Bit 10 **GPTXEIE**: Generic payload transmit error interrupt enable
This bit enables the interrupt generation on generic payload transmit error.
0: Interrupt on generic payload transmit error disabled
1: Interrupt on generic payload transmit error enabled

Bit 9 **GPWREIE**: Generic payload write error interrupt enable
This bit enables the interrupt generation on generic payload write error.
0: Interrupt on generic payload write error disabled
1: Interrupt on generic payload write error enabled

Bit 8 **GCWREIE**: Generic command write error interrupt enable
This bit enables the interrupt generation on generic command write error.
0: Interrupt on generic command write error disabled
1: Interrupt on generic command write error enabled

Bit 7 **LPWREIE**: LTDC payload write error interrupt enable
This bit enables the interrupt generation on LTDC payload write error.
0: Interrupt on LTDC payload write error disabled
1: Interrupt on LTDC payload write error enabled

Bit 6 **EOTPEIE**: EoTp error interrupt enable
This bit enables the interrupt generation on EoTp error.
0: Interrupt on EoTp error disabled
1: Interrupt on EoTp error enabled

Bit 5 **PSEIE**: Packet size error interrupt enable
This bit enables the interrupt generation on packet size error.
0: Interrupt on packet size error disabled
1: Interrupt on packet size error enabled

Bit 4 **CRCEIE**: CRC error interrupt enable
This bit enables the interrupt generation on CRC error.
0: Interrupt on CRC error disabled
1: Interrupt on CRC error enabled

Bit 3 **ECCMEIE**: ECC multi-bit error interrupt enable
This bit enables the interrupt generation on ECC multi-bit error.
0: Interrupt on ECC multi-bit error disabled
1: Interrupt on ECC multi-bit error enabled

Bit 2 **ECCSEIE**: ECC single-bit error interrupt enable
This bit enables the interrupt generation on ECC single-bit error.
0: Interrupt on ECC single-bit error disabled
1: Interrupt on ECC single-bit error enabled

Bit 1 **TOLPRXIE**: Timeout low-power reception interrupt enable
This bit enables the interrupt generation on timeout low-power reception.
0: Interrupt on timeout low-power reception disabled
1: Interrupt on timeout low-power reception enabled

Bit 0 **TOHSTXIE**: Timeout high-speed transmission interrupt enable
This bit enables the interrupt generation on timeout high-speed transmission.
0: Interrupt on timeout high-speed transmission disabled
1: Interrupt on timeout high-speed transmission enabled

Bits 31:21 Reserved, must be kept at reset value.

- **Bit 20**: **FPE4**: Force PHY error 4  
  Writing one to this bit forces a PHY error 4.

- **Bit 19**: **FPE3**: Force PHY error 3  
  Writing one to this bit forces a PHY error 3.

- **Bit 18**: **FPE2**: Force PHY error 2  
  Writing one to this bit forces a PHY error 2.

- **Bit 17**: **FPE1**: Force PHY error 1  
  Writing one to this bit forces a PHY error 1.

- **Bit 16**: **FPE0**: Force PHY error 0  
  Writing one to this bit forces a PHY error 0.

- **Bit 15**: **FAE15**: Force acknowledge error 15  
  Writing one to this bit forces an acknowledge error 15.

- **Bit 14**: **FAE14**: Force acknowledge error 14  
  Writing one to this bit forces an acknowledge error 14.

- **Bit 13**: **FAE13**: Force acknowledge error 13  
  Writing one to this bit forces an acknowledge error 13.

- **Bit 12**: **FAE12**: Force acknowledge error 12  
  Writing one to this bit forces an acknowledge error 12.

- **Bit 11**: **FAE11**: Force acknowledge error 11  
  Writing one to this bit forces an acknowledge error 11.

- **Bit 10**: **FAE10**: Force acknowledge error 10  
  Writing one to this bit forces an acknowledge error 10.

- **Bit 9**: **FAE9**: Force acknowledge error 9  
  Writing one to this bit forces an acknowledge error 9.

- **Bit 8**: **FAE8**: Force acknowledge error 8  
  Writing one to this bit forces an acknowledge error 8.

- **Bit 7**: **FAE7**: Force acknowledge error 7  
  Writing one to this bit forces an acknowledge error 7.

- **Bit 6**: **FAE6**: Force acknowledge error 6  
  Writing one to this bit forces an acknowledge error 6.
Bit 5 **FAE5**: Force acknowledge error 5
   Writing one to this bit forces an acknowledge error 5.

Bit 4 **FAE4**: Force acknowledge error 4
   Writing one to this bit forces an acknowledge error 4.

Bit 3 **FAE3**: Force acknowledge error 3
   Writing one to this bit forces an acknowledge error 3.

Bit 2 **FAE2**: Force acknowledge error 2
   Writing one to this bit forces an acknowledge error 2.

Bit 1 **FAE1**: Force acknowledge error 1
   Writing one to this bit forces an acknowledge error 1.

Bit 0 **FAE0**: Force acknowledge error 0
   Writing one to this bit forces an acknowledge error 0.

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **FPBUE**: Force payload buffer underflow error
   Writing one to this bit forces a payload undrflow error.

Bits 18:13 Reserved, must be kept at reset value.

Bit 12 **FGPRXE**: Force generic payload receive error
   Writing one to this bit forces a generic payload receive error.

Bit 11 **FGPRDE**: Force generic payload read error
   Writing one to this bit forces a generic payload read error.

Bit 10 **FGPTXE**: Force generic payload transmit error
   Writing one to this bit forces a generic payload transmit error.

Bit 9 **FGPWRE**: Force generic payload write error
   Writing one to this bit forces a generic payload write error.

Bit 8 **FGCWRE**: Force generic command write error
   Writing one to this bit forces a generic command write error.

Bit 7 **FLPWRE**: Force LTDC payload write error
   Writing one to this bit forces a LTDC payload write error.
Bit 6 **FEOTPE**: Force EoTp error  
Writing one to this bit forces a EoTp error.

Bit 5 **FPSE**: Force packet size error  
Writing one to this bit forces a packet size error.

Bit 4 **FCRCE**: Force CRC error  
Writing one to this bit forces a CRC error.

Bit 3 **FECCME**: Force ECC multi-bit error  
Writing one to this bit forces a ECC multi-bit error.

Bit 2 **FECCSE**: Force ECC single-bit error  
Writing one to this bit forces a ECC single-bit error.

Bit 1 **FTOLPRX**: Force timeout low-power reception  
Writing one to this bit forces a timeout low-power reception.

Bit 0 **FTOHSTX**: Force timeout high-speed transmission  
Writing one to this bit forces a timeout high-speed transmission.

Bits 31:9  Reserved, must be kept at reset value.

