Re-initialize Channel
  }
else if (ACK)
{
    Reset Error Count
    Mask ACK
}

The application is expected to write the data packets into the transmit FIFO when the space is available in the transmit FIFO and the request queue. The application can make use of the NPTXFE interrupt in OTG_GINTSTS to find the transmit FIFO space.

b) Bulk/control IN

Unmask (TXERR/XFRC/BBERR/STALL/DERR)
if (XFRC)
{
    Reset Error Count
    Unmask CHH
    Disable Channel
    Reset Error Count
    Mask ACK
}
else if (TXERR or BBERR or STALL)
{
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}
else if (ACK)
{
    Reset Error Count
    Mask ACK
}
else if (DTERR)
{
    Reset Error Count
}

The application is expected to write the requests as and when the request queue space is available and until the XFRC interrupt is received.

- **Bulk and control IN transactions**
  A typical bulk or control IN pipelined transaction-level operation is shown in Figure 896. See channel 2 (ch_2). The assumptions are:
  - The application is attempting to receive two maximum-packet-size packets (transfer size = 1024 bytes).
  - The receive FIFO can contain at least one maximum-packet-size packet and two status words per packet (72 bytes for FS).
  - The non-periodic request queue depth = 4.
Figure 896. Bulk/control IN transactions

1. The grayed elements are not relevant in the context of this figure.
The sequence of operations is as follows:

1. Initialize channel 2.
2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the non-periodic request queue.
3. The core attempts to send an IN token after completing the current OUT transaction.
4. The core generates an RXFLVL interrupt as soon as the received packet is written to the receive FIFO.
5. In response to the RXFLVL interrupt, mask the RXFLVL interrupt and read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. Following this, unmask the RXFLVL interrupt.
6. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO.
7. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in OTG_GRXSTSR ≠ 0b0010).
8. The core generates the XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, disable the channel and stop writing the OTG_HCCHAR2 register for further requests. The core writes a channel disable request to the non-periodic request queue as soon as the OTG_HCCHAR2 register is written.
10. The core generates the RXFLVL interrupt as soon as the halt status is written to the receive FIFO.
11. Read and ignore the receive packet status.
12. The core generates a CHH interrupt as soon as the halt status is popped from the receive FIFO.
13. In response to the CHH interrupt, de-allocate the channel for other transfers.

Handling non-ACK responses

- **Control transactions**
  Setup, data, and status stages of a control transfer must be performed as three separate transfers. setup-, data- or status-stage OUT transactions are performed similarly to the bulk OUT transactions explained previously. Data- or status-stage IN transactions are performed similarly to the bulk IN transactions explained previously. For all three stages, the application is expected to set the EPTYP field in
OTG_HCCCHAR1 to control. During the setup stage, the application is expected to set the PID field in OTG_HCTSIZ1 to SETUP.

- **Interrupt OUT transactions**
  
  A typical interrupt OUT operation is shown in *Figure 897*. The assumptions are:
  
  - The application is attempting to send one packet in every frame (up to 1 maximum packet size), starting with the odd frame (transfer size = 1024 bytes)
  
  - The periodic transmit FIFO can hold one packet (1 Kbyte)

  - Periodic request queue depth = 4

  The sequence of operations is as follows:

  1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG_HCCCHAR1.
  2. Write the first packet for channel 1.
  3. Along with the last word write of each packet, the OTG_FS host writes an entry to the periodic request queue.
  4. The OTG_FS host attempts to send an OUT token in the next (odd) frame.
  5. The OTG_FS host generates an XFRC interrupt as soon as the last packet is transmitted successfully.
  6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
Figure 897. Normal interrupt OUT

1. The grayed elements are not relevant in the context of this figure.

- **Interrupt service routine for interrupt OUT/IN transactions**
  
  a) **Interrupt OUT**

Unmask (NAK/TXERR/STALL/XFRC/FRMOR)
if (XFRC) {
    Reset Error Count
    Mask ACK
    De-allocate Channel
} else if (STALL or FRMOR) {
    Mask ACK
    Unmask CHH
    Disable Channel
    if (STALL) {
        Transfer Done = 1
    }
} else if (NAK or TXERR) {
    Rewind Buffer Pointers
    Reset Error Count
    Mask ACK
    Unmask CHH
    Disable Channel
} else if (CHH) {
    Mask CHH
    if (Transfer Done or (Error_count == 3)) {
        De-allocate Channel
    } else {
        Re-initialize Channel (in next b_interval - 1 Frame)
    }
} else if (ACK) {
    Reset Error Count
    Mask ACK
}
The application uses the NPTXFE interrupt in OTG_GINTSTS to find the transmit FIFO space.

Interrupt IN

Unmask (NAK/TXERR/XFRC/BBERR/STALL/FRMOR/DTERR)

if (XFRC)
{
  Reset Error Count
  Mask ACK
  if (OTG_HCTSIZx.PKTCNT == 0)
  {
    De-allocate Channel
  }
else
{
  Transfer Done = 1
  Unmask CHH
  Disable Channel
  }
}
else
if (STALL or FRMOR or NAK or DTERR or BBERR)
{
  Mask ACK
  Unmask CHH
  Disable Channel
  if (STALL or BBERR)
  {
    Reset Error Count
    Transfer Done = 1
  }
else
  if (!FRMOR)
  {
    Reset Error Count
  }
}
else
if (TXERR)
{

  Unmask ACK
  Unmask CHH
  Disable Channel
}
else
if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    Re-initialize Channel (in next b_interval - 1 /Frame)
}
else

if (ACK)
{
    Reset Error Count
    Mask ACK
}

• **Interrupt IN transactions**
  The assumptions are:
  – The application is attempting to receive one packet (up to 1 maximum packet size) in every frame, starting with odd (transfer size = 1 024 bytes).
  – The receive FIFO can hold at least one maximum-packet-size packet and two status words per packet (1 031 bytes).
  – Periodic request queue depth = 4.
• **Normal interrupt IN operation**
  The sequence of operations is as follows:
  1. Initialize channel 2. The application must set the ODDFRM bit in OTG_HCCHAR2.
  2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the periodic request queue.
  3. The OTG_FS host writes an IN request to the periodic request queue for each OTG_HCCHAR2 register write with the CHENA bit set.
  4. The OTG_FS host attempts to send an IN token in the next (odd) frame.
  5. As soon as the IN packet is received and written to the receive FIFO, the OTG_FS host generates an RXFLVL interrupt.
  6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask after reading the entire packet.
  7. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in GRXSTSR ≠ 0b0010).
  8. The core generates an XFRC interrupt as soon as the receive packet status is read.
  9. In response to the XFRC interrupt, read the PKTCNT field in OTG_HCTSIZ2. If the PKTCNT bit in OTG_HCTSIZ2 is not equal to 0, disable the channel before re-
initializing the channel for the next transfer, if any). If PKTCNT bit in OTG_HCTSIZ2 = 0, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG_HCCHAR2.
Figure 898. Normal interrupt IN

1. The grayed elements are not relevant in the context of this figure.

- **Isochronous OUT transactions**

  A typical isochronous OUT operation is shown in Figure 899. The assumptions are:
  - The application is attempting to send one packet every frame (up to 1 maximum...
packet size), starting with an odd frame. (transfer size = 1 024 bytes).

– The periodic transmit FIFO can hold one packet (1 Kbyte).
– Periodic request queue depth = 4.

The sequence of operations is as follows:

1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG_HCCCHAR1.
2. Write the first packet for channel 1.
3. Along with the last word write of each packet, the OTG_FS host writes an entry to the periodic request queue.
4. The OTG_FS host attempts to send the OUT token in the next frame (odd).
5. The OTG_FS host generates the XFRC interrupt as soon as the last packet is transmitted successfully.
6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
7. Handling non-ACK responses

- Isochronous IN transactions
  The assumptions are:
  - The application is attempting to receive one packet (up to 1 maximum packet size) in every frame starting with the next odd frame (transfer size = 1 024 bytes).
  - The receive FIFO can hold at least one maximum-packet-size packet and two status word per packet (1 031 bytes).
  - Periodic request queue depth = 4.

The sequence of operations is as follows:

1. Initialize channel 2. The application must set the ODDFRM bit in OTG_HCCCHAR2.
2. Set the CHENA bit in OTG_HCCCHAR2 to write an IN request to the periodic request queue.
3. The OTG_FS host writes an IN request to the periodic request queue for each OTG_HCCCHAR2 register write with the CHENA bit set.
4. The OTG_FS host attempts to send an IN token in the next odd frame.
5. As soon as the IN packet is received and written to the receive FIFO, the OTG_FS host generates an RXFLVL interrupt.
6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask it after reading the entire packet.
7. The core generates an RXFLVL interrupt for the transfer completion status entry in the receive FIFO. This time, the application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS bit in OTG_GRXSTSR ≠ 0b0010).
8. The core generates an XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, read the PKTCNT field in OTG_HCTSIZ2. If PKTCNT ≠ 0 in OTG_HCTSIZ2, disable the channel before re-initializing the channel for the next transfer, if any. If PKTCNT = 0 in OTG_HCTSIZ2, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG_HCCCHAR2.
1. The grayed elements are not relevant in the context of this figure.

- **Selecting the queue depth**

  Choose the periodic and non-periodic request queue depths carefully to match the number of periodic/non-periodic endpoints accessed.

  The non-periodic request queue depth affects the performance of non-periodic
transfers. The deeper the queue (along with sufficient FIFO size), the more often the core is able to pipeline non-periodic transfers. If the queue size is small, the core is able to put in new requests only when the queue space is freed up.

The core’s periodic request queue depth is critical to perform periodic transfers as scheduled. Select the periodic queue depth, based on the number of periodic transfers scheduled in a microframe. If the periodic request queue depth is smaller than the periodic transfers scheduled in a microframe, a frame overrun condition occurs.

- **Handling babble conditions**

  OTG_FS controller handles two cases of babble: packet babble and port babble. Packet babble occurs if the device sends more data than the maximum packet size for the channel. Port babble occurs if the core continues to receive data from the device at EOF2 (the end of frame 2, which is very close to SOF).

  When OTG_FS controller detects a packet babble, it stops writing data into the Rx buffer and waits for the end of packet (EOP). When it detects an EOP, it flushes already written data in the Rx buffer and generates a Babble interrupt to the application.

  When OTG_FS controller detects a port babble, it flushes the Rx FIFO and disables the port. The core then generates a port disabled interrupt (HPRTINT in OTG_GINTSTS, PENCHNG in OTG_HPRT). On receiving this interrupt, the application must determine that this is not due to an overcurrent condition (another cause of the port disabled interrupt) by checking POCA in OTG_HPRT, then perform a soft reset. The core does not send any more tokens after it has detected a port babble condition.

### 72.16.5 Device programming model

**Endpoint initialization on USB reset**

1. Set the NAK bit for all OUT endpoints
   - SNAK = 1 in OTG_DOEPCTLx (for all OUT endpoints)

2. Unmask the following interrupt bits
   - INEP0 = 1 in OTG_DAINTMSK (control 0 IN endpoint)
   - OUTEP0 = 1 in OTG_DAINTMSK (control 0 OUT endpoint)
   - STUPM = 1 in OTG_DOEPMSK
   - XFRCM = 1 in OTG_DOEPMSK
   - XFRCM = 1 in OTG_DIEPMSK
   - TOM = 1 in OTG_DIEPMSK

3. Set up the data FIFO RAM for each of the FIFOs
   - Program the OTG_GRXFSIZ register, to be able to receive control OUT data and setup data. If thresholding is not enabled, at a minimum, this must be equal to 1 max packet size of control endpoint 0 + 2 words (for the status of the control OUT data packet) + 10 words (for setup packets).
   - Program the OTG_DIEPTXF0 register (depending on the FIFO number chosen) to be able to transmit control IN data. At a minimum, this must be equal to 1 max packet size of control endpoint 0.

4. Program the following fields in the endpoint-specific registers for control OUT endpoint 0 to receive a SETUP packet
   - STUPCNT = 3 in OTG_DOEPTSIZ0 (to receive up to 3 back-to-back SETUP packets)
At this point, all initialization required to receive SETUP packets is done.

**Endpoint initialization on enumeration completion**

1. On the Enumeration Done interrupt (ENUMDNE in OTG_GINTSTS), read the OTG_DSTS register to determine the enumeration speed.
2. Program the MPSIZ field in OTG_DIEPCTL0 to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for a control endpoint depends on the enumeration speed.

At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

**Endpoint initialization on SetAddress command**

This section describes what the application must do when it receives a SetAddress command in a SETUP packet.

1. Program the OTG_DCFG register with the device address received in the SetAddress command
2. Program the core to send out a status IN packet

**Endpoint initialization on SetConfiguration/SetInterface command**

This section describes what the application must do when it receives a SetConfiguration or SetInterface command in a SETUP packet.

1. When a SetConfiguration command is received, the application must program the endpoint registers to configure them with the characteristics of the valid endpoints in the new configuration.
2. When a SetInterface command is received, the application must program the endpoint registers of the endpoints affected by this command.
3. Some endpoints that were active in the prior configuration or alternate setting are not valid in the new configuration or alternate setting. These invalid endpoints must be deactivated.
4. Unmask the interrupt for each active endpoint and mask the interrupts for all inactive endpoints in the OTG_DAINTMSK register.
5. Set up the data FIFO RAM for each FIFO.
6. After all required endpoints are configured; the application must program the core to send a status IN packet.

At this point, the device core is configured to receive and transmit any type of data packet.

**Endpoint activation**

This section describes the steps required to activate a device endpoint or to configure an existing device endpoint to a new type.
1. Program the characteristics of the required endpoint into the following fields of the OTG_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG_DOEPCTLx register (for OUT or bidirectional endpoints).
   - Maximum packet size
   - USB active endpoint = 1
   - Endpoint start data toggle (for interrupt and bulk endpoints)
   - Endpoint type
   - Tx FIFO number

2. Once the endpoint is activated, the core starts decoding the tokens addressed to that endpoint and sends out a valid handshake for each valid token received for the endpoint.

**Endpoint deactivation**

This section describes the steps required to deactivate an existing endpoint.

1. In the endpoint to be deactivated, clear the USB active endpoint bit in the OTG_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG_DOEPCTLx register (for OUT or bidirectional endpoints).

2. Once the endpoint is deactivated, the core ignores tokens addressed to that endpoint, which results in a timeout on the USB.

*Note:* The application must meet the following conditions to set up the device core to handle traffic:
NPTXFEM and RXFLVLM in the OTG_GINTMSK register must be cleared.

**Operational model**

SETUP and OUT data transfers:

This section describes the internal data flow and application-level operations during data OUT transfers and SETUP transactions.

- **Packet read**

This section describes how to read packets (OUT data and SETUP packets) from the receive FIFO.

1. On catching an RXFLVL interrupt (OTG_GINTSTS register), the application must read the receive status pop register (OTG_GRXSTSP).

2. The application can mask the RXFLVL interrupt (in OTG_GINTSTS) by writing to RXFLVLM = 0 (in OTG_GINTMSK), until it has read the packet from the receive FIFO.

3. If the received packet’s byte count is not 0, the byte count amount of data is popped from the receive data FIFO and stored in memory. If the received packet byte count is 0, no data is popped from the receive data FIFO.

4. The receive status readout of the packet of FIFO indicates one of the following:
   a) Global OUT NAK pattern:
      PKTSTS = Global OUT NAK, BCNT = 0x000, EPNUM = (0x0), DPID = (0b00).
      These data indicate that the global OUT NAK bit has taken effect.
   b) SETUP packet pattern:
      PKTSTS = SETUP, BCNT = 0x008, EPNUM = Control EP Num,
DPID = DATA0. These data indicate that a SETUP packet for the specified endpoint is now available for reading from the receive FIFO.

c) Setup stage done pattern:
PKTSTS = Setup Stage Done, BCNT = 0x0, EPNUM = Control EP Num, DPID = (0b00).
These data indicate that the setup stage for the specified endpoint has completed and the data stage has started. After this entry is popped from the receive FIFO, the core asserts a setup interrupt on the specified control OUT endpoint.

d) Data OUT packet pattern:
PKTSTS = Data OUT, BCNT = size of the received data OUT packet (0 ≤ BCNT ≤ 1 024), EPNUM = EPNUM on which the packet was received, DPID = Actual Data PID.

e) Data transfer completed pattern:
PKTSTS = Data OUT transfer done, BCNT = 0x0, EPNUM = OUT EP Num on which the data transfer is complete, DPID = (0b00).
These data indicate that an OUT data transfer for the specified OUT endpoint has completed. After this entry is popped from the receive FIFO, the core asserts a transfer completed interrupt on the specified OUT endpoint.

5. After the data payload is popped from the receive FIFO, the RXFLVL interrupt (OTG_GINTSTS) must be unmasked.

6. Steps 1–5 are repeated every time the application detects assertion of the interrupt line due to RXFLVL in OTG_GINTSTS. Reading an empty receive FIFO can result in undefined core behavior.

Figure 901 provides a flowchart of the above procedure.
This section describes how the core handles SETUP packets and the application’s sequence for handling SETUP transactions.

**Application requirements**

1. To receive a SETUP packet, the STUPCNT field (OTG_DOEPTSIZx) in a control OUT endpoint must be programmed to a non-zero value. When the application programs the STUPCNT field to a non-zero value, the core receives SETUP packets and writes them to the receive FIFO, irrespective of the NAK status and EPENA bit setting in OTG_DOEPCTLx. The STUPCNT field is decremented every time the control endpoint receives a SETUP packet. If the STUPCNT field is not programmed to a proper value before receiving a SETUP packet, the core still receives the SETUP packet and decrements the STUPCNT field, but the application may not be able to determine the correct number of SETUP packets received in the setup stage of a control transfer.
   
   - STUPCNT = 3 in OTG_DOEPTSIZx

2. The application must always allocate some extra space in the receive data FIFO, to be able to receive up to three SETUP packets on a control endpoint.
   
   - The space to be reserved is 10 words. Three words are required for the first SETUP packet, 1 word is required for the setup stage done word and 6 words are required to store two extra SETUP packets among all control endpoints.
   
   - 3 words per SETUP packet are required to store 8 bytes of SETUP data and 4 bytes of SETUP status (setup packet pattern). The core reserves this space in the receive data FIFO to write SETUP data only, and never uses this space for data packets.

3. The application must read the 2 words of the SETUP packet from the receive FIFO.
4. The application must read and discard the setup stage done word from the receive FIFO.

**Internal data flow**

1. When a SETUP packet is received, the core writes the received data to the receive FIFO, without checking for available space in the receive FIFO and irrespective of the endpoint’s NAK and STALL bit settings.
   
   - The core internally sets the IN NAK and OUT NAK bits for the control IN/OUT endpoints on which the SETUP packet was received.

2. For every SETUP packet received on the USB, 3 words of data are written to the receive FIFO, and the STUPCNT field is decremented by 1.
   
   - The first word contains control information used internally by the core
   
   - The second word contains the first 4 bytes of the SETUP command
   
   - The third word contains the last 4 bytes of the SETUP command

3. When the setup stage changes to a data IN/OUT stage, the core writes an entry (setup stage done word) to the receive FIFO, indicating the completion of the setup stage.
4. On the AHB side, SETUP packets are emptied by the application.
5. When the application pops the setup stage done word from the receive FIFO, the core interrupts the application with an STUP interrupt (OTG_DOEPINTx), indicating it can process the received SETUP packet.
6. The core clears the endpoint enable bit for control OUT endpoints.

**Application programming sequence**
1. Program the OTG_DOEPETSIZx register.
   – STUPCNT = 3
2. Wait for the RXFLVL interrupt (OTG_GINTSTS) and empty the data packets from the receive FIFO.
3. Assertion of the STUP interrupt (OTG_DOEPINTx) marks a successful completion of the SETUP data transfer.
   – On this interrupt, the application must read the OTG_DOEPETSIZx register to determine the number of SETUP packets received and process the last received SETUP packet.

**Figure 902. Processing a SETUP packet**

- **Handling more than three back-to-back SETUP packets**
  Per the USB 2.0 specification, normally, during a SETUP packet error, a host does not send more than three back-to-back SETUP packets to the same endpoint. However, the USB 2.0 specification does not limit the number of back-to-back SETUP packets a host can send to the same endpoint. When this condition occurs, the OTG_FS controller generates an interrupt (B2BSTUP in OTG_DOEPINTx).

- **Setting the global OUT NAK**
  Internal data flow:
  1. When the application sets the Global OUT NAK (SGONAK bit in OTG_DCTL), the core stops writing data, except SETUP packets, to the receive FIFO. Irrespective of the
space availability in the receive FIFO, non-isochronous OUT tokens receive a NAK handshake response, and the core ignores isochronous OUT data packets.

2. The core writes the Global OUT NAK pattern to the receive FIFO. The application must reserve enough receive FIFO space to write this data pattern.

3. When the application pops the Global OUT NAK pattern word from the receive FIFO, the core sets the GONAKEFF interrupt (OTG_GINTSTS).

4. Once the application detects this interrupt, it can assume that the core is in Global OUT NAK mode. The application can clear this interrupt by clearing the SGONAK bit in OTG_DCTL.

Application programming sequence:

1. To stop receiving any kind of data in the receive FIFO, the application must set the Global OUT NAK bit by programming the following field:
   - SGONAK = 1 in OTG_DCTL

2. Wait for the assertion of the GONAKEFF interrupt in OTG_GINTSTS. When asserted, this interrupt indicates that the core has stopped receiving any type of data except SETUP packets.

3. The application can receive valid OUT packets after it has set SGONAK in OTG_DCTL and before the core asserts the GONAKEFF interrupt (OTG_GINTSTS).

4. The application can temporarily mask this interrupt by writing to the GONAKEFFM bit in the OTG_GINTMSK register.
   - GONAKEFFM = 0 in the OTG_GINTMSK register

5. Whenever the application is ready to exit the Global OUT NAK mode, it must clear the SGONAK bit in OTG_DCTL. This also clears the GONAKEFF interrupt (OTG_GINTSTS).
   - CGONAK = 1 in OTG_DCTL

6. If the application has masked this interrupt earlier, it must be unmasked as follows:
   - GONAKEFFM = 1 in OTG_GINTMSK

• **Disabling an OUT endpoint**

The application must use this sequence to disable an OUT endpoint that it has enabled.

Application programming sequence:
1. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core.
   - SGONAK = 1 in OTG_DCTL
2. Wait for the GONAKEFF interrupt (OTG_GINTSTS)
3. Disable the required OUT endpoint by programming the following fields:
   - EPDIS = 1 in OTG_DOEPCTLx
   - SNAK = 1 in OTG_DOEPCTLx
4. Wait for the EPDISD interrupt (OTG_DOEPINTx), which indicates that the OUT endpoint is completely disabled. When the EPDISD interrupt is asserted, the core also clears the following bits:
   - EPDIS = 0 in OTG_DOEPCTLx
   - EPENA = 0 in OTG_DOEPCTLx
5. The application must clear the Global OUT NAK bit to start receiving data from other non-disabled OUT endpoints.
   - SGONAK = 0 in OTG_DCTL

• Transfer Stop Programming for OUT endpoints

The application must use the following programing sequence to stop any transfers (because of an interrupt from the host, typically a reset).

Sequence of operations:
1. Enable all OUT endpoints by setting
   - EPENA = 1 in all OTG_DOEPCTLx registers.
2. Flush the RxFIFO as follows
   - Poll OTG_GRSTCTL_AHBIDL until it is 1. This indicates that AHB master is idle.
   - Perform read modify write operation on OTG_GRSTCTL_RXFFLSH = 1
   - Poll OTG_GRSTCTL_RXFFLSH until it is 0, but also using a timeout of less than 10 milli-seconds (corresponds to minimum reset signaling duration). If 0 is seen before the timeout, then the RxFIFO flush is successful. If at the moment the timeout occurs, there is still a 1, (this may be due to a packet on EP0 coming from the host) then go back (once only) to the previous step (“Perform read modify write operation”).
3. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core, according to the instructions in “Setting the global OUT NAK on page 3251”. This ensures that data in the RxFIFO is sent to the application successfully. Set SGONAK = 1 in OTG_DCTL
4. Wait for the GONAKEFF interrupt (OTG_GINTSTS)
5. Disable all active OUT endpoints by programming the following register bits:
   - EPDIS = 1 in registers OTG_DOEPCTLx
   - SNAK = 1 in registers OTG_DOEPCTLx
6. Wait for the EPDIS interrupt in OTG_DOEPINTx for each OUT endpoint programmed in the previous step. The EPDIS interrupt in OTG_DOEPINTx indicates that the
corresponding OUT endpoint is completely disabled. When the EPDIS interrupt is asserted, the following bits are cleared:

- EPENA = 0 in registers OTG_DOEPCTLx
- EPDIS = 0 in registers OTG_DOEPCTLx
- SNAK = 0 in registers OTG_DOEPCTLx

- **Generic non-isochronous OUT data transfers**

This section describes a regular non-isochronous OUT data transfer (control, bulk, or interrupt).

**Application requirements:**

1. Before setting up an OUT transfer, the application must allocate a buffer in the memory to accommodate all data to be received as part of the OUT transfer.
2. For OUT transfers, the transfer size field in the endpoint’s transfer size register must be a multiple of the maximum packet size of the endpoint, adjusted to the word boundary.
   - transfer size[EPNUM] = \( n \times (\text{MPSIZ}[\text{EPNUM}] + 4 – (\text{MPSIZ}[\text{EPNUM}] \mod 4)) \)
   - packet count[EPNUM] = \( n \)
   - \( n > 0 \)
3. On any OUT endpoint interrupt, the application must read the endpoint’s transfer size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
   - Payload size in memory = application programmed initial transfer size – core updated final transfer size
   - Number of USB packets in which this payload was received = application programmed initial packet count – core updated final packet count

**Internal data flow:**

1. The application must set the transfer size and packet count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
2. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the packet count field for that endpoint by 1.
   - OUT data packets received with bad data CRC are flushed from the receive FIFO automatically.
   - After sending an ACK for the packet on the USB, the core discards non-isochronous OUT data packets that the host, which cannot detect the ACK, resends. The application does not detect multiple back-to-back data OUT packets on the same endpoint with the same data PID. In this case the packet count is not decremented.
   - If there is no space in the receive FIFO, isochronous or non-isochronous data packets are ignored and not written to the receive FIFO. Additionally, non-isochronous OUT tokens receive a NAK handshake reply.
   - In all the above three cases, the packet count is not decremented because no data are written to the receive FIFO.
3. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or non-isochronous data packets are ignored and not written to the receive FIFO, and non-isochronous OUT tokens receive a NAK handshake reply.

4. After the data are written to the receive FIFO, the application reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.

5. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.

6. The OUT data transfer completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions:
   - The transfer size is 0 and the packet count is 0
   - The last OUT data packet written to the receive FIFO is a short packet (0 ≤ packet size < maximum packet size)

7. When either the application pops this entry (OUT data transfer completed), a transfer completed interrupt is generated for the endpoint and the endpoint enable is cleared.

Application programming sequence:
1. Program the OTG_DOEPTSIZx register for the transfer size and the corresponding packet count.
2. Program the OTG_DOEPCTLx register with the endpoint characteristics, and set the EPENA and CNAK bits.
   - EPENA = 1 in OTG_DOEPCTLx
   - CNAK = 1 in OTG_DOEPCTLx
3. Wait for the RXFLVL interrupt (in OTG_GINTSTS) and empty the data packets from the receive FIFO.
   - This step can be repeated many times, depending on the transfer size.
4. Asserting the XFRC interrupt (OTG_DOEPINTx) marks a successful completion of the non-isochronous OUT data transfer.
5. Read the OTG_DOEPTSIZx register to determine the size of the received data payload.

- **Generic isochronous OUT data transfer**

This section describes a regular isochronous OUT data transfer.

Application requirements:
1. All the application requirements for non-isochronous OUT data transfers also apply to isochronous OUT data transfers.
2. For isochronous OUT data transfers, the transfer size and packet count fields must always be set to the number of maximum-packet-size packets that can be received in a single frame and no more. Isochronous OUT data transfers cannot span more than 1 frame.
3. The application must read all isochronous OUT data packets from the receive FIFO (data and status) before the end of the periodic frame (EOPF interrupt in OTG_GINTSTS).
4. To receive data in the following frame, an isochronous OUT endpoint must be enabled after the EOPF (OTG_GINTSTS) and before the SOF (OTG_GINTSTS).

Internal data flow:
1. The internal data flow for isochronous OUT endpoints is the same as that for non-isochronous OUT endpoints, but for a few differences.

2. When an isochronous OUT endpoint is enabled by setting the endpoint enable and clearing the NAK bits, the Even/Odd frame bit must also be set appropriately. The core receives data on an isochronous OUT endpoint in a particular frame only if the following condition is met:
   \[ \text{EONUM (in OTG_DOEPCTLx)} = \text{FNSOF}[0] \text{ (in OTG_DSTS)} \]

3. When the application completely reads an isochronous OUT data packet (data and status) from the receive FIFO, the core updates the RXDPID field in OTG_DOEPTSIZx with the data PID of the last isochronous OUT data packet read from the receive FIFO.

Application programming sequence:

1. Program the OTG_DOEPTSIZx register for the transfer size and the corresponding packet count

2. Program the OTG_DOEPCTLx register with the endpoint characteristics and set the endpoint enable, ClearNAK, and Even/Odd frame bits.
   \[ \text{EPENA} = 1 \]
   \[ \text{CNAK} = 1 \]
   \[ \text{EONUM} = (0: \text{Even}/1: \text{Odd}) \]

3. Wait for the RXFLVL interrupt (in OTG_GINTSTS) and empty the data packets from the receive FIFO
   \[ \text{This step can be repeated many times, depending on the transfer size.} \]

4. The assertion of the XFRC interrupt (in OTG_DOEPINTx) marks the completion of the isochronous OUT data transfer. This interrupt does not necessarily mean that the data in memory are good.

5. This interrupt cannot always be detected for isochronous OUT transfers. Instead, the application can detect the INCOMPISOOUT interrupt in OTG_GINTSTS.

6. Read the OTG_DOEPTSIZx register to determine the size of the received transfer and to determine the validity of the data received in the frame. The application must treat the data received in memory as valid only if one of the following conditions is met:
   \[ \text{RXDPID} = \text{DATA0 (in OTG_DOEPTSIZx)} \text{ and the number of USB packets in which this payload was received} = 1 \]
   \[ \text{RXDPID} = \text{DATA1 (in OTG_DOEPTSIZx)} \text{ and the number of USB packets in which this payload was received} = 2 \]
   \[ \text{The number of USB packets in which this payload was received} = \text{Application programmed initial packet count} - \text{core updated final packet count} \]
   \[ \text{The application can discard invalid data packets.} \]

- Incomplete isochronous OUT data transfers

This section describes the application programming sequence when isochronous OUT data packets are dropped inside the core.

Internal data flow:

1. For isochronous OUT endpoints, the XFRC interrupt (in OTG_DOEPINTx) may not always be asserted. If the core drops isochronous OUT data packets, the application
may fail to detect the XFRC interrupt (OTG_DOEPINTx) under the following circumstances:

- When the receive FIFO cannot accommodate the complete ISO OUT data packet, the core drops the received ISO OUT data
- When the isochronous OUT data packet is received with CRC errors
- When the isochronous OUT token received by the core is corrupted
- When the application is very slow in reading the data from the receive FIFO

2. When the core detects an end of periodic frame before transfer completion to all isochronous OUT endpoints, it asserts the incomplete isochronous OUT data interrupt (INCOMPISOOUT in OTG_GINTSTS), indicating that an XFRC interrupt (in OTG_DOEPINTx) is not asserted on at least one of the isochronous OUT endpoints. At this point, the endpoint with the incomplete transfer remains enabled, but no active transfers remain in progress on this endpoint on the USB.

Application programming sequence:

1. Asserting the INCOMPISOOUT interrupt (OTG_GINTSTS) indicates that in the current frame, at least one isochronous OUT endpoint has an incomplete transfer.

2. If this occurs because isochronous OUT data is not completely emptied from the endpoint, the application must ensure that the application empties all isochronous OUT data (data and status) from the receive FIFO before proceeding.
   - When all data are emptied from the receive FIFO, the application can detect the XFRC interrupt (OTG_DOEPINTx). In this case, the application must re-enable the endpoint to receive isochronous OUT data in the next frame.

3. When it receives an INCOMPISOOUT interrupt (in OTG_GINTSTS), the application must read the control registers of all isochronous OUT endpoints (OTG_DOEPCTLx) to determine which endpoints had an incomplete transfer in the current microframe. An endpoint transfer is incomplete if both the following conditions are met:
   - EONUM bit (in OTG_DOEPCTLx) = FNSOF[0] (in OTG_DSTS)
   - EPENA = 1 (in OTG_DOEPCTLx)

4. The previous step must be performed before the SOF interrupt (in OTG_GINTSTS) is detected, to ensure that the current frame number is not changed.

5. For isochronous OUT endpoints with incomplete transfers, the application must discard the data in the memory and disable the endpoint by setting the EPDIS bit in OTG_DOEPCTLx.

6. Wait for the EPDISD interrupt (in OTG_DOEPINTx) and enable the endpoint to receive new data in the next frame.
   - Because the core can take some time to disable the endpoint, the application may not be able to receive the data in the next frame after receiving bad isochronous data.

- **Stalling a non-isochronous OUT endpoint**

  This section describes how the application can stall a non-isochronous endpoint.
1. Put the core in the Global OUT NAK mode.
2. Disable the required endpoint
   - When disabling the endpoint, instead of setting the SNAK bit in OTG_DOEPCTL, set STALL = 1 (in OTG_DOEPCTL).
     The STALL bit always takes precedence over the NAK bit.
3. When the application is ready to end the STALL handshake for the endpoint, the STALL bit (in OTG_DOEPCTLx) must be cleared.
4. If the application is setting or clearing a STALL for an endpoint due to a SetFeature.Endpoint Halt or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the status stage transfer on the control endpoint.

Examples

This section describes and depicts some fundamental transfer types and scenarios.
- Bulk OUT transaction

*Figure 903* depicts the reception of a single Bulk OUT data packet from the USB to the AHB and describes the events involved in the process.

**Figure 903. Bulk OUT transaction**

After a SetConfiguration/SetInterface command, the application initializes all OUT endpoints by setting CNAK = 1 and EPENA = 1 (in OTG_DOEPCTLx), and setting a suitable XFRSIZ and PKTCNT in the OTG_DOEPTSIZx register.
1. host attempts to send data (OUT token) to an endpoint.
2. When the core receives the OUT token on the USB, it stores the packet in the Rx FIFO because space is available there.
3. After writing the complete packet in the Rx FIFO, the core then asserts the RXFLVL interrupt (in OTG_GINTSTS).
4. On receiving the PKTCNT number of USB packets, the core internally sets the NAK bit for this endpoint to prevent it from receiving any more packets.
5. The application processes the interrupt and reads the data from the Rx FIFO.
6. When the application has read all the data (equivalent to XFRSIZ), the core generates an XFRC interrupt (in OTG_DOEPINTx).
7. The application processes the interrupt and uses the setting of the XFRC interrupt bit (in OTG_DOEPINTx) to determine that the intended transfer is complete.

IN data transfers

- Packet write

This section describes how the application writes data packets to the endpoint FIFO when dedicated transmit FIFOs are enabled.

1. The application can either choose the polling or the interrupt mode.
   - In polling mode, the application monitors the status of the endpoint transmit data FIFO by reading the OTG_DTXFSTSx register, to determine if there is enough space in the data FIFO.
   - In interrupt mode, the application waits for the TXFE interrupt (in OTG_DIEPINTx) and then reads the OTG_DTXFSTSx register, to determine if there is enough space in the data FIFO.
   - To write a single non-zero length data packet, there must be space to write the entire packet in the data FIFO.
   - To write zero length packet, the application must not look at the FIFO space.

2. Using one of the above mentioned methods, when the application determines that there is enough space to write a transmit packet, the application must first write into the endpoint control register, before writing the data into the data FIFO. Typically, the application, must do a read modify write on the OTG_DIEPCTLx register to avoid modifying the contents of the register, except for setting the endpoint enable bit.

The application can write multiple packets for the same endpoint into the transmit FIFO, if space is available. For periodic IN endpoints, the application must write packets only for one microframe. It can write packets for the next periodic transaction only after getting transfer complete for the previous transaction.

- Setting IN endpoint NAK

Internal data flow:
1. When the application sets the IN NAK for a particular endpoint, the core stops transmitting data on the endpoint, irrespective of data availability in the endpoint’s transmit FIFO.

2. Non-isochronous IN tokens receive a NAK handshake reply
   - Isochronous IN tokens receive a zero-data-length packet reply

3. The core asserts the INEPNE (IN endpoint NAK effective) interrupt in OTG_DIEPINTx in response to the SNAK bit in OTG_DIEPCTLx.

4. Once this interrupt is seen by the application, the application can assume that the endpoint is in IN NAK mode. This interrupt can be cleared by the application by setting the CNAK bit in OTG_DIEPCTLx.

Application programming sequence:

1. To stop transmitting any data on a particular IN endpoint, the application must set the IN NAK bit. To set this bit, the following field must be programmed.
   - SNAK = 1 in OTG_DIEPCTLx

2. Wait for assertion of the INEPNE interrupt in OTG_DIEPINTx. This interrupt indicates that the core has stopped transmitting data on the endpoint.

3. The core can transmit valid IN data on the endpoint after the application has set the NAK bit, but before the assertion of the NAK Effective interrupt.

4. The application can mask this interrupt temporarily by writing to the INEPNEM bit in OTG_DIEPMSK.
   - INEPNEM = 0 in OTG_DIEPMSK

5. To exit endpoint NAK mode, the application must clear the NAK status bit (NAKSTS) in OTG_DIEPCTLx. This also clears the INEPNE interrupt (in OTG_DIEPINTx).
   - CNAK = 1 in OTG_DIEPCTLx

6. If the application masked this interrupt earlier, it must be unmasked as follows:
   - INEPNEM = 1 in OTG_DIEPMSK

- **IN endpoint disable**

Use the following sequence to disable a specific IN endpoint that has been previously enabled.

Application programming sequence:
1. The application must stop writing data on the AHB for the IN endpoint to be disabled.
2. The application must set the endpoint in NAK mode.
   - SNAK = 1 in OTG_DIEPCTLx
3. Wait for the INEPNE interrupt in OTG_DIEPINTx.
4. Set the following bits in the OTG_DIEPCTLx register for the endpoint that must be disabled.
   - EPDIS = 1 in OTG_DIEPCTLx
   - SNAK = 1 in OTG_DIEPCTLx
5. Assertion of the EPDISD interrupt in OTG_DIEPINTx indicates that the core has completely disabled the specified endpoint. Along with the assertion of the interrupt, the core also clears the following bits:
   - EPENA = 0 in OTG_DIEPCTLx
   - EPDIS = 0 in OTG_DIEPCTLx
6. The application must read the OTG_DIEPTSIZx register for the periodic IN EP, to calculate how much data on the endpoint were transmitted on the USB.
7. The application must flush the data in the endpoint transmit FIFO, by setting the following fields in the OTG_GRSTCTL register:
   - TXFNUM (in OTG_GRSTCTL) = Endpoint transmit FIFO number
   - TXFFLSH in (OTG_GRSTCTL) = 1
   The application must poll the OTG_GRSTCTL register, until the TXFFLSH bit is cleared by the core, which indicates the end of flush operation. To transmit new data on this endpoint, the application can re-enable the endpoint at a later point.

- **Transfer Stop Programming for IN endpoints**
  The application must use the following programming sequence to stop any transfers (because of an interrupt from the host, typically a reset).
  
  **Sequence of operations:**
  1. Disable the IN endpoint by setting:
     - EPDIS = 1 in all OTG_DIEPCTLx registers
  2. Wait for the EPDIS interrupt in OTG_DIEPINTx, which indicates that the IN endpoint is completely disabled. When the EPDIS interrupt is asserted the following bits are cleared:
     - EPDIS = 0 in OTG_DIEPCTLx
     - EPENA = 0 in OTG_DIEPCTLx
  3. Flush the TxFIFO by programming the following bits:
     - TXFFLSH = 1 in OTG_GRSTCTL
     - TXFNUM = “FIFO number specific to endpoint” in OTG_GRSTCTL
  4. The application can start polling till TXFFLSH in OTG_GRSTCTL is cleared. When this bit is cleared, it ensures that there is no data left in the Tx FIFO.

- **Generic non-periodic IN data transfers**
  Application requirements:
1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer are part of a single buffer.

2. For IN transfers, the transfer size field in the endpoint transfer size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
   - To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
     \[ \text{Transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp} \]
     If (sp > 0), then \( \text{packet count}[\text{EPNUM}] = x + 1 \).
     Otherwise, \( \text{packet count}[\text{EPNUM}] = x \).
   - To transmit a single zero-length data packet:
     \[ \text{Transfer size}[\text{EPNUM}] = 0 \]
     \[ \text{Packet count}[\text{EPNUM}] = 1 \]
   - To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer into two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.
     \[ \text{First transfer: transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{epnum}]; \text{packet count} = n; \]
     \[ \text{Second transfer: transfer size}[\text{EPNUM}] = 0; \text{packet count} = 1; \]

3. Once an endpoint is enabled for data transfers, the core updates the transfer size register. At the end of the IN transfer, the application must read the transfer size register to determine how much data posted in the transmit FIFO have already been sent on the USB.

4. Data fetched into transmit FIFO = Application-programmed initial transfer size – core-updated final transfer size
   - Data transmitted on USB = (application-programmed initial packet count – core updated final packet count) \( \times \) \( \text{MPSIZ}[\text{EPNUM}] \)
   - Data yet to be transmitted on USB = (Application-programmed initial transfer size – data transmitted on USB)

Internal data flow:
1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the transmit FIFO for the endpoint.
3. Every time a packet is written into the transmit FIFO by the application, the transfer size for that endpoint is decremented by the packet size. The data is fetched from the memory by the application, until the transfer size for the endpoint becomes 0. After writing the data into the FIFO, the “number of packets in FIFO” count is incremented (this is a 3-bit count, internally maintained by the core for each IN endpoint transmit FIFO. The maximum number of packets maintained by the core at any time in an IN endpoint FIFO is eight). For zero-length packets, a separate flag is set for each FIFO, without any data in the FIFO.
4. Once the data are written to the transmit FIFO, the core reads them out upon receiving an IN token. For every non-isochronous IN data packet transmitted with an ACK.
5. For zero length packets (indicated by an internal zero length flag), the core sends out a zero-length packet for the IN token and decrements the packet count field.

6. If there are no data in the FIFO for a received IN token and the packet count field for that endpoint is zero, the core generates an “IN token received when Tx FIFO is empty” (ITTXFE) interrupt for the endpoint, provided that the endpoint NAK bit is not set. The core responds with a NAK handshake for non-isochronous endpoints on the USB.

7. The core internally rewinds the FIFO pointers and no timeout interrupt is generated.

8. When the transfer size is 0 and the packet count is 0, the transfer complete (XFRC) interrupt for the endpoint is generated and the endpoint enable is cleared.