Bit 8  **UR**: Update register
When set to 1, the LTDC registers are copied to the auxiliary registers. After copying, this bit is auto cleared.
0: No update requested
1: Register update requested

Bits 7:1  Reserved, must be kept at reset value.

Bit 0  **EN**: Enable
When set to 1, DSI Host LTDC interface receives the active configuration from the auxiliary registers.
When this bit is set along with the UR bit, the auxiliary registers are automatically updated.
0: Register update is disabled.
1: Register update is enabled.

1824/3637 RM0456 Rev 5
Bits 31:10  Reserved, must be kept at reset value.

Bit 9  **LPCE**: Low-power command enable
This bit returns the current command transmission state in low-power mode.
0: Command transmission in low-power mode is disabled.
1: Command transmission in low-power mode is enabled.

Bit 8  **FBTAAE**: Frame BTA acknowledge enable
This bit returns the current state of request for an acknowledge response at the end of a frame.
0: Acknowledge response at the end of a frame is disabled.
1: Acknowledge response at the end of a frame is enabled.

Bit 7  **LPHFE**: Low-power horizontal front-porch enable
This bit returns the current state of return to low-power inside the horizontal front-porch (HFP) period when timing allows.
0: Return to low-power inside the HFP period is disabled.
1: Return to low-power inside the HFP period is enabled.

Bit 6  **LPHBPE**: Low-power horizontal back-porch enable
This bit returns the current state of return to low-power inside the horizontal back-porch (HBP) period when timing allows.
0: Return to low-power inside the HBP period is disabled.
1: Return to low-power inside the HBP period is enabled.

Bit 5  **LPVAE**: Low-power vertical active enable
This bit returns the current state of return to low-power inside the vertical active (VACT) period when timing allows.
0: Return to low-power inside the VACT is disabled.
1: Return to low-power inside the VACT is enabled.

Bit 4  **LPVFPE**: Low-power vertical front-porch enable
This bit returns the current state of return to low-power inside the vertical front-porch (VFP) period when timing allows.
0: Return to low-power inside the VFP is disabled.
1: Return to low-power inside the VFP is enabled.

Bit 3  **LPVBPE**: Low-power vertical back-porch enable
This bit returns the current state of return to low-power inside the vertical back-porch (VBP) period when timing allows.
0: Return to low-power inside the VBP is disabled.
1: Return to low-power inside the VBP is enabled.

Bit 2  **LPVSAE**: Low-power vertical sync time enable
This bit returns the current state of return to low-power inside the vertical sync time (VSA) period when timing allows.
0: Return to low-power inside the VSA is disabled.
1: Return to low-power inside the VSA is enabled.

Bits 1:0  **VMT[1:0]**: Video mode type
This field returns the current video mode transmission type:
00: Non-burst with sync pulses
01: Non-burst with sync events
1x: Burst mode
44.15.53 DSI Host video packet current configuration register (DSI_VPCCR)

Bit 6 **APWFE**: Adapted command mode payload write FIFO empty
   This bit indicates the empty status of the adapted command mode write payload FIFO:
   0: Write payload FIFO not empty
   1: Write payload FIFO empty

Bit 5 **ACWFF**: Adapted command mode command write FIFO full
   This bit indicates the full status of the adapted command mode write command FIFO:
   0: Write command FIFO not full
   1: Write command FIFO full

Bit 4 **ACWFE**: Adapted command mode command write FIFO empty
   This bit indicates the empty status of the adapted command mode write command FIFO:
   0: Write command FIFO not empty
   1: Write command FIFO empty

Bit 3 **VPWFF**: Video mode payload write FIFO full
   This bit indicates the full status of the video mode write payload FIFO:
   0: Write payload FIFO not full
   1: Write payload FIFO full

Bit 2 **VPWFE**: Video mode payload write FIFO empty
   This bit indicates the empty status of the video mode write payload FIFO:
   0: Write payload FIFO not empty
   1: Write payload FIFO empty

Bit 1 **VCWFF**: Video mode command write FIFO full
   This bit indicates the full status of the video mode write command FIFO:
   0: Write command FIFO not full
   1: Write command FIFO full

Bit 0 **VCWFE**: Video mode command write FIFO empty
   This bit indicates the empty status of the video mode write command FIFO:
   0: Write command FIFO not empty
   1: Write command FIFO empty
44.16 DSI Wrapper registers

44.16.1 DSI Wrapper configuration register (DSI_WCFGR)

Address offset: 0x0400
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address</th>

</tbody>
</table>

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 VSPOL: VSync polarity
This bit selects the VSync edge on which the LTDC is halted.
0: LTDC halted on a falling edge
1: LTDC halted on a rising edge
This bit must only be changed when DSI is stopped (DSI_WCR.DSIEN = 0 and DSI_CR.EN = 0).

Bit 6 AR: Automatic refresh
This bit selects the refresh mode in DBI mode.
0: automatic refresh mode disabled
1: automatic refresh mode enabled
This bit must only be changed when DSI Host is stopped (DSI_CR.EN = 0).

Bit 5 TEPOL: TE polarity
This bit selects the polarity of the external pin tearing effect (TE) source.
0: rising edge.
1: falling edge.
This bit must only be changed when DSI Host is stopped (DSI_CR.EN = 0).

Bit 4 TESRC: TE source
This bit selects the tearing effect (TE) source.
0: DSI Link
1: External pin
This bit must only be changed when DSI Host is stopped (DSI_CR.EN = 0).

Bits 3:1 COLMUX[2:0]: Color multiplexing
This bit selects the color multiplexing used by DSI Host.
000: 16-bit configuration 1
001: 16-bit configuration 2
010: 16-bit configuration 3
011: 18-bit configuration 1
100: 18-bit configuration 2
101: 24-bit
This field must only be changed when DSI is stopped (DSI_WCR.DSIEN = 0 and DSI_CR.EN = 0).
Bit 0 **DSIM**: DSI mode
- This bit selects the mode for the video transmission.
- 0: Video mode
- 1: Adapted command mode
  
  This bit must only be changed when DSI Host is stopped (DSI_CR.EN = 0).

#### Bits 31:11 Reserved, must be kept at reset value.

- **Bit 10 PLLUIE**: PLL unlock interrupt enable  
  This bit enables the PLL unlock interrupt.  
  0: PLL unlock interrupt disabled  
  1: PLL unlock interrupt enabled

- **Bit 9 PLLLIE**: PLL lock interrupt enable  
  This bit enables the PLL lock interrupt.  
  0: PLL lock interrupt disabled  
  1: PLL lock interrupt enabled

#### Bits 8:2 Reserved, must be kept at reset value.

- **Bit 1 ERIE**: End of refresh interrupt enable  
  This bit enables the end of refresh interrupt.  
  0: End of refresh interrupt disabled  
  1: End of refresh interrupt enabled

- **Bit 0 TEIE**: Tearing effect interrupt enable  
  This bit enables the tearing effect interrupt.  
  0: Tearing effect interrupt disabled  
  1: Tearing effect interrupt enabled

#### Bits 31:11 Reserved, must be kept at reset value.

- **Bit 10 PLLUIF**: PLL unlock interrupt flag  
  This bit is set when the PLL becomes unlocked.  
  0: No PLL unlock event occurred  
  1: PLL unlock event occurred

- **Bit 9 PLLLIF**: PLL lock interrupt flag  
  This bit is set when the PLL becomes locked.  
  0: No PLL lock event occurred  
  1: PLL lock event occurred

- **Bit 8 PLLLS**: PLL lock status  
  This bit is set when the PLL is locked and cleared when it is unlocked.  
  0: PLL is unlocked.  
  1: PLL is locked.

#### Bits 7:3 Reserved, must be kept at reset value.
Bit 2 **BUSY**: Busy flag
   This bit is set when the transfer of a frame in adapted command mode is ongoing.
   0: No transfer on going
   1: Transfer on going

Bit 1 **ERIF**: End of refresh interrupt flag
   This bit is set when the transfer of a frame in adapted command mode is finished.
   0: No end of refresh event occurred
   1: End of refresh event occurred

Bit 0 **TEIF**: Tearing effect interrupt flag
   This bit is set when a tearing effect event occurs.
   0: No tearing effect event occurred
   1: Tearing effect event occurred

### 44.16.5 DSI Wrapper interrupt flag clear register (DSI_WIFCR)

Bits 31:11 Reserved, must be kept at reset value.

- Bit 10 **CPLLUIF**: Clear PLL unlock interrupt flag
  Write 1 clears the PLLUIF flag in the DSI_WSR register.

- Bit 9 **CPLLIF**: Clear PLL lock interrupt flag
  Write 1 clears the PLLLIF flag in the DSI_WSR register.

Bits 8:2 Reserved, must be kept at reset value.

- Bit 1 **CERIF**: Clear end of refresh interrupt flag
  Write 1 clears the ERIF flag in the DSI_WSR register.

- Bit 0 **CTEIF**: Clear tearing effect interrupt flag
  Write 1 clears the TEIF flag in the DSI_WSR register.
44.16.6  DSI Wrapper PHY configuration register 0 (DSI_WPCR0)

Bits 31:14  Reserved, must be kept at reset value.

Bit 13  FTXSMDL: Force in TX Stop mode the data lanes
This bit forces the data lanes in TX stop mode. It is used to initialize a lane module in transmit mode. It causes the lane module to immediately jump to transmit control mode and to begin transmitting a stop state (LP-11). It can be used to go back in TX mode after a wrong BTA sequence.
0: No effect
1: Force the data lanes in TX Stop mode

Bit 12  FTXSMCL: Force in TX Stop mode the clock lane
This bit forces the clock lane in TX stop mode. It is used to initialize a lane module in transmit mode. It causes the lane module to immediately jump to transmit control mode and to begin transmitting a stop state (LP-11). It can be used to go back in TX mode after a wrong BTA sequence.
0: No effect
1: Force the clock lane in TX Stop mode

Bits 11:9  Reserved, must be kept at reset value.

Bit 8  SWDL1: Swap data lane 1 pins
This bit swaps the pins on clock lane.
0: Regular clock lane pin configuration
1: Swapped clock lane pin

Bit 7  SWDL0: Swap data lane 0 pins
This bit swaps the pins on data lane 0.
0: Regular clock lane pin configuration
1: Swapped clock lane pin

Bit 6  SWCL: Swap clock lane pins
This bit swaps the pins on clock lane.
0: Regular clock lane pin configuration
1: Swapped clock lane pin

Bits 5:0  Reserved, must be kept at reset value.
44.16.7  DSI Wrapper regulator and PLL control register (DSI_WRPCR)

Address offset: 0x0430
Reset value: 0x0000 0000

Bit 31  Reserved, must be kept at reset value.

Bits 30:29  **BC[1:0]: Band control**
This field selects the VCO frequency band.
00: 500 to 800 MHz
01: 800 to 1000 MHz
Others: Reserved

Bits 28:20  **ODF[8:0]: PLL output division factor**
This field configures the PLL output division factor.
0: PLL output divided by 1
1: PLL output divided by 2
2: PLL output divided by 2
...
511: PLL output divided by 511

Bits 19:11  **IDF[8:0]: PLL input division factor**
This field configures the PLL input division factor.
0: PLL input divided by 1
1: PLL input divided by 2
2: PLL input divided by 2
...
511: PLL input divided by 511

Bits 10:2  **NDIV[8:0]: PLL loop division factor**
This field configures the PLL loop division factor.
0: PLL loop divided by 1x2
1: PLL loop divided by 1x2
2: PLL loop divided by 2x2
...
511: PLL loop divided by 511x2

Bit 1  Reserved, must be kept at reset value.

Bit 0  **PLLEN: PLL enable**
This bit enables the D-PHY PLL.
0: PLL disabled
1: PLL enabled
### 44.16.8 DSI Wrapper PLL tuning register (DSI_WPTR)

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:4 Reserved, must be kept at reset value.
Bits 3:0 **LPXO[3:0]**: LPX offset

- This field selects the offset added to fine tune the delay associated to the following states: INIT_STATE, STOP_STATE, LP01_STATE and LP11_STATE.
- This field is a 4-bit signed value in complement 2 format (-8 to +7 range).
- The LPX timing is composed of an unsigned fixed 7-bit value dependent of the frequency band selected for the D-PHY and the 4-bit signed value of this field.
- The LPX timing is expressed in lane byte clock period.
- The LPX fixed value is:
  - 80 to 120 MHz: 7'h01
  - 120 to 160 MHz: 7'h02
  - 160 to 320 MHz: 7'h03
  - 320 to 450 MHz: 7'h04
  - 450 to 510 MHz: 7'h05
- As the resulting LPX timing is an unsigned 7-bit value, the user must take care of underflow when the value is negative (complement 2 format).

Refer to Section 2.3 on page 139 for the register boundary addresses.
45 Neo-Chrom graphic processor (GPU2D)

This section only applies to STM32U599/5A9 and STM32U5Fx/5Gx devices.

45.1 GPU2D introduction

The GPU2D is a dedicated graphics processing unit accelerating numerous 2.5D graphics applications such as graphical user interface (GUI), menu display or animations.

The GPU2D works together with an optimized software stack designed for state of the art graphic rendering.