Application programming sequence:

1. Program the OTG_DIEPTSIZx register with the transfer size and corresponding packet count.

2. Program the OTG_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA (endpoint enable) bits.

3. When transmitting non-zero length data packet, the application must poll the OTG_DTXFSTSx register (where x is the FIFO number associated with that endpoint) to determine whether there is enough space in the data FIFO. The application can optionally use TXFE (in OTG_DIEPINTx) before writing the data.

- **Generic periodic IN data transfers**

  This section describes a typical periodic IN data transfer.

  Application requirements:

  1. Application requirements 1, 2, 3, and 4 of *Generic non-periodic IN data transfers on page 3261* also apply to periodic IN data transfers, except for a slight modification of requirement 2.

    - The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To
transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met:

\[
\text{transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + sp
\]

(where \(x\) is an integer \(\geq 0\), and \(0 \leq sp < \text{MPSIZ}[\text{EPNUM}]\))

If \((sp > 0)\), packet count[EPNUM] = \(x + 1\)

Otherwise, packet count[EPNUM] = \(x\);

\(\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]\)

– The application cannot transmit a zero-length data packet at the end of a transfer. It can transmit a single zero-length data packet by itself. To transmit a single zero-length data packet:

– transfer size[EPNUM] = 0

packet count[EPNUM] = 1

\(\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]\)

2. The application can only schedule data transfers one frame at a time.

– \((\text{MCNT} – 1) \times \text{MPSIZ} \leq \text{XFERSIZ} \leq \text{MCNT} \times \text{MPSIZ}\)

– \(\text{PKTCNT} = \text{MCNT} \ (\text{in OTG_DIEPTSIZx})\)

– If \(\text{XFERSIZ} < \text{MCNT} \times \text{MPSIZ}\), the last data packet of the transfer is a short packet.

– Note that: \(\text{MCNT}\) is in OTG_DIEPTSIZx, \(\text{MPSIZ}\) is in OTG_DIEPCTLx, \(\text{PKTCNT}\) is in OTG_DIEPTSIZx and \(\text{XFERSIZ}\) is in OTG_DIEPTSIZx

3. The complete data to be transmitted in the frame must be written into the transmit FIFO by the application, before the IN token is received. Even when 1 word of the data to be transmitted per frame is missing in the transmit FIFO when the IN token is received, the core behaves as when the FIFO is empty. When the transmit FIFO is empty:

– A zero data length packet would be transmitted on the USB for isochronous IN endpoints

– A NAK handshake would be transmitted on the USB for interrupt IN endpoints

Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.

2. The application must also write the required data to the associated transmit FIFO for the endpoint.

3. Every time the application writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data are fetched from application memory until the transfer size for the endpoint becomes 0.

4. When an IN token is received for a periodic endpoint, the core transmits the data in the FIFO, if available. If the complete data payload (complete packet, in dedicated FIFO
mode) for the frame is not present in the FIFO, then the core generates an IN token received when Tx FIFO empty interrupt for the endpoint.

- A zero-length data packet is transmitted on the USB for isochronous IN endpoints
- A NAK handshake is transmitted on the USB for interrupt IN endpoints

5. The packet count for the endpoint is decremented by 1 under the following conditions:
   - For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
   - For interrupt endpoints, when an ACK handshake is transmitted
   - When the transfer size and packet count are both 0, the transfer completed interrupt for the endpoint is generated and the endpoint enable is cleared.

6. At the “Periodic frame Interval” (controlled by PFIVL in OTG_DCFG), when the core finds non-empty any of the isochronous IN endpoint FIFOs scheduled for the current frame non-empty, the core generates an IISOIXFR interrupt in OTG_GINTSTS.

Application programming sequence:
1. Program the OTG_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA bits.
2. Write the data to be transmitted in the next frame to the transmit FIFO.
3. Asserting the ITTXFE interrupt (in OTG_DIEPINTx) indicates that the application has not yet written all data to be transmitted to the transmit FIFO.
4. If the interrupt endpoint is already enabled when this interrupt is detected, ignore the interrupt. If it is not enabled, enable the endpoint so that the data can be transmitted on the next IN token attempt.
5. Asserting the XFRC interrupt (in OTG_DIEPINTx) with no ITTXFE interrupt in OTG_DIEPINTx indicates the successful completion of an isochronous IN transfer. A read to the OTG_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
6. Asserting the XFRC interrupt (in OTG_DIEPINTx), with or without the ITTXFE interrupt (in OTG_DIEPINTx), indicates the successful completion of an interrupt IN transfer. A read to the OTG_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
7. Asserting the incomplete isochronous IN transfer (IISOIXFR) interrupt in OTG_GINTSTS with none of the aforementioned interrupts indicates the core did not receive at least 1 periodic IN token in the current frame.

- Incomplete isochronous IN data transfers
This section describes what the application must do on an incomplete isochronous IN data transfer.

Internal data flow:
1. An isochronous IN transfer is treated as incomplete in one of the following conditions:
   a) The core receives a corrupted isochronous IN token on at least one isochronous IN endpoint. In this case, the application detects an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG_GINTSTS).
   b) The application is slow to write the complete data payload to the transmit FIFO and an IN token is received before the complete data payload is written to the FIFO. In this case, the application detects an IN token received when Tx FIFO empty interrupt in OTG_DIEPINTx. The application can ignore this interrupt, as it
eventually results in an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG_GINTSTS) at the end of periodic frame.

The core transmits a zero-length data packet on the USB in response to the received IN token.

2. The application must stop writing the data payload to the transmit FIFO as soon as possible.

3. The application must set the NAK bit and the disable bit for the endpoint.

4. The core disables the endpoint, clears the disable bit, and asserts the endpoint disable interrupt for the endpoint.

Application programming sequence:

1. The application can ignore the IN token received when Tx FIFO empty interrupt in OTG_DIEPINTx on any isochronous IN endpoint, as it eventually results in an incomplete isochronous IN transfer interrupt (in OTG_GINTSTS).

2. Assertion of the incomplete isochronous IN transfer interrupt (in OTG_GINTSTS) indicates an incomplete isochronous IN transfer on at least one of the isochronous IN endpoints.

3. The application must read the endpoint control register for all isochronous IN endpoints to detect endpoints with incomplete IN data transfers.

4. The application must stop writing data to the Periodic Transmit FIFOs associated with these endpoints on the AHB.

5. Program the following fields in the OTG_DIEPCTLx register to disable the endpoint:
   – SNAK = 1 in OTG_DIEPCTLx
   – EPDIS = 1 in OTG_DIEPCTLx

6. The assertion of the endpoint disabled interrupt in OTG_DIEPINTx indicates that the core has disabled the endpoint.
   – At this point, the application must flush the data in the associated transmit FIFO or overwrite the existing data in the FIFO by enabling the endpoint for a new transfer in the next microframe. To flush the data, the application must use the OTG_GRSTCTL register.

**Stalling non-isochronous IN endpoints**

This section describes how the application can stall a non-isochronous endpoint.

Application programming sequence:
1. Disable the IN endpoint to be stalled. Set the STALL bit as well.
2. EPDIS = 1 in OTG_DIEPCTLx, when the endpoint is already enabled
   – STALL = 1 in OTG_DIEPCTLx
   – The STALL bit always takes precedence over the NAK bit
3. Assertion of the endpoint disabled interrupt (in OTG_DIEPINTx) indicates to the
   application that the core has disabled the specified endpoint.
4. The application must flush the non-periodic or periodic transmit FIFO, depending on
   the endpoint type. In case of a non-periodic endpoint, the application must re-enable
   the other non-periodic endpoints that do not need to be stalled, to transmit data.
5. Whenever the application is ready to end the STALL handshake for the endpoint, the
   STALL bit must be cleared in OTG_DIEPCTLx.
6. If the application sets or clears a STALL bit for an endpoint due to a
   SetFeature.Endpoint Halt command or ClearFeature.Endpoint Halt command, the
   STALL bit must be set or cleared before the application sets up the status stage
   transfer on the control endpoint.

Special case: stalling the control OUT endpoint

The core must stall IN/OUT tokens if, during the data stage of a control transfer, the host
sends more IN/OUT tokens than are specified in the SETUP packet. In this case, the
application must enable the ITTXFE interrupt in OTG_DIEPINTx and the OTEPDIS interrupt
in OTG_DOEPINTx during the data stage of the control transfer, after the core has
transferred the amount of data specified in the SETUP packet. Then, when the application
receives this interrupt, it must set the STALL bit in the corresponding endpoint control
register, and clear this interrupt.

72.16.6 Worst case response time

When the OTG_FS controller acts as a device, there is a worst case response time for any
tokens that follow an isochronous OUT. This worst case response time depends on the AHB
clock frequency.

The core registers are in the AHB domain, and the core does not accept another token
before updating these register values. The worst case is for any token following an
isochronous OUT, because for an isochronous transaction, there is no handshake and the
next token may come sooner. This worst case value is 7 PHY clocks when the AHB clock is
the same as the PHY clock. When the AHB clock is faster, this value is smaller.

If this worst case condition occurs, the core responds to bulk/interrupt tokens with a NAK
and drops isochronous and SETUP tokens. The host interprets this as a timeout condition
for SETUP and retries the SETUP packet. For isochronous transfers, theIncomplete
isochronous IN transfer interrupt (IISOIXFR) and Incomplete isochronous OUT transfer
interrupt (IISOOXFR) inform the application that isochronous IN/OUT packets were
dropped.

Choosing the value of TRDT in OTG_GUSBCFG

The value in TRDT (OTG_GUSBCFG) is the time it takes for the MAC, in terms of PHY
clocks after it has received an IN token, to get the FIFO status, and thus the first data from
the PFC block. This time involves the synchronization delay between the PHY and AHB
clocks. The worst case delay for this is when the AHB clock is the same as the PHY clock.
In this case, the delay is 5 clocks.
Once the MAC receives an IN token, this information (token received) is synchronized to the AHB clock by the PFC (the PFC runs on the AHB clock). The PFC then reads the data from the SPRAM and writes them into the dual clock source buffer. The MAC then reads the data out of the source buffer (4 deep).

If the AHB is running at a higher frequency than the PHY, the application can use a smaller value for TRDT (in OTG_GUSBCFG).

*Figure 904* has the following signals:
- `tkn_rcvd`: Token received information from MAC to PFC
- `dynced_tkn_rcvd`: Doubled sync `tkn_rcvd`, from PCLK to HCLK domain
- `spr_read`: Read to SPRAM
- `spr_addr`: Address to SPRAM
- `spr_rdata`: Read data from SPRAM
- `srcbuf_push`: Push to the source buffer
- `srcbuf_rdata`: Read data from the source buffer. Data seen by MAC

To calculate the value of TRDT, refer to *Table 749: TRDT values.*
72.16.7 OTG programming model

The OTG_FS controller is an OTG device supporting HNP and SRP. When the core is connected to an “A” plug, it is referred to as an A-device. When the core is connected to a “B” plug it is referred to as a B-device. In host mode, the OTG_FS controller turns off VBUS to conserve power. SRP is a method by which the B-device signals the A-device to turn on VBUS power. A device must perform both data-line pulsing and VBUS pulsing, but a host can detect either data-line pulsing or VBUS pulsing for SRP. HNP is a method by which the B-device negotiates and switches to host role. In Negotiated mode after HNP, the B-device suspends the bus and reverts to the device role.

A-device session request protocol

The application must set the SRP-capable bit in the core USB configuration register. This enables the OTG_FS controller to detect SRP as an A-device.

![A-device SRP](image)

1. DRV_VBUS = VBUS drive signal to the PHY
2. VBUS_VALID = VBUS valid signal from PHY
3. A_VALID = A-peripheral VBUS level signal to PHY
4. D+ = Data plus line
5. D- = Data minus line

The following points refer and describe the signal numeration shown in the Figure 905:

1. To save power, the application suspends and turns off port power when the bus is idle by writing the port suspend and port power bits in the host port control and status register.
2. PHY indicates port power off by deasserting the VBUS_VALID signal.
3. The device must detect SE0 for at least 2 ms to start SRP when VBUS power is off.
4. To initiate SRP, the device turns on its data line pull-up resistor for 5 to 10 ms. The OTG_FS controller detects data-line pulsing.
5. The device drives VBUS above the A-device session valid (2.0 V minimum) for VBUS pulsing.
   The OTG_FS controller interrupts the application on detecting SRP. The session
request detected bit is set in Global interrupt status register (SRQINT set in OTG_GINTSTS).

6. The application must service the session request detected interrupt and turn on the port power bit by writing the port power bit in the host port control and status register. The PHY indicates port power-on by asserting the VBUS_VALID signal.

7. When the USB is powered, the device connects, completing the SRP process.

**B-device session request protocol**

The application must set the SRP-capable bit in the core USB configuration register. This enables the OTG_FS controller to initiate SRP as a B-device. SRP is a means by which the OTG_FS controller can request a new session from the host.

---

**Figure 906. B-device SRP**

1. VBUS_VALID = VBUS valid signal from PHY
2. B_VALID = B-peripheral valid session to PHY
3. DISCHRG_VBUS = discharge signal to PHY
4. SESS_END = session end signal to PHY
5. CHRG_VBUS = charge VBUS signal to PHY
6. DP = Data plus line
7. DM = Data minus line
8. VBUS Pulsing

The following points refer and describe the signal numeration shown in the Figure 906:

1. To save power, the host suspends and turns off port power when the bus is idle. The OTG_FS controller sets the early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG_FS controller sets the USB suspend bit in the core interrupt register. The OTG_FS controller informs the PHY to discharge VBUS.

2. The PHY indicates the session’s end to the device. This is the initial condition for SRP. The OTG_FS controller requires 2 ms of SE0 before initiating SRP. For a USB 1.1 full-speed serial transceiver, the application must wait until VBUS discharges to 0.2 V after BSVLD (in OTG_GOTGCTL) is deasserted. This discharge
time can be obtained from the transceiver vendor and varies from one transceiver to another.

3. The OTG_FS core informs the PHY to speed up $V_{BUS}$ discharge.

4. The application initiates SRP by writing the session request bit in the OTG control and status register. The OTG_FS controller perform data-line pulsing followed by $V_{BUS}$ pulsing.

5. The host detects SRP from either the data-line or $V_{BUS}$ pulsing, and turns on $V_{BUS}$. The PHY indicates $V_{BUS}$ power-on to the device.

6. The OTG_FS controller performs $V_{BUS}$ pulsing. The host starts a new session by turning on $V_{BUS}$, indicating SRP success. The OTG_FS controller interrupts the application by setting the session request success status change bit in the OTG interrupt status register. The application reads the session request success bit in the OTG control and status register.

7. When the USB is powered, the OTG_FS controller connects, completing the SRP process.

**A-device host negotiation protocol**

HNP switches the USB host role from the A-device to the B-device. The application must set the HNP-capable bit in the core USB configuration register to enable the OTG_FS controller to perform HNP as an A-device.

![Figure 907. A-device HNP](image)

1. DPPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DP line inside the PHY. DMPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DM line inside the PHY.

The following points refer and describe the signal numeration shown in the **Figure 907:**

1. The OTG_FS controller sends the B-device a SetFeature b_hnp_enable descriptor to enable HNP support. The B-device's ACK response indicates that the B-device supports HNP. The application must set host Set HNP enable bit in the OTG control
and status register to indicate to the OTG_FS controller that the B-device supports HNP.

2. When it has finished using the bus, the application suspends by writing the port suspend bit in the host port control and status register.

3. When the B-device observes a USB suspend, it disconnects, indicating the initial condition for HNP. The B-device initiates HNP only when it must switch to the host role; otherwise, the bus continues to be suspended.

The OTG_FS controller sets the host negotiation detected interrupt in the OTG interrupt status register, indicating the start of HNP.

The OTG_FS controller deasserts the DM pull down and DM pull down in the PHY to indicate a device role. The PHY enables the OTG_DP pull-up resistor to indicate a connect for B-device.

The application must read the current mode bit in the OTG control and status register to determine device mode operation.

4. The B-device detects the connection, issues a USB reset, and enumerates the OTG_FS controller for data traffic.

5. The B-device continues the host role, initiating traffic, and suspends the bus when done.

The OTG_FS controller sets the early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG_FS controller sets the USB suspend bit in the core interrupt register.

6. In Negotiated mode, the OTG_FS controller detects the suspend, disconnects, and switches back to the host role. The OTG_FS controller asserts the DM pull down and DM pull down in the PHY to indicate its assumption of the host role.

7. The OTG_FS controller sets the connector ID status change interrupt in the OTG interrupt status register. The application must read the connector ID status in the OTG control and status register to determine the OTG_FS controller operation as an A-device. This indicates the completion of HNP to the application. The application must read the Current mode bit in the OTG control and status register to determine host mode operation.

8. The B-device connects, completing the HNP process.

**B-device host negotiation protocol**

HNP switches the USB host role from B-device to A-device. The application must set the HNP-capable bit in the core USB configuration register to enable the OTG_FS controller to perform HNP as a B-device.
The following points refer and describe the signal numeration shown in the Figure 908:

1. **DPPULLDOWN** = signal from core to PHY to enable/disable the pull-down on the DP line inside the PHY. **DMPULLDOWN** = signal from core to PHY to enable/disable the pull-down on the DM line inside the PHY.

The A-device sends the SetFeature b_hnp_enable descriptor to enable HNP support.

The OTG_FS controller’s ACK response indicates that it supports HNP. The application must set the device HNP enable bit in the OTG control and status register to indicate HNP support.

The application sets the HNP request bit in the OTG control and status register to indicate to the OTG_FS controller to initiate HNP.

2. When it has finished using the bus, the A-device suspends by writing the port suspend bit in the host port control and status register.

The OTG_FS controller sets the Early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG_FS controller sets the USB suspend bit in the core interrupt register.

The OTG_FS controller disconnects and the A-device detects SE0 on the bus, indicating HNP. The OTG_FS controller asserts the DP pull down and DM pull down in the PHY to indicate its assumption of the host role.

The A-device responds by activating its OTG_DP pull-up resistor within 3 ms of detecting SE0. The OTG_FS controller detects this as a connect.

The OTG_FS controller sets the host negotiation success status change interrupt in the OTG interrupt status register, indicating the HNP status. The application must read the host negotiation success bit in the OTG control and status register to determine host...
negotiation success. The application must read the current Mode bit in the core interrupt register (OTG_GINTSTS) to determine host mode operation.

3. The application sets the reset bit (PRST in OTG_HPRT) and the OTG_FS controller issues a USB reset and enumerates the A-device for data traffic.

4. The OTG_FS controller continues the host role of initiating traffic, and when done, suspends the bus by writing the port suspend bit in the host port control and status register.

5. In Negotiated mode, when the A-device detects a suspend, it disconnects and switches back to the host role. The OTG_FS controller deasserts the DP pull down and DM pull down in the PHY to indicate the assumption of the device role.

6. The application must read the current mode bit in the core interrupt (OTG_GINTSTS) register to determine the host mode operation.

7. The OTG_FS controller connects, completing the HNP process.
73 USB on-the-go high-speed (OTG_HS)

This section applies to STM32U59x/5Ax/5Fx/5Gx devices only.

73.1 Introduction

Portions Copyright (c) Synopsys, Inc. All rights reserved. Used with permission.

This section presents the architecture and the programming model of the OTG_HS controller.

The following acronyms are used throughout the section:

- FS Full-speed
- LS Low-speed
- HS High-speed
- MAC Media access controller
- OTG On-the-go
- PFC Packet FIFO controller
- PHY Physical layer
- USB Universal serial bus
- UTMI USB 2.0 Transceiver Macrocell interface (UTMI)
- LPM Link power management
- BCD Battery charging detector
- HNP Host negotiation protocol
- SRP Session request protocol

References are made to the following documents:

- USB On-The-Go Supplement, Revision 2.0
- Universal Serial Bus Revision 2.0 Specification
- USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007
- Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007
- Battery Charging Specification, Revision 1.2

The USB OTG is a dual-role device (DRD) controller that supports both device and host functions and is fully compliant with the *On-The-Go Supplement to the USB 2.0 Specification*. It can also be configured as a host-only or device-only controller, fully compliant with the *USB 2.0 Specification*. OTG_HS supports the speeds defined in the *Table 752: OTG_HS speeds supported* below. The only external device required is a charge pump for \( V_{BUS} \) in OTG mode.
73.2 OTG_HS main features

The main features can be divided into three categories: general, host-mode, and device-mode features.

73.2.1 General features

The OTG_HS interface general features are the following:

- It is USB-IF certified to the Universal Serial Bus Specification Rev 2.0.
- OTG_HS supports the following PHY interfaces:
  - A UTMI interface for internal HS PHY
- It includes full support (PHY) for the optional On-The-Go (OTG) protocol detailed in the On-The-Go Supplement Rev 2.0 specification
  - Integrated support for A-B device identification (ID line)
  - It allows host to turn VBUS off to conserve battery power in OTG applications.
  - It supports OTG monitoring of VBUS levels with internal comparators.
  - It supports dynamic host-peripheral switch of role.
- It is software-configurable to operate as:
  - USB On-The-Go Full-Speed Dual Role device
- It supports HS SOF and LS Keep-alives with
  - SOF pulse PAD connectivity
  - SOF pulse internal connection to timer (TIMx)
  - Configurable framing period
  - Configurable end of frame interrupt
- OTG_HS embeds an internal DMA with thresholding support and software selectable AHB burst type in DMA mode.
- It includes power saving features such as system stop during USB suspend, switch-off of clock domains internal to the digital core, PHY and DFIFO power management.
- It features a dedicated RAM of 4 Kbytes with advanced FIFO control:
  - Configurable partitioning of RAM space into different FIFOs for flexible and efficient use of RAM
  - Each FIFO can hold multiple packets.
  - Dynamic memory allocation
  - Configurable FIFO sizes that are not powers of 2 to allow the use of contiguous memory locations
- It guarantees max USB bandwidth for up to one frame (1 ms) without system intervention.
- It supports charging port detection as described in Battery Charging Specification Revision 1.2.

73.2.2 Host-mode features

The OTG_HS interface main features and requirements in host-mode are the following:

- External charge pump for VBUS voltage generation
- Up to 16 host channels (pipes): each channel is dynamically reconfigurable to allocate any type of USB transfer.
- Built-in hardware scheduler holding:
  - Up to 16 interrupt plus isochronous transfer requests in the periodic hardware queue
  - Up to 16 control plus bulk transfer requests in the non-periodic hardware queue
- Management of a shared Rx FIFO, a periodic Tx FIFO and a nonperiodic Tx FIFO for efficient usage of the USB data RAM.

73.2.3 Peripheral-mode features

The OTG_HS interface main features in peripheral-mode are the following:

- 1 bidirectional control endpoint0
- 8 IN endpoints (EPs) configurable to support bulk, interrupt or isochronous transfers
- 8 OUT endpoints configurable to support bulk, interrupt or isochronous transfers
- Management of a shared Rx FIFO and a Tx-OUT FIFO for efficient usage of the USB data RAM
- Management of up to 9 dedicated Tx-IN FIFOs (one for each active IN EP) to put less load on the application
- Support for the soft disconnect feature.

73.4.3 OTG_HS core

The OTG_HS receives the 60 MHz clock from the reset and clock controller (RCC). This is typically generated in the PLL associated with the HS PHY and enabled in the RCC. This clock is used for driving the 60 MHz domain at high-speed (480 Mbit/s) and must be enabled prior to configuring the OTG core.

The CPU reads and writes from/to the OTG core registers through the AHB peripheral bus. It is informed of USB events through the single USB OTG interrupt line described in Section 73.12: OTG_HS interrupts.

The CPU submits data over the USB by writing 32-bit words to dedicated OTG locations (push registers). The data are then automatically stored into Tx-data FIFOs configured within the USB data RAM. There is one Tx FIFO push register for each in-endpoint (peripheral mode) or out-channel (host mode).

The CPU receives the data from the USB by reading 32-bit words from dedicated OTG addresses (pop registers). The data are then automatically retrieved from a shared Rx FIFO configured within the 4-Kbyte USB data RAM. There is one Rx FIFO pop register for each out-endpoint or in-channel.

The USB protocol layer is driven by the serial interface engine (SIE) and serialized over the USB by the transceiver module within the on-chip physical layer (PHY).

**Caution:** To guarantee a correct operation for the USB OTG_HS peripheral, the AHB frequency must be higher than 30 MHz.
73.4.4 OTG detections

Additionally the OTG_HS uses the following functions:

- Integrated ID pull-up resistor used to sample the ID line for A/B device identification.
- \( V_{BUS} \) sensing comparators with hysteresis used to detect \( V_{BUS} \) valid, A-B session valid and session-end voltage thresholds. They are used to detect valid startup and end-of-session conditions, and constantly monitor the \( V_{BUS} \) supply during USB operations.

73.4.5 High-speed OTG PHY connected to OTG_HS

**Note:** Refer to implementation table to determine if an HS PHY is embedded.

The USB OTG core includes an internal UTMI interface which is connected to the embedded HS PHY (see Section 73.4.1: OTG_HS block diagram).

73.5 OTG_HS dual role device (DRD)

**Figure 910. OTG_HS A-B device connection**

1. External voltage regulator only needed when building a VBUS powered device.
2. STMPS2141STR needed only if the application has to support a VBUS powered device. A basic power switch can be used if 5 V are available on the application board.

73.5.1 ID line detection

The host or peripheral (the default) role is assumed depending on the ID input pin. The ID line status is determined on plugging in the USB cable, depending on whether a MicroA or MicroB plug is connected to the micro-AB receptacle.

- If the B-side of the USB cable is connected with a floating ID wire, the integrated pull-up resistor detects a high ID level and the default peripheral role is confirmed. In this configuration the OTG_HS complies with the standard FSM described in section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.
- If the A-side of the USB cable is connected with a grounded ID, the OTG_HS issues an ID line status change interrupt (CIDSCHG bit in OTG_GINTSTS) for host software initialization, and automatically switches to the host role. In this configuration the
OTG_HS complies with the standard FSM described by section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.

73.6 **OTG_HS as a USB peripheral**

This section gives the functional description of the OTG_HS in the USB peripheral mode. The OTG_HS works as an USB peripheral in the following circumstances:

- **OTG B-Peripheral**
  - OTG B-device default state if B-side of USB cable is plugged in
- **B-device**
  - If the ID line is present, functional and connected to the B-side of the USB cable.
- **Peripheral only**
  - The force device mode bit (FDMOD) in the [Section 73.14.4: OTG USB configuration register (OTG_GUSBCFG)] is set to 1, forcing the OTG_HS core to work as an USB peripheral-only. In this case, the ID line is ignored even if it is present on the USB connector.

**Note:** To build a bus-powered device implementation in case of the B-device or peripheral-only configuration, an external regulator has to be added, that generates the necessary power-supply from \( V_{BUS} \).

**Figure 911. OTG_HS peripheral-only connection**

1. Use a regulator to build a bus-powered device.

73.6.1 **Peripheral states**

**Powered state**

The \( V_{BUS} \) input detects the B-session valid voltage by which the USB peripheral is allowed to enter the powered state (see USB2.0 section 9.1). The OTG_HS then automatically connects the DP pull-up resistor to signal full-speed device connection to the host and...
generates the session request interrupt (SRQINT bit in OTG_GINTSTS) to notify the powered state.

The VBUS input also ensures that valid VBUS levels are supplied by the host during USB operations. If a drop in VBUS below B-session valid happens to be detected (for instance because of a power disturbance or if the host port has been switched off), the OTG_HS automatically disconnects and the session end detected (SEDET bit in OTG_GOTGINT) interrupt is generated to notify that the OTG_HS has exited the powered state.

In the powered state, the OTG_HS expects to receive some reset signaling from the host. No other USB operation is possible. When a reset signaling is received the reset detected interrupt (USBRST in OTG_GINTSTS) is generated. When the reset signaling is complete, the enumeration done interrupt (ENUMDNE bit in OTG_GINTSTS) is generated and the OTG_HS enters the Default state.

**Soft disconnect**

The powered state can be exited by software with the soft disconnect feature. The DP pull-up resistor is removed by setting the soft disconnect bit in the device control register (SDIS bit in OTG_DCTL), causing a device disconnect detection interrupt on the host side even though the USB cable was not really removed from the host port.

**Default state**

In the Default state the OTG_HS expects to receive a SET_ADDRESS command from the host. No other USB operation is possible. When a valid SET_ADDRESS command is decoded on the USB, the application writes the corresponding number into the device address field in the device configuration register (DAD bit in OTG_DCFG). The OTG_HS then enters the address state and is ready to answer host transactions at the configured USB address.

**Suspended state**

The OTG_HS peripheral constantly monitors the USB activity. After counting 3 ms of USB idleness, the early suspend interrupt (ESUSP bit in OTG_GINTSTS) is issued, and confirmed 3 ms later, if appropriate, by the suspend interrupt (USBSUSP bit in OTG_GINTSTS). The device suspend bit is then automatically set in the device status register (SUSPSTS bit in OTG_DSTS) and the OTG_HS enters the suspended state.

The suspended state may optionally be exited by the device itself. In this case the application sets the remote wake-up signaling bit in the device control register (RWUSIG bit in OTG_DCTL) and clears it after 1 to 15 ms.

When a resume signaling is detected from the host, the resume interrupt (WKUPINT bit in OTG_GINTSTS) is generated and the device suspend bit is automatically cleared.

### 73.6.2 Peripheral endpoints

The OTG_HS core instantiates the following USB endpoints:

- Control endpoint 0:
  - Bidirectional and handles control messages only
  - Separate set of registers to handle in and out transactions
  - Dedicated control (OTG_DIEPCTL0/OTG_DOEPCTL0), transfer configuration (OTG_DIEPTSIZ0/OTG_DOEPTSIZ0), and status-interrupt
(OTG_DIEPINT0)/OTG_DOEPINT0) registers. The available set of bits inside the control and transfer size registers slightly differs from that of other endpoints

- eight IN endpoints
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has dedicated control (OTG_DIEPCTLx), transfer configuration (OTG_DIEPTSIZx), and status-interrupt (OTG_DIEPINTx) registers
  - The device IN endpoints common interrupt mask register (OTG_DIEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the IN endpoints (EP0 included)
  - Support for incomplete isochronous IN transfer interrupt (IISOIXFR bit in OTG_GINTSTS), asserted when there is at least one isochronous IN endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG_GINTSTS/EOPF).

- eight OUT endpoints
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has a dedicated control (OTG_DOEPCTLx), transfer configuration (OTG_DOEPTSIZx) and status-interrupt (OTG_DOEPINTx) register
  - Device OUT endpoints common interrupt mask register (OTG_DOEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the OUT endpoints (EP0 included)
  - Support for incomplete isochronous OUT transfer interrupt (INCOMPISOOUT bit in OTG_GINTSTS), asserted when there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG_GINTSTS/EOPF).

**Endpoint control**

- The following endpoint controls are available to the application through the device endpoint-x IN/OUT control register (OTG_DIEPCTLx/OTG_DOEPCTLx):
  - endpoint enable/disable
  - endpoint activate in current configuration
  - program USB transfer type (isochronous, bulk, interrupt)
  - program supported packet size
  - program Tx FIFO number associated with the IN endpoint
  - program the expected or transmitted data0/data1 PID (bulk/interrupt only)
  - program the even/odd frame during which the transaction is received or transmitted (isochronous only)
  - optionally program the NAK bit to always negative-acknowledge the host regardless of the FIFO status
  - optionally program the STALL bit to always stall host tokens to that endpoint
  - optionally program the SNOOP mode for OUT endpoint not to check the CRC field of received data
Endpoint transfer

The device endpoint-x transfer size registers (OTG_DIEPTSIZx/OTG_DOEPTSIZx) allow the application to program the transfer size parameters and read the transfer status. Programming must be done before setting the endpoint enable bit in the endpoint control register. Once the endpoint is enabled, these fields are read-only as the OTG_HS core updates them with the current transfer status.

The following transfer parameters can be programmed:
- transfer size in bytes
- number of packets that constitute the overall transfer size

Endpoint status/interrupt

The device endpoint-x interrupt registers (OTG_DIEPINTx/OTG_DOPEPINTx) indicate the status of an endpoint with respect to USB- and AHB-related events. The application must read these registers when the OUT endpoint interrupt bit or the IN endpoint interrupt bit in the core interrupt register (OEPINT bit in OTG_GINTSTS or IEPINT bit in OTG_GINTSTS, respectively) is set. Before the application can read these registers, it must first read the device all endpoints interrupt (OTG_DAINT) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.

The peripheral core provides the following status checks and interrupt generation:
- transfer completed interrupt, indicating that data transfer was completed on both the application (AHB) and USB sides
- setup stage has been done (control-out only)
- associated transmit FIFO is half or completely empty (in endpoints)
- NAK acknowledge has been transmitted to the host (isochronous-in only)
- IN token received when Tx FIFO was empty (bulk-in/interrupt-in only)
- Out token received when endpoint was not yet enabled
- babble error condition has been detected
- endpoint disable by application is effective
- endpoint NAK by application is effective (isochronous-in only)
- more than 3 back-to-back setup packets were received (control-out only)
- timeout condition detected (control-in only)
- isochronous out packet has been dropped, without generating an interrupt
73.7 **OTG_HS as a USB host**

This section gives the functional description of the OTG_HS in the USB host mode. The OTG_HS works as a USB host in the following circumstances:

- **OTG A-host**
  - OTG A-device default state when the A-side of the USB cable is plugged in

- **A-device**
  - If the ID line is present, functional and connected to the A-side of the USB cable. Integrated pull-down resistors are automatically set on the DP/DM lines.

- **Host only**
  - The force host mode bit (FHMOD) in the OTG USB configuration register (OTG_GUSBCFG) forces the OTG_HS core to work as a USB host-only. In this case, the ID line is ignored even if present on the USB connector. Integrated pull-down resistors are automatically set on the DP/DM lines.

**Note:** On-chip 5 V VBUS generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch must be added externally to drive the 5 V VBUS line. The external charge pump can be driven by any GPIO output. This is required for the OTG A-host, A-device and host-only configurations.

Figure 912. OTG_HS host-only connection

1. VDD range is between 2 V and 3.6 V.

### 73.7.1 USB host states

**Host port power**

On-chip 5 V VBUS generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch, must be added externally to drive the 5 V VBUS line. The external charge pump can be driven by any GPIO output or via an I^2^C interface connected to an external PMIC (power management IC). When the application decides to power on VBUS, it must also set the port power bit in the host port control and status register (PPWR bit in OTG_HPRT).

**VBUS valid**

In Host mode, the VBUS sensing pin does not need to be connected to VBUS.
The charge pump overcurrent flag can also be used to prevent electrical damage. Connect the overcurrent flag output from the charge pump to any GPIO input and configure it to generate a port interrupt on the active level. The overcurrent ISR must promptly disable the \( V_{BUS} \) generation and clear the port power bit.

**Host detection of a peripheral connection**

USB peripherals or B-device are detected as soon as they are connected. The OTG_H5 core issues a host port interrupt triggered by the device connected bit in the host port control and status (PCDET bit in OTG_HPRT).

**Host detection of peripheral a disconnection**

The peripheral disconnection event triggers the disconnect detected interrupt (DISCINT bit in OTG_GINTSTS).

**Host enumeration**

After detecting a peripheral connection the host must start the enumeration process by sending USB reset and configuration commands to the new peripheral.

The application drives a USB reset signaling (single-ended zero) over the USB by keeping the port reset bit set in the host port control and status register (PRST bit in OTG_HPRT) for a minimum of 10 ms and a maximum of 20 ms. The application takes care of the timing count and then of clearing the port reset bit.

Once the USB reset sequence has completed, the host port interrupt is triggered by the port enable/disable change bit (PENCHNG bit in OTG_HPRT). This informs the application that the speed of the enumerated peripheral can be read from the port speed field in the host port control and status register (PSPD bit in OTG_HPRT) and that the host is starting to drive SOFs (FS) or Keep alives (LS). The host is now ready to complete the peripheral enumeration by sending peripheral configuration commands.

**Host suspend**

The application decides to suspend the USB activity by setting the port suspend bit in the host port control and status register (PSUSP bit in OTG_HPRT). The OTG_HS core stops sending SOFs and enters the suspended state.

The suspended state can be optionally exited on the remote device’s initiative (remote wake-up). In this case the remote wake-up interrupt (WKUPINT bit in OTG_GINTSTS) is generated upon detection of a remote wake-up signaling, the port resume bit in the host port control and status register (PRES bit in OTG_HPRT) self-sets, and resume signaling is automatically driven over the USB. The application must time the resume window and then clear the port resume bit to exit the suspended state and restart the SOF.

If the suspended state is exited on the host initiative, the application must set the port resume bit to start resume signaling on the host port, time the resume window and finally clear the port resume bit.

**73.7.2 Host channels**

The OTG_HS core instantiates 16 host channels. Each host channel supports an USB host transfer (USB pipe). The host is not able to support more than 16 transfer requests at the same time. If more than 16 transfer requests are pending from the application, the host...
controller driver (HCD) must re-allocate channels when they become available from previous duty, that is, after receiving the transfer completed and channel halted interrupts.

Each host channel can be configured to support in/out and any type of periodic/nonperiodic transaction. Each host channel makes use of dedicated control (OTG_HCCHARRx), transfer configuration (OTG_HCTSIZx) and status/interrupt (OTG_HCINTx) registers with associated mask (OTG_HCINTMSKx) registers.

**Host channel control**
- The following host channel controls are available to the application through the host channel-x characteristics register (OTG_HCCHARRx):
  - Channel enable/disable
  - Program the HS/FS/LS speed of target USB peripheral
  - Program the address of target USB peripheral
  - Program the endpoint number of target USB peripheral
  - Program the transfer IN/OUT direction
  - Program the USB transfer type (control, bulk, interrupt, isochronous)
  - Program the maximum packet size (MPS)
  - Program the periodic transfer to be executed during odd/even frames

**Host channel transfer**
The host channel transfer size registers (OTG_HCTSIZx) allow the application to program the transfer size parameters, and read the transfer status. Programming must be done before setting the channel enable bit in the host channel characteristics register. Once the endpoint is enabled the packet count field is read-only as the OTG_HS core updates it according to the current transfer status.
- The following transfer parameters can be programmed:
  - transfer size in bytes
  - number of packets making up the overall transfer size
  - initial data PID

**Host channel status/interrupt**
The host channel-x interrupt register (OTG_HCINTx) indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read these register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG_GINTSTS) is set. Before the application can read these registers, it must first read the host all channels interrupt (OTG_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_HAINT and OTG_GINTSTS registers.
The mask bits for each interrupt source of each channel are also available in the OTG_HCINTMSKx register.

- The host core provides the following status checks and interrupt generation:
  - Transfer completed interrupt, indicating that the data transfer is complete on both the application (AHB) and USB sides
  - Channel has stopped due to transfer completed, USB transaction error or disable command from the application
  - Associated transmit FIFO is half or completely empty (IN endpoints)
  - ACK response received
  - NAK response received
  - STALL response received
  - USB transaction error due to CRC failure, timeout, bit stuff error, false EOP
  - Babble error
  - frame overrun
  - data toggle error

### 73.7.3 Host scheduler

The host core features a built-in hardware scheduler which is able to autonomously re-order and manage the USB transaction requests posted by the application. At the beginning of each frame the host executes the periodic (isochronous and interrupt) transactions first, followed by the nonperiodic (control and bulk) transactions to achieve the higher level of priority granted to the isochronous and interrupt transfer types by the USB specification.

The host processes the USB transactions through request queues (one for periodic and one for nonperiodic). Each request queue can hold up to 8 entries. Each entry represents a pending transaction request from the application, and holds the IN or OUT channel number along with other information to perform a transaction on the USB. The order in which the requests are written to the queue determines the sequence of the transactions on the USB interface.

At the beginning of each frame, the host processes the periodic request queue first, followed by the nonperiodic request queue. The host issues an incomplete periodic transfer interrupt (IPXFR bit in OTG_GINTSTS) if an isochronous or interrupt transaction scheduled for the current frame is still pending at the end of the current frame. The OTG_HS core is fully responsible for the management of the periodic and nonperiodic request queues. The periodic transmit FIFO and queue status register (OTG_HPTXSTS) and nonperiodic transmit FIFO and queue status register (OTG_HNPTXSTS) are read-only registers which can be used by the application to read the status of each request queue. They contain:

- The number of free entries currently available in the periodic (nonperiodic) request queue (8 max)
- Free space currently available in the periodic (nonperiodic) Tx FIFO (out-transactions)
- IN/OUT token, host channel number and other status information.

As request queues can hold a maximum of eight entries each, the application can push to schedule host transactions in advance with respect to the moment they physically reach the SB for a maximum of eight pending periodic transactions plus 8 pending non-periodic transactions.

To post a transaction request to the host scheduler (queue) the application must check that there is at least 1 entry available in the periodic (nonperiodic) request queue by reading the
PTXQSAV bits in the OTG_HNPTXSTS register or NPTQXSAV bits in the OTG_HNPTXSTS register.

73.8 OTG_HS SOF trigger

The OTG_HS core provides means to monitor, track and configure SOF framing in the host and peripheral, as well as an SOF pulse output connectivity feature. Such utilities are especially useful for adaptive audio clock generation techniques, where the audio peripheral needs to synchronize to the isochronous stream provided by the PC, or the host needs to trim its framing rate according to the requirements of the audio peripheral.

73.8.1 Host SOFs

In host mode the number of PHY clocks occurring between the generation of two consecutive SOF (HS/FS) or Keep-alive (LS) tokens is programmable in the host frame interval register (HFIR), thus providing application control over the SOF framing period. An interrupt is generated at any start of frame (SOF bit in OTG_GINTSTS). The current frame number and the time remaining until the next SOF are tracked in the host frame number register (HFNUM).

A SOF pulse signal, is generated at any SOF starting token and with a width of 20 HCLK cycles. The SOF pulse is also internally connected to the input trigger of the timer, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.

73.8.2 Peripheral SOFs

In device mode, the start of frame interrupt is generated each time an SOF token is received on the USB (SOF bit in OTG_GINTSTS). The corresponding frame number can be read from the device status register (FNSOF bit in OTG_DSTS). A SOF pulse signal with a width of 20 HCLK cycles is also generated. The SOF pulse signal is also internally connected to the TIM input trigger, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.
The end of periodic frame interrupt (OTG_GINTSTS/EOPF) is used to notify the application when 80%, 85%, 90% or 95% of the time frame interval elapsed depending on the periodic frame interval field in the device configuration register (PFIVL bit in OTG_DCFG). This feature can be used to determine if all of the isochronous traffic for that frame is complete.