45.2 GPU2D main features

Main features
- Multi-threaded fragment (pixel) processing core with a VLIW (very-long instruction word) instruction set
- Fixed point functional units
- Command list based DMAs to minimize CPU overhead
- Two 32-bit AHB master interfaces for texture, command list and framebuffer access
- 32-bit AHB slave interface for register bank access
- Up to 4 general-purpose flags for system-level synchronization
- Texture decompression unit with TSC™4 and TSC™6/TSC™6a support

2D drawing features
- Pixel/line drawing
- Filled rectangles
- Triangles, quadrilateral drawing
- Anti-aliasing 8xMSAA (multi-sample anti-aliasing)

Vector graphic acceleration
- Path drawing (lines, polygons, rectangles, arcs, ellipses, circles)
- Bezier curves (cubic and quadratic)
- Path transformation (3x3 matrix)
- Path stroking
- Filling (event-odd and non-zero with 8x MSAA anti-aliasing)
- Gradient generation (linear, radial, conic)

Image transformations
- 3D perspective correct projections
- Texture mapping with bilinear filtering or point sampling
Blit support
- Rotation, mirroring, stretching (independently on x and y axis)
- Source and/or destination color keying
- Pixel format conversions

Text rendering support
- A1, A2, A4, and A8 bitmap anti-aliased
- Subsampled anti-aliased

Color formats
- ABGR8888, ARGB8888, BGRA8888, RGBA8888
- xBGR8888, xRGB8888, BGRx8888, RGBx8888, RGB8888, BGR8888
- BGR565, RGB565
- ABGR1555, BGRA5551, RGBA5551, ARGB1555
- ABGR4444, BGRA4444, RGBA4444, ARGB4444
- RGB322, BGR322
- ABGR2222, BGRA2222, RGBA2222, ARGB2222
- TSC4, TSC6, TSC6A
- LUT1, LUT2, LUT4, LUT8
- L1, L2, L4, L8 (grayscale)
- A1, A2, A4, A8

Full alpha blending with hardware blender
- Programmable blending modes
- Source/destination color keying

45.3 GPU2D implementation
The table below shows the various implementation of the GPU2D.

46  JPEG codec (JPEG)

This section only applies to STM32U5Fx/5Gx.

46.1  Introduction

The hardware 8-bit JPEG codec encodes uncompressed image data stream or decodes JPEG-compressed image data stream. It also fully manages JPEG headers.

46.2  JPEG codec main features

- High-speed fully-synchronous operation
- Configurable as encoder or decoder
- Single-clock-per-pixel encode/decode
- RGB, YCbCr, YCMK and BW (grayscale) image color space support
- 8-bit depth per image component at encode/decode
- JPEG header generator/parser with enable/disable
- Four programmable quantization tables
- Single-clock Huffman coding and decoding
- Fully-programmable Huffman tables (two AC and two DC)
- Fully-programmable minimum coded unit (MCU)
- Concurrent input and output data stream interfaces
46.3 JPEG codec block functional description

46.3.1 General description

The block diagram of the JPEG codec is shown in Figure 444.

Figure 444. JPEG codec block diagram

46.3.2 JPEG internal signals

Table 448 lists the JPEG internal signals.

46.3.3 JPEG decoding procedure

The JPEG codec can decode a JPEG stream as defined in the ISO/IEC 10918-1 specification.

It can optionally parse the JPEG header and update accordingly the JPEG codec registers, the quantization tables and the Huffman tables.

The JPEG codec is configured in decode mode setting the DE bit (decode enable) of the JPEG_CONFR1 register.

The JPEG decode starts by setting the START bit of the JPEG_CONFR0 register.

The JPEG codec requests data for its input FIFO through generating one of:
- DMA request
- DMA trigger
- interrupts

**DMA generation for input FIFO**

DMA request is generated when the 32-byte input FIFO becomes at least half-empty, that is, when there is free room for writing 16 bytes of data.

The DMA request generation is independent of the START bit of the JPEG_CONFR0 register. If the input FIFO can accept 16 bytes and the DMA for the input FIFO is enabled (setting the IDMAEN bit of the JPEG_CR register), a DMA request is generated regardless of the state of the JPEG codec kernel.

A burst transfer is launched by the DMA to write 16 bytes of data.

Writes are ignored if the input FIFO is full.

At the end of the decoding process, extra bytes may remain in the input FIFO and/or a DMA request may be pending. The FIFO can be flushed by setting the IFF bit (input FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO, the DMA for the input FIFO must be disabled to prevent unwanted DMA request upon flushing the FIFO.
The consequence of not flushing the FIFO at the end of the decoding process is that any remaining data is taken into the next JPEG decoding.

DMA requests are no more generated once the EOCF flag of the JPEG_SR register is set.

**Interrupt or DMA trigger generation for input FIFO**

Input FIFO can be managed using interrupts or DMA triggers through two flags according to the FIFO state:
- Input FIFO not full flag: a 32-bit value can be written in.
- Input FIFO threshold flag: 8 words (32 bytes) can be written in.

The interrupt or DMA trigger generation is independent of the START bit of the JPEG_CONFR0 register. The input FIFO flags are generated regardless of the state of the JPEG codec kernel.

Writes are ignored if the input FIFO is full.

At the end of the decoding process, extra bytes may remain in the input FIFO and/or an interrupt request / DMA trigger may be pending. The FIFO can be flushed by setting the IFF (Input FIFO Flush) bit of the JPEG_CR register.

Prior to flushing the FIFO:
- The interrupts for the input FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The DMA channel must be stopped to prevent unwanted DMA trigger.

The consequence of not flushing the FIFO at the end of the decoding process is that any remaining data is taken into the next JPEG decoding.

**Header parsing**

The header parsing can be activated setting the HDR bit of the JPEG_CONFR1 register.

The JPEG header parser supports all markers relevant to the JPEG baseline algorithm indicated in Annex B of the ISO/IEC 10918-1.

When parsing a supported marker, the JPEG header parser extracts the required parameters and stores them in shadow registers. At the end of the parsing the JPEG codec registers are updated.

If a DQT marker segment is located, quantization data associated with it is written into the quantization table memory.

If a DHT marker segment is located, the Huffman table data associated with it is converted into three different table formats (HuffMin, HuffBase and HuffSymb) and stored in their respective memories.

Once the parsing operation is completed, the HPDF (header parsing done flag) bit of the JPEG_SR register is set. An interrupt is generated if the EHPIE (end of header parsing interrupt enable) bit of the JPEG_CR register is set.

**JPEG decoding**

Once the JPEG header is parsed or JPEG codec registers and memories are properly programmed, the incoming data stream is decoded and the resulting MCUs are sent to the output FIFO.
When decoding two images successively, the START bit of the JPEG_CONFR0 register must be set again (even if already 1) after the header processing of the second image is completed.

**DMA generation for output FIFO**

DMA request is generated when the 32-byte output FIFO becomes at least half-full, that is, when there are at least 16 bytes of data.

A burst transfer is launched by the DMA to read 16 bytes of data.

Reads return 0 if the output FIFO is empty.

Once the decoding process is done, no extra bytes must remain in the output FIFO and no DMA request must be pending as the JPEG decoding generates blocks of 64 bytes.