### 73.9 OTG_HS low-power modes

*Table 756* below defines the STM32 low power modes and their compatibility with the OTG.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
<th>USB compatibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run</td>
<td>MCU fully active</td>
<td>Required when USB not in suspend state.</td>
</tr>
<tr>
<td>Sleep</td>
<td>USB suspend exit causes the device to exit Sleep mode. Peripheral registers content is kept.</td>
<td>Available while USB is in suspend state.</td>
</tr>
<tr>
<td>Stop</td>
<td>USB suspend exit causes the device to exit Stop mode. Peripheral registers content is kept(^1).</td>
<td>Available while USB is in suspend state.</td>
</tr>
<tr>
<td>Standby</td>
<td>Powered-down. The peripheral must be reinitialized after exiting Standby mode.</td>
<td>Not compatible with USB applications.</td>
</tr>
</tbody>
</table>

\(^1\) Within Stop mode there are different possible settings. Some restrictions may also exist, refer to *Section 10: Power control (PWR)* to understand which (if any) restrictions apply when using OTG.

The following bits and procedures reduce power consumption.

The power consumption of the OTG PHY is controlled by the following bit in the general core configuration register:

- **V<sub>BUS</sub>** detection enable (OTG_GCCFG/VBDEN)
  
  It switches on/off the V<sub>BUS</sub> sensing comparators associated with OTG operations

Power reduction techniques are available while in the USB suspended state, when the USB session is not yet valid or the device is disconnected.

- **Stop PHY clock** (STPPCLK bit in OTG_PCGCCTL)
  
  When setting the stop PHY clock bit in the clock gating control register, most of the transceiver is disabled, and only the part in charge of detecting the asynchronous resume or remote wake-up event is kept alive.

- **Gate HCLK** (GATEHCLK bit in OTG_PCGCCTL)
  
  When setting the Gate HCLK bit in the clock gating control register, most of the system clock domain internal to the OTG_HS core is switched off by clock gating. Only the register read and write interface is kept alive. The dynamic power consumption due to the USB clock switching activity is cut even if the system clock is kept running by the application for other purposes.

- **USB system stop**
  
  When the OTG_HS is in the USB suspended state, the application may decide to drastically reduce the overall power consumption by a complete shut down of all the clock sources in the system. USB System Stop is activated by first setting the Stop
PHY clock bit and then configuring the system deep sleep mode in the power control system module (PWR).

The OTG_HS core automatically reactivates both system and USB clocks by asynchronous detection of remote wake-up (as an host) or resume (as a device) signaling on the USB.

To save dynamic power, the USB data FIFO is clocked only when accessed by the OTG_HS core.

### 73.10 OTG_HS Dynamic update of the OTG_HFIR register

The USB core embeds a dynamic trimming capability of micro-SOF framing period in host mode allowing to synchronize an external device with the micro-SOF frames.

When the OTG_HFIR register is changed within a current micro-SOF frame, the SOF period correction is applied in the next frame as described in Figure 914.

For a dynamic update, it is required to set RLDCTRL=1.

**Figure 914. Updating OTG_HFIR dynamically (RLDCTRL = 1)**

![Figure 914](image)

### 73.11 OTG_HS data FIFOs

The USB system features 4 Kbytes of dedicated RAM with a sophisticated FIFO control mechanism. The packet FIFO controller module in the OTG_HS core organizes RAM space into Tx FIFOs into which the application pushes the data to be temporarily stored before the USB transmission, and into a single Rx FIFO where the data received from the USB are temporarily stored before retrieval (popped) by the application. The number of instructed FIFOs and how these are organized inside the RAM depends on the device’s role. In peripheral mode an additional Tx FIFO is instructed for each active IN endpoint. Any FIFO size is software configured to better meet the application requirements.
### Peripheral FIFO architecture

**Figure 915. Device-mode FIFO address mapping and AHB FIFO access mapping**

#### Peripheral Rx FIFO

The OTG peripheral uses a single receive FIFO that receives the data directed to all OUT endpoints. Received packets are stacked back-to-back until free space is available in the Rx FIFO. The status of the received packet (which contains the OUT endpoint destination number, the byte count, the data PID and the validity of the received data) is also stored by the core on top of the data payload. When no more space is available, host transactions are NACKed and an interrupt is received on the addressed endpoint. The size of the receive FIFO is configured in the receive FIFO size register (OTG_GRXFSIZ).

The single receive FIFO architecture makes it more efficient for the USB peripheral to fill in the receive RAM buffer:

- All OUT endpoints share the same RAM buffer (shared FIFO)
- The OTG_HS core can fill in the receive FIFO up to the limit for any host sequence of OUT tokens

The application keeps receiving the Rx FIFO non-empty interrupt (RXFLVL bit in OTG_GINTSTS) as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register (OTG_GRXSTSP) and finally pops data off the receive FIFO by reading from the endpoint-related pop address.
Peripheral Tx FIFOs

The core has a dedicated FIFO for each IN endpoint. The application configures FIFO sizes by writing the endpoint 0 transmit FIFO size register (OTG_DIEPTXF0) for IN endpoint 0 and the device IN endpoint transmit FIFOx registers (OTG_DIEPTXFx) for IN endpoint-x.

73.11.2 Host FIFO architecture

Host Rx FIFO

The host uses one receiver FIFO for all periodic and nonperiodic transactions. The FIFO is used as a receive buffer to hold the received data (payload of the received packet) from the USB until it is transferred to the system memory. Packets received from any remote IN endpoint are stacked back-to-back until free space is available. The status of each received packet with the host channel destination, byte count, data PID and validity of the received data are also stored into the FIFO. The size of the receive FIFO is configured in the receive FIFO size register (OTG_GRXFSIZ).

The single receive FIFO architecture makes it highly efficient for the USB host to fill in the receive data buffer:
- All IN configured host channels share the same RAM buffer (shared FIFO)
- The OTG_HS core can fill in the receive FIFO up to the limit for any sequence of IN tokens driven by the host software

The application receives the Rx FIFO not-empty interrupt as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register and finally pops the data off the receive FIFO.
Host Tx FIFOs

The host uses one transmit FIFO for all non-periodic (control and bulk) OUT transactions and one transmit FIFO for all periodic (isochronous and interrupt) OUT transactions. FIFOs are used as transmit buffers to hold the data (payload of the transmit packet) to be transmitted over the USB. The size of the periodic (nonperiodic) Tx FIFO is configured in the host periodic (nonperiodic) transmit FIFO size OTG_HPTXFISIZ / OTG_HNPTXFISIZ) register.

The two Tx FIFO implementation derives from the higher priority granted to the periodic type of traffic over the USB frame. At the beginning of each frame, the built-in host scheduler processes the periodic request queue first, followed by the nonperiodic request queue.

The two transmit FIFO architecture provides the USB host with separate optimization for periodic and nonperiodic transmit data buffer management:

- All host channels configured to support periodic (nonperiodic) transactions in the OUT direction share the same RAM buffer (shared FIFOs)
- The OTG_HS core can fill in the periodic (nonperiodic) transmit FIFO up to the limit for any sequence of OUT tokens driven by the host software

The OTG_HS core issues the periodic Tx FIFO empty interrupt (PTXFE bit in OTG_GINTSTS) as long as the periodic Tx FIFO is half or completely empty, depending on the value of the periodic Tx FIFO empty level bit in the AHB configuration register (PTXFELVL bit in OTG_GAHBCFG). The application can push the transmission data in advance as long as free space is available in both the periodic Tx FIFO and the periodic request queue. The host periodic transmit FIFO and queue status register (OTG_HPTXSTS) can be read to know how much space is available in both.

OTG_HS core issues the non periodic Tx FIFO empty interrupt (NPTXFE bit in OTG_GINTSTS) as long as the nonperiodic Tx FIFO is half or completely empty depending on the non periodic Tx FIFO empty level bit in the AHB configuration register (TXFELVL bit in OTG_GAHBCFG). The application can push the transmission data as long as free space is available in both the nonperiodic Tx FIFO and nonperiodic request queue. The host nonperiodic transmit FIFO and queue status register (OTG_HNPTXSTS) can be read to know how much space is available in both.

73.11.3 FIFO RAM allocation

Device mode

Receive FIFO RAM allocation: the application must allocate RAM for SETUP packets:

- 10 locations must be reserved in the receive FIFO to receive SETUP packets on control endpoint. The core does not use these locations, which are reserved for SETUP packets, to write any other data.
- One location is to be allocated for Global OUT NAK.
- Status information is written to the FIFO along with each received packet. Therefore, a minimum space of (largest packet size / 4) + 1 must be allocated to receiver packets. If multiple isochronous endpoints are enabled, then at least two (largest packet size / 4) + 1 spaces must be allocated to receive back-to-back packets. Typically, two (largest packet size / 4) + 1 spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.
- Along with the last packet for each endpoint, transfer complete status information is also pushed to the FIFO. One location for each OUT endpoint is recommended.
Device RxFIFO =

\[(5 \times \text{number of control endpoints} + 8) + ((\text{largest USB packet used} / 4) + 1 \text{ for status information}) + (2 \times \text{number of OUT endpoints}) + 1 \text{ for Global NAK}\]

Example: The MPS is 1,024 bytes for a periodic USB packet and 512 bytes for a non-periodic USB packet. There are three OUT endpoints, three IN endpoints, one control endpoint, and three host channels.

Device RxFIFO = \((5 \times 1 + 8) + ((1,024 / 4) + 1) + (2 \times 4) + 1 = 279\)

Transmit FIFO RAM allocation: the minimum RAM space required for each IN endpoint Transmit FIFO is the maximum packet size for that particular IN endpoint.

Note: More space allocated in the transmit IN endpoint FIFO results in better performance on the USB.

Host mode

Receive FIFO RAM allocation:
Status information is written to the FIFO along with each received packet. Therefore, a minimum space of \((\text{largest packet size} / 4) + 1\) must be allocated to receive packets. If multiple isochronous channels are enabled, then at least two \((\text{largest packet size} / 4) + 1\) spaces must be allocated to receive back-to-back packets. Typically, two \((\text{largest packet size} / 4) + 1\) spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.

Along with the last packet in the host channel, transfer complete status information is also pushed to the FIFO. So one location must be allocated for this.

Host RxFIFO = \((\text{largest USB packet used} / 4) + 1 \text{ for status information} + 1 \text{ transfer complete}\)

Example: Host RxFIFO = \(((1,024 / 4) + 1) + 1 = 258\)

Transmit FIFO RAM allocation:

The minimum amount of RAM required for the host Non-periodic Transmit FIFO is the largest maximum packet size among all supported non-periodic OUT channels.

Typically, two largest packet sizes worth of space is recommended, so that when the current packet is under transfer to the USB, the CPU can get the next packet.

Non-Periodic TxFIFO = \(\text{largest non-periodic USB packet used} / 4\)

Example: Non-Periodic TxFIFO = \((512 / 4) = 128\)

The minimum amount of RAM required for host periodic Transmit FIFO is the largest maximum packet size out of all the supported periodic OUT channels. If there is at least one isochronous OUT endpoint, then the space must be at least two times the maximum packet size of that channel.

Host Periodic TxFIFO = \(\text{largest periodic USB packet used} / 4\)

Example: Host Periodic TxFIFO = \((1,024 / 4) = 256\)

Note: More space allocated in the Transmit Non-periodic FIFO results in better performance on the USB.
73.12 OTG_HS interrupts

When the OTG_HS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

*Figure 917* shows the interrupt hierarchy.
OTG_HS_WKUP becomes active (high state) when resume condition occurs during L1 SLEEP or L2 SUSPEND states.
73.13 OTG_HS control and status registers

By reading from and writing to the control and status registers (CSRs) through the AHB slave interface, the application controls the OTG_HS controller. These registers are 32 bits wide, and the addresses are 32-bit block aligned. The OTG_HS registers must be accessed by words (32 bits).

CSRs are classified as follows:
- Core global registers
- Host-mode registers
- Host global registers
- Host port CSRs
- Host channel-specific registers
- Device-mode registers
- Device global registers
- Device endpoint-specific registers
- Power and clock-gating registers
- Data FIFO (DFIFO) access registers

Only the core global, power and clock-gating, data FIFO access, and host port control and status registers can be accessed in both host and device modes. When the OTG_HS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

73.13.1 CSR memory map

The host and device mode registers occupy different addresses. All registers are implemented in the AHB clock domain.

Global CSR map

These registers are available in both host and device modes.

Data FIFO (DFIFO) access register map

These registers, available in both host and device modes, are used to read or write the FIFO space for a specific endpoint or a channel, in a given direction. If a host channel is of type IN, the FIFO can only be read on the channel. Similarly, if a host channel is of type OUT, the FIFO can only be written on the channel.

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 CURMOD: Current mode of operation
Indicates the current mode (host or device).
0: Device mode
1: Host mode

Bit 20 OTGVER: OTG version
Selects the OTG revision.
0: OTG Version 1.3. OTG1.3 is obsolete for new product development.
1: OTG Version 2.0. In this version the core supports only data line pulsing for SRP.

Bit 19 BSVLD: B-session valid
Indicates the device mode transceiver status.
0: B-session is not valid.
1: B-session is valid.

In OTG mode, the user can use this bit to determine if the device is connected or disconnected.

Note: Only accessible in device mode.
Bit 18 **ASVLD**: A-session valid
Indicates the host mode transceiver status.
0: A-session is not valid
1: A-session is valid
*Note:* Only accessible in host mode.

Bit 17 **DBCT**: Long/short debounce time
Indicates the debounce time of a detected connection.
0: Long debounce time, used for physical connections (100 ms + 2.5 µs)
1: Short debounce time, used for soft connections (2.5 µs)
*Note:* Only accessible in host mode.

Bit 16 **CIDSTS**: Connector ID status
Indicates the connector ID status on a connect event.
0: The OTG_HS controller is in A-device mode
1: The OTG_HS controller is in B-device mode
*Note:* Accessible in both device and host modes.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **EHEN**: Embedded host enable
It is used to select between OTG A device state machine and embedded host state machine.
0: OTG A device state machine is selected
1: Embedded host state machine is selected

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **BVALOVAL**: B-peripheral session valid override value.
This bit is used to set override value for Bvalid signal when BVALOEN bit is set.
0: Bvalid value is '0' when BVALOEN = 1
1: Bvalid value is '1' when BVALOEN = 1
*Note:* Only accessible in device mode.

Bit 6 **BVALOEN**: B-peripheral session valid override enable.
This bit is used to enable/disable the software to override the Bvalid signal using the BVALOVAL bit.
0: Override is disabled and Bvalid signal from the respective PHY selected is used internally by the core
1: Internally Bvalid received from the PHY is overridden with BVALOVAL bit value
*Note:* Only accessible in device mode.

Bit 5 **AVALOVAL**: A-peripheral session valid override value.
This bit is used to set override value for Avalid signal when AVALOEN bit is set.
0: Avalid value is '0' when AVALOEN = 1
1: Avalid value is '1' when AVALOEN = 1
*Note:* Only accessible in host mode.

Bit 4 **AVALOEN**: A-peripheral session valid override enable.
This bit is used to enable/disable the software to override the Avalid signal using the AVALOVAL bit.
0: Override is disabled and Avalid signal from the respective PHY selected is used internally by the core
1: Internally Avalid received from the PHY is overridden with AVALOVAL bit value
*Note:* Only accessible in host mode.
Bit 3 **VBVALOVAL**: \( V_{BUS} \) valid override value.
This bit is used to set override value for vbusvalid signal when VBVALOEN bit is set.
0: vbusvalid value is '0' when VBVALOEN = 1
1: vbusvalid value is '1' when VBVALOEN = 1

*Note:* Only accessible in host mode.

Bit 2 **VBVALOEN**: \( V_{BUS} \) valid override enable.
This bit is used to enable/disable the software to override the vbusvalid signal using the VBVALOVAL bit.
0: Override is disabled and vbusvalid signal from the respective PHY selected is used internally by the core.
1: Internally vbusvalid received from the PHY is overridden with VBVALOVAL bit value

*Note:* Only accessible in host mode.

Bits 1:0 Reserved, must be kept at reset value.

### 73.14.2 OTG interrupt register (OTG_GOTGINT)

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

**Address offset:** 0x004

**Reset value:** 0x0000 0000

<table>

Bits 31:19 Reserved, must be kept at reset value.

**Bit 18** **ADTOCHG**: A-device timeout change
The core sets this bit to indicate that the A-device has timed out while waiting for the B-device to connect.

*Note:* Accessible in both device and host modes.

Bits 17:3 Reserved, must be kept at reset value.

**Bit 2** **SEDET**: Session end detected
The core sets this bit to indicate that the level of the voltage on \( V_{BUS} \) is no longer valid for a B-Peripheral session when \( V_{BUS} < 0.8 \) V.

*Note:* Accessible in both device and host modes.

Bits 1:0 Reserved, must be kept at reset value.
73.14.3 OTG AHB configuration register (OTG_GAHBCFG)

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

Address offset: 0x008
Reset value: 0x0000 0000

<table>

</tbody>
</table>

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 PTXFELVL: Periodic Tx FIFO empty level
Indicates when the periodic Tx FIFO empty interrupt bit in the OTG_GINTSTS register (PTXFE bit in OTG_GINTSTS) is triggered.
0: PTXFE (in OTG_GINTSTS) interrupt indicates that the Periodic Tx FIFO is half empty
1: PTXFE (in OTG_GINTSTS) interrupt indicates that the Periodic Tx FIFO is completely empty

Note: Only accessible in host mode.

Bit 7 TXFELVL: Tx FIFO empty level
Condition: device mode
This bit indicates when IN endpoint Transmit FIFO empty interrupt (TXFE in OTG_DIEPINTx) is triggered:
0: The TXFE (in OTG_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is half empty
1: The TXFE (in OTG_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is completely empty

Condition: host mode
This bit indicates when the nonperiodic Tx FIFO empty interrupt (NPTXFE bit in OTG_GINTSTS) is triggered:
0: The NPTXFE (in OTG_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is half empty
1: The NPTXFE (in OTG_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is completely empty

Bit 6 Reserved, must be kept at reset value.
Bit 5 **DMAEN**: DMA enabled
   0: The core operates in slave mode
   1: The core operates in DMA mode

Bits 4:1 **HBSTLEN[3:0]**: Burst length/type
   0000 Single: Bus transactions use single 32 bit accesses (not recommended)
   0001 INCR: Bus transactions use unspecified length accesses (not recommended, uses the INCR AHB bus command)
   0011 INCR4: Bus transactions target 4x 32 bit accesses
   0101 INCR8: Bus transactions target 8x 32 bit accesses
   0111 INCR16: Bus transactions based on 16x 32 bit accesses
   Others: Reserved

Bit 0 **GINTMSK**: Global interrupt mask
   The application uses this bit to mask or unmask the interrupt line assertion to itself. Irrespective of this bit setting, the interrupt status registers are updated by the core.
   0: Mask the interrupt assertion to the application.
   1: Unmask the interrupt assertion to the application.

*Note: Accessible in both device and host modes.*

### 73.14.4 OTG USB configuration register (OTG_GUSBCFG)

This register can be used to configure the core after power-on or a changing to host mode or device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

Address offset: 0x00C

Reset value: 0x0000 1400
Bit 31  Reserved, must be kept at reset value.

Bit 30  **FDMOD**: Force device mode  
Writing a 1 to this bit, forces the core to device mode irrespective of the OTG_ID input pin.  
0: Normal mode  
1: Force device mode  
After setting the force bit, the application must wait at least 25 ms before the change takes effect.  
*Note:* Accessible in both device and host modes.

Bit 29  **FHMOD**: Force host mode  
Writing a 1 to this bit, forces the core to host mode irrespective of the OTG_ID input pin.  
0: Normal mode  
1: Force host mode  
After setting the force bit, the application must wait at least 25 ms before the change takes effect.  
*Note:* Accessible in both device and host modes.

Bits 28:26  Reserved, must be kept at reset value.

Bits 25:23  Reserved, must be kept at reset value.

Bit 22  **TSDPS**: TermSel DLine pulsing selection  
This bit selects utmi_termselect to drive the data line pulse during SRP (session request protocol).  
0: Data line pulsing using utmi_tvalid (default)  
1: Data line pulsing using utmi_termsel

Bits 21:16  Reserved, must be kept at reset value.

Bit 15  **PHYLPC**: PHY Low-power clock select  
This bit selects either 480 MHz or 48 MHz (low-power) PHY mode. In FS and LS modes, the PHY can usually operate on a 48 MHz clock to save power.  
0: 480 MHz internal PLL clock  
1: 48 MHz external clock  
In 480 MHz mode, the UTMI interface operates at either 60 or 30 MHz, depending on whether the 8- or 16-bit data width is selected. In 48 MHz mode, the UTMI interface operates at 48 MHz in FS and LS modes.

Bit 14  Reserved, must be kept at reset value.

Bits 13:10  **TRDT[3:0]**: USB turnaround time  
These bits allow to set the turnaround time in PHY clocks. They must be configured according to *Table 762: TRDT values*, depending on the application AHB frequency. Higher TRDT values allow stretching the USB response time to IN tokens in order to compensate for longer AHB read access latency to the data FIFO.  
*Note:* Only accessible in device mode.

Bits 9:8  Reserved, must be kept at reset value.

Bit 7  Reserved, must be kept at reset value.

Bit 6  Reserved, must be kept at reset value.

Bit 5  Reserved, must be kept at reset value.
Bit 4 Reserved, must be kept at reset value.
Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **TOCAL[2:0]: FS timeout calibration**

The number of PHY clocks that the application programs in this field is added to the full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the line state condition can vary from one PHY to another. The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock is 0.25 bit times.

Bit 31 **AHBIDL: AHB master idle**

Indicates that the AHB master state machine is in the Idle condition.

*Note:* Accessible in both device and host modes.

Bit 30 **DMAREQ: DMA request signal enabled**

This bit indicates that the DMA request is in progress. Used for debug.

Bits 29:11 Reserved, must be kept at reset value.
Bits 10:6 **TXFNUM[4:0]**: Tx FIFO number

This is the FIFO number that must be flushed using the Tx FIFO Flush bit. This field must not be changed until the core clears the Tx FIFO Flush bit.

**Condition: host mode**
- 00000: Non-periodic Tx FIFO flush
- 00001: Periodic Tx FIFO flush
- 10000: Flush all the transmit FIFOs

**Condition: device mode**
- 00000: Tx FIFO 0 flush
- 00001: Tx FIFO 1 flush
- 00010: Tx FIFO 2 flush
- ...
- 01111: Tx FIFO 15 flush
- 10000: Flush all the transmit FIFOs

*Note: Accessible in both device and host modes.*

**Bit 5 TXFFLSH**: Tx FIFO flush

This bit selectively flushes a single or all transmit FIFOs, but cannot do so if the core is in the midst of a transaction.

The application must write this bit only after checking that the core is neither writing to the Tx FIFO nor reading from the Tx FIFO. Verify using these registers:

- **Read**—NAK Effective interrupt ensures the core is not reading from the FIFO
- **Write**—AHBIDL bit in OTG_GRSTCTL ensures the core is not writing anything to the FIFO.

Flushing is normally recommended when FIFOs are reconfigured. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower clock of phy_clk or hclk.

*Note: Accessible in both device and host modes.*

**Bit 4 RXFFLSH**: Rx FIFO flush

The application can flush the entire Rx FIFO using this bit, but must first ensure that the core is not in the middle of a transaction.

The application must only write to this bit after checking that the core is neither reading from the Rx FIFO nor writing to the Rx FIFO.

The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear.

*Note: Accessible in both device and host modes.*

**Bit 3** Reserved, must be kept at reset value.
Bit 2 **FCRST**: Host frame counter reset  
The application writes this bit to reset the (micro-)frame number counter inside the core.  
When the (micro-)frame counter is reset, the subsequent SOF sent out by the core has a frame number of 0.  
When application writes "1" to the bit, it might not be able to read back the value as it gets cleared by the core in a few clock cycles.  
*Note: Only accessible in host mode.*

Bit 1 **PSRST**: Partial soft reset  
Resets the internal state machines but keeps the enumeration info. Can be used to recover some specific PHY errors.  
*Note: Accessible in both device and host modes.*

Bit 0 **CSRST**: Core soft reset  
Resets the HCLK and PHY clock domains as follows:  
Clears the interrupts and all the CSR register bits except for the following bits:  
- GATEHCLK bit in OTG_PCGCCTL  
- STPPCLK bit in OTG_PCGCCTL  
- FLSPCS bits in OTG_HCFG  
- DSPD bit in OTG_DCFG  
- SDIS bit in OTG_DCTL  
- OTG_GCCFG register  
All module state machines (except for the AHB slave unit) are reset to the Idle state, and all the transmit FIFOs and the receive FIFO are flushed.  
Any transactions on the AHB Master are terminated as soon as possible, after completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately. The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit has been cleared, the software must wait at least 3 PHY clocks before accessing the PHY domain (synchronization delay). The software must also check that bit 31 in this register is set to 1 (AHB Master is Idle) before starting any operation.  
Typically, the software reset is used during software development and also when the user dynamically changes the PHY selection bits in the above listed USB configuration registers. When the user changes the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.  
*Note: Accessible in both device and host modes.*
### 73.14.6 OTG core interrupt register [alternate] (OTG_GINTSTS)

Valid for Host mode, see next section for Device mode.

This register also indicates the current mode. To clear the interrupt status bits of the rc_w1 type, the application must write 1 into the bit.

This register interrupts the application for system-level events in the current mode (device mode or host mode).

The FIFO status interrupts are read-only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the OTG_GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

**Address offset:** 0x014

**Reset value:** 0x0400 0020

</tbody>
</table>
Bit 27  **LPMINT**: LPM interrupt
In device mode, this interrupt is asserted when the device receives an LPM transaction and responds with a non-ERRORed response.
In host mode, this interrupt is asserted when the device responds to an LPM transaction with a non-ERRORed response or when the host core has completed LPM transactions for the programmed number of times (RETRYCNT bit in OTG_GLPMCFG).
This field is valid only if the LPMEN bit in OTG_GLPMCFG is set to 1.

Bit 26  **PTXFE**: Periodic Tx FIFO empty
Asserted when the periodic transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the periodic request queue. The half or completely empty status is determined by the periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (PTXFELVL bit in OTG_GAHBCFG).
*Note: Only accessible in host mode.*

Bit 25  **HCINT**: Host channels interrupt
The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in host mode). The application must read the OTG_HAINT register to determine the exact number of the channel on which the interrupt occurred, and then read the corresponding OTG_HCINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the OTG_HCINTx register to clear this bit.
*Note: Only accessible in host mode.*

Bit 24  **HPRTINT**: Host port interrupt
The core sets this bit to indicate a change in port status of one of the OTG_HS controller ports in host mode. The application must read the OTG_HPRT register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_HPRT register to clear this bit.
*Note: Only accessible in host mode.*

Bit 23  **RSTDET**: Reset detected interrupt
In device mode, this interrupt is asserted when a reset is detected on the USB in partial power-down mode when the device is in suspend.
*Note: Only accessible in device mode.*

Bit 22  **DATAFSUSP**: Data fetch suspended
This interrupt is valid only in DMA mode. This interrupt indicates that the core has stopped fetching data for IN endpoints due to the unavailability of TxFIFO space or request queue space. This interrupt is used by the application for an endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application:
- Sets a global nonperiodic IN NAK handshake
- Disables IN endpoints
- Flushes the FIFO
- Determines the token sequence from the IN token sequence learning queue
- Re-enables the endpoints
Clears the global nonperiodic IN NAK handshake if the global nonperiodic IN NAK is cleared, the core has not yet fetched data for the IN endpoint, and the IN token is received: the core generates an "IN token received when FIFO empty" interrupt. The OTG then sends a NAK response to the host. To avoid this scenario, the application can check the FetSusp interrupt in OTG_GINTSTS, which ensures that the FIFO is full before clearing a global NAK handshake. Alternatively, the application can mask the "IN token received when FIFO empty" interrupt when clearing a global IN NAK handshake.

Bit 21  **IPXFR**: Incomplete periodic transfer
In host mode, the core sets this interrupt bit when there are incomplete periodic transactions still pending, which are scheduled for the current frame.
<table>
<thead>
<tr>
<th>Bit 20</th>
<th>ISOIXFR: Incomplete isochronous IN transfer</th>
</tr>

| Bits 9:8 | Reserved, must be kept at reset value. |
Bit 7 **GONAKEFF**: Global OUT NAK effective
Indicates that the Set global OUT NAK bit in the OTG_DCTL register (SGONAK bit in OTG_DCTL), set by the application, has taken effect in the core. This bit can be cleared by writing the Clear global OUT NAK bit in the OTG_DCTL register (CGONAK bit in OTG_DCTL).

*Note: Only accessible in device mode.*

Bit 6 **GINAKEFF**: Global IN non-periodic NAK effective
Indicates that the Set global non-periodic IN NAK bit in the OTG_DCTL register (SGINAK bit in OTG_DCTL), set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. This bit can be cleared by clearing the Clear global non-periodic IN NAK bit in the OTG_DCTL register (CGINAK bit in OTG_DCTL). This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit.

*Note: Only accessible in device mode.*

Bit 5 **NPTXFE**: Non-periodic Tx FIFO empty
This interrupt is asserted when the non-periodic Tx FIFO is either half or completely empty, and there is space for at least one entry to be written to the non-periodic transmit request queue. The half or completely empty status is determined by the non-periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (TXFELVL bit in OTG_GAHBCFG).

*Note: Accessible in host mode only.*

Bit 4 **RXFLVL**: Rx FIFO non-empty
Indicates that there is at least one packet pending to be read from the Rx FIFO.

*Note: Accessible in both host and device modes.*

Bit 3 **SOF**: Start of frame
In host mode, the core sets this bit to indicate that an SOF (FS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt.
In device mode, in the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the OTG_DSTS register to get the current frame number. This interrupt is seen only when the core is operating in FS.

*Note: This register may return ‘1’ if read immediately after power on reset. If the register bit reads ‘1’ immediately after power on reset it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit.*

*Note: Accessible in both host and device modes.*
Bit 2 **OTGINT**: OTG interrupt

The core sets this bit to indicate an OTG protocol event. The application must read the OTG interrupt status (OTG_GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_GOTGINT register to clear this bit.

*Note*: Accessible in both host and device modes.

Bit 1 **MMIS**: Mode mismatch interrupt

The core sets this bit when the application is trying to access:
- A host mode register, when the core is operating in device mode
- A device mode register, when the core is operating in host mode

The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core.

*Note*: Accessible in both host and device modes.

Bit 0 **CMOD**: Current mode of operation

Indicates the current mode.
- 0: Device mode
- 1: Host mode

*Note*: Accessible in both host and device modes.

### 73.14.7 OTG core interrupt register [alternate] (OTG_GINTSTS)

Valid for Device mode, see previous section for Host mode.

This register also indicates the current mode. To clear the interrupt status bits of the rc_w1 type, the application must write 1 into the bit.

This register interrupts the application for system-level events in the current mode (device mode or host mode).

The FIFO status interrupts are read-only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the OTG_GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

Address offset: 0x014

Reset value: 0x0040 0020

</table>
Bit 31 **WKUPINT:** Resume/remote wake-up detected interrupt
Wake-up interrupt during suspend(L2) or LPM(L1) state.
– During suspend(L2):
  In device mode, this interrupt is asserted when a resume is detected on the USB. In host mode, this interrupt is asserted when a remote wake-up is detected on the USB.
– During LPM(L1):
  This interrupt is asserted for either host initiated resume or device initiated remote wake-up on USB.
*Note:* Accessible in both device and host modes.

Bit 30 **SRQINT:** Session request/new session detected interrupt
In host mode, this interrupt is asserted when a session request is detected from the device. In device mode, this interrupt is asserted when VBUS is in the valid range for a B-peripheral device. Accessible in both device and host modes.

Bit 29 **DISCINT:** Disconnect detected interrupt
Asserted when a device disconnect is detected.
*Note:* Only accessible in host mode.

Bit 28 **CIDSCHG:** Connector ID status change
The core sets this bit when there is a change in connector ID status.
*Note:* Accessible in both device and host modes.

Bit 27 **LPMINT:** LPM interrupt
In device mode, this interrupt is asserted when the device receives an LPM transaction and responds with a non-ERRORed response.
In host mode, this interrupt is asserted when the device responds to an LPM transaction with a non-ERRORed response or when the host core has completed LPM transactions for the programmed number of times (RETRYCNT bit in OTG_GLMCFG).
This field is valid only if the LPMEN bit in OTG_GLMCFG is set to 1.

Bit 26 **PTXFE:** Periodic Tx FIFO empty
Asserted when the periodic transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the periodic request queue. The half or completely empty status is determined by the periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (PTXFELVL bit in OTG_GAHBCFG).
*Note:* Only accessible in host mode.

Bit 25 **HCINT:** Host channels interrupt
The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in host mode). The application must read the OTG_HAINT register to determine the exact number of the channel on which the interrupt occurred, and then read the corresponding OTG_HCINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the OTG_HCINTx register to clear this bit.
*Note:* Only accessible in host mode.

Bit 24 **HPRTINT:** Host port interrupt
The core sets this bit to indicate a change in port status of one of the OTG_HS controller ports in host mode. The application must read the OTG_HPRT register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_HPRT register to clear this bit.
*Note:* Only accessible in host mode.
Bit 23  **RSTDET**: Reset detected interrupt
In device mode, this interrupt is asserted when a reset is detected on the USB in partial power-down mode when the device is in suspend.
*Note: Only accessible in device mode.*

Bit 22  **DATAFSUSP**: Data fetch suspended
This interrupt is valid only in DMA mode. This interrupt indicates that the core has stopped fetching data for IN endpoints due to the unavailability of TxFIFO space or request queue space. This interrupt is used by the application for an endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application:
- Sets a global nonperiodic IN NAK handshake
- Disables IN endpoints
- Flushes the FIFO
- Determines the token sequence from the IN token sequence learning queue
- Re-enables the endpoints
Clears the global nonperiodic IN NAK handshake If the global nonperiodic IN NAK is cleared, the core has not yet fetched data for the IN endpoint, and the IN token is received: the core generates an "IN token received when FIFO empty" interrupt. The OTG then sends a NAK response to the host. To avoid this scenario, the application can check the FetSusp interrupt in OTG_GINTSTS, which ensures that the FIFO is full before clearing a global NAK handshake. Alternatively, the application can mask the "IN token received when FIFO empty" interrupt when clearing a global IN NAK handshake.

Bit 21  **INCOMPISOOUT**: Incomplete isochronous OUT transfer
In device mode, the core sets this interrupt to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

Bit 20  **IISOIXFR**: Incomplete isochronous IN transfer
The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.
*Note: Only accessible in device mode.*

Bit 19  **OEPINT**: OUT endpoint interrupt
The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in device mode). The application must read the OTG_DAINT register to determine the exact number of the OUT endpoint on which the interrupt occurred, and then read the corresponding OTG_DOEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG_DOEPINTx register to clear this bit.
*Note: Only accessible in device mode.*

Bit 18  **IEPINT**: IN endpoint interrupt
The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in device mode). The application must read the OTG_DAINT register to determine the exact number of the IN endpoint on which the interrupt occurred, and then read the corresponding OTG_DIEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG_DIEPINTx register to clear this bit.
*Note: Only accessible in device mode.*

Bits 17:16  Reserved, must be kept at reset value.
Bit 15 **EOPF**: End of periodic frame interrupt
Indicates that the period specified in the periodic frame interval field of the OTG_DCFG register (PFIVL bit in OTG_DCFG) has been reached in the current frame.
*Note: Only accessible in device mode.*

Bit 14 **ISOODRP**: Isochronous OUT packet dropped interrupt
The core sets this bit when it fails to write an isochronous OUT packet into the Rx FIFO because the Rx FIFO does not have enough space to accommodate a maximum size packet for the isochronous OUT endpoint.
*Note: Only accessible in device mode.*

Bit 13 **ENUMDNE**: Enumeration done
The core sets this bit to indicate that speed enumeration is complete. The application must read the OTG_DSTS register to obtain the enumerated speed.
*Note: Only accessible in device mode.*

Bit 12 **USBRST**: USB reset
The core sets this bit to indicate that a reset is detected on the USB.
*Note: Only accessible in device mode.*

Bit 11 **USBSUSP**: USB suspend
The core sets this bit to indicate that a suspend was detected on the USB. The core enters the suspended state when there is no activity on the data lines for an extended period of time.
*Note: Only accessible in device mode.*

Bit 10 **ESUSP**: Early suspend
The core sets this bit to indicate that an Idle state has been detected on the USB for 3 ms.
*Note: Only accessible in device mode.*

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **GONAKEFF**: Global OUT NAK effective
Indicates that the Set global OUT NAK bit in the OTG_DCTL register (SGONAK bit in OTG_DCTL), set by the application, has taken effect in the core. This bit can be cleared by writing the Clear global OUT NAK bit in the OTG_DCTL register (CGONAK bit in OTG_DCTL).
*Note: Only accessible in device mode.*

Bit 6 **GINAKEFF**: Global IN non-periodic NAK effective
Indicates that the Set global non-periodic IN NAK bit in the OTG_DCTL register (SGINAK bit in OTG_DCTL), set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. This bit can be cleared by clearing the Clear global non-periodic IN NAK bit in the OTG_DCTL register (CGINAK bit in OTG_DCTL). This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit.
*Note: Only accessible in device mode.*

Bit 5 **NPTXFE**: Non-periodic Tx FIFO empty
This interrupt is asserted when the non-periodic Tx FIFO is either half or completely empty, and there is space for at least one entry to be written to the non-periodic transmit request queue. The half or completely empty status is determined by the non-periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (TXFELVL bit in OTG_GAHBCFG).
*Note: Accessible in host mode only.*
Bit 4 **RXFLVL**: Rx FIFO non-empty
Indicates that there is at least one packet pending to be read from the Rx FIFO.

*Note: Accessible in both host and device modes.*

Bit 3 **SOF**: Start of frame
In host mode, the core sets this bit to indicate that an SOF (FS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt.
In device mode, in the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the OTG_DSTS register to get the current frame number. This interrupt is seen only when the core is operating in FS.

*Note: This register may return ‘1’ if read immediately after power on reset. If the register bit reads ‘1’ immediately after power on reset it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit.*

*Note: Accessible in both host and device modes.*

Bit 2 **OTGINT**: OTG interrupt
The core sets this bit to indicate an OTG protocol event. The application must read the OTG interrupt status (OTG_GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_GOTGINT register to clear this bit.

*Note: Accessible in both host and device modes.*

Bit 1 **MMIS**: Mode mismatch interrupt
The core sets this bit when the application is trying to access:

– A host mode register, when the core is operating in device mode
– A device mode register, when the core is operating in host mode

The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core.

*Note: Accessible in both host and device modes.*

Bit 0 **CMOD**: Current mode of operation
Indicates the current mode.
0: Device mode
1: Host mode

*Note: Accessible in both host and device modes.*
## 73.14.8 OTG interrupt mask register [alternate] (OTG_GINTMSK)

Valid for Host mode, see next section for Device mode.

This register works with the core interrupt register to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the core interrupt (OTG_GINTSTS) register bit corresponding to that interrupt is still set.

### 73.14.10 OTG receive status debug read register [alternate]  
(OTG_GRXSTSR)

This description is for register OTG_GRXSTSR in Device mode.  

A read to the receive status debug read register returns the contents of the top of the receive FIFO.  

The core ignores the receive status read when the receive FIFO is empty and returns a value of 0x0000 0000.  

Address offset: 0x01C  
Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.  

Bit 27 **STSPHST**: Status phase start  
Indicates the start of the status phase for a control write transfer. This bit is set along with the OUT transfer completed PKTSTS pattern.  

Bits 26:25 Reserved, must be kept at reset value.
73.14.11 OTG receive status debug read register [alternate] (OTG_GRXSTSR)

This description is for register OTG_GRXSTSR in Host mode.

A read to the receive status debug read register returns the contents of the top of the receive FIFO.

The core ignores the receive status read when the receive FIFO is empty and returns a value of 0x0000 0000.

Address offset: 0x01C

Reset value: 0x0000 0000

73.14.12 OTG status read and pop registers (OTG_GRXSTSP)

This description is for register OTG_GRXSTSP in Device mode.

Similarly to OTG_GRXSTSR (receive status debug read register) where a read returns the contents of the top of the receive FIFO, a read to OTG_GRXSTSP (receive status read and pop register) additionally pops the top data entry out of the Rx FIFO.

The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x0000 0000. The application must only pop the receive status FIFO when the receive FIFO non-empty bit of the core interrupt register (RXFLVL bit in OTG_GINTSTS) is asserted.

Address offset: 0x020
Reset value: 0x0000 0000
73.14.13 OTG status read and pop registers [alternate] (OTG_GRXSTSP)

This description is for register OTG_GRXSTSP in Host mode.

Similarly to OTG_GRXSTSR (receive status debug read register) where a read returns the contents of the top of the receive FIFO, a read to OTG_GRXSTSP (receive status read and pop register) additionally pops the top data entry out of the Rx FIFO.

The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x0000 0000. The application must only pop the receive status FIFO when the receive FIFO non-empty bit of the core interrupt register (RXFLVL bit in OTG_GINTSTS) is asserted.

Bit 31: Reserved, must be kept at reset value.

Bits 30:24 **NPTXQTOP[6:0]:** Top of the non-periodic transmit request queue
Entry in the non-periodic Tx request queue that is currently being processed by the MAC.
Bits 30:27: Channel/endpoint number
Bits 26:25:
XXXX00X: IN/OUT token
XXXX01X: Zero-length transmit packet (device IN/host OUT)
XXXX11X: Channel halt command
Bit 24: Terminate (last entry for selected channel/endpoint)

Bits 23:16 **NPTQXSAV[7:0]:** Non-periodic transmit request queue space available
Indicates the amount of free space available in the non-periodic transmit request queue.
This queue holds both IN and OUT requests.
0: Non-periodic transmit request queue is full
1: 1 location available
2: locations available
n: n locations available (0 ≤ n ≤ 8)
Others: Reserved

Bits 15:0 **NPTXFSAV[15:0]:** Non-periodic Tx FIFO space available
Indicates the amount of free space available in the non-periodic Tx FIFO.
Values are in terms of 32-bit words.
0: Non-periodic Tx FIFO is full
1: 1 word available
2: 2 words available
n: n words available (where 0 ≤ n ≤ 512)
Others: Reserved
### 73.14.18 OTG general core configuration register (OTG_GCCFG)

This register is available in host and device modes.