In case of abort of the JPEG codec operations by resetting the START bit of the JPEG_CONFR0 register, the output FIFO can be flushed by setting the OFF bit (input FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO, the DMA for the output FIFO must be disabled to prevent unwanted DMA request upon flushing the FIFO.

**Interrupt or DMA trigger generation for output FIFO**

The output FIFO can be managed using interrupts or DMA triggers through two flags according to the FIFO state:

- Output FIFO not empty flag: a 32-bit value can be read out.
- Output FIFO Threshold flag: 8 words (32 bytes) can be read out.

Reads return 0 if the output FIFO is empty.

In case of abort of the JPEG codec operations by resetting the START bit of the JPEG_CONFR0 register, the output FIFO can be flushed. If the FIFO needs to be flushed, it must be done by software setting the FF bit (FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO:

- The interrupts for the output FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The DMA channel must be stopped to prevent unwanted DMA trigger.

The output FIFO must be flushed at the end of processing before any JPEG configuration change.

### 46.3.4 JPEG encoding procedure

The JPEG codec can encode a JPEG stream as defined in the *ISO/IEC 10918-1* specification.

It can optionally generate the JPEG Header.

The JPEG codec is configured in encode mode resetting the DE bit (decode enable) of the JPEG_CONFR1 register.

The configuration used for encoding the JPEG must be loaded in the JPEG codec:

- JPEG codec configuration registers
- quantization tables
- Huffman tables
The JPEG codec is started setting the START bit of the JPEG_CONFR0 register.

Once the JPEG codec has been started, it request data for its input FIFO generating one of:
- DMA request
- DMA trigger
- interrupts

**DMA generation for input FIFO**

DMA request is generated when the 32-byte input FIFO becomes at least half-empty, that is, when there is free room for writing 16 bytes of data.

The DMA request generation is independent of the START bit of the JPEG_CONFR0 register. If the input FIFO can accept 16 bytes and the DMA for the input FIFO is enabled (setting the IDMAEN bit of the JPEG_CR register), a DMA request is generated regardless of the state of the JPEG codec kernel.

A burst transfer is launched by the DMA to write 16 bytes of data.

Writes are ignored if the input FIFO is full.

At the end of the encoding process, extra bytes may remain in the input FIFO and/or a DMA request may be pending. The FIFO can be flushed by setting the IFF bit (input FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO, the DMA for the input FIFO must be disabled to prevent unwanted DMA request upon flushing the FIFO.

The consequence of not flushing the FIFO at the end of the encoding process is that any remaining data is taken into the next JPEG encoding.

The DMA requests are no more generated once the EOCF flag of the JPEG_SR register is set.

**Interrupt or DMA trigger generation for input FIFO**

Input FIFO can be managed using interrupts or DMA triggers through two flags according to the FIFO state:
- Input FIFO not full flag: a 32-bit value can be written in.
- Input FIFO threshold flag: 8 words (32 bytes) can be written in.

The interrupt or DMA trigger generation is independent of the START bit of the JPEG_CONFR0 register. The input FIFO flags are generated regardless of the state of the JPEG codec kernel.

Writes are ignored if the input FIFO is full.

At the end of the encoding process, extra bytes may remain in the input FIFO and/or an interrupt request / DMA trigger may be pending. The FIFO can be flushed by setting the IFF bit (input FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO:
- The interrupts for the input FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The DMA channel must be stopped to prevent unwanted DMA trigger.

The consequence of not flushing the FIFO at the end of the encoding process is that any remaining data is taken into the next JPEG encoding.
JPEG encoding

Once the JPEG header generated, the incoming MCUs are encoded and the resulting data stream sent to the output FIFO.

DMA generation for output FIFO

DMA request is generated when the 32-byte output FIFO becomes at least half-full, that is, when there are at least 16 bytes of data.
A burst transfer is launched by the DMA to read 16 bytes of data.
Read returns 0 if the output FIFO is empty.
At the end of the encoding process, the last bytes may remain in the output FIFO as the stream padding may not be on 16 bytes.
These additional bytes must be managed by the CPU using the output FIFO not empty flag.

In case of abort of the JPEG codec operations by resetting the START bit of the JPEG_CONFR0 register, the output FIFO can be flushed. The FIFO can be flushed by setting the OFF bit (output FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO, the DMA for the input FIFO must be disabled to prevent unwanted DMA request upon flushing the FIFO.

Interrupt or DMA trigger generation for output FIFO

Output FIFO can be managed using interrupts or DMA triggers through two flags according to the FIFO state:
• Output FIFO not empty flag: a 32-bit value can be read out.
• Output FIFO threshold flag: 8 words (32 bytes) can be read out.
Reads return 0 if the output FIFO is empty.

In case of abort of the JPEG codec operations by resetting the START bit of the JPEG_CONFR0 register, the output FIFO can be flushed. The FIFO can be flushed by setting the FF bit (FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO:
• The interrupts for the output FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
• The DMA channel must be stopped to prevent unwanted DMA trigger.
The output FIFO must be flushed at the end of processing before any JPEG configuration change.
The EOCF bit (end of conversion flag) of the JPEG_SR register can only be cleared when the output FIFO is empty.

Clearing either of the HDR bit (header processing) of the JPEG_CONFR1 register and the JCEN bit (JPEG codec enable) of the JPEG_CR register is allowed only when the EOCF bit of the JPEG_SR register is cleared.
46.4 JPEG codec interrupts

An interrupt can be produced on the following events:

- input FIFO threshold reached
- input FIFO not full
- output FIFO threshold reached
- output FIFO not empty
- end of conversion
- header parsing done

Separate interrupt enable bits are available for flexibility.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **HSF[3:0]:** Horizontal sampling factor
Horizontal sampling factor for component {x-4}.

Bits 11:8 **VSF[3:0]:** Vertical sampling factor
Vertical sampling factor for component {x-4}.

Bits 7:4 **NB[3:0]:** Number of blocks
Number of data units minus 1 that belong to a particular color in the MCU.

Bits 3:2 **QT[1:0]:** Quantization table
Selects quantization table used for component {x-4}.
- 00: Quantization table 0
- 01: Quantization table 1
- 10: Quantization table 2
- 11: Quantization table 3

Bit 1 **HA:** Huffman AC
Selects the Huffman table for encoding AC coefficients.
- 0: Huffman AC table 0
- 1: Huffman AC table 1

Bit 0 **HD:** Huffman DC
Selects the Huffman table for encoding DC coefficients.
- 0: Huffman DC table 0
- 1: Huffman DC table 1

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **OFF**: Output FIFO flush
This bit flushes the output FIFO.
0: No effect
1: Output FIFO is flushed
*Note: Reads always return 0.*

Bit 13 **IFF**: Input FIFO flush
This bit flushes the input FIFO.
0: No effect
1: Input FIFO is flushed
*Note: Reads always return 0.*

Bit 12 **ODMAEN**: Output DMA enable
Enables DMA request generation for the output FIFO.
0: Disabled
1: Enabled

Bit 11 **IDMAEN**: Input DMA enable
Enables DMA request generation for the input FIFO.
0: Disabled
1: Enabled

Bits 10:7 Reserved, must be kept at reset value.