Address offset: 0x038

Reset value: 0x0000 XXXX

| Bit 31:29 | Reserved, must be kept at reset value. |
| Bit 28   | Reserved, must be kept at reset value. |
| Bit 27   | Reserved, must be kept at reset value. |
| Bit 26   | Reserved, must be kept at reset value. |
| Bit 25   | **FORCEHOSTPD**: Force host mode pull-downs  |
|          | If the ID pin functions are enabled, the host mode pull-downs on DP and DM activate automatically. However, whenever that is not the case, yet host mode is required, this bit must be used to force the pull-downs active.  |
|          | 0: Do not force host mode pull-downs  |
|          | 1: Force host mode pull-downs  |
| Bit 24   | **VBVALOVEN**: Enables a software override of the VBUS B-session detection.  |
|          | 0: Use hardware  |
|          | 1: Use VBVALOVAL to indicate B-session active  |
| Bit 23   | **VBVALOVAL**: Software override value of the VBUS B-session detection  |
|          | 0: B-session inactive  |
|          | 1: B-session active  |
| Bit 22   | **SDEN**: Secondary detection enable  |
|          | 0: Secondary detection disabled  |
|          | 1: Secondary detection enabled  |
| Bit 21   | **VBDEN**: VBUS detection enable  |
|          | Enables VBUS Sensing Comparators in order to detect VBUS presence and/or perform OTG operation.  |
|          | 0: VBUS detection disabled  |
|          | 1: VBUS detection enabled  |
| Bit 20   | **PDEN**: Primary detection enable  |
|          | 0: Primary detection disabled  |
|          | 1: Primary detection enabled  |
| Bit 19   | **DCDEN**: Data Contact Detection enable  |
|          | 0: Data Contact Detection disabled  |
|          | 1: Data Contact Detection enabled  |
Bit 18 **HVDMSRCEN**: Host CDP port Voltage source enable on DM
0: DM voltage source disabled
1: DM Voltage source enabled

Bit 17 **HCDPDETEN**: Host CDP port voltage detector enable on DP
0: DP voltage detection disabled
1: DP voltage detection enabled

Bit 16 **HCDPEN**: Host CDP behavior enable
0: Disable CDP behavior
1: Enable CDP behavior

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **SESSVLD**: VBUS session indicator
Indicates if VBUS is above VBUS session threshold.
0: VBUS is below VBUS session threshold
1: VBUS is above VBUS session threshold

Bit 2 **FSVMINUS**: Single-Ended DM indicator
This bit gives the voltage level on DM (also result of the comparison with $V_{LGC}$ threshold as defined in BC v1.2 standard).
0: DM voltage at low level
1: DM voltage at high level

Bit 1 **FSVPLUS**: Single-Ended DP indicator
This bit gives the voltage level on DP (also result of the comparison with $V_{LGC}$ threshold as defined in BC v1.2 standard).
0: DM voltage at low level
1: DM voltage at high level

Bit 0 **CHGDET**: Charger detection, result of the current mode (primary or secondary).
0: Low value on pin
1: High value on pin

### 73.14.19 OTG core ID register (OTG_CID)
This is a register containing the Product ID as reset value.
Address offset: 0x03C
Reset value: 0x0000 5000

<td><em>Note: Accessible only in host mode.</em></td>
</tr>
</tbody>
</table>
Bit 16 **L1RSMOK**: Sleep state resume OK
Indicates that the device or host can start resume from Sleep state. This bit is valid in LPM sleep (L1) state. It is set in sleep mode after a delay of 50 μs (TL1Residency).
This bit is reset when SLPSTS is 0.
1: The application or host can start resume from Sleep state
0: The application or host cannot start resume from Sleep state

Bit 15 **SLPSTS**: Port sleep status
**Device mode:**
This bit is set as long as a Sleep condition is present on the USB bus. The core enters the Sleep state when an ACK response is sent to an LPM transaction and the TL1TokenRetry timer has expired. To stop the PHY clock, the application must set the STPPCLK bit in OTG_PCGCCTL, which asserts the PHY suspend input signal.
The application must rely on SLPSTS and not ACK in LPMRSP to confirm transition into sleep.
The core comes out of sleep:
- When there is any activity on the USB linestate
- When the application writes to the RWUSIG bit in OTG_DCTL or when the application resets or soft-disconnects the device.

**Host mode:**
The host transitions to Sleep (L1) state as a side-effect of a successful LPM transaction by the core to the local port with ACK response from the device. The read value of this bit reflects the current Sleep status of the port.
The core clears this bit after:
- The core detects a remote L1 wake-up signal,
- The application sets the PRST bit or the PRES bit in the OTG_HPRT register, or
- The application sets the L1Resume/ remote wake-up detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT bit in OTG_GINTSTS, respectively).
0: Core not in L1
1: Core in L1

Bits 14:13 **LPMRSP[1:0]**: LPM response
**Device mode:**
The response of the core to LPM transaction received is reflected in these two bits.

**Host mode:**
Handshake response received from local device for LPM transaction
11: ACK
10: NYET
01: STALL
00: ERROR (No handshake response)

Bit 12 **L1DSEN**: L1 deep sleep enable
Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit must be set to ‘1’ by application SW in all the cases.
Bits 11:8 **BESLTHRS[3:0]: BESL threshold**

**Device mode:**
The core puts the PHY into deep low power mode in L1 when BESL value is greater than or equal to the value defined in this field BESL_Thres[3:0].

**Host mode:**
The core puts the PHY into deep low power mode in L1. BESLTHRS[3:0] specifies the time for which resume signaling is to be reflected by host ($T_{L1HubDrvResume2}$) on the USB bus when it detects device initiated resume.

BESLTHRS must not be programmed with a value greater than 1100b in host mode, because this exceeds maximum $T_{L1HubDrvResume2}$.

**Thres[3:0] host mode resume signaling time ($\mu$s):**

- 0000: 75
- 0001: 100
- 0010: 150
- 0011: 250
- 0100: 350
- 0101: 450
- 0110: 950

All other values: reserved

Bit 7 **L1SSEN: L1 Shallow Sleep enable**
Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit must be set to ‘1’ by application SW in all the cases.

Bit 6 **REMWAKE: bRemoteWake value**

**Host mode:**
The value of remote wake up to be sent in the wIndex field of LPM transaction.

**Device mode (read-only):**
This field is updated with the received LPM token bRemoteWake bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.
Bits 5:2  **BESL[3:0]**: Best effort service latency

**Host mode:**
The value of BESL to be sent in an LPM transaction. This value is also used to initiate resume for a duration $T_{\text{L1HubDrvResume}}$ for host initiated resume.

**Device mode (read-only):**
This field is updated with the received LPM token BESL bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.

$\text{BESL[3:0]} T_{\text{BESL}} \ (\mu s)$

- 0000: 125
- 0001: 150
- 0010: 200
- 0011: 300
- 0100: 400
- 0101: 500
- 0110: 1000
- 0111: 2000
- 1000: 3000
- 1001: 4000
- 1010: 5000
- 1011: 6000
- 1100: 7000
- 1101: 8000
- 1110: 9000
- 1111: 10000

Bit 1  **LPMACK**: LPM token acknowledge enable

Handshake response to LPM token preprogrammed by device application software.

- 1: ACK
  Even though ACK is preprogrammed, the core device responds with ACK only on successful LPM transaction. The LPM transaction is successful if:
  - No PID/CRC5 errors in either EXT token or LPM token (else ERROR)
  - Valid bLinkState = 0001B (L1) received in LPM transaction (else STALL)
  - No data pending in transmit queue (else NYET).
- 0: NYET
  The preprogrammed software bit is over-ridden for response to LPM token when:
  - The received bLinkState is not L1 (STALL response), or
  - An error is detected in either of the LPM token packets because of corruption (ERROR response).

*Note:* Accessible only in device mode.

Bit 0  **LPMEN**: LPM support enable

The application uses this bit to control the OTG_HS core LPM capabilities.

If the core operates as a non-LPM-capable host, it cannot request the connected device or hub to activate LPM mode.
If the core operates as a non-LPM-capable device, it cannot respond to any LPM transactions.

- 0: LPM capability is not enabled
- 1: LPM capability is enabled
73.14.21 OTG host periodic transmit FIFO size register

73.14.23 Host-mode registers

Bit values in the register descriptions are expressed in binary unless otherwise specified.

Host-mode registers affect the operation of the core in the host mode. Host mode registers must not be accessed in device mode, as the results are undefined. Host mode registers can be categorized as follows:
### 73.14.24 OTG host configuration register (OTG_HCFG)

This register configures the core after power-on. Do not make changes to this register after initializing the host.

**Address offset:** 0x400  
**Reset value:** 0x0000 0000

<table>

</tbody>
</table>

---

3338/3637  
RM0456 Rev 5
Bits 31:17  Reserved, must be kept at reset value.

Bit 16  **RLDCTRL**: Reload control

This bit allows dynamic reloading of the HFIR register during run time.

0: The HFIR cannot be reloaded dynamically
1: The HFIR can be dynamically reloaded during run time.

This bit needs to be programmed during initial configuration and its value must not be changed during run time.

**Caution**: RLDCTRL = 0 is not recommended.

Bits 15:0  **FRIVL[15:0]**: Frame interval

The value that the application programs to this field, specifies the interval between two consecutive micro-SOFs (HS) or Keep-Alive tokens (LS). This field contains the number of PHY clocks that constitute the required frame interval. The application can write a value to this register only after the port enable bit of the host port control and status register (PENA bit in OTG_HPRT) has been set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS/LS PHY clock select field of the host configuration register (FSLSPCS in OTG_HCFG). Do not change the value of this field after the initial configuration, unless the RLDCTRL bit is set. In such case, the FRIVL is reloaded with each SOF event.

- Frame interval = 125 μs × (FRIVL - 1) in high speed operation
- Frame interval = 1 ms × (FRIVL - 1) in low/full speed operation

### 73.14.26  OTG host frame number/frame time remaining register (OTG_HFNUM)

This register indicates the current frame number. It also indicates the time remaining (in terms of the number of PHY clocks) in the current frame.

**Address offset**: 0x408

**Reset value**: 0x0000 3FFF

Bits 31:16  **FTREM[15:0]**: Frame time remaining

Indicates the amount of time remaining in the current frame, in terms of PHY clocks. This field decrements on each PHY clock. When it reaches zero, this field is reloaded with the value in the Frame interval register and a new SOF is transmitted on the USB.

Bits 15:0  **FRNUM[15:0]**: Frame number

This field increments when a new SOF is transmitted on the USB, and is cleared to 0 when it reaches 0x3FFF.
73.14.27 OTG_Host periodic transmit FIFO/queue status register
(OTG_HPTXSTS)

This read-only register contains the free space information for the periodic Tx FIFO and the periodic transmit request queue.

Bits 31:24 **PTXQTOP[7:0]**: Top of the periodic transmit request queue
This indicates the entry in the periodic Tx request queue that is currently being processed by the MAC.
This register is used for debugging.
Bit 31: Odd/Even frame
0XXXXXXX: send in even frame
1XXXXXXX: send in odd frame
Bits 30:27: Channel/endpoint number
Bits 26:25: Type
XXXXX00X: IN/OUT
XXXXX01X: Zero-length packet
XXXXX11X: Disable channel command
Bit 24: Terminate (last entry for the selected channel/endpoint)

Bits 23:16 **PTXQSAV[7:0]**: Periodic transmit request queue space available
Indicates the number of free locations available to be written in the periodic tx request queue. This queue holds both IN and OUT requests.
0: Periodic transmit request queue is full
1: 1 location available
2: 2 locations available
n: n locations available (0 ≤ n ≤ 8)
Others: Reserved

Bits 15:0 **PTXFSAVL[15:0]**: Periodic transmit data FIFO space available
Indicates the number of free locations available to be written to in the periodic Tx FIFO.
Values are in terms of 32-bit words
0: Periodic Tx FIFO is full
1: 1 word available
2: 2 words available
n: n words available (where 0 ≤ n ≤ PTXFD)
Others: Reserved
73.14.28 OTG host all channels interrupt register (OTG_HAINT)

When a significant event occurs on a channel, the host all channels interrupt register interrupts the application using the host channels interrupt bit of the core interrupt register (HCINT bit in OTG_GINTSTS). This is shown in Figure 917. There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding host channel-x interrupt register.

HAINTM[15:0]

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 HAINTM[15:0]: Channel interrupt mask
0: Masked interrupt
1: Unmasked interrupt
One bit per channel: Bit 0 for channel 0, bit 15 for channel 15
### 73.14.30 OTG host port control and status register (OTG_HPRT)

This register is available only in host mode. Currently, the OTG host supports only one port. A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. It is shown in Figure 917. The rc_w1 bits in this register can trigger an interrupt to the application through the host port interrupt bit of the core interrupt register (HPRTINT bit in OTG_GINTSTS). On a port interrupt, the application must read this register and clear the bit that caused the interrupt. For the rc_w1 bits, the application must write a 1 to the bit to clear the interrupt.

Address offset: 0x440
Reset value: 0x0000 0000

| Bit 31:19 | Reserved, must be kept at reset value. |
| Bit 18:17 | PSPD[1:0]: Port speed |
|          | Indicates the speed of the device attached to this port. |
|          | 01: Full speed |
|          | 10: Low speed |
|          | 11: Reserved |
|          | 00: High speed |
| Bit 16:13 | PTCTL[3:0]: Port test control |
|          | The application writes a nonzero value to this field to put the port into a Test mode, and the corresponding pattern is signaled on the port. |
|          | 0000: Test mode disabled |
|          | 0001: Test_J mode |
|          | 0010: Test_K mode |
|          | 0011: Test_SE0_NAK mode |
|          | 0100: Test_Packet mode |
|          | 0101: Test_Force_Enable |
|          | Others: Reserved |
| Bit 12   | PPWR: Port power |
|          | The application uses this field to control power to this port, and the core clears this bit on an overcurrent condition. Note that this bit does not directly activate the voltage on the connector VBUS. |
|          | 0: Power off |
|          | 1: Power on |
| Bit 11:10 | PLSTS[1:0]: Port line status |
|          | Indicates the current logic level USB data lines |
| Bit 10   | Logic level of OTG_DP |
| Bit 11   | Logic level of OTG_DM |
Bit 9  Reserved, must be kept at reset value.

Bit 8  **PRST**: Port reset  
When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete.
0: Port not in reset  
1: Port in reset  
The application must leave this bit set for a minimum duration of at least 10 ms to start a reset on the port. The application can leave it set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by the USB standard.  
High speed: 50 ms  
Full speed/Low speed: 10 ms

Bit 7  **PSUSP**: Port suspend  
The application sets this bit to put this port in suspend mode. The core only stops sending SOFs when this is set. To stop the PHY clock, the application must set the port clock stop bit, which asserts the suspend input pin of the PHY.  
The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wake-up signal is detected or the application sets the port reset bit or port resume bit in this register or the resume/remote wake-up detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT in OTG_GINTSTS, respectively).  
0: Port not in suspend mode  
1: Port in suspend mode

Bit 6  **PRES**: Port resume  
The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit.  
If the core detects a USB remote wake-up sequence, as indicated by the port resume/remote wake-up detected interrupt bit of the core interrupt register (WKUPINT bit in OTG_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently driving resume signaling.  
0: No resume driven  
1: Resume driven  
When LPM is enabled and the core is in L1 state, the behavior of this bit is as follow:  
1. The application sets this bit to drive resume signaling on the port.  
2. The core continues to drive the resume signal until a predetermined time specified in BESLTHRS[3:0] field of OTG_GLPMCFG register.  
3. If the core detects a USB remote wake-up sequence, as indicated by the port L1Resume/Remote L1wake-up detected interrupt bit of the core interrupt register (WKUPINT in OTG_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit at the end of resume. This bit can be set or cleared by both the core and the application. This bit is cleared by the core even if there is no device connected to the host.

Bit 5  **POCCHNG**: Port overcurrent change  
The core sets this bit when the status of the port overcurrent active bit (bit 4) in this register changes.

Bit 4  **POCA**: Port overcurrent active  
Indicates the overcurrent condition of the port.  
0: No overcurrent condition  
1: Overcurrent condition
Bit 3 **PENCHNG**: Port enable/disable change
The core sets this bit when the status of the port enable bit 2 in this register changes.

Bit 2 **PENA**: Port enable
A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot set this bit by a register write. It can only clear it to disable the port. This bit does not trigger any interrupt to the application.
0: Port disabled
1: Port enabled

Bit 1 **PCDET**: Port connect detected
The core sets this bit when a device connection is detected to trigger an interrupt to the application using the host port interrupt bit in the core interrupt register (HPRTINT bit in OTG_GINTSTS). The application must write a 1 to this bit to clear the interrupt.

Bit 0 **PCSTS**: Port connect status
0: No device is attached to the port
1: A device is attached to the port

### 73.14.31 OTG host channel x characteristics register (OTG_HCCHARx)

Bit 31 **CHENA**: Channel enable
This field is set by the application and cleared by the OTG host.
0: Channel disabled
1: Channel enabled

Bit 30 **CHDIS**: Channel disable
The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the Channel disabled interrupt before treating the channel as disabled.

Bit 29 **ODDFRM**: Odd frame
This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd frame. This field is applicable for only periodic (isochronous and interrupt) transactions.
0: Even frame
1: Odd frame

Bits 28:22 **DAD[6:0]**: Device address
This field selects the specific device serving as the data source or sink.
Bits 21:20 **MCNT[1:0]:** Multicount  
This field indicates to the host the number of transactions that must be executed per frame  
for this periodic endpoint. For non-periodic transfers, this field is not used  
00: Reserved. This field yields undefined results  
01: 1 transaction  
10: 2 transactions per frame to be issued for this endpoint  
11: 3 transactions per frame to be issued for this endpoint  
*Note:* This field must be set to at least 01.

Bits 19:18 **EPTYP[1:0]:** Endpoint type  
Indicates the transfer type selected.  
00: Control  
01: Isochronous  
10: Bulk  
11: Interrupt

Bit 17 **LSDEV:** Low-speed device  
This field is set by the application to indicate that this channel is communicating to a low-speed device.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **EPDIR:** Endpoint direction  
Indicates whether the transaction is IN or OUT.  
0: OUT  
1: IN

Bits 14:11 **EPNUM[3:0]:** Endpoint number  
Indicates the endpoint number on the device serving as the data source or sink.

Bits 10:0 **MPSIZ[10:0]:** Maximum packet size  
Indicates the maximum packet size of the associated endpoint.

### 73.14.32 OTG host channel x split control register (OTG_HCSPLTx)

Bit 31 **SPLITEN:** Split enable  
The application sets this bit to indicate that this channel is enabled to perform split transactions.

Bits 30:17 Reserved, must be kept at reset value.

Bit 16 **COMPLSPLT:** Do complete split  
The application sets this bit to request the OTG host to perform a complete split transaction.
73.14.33 OTG host channel x interrupt register (OTG_HCINTx)

This register indicates the status of a channel with respect to USB- and AHB-related events. It is shown in Figure 917. The application must read this register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG_GINTSTS) is set. Before the application can read this register, it must first read the host all channels interrupt (OTG_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_HAINT and OTG_GINTSTS registers.

Address offset: 0x508 + 0x20 * x, (x = 0 to 15)
Reset value: 0x0000 0000

Bit 3 **STALL**: STALL response received interrupt.

Bit 2 **AHBERR**: AHB error

This error is generated only in Internal DMA mode when an AHB error occurs during an AHB read/write operation. The application can read the corresponding DMA channel address register to get the error address.

Bit 1 **CHH**: Channel halted.

Indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application.

Bit 0 **XFRC**: Transfer completed.

Transfer completed normally without any errors.

73.14.34 OTG host channel x interrupt mask register (OTG_HCINTMSKx)

This register reflects the mask for each channel status described in the previous section.

Address offset: 0x50C + 0x20 * x, (x = 0 to 15)

Reset value: 0x0000 0000

**Note:** Do not set this bit for IN transfers. If this bit is set for IN transfers, it disables the channel.
Bits 30:29 **DPID[1:0]**: Data PID

The application programs this field with the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer.

- 00: DATA0
- 01: DATA2
- 10: DATA1
- 11: SETUP (control) / MDATA (non-control)

Bits 28:19 **PKTCNT[9:0]**: Packet count

This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN).

The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion.

Bits 18:0 **XFRSIZ[18:0]**: Transfer size

For an OUT, this field is the number of data bytes the host sends during the transfer.
For an IN, this field is the buffer size that the application has reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).

### 73.14.36 OTG host channel x DMA address register(OTG_HCDMAx)

DMAADDR[15:0]

Bits 31:0 **DMAADDR[31:0]**: DMA address

This field holds the start address in the external memory from which the data for the endpoint must be fetched or to which it must be stored. This register is incremented on every AHB transaction.
73.14.37 Device-mode registers

These registers must be programmed every time the core changes to device mode.

73.14.38 OTG device configuration register (OTG_DCFG)

This register configures the core in device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

Address offset: 0x800
Reset value: 0x0220 0000

</tbody>
</table>

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 PERSCHIVL[1:0]: Periodic schedule interval

This field specifies the amount of time the Internal DMA engine must allocate for fetching periodic IN endpoint data. Based on the number of periodic endpoints, this value must be specified as 25, 50 or 75% of the (micro)frame.

- When any periodic endpoints are active, the internal DMA engine allocates the specified amount of time in fetching periodic IN endpoint data.
- When no periodic endpoint is active, then the internal DMA engine services nonperiodic endpoints, ignoring this field.
- After the specified time within a (micro)frame, the DMA switches to fetching nonperiodic endpoints.

00: 25% of (micro)frame
01: 50% of (micro)frame
10: 75% of (micro)frame
11: Reserved

Bits 23:16 Reserved, must be kept at reset value.

Bit 15 ERRATIM: Erratic error interrupt mask

1: Mask early suspend interrupt on erratic error
0: Early suspend interrupt is generated on erratic error

Bit 14 Reserved, must be kept at reset value.

Bit 13 Reserved, must be kept at reset value.
Bits 12:11 **PFIVL[1:0]**: Periodic frame interval
- Indicates the time within a frame at which the application must be notified using the end of periodic frame interrupt. This can be used to determine if all the isochronous traffic for that frame is complete.
- 00: 80% of the frame interval
- 01: 85% of the frame interval
- 10: 90% of the frame interval
- 11: 95% of the frame interval

Bits 10:4 **DAD[6:0]**: Device address
- The application must program this field after every SetAddress control command.

Bit 3 **Reserved**, must be kept at reset value.

Bit 2 **NZLSOHKS**: Non-zero-length status OUT handshake
- The application can use this field to select the handshake the core sends on receiving a non-zero-length data packet during the OUT transaction of a control transfer’s status stage.
- 1: Send a STALL handshake on a non-zero-length status OUT transaction and do not send the received OUT packet to the application.
- 0: Send the received OUT packet to the application (zero-length or non-zero-length) and send a handshake based on the NAK and STALL bits for the endpoint in the device endpoint control register.

Bits 1:0 **DSPD[1:0]**: Device speed
- Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected.
- 00: High speed
- 01: Full speed
- 10: Reserved
- 11: Reserved

```
Bits 31:19  Reserved, must be kept at reset value.

Bit 18 **DSBESLRJCT**: Deep sleep BESL reject
Core rejects LPM request with BESL value greater than BESL threshold programmed. NYET response is sent for LPM tokens with BESL value greater than BESL threshold. By default, the deep sleep BESL reject feature is disabled.

Bits 17:12  Reserved, must be kept at reset value.

Bit 11 **POPRGDNE**: Power-on programming done
The application uses this bit to indicate that register programming is completed after a wake-up from power down mode.

Bit 10 **CGONAK**: Clear global OUT NAK
Writing 1 to this field clears the Global OUT NAK.

Bit 9 **SGONAK**: Set global OUT NAK
Writing 1 to this field sets the Global OUT NAK.
The application uses this bit to send a NAK handshake on all OUT endpoints.
The application must set the this bit only after making sure that the Global OUT NAK effective bit in the core interrupt register (GONAKEFF bit in OTG_GINTSTS) is cleared.

Bit 8 **CGINAK**: Clear global IN NAK
Writing 1 to this field clears the Global IN NAK.

Bit 7 **SGINAK**: Set global IN NAK
Writing 1 to this field sets the Global non-periodic IN NAK. The application uses this bit to send a NAK handshake on all non-periodic IN endpoints.
The application must set this bit only after making sure that the Global IN NAK effective bit in the core interrupt register (GINAKEFF bit in OTG_GINTSTS) is cleared.

Bits 6:4 **TCTL[2:0]**: Test control
000: Test mode disabled
001: Test_J mode
010: Test_K mode
011: Test_SE0_NAK mode
100: Test_Packet mode
101: Test_Force_Enable
Others: Reserved

Bit 3 **GONSTS**: Global OUT NAK status
0: A handshake is sent based on the FIFO status and the NAK and STALL bit settings.
1: No data is written to the Rx FIFO, irrespective of space availability. Sends a NAK handshake on all packets, except on SETUP transactions. All isochronous OUT packets are dropped.
Bit 2  **GINSTS:** Global IN NAK status
   0: A handshake is sent out based on the data availability in the transmit FIFO.
   1: A NAK handshake is sent out on all non-periodic IN endpoints, irrespective of the data availability in the transmit FIFO.

Bit 1  **SDIS:** Soft disconnect
   The application uses this bit to signal the USB OTG core to perform a soft disconnect. As long as this bit is set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit.
   0: Normal operation. When this bit is cleared after a soft disconnect, the core generates a device disconnect event to the USB host. When the device is reconnected, the USB host restarts device enumeration.
   1: The core generates a device disconnect event to the USB host.

Bit 0  **RWUSIG:** Remote wake-up signaling
   When the application sets this bit, the core initiates remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the suspend state. As specified in the USB 2.0 specification, the application must clear this bit 1 ms to 15 ms after setting it.
   If LPM is enabled and the core is in the L1 (sleep) state, when the application sets this bit, the core initiates L1 remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the sleep state. As specified in the LPM specification, the hardware automatically clears this bit 50 µs (T_{L1DevDrvResume}) after being set by the application. The application must not set this bit when bRemoteWake from the previous LPM transaction is zero (refer to REMWAKE bit in GLPMCFG register).

*Table 763* contains the minimum duration (according to device state) for which the Soft disconnect (SDIS) bit must be set for the USB host to detect a device disconnect. To accommodate clock jitter, it is recommended that the application add some extra delay to the specified minimum duration.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 DEVLNSTS[1:0]: Device line status
- Indicates the current logic level USB data lines.
- Bit [23]: Logic level of D+
- Bit [22]: Logic level of D-

Bits 21:8 FNSOF[13:0]: Frame number of the received SOF

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 EERR: Erratic error
- The core sets this bit to report any erratic errors.
- Due to erratic errors, the OTG_HS controller goes into suspended state and an interrupt is generated to the application with Early suspend bit of the OTG_GINTSTS register (ESUSP bit in OTG_GINTSTS). If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover.

Bits 2:1 ENUMSPD[1:0]: Enumerated speed
- Indicates the speed at which the OTG_HS controller has come up after speed detection through a chirp sequence.
- 00: High Speed
- 01: Full Speed
- 11: Reserved
- Others: reserved

Bit 0 SUSPSTS: Suspend status
- In device mode, this bit is set as long as a suspend condition is detected on the USB. The core enters the suspended state when there is no activity on the USB data lines for a period of 3 ms. The core comes out of the suspend:
  - When there is an activity on the USB data lines
  - When the application writes to the remote wake-up signaling bit in the OTG_DCTL register (RWUSIG bit in OTG_DCTL).
73.14.41 OTG device IN endpoint common interrupt mask register (OTG_DIEPMSK)

This register works with each of the OTG_DIEPINTx registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the OTG_DIEPINTx register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

Address offset: 0x810

Reset value: 0x0000 0000

| Bit 31:14 | Reserved, must be kept at reset value. |
| Bit 13   | **NAKM**: NAK interrupt mask |
| 0        | Masked interrupt |

| Bit 6     | **INEPNEM**: IN endpoint NAK effective mask |
| 0         | Masked interrupt |
| 1         | Unmasked interrupt |

| Bit 5     | **INEPNMM**: IN token received with EP mismatch mask |
| 0         | Masked interrupt |
| 1         | Unmasked interrupt |

| Bit 4     | **ITTXFEMSK**: IN token received when Tx FIFO empty mask |
| 0         | Masked interrupt |
| 1         | Unmasked interrupt |

| Bit 3     | **TOM**: Timeout condition mask (Non-isochronous endpoints) |
| 0         | Masked interrupt |
| 1         | Unmasked interrupt |
Bit 2 **AHBERRM**: AHB error mask  
0: Masked interrupt  
1: Unmasked interrupt  

Bit 1 **EPDM**: Endpoint disabled interrupt mask  
0: Masked interrupt  
1: Unmasked interrupt  

Bit 0 **XFRCM**: Transfer completed interrupt mask  
0: Masked interrupt  
1: Unmasked interrupt  

### 73.14.42 OTG device OUT endpoint common interrupt mask register (OTG_DOEPMSK)

This register works with each of the OTG_DOEPINTx registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the OTG_DOEPINTx register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

### OTG device all endpoints interrupt register (OTG_DAINT)

When a significant event occurs on an endpoint, a OTG_DAINT register interrupts the application using the device OUT endpoints interrupt bit or device IN endpoints interrupt bit of the OTG_GINTSTS register (OEPINT or IEPINT in OTG_GINTSTS, respectively). There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding device endpoint-x interrupt register (OTG_DIEPINTx/OTG_DOEPINTx).

USB on-the-go high-speed (OTG_HS) RM0456

73.14.44 OTG all endpoints interrupt mask register (OTG_DAINTMSK)

The OTG_DAINTMSK register works with the device endpoint interrupt register to interrupt the application when an event occurs on a device endpoint. However, the OTG_DAINT register bit corresponding to that interrupt is still set.

Address offset: 0x81C  
Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **ARPEN**: Arbiter parking enable
This bit controls internal DMA arbiter parking for IN endpoints. When thresholding is enabled and this bit is set to one, then the arbiter parks on the IN endpoint for which there is a token received on the USB. This is done to avoid getting into underrun conditions. By default parking is enabled.

Bit 26 Reserved, must be kept at reset value.

Bits 25:17 **RXTHRLN[8:0]**: Receive threshold length
This field specifies the receive thresholding size in 32-bit words. This field also specifies the amount of data received on the USB before the core can start transmitting on the AHB. The threshold length has to be at least eight 32-bit words. The recommended value for RXTHRLN is to be the same as the programmed AHB burst length (HBSTLEN bit in OTG_GAHBCFG).

Bit 16 **RXTHREN**: Receive threshold enable
When this bit is set, the core enables thresholding in the receive direction.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:2 **TXTHRLN[8:0]**: Transmit threshold length
This field specifies the transmit thresholding size in 32-bit words. This field specifies the amount of data in bytes to be in the corresponding endpoint transmit FIFO, before the core can start transmitting on the USB. The threshold length has to be at least eight 32-bit words. This field controls both isochronous and nonisochronous IN endpoint thresholds. The recommended value for TXTHRLN is to be the same as the programmed AHB burst length (HBSTLEN bit in OTG_GAHBCFG).

Bit 1 **ISOTHREN**: ISO IN endpoint threshold enable
When this bit is set, the core enables thresholding for isochronous IN endpoints.

Bit 0 **NONISOTHREN**: Nonisochronous IN endpoints threshold enable
When this bit is set, the core enables thresholding for nonisochronous IN endpoints.

### 73.14.46 OTG device IN endpoint FIFO empty interrupt mask register (OTG_DIEPEMPMSK)

This register is used to control the IN endpoint FIFO empty interrupt generation (TXFE_OTG_DIEPINTx).

Address offset: 0x834

Reset value: 0x0000 0000
Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INPTXFEM[15:0]:** IN EP Tx FIFO empty interrupt mask bits
These bits act as mask bits for OTG_DIEPINTx.
TXFE interrupt one bit per IN endpoint:
0: Masked interrupt
1: Unmasked interrupt

### 73.14.47 OTG device IN endpoint x control register [alternate] (OTG_DIEPCTLx)

Valid for INT/BULK endpoints, see next section for ISO endpoints.

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

Address offset: 0x900 + 0x20 \* x, (x = 0 to 8)

Reset value: 0x0000 0000

<td></td>
<td>Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.</td>
</tr>
</tbody>
</table>
Bit 27 **SNAK**: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 **TXFNUM[3:0]**: Tx FIFO number
These bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number.
This field is valid only for IN endpoints.

Bit 21 **STALL**: STALL handshake
Applies to non-control, non-isochronous IN endpoints only (access type is rw). The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **EPTYP[1:0]**: Endpoint type
This is the transfer type supported by this logical endpoint.
00: Control
01: Isochronous
10: Bulk
11: Interrupt

Bit 17 **NAKSTS**: NAK status
It indicates the following:
0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.
When either the application or the core sets this bit:
For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there are data available in the Tx FIFO.
For isochronous IN endpoints: The core sends out a zero-length data packet, even if there are data available in the Tx FIFO.
Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 **DPID**: Endpoint data PID
Applies to interrupt/bulk IN endpoints only.
Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID and SD1PID register fields to program either DATA0 or DATA1 PID.
0: DATA0
1: DATA1
Bit 15 **USBEP**: USB active endpoint  
Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size  
The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

### 73.14.48 OTG device IN endpoint x control register [alternate]  
(OTG_DIEPCTLx)

Valid for ISO endpoints, see previous section for INT/BULK endpoints.

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

Address offset: 0x900 + 0x20 * x, (x = 0 to 8)

Reset value: 0x0000 0000

Bit 31 **EPENA**: Endpoint enable  
The application sets this bit to start transmitting data on an endpoint.  
The core clears this bit before setting any of the following interrupts on this endpoint:  
– SETUP phase done  
– Endpoint disabled  
– Transfer completed

Bit 30 **EPDIS**: Endpoint disable  
The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

Bit 29 **SODDFRM**: Set odd frame  
Applies to isochronous IN and OUT endpoints only.  
Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.

Bit 28 **SEVEN**: Set even frame  
Applies to isochronous IN endpoints only.  
Writing to this field sets the Even/Odd frame (EONUM) field to even frame.
Bit 27 **SNAK**: Set NAK  
A write to this bit sets the NAK bit for the endpoint.  
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK  
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 **TXFNUM[3:0]**: Tx FIFO number  
These bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number.  
This field is valid only for IN endpoints.

Bit 21 **STALL**: STALL handshake  
Applies to non-control, non-isochronous IN endpoints only (access type is rw).  
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority.  
Only the application can clear this bit, never the core.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **EPTYP[1:0]**: Endpoint type  
This is the transfer type supported by this logical endpoint.  
00: Control  
01: Isochronous  
10: Bulk  
11: Interrupt

Bit 17 **NAKSTS**: NAK status  
It indicates the following:  
0: The core is transmitting non-NAK handshakes based on the FIFO status.  
1: The core is transmitting NAK handshakes on this endpoint.  
When either the application or the core sets this bit:  
For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there are data available in the Tx FIFO.  
For isochronous IN endpoints: The core sends out a zero-length data packet, even if there are data available in the Tx FIFO.  
Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 **EONUM**: Even/odd frame  
Applies to isochronous IN endpoints only.  
Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.  
0: Even frame  
1: Odd frame
Bit 15 **USBAEP**: USB active endpoint
Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size
The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

### 73.14.49 OTG device IN endpoint x interrupt register (OTG DIEPINTx)

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in Figure 917. The application must read this register when the IN endpoints interrupt bit of the core interrupt register (IEPINT in OTG_GINTSTS) is set. Before the application can read this register, it must first read the device all endpoints interrupt (OTG DAINT) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG DAINT and OTG GINTSTS registers.

Address offset: 0x908 + 0x20 * x, (x = 0 to 8)
Reset value: 0x0000 0080

</table>

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NAK**: NAK input
The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 Reserved, must be kept at reset value.

Bit 11 **PKTDRPSTS**: Packet dropped status
This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt.

Bit 10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 **TXFIFOUDRN**: Transmit Fifo Underrun (TxfifoUndrn)
The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. Dependency: This interrupt is valid only when Thresholding is enabled.
Bit 7 **TXFE**: Transmit FIFO empty
   This interrupt is asserted when the Tx FIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the Tx FIFO Empty Level bit in the OTG_GAHBCFG register (TXFELVL bit in OTG_GAHBCFG).

Bit 6 **INEPNE**: IN endpoint NAK effective
   This bit can be cleared when the application clears the IN endpoint NAK by writing to the CNAK bit in OTG_DIEPCTLx.
   This interrupt indicates that the core has sampled the NAK bit set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core.
   This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.

Bit 5 **INEPNM**: IN token received with EP mismatch
   Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 4 **ITTXFE**: IN token received when Tx FIFO is empty
   Indicates that an IN token was received when the associated Tx FIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 3 **TOC**: Timeout condition
   Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint.

Bit 2 **AHBERR**: AHB error
   This is generated only in internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address.

Bit 1 **EPDISD**: Endpoint disabled interrupt
   This bit indicates that the endpoint is disabled per the application's request.

Bit 0 **XFRC**: Transfer completed interrupt
   This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.
73.14.50 OTG device IN endpoint 0 transfer size register
(OTG_DIEPTSIZ0)

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the device control endpoint 0 control registers (EPENA in OTG_DIEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–3.

Bits 31:21  Reserved, must be kept at reset value.

Bits 20:19  PKTCNT[1:0]: Packet count
Indicates the total number of USB packets that constitute the transfer size amount of data for endpoint 0.
This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:7  Reserved, must be kept at reset value.

Bits 6:0  XFRSIZ[6:0]: Transfer size
Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

**INPTFSAV[15:0]**

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INPTFSAV[15:0]**: IN endpoint Tx FIFO space available

Indicates the amount of free space available in the endpoint Tx FIFO.

Values are in terms of 32-bit words:

0x0: Endpoint Tx FIFO is full

0x1: 1 word available

0x2: 2 words available

0xn: n words available

Others: Reserved

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16

**73.14.53 OTG device IN endpoint x transfer size register (OTG_DIEPTSIZx)**

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using the endpoint enable bit in the OTG_DIEPCTLx registers (EPENA bit in OTG_DIEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Bit 31  Reserved, must be kept at reset value.

Bits 30:29 **MCNT[1:0]:** Multi count
For periodic IN endpoints, this field indicates the number of packets that must be transmitted per frame on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints.
01: 1 packet
10: 2 packets
11: 3 packets

Bits 28:19 **PKTCNT[9:0]:** Packet count
Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.
This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:0 **XFRSIZ[18:0]:** Transfer size
This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

### 73.14.54  OTG device control OUT endpoint 0 control register (OTG_DOEPCTL0)

This section describes the OTG_DOEPCTL0 register. Nonzero control endpoints use registers for endpoints 1–8.

**Bit 31 EPENA:** Endpoint enable
The application sets this bit to start transmitting data on endpoint 0.
The core clears this bit before setting any of the following interrupts on this endpoint:
- SETUP phase done
- Endpoint disabled
- Transfer completed

**Bit 30 EPDIS:** Endpoint disable
The application cannot disable control OUT endpoint 0.

Bits 29:28  Reserved, must be kept at reset value.
Bit 27 **SNAK**: Set NAK  
A write to this bit sets the NAK bit for the endpoint.  
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK  
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **STALL**: STALL handshake  
The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 20 **SNPM**: Snoop mode  
This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.

Bits 19:18 **EPTYP[1:0]**: Endpoint type  
Hardcoded to 00 for control.

Bit 17 **NAKSTS**: NAK status  
Indicates the following:  
0: The core is transmitting non-NAK handshakes based on the FIFO status.  
1: The core is transmitting NAK handshakes on this endpoint.  
When either the application or the core sets this bit, the core stops receiving data, even if there is space in the Rx FIFO to accommodate the incoming packet. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **USBAEP**: USB active endpoint  
This bit is always set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces.

Bits 14:2 Reserved, must be kept at reset value.

Bits 1:0 **MPSIZ[1:0]**: Maximum packet size  
The maximum packet size for control OUT endpoint 0 is the same as what is programmed in control IN endpoint 0.  
00: 64 bytes  
01: 32 bytes  
10: 16 bytes  
11: 8 bytes
OTG device OUT endpoint x interrupt register (OTG_DOEPINTx)

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in Figure 917. The application must read this register when the OUT endpoints interrupt bit of the OTG_GINTSTS register (OEPINT bit in OTG_GINTSTS) is set. Before the application can read this register, it must first read the OTG_DAINT register to get the exact endpoint number for the OTG_DOEPINTx register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.

Address offset: 0xB08 + 0x20 * x, (x = 0 to 8)
Reset value: 0x0000 0080

Bit 15 STPKTRX: Setup packet received
Applicable for control OUT endpoints in only in the Buffer DMA Mode. Set by the OTG_HS, this bit indicates that this buffer holds 8 bytes of setup data. There is only one setup packet per buffer. On receiving a setup packet, the OTG_HS closes the buffer and disables the corresponding endpoint after SETUP_COMPLETE status is seen in the Rx FIFO. OTG_HS puts a SETUP_COMPLETE status into the Rx FIFO when it sees the first IN or OUT token after the SETUP packet for that particular endpoint. The application must then re-enable the endpoint to receive any OUT data for the control transfer and reprogram the buffer start address. Because of the above behavior, OTG_HS can receive any number of back to back setup packets and one buffer for every setup packet is used.

Bit 14 NYET: NYET interrupt
This interrupt is generated when a NYET response is transmitted for a non isochronous OUT endpoint.

Bit 13 NAK: NAK input
The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 BERR: Babble error interrupt
The core generates this interrupt when babble is received for the endpoint.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 OUTPKTERR: OUT packet error
This interrupt is asserted when the core detects an overflow or a CRC error for an OUT packet. This interrupt is valid only when thresholding is enabled.

Bit 7 Reserved, must be kept at reset value.
Bit 6 **B2BSTUP**: Back-to-back SETUP packets received  
Applies to control OUT endpoint only.  
This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint.

Bit 5 **STSPHRSX**: Status phase received for control write  
This interrupt is valid only for control OUT endpoints. This interrupt is generated only after OTG_HS has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a control write transfer. The application can use this interrupt to ACK or STALL the status phase, after it has decoded the data phase.

Bit 4 **OTEPDIS**: OUT token received when endpoint disabled  
Applies only to control OUT endpoints.  
Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received.

Bit 3 **STUP**: SETUP phase done  
Applies to control OUT endpoint only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet.

Bit 2 **AHBERR**: AHB error  
This is generated only in internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address.

Bit 1 **EPDISD**: Endpoint disabled interrupt  
This bit indicates that the endpoint is disabled per the application’s request.

Bit 0 **XFRC**: Transfer completed interrupt  
This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.

### 73.14.56 OTG device OUT endpoint 0 transfer size register  
**OTG_DOEPTSIZ0**

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the OTG_DOEPCTL0 registers (EPENA bit in OTG_DOEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–8.

**Address offset**: 0xB10  
**Reset value**: 0x0000 0000
Bit 31  Reserved, must be kept at reset value.

Bits 30:29  **STUPCNT[1:0]:** SETUP packet count
  This field specifies the number of back-to-back SETUP data packets the endpoint can receive.
  01: 1 packet
  10: 2 packets
  11: 3 packets

Bits 28:20  Reserved, must be kept at reset value.

Bit 19  **PKTCNT:** Packet count
  This field is decremented to zero after a packet is written into the Rx FIFO.

Bits 18:7  Reserved, must be kept at reset value.

Bits 6:0  **XFRSIZ[6:0]:** Transfer size
  Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet is read from the Rx FIFO and written to the external memory.

73.14.57  **OTG device OUT endpoint x DMA address register**
(OTG_DOEPDMAx)

Address offset: 0xB14 + 0x20 * x, (x = 0 to 8)

Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:0  **DMAADDR[31:0]:** DMA Address
  This field holds the start address in the external memory from which the data for the endpoint must be fetched. This register is incremented on every AHB transaction.
### 73.14.58 OTG device OUT endpoint x control register [alternate] (OTG_DOEPCTLx)

Valid for INT/BULK endpoints, see next section for ISO endpoints.

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

Address offset: 0xB00 + 0x20 * x, (x = 1 to 8)

Reset value: 0x0000 0000

#### Bit 31 EPENA: Endpoint enable
Applies to IN and OUT endpoints.
The application sets this bit to start transmitting data on an endpoint.
The core clears this bit before setting any of the following interrupts on this endpoint:
- SETUP phase done
- Endpoint disabled
- Transfer completed

#### Bit 30 EPDIS: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

#### Bit 29 SD1PID: Set DATA1 PID
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA1.

#### Bit 28 SD0PID: Set DATA0 PID
Applies to interrupt/bulk OUT endpoints only.
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.

#### Bit 27 SNAK: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.

#### Bit 26 CNAK: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.
Bit 21  **STALL**: STALL handshake
Applications to non-control, non-isochronous OUT endpoints only (access type is rw).
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK
bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes
priority. Only the application can clear this bit, never the core.
Applications to control endpoints only (access type is rs).
The application can only set this bit, and the core clears it, when a SETUP token is received
for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit,
the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to
SETUP data packets with an ACK handshake.

Bit 20  **SNPM**: Snoop mode
This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check
the correctness of OUT packets before transferring them to application memory.

Bits 19:18  **EPTYP[1:0]**: Endpoint type
This is the transfer type supported by this logical endpoint.
00: Control
01: Isochronous
10: Bulk
11: Interrupt

Bit 17  **NAKSTS**: NAK status
Indicates the following:
0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.
When either the application or the core sets this bit:
The core stops receiving any data on an OUT endpoint, even if there is space in the Rx
FIFO to accommodate the incoming packet.
Irrespective of this bit’s setting, the core always responds to SETUP data packets with an
ACK handshake.

Bit 16  **DPID**: Endpoint data PID
Applications to interrupt/bulk OUT endpoints only.
Contains the PID of the packet to be received or transmitted on this endpoint. The
application must program the PID of the first packet to be received or transmitted on this
endpoint, after the endpoint is activated. The application uses the SD0PID and SD1PID
register fields to program either DATA0 or DATA1 PID.
0: DATA0
1: DATA1

Bit 15  **USBAEP**: USB active endpoint
Indicates whether this endpoint is active in the current configuration and interface. The core
clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving
the SetConfiguration and SetInterface commands, the application must program endpoint
registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0  **MPSIZ[10:0]**: Maximum packet size
The application must program this field with the maximum packet size for the current logical
endpoint. This value is in bytes.
73.14.59 OTG device OUT endpoint x control register [alternate] (OTG_DOEPCTLx)

Valid for ISO endpoints, see previous section for INT/BULK endpoints.

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

Address offset: 0xB00 + 0x20 * x, (x = 1 to 8)

Reset value: 0x0000 0000

</tbody>
</table>

| Bits 31:22 | Reserved, must be kept at reset value. |

Bit 31 **EPENA**: Endpoint enable
Applies to IN and OUT endpoints.
The application sets this bit to start transmitting data on an endpoint.
The core clears this bit before setting any of the following interrupts on this endpoint:
- SETUP phase done
- Endpoint disabled
- Transfer completed

Bit 30 **EPDIS**: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

Bit 29 **SODDFRM**: Set odd frame
Applies to isochronous IN and OUT endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.

Bit 28 **SEVNFRM**: Set even frame
Applies to isochronous OUT endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to even frame.

Bit 27 **SNAK**: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK
A write to this bit clears the NAK bit for the endpoint.
Bit 21 **STALL**: STALL handshake  
Applies to non-control, non-isochronous OUT endpoints only (access type is rw).  
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK  
bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes  
priority. Only the application can clear this bit, never the core.  
Applies to control endpoints only (access type is rs).  
The application can only set this bit, and the core clears it, when a SETUP token is received  
for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit,  
the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to  
SETUP data packets with an ACK handshake.

Bit 20 **SNPM**: Snoop mode  
This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check  
the correctness of OUT packets before transferring them to application memory.

Bits 19:18 **EPTYP[1:0]**: Endpoint type  
This is the transfer type supported by this logical endpoint.  
00: Control  
01: Isochronous  
10: Bulk  
11: Interrupt  

Bit 17 **NAKSTS**: NAK status  
Indicates the following:  
0: The core is transmitting non-NAK handshakes based on the FIFO status.  
1: The core is transmitting NAK handshakes on this endpoint.  
When either the application or the core sets this bit:  
The core stops receiving any data on an OUT endpoint, even if there is space in the Rx  
FIFO to accommodate the incoming packet.  
Irrespective of this bit’s setting, the core always responds to SETUP data packets with an  
ACK handshake.

Bit 16 **EONUM**: Even/odd frame  
Applies to isochronous OUT endpoints only.  
Indicates the frame number in which the core transmits/receives isochronous data for this  
endpoint. The application must program the even/odd frame number in which it intends to  
transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM  
fields in this register.  
0: Even frame  
1: Odd frame  

Bit 15 **USBAEP**: USB active endpoint  
Indicates whether this endpoint is active in the current configuration and interface. The core  
clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving  
the SetConfiguration and SetInterface commands, the application must program endpoint  
registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size  
The application must program this field with the maximum packet size for the current logical  
endpoint. This value is in bytes.
73.14.60 OTG device OUT endpoint x transfer size register (OTG_DOEPTSIZx)

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using endpoint enable bit of the OTG_DOEPCTLx registers (EPENA bit in OTG_DOEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Address offset: 0xB10 + 0x20 * x, (x = 1 to 8)

Reset value: 0x0000 0000

</table>

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 RXDPID[1:0]:
Condition: isochronous OUT endpoints
Received data PID
This is the data PID received in the last packet for this endpoint.
00: DATA0
01: DATA2
10: DATA1
11: MDATA
Condition: control OUT endpoints
STUPCNT[1:0]: SETUP packet count
This field specifies the number of back-to-back SETUP data packets the endpoint can receive.
01: 1 packet
10: 2 packets
11: 3 packets

Bits 28:19 PKTCNT[9:0]: Packet count
Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.
This field is decremented every time a packet (maximum size or short packet) is written to the Rx FIFO.

Bits 18:0 XFRSIZ[18:0]: Transfer size
This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
The core decrements this field every time a packet is read from the Rx FIFO and written to the external memory.
### 73.14.61 OTG power and clock gating control register (OTG_PCGCCTL)

This register is available in host and device modes.

**Address offset**: 0xE00

**Reset value**: 0x200B 8000

<table>

Bits 7:0 Reserved, must be kept at reset value.

- Bit 7 **SUSP**: Deep Sleep
  - This bit indicates that the PHY is in Deep Sleep when in L1 state.
- Bit 6 **PHYSLEEP**: PHY in Sleep
  - This bit indicates that the PHY is in the Sleep state.
- Bit 5 **ENL1GTG**: Enable sleep clock gating
  - When this bit is set, core internal clock gating is enabled in Sleep state if the core cannot assert utmi_l1_suspend_n. When this bit is not set, the PHY clock is not gated in Sleep state.
- Bit 4 **PHYSUSP**: PHY suspended
  - Indicates that the PHY has been suspended. This bit is updated once the PHY is suspended after the application has set the STPPCLK bit.

Bits 3:2 Reserved, must be kept at reset value.

- Bit 1 **GATEHCLK**: Gate HCLK
  - The application sets this bit to gate HCLK to modules other than the AHB Slave and Master and wake-up logic when the USB is suspended or the session is not valid. The application clears this bit when the USB is resumed or a new session starts.

- Bit 0 **STPPCLK**: Stop PHY clock
  - The application sets this bit to stop the PHY clock when the USB is suspended, the session is not valid, or the device is disconnected. The application clears this bit when the USB is resumed or a new session starts.
73.14.62 OTG power and clock gating control register 1 (OTG_PCGCCTL1)

</table>

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RAMGATEEN**: Enable RAM clock gating
Enable gating of the FIFO RAM.

Bits 2:1 **CNTGATECLK[1:0]**: Counter for clock gating
Indicates to the controller how many PHY Clock cycles and AHB Clock cycles of 'IDLE' (no activity) the controller waits for before Gating the respective PHY and AHB clocks internal to the controller.
00: 64 clocks
01: 128 clocks
10: Reserved
11: Reserved

Bit 0 **GATEEN**: Enable active clock gating
The application programs GATEEN to enable Active Clock Gating feature for the PHY and AHB clocks.

73.15  OTG_HS programming model

73.15.1  Core initialization

The application must perform the core initialization sequence. If the cable is connected during power-up, the current mode of operation bit in the OTG_GINTSTS (CMOD bit in OTG_GINTSTS) reflects the mode. The OTG_HS controller enters host mode when an “A” plug is connected or device mode when a “B” plug is connected.

This section explains the initialization of the OTG_HS controller after power-on. The application must follow the initialization sequence irrespective of host or device mode operation. All core global registers are initialized according to the core’s configuration:

1. Program the following fields in the OTG_GAHBCFG register:
   - Global interrupt mask bit GINTMSK = 1
   - Rx FIFO non-empty (RXFLVL bit in OTG_GINTSTS)
   - Periodic Tx FIFO empty level

2. Program the following fields in the OTG_GUSBCFG register:
   - OTG_HS timeout calibration field
   - USB turnaround time field

3. The software must unmask the following bits in the OTG_GINTMSK register:
   OTG interrupt mask
   Mode mismatch interrupt mask

4. The software can read the CMOD bit in OTG_GINTSTS to determine whether the OTG_HS controller is operating in host or device mode.
73.15.2 Host initialization

To initialize the core as host, the application must perform the following steps:

1. Program the HPRTINT in the OTG_GINTMSK register to unmask
2. Program the OTG_HCFG register to select full-speed host
3. Program the PPWR bit in OTG_HPRT to 1. The port is now considered powered however this does not actually drive $V_{BUS}$ on the USB, so a further action must be taken to control the external circuitry in the system so as to enable $V_{BUS}$ generation.
4. Wait for the PCDET interrupt in OTG_HPRT0. This indicates that a device is connecting to the port.
5. Program the PRST bit in OTG_HPRT to 1. This starts the reset process.
6. Wait at least 10 ms for the reset process to complete.
7. Program the PRST bit in OTG_HPRT to 0.
8. Wait for the PENCHNG interrupt in OTG_HPRT.
9. Read the PSPD bit in OTG_HPRT to get the enumerated speed.
10. Program the HFIR register with a value corresponding to the selected PHY clock 1
11. Program the FSLSPCS field in the OTG_HCFG register following the speed of the device detected in step 9. If FSLSPCS has been changed a port reset must be performed.
12. Program the OTG_GRXFSIZ register to select the size of the receive FIFO.
13. Program the OTG_HNPTXFSIZ register to select the size and the start address of the Non-periodic transmit FIFO for non-periodic transactions.
14. Program the OTG_HPTXFSIZ register to select the size and start address of the periodic transmit FIFO for periodic transactions.

To communicate with devices, the system software must initialize and enable at least one channel.
73.15.3 Device initialization

The application must perform the following steps to initialize the core as a device on power-up or after a mode change from host to device.

1. Program the following fields in the OTG_DCFG register:
   - Device speed
   - Non-zero-length status OUT handshake
   - Periodic Frame Interval
2. Program the Device threshold control register. This is required only if you are using DMA mode and you are planning to enable thresholding.
3. Clear the DCTL.SDIS bit. The core issues a connect after this bit is cleared.
4. Program the OTG_GINTMSK register to unmask the following interrupts:
   - USB reset
   - Enumeration done
   - Early suspend
   - USB suspend
   - SOF
5. Wait for the USBRST interrupt in OTG_GINTSTS. It indicates that a reset has been detected on the USB that lasts for about 10 ms on receiving this interrupt.
6. Wait for the ENUMDNE interrupt in OTG_GINTSTS. This interrupt indicates the end of reset on the USB. On receiving this interrupt, the application must read the OTG_DSTS register to determine the enumeration speed and perform the steps listed in "Endpoint initialization on enumeration completion on page 3423."

At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0.

73.15.4 DMA mode

The OTG host uses the AHB master interface to fetch the transmit packet data (AHB to USB) and receive the data update (USB to AHB). The AHB master uses the programmed DMA address (OTG_HCDMAx register in host mode and OTG_DIEPDMAx/OTG_DOEPDMAx register in peripheral mode) to access the data buffers.

73.15.5 Host programming model

Channel initialization

The application must initialize one or more channels before it can communicate with connected devices. To initialize and enable a channel, the application must perform the following steps:
1. Program the OTG_GINTMSK register to unmask the following:

2. Channel interrupt
   - Non-periodic transmit FIFO empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
   - Non-periodic transmit FIFO half-empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).

3. Program the OTG_HAINTMSK register to unmask the selected channels’ interrupts.

4. Program the OTG_HCINTMSK register to unmask the transaction-related interrupts of interest given in the host channel interrupt register.

5. Program the selected channel’s OTG_HCTSIZx register with the total transfer size, in bytes, and the expected number of packets, including short packets. The application must program the PID field with the initial data PID (to be used on the first OUT transaction or to be expected from the first IN transaction).

6. Program the OTG_HCCCHARx register of the selected channel with the device’s endpoint characteristics, such as type, speed, direction, and so forth. (The channel can be enabled by setting the channel enable bit to 1 only when the application is ready to transmit or receive any packet).

7. Program the selected channels in the OTG_HCSPLITx register(s) with the hub and port addresses (split transactions only).

8. Program the selected channels in the OTG_HCDMAx register(s) with the buffer start address (DMA transactions only).

Halting a channel

The application can disable any channel by programming the OTG_HCCCHARx register with the CHDIS and CHENA bits set to 1. This enables the OTG_HS host to flush the posted requests (if any) and generates a channel halted interrupt. The application must wait for the CHH interrupt in OTG_HCINTx before reallocating the channel for other transactions. The OTG_HS host does not interrupt the transaction that has already been started on the USB.

To disable a channel in DMA mode operation, the application does not need to check for space in the request queue. The OTG_HS host checks for space to write the disable request on the disabled channel’s turn during arbitration. Meanwhile, all posted requests are dropped from the request queue when the CHDIS bit in OTG_HCCCHARx is set to 1.

Before disabling a channel, the application must ensure that there is at least one free space available in the non-periodic request queue (when disabling a non-periodic channel) or the periodic request queue (when disabling a periodic channel). The application can simply flush the posted requests when the request queue is full (before disabling the channel), by programming the OTG_HCCCHARx register with the CHDIS bit set to 1 which automatically clears the CHENA bit to 0.

The application is expected to disable a channel on any of the following conditions:
1. When an STALL, TXERR, BBERR or DTERR interrupt in OTG_HCINTx is received for an IN or OUT channel. The application must be able to receive other interrupts (DTERR, Nak, data, TXERR) for the same channel before receiving the halt.

2. When an XFRC interrupt in OTG_HCINTx is received during a non periodic IN transfer or high-bandwidth interrupt IN transfer

3. When a DISCINT (disconnect device) interrupt in OTG_GINTSTS is received. (The application is expected to disable all enabled channels).

4. When the application aborts a transfer before normal completion.

**Ping protocol**

When the OTG_HS host operates in high speed, the application must initiate the ping protocol when communicating with high-speed bulk or control (data and status stage) OUT endpoints. The application must initiate the ping protocol when it receives a NAK/NYET/TXERR interrupt. When the OTG_HS host receives one of the above responses, it does not continue any transaction for a specific endpoint, drops all posted or fetched OUT requests (from the request queue), and flushes the corresponding data (from the transmit FIFO). This is valid in slave mode only. In Slave mode, the application can send a ping token either by setting the DOPING bit in OTG_HCTSIZx before enabling the channel or by just writing the OTG_HCTSIZx register with the DOPING bit set when the channel is already enabled. This enables the OTG_HS host to write a ping request entry to the request queue. The application must wait for the response to the ping token (a NAK, ACK, or TXERR interrupt) before continuing the transaction or sending another ping token. The application can continue the data transaction only after receiving an ACK from the OUT endpoint for the requested ping. In DMA mode operation, the application does not need to set the DOPING bit in OTG_HCTSIZx for a NAK/NYET response in case of bulk/control OUT. The OTG_HS host automatically sets the DOPING bit in OTG_HCTSIZx, and issues the ping tokens for bulk/control OUT. The OTG_HS host continues sending ping tokens until it receives an ACK, and then switches automatically to the data transaction.

**Operational model**

The application must initialize a channel before communicating to the connected device. This section explains the sequence of operation to be performed for different types of USB transactions.

- **Writing the transmit FIFO**
  The OTG_HS host automatically writes an entry (OUT request) to the periodic/non-periodic request queue, along with the last 32-bit word write of a packet. The application must ensure that at least one free space is available in the periodic/non-periodic request queue before starting to write to the transmit FIFO. The application must always write to the transmit FIFO in 32-bit words. If the packet size is non-32-bit word aligned, the application must use padding. The OTG_HS host determines the actual packet size based on the programmed maximum packet size and transfer size.
Figure 918. Transmit FIFO write task

- **Reading the receive FIFO**
  
The application must ignore all packet statuses other than IN data packet (bx0010).
**Bulk and control OUT/SETUP transactions**

A typical bulk or control OUT/SETUP pipelined transaction-level operation is shown in Figure 920. See channel 1 (ch_1). Two bulk OUT packets are transmitted. A control SETUP transaction operates in the same way but has only one packet. The assumptions are:

- The application is attempting to send two maximum-packet-size packets (transfer size = 1,024 bytes).
- The non-periodic transmit FIFO can hold two packets (1 Kbyte for HS).
- The non-periodic request queue depth = 4.

**Normal bulk and control OUT/SETUP operations**

The sequence of operations in (channel 1) is as follows:

1. Initialize channel 1
2. Write the first packet for channel 1
3. Along with the last word write, the core writes an entry to the non-periodic request queue
4. As soon as the non-periodic queue becomes non-empty, the core attempts to send an OUT token in the current frame
5. Write the second (last) packet for channel 1
6. The core generates the XFRC interrupt as soon as the last transaction is completed successfully
7. In response to the XFRC interrupt, de-allocate the channel for other transfers
8. Handling non-ACK responses
Figure 920. Normal bulk/control OUT/SETUP

1. The grayed elements are not relevant in the context of this figure.
The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions is shown in the following code samples.

- **Interrupt service routine for bulk/control OUT/SETUP and bulk/control IN transactions**
  
a) **Bulk/control OUT/SETUP**

Unmask (NAK/TXERR/STALL/XFRC)

```c
if (XFRC) {
  Reset Error Count
  Mask ACK
  De-allocate Channel
}
else if (STALL) {
  Transfer Done = 1
  Unmask CHH
  Disable Channel
}
else if (NAK or TXERR ) {
  Rewind Buffer Pointers
  Unmask CHH
  Disable Channel
  if (TXERR) {
    Increment Error Count

The application is expected to write the data packets into the transmit FIFO when the space is available in the transmit FIFO and the request queue. The application can make use of the NPTXFE interrupt in OTG_GINTSTS to find the transmit FIFO space.

b) Bulk/control IN

Unmask (TXERR/XFRC/BBERR/STALL/DERR)

if (XFRC)
{
    Reset Error Count
    Unmask CHH
    Disable Channel
    Reset Error Count
    Mask ACK
}
else if (TXERR or BBERR or STALL)
{
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}
else if (ACK)
{
    Reset Error Count
    Mask ACK
}
else if (DTERR)
{

}

The application is expected to write the requests as and when the request queue space is available and until the XFRC interrupt is received.

- **Bulk and control IN transactions**
  A typical bulk or control IN pipelined transaction-level operation is shown in Figure 921. See channel 2 (ch_2). The assumptions are:
  - The application is attempting to receive two maximum-packet-size packets (transfer size = 1024 bytes).
  - The receive FIFO can contain at least one maximum-packet-size packet and two status words per packet (520 bytes for HS).
  - The non-periodic request queue depth = 4.
Figure 921. Bulk/control IN transactions

1. The grayed elements are not relevant in the context of this figure.
The sequence of operations is as follows:

1. Initialize channel 2.
2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the non-periodic request queue.
3. The core attempts to send an IN token after completing the current OUT transaction.
4. The core generates an RXFLVL interrupt as soon as the received packet is written to the receive FIFO.
5. In response to the RXFLVL interrupt, mask the RXFLVL interrupt and read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. Following this, unmask the RXFLVL interrupt.
6. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO.
7. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in OTG_GRXSTSR ≠ 0b0010).
8. The core generates the XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, disable the channel and stop writing the OTG_HCCHAR2 register for further requests. The core writes a channel disable request to the non-periodic request queue as soon as the OTG_HCCHAR2 register is written.
10. The core generates the RXFLVL interrupt as soon as the halt status is written to the receive FIFO.
11. Read and ignore the receive packet status.
12. The core generates a CHH interrupt as soon as the halt status is popped from the receive FIFO.
13. In response to the CHH interrupt, de-allocate the channel for other transfers.
14. Handling non-ACK responses

- **Control transactions**
  Setup, data, and status stages of a control transfer must be performed as three separate transfers. setup-, data- or status-stage OUT transactions are performed similarly to the bulk OUT transactions explained previously. Data- or status-stage IN transactions are performed similarly to the bulk IN transactions explained previously. For all three stages, the application is expected to set the EPTYP field in
OTG_HCCHAR1 to control. During the setup stage, the application is expected to set the PID field in OTG_HCTSIZ1 to SETUP.

- **Interrupt OUT transactions**
  A typical interrupt OUT operation is shown in Figure 922. The assumptions are:
  - The application is attempting to send one packet in every frame (up to 1 maximum packet size), starting with the odd frame (transfer size = 1024 bytes)
  - The periodic transmit FIFO can hold one packet (1 Kbyte)
  - Periodic request queue depth = 4
  
  The sequence of operations is as follows:
  1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG_HCCHAR1.
  2. Write the first packet for channel 1.
  3. Along with the last word write of each packet, the OTG_HS host writes an entry to the periodic request queue.
  4. The OTG_HS host attempts to send an OUT token in the next (odd) frame.
  5. The OTG_HS host generates an XFRC interrupt as soon as the last packet is transmitted successfully.
  6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
1. The grayed elements are not relevant in the context of this figure.

• Interrupt IN transactions
The assumptions are:
– The application is attempting to receive one packet (up to 1 maximum packet size) in every frame, starting with odd (transfer size = 1 024 bytes).
– The receive FIFO can hold at least one maximum-packet-size packet and two status words per packet (1 031 bytes).
– Periodic request queue depth = 4.

• Normal interrupt IN operation
The sequence of operations is as follows:
1. Initialize channel 2. The application must set the ODDFRM bit in OTG_HCCHAR2.
2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the periodic request queue.
3. The OTG_HS host writes an IN request to the periodic request queue for each OTG_HCCHAR2 register write with the CHENA bit set.
4. The OTG_HS host attempts to send an IN token in the next (odd) frame.
5. As soon as the IN packet is received and written to the receive FIFO, the OTG_HS host generates an RXFLVL interrupt.
6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask after reading the entire packet.
7. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in GRXSTSR ≠ 0b0010).
8. The core generates an XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, read the PKTCNT field in OTG_HCTSIZ2. If the PKTCNT bit in OTG_HCTSIZ2 is not equal to 0, disable the channel before re-
initializing the channel for the next transfer, if any). If PKTCNT bit in OTG_HCTSIZ2 = 0, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG_HCCHAR2.
1. The grayed elements are not relevant in the context of this figure.

- **Isochronous OUT transactions**

  A typical isochronous OUT operation is shown in Figure 924. The assumptions are:
  - The application is attempting to send one packet every frame (up to 1 maximum
packet size), starting with an odd frame. (transfer size = 1 024 bytes).

– The periodic transmit FIFO can hold one packet (1 Kbyte).
– Periodic request queue depth = 4.

The sequence of operations is as follows:

1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG_HCCHAR1.
2. Write the first packet for channel 1.
3. Along with the last word write of each packet, the OTG_HS host writes an entry to the periodic request queue.
4. The OTG_HS host attempts to send the OUT token in the next frame (odd).
5. The OTG_HS host generates the XFRC interrupt as soon as the last packet is transmitted successfully.
6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
7. Handling non-ACK responses

- Isochronous IN transactions

The assumptions are:
- The application is attempting to receive one packet (up to 1 maximum packet size) in every frame starting with the next odd frame (transfer size = 1 024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status word per packet (1 031 bytes).
- Periodic request queue depth = 4.

The sequence of operations is as follows:
1. Initialize channel 2. The application must set the ODDFRM bit in OTG_HCCHAR2.
2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the periodic request queue.
3. The OTG_HS host writes an IN request to the periodic request queue for each OTG_HCCHAR2 register write with the CHENA bit set.
4. The OTG_HS host attempts to send an IN token in the next odd frame.
5. As soon as the IN packet is received and written to the receive FIFO, the OTG_HS host generates an RXFLVL interrupt.
6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask it after reading the entire packet.
7. The core generates an RXFLVL interrupt for the transfer completion status entry in the receive FIFO. This time, the application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS bit in OTG_GRXSTSR ≠ 0b0010).
8. The core generates an XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, read the PKTCNT field in OTG_HCTSIZ2. If PKTCNT ≠ 0 in OTG_HCTSIZ2, disable the channel before re-initializing the channel for the next transfer, if any. If PKTCNT = 0 in OTG_HCTSIZ2, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG_HCCHAR2.
Figure 925. Isochronous IN transactions

1. The grayed elements are not relevant in the context of this figure.

- **Selecting the queue depth**

  Choose the periodic and non-periodic request queue depths carefully to match the number of periodic/non-periodic endpoints accessed.

  The non-periodic request queue depth affects the performance of non-periodic
transfers. The deeper the queue (along with sufficient FIFO size), the more often the core is able to pipeline non-periodic transfers. If the queue size is small, the core is able to put in new requests only when the queue space is freed up.

The core’s periodic request queue depth is critical to perform periodic transfers as scheduled. Select the periodic queue depth, based on the number of periodic transfers scheduled in a microframe. If the periodic request queue depth is smaller than the periodic transfers scheduled in a microframe, a frame overrun condition occurs.

- **Handling babble conditions**
  OTG_HS controller handles two cases of babble: packet babble and port babble. Packet babble occurs if the device sends more data than the maximum packet size for the channel. Port babble occurs if the core continues to receive data from the device at EOF2 (the end of frame 2, which is very close to SOF).

  When OTG_HS controller detects a packet babble, it stops writing data into the Rx buffer and waits for the end of packet (EOP). When it detects an EOP, it flushes already written data in the Rx buffer and generates a Babble interrupt to the application.

  When OTG_HS controller detects a port babble, it flushes the Rx FIFO and disables the port. The core then generates a port disabled interrupt (HPRTINT in OTG_GINTSTS, PENCHNG in OTG_HPRT). On receiving this interrupt, the application must determine that this is not due to an overcurrent condition (another cause of the port disabled interrupt) by checking POCA in OTG_HPRT, then perform a soft reset. The core does not send any more tokens after it has detected a port babble condition.

- **Bulk and control OUT/SETUP transactions in DMA mode**
  The sequence of operations is as follows:
  1. Initialize and enable channel 1 as explained in [Section : Channel initialization](#).
  2. The OTG_HS host starts fetching the first packet as soon as the channel is enabled. For internal DMA mode, the OTG_HS host uses the programmed DMA address to fetch the packet.
  3. After fetching the last 32-bit word of the second (last) packet, the OTG_HS host masks channel 1 internally for further arbitration.
  4. The OTG_HS host generates a CHH interrupt as soon as the last packet is sent.
  5. In response to the CHH interrupt, de-allocate the channel for other transfers.
**NAK and NYET handling with internal DMA:**

1. The OTG_HS host sends a bulk OUT transaction.
2. The device responds with NAK or NYET.
3. If the application has unmasked NAK or NYET, the core generates the corresponding interrupt(s) to the application. The application is not required to service these interrupts, since the core takes care of rewinding the buffer pointers and re-initializing the Channel without application intervention.
4. The core automatically issues a ping token.
5. When the device returns an ACK, the core continues with the transfer. Optionally, the application can utilize these interrupts, in which case the NAK or NYET interrupt is masked by the application.
The core does not generate a separate interrupt when NAK or NYET is received by the host functionality.

- **Bulk and control IN transactions in DMA mode**
  The sequence of operations is as follows:
  1. Initialize and enable the used channel (channel x) as explained in *Section: Channel initialization*.
  2. The OTG_HS host writes an IN request to the request queue as soon as the channel receives the grant from the arbiter (arbitration is performed in a round-robin fashion).
  3. The OTG_HS host starts writing the received data to the system memory as soon as the last byte is received with no errors.
  4. When the last packet is received, the OTG_HS host sets an internal flag to remove any extra IN requests from the request queue.
  5. The OTG_HS host flushes the extra requests.
  6. The final request to disable channel x is written to the request queue. At this point, channel 2 is internally masked for further arbitration.
  7. The OTG_HS host generates the CHH interrupt as soon as the disable request comes to the top of the queue.
  8. In response to the CHH interrupt, de-allocate the channel for other transfers.
• **Interrupt OUT transactions in DMA mode**

1. Initialize and enable channel x as explained in *Section: Channel initialization*.
2. The OTG_HS host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last 32-bit word fetch. In high-bandwidth transfers, the OTG_HS host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.
3. The OTG_HS host attempts to send the OUT token at the beginning of the next odd frame/micro-frame.
4. After successfully transmitting the packet, the OTG_HS host generates a CHH interrupt.

5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 928. Normal interrupt OUT transactions - DMA mode**

- **Interrupt IN transactions in DMA mode**
  
  The sequence of operations (channelx) is as follows:
  
  1. Initialize and enable channel x as explained in Section: Channel initialization.
  2. The OTG_HS host writes an IN request to the request queue as soon as the channel x gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the OTG_HS host writes consecutive writes up to MC times.
3. The OTG_HS host attempts to send an IN token at the beginning of the next (odd) frame/micro-frame.
4. As soon the packet is received and written to the receive FIFO, the OTG_HS host generates a CHH interrupt.
5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 929. Normal interrupt IN transactions - DMA mode**

- **Isochronous OUT transactions in DMA mode**
  1. Initialize and enable channel x as explained in Section: Channel initialization.
  2. The OTG_HS host starts fetching the first packet as soon as the channel is enabled, and writes the OUT request along with the last 32-bit word fetch. In high-bandwidth
transfers, the OTG_HS host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.

3. The OTG_HS host attempts to send an OUT token at the beginning of the next (odd) frame/micro-frame.

4. After successfully transmitting the packet, the OTG_HS host generates a CHH interrupt.

5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

Figure 930. Normal isochronous OUT transaction - DMA mode

- **Isochronous IN transactions in DMA mode**
  
  The sequence of operations ((channel x) is as follows:
  
  1. Initialize and enable channel x as explained in **Section : Channel initialization**.
  
  2. The OTG_HS host writes an IN request to the request queue as soon as the channel x gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the OTG_HS host performs consecutive write operations up to MC times.
3. The OTG_HS host attempts to send an IN token at the beginning of the next (odd) frame/micro-frame.
4. As soon the packet is received and written to the receive FIFO, the OTG_HS host generates a CHH interrupt.
5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 931. Normal isochronous IN transactions - DMA mode**

- **Bulk and control OUT/SETUP split transactions in DMA mode**
  
  The sequence of operations in (channel x) is as follows:
  
  1. Initialize and enable channel x for start split as explained in *Section: Channel initialization*.
  2. The OTG_HS host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last 32-bit word fetch.
  3. After successfully transmitting start split, the OTG_HS host generates the CHH interrupt.
  4. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT1 to send the complete split.
5. After successfully transmitting complete split, the OTG_HS host generates the CHH interrupt.

6. In response to the CHH interrupt, de-allocate the channel.

• **Bulk/control IN split transactions in DMA mode**
  The sequence of operations (channel x) is as follows:
  1. Initialize and enable channel x as explained in Section : Channel initialization.
  2. The OTG_HS host writes the start split request to the nonperiodic request after getting the grant from the arbiter. The OTG_HS host masks the channel x internally for the arbitration after writing the request.
  3. As soon as the IN token is transmitted, the OTG_HS host generates the CHH interrupt.
  4. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT2 and re-enable the channel to send the complete split token. This unmasks channel x for arbitration.
  5. The OTG_HS host writes the complete split request to the nonperiodic request after receiving the grant from the arbiter.
  6. The OTG_HS host starts writing the packet to the system memory after receiving the packet successfully.
  7. As soon as the received packet is written to the system memory, the OTG_HS host generates a CHH interrupt.
  8. In response to the CHH interrupt, de-allocate the channel.

• **Interrupt OUT split transactions in DMA mode**
  The sequence of operations in (channel x) is as follows:
  1. Initialize and enable channel 1 for start split as explained in Section : Channel initialization. The application must set the ODDFRM bit in OTG_HCCHAR1.
  2. The OTG_HS host starts reading the packet.
  3. The OTG_HS host attempts to send the start split transaction.
  4. After successfully transmitting the start split, the OTG_HS host generates the CHH interrupt.
  5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT1 to send the complete split.
  6. After successfully completing the complete split transaction, the OTG_HS host generates the CHH interrupt.
  7. In response to CHH interrupt, de-allocate the channel.

• **Interrupt IN split transactions in DMA mode**
  The sequence of operations in (channel x) is as follows:
  1. Initialize and enable channel x for start split as explained in Section : Channel initialization.
  2. The OTG_HS host writes an IN request to the request queue as soon as channel x receives the grant from the arbiter.
  3. The OTG_HS host attempts to send the start split IN token at the beginning of the next odd micro-frame.
  4. The OTG_HS host generates the CHH interrupt after successfully transmitting the start split IN token.
  5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT2 to send the complete split.
6. As soon as the packet is received successfully, the OTG_HS host starts writing the data to the system memory.
7. The OTG_HS host generates the CHH interrupt after transferring the received data to the system memory.
8. In response to the CHH interrupt, de-allocate or reinitialize the channel for the next start split.

- **Isochronous OUT split transactions in DMA mode**
  The sequence of operations (channel x) is as follows:
  1. Initialize and enable channel x for start split (begin) as explained in Section : Channel initialization. The application must set the ODDFRM bit in OTG_HCCHAR1. Program the MPS field.
  2. The OTG_HS host starts reading the packet.
  3. After successfully transmitting the start split (begin), the OTG_HS host generates the CHH interrupt.
  4. In response to the CHH interrupt, reinitialize the registers to send the start split (end).
  5. After successfully transmitting the start split (end), the OTG_HS host generates a CHH interrupt.
  6. In response to the CHH interrupt, de-allocate the channel.

- **Isochronous IN split transactions in DMA mode**
  The sequence of operations (channel x) is as follows:
  1. Initialize and enable channel x for start split as explained in Section : Channel initialization.
  2. The OTG_HS host writes an IN request to the request queue as soon as channel x receives the grant from the arbiter.
  3. The OTG_HS host attempts to send the start split IN token at the beginning of the next odd micro-frame.
  4. The OTG_HS host generates the CHH interrupt after successfully transmitting the start split IN token.
  5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT2 to send the complete split.
  6. As soon as the packet is received successfully, the OTG_HS host starts writing the data to the system memory.
     The OTG_HS host generates the CHH interrupt after transferring the received data to the system memory. In response to the CHH interrupt, de-allocate the channel or reinitialize the channel for the next start split.
73.15.6 Device programming model

Endpoint initialization on USB reset

1. Set the NAK bit for all OUT endpoints
   - SNAK = 1 in OTG_DOEPCTLx (for all OUT endpoints)
2. Unmask the following interrupt bits
   - INEPO = 1 in OTG_DAINTMSK (control 0 IN endpoint)
   - OUTEP0 = 1 in OTG_DAINTMSK (control 0 OUT endpoint)
   - STUPM = 1 in OTG_DOEPMSK
   - XFRCM = 1 in OTG_DOEPMSK
   - XFRCM = 1 in OTG_DIEPMSK
   - TOM = 1 in OTG_DIEPMSK
3. Set up the data FIFO RAM for each of the FIFOs
   - Program the OTG_GRXFSIZ register, to be able to receive control OUT data and setup data. If thresholding is not enabled, at a minimum, this must be equal to 1 max packet size of control endpoint 0 + 2 words (for the status of the control OUT data packet) + 10 words (for setup packets).
   - Program the OTG_DIEPTXF0 register (depending on the FIFO number chosen) to be able to transmit control IN data. At a minimum, this must be equal to 1 max packet size of control endpoint 0.
4. Program the following fields in the endpoint-specific registers for control OUT endpoint 0 to receive a SETUP packet
   - STUPCNT = 3 in OTG_DOEPTSIZ0 (to receive up to 3 back-to-back SETUP packets)
5. For USB OTG_HS in DMA mode, the OTG_DOEPDMA0 register must have a valid memory address to store any SETUP packets received.

At this point, all initialization required to receive SETUP packets is done.

Endpoint initialization on enumeration completion

1. On the Enumeration Done interrupt (ENUMDNE in OTG_GINTSTS), read the OTG_DSTS register to determine the enumeration speed.
2. Program the MPSIZ field in OTG_DIEPCTL0 to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for a control endpoint depends on the enumeration speed.
3. For USB OTG_HS in DMA mode, program the OTG_DOEPCTL0 register to enable control OUT endpoint 0, to receive a SETUP packet.

At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

Endpoint initialization on SetAddress command

This section describes what the application must do when it receives a SetAddress command in a SETUP packet.
1. Program the OTG_DCFG register with the device address received in the SetAddress command
2. Program the core to send out a status IN packet
Endpoint initialization on SetConfiguration/SetInterface command

This section describes what the application must do when it receives a SetConfiguration or SetInterface command in a SETUP packet.

1. When a SetConfiguration command is received, the application must program the endpoint registers to configure them with the characteristics of the valid endpoints in the new configuration.

2. When a SetInterface command is received, the application must program the endpoint registers of the endpoints affected by this command.

3. Some endpoints that were active in the prior configuration or alternate setting are not valid in the new configuration or alternate setting. These invalid endpoints must be deactivated.

4. Unmask the interrupt for each active endpoint and mask the interrupts for all inactive endpoints in the OTG_DAINTMSK register.

5. Set up the data FIFO RAM for each FIFO.

6. After all required endpoints are configured; the application must program the core to send a status IN packet.

At this point, the device core is configured to receive and transmit any type of data packet.

Endpoint activation

This section describes the steps required to activate a device endpoint or to configure an existing device endpoint to a new type.

1. Program the characteristics of the required endpoint into the following fields of the OTG_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG_DOEPCTLx register (for OUT or bidirectional endpoints).
   - Maximum packet size
   - USB active endpoint = 1
   - Endpoint start data toggle (for interrupt and bulk endpoints)
   - Endpoint type
   - Tx FIFO number

2. Once the endpoint is activated, the core starts decoding the tokens addressed to that endpoint and sends out a valid handshake for each valid token received for the endpoint.

Endpoint deactivation

This section describes the steps required to deactivate an existing endpoint.

1. In the endpoint to be deactivated, clear the USB active endpoint bit in the OTG_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG_DOEPCTLx register (for OUT or bidirectional endpoints).

2. Once the endpoint is deactivated, the core ignores tokens addressed to that endpoint, which results in a timeout on the USB.

Note: The application must meet the following conditions to set up the device core to handle traffic:
NPTXFEM and RXFLVLM in the OTG_GINTMSK register must be cleared.
**Operational model**

**SETUP and OUT data transfers:**

This section describes the internal data flow and application-level operations during data OUT transfers and SETUP transactions.

- **Packet read**

  This section describes how to read packets (OUT data and SETUP packets) from the receive FIFO.

  1. On catching an RXFLVL interrupt (OTG_GINTSTS register), the application must read the receive status pop register (OTG_GRXSTSP).

  2. The application can mask the RXFLVL interrupt (in OTG_GINTSTS) by writing to RXFLVLM = 0 (in OTG_GINTMSK), until it has read the packet from the receive FIFO.

  3. If the received packet's byte count is not 0, the byte count amount of data is popped from the receive data FIFO and stored in memory. If the received packet byte count is 0, no data is popped from the receive data FIFO.

  4. The receive status readout of the packet of FIFO indicates one of the following:

    a) Global OUT NAK pattern:
       
       PKTSTS = Global OUT NAK, BCNT = 0x000, EPNUM = (0x0), DPID = (0b00).

       These data indicate that the global OUT NAK bit has taken effect.

    b) SETUP packet pattern:
       
       PKTSTS = SETUP, BCNT = 0x008, EPNUM = Control EP Num, DPID = DATA0. These data indicate that a SETUP packet for the specified endpoint is now available for reading from the receive FIFO.

    c) Setup stage done pattern:
       
       PKTSTS = Setup Stage Done, BCNT = 0x0, EPNUM = Control EP Num, DPID = (0b00).

       These data indicate that the setup stage for the specified endpoint has completed and the data stage has started. After this entry is popped from the receive FIFO, the core asserts a setup interrupt on the specified control OUT endpoint.

    d) Data OUT packet pattern:
       
       PKTSTS = Data OUT, BCNT = size of the received data OUT packet (0 ≤ BCNT ≤ 1 024), EPNUM = EPNUM on which the packet was received, DPID = Actual Data PID.

    e) Data transfer completed pattern:
       
       PKTSTS = Data OUT transfer done, BCNT = 0x0, EPNUM = OUT EP Num on which the data transfer is complete, DPID = (0b00).

       These data indicate that an OUT data transfer for the specified OUT endpoint has completed. After this entry is popped from the receive FIFO, the core asserts a transfer completed interrupt on the specified OUT endpoint.

  5. After the data payload is popped from the receive FIFO, the RXFLVL interrupt (OTG_GINTSTS) must be unmasked.

  6. Steps 1–5 are repeated every time the application detects assertion of the interrupt line due to RXFLVL in OTG_GINTSTS. Reading an empty receive FIFO can result in undefined core behavior.

*Figure 932* provides a flowchart of the above procedure.
SETUP transactions

This section describes how the core handles SETUP packets and the application’s sequence for handling SETUP transactions.

- **Application requirements**
  1. To receive a SETUP packet, the STUPCNT field (OTG_DOEPTSIZx) in a control OUT endpoint must be programmed to a non-zero value. When the application programs the STUPCNT field to a non-zero value, the core receives SETUP packets and writes them to the receive FIFO, irrespective of the NAK status and EPENA bit setting in OTG_DOEPCTLx. The STUPCNT field is decremented every time the control endpoint receives a SETUP packet. If the STUPCNT field is not programmed to a proper value before receiving a SETUP packet, the core still receives the SETUP packet and decrements the STUPCNT field, but the application may not be able to determine the correct number of SETUP packets received in the setup stage of a control transfer.
    - STUPCNT = 3 in OTG_DOEPTSIZx
  2. The application must always allocate some extra space in the receive data FIFO, to be able to receive up to three SETUP packets on a control endpoint.
    - The space to be reserved is 10 words. Three words are required for the first SETUP packet, 1 word is required for the setup stage done word and 6 words are required to store two extra SETUP packets among all control endpoints.
    - 3 words per SETUP packet are required to store 8 bytes of SETUP data and 4 bytes of SETUP status (setup packet pattern). The core reserves this space in the
receive data FIFO to write SETUP data only, and never uses this space for data packets.