Bit 6 **HPDIE**: Header parsing done interrupt enable
This bit enables interrupt generation upon the completion of the header parsing operation.
0: Disabled
1: Enabled

Bit 5 **EOCIE**: End of conversion interrupt enable
This bit enables interrupt generation at the end of conversion.
0: Disabled
1: Enabled

Bit 4 **OFNEIE**: Output FIFO not empty interrupt enable
This bit enables interrupt generation when the output FIFO is not empty.
0: Disabled
1: Enabled
Bit 3 **OFTIE**: Output FIFO threshold interrupt enable
This bit enables interrupt generation when the output FIFO reaches a threshold.
0: Disabled
1: Enabled

Bit 2 **IFNFIIE**: Input FIFO not full interrupt enable
This bit enables interrupt generation when the input FIFO is not empty.
0: Disabled
1: Enabled

Bit 1 **IFTIE**: Input FIFO threshold interrupt enable
This bit enables interrupt generation when the input FIFO reaches a threshold.
0: Disabled
1: Enabled

Bit 0 **JCEN**: JPEG core enable
This bit enables the JPEG codec core.
0: Disabled (internal registers are reset).
1: Enabled (internal registers are accessible).

### 46.5.7 JPEG status register (JPEG_SR)

Address offset: 0x034
Reset value: 0x0000 0006

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **COF**: Codec operation flag
This bit flags code/decode operation in progress.
0: Not in progress
1: In progress

Bit 6 **HPDF**: Header parsing done flag
In decode mode, this bit flags the completion of header parsing and updating internal registers.
0: Not completed
1: Completed

Bit 5 **EOCF**: End of conversion flag
This bit flags the completion of encode/decode process and data transfer to the output FIFO.
0: Not completed
1: Completed
Bit 4 **OFNEF**: Output FIFO not empty flag
This bit flags that data is available in the output FIFO. This flag must not be considered when using DMA.
0: Empty (data not available)
1: Not empty (data available)

Bit 3 **OFTF**: Output FIFO threshold flag
This bit flags that the amount of data in the output FIFO reaches or exceeds a threshold. This flag must not be considered when using DMA.
0: Below threshold
1: At or above threshold

Bit 2 **IFNFF**: Input FIFO not full flag
This bit flags that the input FIFO is not full (data can be written). This flag must not be considered when using DMA.
0: Full
1: Not full

Bit 1 **IFTF**: Input FIFO threshold flag
This bit flags that the amount of data in the input FIFO is below a threshold. This flag must not be considered when using DMA.
0: At or above threshold
1: Below threshold.

Bit 0 Reserved, must be kept at reset value.

15  14  13  12  11  10  9   8   7   6   5   4   3   2   1   0

Bits 31:0 DATAOUT[31:0]: Data output FIFO  
Output FIFO data register.
46.5.11 JPEG quantization memory x (JPEG_QMEMx_y)
Address offset: 0x0050 + 0x40 * x + 0x4 * y, (x = 0 to 3; y = 0 to 15)
Reset value: 0xXXXX XXXX
Four quantization tables as specified by ISO documentation.
For decoding with header parsing, no quantization table programming is required, the coefficients are directly written in the quantization memories by header parser.
For decoding without header parsing or for encoding, the quantization table must be written by software in zig zag order.

| Address offset: 0x050 + 0x40 * x + 0x4 * y, (x = 0 to 3; y = 0 to 15) |
| Reset value: 0xXXXX XXXX |

46.5.12 JPEG Huffman min (JPEG_HUFFMINx_y)
Address offset: 0x1050 + 0x10 * x + 0x4 * y, (x = 0 to 3; y = 0 to 2)
Reset value: 0xXXXX XXXX
This memory stores the minimum Huffman values used internally by the JPEG decoder. The memory content is written by hardware during the header parsing.
- DATA0: Min AC0 value
- DATA1: Min DC0 value
- DATA2: Min AC1 value
- DATA3: Min DC1 value

| Address offset: 0x1050 + 0x10 * x + 0x4 * y, (x = 0 to 3; y = 0 to 2) |
| Reset value: 0xXXXX XXXX |
46.5.13 JPEG Huffman min x (JPEG_HUFFMINx_y)

Address offset: 0x150 + 0x10 * x + 0x4 * y, (x = 0 to 3; y = 3)
Reset value: 0xXXXX XXXX

This memory stores the minimum Huffman values used internally by the JPEG decoder. The memory content is written by hardware during the header parsing.

- DATA0: Min AC0 value
- DATA1: Min DC0 value
- DATA2: Min AC1 value
- DATA3: Min DC1 value

46.5.14 JPEG Huffman base (JPEG_HUFFBASEx)

Address offset: 0x190 + 0x4*x, (x = 0 to 31)
Reset value: 0xXXXX XXXX

This memory stores the base Huffman values used internally by the JPEG decoder. The memory content is written by hardware during the header parsing:

- DATA0 to DATA15: Base AC0 value
- DATA16 to DATA31: Base DC0 value
- DATA32 to DATA47: Base AC1 value
- DATA48 to DATA63: Base DC1 value
Bits 31:25  Reserved, must be kept at reset value.

Bits 24:16  \( \text{DATA}(2^x+1)[8:0] \): Data \( 2^x+1 \)
Base Huffman value.

Bits 15:9  Reserved, must be kept at reset value.

Bits 8:0  \( \text{DATA}(2^x)[8:0] \): Data \( 2^x \)
Base Huffman value.

**46.5.15  JPEG Huffman symbol (JPEG_HUFFSYMBx)**

Address offset: \( 0x210 + 0x4 \times x \), \( x = 0 \) to 83

Reset value: \( 0xXXXX \) XXXX

This memory stores the Huffman symbols used internally by the JPEG decoder. The memory content is written by hardware during the header parsing:

- DATA0 to DATA161: AC0 symbols
- DATA162 to DATA173: DC0 and DC1 symbols
- DATA174 to DATA335: AC1 symbols

Bits 31:24  \( \text{DATA}(4^x+3)[7:0] \): Data \( 4^x+3 \)
Huffman symbol.

Bits 23:16  \( \text{DATA}(4^x+2)[7:0] \): Data \( 4^x+2 \)
Huffman symbol.

Bits 15:8  \( \text{DATA}(4^x+1)[7:0] \): Data \( 4^x+1 \)
Huffman symbol.