3. The application must read the 2 words of the SETUP packet from the receive FIFO.

4. The application must read and discard the setup stage done word from the receive FIFO.

- **Internal data flow**
  1. When a SETUP packet is received, the core writes the received data to the receive FIFO, without checking for available space in the receive FIFO and irrespective of the endpoint’s NAK and STALL bit settings.
     - The core internally sets the IN NAK and OUT NAK bits for the control IN/OUT endpoints on which the SETUP packet was received.
  2. For every SETUP packet received on the USB, 3 words of data are written to the receive FIFO, and the STUPCNT field is decremented by 1.
     - The first word contains control information used internally by the core
     - The second word contains the first 4 bytes of the SETUP command
     - The third word contains the last 4 bytes of the SETUP command
  3. When the setup stage changes to a data IN/OUT stage, the core writes an entry (setup stage done word) to the receive FIFO, indicating the completion of the setup stage.
  4. On the AHB side, SETUP packets are emptied by the application.
  5. When the application pops the setup stage done word from the receive FIFO, the core interrupts the application with an STUP interrupt (OTG_DOEPINTx), indicating it can process the received SETUP packet.
  6. The core clears the endpoint enable bit for control OUT endpoints.

- **Application programming sequence**
  1. Program the OTG_DOEPTSIZx register.
     - STUPCNT = 3
  2. Wait for the RXFLVL interrupt (OTG_GINTSTS) and empty the data packets from the receive FIFO.
  3. Assertion of the STUP interrupt (OTG_DOEPINTx) marks a successful completion of the SETUP data transfer.
     - On this interrupt, the application must read the OTG_DOEPTSIZx register to determine the number of SETUP packets received and process the last received SETUP packet.
Handling more than three back-to-back SETUP packets

Per the USB 2.0 specification, normally, during a SETUP packet error, a host does not send more than three back-to-back SETUP packets to the same endpoint. However, the USB 2.0 specification does not limit the number of back-to-back SETUP packets a host can send to the same endpoint. When this condition occurs, the OTG_HS controller generates an interrupt (B2BSTUP in OTG_DOEPINTx).

Setting the global OUT NAK

Internal data flow:
1. When the application sets the Global OUT NAK (SGONAK bit in OTG_DCTL), the core stops writing data, except SETUP packets, to the receive FIFO. Irrespective of the space availability in the receive FIFO, non-isochronous OUT tokens receive a NAK handshake response, and the core ignores isochronous OUT data packets.
2. The core writes the Global OUT NAK pattern to the receive FIFO. The application must reserve enough receive FIFO space to write this data pattern.
3. When the application pops the Global OUT NAK pattern word from the receive FIFO, the core sets the GONAKEFF interrupt (OTG_GINTSTS).
4. Once the application detects this interrupt, it can assume that the core is in Global OUT NAK mode. The application can clear this interrupt by clearing the SGONAK bit in OTG_DCTL.

Application programming sequence:
1. To stop receiving any kind of data in the receive FIFO, the application must set the Global OUT NAK bit by programming the following field:
   – SGONAK = 1 in OTG_DCTL
2. Wait for the assertion of the GONAKEFF interrupt in OTG_GINTSTS. When asserted, this interrupt indicates that the core has stopped receiving any type of data except SETUP packets.
3. The application can receive valid OUT packets after it has set SGONAK in OTG_DCTL and before the core asserts the GONAKEFF interrupt (OTG_GINTSTS).
4. The application can temporarily mask this interrupt by writing to the GONAKEFFM bit in the OTG_GINTMSK register.
   – GONAKEFFM = 0 in the OTG_GINTMSK register
5. Whenever the application is ready to exit the Global OUT NAK mode, it must clear the SGONAK bit in OTG_DCTL. This also clears the GONAKEFF interrupt (OTG_GINTSTS).
   – CGONAK = 1 in OTG_DCTL
6. If the application has masked this interrupt earlier, it must be unmasked as follows:
   – GONAKEFFM = 1 in OTG_GINTMSK

**Disabling an OUT endpoint**

The application must use this sequence to disable an OUT endpoint that it has enabled.

Application programming sequence:
1. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core.
   – SGONAK = 1 in OTG_DCTL
2. Wait for the GONAKEFF interrupt (OTG_GINTSTS)
3. Disable the required OUT endpoint by programming the following fields:
   – EPDIS = 1 in OTG_DOEPCTLx
   – SNAK = 1 in OTG_DOEPCTLx
4. Wait for the EPDISD interrupt (OTG_DOEPINTx), which indicates that the OUT endpoint is completely disabled. When the EPDISD interrupt is asserted, the core also clears the following bits:
   – EPDIS = 0 in OTG_DOEPCTLx
   – EPENA = 0 in OTG_DOEPCTLx
5. The application must clear the Global OUT NAK bit to start receiving data from other non-disabled OUT endpoints.
   – SGONAK = 0 in OTG_DCTL

**Transfer Stop Programming for OUT endpoints**

The application must use the following programming sequence to stop any transfers (because of an interrupt from the host, typically a reset).

**Sequence of operations:**
1. Enable all OUT endpoints by setting
   - EPENA = 1 in all OTG_DOEPCTLx registers.
2. Flush the RxFIFO as follows
   - Poll OTG_GRSTCTL.AHBIDL until it is 1. This indicates that AHB master is idle.
   - Perform read modify write operation on OTG_GRSTCTL.RXFFLSH = 1
   - Poll OTG_GRSTCTL.RXFFLSH until it is 0, but also using a timeout of less than
     10 milli-seconds (corresponds to minimum reset signaling duration). If 0 is seen
     before the timeout, then the RxFIFO flush is successful. If at the moment the
     timeout occurs, there is still a 1, (this may be due to a packet on EP0 coming from
     the host) then go back (once only) to the previous step (“Perform read modify write
     operation”).
3. Before disabling any OUT endpoint, the application must enable Global OUT NAK
   mode in the core, according to the instructions in “Setting the global OUT NAK
   on page 3428”. This ensures that data in the RxFIFO is sent to the application
   successfully. Set SGONAK = 1 in OTG_DCTL
4. Wait for the GONAKEFF interrupt (OTG_GINTSTS)
5. Disable all active OUT endpoints by programming the following register bits:
   - EPDIS = 1 in registers OTG_DOEPCTLx
   - SNAK = 1 in registers OTG_DOEPCTLx
6. Wait for the EPDIS interrupt in OTG_DOEPINTx for each OUT endpoint programmed
   in the previous step. The EPDIS interrupt in OTG_DOEPINTx indicates that the
   corresponding OUT endpoint is completely disabled. When the EPDIS interrupt is
   asserted, the following bits are cleared:
   - EPENA = 0 in registers OTG_DOEPCTLx
   - EPDIS = 0 in registers OTG_DOEPCTLx
   - SNAK = 0 in registers OTG_DOEPCTLx

- **Generic non-isochronous OUT data transfers**

This section describes a regular non-isochronous OUT data transfer (control, bulk, or
interrupt).

Application requirements:
1. Before setting up an OUT transfer, the application must allocate a buffer in the memory
   to accommodate all data to be received as part of the OUT transfer.
2. For OUT transfers, the transfer size field in the endpoint’s transfer size register must be
   a multiple of the maximum packet size of the endpoint, adjusted to the word boundary.
   - transfer size[EPNUM] = n × (MPSIZ[EPNUM] + 4 – (MPSIZ[EPNUM] mod 4))
   - packet count[EPNUM] = n
   - n > 0
3. On any OUT endpoint interrupt, the application must read the endpoint’s transfer size
   register to calculate the size of the payload in the memory. The received payload size
   can be less than the programmed transfer size.
   - Payload size in memory = application programmed initial transfer size – core
     updated final transfer size
   - Number of USB packets in which this payload was received = application
     programmed initial packet count – core updated final packet count
Internal data flow:
1. The application must set the transfer size and packet count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
2. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the packet count field for that endpoint by 1.
   - OUT data packets received with bad data CRC are flushed from the receive FIFO automatically.
   - After sending an ACK for the packet on the USB, the core discards non-isochronous OUT data packets that the host, which cannot detect the ACK, resends. The application does not detect multiple back-to-back data OUT packets on the same endpoint with the same data PID. In this case the packet count is not decremented.
   - If there is no space in the receive FIFO, isochronous or non-isochronous data packets are ignored and not written to the receive FIFO. Additionally, non-isochronous OUT tokens receive a NAK handshake reply.
   - In all the above three cases, the packet count is not decremented because no data are written to the receive FIFO.
3. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or non-isochronous data packets are ignored and not written to the receive FIFO, and non-isochronous OUT tokens receive a NAK handshake reply.
4. After the data are written to the receive FIFO, the application reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.
5. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.
6. The OUT data transfer completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions:
   - The transfer size is 0 and the packet count is 0
   - The last OUT data packet written to the receive FIFO is a short packet (0 ≤ packet size < maximum packet size)
7. When either the application pops this entry (OUT data transfer completed), a transfer completed interrupt is generated for the endpoint and the endpoint enable is cleared.

Application programming sequence:
1. Program the OTG_DOEPTSIZx register for the transfer size and the corresponding packet count.
2. Program the OTG_DOEPCTLx register with the endpoint characteristics, and set the EPENA and CNAK bits.
   - EPENA = 1 in OTG_DOEPCTLx
   - CNAK = 1 in OTG_DOEPCTLx
3. Wait for the RXFLVL interrupt (in OTG_GINTSTS) and empty the data packets from the receive FIFO.
   - This step can be repeated many times, depending on the transfer size.
4. Asserting the XFRC interrupt (OTG_DOEPINTx) marks a successful completion of the non-isochronous OUT data transfer.
5. Read the OTG_DOEPTSIZx register to determine the size of the received data payload.

- **Generic isochronous OUT data transfer**

This section describes a regular isochronous OUT data transfer.

Application requirements:

1. All the application requirements for non-isochronous OUT data transfers also apply to isochronous OUT data transfers.
2. For isochronous OUT data transfers, the transfer size and packet count fields must always be set to the number of maximum-packet-size packets that can be received in a single frame and no more. Isochronous OUT data transfers cannot span more than 1 frame.
3. The application must read all isochronous OUT data packets from the receive FIFO (data and status) before the end of the periodic frame (EOPF interrupt in OTG_GINTSTS).
4. To receive data in the following frame, an isochronous OUT endpoint must be enabled after the EOPF (OTG_GINTSTS) and before the SOF (OTG_GINTSTS).

Internal data flow:

1. The internal data flow for isochronous OUT endpoints is the same as that for non-isochronous OUT endpoints, but for a few differences.
2. When an isochronous OUT endpoint is enabled by setting the endpoint enable and clearing the NAK bits, the Even/Odd frame bit must also be set appropriately. The core receives data on an isochronous OUT endpoint in a particular frame only if the following condition is met:
   - EONUM (in OTG_DOEPCTLx) = FNSOF[0] (in OTG_DSTS)
3. When the application completely reads an isochronous OUT data packet (data and status) from the receive FIFO, the core updates the RXDPID field in OTG_DOEPTSIZx with the data PID of the last isochronous OUT data packet read from the receive FIFO.

Application programming sequence:
1. Program the OTG_DOEPTSIZx register for the transfer size and the corresponding packet count
2. Program the OTG_DOEPCTLx register with the endpoint characteristics and set the endpoint enable, ClearNAK, and Even/Odd frame bits.
   - EPENA = 1
   - CNAK = 1
   - EONUM = (0: Even/1: Odd)
3. Wait for the RXFLVL interrupt (in OTG_GINTSTS) and empty the data packets from the receive FIFO
   - This step can be repeated many times, depending on the transfer size.
4. The assertion of the XFRC interrupt (in OTG_DOEPINTx) marks the completion of the isochronous OUT data transfer. This interrupt does not necessarily mean that the data in memory are good.
5. This interrupt cannot always be detected for isochronous OUT transfers. Instead, the application can detect the INCOMPISOOUT interrupt in OTG_GINTSTS.
6. Read the OTG_DOEPTSIZx register to determine the size of the received transfer and to determine the validity of the data received in the frame. The application must treat the data received in memory as valid only if one of the following conditions is met:
   - RXDPID = DATA0 (in OTG_DOEPTSIZx) and the number of USB packets in which this payload was received = 1
   - RXDPID = DATA1 (in OTG_DOEPTSIZx) and the number of USB packets in which this payload was received = 2
   - RXDPID = D2 (in OTG_DOEPTSIZx) and the number of USB packets in which this payload was received = 3

   The number of USB packets in which this payload was received = Application programmed initial packet count – core updated final packet count

   The application can discard invalid data packets.

- Incomplete isochronous OUT data transfers

This section describes the application programming sequence when isochronous OUT data packets are dropped inside the core.

Internal data flow:
1. For isochronous OUT endpoints, the XFRC interrupt (in OTG_DOEPINTx) may not always be asserted. If the core drops isochronous OUT data packets, the application may fail to detect the XFRC interrupt (OTG_DOEPINTx) under the following circumstances:
   - When the receive FIFO cannot accommodate the complete ISO OUT data packet, the core drops the received ISO OUT data
   - When the isochronous OUT data packet is received with CRC errors
   - When the isochronous OUT token received by the core is corrupted
   - When the application is very slow in reading the data from the receive FIFO
2. When the core detects an end of periodic frame before transfer completion to all isochronous OUT endpoints, it asserts the incomplete isochronous OUT data interrupt (INCOMPISOOUT in OTG_GINTSTS), indicating that an XFRC interrupt (in OTG_DOEPINTx) is not asserted on at least one of the isochronous OUT endpoints. At
this point, the endpoint with the incomplete transfer remains enabled, but no active transfers remain in progress on this endpoint on the USB.

Application programming sequence:
1. Asserting the INCOMPOISOUT interrupt (OTG_GINTSTS) indicates that in the current frame, at least one isochronous OUT endpoint has an incomplete transfer.
2. If this occurs because isochronous OUT data is not completely emptied from the endpoint, the application must ensure that the application empties all isochronous OUT data (data and status) from the receive FIFO before proceeding.
   - When all data are emptied from the receive FIFO, the application can detect the XFRC interrupt (OTG_DOEPINTx). In this case, the application must re-enable the endpoint to receive isochronous OUT data in the next frame.
3. When it receives an INCOMPOISOUT interrupt (in OTG_GINTSTS), the application must read the control registers of all isochronous OUT endpoints (OTG_DOEPCTLx) to determine which endpoints had an incomplete transfer in the current microframe. An endpoint transfer is incomplete if both the following conditions are met:
   - EONUM bit (in OTG_DOEPCTLx) = FNSOF[0] (in OTG_DSTS)
   - EPENA = 1 (in OTG_DOEPCTLx)
4. The previous step must be performed before the SOF interrupt (in OTG_GINTSTS) is detected, to ensure that the current frame number is not changed.
5. For isochronous OUT endpoints with incomplete transfers, the application must discard the data in the memory and disable the endpoint by setting the EPDIS bit in OTG_DOEPCTLx.
6. Wait for the EPDISD interrupt (in OTG_DOEPINTx) and enable the endpoint to receive new data in the next frame.
   - Because the core can take some time to disable the endpoint, the application may not be able to receive the data in the next frame after receiving bad isochronous data.

- **Stalling a non-isochronous OUT endpoint**
This section describes how the application can stall a non-isochronous endpoint.
1. Put the core in the Global OUT NAK mode.
2. Disable the required endpoint
   - When disabling the endpoint, instead of setting the SNAK bit in OTG_DOEPCTL, set STALL = 1 (in OTG_DOEPCTL).
     The STALL bit always takes precedence over the NAK bit.
3. When the application is ready to end the STALL handshake for the endpoint, the STALL bit (in OTG_DOEPCTLx) must be cleared.
4. If the application is setting or clearing a STALL for an endpoint due to a SetFeature.Endpoint Halt or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the status stage transfer on the control endpoint.

**Examples**
This section describes and depicts some fundamental transfer types and scenarios.
- **Bulk OUT transaction**
**Figure 934** depicts the reception of a single Bulk OUT data packet from the USB to the AHB and describes the events involved in the process.

**Figure 934. Bulk OUT transaction**

1. host attempts to send data (OUT token) to an endpoint.
2. When the core receives the OUT token on the USB, it stores the packet in the Rx FIFO because space is available there.
3. After writing the complete packet in the Rx FIFO, the core then asserts the RXFLVL interrupt (in OTG_GINTSTS).
4. On receiving the PKTCNT number of USB packets, the core internally sets the NAK bit for this endpoint to prevent it from receiving any more packets.
5. The application processes the interrupt and reads the data from the Rx FIFO.
6. When the application has read all the data (equivalent to XFRSIZ), the core generates an XFRC interrupt (in OTG_DOEPINTx).
7. The application processes the interrupt and uses the setting of the XFRC interrupt bit (in OTG_DOEPINTx) to determine that the intended transfer is complete.

**IN data transfers**

- **Packet write**

This section describes how the application writes data packets to the endpoint FIFO when dedicated transmit FIFOs are enabled.
1. The application can either choose the polling or the interrupt mode.
   - In polling mode, the application monitors the status of the endpoint transmit data FIFO by reading the OTG_DTXFSTSx register, to determine if there is enough space in the data FIFO.
   - In interrupt mode, the application waits for the TXFE interrupt (in OTG_DIEPINTx) and then reads the OTG_DTXFSTSx register, to determine if there is enough space in the data FIFO.
   - To write a single non-zero length data packet, there must be space to write the entire packet in the data FIFO.
   - To write zero length packet, the application must not look at the FIFO space.
2. Using one of the above mentioned methods, when the application determines that there is enough space to write a transmit packet, the application must first write into the endpoint control register, before writing the data into the data FIFO. Typically, the application, must do a read modify write on the OTG_DIEPCTLx register to avoid modifying the contents of the register, except for setting the endpoint enable bit.

The application can write multiple packets for the same endpoint into the transmit FIFO, if space is available. For periodic IN endpoints, the application must write packets only for one microframe. It can write packets for the next periodic transaction only after getting transfer complete for the previous transaction.

- **Setting IN endpoint NAK**

Internal data flow:
1. When the application sets the IN NAK for a particular endpoint, the core stops transmitting data on the endpoint, irrespective of data availability in the endpoint’s transmit FIFO.
2. Non-isochronous IN tokens receive a NAK handshake reply
   - Isochronous IN tokens receive a zero-data-length packet reply
3. The core asserts the INEPNE (IN endpoint NAK effective) interrupt in OTG_DIEPINTx in response to the SNAK bit in OTG_DIEPCTLx.
4. Once this interrupt is seen by the application, the application can assume that the endpoint is in IN NAK mode. This interrupt can be cleared by the application by setting the CNAK bit in OTG_DIEPCTLx.

Application programming sequence:
1. To stop transmitting any data on a particular IN endpoint, the application must set the IN NAK bit. To set this bit, the following field must be programmed.
   - SNAK = 1 in OTG_DIEPCTLx
2. Wait for assertion of the INEPNE interrupt in OTG_DIEPINTx. This interrupt indicates that the core has stopped transmitting data on the endpoint.
3. The core can transmit valid IN data on the endpoint after the application has set the NAK bit, but before the assertion of the NAK Effective interrupt.
4. The application can mask this interrupt temporarily by writing to the INEPNEM bit in OTG_DIEPMSK.
   - INEPNEM = 0 in OTG_DIEPMSK
5. To exit endpoint NAK mode, the application must clear the NAK status bit (NAKSTS) in OTG_DIEPCTLx. This also clears the INEPNE interrupt (in OTG_DIEPINTx).
6. If the application masked this interrupt earlier, it must be unmasked as follows:
   - \texttt{INEPNEM} = 1 in OTG\_DIEPMSK

### IN endpoint disable

Use the following sequence to disable a specific IN endpoint that has been previously enabled.

**Application programming sequence:**

1. The application must stop writing data on the AHB for the IN endpoint to be disabled.
2. The application must set the endpoint in NAK mode.
   - \texttt{SNAK} = 1 in OTG\_DIEPCTLx
3. Wait for the INEPNE interrupt in OTG\_DIEPINTx.
4. Set the following bits in the OTG\_DIEPCTLx register for the endpoint that must be disabled.
   - \texttt{EPDIS} = 1 in OTG\_DIEPCTLx
   - \texttt{SNAK} = 1 in OTG\_DIEPCTLx
5. Assertion of the EPDISD interrupt in OTG\_DIEPINTx indicates that the core has completely disabled the specified endpoint. Along with the assertion of the interrupt, the core also clears the following bits:
   - \texttt{EPENA} = 0 in OTG\_DIEPCTLx
   - \texttt{EPDIS} = 0 in OTG\_DIEPCTLx
6. The application must read the OTG\_DIEPTSIZx register for the periodic IN EP, to calculate how much data on the endpoint were transmitted on the USB.
7. The application must flush the data in the endpoint transmit FIFO, by setting the following fields in the OTG\_GRSTCTL register:
   - \texttt{TXFNUM} (in OTG\_GRSTCTL) = Endpoint transmit FIFO number
   - \texttt{TXFFLSH} in (OTG\_GRSTCTL) = 1

   The application must poll the OTG\_GRSTCTL register, until the TXFFLSH bit is cleared by the core, which indicates the end of flush operation. To transmit new data on this endpoint, the application can re-enable the endpoint at a later point.

### Transfer Stop Programming for IN endpoints

The application must use the following programming sequence to stop any transfers (because of an interrupt from the host, typically a reset).
Sequence of operations:
1. Disable the IN endpoint by setting:
   – EPDIS = 1 in all OTG_DIEPCTLx registers
2. Wait for the EPDIS interrupt in OTG_DIEPINTx, which indicates that the IN endpoint is completely disabled. When the EPDIS interrupt is asserted the following bits are cleared:
   – EPDIS = 0 in OTG_DIEPCTLx
   – EPENA = 0 in OTG_DIEPCTLx
3. Flush the TxFIFO by programming the following bits:
   – TXFFLSH = 1 in OTG_GRSTCTL
   – TXFNUM = “FIFO number specific to endpoint” in OTG_GRSTCTL
4. The application can start polling till TXFFLSH in OTG_GRSTCTL is cleared. When this bit is cleared, it ensures that there is no data left in the Tx FIFO.

• Generic non-periodic IN data transfers

Application requirements:
1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer are part of a single buffer.
2. For IN transfers, the transfer size field in the endpoint transfer size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
   – To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
     \[
     \text{Transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}
     \]
     If \((\text{sp} > 0)\), then packet count[EPNUM] = \(x + 1\).
     Otherwise, packet count[EPNUM] = \(x\)
   – To transmit a single zero-length data packet:
     \[
     \text{Transfer size}[\text{EPNUM}] = 0
     \]
     Packet count[EPNUM] = 1
   – To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer into two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.
     First transfer: transfer size[EPNUM] = \(x \times \text{MPSIZ}[\text{epnum}]\); packet count = \(n\);
     Second transfer: transfer size[EPNUM] = 0; packet count = 1;
3. Once an endpoint is enabled for data transfers, the core updates the transfer size register. At the end of the IN transfer, the application must read the transfer size register to determine how much data posted in the transmit FIFO have already been sent on the USB.
4. Data fetched into transmit FIFO = Application-programmed initial transfer size – core-updated final transfer size
   – Data transmitted on USB = (application-programmed initial packet count – core updated final packet count) \(\times\) MPSIZ[EPNUM]
   – Data yet to be transmitted on USB = (Application-programmed initial transfer size – data transmitted on USB)
Internal data flow:
1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the transmit FIFO for the endpoint.
3. Every time a packet is written into the transmit FIFO by the application, the transfer size for that endpoint is decremented by the packet size. The data is fetched from the memory by the application, until the transfer size for the endpoint becomes 0. After writing the data into the FIFO, the “number of packets in FIFO” count is incremented (this is a 3-bit count, internally maintained by the core for each IN endpoint transmit FIFO. The maximum number of packets maintained by the core at any time in an IN endpoint FIFO is eight). For zero-length packets, a separate flag is set for each FIFO, without any data in the FIFO.
4. Once the data are written to the transmit FIFO, the core reads them out upon receiving an IN token. For every non-isochronous IN data packet transmitted with an ACK handshake, the packet count for the endpoint is decremented by one, until the packet count is zero. The packet count is not decremented on a timeout.
5. For zero length packets (indicated by an internal zero length flag), the core sends out a zero-length packet for the IN token and decrements the packet count field.
6. If there are no data in the FIFO for a received IN token and the packet count field for that endpoint is zero, the core generates an “IN token received when Tx FIFO is empty” (ITTXFE) interrupt for the endpoint, provided that the endpoint NAK bit is not set. The core responds with a NAK handshake for non-isochronous endpoints on the USB.
7. The core internally rewinds the FIFO pointers and no timeout interrupt is generated.
8. When the transfer size is 0 and the packet count is 0, the transfer complete (XFRC) interrupt for the endpoint is generated and the endpoint enable is cleared.

Application programming sequence:
1. Program the OTG_DIEPTSIZx register with the transfer size and corresponding packet count.
2. Program the OTG_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA (endpoint enable) bits.
3. When transmitting non-zero length data packet, the application must poll the OTG_DTXFSTSx register (where x is the FIFO number associated with that endpoint) to determine whether there is enough space in the data FIFO. The application can optionally use TXFE (in OTG_DIEPINTx) before writing the data.

• Generic periodic IN data transfers
This section describes a typical periodic IN data transfer.

Application requirements:
1. Application requirements 1, 2, 3, and 4 of Generic non-periodic IN data transfers on page 3438 also apply to periodic IN data transfers, except for a slight modification of requirement 2.
   – The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To
transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met:

\[
\text{transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + sp
\]

(where \(x\) is an integer \(\geq 0\), and \(0 \leq sp < \text{MPSIZ}[\text{EPNUM}]\))

- If \((sp > 0)\), \(\text{packet count}[\text{EPNUM}] = x + 1\)
- Otherwise, \(\text{packet count}[\text{EPNUM}] = x\);

\[
\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]
\]

- The application cannot transmit a zero-length data packet at the end of a transfer. It can transmit a single zero-length data packet by itself. To transmit a single zero-length data packet:

\[
\text{transfer size}[\text{EPNUM}] = 0
\]

\[
\text{packet count}[\text{EPNUM}] = 1
\]

\[
\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]
\]

2. The application can only schedule data transfers one frame at a time.

- \((\text{MCNT} – 1) \times \text{MPSIZ} \leq \text{XFERSIZ} \leq \text{MCNT} \times \text{MPSIZ}\)

- \(\text{PKTCNT} = \text{MCNT}\) (in OTG_DIEPTSIZx)

- If \(\text{XFERSIZ} < \text{MCNT} \times \text{MPSIZ}\), the last data packet of the transfer is a short packet.

- Note that: \(\text{MCNT}\) is in OTG_DIEPTSIZx, \(\text{MPSIZ}\) is in OTG_DIEPCTLx, \(\text{PKTCNT}\) is in OTG_DIEPTSIZx and \(\text{XFERSIZ}\) is in OTG_DIEPTSIZx

3. The complete data to be transmitted in the frame must be written into the transmit FIFO by the application, before the IN token is received. Even when 1 word of the data to be transmitted per frame is missing in the transmit FIFO when the IN token is received, the core behaves as when the FIFO is empty. When the transmit FIFO is empty:

- A zero data length packet would be transmitted on the USB for isochronous IN endpoints

- A NAK handshake would be transmitted on the USB for interrupt IN endpoints

**Internal data flow:**

1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.

2. The application must also write the required data to the associated transmit FIFO for the endpoint.

3. Every time the application writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data are fetched from application memory until the transfer size for the endpoint becomes 0.

4. When an IN token is received for a periodic endpoint, the core transmits the data in the FIFO, if available. If the complete data payload (complete packet, in dedicated FIFO
mode) for the frame is not present in the FIFO, then the core generates an IN token received when Tx FIFO empty interrupt for the endpoint.

- A zero-length data packet is transmitted on the USB for isochronous IN endpoints
- A NAK handshake is transmitted on the USB for interrupt IN endpoints

5. The packet count for the endpoint is decremented by 1 under the following conditions:
   - For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
   - For interrupt endpoints, when an ACK handshake is transmitted
   - When the transfer size and packet count are both 0, the transfer completed interrupt for the endpoint is generated and the endpoint enable is cleared.

6. At the “Periodic frame Interval” (controlled by PFIVL in OTG_DCFG), when the core finds non-empty any of the isochronous IN endpoint FIFOs scheduled for the current frame non-empty, the core generates an IISOIXFR interrupt in OTG_GINTSTS.

Application programming sequence:
1. Program the OTG_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA bits.
2. Write the data to be transmitted in the next frame to the transmit FIFO.
3. Asserting the ITTXFE interrupt (in OTG_DIEPINTx) indicates that the application has not yet written all data to be transmitted to the transmit FIFO.
4. If the interrupt endpoint is already enabled when this interrupt is detected, ignore the interrupt. If it is not enabled, enable the endpoint so that the data can be transmitted on the next IN token attempt.
5. Asserting the XFRC interrupt (in OTG_DIEPINTx) with no ITTXFE interrupt in OTG_DIEPINTx indicates the successful completion of an isochronous IN transfer. A read to the OTG_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
6. Asserting the XFRC interrupt (in OTG_DIEPINTx), with or without the ITTXFE interrupt (in OTG_DIEPINTx), indicates the successful completion of an interrupt IN transfer. A read to the OTG_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
7. Asserting the incomplete isochronous IN transfer (IISOIXFR) interrupt in OTG_GINTSTS with none of the aforementioned interrupts indicates the core did not receive at least 1 periodic IN token in the current frame.

- **Incomplete isochronous IN data transfers**

This section describes what the application must do on an incomplete isochronous IN data transfer.

Internal data flow:
1. An isochronous IN transfer is treated as incomplete in one of the following conditions:
   a) The core receives a corrupted isochronous IN token on at least one isochronous IN endpoint. In this case, the application detects an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG_GINTSTS).
   b) The application is slow to write the complete data payload to the transmit FIFO and an IN token is received before the complete data payload is written to the FIFO. In this case, the application detects an IN token received when Tx FIFO empty interrupt in OTG_DIEPINTx. The application can ignore this interrupt, as it
eventually results in an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG_GINTSTS) at the end of periodic frame.

The core transmits a zero-length data packet on the USB in response to the received IN token.

2. The application must stop writing the data payload to the transmit FIFO as soon as possible.

3. The application must set the NAK bit and the disable bit for the endpoint.

4. The core disables the endpoint, clears the disable bit, and asserts the endpoint disable interrupt for the endpoint.

Application programming sequence:

1. The application can ignore the IN token received when Tx FIFO empty interrupt in OTG_DIEPINTx on any isochronous IN endpoint, as it eventually results in an incomplete isochronous IN transfer interrupt (in OTG_GINTSTS).

2. Assertion of the incomplete isochronous IN transfer interrupt (in OTG_GINTSTS) indicates an incomplete isochronous IN transfer on at least one of the isochronous IN endpoints.

3. The application must read the endpoint control register for all isochronous IN endpoints to detect endpoints with incomplete IN data transfers.

4. The application must stop writing data to the Periodic Transmit FIFOs associated with these endpoints on the AHB.

5. Program the following fields in the OTG_DIEPCTLx register to disable the endpoint:
   - SNAK = 1 in OTG_DIEPCTLx
   - EPDIS = 1 in OTG_DIEPCTLx

6. The assertion of the endpoint disabled interrupt in OTG_DIEPINTx indicates that the core has disabled the endpoint.
   - At this point, the application must flush the data in the associated transmit FIFO or overwrite the existing data in the FIFO by enabling the endpoint for a new transfer in the next microframe. To flush the data, the application must use the OTG_GRSTCTL register.

- **Stalling non-isochronous IN endpoints**

This section describes how the application can stall a non-isochronous endpoint.

Application programming sequence:
1. Disable the IN endpoint to be stalled. Set the STALL bit as well.
2. EPDIS = 1 in OTG_DIEPCTLx, when the endpoint is already enabled
   - STALL = 1 in OTG_DIEPCTLx
   - The STALL bit always takes precedence over the NAK bit
3. Assertion of the endpoint disabled interrupt (in OTG_DIEPINTx) indicates to the application that the core has disabled the specified endpoint.
4. The application must flush the non-periodic or periodic transmit FIFO, depending on the endpoint type. In case of a non-periodic endpoint, the application must re-enable the other non-periodic endpoints that do not need to be stalled, to transmit data.
5. Whenever the application is ready to end the STALL handshake for the endpoint, the STALL bit must be cleared in OTG_DIEPCTLx.
6. If the application sets or clears a STALL bit for an endpoint due to a SetFeature.Endpoint Halt command or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the status stage transfer on the control endpoint.

    Special case: stalling the control OUT endpoint

The core must stall IN/OUT tokens if, during the data stage of a control transfer, the host sends more IN/OUT tokens than are specified in the SETUP packet. In this case, the application must enable the ITTXFE interrupt in OTG_DIEPINTx and the OTEPDIS interrupt in OTG_DOEPINTx during the data stage of the control transfer, after the core has transferred the amount of data specified in the SETUP packet. Then, when the application receives this interrupt, it must set the STALL bit in the corresponding endpoint control register, and clear this interrupt.

### 73.15.7 Worst case response time

When the OTG_HS controller acts as a device, there is a worst case response time for any tokens that follow an isochronous OUT. This worst case response time depends on the AHB clock frequency.

The core registers are in the AHB domain, and the core does not accept another token before updating these register values. The worst case is for any token following an isochronous OUT, because for an isochronous transaction, there is no handshake and the next token may come sooner. This worst case value is 7 PHY clocks when the AHB clock is the same as the PHY clock. When the AHB clock is faster, this value is smaller.

If this worst case condition occurs, the core responds to bulk/interrupt tokens with a NAK and drops isochronous and SETUP tokens. The host interprets this as a timeout condition for SETUP and retries the SETUP packet. For isochronous transfers, the Incomplete isochronous IN transfer interrupt (IISOIXFR) and Incomplete isochronous OUT transfer interrupt (IISOOXFR) inform the application that isochronous IN/OUT packets were dropped.

### Choosing the value of TRDT in OTG_GUSBCFG

The value in TRDT (OTG_GUSBCFG) is the time it takes for the MAC, in terms of PHY clocks after it has received an IN token, to get the FIFO status, and thus the first data from the PFC block. This time involves the synchronization delay between the PHY and AHB clocks. The worst case delay for this is when the AHB clock is the same as the PHY clock. In this case, the delay is 5 clocks.
Once the MAC receives an IN token, this information (token received) is synchronized to the AHB clock by the PFC (the PFC runs on the AHB clock). The PFC then reads the data from the SPRAM and writes them into the dual clock source buffer. The MAC then reads the data out of the source buffer (4 deep).

If the AHB is running at a higher frequency than the PHY, the application can use a smaller value for TRDT (in OTG_GUSBCFG).

Figure 935 has the following signals:
- tkn_rcvd: Token received information from MAC to PFC
- dsync_set_tkn_rcvd: Doubled sync tkn_rcvd, from PCLK to HCLK domain
- spr_read: Read to SPRAM
- spr_addr: Address to SPRAM
- spr_rdata: Read data from SPRAM
- srcbuf_push: Push to the source buffer
- srcbuf_rdata: Read data from the source buffer. Data seen by MAC

To calculate the value of TRDT, refer to Table 762: TRDT values.

Figure 935. TRDT max timing case
73.15.8 OTG programming model

The OTG_HS controller is an OTG device. When the core is connected to an “A” plug, it is referred to as an A-device. When the core is connected to a “B” plug it is referred to as a B-device.
74 USB Type-C®/USB Power Delivery interface (UCPD)

74.1 Introduction

The USB Type-C/USB Power Delivery interface complies with:
- Universal Serial Bus Type-C Cable and Connector Specification: release 2.2, Oct 2022
- Universal Serial Bus Power Delivery specifications:
  - revision 2.0, version 1.3, January 12, 2017
  - revision 3.1, version 1.6, October 2022

It integrates the physical layer of the Power Delivery (PD) specification, with CC signaling method (no VBUS), for operation with Type-C cables.

74.2 UCPD main features

- Compliance with USB Type-C specification release 2.2
- Compliance with USB Power Delivery specifications revision 2.0 and 3.1
  - Enabling advanced applications such as PPS (programmable power supply)
- Stop mode low-power operation support
- Built-in analog PHY
  - USB Type-C pull-up (Rp, all values) and pull-down (Rd) resistors
  - “Dead battery” Rd support
  - USB Power Delivery message transmission and reception
  - FRS (fast role swap) Rx support
- Digital controller
  - BMC (bi-phase mark coding) encode and decode
  - 4b5b encode and decode
  - USB Type-C level detection with de-bounce, generating interrupts
  - FRS signaling
  - FRS detection, generating an interrupt
  - DMA-compatible byte-level interface for USB Power Delivery payload, generating interrupts
  - USB Power Delivery clock pre-scaler / dividers
  - CRC generation/checking
  - Support of ordered sets, with a programmable ordered set mask at receive
  - Clock recovery from incoming Rx stream

74.3 UCPD implementation

The devices have one UCPD controller to support one USB Type-C port.
Table 765. UCPD implementation(1)

74.4 UCPD functional description

The UCPD peripheral provides hardware support for the USB Power Delivery control interface specification, using I/Os specifically designed for that purpose.

The built-in PHY directly detects Type-C voltage levels, supports Power Delivery BIST carrier mode 2 (Tx only), BIST test data (Tx and Rx), and Power Delivery Rx FRS signaling.

For Power Delivery FRS Tx signaling, the device can be configured to control, through UCPD_FRSTX1/2 pins (alternate functions), external NMOS transistors that ensure low-resistance pull-down on CC lines.

The UCPD transmitter BMC (bi-phase mark) encodes and transmits data: preamble, SOP, payload data from protocol layer (after 4b5b-encoding), CRC, and EOP on the Type-C connector CC lines. It automatically inserts inter-frame gap and executes “Hard Reset”.
The UCPD receiver detects SOP, BMC-decodes the incoming stream, recovers the preamble, 4b5b-decodes payload data, detects EOP, and checks CRC. It automatically detects five K-code SOP and two Reset ordered sets, plus two software-defined patterns (allows for only three out of four K-codes being correctly received, as defined by the standard).

In Stop mode, the peripheral maintains the ability to detect incoming USB Power Delivery messages and FRS signaling, which allows low-power operation.

**74.4.2 UCPD reset and clocks**

The peripheral has a single reset signal (APB bus reset).

The register section is clocked with the APB clock (ucpd_pclk).

The main functional part of the transmitter is clocked with ucpd_clk clock, pre-scaled from the ucpd_ker_ck (HSI16) clock according to the PSC_USBPDCLK[2:0] bitfield of the UCPD_CFGR1 register. The main functional part of the receiver is clocked with the ucpd_rx_clk recovered from the incoming bitstream.

The receiver is designed to work in the clock frequency range from 6 to 18 MHz. However, the optimum performance is ensured in the range from 9 to 18 MHz.

The following diagram shows the clocking and timing elements of the UCPD peripheral.
Refer to the USB PD specification in order to set appropriate delays. For \( t_{TransitionWindow} \) and especially for \( t_{InterFrameGap} \), the clock frequency uncertainty must be taken into account so as to respect specified timings in all cases.

### 74.4.3 Physical layer protocol

The physical layer covers the signaling underlying the USB Power Delivery specification. On the transmitter side its main function is to form packets according to the defined packet format including generally:

- preamble
- start of packet (SOP, ordered set)
- payload header
- payload data
- cyclic redundancy check (CRC) information
- end of packet (EOP)

Before going on the CC line, the data stream is BMC-encoded, respecting specified timing restrictions.

On the receive side, the principle task is to:

- extract start of packet (SOP, ordered set) information
- extract payload header
- extract payload data
- receive and check CRC
- receive end of packet (EOP)

The receive is basically a reverse of the transmit process, thus starting with BMC data stream decoding.

**Symbol encoding**

Apart from the preamble all symbols are encoded with a 4b5b scheme according to the specification shown in the following table.
<table>
<thead>
<tr>
<th>Name</th>

The bit transmission order is shown in the following figure.

**Figure 939. Transmit order for various sizes of data**
Packet format

Messages other than Hard Reset and Cable Reset

The packet format is shown in the following figure, with information on 4b5b encode and data source.

![Packet format](image)

**Hard Reset**

The physical layer handles the Hard Reset signaling differently than the other types of message as it has higher priority to be able to interrupt an ongoing transfer.

The physical layer specification implies the following sequence in the case of an ongoing Tx message:

1. Terminate the message by sending an EOP K-code and discard the rest of the message.
2. Wait for InterFrameGap time.
3. If the CC line is not idle, wait until it goes idle.
4. Send the preamble followed by the four K-codes of Hard Reset signaling.
5. Disable the CC channel (stop sending and receiving), reset the physical layer and inform the protocol layer that the physical layer is reset.
6. Re-enable the channel when requested by the protocol layer.

![Line format of Hard Reset](image)
Cable Reset

Cable Reset shown in the following figure is similar in format to Hard Reset, but unlike Hard Reset it does not require a specific high-priority treatment.

**Figure 942. Line format of Cable Reset**

Collision avoidance

The physical layer respects the $t_{InterFrameGap}$ delay between end of last-transmitted bit of a Tx message, and the first bit of a following message.

It also checks the idle state of the CC line before starting transmission. The CC line is considered idle if it shows less than three ($n_{TransitionCount}$) transitions within $t_{TransitionWindow}$ (12 to 20 $\mu$s). The Power Delivery specification revision 3.1 also requires to manage the Rp value (source) and monitor Type-C voltage level for these Rp modifications (at the sink).

Physical layer signaling schemes

The bit are signaled with bi-phase mark coding (BMC).

BIST

Depending on the BIST action required by the protocol layer, either of the following can be run:

- a Tx BIST pattern test, achieved by writing TXMODE and TXSEND
- an Rx BIST pattern test, achieved by writing RXMODE to the correct value for RXBIST.

The two possible patterns supported in UCPD (corresponding to “BMC” mode) are:

- **BIST Test Data** (192 bit pattern), applies to Tx and Rx. In the case of Rx, the message is received (but discarded rather than passing to the protocol layer, which must nevertheless still generate a GoodCRC Tx message in acknowledgment).
- **BIST Carrier Mode 2** (single pattern, infinite length message), applies to Tx only. As opposed to Tx, the receiver in this mode simply ignores the CC line during this state.

BIST test data pattern

The test data pattern is not viewed as a special case in UCPD.
The BIST test data packet frame format is shown in the following figure.

**Figure 943. BIST test data frame**

![BIST test data frame](image)

This is a fixed length test data pattern. In reality the only aspect that marks its difference from the general packet format already shown in *Figure 940: Packet format* is the contents of the Header. As UCPD receives the Tx Header contents via programming (it is simply viewed as part of the payload), it is only this programming (and not the block’s behavior) that differentiates the general packet from the BIST Test Data packet.

**BIST Carrier Mode 2**

When required, this BIST test mode sends an alternating pattern of 1010 that is continually repeated. As this mode is intended for signal analysis it is stable condition with (in V1.0 of the USB PD specification) no defined length. Starting from V1.1 of the USB PD specification, the protocol layer defines a counter that indicates when to exit this mode.

The way to quit the infinite 1010 sequence (according to requirements of the USB PD specification) is to disable the UCPD peripheral via the UCPDEN bit.

**Figure 944. BIST Carrier Mode 2 frame**

![BIST Carrier Mode 2 frame](image)

**74.4 UCPD BMC transmitter**

The BMC transmitter comprises 4b5b encoding, CRC generation, and BMC encode, as shown in the following figure. Its output goes to the analog PHY through a channel switch.
Figure 945. UCPD BMC transmitter architecture

### BMC encoder

The half-bit clock hbit_clk is derived from ucpd_clk through a simple divider controlled by the HBITCLKDIV[5:0] bitfield of the UCPD_CFGR1 register. This ensures the same duration of high and low half-bit periods (if neglecting a small difference due to different rising and falling edge duration and due to jitter), and the same bit duration (if neglecting jitter).

#### Transmitter timing and collision avoidance

Hardware support of collision avoidance is made as a function of the half bit time for the transmitter. Two counters are implemented:

- \( t_{\text{InterFrameGap}} \): via IFRGAP (pre-defined value, can be altered)
- \( t_{\text{TransitionWindow}} \): via TRANSWIN (pre-defined value, can be altered)

These two counters once set correctly generates the interframe gap.

#### Hard Reset in transmitter

In order to facilitate generation of a Hard Reset, a special code of TXMODE field is used. No other fields need to be written.

On writing the correct code, the hardware forces Hard Reset Tx under the correct (optimal) timings with respect to an ongoing Tx message, which (if still in progress) is cleanly terminated by truncating the current Tx message and directly appending an EOP K-code sequence. No specific interrupt is generated relating to this truncation event.

#### Transmitter behavior in the case of errors

The under-run condition (TXUND interrupt) may happen by accident and in this case, the UCPD is starved of (the correct) Tx payload and is not able to complete the Tx message correctly. This is a serious error (for this to happen the software fails to respond in time). As a result the hardware ensures the CRC is incorrect at the end of the message, thus guaranteeing the message to be discarded at the receiver.
74.4.5 UCPD BMC receiver

The UCPD BMC receiver performs:

- Clock recovery
- Preamble detection / timing derivation
- BMC decoding
- 4b5b decoding
- K-code ordered set recognition
- CRC checking
- SOP detection
- EOP detection

The receiver is activated as soon as the UCPD peripheral is enabled (via UCPDEN), but it waits for an idle CC line state before attempting to receive a message.

The following figure shows the UCPD BMC receiver high-level architecture.

**CRC checker**

The received bits are fed into a CRC checker which evolves a 32-bit state during the received the payload bitstream. At the end the 32 bits of the CRC also fed into the logic

The EOP detection (5 bits) halts the process and a check is performed for the fixed residual state which confirms correct reception of the payload (in fact the residual is 0xC704DD78).

At this point the UCPD raises interrupt RXMSGEND. If the CRC was not correct then RXERR is set true and the receive data must be discarded.

Under normal operation, this interrupt would previously have been acknowledged and thus cleared. If this is not the case, a different interrupt RXOVR is generated in place of RXMSGEND.
Ordered set detection

This function detects the different ordered sets each consisting of four 5-bit K-codes. Once we are in the preamble we opens a sliding window detection of the ordered set (4 words of 5 bits).

The ordered sets detected include all SOP* codes (SOP, SOP', and SOP''), but also Hard Reset, Cable Reset, SOP'_Debug, SOP''_Debug, and two extensions defined by registers UCPD_RX_ORDEXT1 and UCPD_RX_ORDEXT2.

EOP detection and Hard Reset exception handling

EOP is a fixed 5-bit K-code marking the end of a message. The way in which a transmitter is required to send a Hard Reset (if a previous message transmit is still in progress) is that this previous message is truncated early with an EOP.

If Hard Reset were ignored, then the EOP detection can be done only at the expected time. However, due to the Hard Reset issue, the EOP detector must be active while an Rx message is arriving. When an “early EOP” is detected, the truncated Rx message is immediately discarded.

Truncated or corrupted message exception

Once the ordered set has been detected, depending on the message, there may be data bytes to be received which is completed with a CRC and EOP. If at any point during these phases an error condition happens:

- the line becomes static for a time significantly longer than one “UI” period (the exact threshold for this condition is not critical but the exception must occur before three UIs), or
- the message goes to the end but it is not recognized (for example EOP is corrupted).

In both cases, the receiver quits the current message, raising RXMSGEND and RXERR flags.

Short preamble or incomplete ordered set exception

In the exceptional case of the receiver seeing less that half of the expected preamble, the frequency estimation allowing correct BMC-decode becomes impossible. Even if the full preamble is seen, allowing frequency estimation, but the ordered set is not fully received before the line becomes static, the receiver state machine does not start.

In both of these cases, the clock-recovery/BMC decoder re-starts, checking initially for an IDLE condition, followed by a preamble, and then estimating frequency.

74.4.6 UCPD Type-C pull-ups (Rp) and pull-downs (Rd)

UCPD offers simple control of these resistors via ANAMODE and ANASUBMODE[1:0]. In case only one of the CC lines is to be used, it is possible to optimize power consumption by disabling control on the other line, through the CCENABLE[1:0] bitfield.

When the MCU is unpowered, it still presents the “dead battery” Rd, provided that UCPDx_DBCC1 and UCPDx_DBCC2 pins are each connected to UCPDx_CC1 and UCPDx_CC2 pins, respectively.

If dead battery behavior is not required (for example for source only products), then UCPDx_DBCC1 and UCPDx_DBCC2 pins must both be tied to ground.
After power arrives and the MCU boots, the desired behavior (for example source) must be programmed into ANAMODE and ANASUBMODE[1:0] before setting the UCPD_DBDIS bit of the PWR_CR3 register to remove dead battery pull-down resistor and allow the values just programmed to take effect.

Use of Standby low-power mode is possible for sinks in the unattached state.

74.4.7 UCPD Type-C voltage monitoring and de-bouncing

For correct operation of the Type-C state machine and for detecting the cable orientation, the CC1/2 lines must be monitored for voltage level, while ignoring fast events such as peaks.

Thresholds between voltage levels on the CC1/2 lines are determined through PHY threshold detector settings.

The TYPEC_VSTATE_CC1/2[1:0] bitfields reflect the CC1/2 line levels processed with a hardware de-bouncing filter that suppresses high-speed line events such as peaks. The PHYCCSEL bit selects the line, CC1 or CC2, to be used for Power Delivery signaling.

For minimizing the power consumption, it is recommended to use the polling method, with the Type-C detectors only turned on for the instant of polling, rather than keeping the Type-C detectors permanently on and wake the device up from Stop mode upon CC1/2 line events.

74.4.8 UCPD fast role swap (FRS)

FRS signaling
The FRS condition (a pulse of a specific length), is generated upon setting the FRSTX bit.

For the duration of FRS condition, the currently active I/O configured as UCPD_FRSTX1 (or 2) (alternate function) controls, with high level, the gate of an external NMOS transistor that pulls the active CC line down.

FRS detection
FRS monitoring is enabled by setting the bit FRSRXEN, after writing PHYCCSEL that selects the active CC line depending on the cable orientation detected.

74.4.9 UCPD DMA Interface

DMA is implemented in the UCPD and when it is enabled the byte-level interrupts to handle UCPD1_TXDR and UCPD1_RXDR registers (Tx and Rx data register, each one byte) are no longer needed.

By enabling bits TXDMAEN and/or RXDMAEN, DMA can be activated independently for Tx and/or Rx functionality.

74.4.10 Wake-up from Stop mode

For power consumption optimization, it is useful to use Stop mode and wait for events on CC lines to wake the MCU up.

In order for this to work, it must be first enabled by writing a 1 to WUPEN.
The events causing the wake-up can be:
- Events on the BMC receiver (RXORDDET, RXHRSTDET), hardware enable PHYRXEN
- Event on the FRS detector (FRSEVT), hardware enable FRSRXEN
- Events on the Type-C detectors (TYPECEVT1, TYPECEVT2), hardware enables CC1TCDIS, CC2TCDIS

74.5 UCPD programming sequences

The normal sequence of use of the UCPD unit is:
1. Configure UCPD.
2. Enable UCPD.
3. Concurrently:
   - On demand from protocol layer, send Tx message
   - Intercept (poll or wait for interrupt) relevant Rx messages and recover detail to hand off to protocol layer

Repeat the last point infinitely.

74.5.1 Initialization phase

Use the following sequence for a clean startup:
1. Prepare all initial clock divider values, by writing the UCPD_CFG register.
2. Enable the unit, by setting the UCPDEN bit.
3. Enable the analog Rx filter of either CC line, via the RXAFILTEN bit of the UCPD_CFGR2 register.

74.5.2 Type-C state machine handling

For the general application cases of source, sink, or dual-role port (the last alternating the source and the sink), the software must implement a corresponding USB Type-C state machine. The basic coding is in the following table.

<table>
<thead>
<tr>
<th>ANAMODE</th>
<th>ANASUBMODE[1:0]</th>
<th>Notes</th>
<th>TYPEC_VSTATE_CCx[1:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0: Source</td>
<td>00: Disabled</td>
<td>Disabled</td>
<td>N/A</td>
</tr>
<tr>
<td></td>
<td>01: Default USB Rp</td>
<td>-</td>
<td>vRa[Def] vRd[Def] vOPEN[Def]</td>
</tr>
<tr>
<td></td>
<td>10: 1.5A Rp</td>
<td>-</td>
<td>vRa[1.5] vRd[1.5] vOPEN[1.5]</td>
</tr>
<tr>
<td>1: Sink</td>
<td>xx</td>
<td>-</td>
<td>vRa vRd-USB vRd-1.5 vRd-3.0</td>
</tr>
</tbody>
</table>

The CCENABLE[1:0] bitfield can disable pull-up/pull-downs on one of the CC lines.

Note: The Type-C state machine depends not only on CC line levels, but also on VBUS presence detection (sink mode) and, when in source mode, determines VCONN generation and...
VBUS state (ON/OFF/+voltage level; discharge). UCPD does not directly control VBUS generation circuitry nor VCONN load switch (enabling VCONN supply generator to be connected to the CC line), but the application needs these inputs and controls, to function correctly.

General programming sequence (with UCPD configured then enabled)
1. Set ANAMODE and ANASUBMODE[1:0] based on the current position in USB Type-C state machine (and also the current advertisement in the case of a source). This turns on the appropriate pull-ups/pull-downs on the CC lines, and defines the voltage levels that the TYPEC_VSTATE fields represent. Note that before programming, the PHY is effectively off.
2. Read TYPEC_VSTATE_CC1/2 to determine the initial Type-C state (for example whether the local source is connected to a remote sink).
3. In the case of no connection, wait for a connection event.
4. Assuming a connection is detected and assuming a local Power Delivery functionality is implemented, start sending/receiving Power Delivery messages.
5. When a new interrupt/event occurs on PHY_EVT1/2 indicating a change in stable voltage, re-evaluate the implications and give this input to the Type-C state machine.

Case of a source that needs to change between one of the three possible Rp values (Default-USB / 1.5A / 3.0A) and the sink connected to it:
- [Source] Simply reprogram ANASUBMODE[1:0]
- [Sink behavior from that time] PHY_EVT1/2 occurs and the TYPEC_VSTATE1/2 changes accordingly

Programming for a dual-role port (DRP) toggling from source to sink:
- Simply re-program ANAMODE and ANASUBMODE[1:0] to start the new behavior

Detailed programming sequence (example):

1. Two GPIOs to enable VCONN through external load switch components

### 74.5.3 USB PD transmit

On reception of a message from the protocol layer (that is, to be sent), prepare Tx message contents by writing the UCPD_TX_ORDSET and UCPD_TX_PAYSZ registers.

The message transmission is triggered by setting the TXSEND bit, with an appropriate value of the TXMODE bitfield.

When the data byte is transmitted, the TXIS flag is raised to request a new data write to the UCPD_TXDR register.

This re-iterates until the entire payload of data is transmitted.
Upon sending the CRC packet, the TXMSGSENT flag is set to indicate the completion of the message transmission.

**Hard Reset transmission**

As soon as it is known that a Hard Reset needs to be transmitted, setting the TXHRST bit of the UCPD_CR register forces the internal state machine to generate the correct sequence. The value of UCPD_TX_ORDSET does not require update in this precise case (the correct code for Hard Reset is sent by UCPD).

The USB Power Delivery specification requires that in the case of an ongoing message transmission, the Hard Reset takes precedence. In this case, for example, UCPD truncates the payload of the current message, appending EOP to the end. No notification is available via the registers (for example through the TXMSGSEND flag). This is justified by the fact that the Hard Reset takes precedence over any previous activity (for which it is therefore no longer important to know if it is completed).

**Use of DMA for transmission**

DMA (Direct Memory Access) can be enabled for transmission by setting the TXDMAEN bit in the UCPD_CR register.

For each message:
- Prepare the whole message in memory (starting with two header bytes)
- Program the DMA operation with a length corresponding to the two header bytes plus a number of data bytes corresponding to the number of data words multiplied by four
- Write TXSEND to initiate the message transfer
- If TXMSGDISC then go back to previous line (TXSEND)
- Wait for DMA transfer complete interrupt (that is, when last Tx byte written to UCPD)
- Double-check subsequent TXMSGSENT interrupt appears

**74.5.4 USB PD receive**

Notification of start of the receive message sequence is triggered by an interrupt on UCPD_SR (bit RXORDDET).

The information is recovered by reading:
- UCPD_RX_SOP (on interrupt RXORDDET)
- UCPD_RXDR (on interrupt RXNE, repeats for each byte)
- UCPD_RXPAYSZ (on interrupt RXMSGEND)

The data previously read from UCPD_RXDR above must be discarded at this point if the RXERR flag is set.

If the CRC is valid, the received data is transferred to the protocol layer.

For debug purposes, it may be desirable to track statistics of the number of incorrect K-codes received (this is done only when 3/4 K-codes were valid as defined in the specification). This is facilitated through:
- RXSOP3OF4 bit indicating the presence of at least one invalid K-code
- RXSOPKINVALID bitfield identifying the order of invalid K-code in the ordered set
Use of DMA for reception

DMA (Direct Memory Access) can be enabled for reception by setting the RXDMAEN bit in the UCPD_CR register.

Whenever a Rx message is expected:
- Program a DMA receive operation (and spare buffer) a little longer than the maximum possible message (length depends on extended message support).
- After receiving RXORDDET, DMA operation starts working in the background.
- On reception of RXMSGEND interrupt, read RXPAYSZ.
- Double-check RXPAYSZ vs. the number of DMA Rx bytes (must correspond but DMA read of RXDR is slightly after RXDR gets last byte).
- Process the DMA Rx buffer.
- Prepare next Rx DMA buffer as soon as possible in order to be ready.

74.5.5 UCPD software trimming

The CC pull-up (Rp) and pull-down (Rd) devices must be trimmed on each part, to meet the required accuracy. The trimming values are saved in the non-volatile memory.

To trim the CC pull-up and pull-down devices by software, apply the following procedure:

1. Retrieve the trim values from the non-volatile memory (refer to Table 766: UCPD software trim data)
2. At initialization, write the trim values to the UCPD_CFRG3 register bitfields as follows:
   - 3A0_CC1[3:0] to TRIM_CC1_RP[3:0]
   - 3A0_CC2[3:0] to TRIM_CC2_RP[3:0]
   - Rd_CC1[3:0] to TRIM_CC1_RD[3:0]
   - Rd_CC2[3:0] to TRIM_CC2_RD[3:0]
3. At each setting of ANASUBMODE to 1A5 or 3A0, respectively, write the trimming values to the UCPD_CFRG3 register bitfields as follows:
   - 1A5_CC1[3:0] or 3A0_CC1[3:0], respectively, to TRIM_CC1_RP[3:0]
   - 1A5_CC2[3:0] or 3A0_CC2[3:0], respectively, to TRIM_CC2_RP[3:0]

74.6 UCPD low-power modes

A summary of low-power modes is shown below in Table 775: Effect of low power modes on the UCPD.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect</td>
</tr>
<tr>
<td>Stop</td>
<td>Detection of events (Type-C, BMC Rx, FRS detection) remains operational and can wake up the MCU.</td>
</tr>
<tr>
<td>Standby</td>
<td>UCPD is not operating, and cannot wake up the MCU. Pull-downs remain active if configured.</td>
</tr>
<tr>
<td>Unpowered</td>
<td>Dead battery pull-downs remain active.</td>
</tr>
</tbody>
</table>
The UCPD is able to wake up the MCU from Stop mode when it recognizes a relevant event, either:

- Type-C event relating to a change in the voltage range seen on either of the CC lines, visible in TYPEC_VSTATE_CCx
- Power delivery receive message with an ordered set matching those filtered according to RXORDSETEN[8:0], visible by reading RXORDSET

Wake-up from Stop mode is enabled by setting the WUPEN bit in the UCPD_CFG2 register.

At UCPD level three types of event requiring kernel clock activity may occur during Stop mode:

- Activity on the analog PHY voltage threshold detectors which can later be confirmed to be a stable change between voltage ranges defined in the Type-C specification
- Activity on Power Delivery BMC receiver (coming from the selected CC line) which can potentially generate an Rx message event (that is, RXORDSET) later
- Activity on Power Delivery FRS detector which can potentially generate an FRS signaling detection event (that is, FRSEVT) later

It order to function correctly with the RCC, the clock request signal is activated (conditional on WUPEN) when there is asynchronous activity on:

- Type-C voltage threshold detectors (coming from either CC line)
- Power Delivery receiver signal (from the selected CC line)
- FRS detection signal (from the selected CC line)

### 74.7 UCPD interrupts

The table below lists the UCPD event flags, with the associated flag clear bits and interrupt enable bits.

</table>
When an interrupt from the UCPD is received, then the software has to check what is the source of the interrupt by reading the UCPD_SR register.

Depending on which bit is at 1, the ISR must handle that condition and clear the bit by a write to the appropriate bit of the UCPD_ICR register.

### 74.8 UCPD registers

#### 74.8.1 UCPD configuration register 1 (UCPD_CFG1)

Address offset: 0x000

Reset value: 0x0000 0000

General configuration of the peripheral. Writing to this register is only effective when UCPD is disabled (UCPDEN = 0).

<table>
<thead>
<tr>

</tbody>
</table>
Bit 29 **TXDMAEN**: Transmission DMA mode enable
When set, the bit enables DMA mode for transmission.
0: Disable
1: Enable

Bits 28:20 **RXORDSETEN[8:0]**: Receiver ordered set enable
The bitfield determines the types of ordered sets that the receiver must detect. When set/cleared, each bit enables/disables a specific function:
- 0bXXXXXXXX1: SOP detect enabled
- 0bXXXXXXX1X: SOP’ detect enabled
- 0bXXXXXX1XX: SOP” detect enabled
- 0bXXXXX11XX: Hard Reset detect enabled
- 0bXXXX111XX: Cable Detect reset enabled
- 0bXX1XXXXXX: SOP_Debug enabled
- 0bX1XXXXX: SOP”_Debug enabled
- 0b1XXXXXX: SOP extension#1 enabled
- 0b11XXXXX: SOP extension#2 enabled

Bits 19:17 **PSC_USBPDCLK[2:0]**: Pre-scaler division ratio for generating ucpd_clk
The bitfield determines the division ratio of a kernel clock pre-scaler producing UCPD peripheral clock (ucpd_clk).
0x0: 1 (bypass)
0x1: 2
0x2: 4
0x3: 8
0x4: 16
It is recommended to use the pre-scaler so as to set the ucpd_clk frequency in the range from 6 to 9 MHz.

Bit 16 Reserved, must be kept at reset value.

Bits 15:11 **TRANSWIN[4:0]**: Transition window duration
The bitfield determines the division ratio (the bitfield value minus one) of a hbit_clk divider producing \( t_{\text{TransitionWindow}} \) interval.
0x00: Not supported
0x01: 2
0x09: 10 (recommended)
0x1F: 32
Set a value that produces an interval of 12 to 20 us, taking into account the ucpd_clk frequency and the HBITCLKDIV[5:0] bitfield setting.

Bits 10:6 **IFRGAP[4:0]**: Division ratio for producing inter-frame gap timer clock
The bitfield determines the division ratio (the bitfield value minus one) of a ucpd_clk divider producing inter-frame gap timer clock \( t_{\text{InterFrameGap}} \).
0x00: Not supported
0x01: 2
0x0D: 14
0x0E: 15
0x0F: 16
0x1F: 32
The division ratio 15 is to apply for Tx clock at the USB PD 2.0 specification nominal value. The division ratios below 15 are to apply for Tx clock below nominal, and the division ratios above 15 for Tx clock above nominal.
Bits 5:0 **HBITCLKDIV[5:0]**: Division ratio for producing half-bit clock
The bitfield determines the division ratio (the bitfield value plus one) of a ucpd_clk divider producing half-bit clock (hbit_clk).
0x00: 1 (bypass)
0x1A: 27
0x3F: 64

### 74.8.2 UCPD configuration register 2 (UCPD_CFGR2)

Address offset: 0x004

Reset value: 0x0000 0000

Configuration of the UCPD Rx signal filtering. Writing to this register is only effective when UCPD is disabled (UCPDEN = 0).

<table>

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **RXAFILTEN**: Rx analog filter enable
Setting the bit enables the Rx analog filter required for optimum Power Delivery reception.
0: Disable
1: Enable

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **WUPEN**: Wake-up from Stop mode enable
Setting the bit enables the UCPD_ASYNC_INT signal.
0: Disable
1: Enable

Bit 2 **FORCECLK**: Force ClkReq clock request
0: Do not force clock request
1: Force clock request

Bit 1 **RXFILT2N3**: BMC decoder Rx pre-filter sampling method
Number of consistent consecutive samples before confirming a new value.
0: 3 samples
1: 2 samples

Bit 0 **RXFILTDIS**: BMC decoder Rx pre-filter enable
0: Enable
1: Disable
The sampling clock is that of the receiver (that is, after pre-scaler).
74.8.3  UCPD configuration register 3 (UCPD_CFGR3)

Address offset: 0x008
Reset value: 0x0000 0000

Configuration of UCPD trimming of the CC pull-up and pull-down devices. The trimming is managed by hardware until the first software write into this register.

The register is reserved (must not be written) for devices that support the fully automatic trimming. Refer to Table 765: UCPD implementation.

| Bit 31:29 | Reserved, must be kept at reset value. |
| Bit 28:25 | TRIM_CC2_RP[3:0]: SW trim value for Rp current sources on the CC2 line |
| Bit 24:20 | Reserved, must be kept at reset value. |
| Bit 19:16 | TRIM_CC2_RD[3:0]: SW trim value for Rd resistor on the CC2 line |
| Bit 15:13 | Reserved, must be kept at reset value. |
| Bit 12:9  | TRIM_CC1_RP[3:0]: SW trim value for Rp current sources on the CC1 line |
| Bit 8:4  | Reserved, must be kept at reset value. |
| Bit 3:0  | TRIM_CC1_RD[3:0]: SW trim value for Rd resistor on the CC1 line |

74.8.4  UCPD control register (UCPD_CR)

Address offset: 0x00C
Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).
Bits 31:22  Reserved, must be kept at reset value.

Bit 21  **CC2TCDIS**: CC2 Type-C detector disable

The bit disables the Type-C detector on the CC2 line.

0: Enable
1: Disable

When enabled, the Type-C detector for CC2 is configured through ANAMODE and ANASUBMODE[1:0].

Bit 20  **CC1TCDIS**: CC1 Type-C detector disable

The bit disables the Type-C detector on the CC1 line.

0: Enable
1: Disable

When enabled, the Type-C detector for CC1 is configured through ANAMODE and ANASUBMODE[1:0].

Bit 19  Reserved, must be kept at reset value.

Bit 18  **RDCH**: Rdch condition drive

The bit drives Rdch condition on the CC line selected through the PHYCCSEL bit (thus associated with VCONN), by remaining set during the source-only UnattachedWait.SRC state, to respect the Type-C state. Refer to "USB Type-C ECN for Source VCONN Discharge". The CCENABLE[1:0] bitfield must be set accordingly, too.

0: No effect
1: Rdch condition drive

Bit 17  **FRSTX**: FRS Tx signaling enable.

Setting the bit enables FRS Tx signaling.

0: No effect
1: Enable

The bit is cleared by hardware after a delay respecting the USB Power Delivery specification Revision 3.1.

Bit 16  **FRSRXEN**: FRS event detection enable

Setting the bit enables FRS Rx event (FRSEVT) detection on the CC line selected through the PHYCCSEL bit. 0: Disable
1: Enable

Clear the bit when the device is attached to an FRS-incapable source/sink.

Bit 15  Reserved, must be kept at reset value.

Bit 14  Reserved, must be kept at reset value.

Bit 13  Reserved, must be kept at reset value.

Bit 12  Reserved, must be kept at reset value.

Bits 11:10  **CCENABLE[1:0]**: CC line enable

This bitfield enables CC1 and CC2 line analog PHYs (pull-ups and pull-downs) according to ANAMODE and ANASUBMODE[1:0] setting.

0x0: Disable both PHYs
0x1: Enable CC1 PHY
0x2: Enable CC2 PHY
0x3: Enable CC1 and CC2 PHY

A single line PHY can be enabled when, for example, the other line is driven by VCONN via an external VCONN switch. Enabling both PHYs is the normal usage for sink/source.
Bit 9 **ANAMODE**: Analog PHY operating mode

0: Source
1: Sink

The use of CC1 and CC2 depends on CCENABLE. Refer to *Table 773: Coding for ANAMODE, ANASUBMODE and link with TYPEC_VSTATE_CCx* for the effect of this bitfield in conjunction with ANASUBMODE[1:0].

Bits 8:7 **ANASUBMODE[1:0]**: Analog PHY sub-mode

Refer to *Table 773: Coding for ANAMODE, ANASUBMODE and link with TYPEC_VSTATE_CCx* for the effect of this bitfield.

Bit 6 **PHYCCSEL**: CC1/CC2 line selector for USB Power Delivery signaling

0: Use CC1 IO for Power Delivery communication
1: Use CC2 IO for Power Delivery communication

The selection depends on the cable orientation as discovered at attach.

Bit 5 **PHYRXEN**: USB Power Delivery receiver enable

0: Disable
1: Enable

Both CC1 and CC2 receivers are disabled when the bit is cleared. Only the CC receiver selected via the PHYCCSEL bit is enabled when the bit is set.

Bit 4 **RXMODE**: Receiver mode

Determines the mode of the receiver.

0: Normal receive mode
1: BIST receive mode (BIST test data mode)

When the bit is set, RXORDSET behaves normally, RXDR no longer receives bytes yet the CRC checking still proceeds as for a normal message. As this mode prevents reception of the header (containing MessageID), software has to auto-increment a received MessageID counter for inclusion in the GoodCRC acknowledge that must still be transmitted during this test.

Bit 3 **TXHRST**: Command to send a Tx Hard Reset

0: No effect
1: Start Tx Hard Reset message

The bit is cleared by hardware as soon as the message transmission begins or is discarded.

Bit 2 **TXSEND**: Command to send a Tx packet

0: No effect
1: Start Tx packet transmission

The bit is cleared by hardware as soon as the packet transmission begins or is discarded.

Bits 1:0 **TXMODE[1:0]**: Type of Tx packet

Writing the bitfield triggers the action as follows, depending on the value:

0x0: Transmission of Tx packet previously defined in other registers
0x1: Cable Reset sequence
0x2: BIST test sequence (BIST Carrier Mode 2)
Others: invalid

From V1.1 of the USB PD specification, there is a counter defined for the duration of the BIST Carrier Mode 2. To quit this mode correctly (after the "tBISTContMode" delay), disable the peripheral (UCPDEN = 0).
### 74.8.5 UCPD interrupt mask register (UCPD_IMR)

Address offset: 0x010  
Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

<table>

- 1: Enable

### 74.8.6 UCPD status register (UCPD_SR)

Address offset: 0x014

Reset value: 0x0000 0000

The flags (single-bit status bitfields) are associated with interrupt request. Interrupt is generated if enabled by the corresponding bit of the UCPD_IMR register.

<table>
<thead>
<tr>

</tbody>
</table>

3474/3637  RM0456 Rev 5
Bit 20  **FRSEVT**: FRS detection event  
The flag is cleared by setting the FRSEVTCF bit.  
0: No new event  
1: New FRS receive event occurred

Bits 19:18  **TYPEC_VSTATE_CC2[1:0]**: CC2 line voltage level  
The status bitfield indicates the voltage level on the CC2 line in its steady state.  
0x0: Lowest  
0x1: Low  
0x2: High  
0x3: Highest  
The voltage variation on the CC2 line during USB PD messages due to the BMC PHY modulation does not impact the bitfield value.

Bits 17:16  **TYPEC_VSTATE_CC1[1:0]**:  
The status bitfield indicates the voltage level on the CC1 line in its steady state.  
0x0: Lowest  
0x1: Low  
0x2: High  
0x3: Highest  
The voltage variation on the CC1 line during USB PD messages due to the BMC PHY modulation does not impact the bitfield value.

Bit 15  **TYPECEVT2**: Type-C voltage level event on CC2 line  
The flag indicates a change of the TYPEC_VSTATE_CC2[1:0] bitfield value, which corresponds to a new Type-C event. It is cleared by setting the TYPECEVT2CF bit.  
0: No new event  
1: A new Type-C event

Bit 14  **TYPECEVT1**: Type-C voltage level event on CC1 line  
The flag indicates a change of the TYPEC_VSTATE_CC1[1:0] bitfield value, which corresponds to a new Type-C event. It is cleared by setting the TYPECEVT2CF bit.  
0: No new event  
1: A new Type-C event

Bit 13  **RXERR**: Receive message error  
The flag indicates errors of the last Rx message declared (via RXMSGEND), such as incorrect CRC or truncated message (a line becoming static before EOP is met). It is asserted whenever the RXMSGEND flag is set.  
0: No error detected  
1: Error(s) detected

Bit 12  **RXMSGEND**: Rx message received  
The flag indicates whether a message (except Hard Reset message) has been received, regardless the CRC value. The flag is cleared by setting the RXMSGENDCF bit.  
0: No new Rx message received  
1: A new Rx message received  
The RXERR flag set when the RXMSGEND flag goes high indicates errors in the last-received message.

Bit 11  **RXOVR**: Rx data overflow detection  
The flag indicates Rx data buffer overflow. It is cleared by setting the RXOVRRCF bit.  
0: No overflow  
1: Overflow  
The buffer overflow can occur if the received data are not read fast enough.
Bit 10 **RXHRSTDET**: Rx Hard Reset receipt detection
   The flag indicates the receipt of valid Hard Reset message. It is cleared by setting the RXHRSTDETCF bit.
   0: Hard Reset not received
   1: Hard Reset received

Bit 9 **RXORDDET**: Rx ordered set (4 K-codes) detection
   The flag indicates the detection of an ordered set. The relevant information is stored in the RXORDSET[2:0] bitfield of the UCPD_RX_ORDSET register. It is cleared by setting the RXORDDETCF bit.
   0: No ordered set detected
   1: A new ordered set detected

Bit 8 **RXNE**: Receive data register not empty detection
   The flag indicates that the UCPD_RXDR register is not empty. It is automatically cleared upon reading UCPD_RXDR.
   0: Rx data register empty
   1: Rx data register not empty

Bit 7 Reserved, must be kept at reset value.

Bit 6 **TXUND**: Tx data underrun detection
   The flag indicates that the Tx data register (UCPD_TXDR) was not written in time for a transmit message to execute normally. It is cleared by setting the TXUNDCF bit.
   0: No Tx data underrun detected
   1: Tx data underrun detected

Bit 5 **HRSTSENT**: Hard Reset message sent
   The flag indicates that the Hard Reset message is sent. The flag is cleared by setting the HRSTSENCF bit.
   0: No Hard Reset message sent
   1: Hard Reset message sent

Bit 4 **HRSTDISC**: Hard Reset discarded
   The flag indicates that the Hard Reset message is discarded. The flag is cleared by setting the HRSTDISCCF bit.
   0: No Hard Reset discarded
   1: Hard Reset discarded

Bit 3 **TXMSGABT**: Transmit message abort
   The flag indicates that a Tx message is aborted due to a subsequent Hard Reset message send request taking priority during transmit. It is cleared by setting the TXMSGABTCF bit.
   0: No transmit message abort
   1: Transmit message abort

Bit 2 **TXMSGSENT**: Message transmission completed
   The flag indicates the completion of packet transmission. It is cleared by setting the TXMSGSENTCF bit.
   0: No Tx message completed
   1: Tx message completed
   In the event of a message transmission interrupted by a Hard Reset, the flag is not raised.
Bit 1 **TXMSGDISC**: Message transmission discarded
The flag indicates that a message transmission was dropped. The flag is cleared by setting the TXMSGDISCCF bit.
0: No Tx message discarded
1: Tx message discarded
Transmission of a message can be dropped if there is a concurrent receive in progress or at excessive noise on the line. After a Tx message is discarded, the flag is only raised when the CC line becomes idle.

Bit 0 **TXIS**: Transmit interrupt status
The flag indicates that the UCPD_TXDR register is empty and new data write is required (as the amount of data sent has not reached the payload size defined in the TXPAYSZ bitfield). The flag is cleared with the data write into the UCPD_TXDR register.
0: New Tx data write not required
1: New Tx data write required

### 74.8.7 UCPD interrupt clear register (UCPD_ICR)

**Address offset**: 0x018

**Reset value**: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

Bits 31:21 Reserved, must be kept at reset value.

**Bit 20** **FRSEVTCF**: FRS event flag (FRSEVT) clear
Setting the bit clears the FRSEVT flag in the UCPD_SR register.

Bits 19:16 Reserved, must be kept at reset value.

**Bit 15** **TYPECEVT2CF**: Type-C CC2 line event flag (TYPECEVT2) clear
Setting the bit clears the TYPECEVT2 flag in the UCPD_SR register.

**Bit 14** **TYPECEVT1CF**: Type-C CC1 event flag (TYPECEVT1) clear
Setting the bit clears the TYPECEVT1 flag in the UCPD_SR register.

**Bit 13** Reserved, must be kept at reset value.

**Bit 12** **RXMSGENDCF**: Rx message received flag (RXMSGEND) clear
Setting the bit clears the RXMSGEND flag in the UCPD_SR register.
74.8.8  UCPD Tx ordered set type register (UCPD_TX_ORDSETR)

Address offset: 0x01C
Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1) and no packet transmission is in progress (TXSEND and TXHRST bits are both low).

<table>
<thead>
<tr>

74.8.10 UCPD Tx data register (UCPD_TXDR)

Address offset: 0x024
Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

</table>

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 RXPAYSZ[9:0]: Rx payload size received

This bitfield contains the number of bytes of a payload (including header but excluding CRC) received: each time a new data byte is received in the UCPD_RXDR register, the bitfield value increments and the RXMSGEND flag is set (and an interrupt generated if enabled).

- 0x2: 2 bytes - the size of Control message from the protocol layer
- 0x6: 6 bytes - the shortest Data message allowed from the protocol layer
- 0x1E: 30 bytes - the longest non-extended Data message allowed from the protocol layer
- 0x106: 262 bytes - the longest possible extended message
- 0x3FF: 1024 bytes - the longest possible payload (for future expansion)

The bitfield may return a spurious value when a byte reception is ongoing (the RXMSGEND flag is low).

74.8.13 UCPD receive data register (UCPD_RXDR)

Refer to Section 2.3 on page 139 for the register boundary addresses.
75 Debug support (DBG)

75.1 DBG introduction

A comprehensive set of debug features is provided to support software development and system integration:

- Breakpoint debugging of the CPU core
- Code execution tracing
- Software instrumentation
- Cross-triggering

The debug features can be controlled via a JTAG/Serial-wire debug access port, using industry standard debugging tools. A trace port allows data to be captured for logging and analysis.

The debug features are based on Arm CoreSight components.

- SWJ-DP: JTAG/Serial-wire debug port
- AHB-AP: AHB access port
- ROM table
- System control space (SCS)
- Breakpoint unit (BPU)
- Data watchpoint and trace unit (DWT)
- Instrumentation trace macrocell (ITM)
- Embedded Trace Macrocell™ (ETM)
- Cross trigger interface (CTI)
- Trace port interface unit (TPU)

The debug features are accessible by the debugger via the AHB-AP.

Additional information can be found in the Arm documents referenced in Section 75.13.

75.2.3 DBG reset and clocks

The debug port (SWJ-DP) is reset by a power-on reset and when waking up from Standby mode.

The debugger supplies the clock for the debug port via the debug interface pin JTCK/SWCLK. This clock is used to register the serial input data in both serial-wire and JTAG modes, as well as to operate the state machines and internal logic of the debug port. This clock must therefore continue to toggle for several cycles after the end of an access, to ensure that the debug port returns to the idle state.

The SWJ-DP contains an asynchronous interface to the DCLK domain, that covers the rest of the SWJ-DP and the access port.

The DCLK is a gated version of the system clock.

The DCLK domain is enabled by the debugger using CDBGPWRUPREQ in DP_CTRL/STATR. The clock must be enabled before the debugger can access any of the device debug features. The availability of the clock is reflected by CDBGPWRUPACK in DP_CTRL/STATR. The DCLK is disabled at power-up, and must be disabled when the debugger is disconnected, to avoid wasting energy.

The debug and trace components included in the processor are clocked with the processor clock.

75.2.4 DBG power domains

The debug components are located in the core power domain. This means that the debugger connection is not possible in Shutdown or Standby low-power mode. To avoid losing the connection when the device enters Standby mode, the power can be maintained to the core by setting a bit in DBGMCU_CR. This also keeps the processor clocks active and holds off the reset, so that the debug session is maintained.

75.2.5 Debug and low-power modes

The devices include power saving features that allow the core power domain to be switched off or stopped when not required. If the power is switched off or if the core is not clocked, all debug components are inaccessible to the debugger. To avoid this, power-saving mode emulation is implemented. If the emulation is enabled for a domain, the domain still enters power-saving mode, but its clock and power are maintained. In other words, the domain behaves as if it is in power-saving mode, but the debugger does not lose the connection.

The emulation mode is programmed in the microcontroller debug (DBGMCU) unit. For more information, refer to Section 75.12.

### Table 780. Single-wire trace port pins

<table>
<thead>
<tr>
<th>Pin name</th>
<th>Type</th>
<th>Description</th>
<th>Pin assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRACESWO</td>
<td>O</td>
<td>Single-wire trace asynchronous data out</td>
<td>PB3(^{(1)})</td>
</tr>
</tbody>
</table>

1. TRACESWO is multiplexed with JTDO. This means that single-wire trace is only available when using the serial-wire debug interface, and not when using JTAG.
The trace and debug components allow a high degree of access to the processor and system during product development. In order to protect user code and ensure that the debug features can not be used to alter or compromise the normal operation of the finished product, these features can be disabled or limited in scope. For example, secure software debug and trace can be disabled without preventing the debug of nonsecure code.

The following authentication signals are used by the system to determine which debug features are enabled or disabled:

- **dbgen**: global enable for all debug features
  - 0: All debug features are disabled.
  - 1: Debug features in nonsecure state are enabled. Debug features in secure state are dependent on the state of the **spiden** signal.

- **spiden**: enables debug in secure state when **dbgen** = 1.
  - 0: Debug features are disabled in secure state.
  - 1: Debug features are enabled in secure state.

- **niden**: enables trace and performance monitoring (non-invasive debug).
  - 0: Trace generation is disabled.
  - 1: Trace generation in nonsecure state is enabled. Trace generation in secure state is dependent on the state of the **spniden** signal.

- **spniden**: enables trace and performance monitoring in secure state when **niden** = 1.
  - 0: Trace generation is disabled in secure state.
  - 1: Trace generation is enabled in secure state.

For detailed information on the behavior of each component according to the state of the authentication signals, refer to the relevant component chapter or to the relevant Arm technical documentation.

The state of the signals are set according to the readout protection (RDP) level (see Section 7.6.2: Readout protection (RDP)), as shown in the table below:

<table>
<thead>
<tr>
<th>RDP level</th>
<th>Authentication signal state</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>dbgen = 1, spiden = 1, niden = 1, spniden = 1</td>
<td>Debug and trace is enabled whatever the state of the processor. The debugger access to secure memory is permitted.</td>
</tr>
<tr>
<td>0.5</td>
<td>dbgen = 1, spiden = 0, niden = 1, spniden = 0</td>
<td>Debug and trace is enabled when the processor is in nonsecure state. The debugger access to secure memory is disabled.</td>
</tr>
<tr>
<td>1</td>
<td>dbgen = 1, spiden = 0, niden = 1, spniden = 0</td>
<td>Debug and trace is enabled when the processor is in nonsecure state. The debugger access to secure memory is disabled, as well as to the following areas: flash memory, SRAM2, backup registers, ICACHE, on-the-fly decryption region (OCTOSPI).</td>
</tr>
<tr>
<td>2</td>
<td>dbgen = 0, spiden = 0, niden = 0, spniden = 0</td>
<td>Debug and trace is disabled.</td>
</tr>
</tbody>
</table>
Note: Security features are only relevant when the option bit TZEN = 1. If security features are disabled, the authentication signals are still set according to the RDP level, but since the processor and all memories are nonsecure, spniden and spiden are redundant.

The state of the authentication signals can be read from DAUTHSTATUS register in the system control space (SCS) of the Cortex-M33.

The debugger access to secure memory (when permitted) must be performed using secure transactions on the debug AHB, that is, with PROT[6] set in AP_CSWR.

The debugger access is disabled while the processor is booting from system flash memory (RSS), whatever the RDP level, if security features are enabled (TZEN = 1).

75.3 Serial-wire and JTAG debug port (SWJ-DP)

The SWJ-DP is a CoreSight component that implements an external access port for connecting debugging equipment.

Two types of interface can be configured:
- a 5-pin standard JTAG interface (JTAG-DP)
- a 2-pin (clock + data) serial-wire debug port (SW-DP)

These two modes are mutually exclusive, since they share the same IO pins.

By default, the JTAG-DP is selected after a system or a power-on reset. The five IO pins are configured by hardware in debug alternative function mode. The SWJ-DP incorporates pull-up resistors on JTDI, JTMS/SWDIO, and nJTRST, as well as a pull-down resistor on JTCK/SWCLK.

A debugger can select the SW-DP by transmitting the following serial data sequence on JTMS/SWDIO:

... (50 or more ones) ..., 0, 1, 1, 1, 1, 0, 0, 1, 1, 1, 0, 0, 1, 1, 1, ... (50 or more ones) ...

JTCK/SWCLK must be cycled for each data bit.

In SW-DP mode, the unused JTAG pins JTDI, JTDO and nJTRST can be used for other functions.