Bits 7:0  \( \text{DATA}(4^x)[7:0] \): Data \( 4^x \)
Huffman symbol.
46.5.16 JPEG DHT memory (JPEG_DHTMEMx)

Address offset: 0x360 + 0x4 * x, (x = 0 to 102)

Reset value: 0xXXXX XXXX

For encoding process with header generation, this memory stores the DHT marker segment AC and DC Huffman tables in the ISO/IEC specification format:

- DATA0 to DATA27: DC Huffman table0
- DATA28 to DATA205: AC Huffman table0
- DATA206 to DATA233: DC Huffman table1
- DATA234 to DATA411: AC Huffman table1

46.5.17 JPEG Huffman encoder ACx (JPEG_HUFFENC_ACx_y)

Address offset: 0x500 + 0x160 * x + 0x4 * y, (x = 0 to 1; y = 0 to 87)

Reset value: 0xXXXX XXXX

This memory defines the Huffman codes used during the encoding process of AC components.

| Bits 31:28 | Reserved, must be kept at reset value. |
Bits 27:24 \textbf{HLEN(2*y+1)[3:0]}: Huffman length \((2^y+1)\)
Number of bits in the Huffman code \textbf{HCODE(2*y+1)} minus 1.

Bits 23:16 \textbf{HCODE(2*y+1)[7:0]}: Huffman code \((2^y+1)\)
8 least significant bits of the Huffman code.
If the Huffman code is less than 8 bits long, the unused bits must be 0.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 \textbf{HLEN(2*y)[3:0]}: Huffman length \((2^y)\)
Number of bits in the Huffman code \textbf{HCODE(2*y)} minus 1.

Bits 7:0 \textbf{HCODE(2*y)[7:0]}: Huffman code \((2^y)\)
8 least significant bits of the Huffman code.
If the Huffman code is less than 8 bits long, the unused bits must be 0.

46.5.18 JPEG Huffman encoder DCx (JPEG_HUFFENC_DCx_y)

Address offset: \(0x7C0 + 0x20*x + 0x4*y\), \((x = 0 \text{ to } 1; y = 0 \text{ to } 7)\)
Reset value: \(0xXXXX XXXX\)
This memory defines the Huffman codes used during the encoding process of DC components.

47 Touch sensing controller (TSC)

47.1 Introduction

The touch sensing controller provides a simple solution for adding capacitive sensing functionality to any application. Capacitive sensing technology is able to detect finger presence near an electrode that is protected from direct touch by a dielectric (for example glass, plastic). The capacitive variation introduced by the finger (or any conductive object) is measured using a proven implementation based on a surface charge transfer acquisition principle.

The touch sensing controller is fully supported by the STMTouch touch sensing firmware library, which is free to use and allows touch sensing functionality to be implemented reliably in the end application.

47.2 TSC main features

The touch sensing controller has the following main features:

- Proven and robust surface charge transfer acquisition principle
- Supports up to 24 capacitive sensing channels
- Up to 8 capacitive sensing channels can be acquired in parallel offering a very good response time
- Spread spectrum feature to improve system robustness in noisy environments
- Full hardware management of the charge transfer acquisition sequence
- Programmable charge transfer frequency
- Programmable sampling capacitor I/O pin
- Programmable channel I/O pin
- Programmable max count value to avoid long acquisition when a channel is faulty
- Dedicated end of acquisition and max count error flags with interrupt capability
- One sampling capacitor for up to 3 capacitive sensing channels to reduce the system components
- Compatible with proximity, touchkey, linear and rotary touch sensor implementation
- Designed to operate with STMTouch touch sensing firmware library

Note: The number of capacitive sensing channels is dependent on the size of the packages and subject to IO availability.
47.3 TSC functional description

47.3.1 TSC block diagram

The block diagram of the touch sensing controller is shown in Figure 445.

Figure 445. TSC block diagram

47.3.2 Surface charge transfer acquisition overview

The surface charge transfer acquisition is a proven, robust and efficient way to measure a capacitance. It uses a minimum number of external components to operate with a single ended electrode type. This acquisition is designed around an analog I/O group composed of up to four GPIOs (see Figure 446). Several analog I/O groups are available to allow the acquisition of several capacitive sensing channels simultaneously and to support a larger number of capacitive sensing channels. Within a same analog I/O group, the acquisition of the capacitive sensing channels is sequential.

One of the GPIOs is dedicated to the sampling capacitor \( C_S \). Only one sampling capacitor I/O per analog I/O group must be enabled at a time.

The remaining GPIOs are dedicated to the electrodes and are commonly called channels. For some specific needs (such as proximity detection), it is possible to simultaneously enable more than one channel per analog I/O group.
The surface charge transfer acquisition principle consists of charging an electrode capacitance (C\textsubscript{X}) and transferring a part of the accumulated charge into a sampling capacitor (C\textsubscript{S}). This sequence is repeated until the voltage across C\textsubscript{S} reaches a given threshold (V\textsubscript{IH} in our case). The number of charge transfers required to reach the threshold is a direct representation of the size of the electrode capacitance.

Table 452 details the charge transfer acquisition sequence of the capacitive sensing channel 1. States 3 to 7 are repeated until the voltage across C\textsubscript{S} reaches the given threshold. The same sequence applies to the acquisition of the other channels. The electrode serial resistor R\textsubscript{S} improves the ESD immunity of the solution.

Note: Gx_IOy where x is the analog I/O group number and y the GPIO number within the selected group.

The voltage variation over the time on the sampling capacitor CS is detailed below (refer to Figure 446 for VSENSOR and VCS definition):

**Figure 447. Sampling capacitor voltage variation**
47.3.3 Reset and clocks

The TSC clock source is the AHB clock (HCLK). Two programmable prescalers are used to generate the pulse generator and the spread spectrum internal clocks:

- The pulse generator clock (PGCLK) is defined using the PGPSC[2:0] bits of the TSC_CR register
- The spread spectrum clock (SSCLK) is defined using the SSPSC bit of the TSC_CR register

The Reset and Clock Controller (RCC) provides dedicated bits to enable the touch sensing controller clock and to reset this peripheral. For more information, refer to Section 11: Reset and clock control (RCC).

47.3.4 Charge transfer acquisition sequence

An example of a charge transfer acquisition sequence is detailed in Figure 448.

For higher flexibility, the charge transfer frequency is fully configurable. Both the pulse high state (charge of $C_X$) and the pulse low state (transfer of charge from $C_X$ to $C_S$) duration can be defined using the CTPH[3:0] and CTPL[3:0] bits in the TSC_CR register. The standard range for the pulse high and low states duration is 500 ns to 2 µs. To ensure a correct measurement of the electrode capacitance, the pulse high state duration must be set to ensure that $C_X$ is always fully charged.

A dead time where both the sampling capacitor I/O and the channel I/O are in input floating state is inserted between the pulse high and low states to ensure an optimum charge transfer acquisition sequence. This state duration is 2 periods of HCLK.