Note: All SWJ port I/Os can be reconfigured to other functions by software, but debugging is no longer possible.
75.3.1 JTAG debug port

The JTAG-DP implements a TAP state machine (TAPSM), shown in the figure below, based on IEEE Std 1149.1-1990. The state machine controls two scan chains, one associated with an instruction register (IR) and the other one with a number of data registers (DR).

Figure 948. JTAG TAP state machine

The operation of the JTAG-DP is as follows:
1. When the TAPSM goes through the Capture-IR state, 0b0001 is transferred to the instruction register (IR) scan chain. The IR scan chain is connected between JTDI and JTDO.
2. While the TAPSM is in the Shift-IR state, the IR scan chain shifts one bit for each rising edge of JTCK. This means that on the first tick:
   - The LSB of the IR scan chain is output on JTDO.
   - Bit[n] of the IR scan chain is transferred to bit[n-1].
   - The value on JTDI is transferred to the MSB of the IR scan chain.
3. When the TAPSM goes through the Update-IR state, the value scanned into the IR scan chain is transferred to the instruction register.

4. When the TAPSM goes through the Capture-DR state, a value is transferred from one of the data registers to one of the DR scan chains, connected between JTDI and JTDO.

5. The value held in the instruction register determines which data register, and associated DR scan chain, are selected.

6. This data is then shifted while the TAPSM is in the Shift-DR state, in the same manner as the IR shifts in the Shift-IR state.

7. When the TAPSM goes through the Update-DR state, the value scanned into the DR scan chain is transferred to the selected data register.

8. When the TAPSM is in the Run-Test/Idle state, no special actions occurs. The IDCODE instruction is loaded in IR.

When active, the nJTRST signal resets the state machine asynchronously to the test-logic-reset state.

The data registers corresponding to the 4-bit IR instructions are listed in the table below.

Table 782. JTAG-DP data registers

<table>
<thead>
<tr>

    bits 2:1 = A[3:2] = 2-bit address of a debug port register  
    bit 0 = RnW = read request (1) or write request (0)  
  – When transferring data OUT:  
    bits 34:3 = DATA[31:0] = 32-bit data read following a read request  
    bits 2:0 = ACK[2:0] = 3-bit acknowledge:  
      – 010 = OK/FAULT  
      – 001 = WAIT  
      – others = reserved |
The DR registers are detailed in the Arm Debug Interface Architecture Specification (see Section 75.13).

### Serial-wire debug port

The serial-wire debug protocol uses the following pins:
- SWCLK: clock from host to target
- SWDIO: bi-directional serial data

Serial data is transferred LSB first, synchronously with the clock.

A transfer comprises three phases:
1. packet request (8 bits) transmitted by the host (see Table 783)
2. acknowledge response (3 bits) transmitted by the target (see Table 784)
3. data transfer (33 bits) transmitted by the host (in case of a write) or target (in case of a read) (see Table 785)

The data transfer only occurs if the acknowledge response is OK.

Between each phase, if the direction of the data is reversed, a single clock cycle turn-around time is inserted.

In the case of a FAULT or WAIT ACK response from the target, the data transfer phase is canceled, unless overrun detection is enabled: in this case, the data is ignored by the target (in the case of a write), or not driven (in the case of a read).

A line reset must be generated by the host when it is first connected, or following a protocol error. The line reset consists in 50 or more SWCLK cycles with SWDIO high, followed by two SWCLK cycles with SWDIO low.

For more details on the serial-wire debug protocol, refer to the Arm Debug Interface Architecture Specification [1].

Note: The SWJ-DP implements SWD protocol version 2.

### 75.3.3 Debug port registers

Both SW-DP and JTAG-DP access the debug port (DP) registers listed in Table 786.

The debugger can access the DP registers as follows:

1. Program the A(3:2) field in the DPACC register, if using JTAG, with the register address within the bank. Program the RnW bit to select a read or write. In the case of a write, program the data field with the write data. If using SWD, the A(3:2) and RnW fields are part of the packet request word sent to the SW-DP with the APnDP bit reset (see Table 783). The write data are sent in the data phase.

2. To access one of the banked DP registers at address 0x4, the register number must first be written to the DP_SELECTR register at address 0x8. Any subsequent read or

Bits 31:28  **REVISION[3:0]**: revision code
0x0 (JTAG-DP): r0p0
0x0 (SW-DP): r0p0

Bits 27:20  **PARTNO[7:0]**: part number for the debug port
0xBE

Bits 19:17  Reserved, must be kept at reset value.

Bit 16  **MIN**: minimal debug port (MINDP) implementation
0x1: MINDP implemented (transaction counter and pushed operations are not supported)

Bits 15:12  **VERSION[3:0]**: debug port architecture version
0x1 (JTAG-DP): DPv1
0x2 (SW-DP): DPv2

Bits 11:1  **DESIGNER[10:0]**: JEDEC designer identity code
0x23B: Arm JEDEC code

Bit 0  Reserved, must be kept at reset value.

**DP abort register (DP_ABORTR)**

Address offset: 0x0

Reset value: 0x0000 0000

Bits 31:5  Reserved, must be kept at reset value.
Bit 4 **ORUNERRCLR**: overrun error clear
   0: no effect
   1: STICKYORUN bit cleared in DP_CTRL/STATR register

Bit 3 **WDERRCLR**: write data error clear
   0: no effect
   1: WDATAERR bit cleared in DP_CTRL/STATR register

Bit 2 **STKERRCLR**: sticky error clear
   0: no effect
   1: STICKYERR bit cleared in DP_CTRL/STATR register

Bit 1 Reserved, must be kept at reset value.

Bit 0 **DAPABORT**: current AP transaction aborted if excessive number of WAIT responses returned
   This bit indicates that the transaction is stalled.
   0: no effect
   1: transaction aborted

**DP control and status register (DP_CTRL/STATR)**

Address offset: 0x4
Reset value: 0x0000 0000

This register is accessible when DP_SELECTR.DPBANKSEL[3:0] = 0x0.

</tr>
</tbody>
</table>

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **CDBGPWRUPACK**: debug power-up acknowledge (see description in Section 75.2.5)
   0: DCLK gated
   1: DCLK enabled

Bit 28 **CDBGPWRUPREQ**: debug power-up request
   This bit controls the DCLK enable request signal.
   0: requests DCLK gating
   1: requests DCLK enable

Bits 27:8 Reserved, must be kept at reset value.
Bit 7 **WDATAERR**: write data error (read-only) in SW-DP
   This bit indicates that there is a parity or framing error on the data phase of a write, or a write accepted by the DP is then discarded without being submitted to the AP.
   This bit is reset by writing one to the ABORT.WDERRCLR bit.
   0: no error
   1: an error occurred
   *Note: This bit is reserved in JTAG-DP.*

Bit 6 **READOK**: AP read response (read-only) in SW-DP
   This bit indicates the response to the last AP read access.
   0: read not OK
   1: read OK
   *Note: This bit is reserved in JTAG-DP.*

Bit 5 **STICKYERR**: transaction error (read-only in SW-DP, read/write in JTAG-DP)
   This bit indicates that an error occurred in an AP transaction. It is reset by writing 1 to the DP_ABORTR.STKERRCLR bit (in SW-DP and JTAG-DP)
   0: no error
   1: an error occurred

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **STICKYORUN**: overrun (read-only in SW-DP, read/write in JTAG-DP).
   This bit indicates that an overrun occurred (new transaction received before previous transaction completed). This bit is only set if the ORUNDETECT bit is set. It is reset by writing 1 to the DP_ABORTR.ORUNERRCLR bit (in SW-DP and JTAG-DP).
   0: no overrun
   1: an overrun occurred

Bit 0 **ORUNDETECT**: overrun detection mode enable.
   0: disabled
   1: enabled. In the event of an overrun, the STICKYORUN bit is set and subsequent transactions are blocked until the STICKYORUN bit is cleared.

**DP data link control register (DP_DLCR)**

Address offset: 0x4

Reset value: 0x0000 0000

This register is accessible when DP_SELECTR.DPBANKSEL[3:0] = 0x1.

Bits 31:24 **APSEL[7:0]**: access port select  
This field selects the access port for the next transaction.  
0x0: AP0 - Cortex-M33 debug access port (AHB-AP)  
others: reserved

Bits 23:8 Reserved, must be kept at reset value.

Bits 7:4 **APBANKSEL[3:0]**: AP register bank select  
This field selects the 4-word register bank on the active AP for the next transaction.

Bits 3:0 **DPBANKSEL[3:0]**: DP register bank select  
This field selects the register at address 0x4 of the debug port.  
0x0: DP_CTRL/STAT register  
0x1: DP_DLCR register  
0x2: DP_TARGETID register  
0x3: DP_DLPIDR register  
0x4: DP_EVENTSTAT register  
others: reserved
DP read buffer register (DP_RDBUFFR)

Address offset: 0xC
Reset value: 0x0000 0000

Bits 31:0  **RDBUFF[31:0]**: value returned by the last AP read access

The value returned by an AP read access can either be obtained using a second read access to the same address, that initiates a new transaction on the corresponding bus, or else it can be read from this register, in which case no new AP transaction occurs.

### 75.3.4 Debug port register map

These registers are not on the CPU memory bus, they are only accessed through SW-DP and JTAG-DP debug interface.

The debug port address is 2-bit wide, defined in the JTAG-DP register DPACC or SW-DP packet request A[3:2] field.

3500/3637 RM0456 Rev 5
75.4 Access ports

There is one access port (AP) attached to the DP. It enables the access to the debug and trace features integrated in the Cortex-M33 processor core via its internal AHB bus.

75.4.1 Access port registers

The access port is of MEM-AP type: the debug and trace component registers are mapped in the address space of the AHB. The AP is seen by the debugger as a set of 32-bit registers organized in banks of four registers each. Some of these registers are used to configure or monitor the AP itself, while others are used to perform a transfer on the bus. The AP registers are listed in Table 787.

The address of the AP registers is composed of the following fields:

- bits [7:4]: content of APBANKSEL[3:0] in DP_SELECTR
- bits [3:2]: content of the A(3:2) field of the APACC data register in the JTAG-DP (see Table 782), or of the SW-DP packet request (see Table 783), depending on the debug interface used
- bits [1:0]: always set to 0

The content of DP_SELECTR.APSEL[3:0] defines which MEM-AP is being accessed.

The debugger can access the AP registers as follows:
1. Program APSEL[3:0] in DP_SELECTR to choose the AP, and APBANKSEL[3:0] in DP_SELECTR to select the register bank to be accessed.

2. Program the A(3:2) field in the APACC data register, if using JTAG, with the register address within the bank. Program the RnW bit to select a read or write. In the case of a write, program the DATA field with the write data. If using SWD, the A(3:2) and RnW fields are part of the packet request word sent to the SW-DP with the APnDP bit set (see Table 783). The write data is sent in the data phase.

The debugger can access the memory mapped debug component registers through the AP registers (using the above AP register access procedure) as follows:

1. Program the transaction target address in AP_TAR.

2. Program AP_CSWR, if necessary, with the transfer parameters (AddrInc for example).

3. Write to or read from AP_DRWR to initiate a bus transaction at the address held in AP_TAR. Alternatively, a read or write to AP_BDnR triggers an access to TAR[31:4] + n address, allowing up to four consecutive addresses to be accessed without changing the address in the AP_TAR register.

For more detailed information on the MEM-AP, refer to the Arm Debug Interface Architecture Specification [1].

**AP control/status word register (AP_CSWR)**

Address offset: 0x0

Reset value: 0x0100 00X0

Bit 31 Reserved, must be kept at reset value.

Bit 30 **PROT[6]**: secure transfer request

This field sets the protection attribute HPROT[6] of the bus transfer.

0: secure transfer

1: nonsecure transfer

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:24 **PROT[3:0]**: bus transfer protection

This field sets the protection attributes HPROT[3:0] of the bus transfer.

0bXXX1: data access (bit 24 is read only)

0bXX0X: non-privilege mode

0bXX1X: privilege mode

0bX0XX: non-bufferable

0bX1XX: bufferable

0b0XXX: non-shareable, no look-up, non-modifiable

0b1XXX: shareable, look-up, modifiable

Bits 23:7 Reserved, must be kept at reset value.
Bit 6 **DBGSTATUS**: device enable (DEVICEEN) status  
0: AHB transfers blocked  
1: AHB transfers enabled

Bits 5:4 **ADDRINC[1:0]**: auto-increment mode  
Defines whether TAR address is automatically incremented after a transaction.  
0x0: no auto-increment  
0x1: address incremented by the size in bytes of the transaction (SIZE field)  
other: reserved

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **SIZE[2:0]**: size of next memory access transaction  
0x0: byte (8-bit)  
0x1: halfword (16-bit)  
0x2: word (32-bit)  
others: reserved

75.5 ROM tables

The ROM table is a CoreSight component that contains the base addresses of all the CoreSight debug components accessible via the AHB-AP. These tables allow a debugger to discover the topology of the CoreSight system automatically.

There are two ROM tables in the CPU sub-system. The MCU ROM table is pointed to by the base register in the AHB-AP. It contains the base-address pointer for the processor ROM table and for the TPIU registers, as well as for the MCU debug unit.

The MCU ROM table (see the table below) occupies a 4-Kbyte, 32-bit wide chunk of address space, from 0xE00F E000 to 0xE00F EFFC.

<table>

</tr>
</tbody>
</table>

The processor ROM table contains the base-address pointer for the system control space (SCS) registers, that allow the debugger to identify the CPU core, as well as for the BPU, DWT, ITM, ETM and CTI.

The processor ROM table (see the table below) occupies a 4-Kbyte, 32-bit wide chunk of address space, from 0xE00F F000 to 0xE00F FFFC.

RM0456 Rev 5 3517/3637
Refer to Table 789: Processor ROM table for register boundary addresses.

75.6 Data watchpoint and trace unit (DWT)

The DWT provides four comparators that can be used as one of the following:

- watchpoint
- ETM trigger
- PC sampling trigger
- data address sampling trigger
- data comparator (COMP 1 only)
- clock cycle counter comparator (COMP 0 only)

It also contains counters for:

- clock cycles
- folded instructions
- load store unit (LSU) operations
- sleep cycles
- number of cycles per instruction
• interrupt overhead

A DWT comparator compares the value held in its DWT_COMPxR with one of the following:
• a data address
• an instruction address
• a data value
• the cycle-count value, for COMP 0 only

For address matching, the comparator can use a mask, so it matches a range of addresses.

On a successful match, the comparator generates one of the following:
• one or more DWT data trace packets, containing one or more of:
  – the address of the instruction that caused a data access
  – an address offset, bits[15:0] of the data access address
  – the matched data value
• a watchpoint debug event, on either the PC value or the accessed data address
• a CMPMATCH[N] event, that signals the match outside the DWT unit

A watchpoint debug event either generates a DebugMonitor exception, or causes the processor to halt execution and enter debug state.

For more details on how to use the DWT, refer to the Armv8-M Architecture Reference Manual [3].

75.6.1 DWT registers

The DWT registers are located at address range 0xE000 1000 to 0xE000 1FFC.

DWT control register (DWT_CTRLR)

**Bits 31:27 ID[4:0]: capability identification**
- Identifies the capability for match for comparator 0.
- 0b01011: cycle counter, instruction address, data address, and data address with value

**Bits 26:25** Reserved, must be kept at reset value.

**Bit 24 MATCHED:** comparator match
- Indicates if a comparator match has occurred since the register was last read.
- 0: no match
- 1: a match occurred.

**Bits 23:12** Reserved, must be kept at reset value.

**Bits 11:10 DATAVSIZE[1:0]: data value size**
- Defines the size of the object being watched for by data value and data address comparators.
- 0x0: 1 byte
- 0x1: 2 bytes
- 0x2: 4 bytes
- 0x3: reserved

**Bits 9:6** Reserved, must be kept at reset value.

**Bits 5:4 ACTION[1:0]: action on match**
- 0x0: trigger only
- 0x1: generate debug event
- 0x2: For a cycle counter, instruction address, data address, data value, or linked data value comparator, generate a data trace match packet. For a data address With value comparator, generate a data trace data value packet.
- 0x3: For a data address limit comparator, generate a data trace data address packet. For a cycle counter, instruction address limit, or data address comparator, generate a data trace PC value packet. For a data address with value comparator, generate both a data trace PC value packet and a data trace data value packet.

**Bits 3:0 MATCH[3:0]: match type**
- Controls the type of match generated by comparator 0.
- For possible values of this field, refer to [3].
**DWT function register 1 (DWT_FUNCTR1)**

Address offset: 0x038  
Reset value: 0xD000 0000

| Bits 31:27 | ID[4:0]: capability identification

0x0: trigger only  
0x1: generate debug event  
0x2: For a cycle counter, instruction address, data address, data value, or linked data value comparator, generate a data trace match packet. For a data address with value comparator, generate data trace Data value packet.  
0x3: For a data address limit comparator, generate a data trace data address packet. For a cycle counter, instruction address limit, or data address comparator, generate a data trace PC value packet. For a data address with value comparator, generate both a data trace PC value packet and a data trace data value packet.

**Bits 3:0** MATCH[3:0]: match type  
Controls the type of match generated by comparator 1.  
For possible values of this field, refer to [3].
DWT function register 2 (DWT_FUNCTR2)

Address offset: 0x048
Reset value: 0x5000 0000

|   |   |   |   |   | MATCHED |   |   |   |   |   |   |   |   |   |   |

Bits 31:27 **ID[4:0]**: capability identification
- Identifies the capability for match for comparator 2
  - 0b01010: instruction address, data address, and data address with value

Bits 26:25 Reserved, must be kept at reset value.

Bit 24 **MATCHED**: comparator match
- Indicates if a comparator match has occurred since the register was last read.
  - 0: no match
  - 1: a match occurred

Bits 23:12 Reserved, must be kept at reset value.

Bits 11:10 **DATAVSIZE[1:0]**: Data value size:
- Defines the size of the object being watched for by data value and data address comparators.
  - 0x0: 1 byte
  - 0x1: 2 bytes
  - 0x2: 4 bytes
  - 0x3: reserved

Bits 9:6 Reserved, must be kept at reset value.

Bits 5:4 **ACTION[1:0]**: action on match
- 0x0: trigger only
- 0x1: Generate debug event
- 0x2: For a cycle counter, instruction address, data address, data value, or linked data value comparator, generate a data trace match packet. For a data address with value comparator, generate a data trace data value packet.
- 0x3: For a data address limit comparator, generate a data trace data address packet. For a cycle counter, instruction address limit, or data address comparator, generate a data trace PC value packet. For a data address with value comparator, generate both a data trace PC value packet and a data trace data value packet.

Bits 3:0 **MATCH[3:0]**: match type
- Controls the type of match generated by comparator 2.
- For possible values of this field, refer to [3]

Refer to *Table 789: Processor ROM table* for register boundary addresses.

### 75.7 Instrumentation trace macrocell (ITM)

The ITM generates trace information in packets. Three sources can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The three sources in decreasing order of priority are the following:

- **Software trace**
  The software can write directly to any of 32 x 32-bit ITM stimulus registers to generate packets. The permission level for each port can be programmed. When software writes to an enabled stimulus port, the ITM combines the identity of the port, the size of the write access and the data written, into a packet that it writes to a FIFO. The ITM outputs packets from the FIFO onto the trace bus. Reading a stimulus port register returns the status of the stimulus register (empty or pending) in bit 0.

- **Hardware trace**
  The DWT generates trace packets in response to a data trace event, a PC sample or a performance profiling counter wraparound. The ITM outputs these packets on the trace bus.

- **Local timestamping**
  The ITM contains a 21-bit counter clocked by the (pre-divided) processor clock. The counter value is output in a timestamp packet on the trace bus. The counter is reset to...
zero every time a timestamp packet is generated. The timestamps thus indicate the
time elapsed since the previous timestamp packet.

For more information on the ITM and how to use it, refer to [3].

75.7.1 ITM registers

The ITM registers are located at address range 0xE000 0000 to 0xE000 0FFC.

ITM stimulus register x (ITM_STIMRx)

Address offset: 0x000 + 0x4 * x, (x = 0 to 31)
Reset value: 0xXXXX XXXX

<table>
<thead>
<tr>
<th>STIMULUS[31:16]</th>
<th>STIMULUS[15:0]</th>

<td>0</td>
</tr>
</tbody>
</table>

Bits 31:0 STIMULUS[31:0]: trace output data

When writing, write data is output on the trace bus as a software event packet.
When reading:

- bit 1 is a disable flag:
  - 0: stimulus port and ITM enabled
  - 1: stimulus port and ITM disabled
- bit 0 is a FIFO ready indicator:
  - 0: stimulus port buffer is full (or port is disabled)
  - 1: stimulus port can accept new write data

ITM trace enable register (ITM_TER)

Address offset: 0xE00
Reset value: 0x0000 0000

Bits 31:24  Reserved, must be kept at reset value.

Bit 23  **BUSY**: indicates whether the ITM is currently processing events

- 0: not busy
- 1: busy

Bits 22:16  **TRACEBUSID[6:0]**: identifier for multi-source trace stream formatting

  If multi-source trace is in use, the debugger must write a non-zero value to this field.

  *Note*: Different identifiers must be used for each trace source in the system.

Bits 15:10  Reserved, must be kept at reset value.
Bits 9:8  **TSPRESCALE[1:0]**: local timestamp prescaler, used with the trace packet reference clock
   0x0: no prescaling
   0x1: Divide by 4.
   0x2: Divide by 16.
   0x3: Divide by 64.

Bits 7:6  Reserved, must be kept at reset value.

Bit 5  **STALLEN**: stall enable
   0: Drop hardware source packets and generate an overflow if the ITM output is stalled.
   1: Stall the processor to guarantee delivery of data trace packets.

Bit 4  **SWOENA**: SWO enable
   Enables asynchronous clocking of the timestamp counter (read only).
   0: Timestamp counter uses processor clock.
   1: enabled

Bit 3  **TXENA**: transmit enable
   Enables forwarding of hardware event packets from the DWT unit to the trace port.
   0: disabled
   1: enabled

Bit 2  **SYNCENA**: synchronization packet transmission enable
   The debugger setting this bit must also configure the DWT_CTRLR.SYNCTAP field for the correct synchronization speed.
   0: disabled
   1: enabled

Bit 1  **TSENA**: local timestamp generation enable
   0: disabled
   1: enabled

Bit 0  **ITMENA**: ITM enable
   0: disabled
   1: enabled

Bits 7:0 **PREAMBLE[27:20]**: Component identification bits [31:24]

0xB1: Common identification value
75.8 Breakpoint unit (BPU)

The BPU allows the user to set hardware breakpoints. It contains eight comparators that monitor the instruction fetch address. If a match occurs, the instruction comparators can be configured to generate a breakpoint instruction.

For more information on the breakpoint unit and how to use it, refer to [3].

75.8.1 BPU registers

The BPU registers are located at address range 0xE0002000 to 0xE0002FFC.

**BPU control register (BPU_CTRLR)**

Address offset: 0x000

Reset value: 0x1000 0080

**Bits 7:0 PREAMBLE[27:20]: component identification bits [31:24]**

**0xB1: common identification value**
75.9 Embedded Trace Macrocell (ETM)

The ETM is a CoreSight component closely coupled to the CPU. The ETM generates trace packets that allow the execution of the Cortex-M33 core to be traced. In STM32U5 Series, the ETM is configured for instruction trace only. Data accesses are not included in the trace information.

The ETM receives information from the CPU over the processor trace interface, including:
- number of instructions executed in the same cycle
- changes in program flow
- current processor instruction state
- addresses of memory locations accessed by load and store instructions
- type, direction and size of a transfer
- Condition code information
- exception information
- wait for interrupt state information

For more information, refer to the Arm CoreSight ETM-M33 Technical Reference Manual [5].

75.9.1 ETM registers

The ETM registers are located at address range 0xE004 1000 to 0xE004 1FFC.

**ETM programming control register (ETM_PRGCTLR)**

Address offset: 0x004

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-1</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>

Refer to Table 789: Processor ROM table for register boundary addresses.
Bit 0 **EN**: trace unit enable
   0: disabled
   1: enabled

**ETM status register (ETM_STATR)**

Address offset: 0x00C
Reset value: 0xXXXX XXXX

<table>
<thead>
<tr>
<th>31</th>

</tr>
</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **PMSTABLE**: stability status
Indicates that the ETM-M33 registers are stable and can be read.
0: not stable
1: stable

Bit 0 **IDLE**: trace unit status
Indicates that the trace unit is inactive.
0: not idle
1: idle

**ETM configuration register (ETM_CONFIGR)**

Address offset: 0x010
Reset value: 0xXXXX XXXX

<table>
<thead>
<tr>

#### Bits 31:13
Reserved, must be kept at reset value.

- **Bit 12** LPOVERRIDE: low-power state behavior override
  - 0: normal low-power state behavior
  - 1: The resources and event trace generation are not affected by entry to a low-power state.

- **Bit 11** ATB: ATB trigger enable
  - 0: disabled
  - 1: enabled

#### Bits 10:2
Reserved, must be kept at reset value.

- **Bits 1:0** INSTEN[1:0]: instruction event generation
  - Enables generation of an event element in the instruction stream.
    - 0bX0: Event0 does not cause an event element.
    - 0bX1: Event0 causes an event element when it occurs.
    - 0b0X: Event1 does not cause an event element.
    - 0b1X: Event1 causes an event element when it occurs.

### ETM stall control register (ETMSTALLCTRLR)

Address offset: 0x02C

Reset value: 0xXXXX XXXX

<table>

<th>16</th>
</tr>
</thead>
</table>

#### Bits 31:11
Reserved, must be kept at reset value.

- **Bit 10** INSTPRIORITY: instruction trace priority
  - Prioritizes instruction trace if instruction trace buffer space is less than LEVEL[3:0].
  - 0: The ETM must not prioritize instruction trace.
  - 1: The ETM can prioritize instruction trace.

- **Bit 9** Reserved, must be kept at reset value.
Bit 8 ISTALL: processor stalling
Stalls processor based on instruction trace buffer space.
0: The ETM must not stall the processor.
1: The ETM can stall the processor.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 LEVEL[3:0]: Threshold at which stalling becomes active
This field provides four levels. This level can be varied to optimize the level of invasion caused by stalling, balanced against the risk of a FIFO overflow.
0x0: zero invasion, but greater risk of FIFO overflow
...  
0xF: maximum invasion but less risk of FIFO overflow

**ETM synchronization period register (ETM_SYNCPR)**
Address offset: 0x034
Reset value: 0x0000 000A

<table>

**Note:** The table above shows the register map and reset values for ETM registers, including detailed bit fields and reset values for each register. Each register is represented with its offset, register name, and corresponding bit fields along with their reset values.
Refer to Table 789: Processor ROM table for register boundary addresses.

### 75.10 Trace port interface unit (TPIU)

The TPIU formats the trace stream and outputs it on the external trace port signals. As shown in the figure below, the TPIU has two ATB slave ports for incoming trace data from the ETM and ITM respectively. The trace port is a synchronous parallel port, comprising a
clock output, TRACECLK, and four data outputs, TRACEDATA(3:0). The trace port width is programmable in the range 1 to 4. Using a smaller port width reduces the number of test points/connector pins needed, and frees up IOs for other purposes, at the expenses of bandwidth restriction of the trace port, and hence of the quantity of trace information that can be output in real time.

Figure 950. Trace port interface unit (TPIU)

Trace data can also be output on the serial-wire output, TRACESWO.

For more information on the trace port interface in the Cortex-M33, refer to the Arm Cortex-M33 Technical Reference Manual [4].

75.10.1 TPIU registers

TPIU supported port size register (TPIU_SPSR)

Address offset: 0x000

Reset value: 0x0000 000F

<table>

Bits 31:4  Reserved, must be kept at reset value.

Bit 3  **FTNONSTOP**: formatter stop
Indicates whether formatter can be stopped or not.
1: The formatter cannot be stopped.

Bit 2  **TCPRESENT**: TRACECTL output pin availability
Indicates whether the optional TRACECTL output pin is available for use.
0: TRACECTL pin is not present in this device.

Bit 1  **FTSTOPPED**: formatter stop
The formatter has received a stop request signal and all trace data and post-amble is sent.
Any additional trace data on the ATB interface is ignored.
0: The formatter has not stopped.

Bit 0  **FLINPROG**: flush in progress
Indicates whether a flush on the ATB slave port is in progress. This bit reflects the status of the AFVALIDS output. A flush can be initiated by the flush control bits in the TPIU_FFCR register.
0: no flush in progress
1: flush in progress

**TPIU formatter and flush control register (TPIU_FFCR)**
Address offset: 0x304
Reset value: 0x0000 0102

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **TRIGIN**: trigger on trigger in
1: Indicates a trigger in the trace stream when the TRIGIN input is asserted.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FONMAN**: flush on manual
0: flush completed
1: Generates a flush.

Bits 5:2 Reserved, must be kept at reset value.

Bit 1 **ENFCONT**: continuous formatting enable
Setting this bit to zero in SWO mode bypasses the formatter and only ITM/DWT trace is output. ETM trace is discarded.
0: continuous formatting disabled
1: continuous formatting enabled

Bit 0 Reserved, must be kept at reset value.

</table>

Bits 31:13 Reserved, must be kept at reset value.

Bits 12:0 **PSCOUNT[12:0]**: formatter frames counter

Enables effective use of different sized TPAs without wasting large amounts of the storage capacity of the capture device. This counter contains the number of formatter frames since the last synchronization packet of 128 bits. It is a 12-bit counter with a maximum count value of 4096. This equates to synchronization every 65536 bytes, that is, 4096 packets x 16 bytes per packet. The default is set up for a synchronization packet every 1024 bytes, that is, every 64 formatter frames. If the formatter is configured for continuous mode, full and half-word synchronization frames are inserted during normal operation. Under these circumstances, the count value is the maximum number of complete frames between full synchronization packets.
### TPIU claim tag set register (TPIU_CLAIMSETR)

3586/3637 RM0456 Rev 5
Refer to Table 788: MCU ROM table for register boundary addresses.
75.11 Cross-trigger interface (CTI)

The CTI allows cross triggering between the processor and the ETM (see the figure below).

Figure 951. Embedded cross trigger

The CTI enables events from various sources to trigger debug and/or trace activity. For example, a watchpoint reached in the processor can start or stop code trace, or a trace comparator can halt the processor.

The trigger input and output signals for the CTI are listed in the tables below.

Table 797. CTI inputs

<table>
<thead>
<tr>
<th>Number</th>
<th>Source signal</th>
<th>Source component</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>HALTED</td>

</tbody>
</table>
For more information on the cross-trigger interface CoreSight component, refer to the Arm CoreSight SoC-400 Technical Reference Manual [2].

### 75.11.1 CTI registers

The register file base address for the CTI is 0xE004 2000.

#### CTI control register (CTI_CONTROLR)

Address offset: 0x000

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits</th>
<th>GLBEN</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-1</td>
<td>0000</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>0</td>
<td></td>
<td>0: disabled</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: enabled</td>
</tr>
</tbody>
</table>

#### CTI trigger acknowledge register (CTI_INTACKR)

Address offset: 0x010

Reset value: 0xXXXX XXXX

<table>
<thead>
<tr>
<th>Bits</th>
<th>INTACK[7:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>
Bits 7:0  **INTACK[7:0]: trigger acknowledge**

There is one bit of the register for each CTITRIGOUT output. When a 1 is written to a bit in this register, the corresponding CTITRIGOUT output is acknowledged, causing it to be cleared.

**CTI application trigger set register (CTI_APPSETR)**

Address offset: 0x014

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>

<td></td>
</tr>
</tbody>
</table>

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **APPSET[3:0]: channel event setting**

Read:
- XXX0: channel 0 event inactive
- XXX0: channel 0 event active
- X0X0: channel 1 event inactive
- XX1X: channel 1 event active
- X0XX: channel 2 event inactive
- X1XX: channel 2 event active
- 0XXX: channel 3 event inactive
- 1XXX: channel 3 event active

Write:
- XXX0: no effect
- XXXX: Sets event on channel 0.
- X0XX: no effect
- XX1X: Sets event on channel 1.
- X0XX: no effect
- X1XX: Sets event on channel 2.
- 0XXX: no effect
- 1XXX: Sets event on channel 3.

**CTI application trigger clear register (CTI_APPCLEAR)**

Address offset: 0x018

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>

Refer to Table 789: Processor ROM table for register boundary addresses.
75.12 Microcontroller debug unit (DBGMCU)

The DBGMCU is a component containing a number of registers that control the power and clock behavior in debug mode. It allows the debugger (or the software):

- to maintain the clock and power to the processor cores when in low-power modes (Sleep, Stop, or Standby mode)
- to maintain the clock and power to the system debug and trace components when in low-power modes
- to stop the clock to certain peripherals (SMBUS timeout, watchdogs, timers, RTC) when either processor core is stopped in debug mode

75.12.1 Device ID

The DBGMCU includes an identity code register, DBGMCU_IDCODE. This register contains the ID code for the device. Debug tools can locate this register via the CoreSight discovery procedure described in Table 75.5.

75.12.2 Low-power mode emulation

When the device enters either Stop mode (clocks are stopped) or Standby mode (core power is switched off), the debugger can no longer access the debug access port and loses the connection with the device. To avoid this, the debugger (or software) can set DBG_STANDBY and/or DBG_STOP in DBGMCU_CR. These bits, when set, maintain the clock and power to the processor while the device is in the corresponding low-power mode. The processor remains in Sleep mode, and exits the low-power mode in the normal way. Peripheral devices continue to operate, so the device behaviour may not be identical to the one in the actual low-power mode.

75.12.3 Peripheral clock freeze

The DBGMCU peripheral clock freeze registers allow the operation of certain peripherals to be suspended in debug mode. The peripheral units which support this feature are listed in the table below.

<table>
<thead>
<tr>
<th>Bus</th>

</tbody>
</table>
Each peripheral unit or DMA channel has a corresponding control bit, DBG_xxx_STOP, where xxx is the acronym of the peripheral (or DMA channel). The control bits are organized in DBGMCU_zzzFZR registers, where zzz corresponds to the name of the bus (AHB or APB). For example, DBGMCU_APB1LFZR contains the control bits for peripherals on the APB1L bus.

The control bit, when set, causes the corresponding peripheral operation to be suspended when the CPU is stopped in debug (HALTED = 1), according to the table below:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The accessibility of DBG_xxx_STOP bits by the debugger depends on the state of the authentication signal spiden.

When spiden = 1 (secure privilege debug enabled), all bits can be modified by a secure access. Only bits corresponding to nonsecure peripherals (or DMA channels) can be modified by a nonsecure access. All bits can be read by both nonsecure or secure accesses.
When spiden = 0 (secure privilege debug disabled), only nonsecure accesses are possible (secure access requests by the debugger are converted to nonsecure by the CPU). Only bits corresponding to nonsecure peripherals (or DMA channels) can be modified. All bits can be read. This is summarized in the table below.

### Table 802. Debugger access to freeze register bits

<table>
<thead>
<tr>
<th>spiden</th>
<th>Peripheral xxx status</th>
<th>Access security attribute</th>
<th>DBG_xxx_STOP can be modified?</th>
<th>DBG_xxx_STOP can be read?</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Nonsecure</td>
<td>Nonsecure</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td>Secure</td>
<td>Secure</td>
<td>Yes (1)</td>
<td>Yes (1)</td>
</tr>
<tr>
<td>1</td>
<td>Nonsecure</td>
<td>Nonsecure</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td>Secure</td>
<td>Secure</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

1. When spiden = 0, secure access requests by the debugger are converted to nonsecure.

The status (secure or nonsecure) of a TrustZone–aware peripheral or a DMA channel, is signaled to the DBGMCU by the peripheral.

The CPU access to the DBG_xxx_STOP bits does not depend on spiden. This access depends only on the security status of the peripheral. The bits corresponding to a secure peripheral (or DMA channel) can only be modified by a secure access (when CPU is in secure state).

### 75.12.4 DBGMCU registers

The DBGMCU registers are not reset by a system reset, only by a power-on reset. They are accessible to the debugger via the AHB access port, and to software, at base address 0xE004 4000.

**DBGMCU identity code register (DBGMCU_IDCODE)**

Address offset: 0x00

Reset value: 0xFFFF 6XXX

3604/3637 RM0456 Rev 5
Bit 4 **TRACE_IOEN**: trace pin enable
   0: disabled - trace pins not assigned
   1: enabled - trace pins assigned according to the value of TRACE_MODE field

Bit 3 **Reserved, must be kept at reset value.**

Bit 2 **DBG_STANDBY**: Allows debug in Standby mode
   0: normal operation
   All clocks are disabled and the core powered down automatically in Standby mode.
   1: automatic clock stop/power down disabled
   All active clocks and oscillators continue to run during Standby mode, and the core supply is maintained, allowing full debug capability. On exit from Standby mode, a system reset is performed.

Bit 1 **DBG_STOP**: Allows debug in Stop mode
   0: normal operation
   All clocks are disabled automatically in Stop mode.
   1: automatic clock stop disabled
   All active clocks and oscillators continue to run during Stop mode, allowing full debug capability. On exit from Stop mode, the clock settings are set to the Stop mode exit state.

Bit 0 **Reserved, must be kept at reset value.**

76 Device electronic signature

The device electronic signature is stored in the system memory area of the flash memory module and can be read using the debug interface or by the CPU. It contains factory-programmed identification and calibration data that allow the user firmware or other external devices to automatically match to the characteristics of the devices.

76.1 Unique device ID register (96 bits)

The unique device identifier is ideally suited:
- for use as serial numbers (for example USB string serial numbers or other end applications)
- for use as part of the security keys in order to increase the security of code in flash memory while using and combining this unique ID with software cryptographic primitives and protocols before programming the internal flash memory
- to activate secure boot processes

The 96-bit unique device identifier provides a reference number which is unique for any device and in any context. These bits cannot be altered by the user.

Base address: 0x0BFA 0700
Address offset: 0x00
Read only = 0xXXXX XXXX where X is factory-programmed

*Note: Refer to product datasheet for availability of packages on a specific device.*
The STMicroelectronics group of companies (ST) places a high value on product security, which is why the ST product(s) identified in this documentation may be certified by various security certification bodies and/or may implement our own security measures as set forth herein. However, no level of security certification and/or built-in security measures can guarantee that ST products are resistant to all forms of attacks. As such, it is the responsibility of each of ST’s customers to determine if the level of security provided in an ST product meets the customer needs both in relation to the ST product alone, as well as when combined with other components and/or software for the customer end product or application. In particular, take note that:

- ST products may have been certified by one or more security certification bodies, such as Platform Security Architecture (www.psacertified.org) and/or Security Evaluation standard for IoT Platforms (www.trustcb.com). For details concerning whether the ST product(s) referenced herein have received security certification along with the level and current status of such certification, either visit the relevant certification standards website or go to the relevant product page on www.st.com for the most up to date information. As the status and/or level of security certification for an ST product can change from time to time, customers should re-check security certification status/level as needed. If an ST product is not shown to be certified under a particular security standard, customers should not assume it is certified.

- Certification bodies have the right to evaluate, grant and revoke security certification in relation to ST products. These certification bodies are therefore independently responsible for granting or revoking security certification for an ST product, and ST does not take any responsibility for mistakes, evaluations, assessments, testing, or other activity carried out by the certification body with respect to any ST product.

- Industry-based cryptographic algorithms (such as AES, DES, or MD5) and other open standard technologies which may be used in conjunction with an ST product are based on standards which were not developed by ST. ST does not take responsibility for any flaws in such cryptographic algorithms or open technologies or for any methods which have been or may be developed to bypass, decrypt or crack such algorithms or technologies.

- While robust security testing may be done, no level of certification can absolutely guarantee protections against all attacks, including, for example, against advanced attacks which have not been tested for, against new or unidentified forms of attack, or against any form of attack when using an ST product outside of its specification or intended use, or in conjunction with other components or software which are used by customer to create their end product or application. ST is not responsible for resistance against such attacks. As such, regardless of the incorporated security features and/or any information or support that may be provided by ST, each customer is solely responsible for determining if the level of attacks tested for meets their needs, both in relation to the ST product alone and when incorporated into a customer end product or application.

- All security features of ST products (inclusive of any hardware, software, documentation, and the like), including but not limited to any enhanced security features added by ST, are provided on an "AS IS" BASIS. AS SUCH, TO THE EXTENT PERMITTED BY APPLICABLE LAW, ST DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE, unless the applicable written and signed contract terms specifically provide otherwise.

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 16-Mar-2022 | 3 (cont’d) | – Line 23 in Table 156: EXTI line connections  
– Bit 23 in Section 21.6.1 to Section 21.6.10, and Section 21.6.11  
– Section 21.6.8: EXTI external interrupt selection register (EXTI_EXTICRm)  
– Bulb sampling mode  
– CALINDEX[3:0] in ADC_CR  
– New Extended calibration mode  
– Table 249: Memory location of the temperature sensor calibration values  
– Section 21.7.13: ADC power register (ADC_PWR)  
– New Section 55.3: TAMP implementation  
– Active tamper detection  
– ATCKSEL desc in Section 50.6.5: TAMP active tamper control register 1 (TAMP_ATCR1)  
– Note in Table 514: STM32U575/585 IWDG features  
– Configuring the IWDG when the window option is enabled  
– New Updating the window comparator  
– Section 48.4.6: Register access protection  
– KEY[15:0] desc in Section 48.7.1: IWDG key register (IWDG_KR)  
– Table 653: UCPD implementation and Table 654: UCPD software trim data  
– New Section 64.5.5: UCPD software trimming  
– Section 64.8.3: UCPD configuration register 3 (UCPD_CFGR3)  
– TREV_ID desc in DP target identification register (DP_TARGETIDR)  
– REV_ID desc in DBGMCU identity code register (DBGMCU_IDCODE)                                                   |
| 16-Feb-2023 | 4        | Full scope updated to cover all STM32U5 series products:  
– STM32U535/545,  
– STM32U575/585 rev X and above,  
– STM32U59x/5Ax,  
– STM32U5Fx/5Gx.  
Updated:  
– Reset value for Section 5.6.9: GTZC1 TZSC memory x sub-region A watermark register (GTZC1_TZSC_MPCWMxAR) and Section 5.6.10: GTZC1 TZSC memory x sub-region B watermark register (GTZC1_TZSC_MPCWMxBR)  
– SRAM3 ECC specific management  
– Section 7.3.8: Flash memory endurance  
– Section 10: Power control (PWR)  
– Section 11.4.6: PLL  
– Section 11.8.12: RCC PLL1 dividers register (RCC_PLL1DIVR)  
– Reset value for Section 11.8.30: RCC AHB2 peripheral clock enable register 1 (RCC_AHB2ENR1) and Section 11.8.31: RCC AHB2 peripheral clock enable register 2 (RCC_AHB2ENR2)  
– Table 682: LPUART interconnections (LPUART1)  
– Section 33: Analog-to-digital converter (ADC12)  
– DP target identification register (DP_TARGETIDR)  
– DBGMCU identity code register (DBGMCU_IDCODE)  
– DBGMCU status register (DBGMCU_SR)                                                   |
| 19-Oct-2023 | 5        | Updated the cover page to include STM32U5Fxxx and STM32U5Gxxx documents.                                                                 |