At the end of the pulse high state and if the spread spectrum feature is enabled, a variable number of periods of the SSCLK clock are added.
The reading of the sampling capacitor I/O, to determine if the voltage across \( C_S \) has reached the given threshold, is performed at the end of the pulse low state.

**Note:** The following TSC control register configurations are forbidden:
- bits PGPSC are set to ‘000’ and bits CTPL are set to ‘0000’
- bits PGPSC are set to ‘000’ and bits CTPL are set to ‘0001’
- bits PGPSC are set to ‘001’ and bits CTPL are set to ‘0000’
47.3.5 Spread spectrum feature

The spread spectrum feature generates a variation of the charge transfer frequency. This is done to improve the robustness of the charge transfer acquisition in noisy environments and also to reduce the induced emission. The maximum frequency variation is in the range of 10% to 50% of the nominal charge transfer period. For instance, for a nominal charge transfer frequency of 250 kHz (4 µs), the typical spread spectrum deviation is 10% (400 ns) which leads to a minimum charge transfer frequency of ~227 kHz.

In practice, the spread spectrum consists of adding a variable number of SSCLK periods to the pulse high state using the principle shown below:

![Figure 449. Spread spectrum variation principle](MS30933V1)

The table below details the maximum frequency deviation with different HCLK settings:

<table>
<thead>
<tr>
<th>f_HCLK</th>
<th>Spread spectrum step</th>
<th>Maximum spread spectrum deviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>80 MHz</td>
<td>12.5 ns</td>
<td>3205.1 ns</td>
</tr>
<tr>
<td>160 MHz</td>
<td>6.25 ns</td>
<td>1602.6 ns</td>
</tr>
</tbody>
</table>

The spread spectrum feature can be disabled/enabled using the SSE bit in the TSC_CR register. The frequency deviation is also configurable to accommodate the device HCLK clock frequency and the selected charge transfer frequency through the SSPSC and SSD[6:0] bits in the TSC_CR register.

47.3.6 Max count error

The max count error prevents long acquisition times resulting from a faulty capacitive sensing channel. It consists of specifying a maximum count value for the analog I/O group counters. This maximum count value is specified using the MCV[2:0] bits in the TSC_CR register. As soon as an acquisition group counter reaches this maximum value, the ongoing acquisition is stopped and the end of acquisition (EOAF bit) and max count error (MCEF bit) flags are both set. An interrupt can also be generated if the corresponding end of acquisition (EOAIE bit) or/and max count error (MCEIE bit) interrupt enable bits are set.
# 47.3.7 Sampling capacitor I/O and channel I/O mode selection

To allow the GPIOs to be controlled by the touch sensing controller, the corresponding alternate function must be enabled through the standard GPIO registers and the GPIOxAFR registers.

The GPIOs modes controlled by the TSC are defined using the TSC_IOSCR and TSC_IOCCR register.

When there is no ongoing acquisition, all the I/Os controlled by the touch sensing controller are in default state. While an acquisition is ongoing, only unused I/Os (neither defined as sampling capacitor I/O nor as channel I/O) are in default state. The IODEF bit in the TSC_CR register defines the configuration of the I/Os which are in default state. The table below summarizes the configuration of the I/O depending on its mode.

<table>
<thead>
<tr>
<th>IODEF bit</th>

<td>-</td>
</tr>
</tbody>
</table>

Unused I/O mode

An unused I/O corresponds to a GPIO controlled by the TSC peripheral but not defined as an electrode I/O nor as a sampling capacitor I/O.

Sampling capacitor I/O mode

To allow the control of the sampling capacitor I/O by the TSC peripheral, the corresponding GPIO must be first set to alternate output open drain mode and then the corresponding Gx_IOy bit in the TSC_IOSCR register must be set.

Only one sampling capacitor per analog I/O group must be enabled at a time.

Channel I/O mode

To allow the control of the channel I/O by the TSC peripheral, the corresponding GPIO must be first set to alternate output push-pull mode and the corresponding Gx_IOy bit in the TSC_IOCCR register must be set.

For proximity detection where a higher equivalent electrode surface is required or to speed-up the acquisition process, it is possible to enable and simultaneously acquire several channels belonging to the same analog I/O group.

Note: During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC_IOSCR or TSC_IOCCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.
47.3.8 Acquisition mode

The touch sensing controller offers two acquisition modes:

- Normal acquisition mode: the acquisition starts as soon as the START bit in the TSC_CR register is set.
- Synchronized acquisition mode: the acquisition is enabled by setting the START bit in the TSC_CR register but only starts upon the detection of a falling edge or a rising edge and high level on the SYNC input pin. This mode is useful for synchronizing the capacitive sensing channels acquisition with an external signal without additional CPU load.

The GxE bits in the TSC_IOGCSR registers specify which analog I/O groups are enabled (corresponding counter is counting). The CS voltage of a disabled analog I/O group is not monitored and this group does not participate in the triggering of the end of acquisition flag. However, if the disabled analog I/O group contains some channels, they are pulsed.

When the CS voltage of an enabled analog I/O group reaches the given threshold, the corresponding GxS bit of the TSC_IOGCSR register is set. When the acquisition of all enabled analog I/O groups is complete (all GxS bits of all enabled analog I/O groups are set), the EOAF flag in the TSC_ISR register is set. An interrupt request is generated if the EOAIE bit in the TSC_IER register is set.

In the case that a max count error is detected, the ongoing acquisition is stopped and both the EOAF and MCEF flags in the TSC_ISR register are set. Interrupt requests can be generated for both events if the corresponding bits (EOAIE and MCEIE bits of the TSCIER register) are set. Note that when the max count error is detected the remaining GxS bits in the enabled analog I/O groups are not set.

To clear the interrupt flags, the corresponding EOAIC and MCEIC bits in the TSC_ICR register must be set.

The analog I/O group counters are cleared when a new acquisition is started. They are updated with the number of charge transfer cycles generated on the corresponding channel(s) upon the completion of the acquisition.

47.3.9 I/O hysteresis and analog switch control

In order to offer a higher flexibility, the touch sensing controller is able to take the control of the Schmitt trigger hysteresis and analog switch of each Gx_IOy. This control is available whatever the I/O control mode is (controlled by standard GPIO registers or other peripherals) assuming that the touch sensing controller is enabled. This may be useful to perform a different acquisition sequence or for other purposes.

In order to improve the system immunity, the Schmitt trigger hysteresis of the GPIOs controlled by the TSC must be disabled by resetting the corresponding Gx_IOy bit in the TSC_IOHCR register.

Bits 31:28 **CTPH[3:0]**: Charge transfer pulse high
These bits are set and cleared by software. They define the duration of the high state of the charge transfer pulse (charge of $C_X$).
0000: 1x $t_{PCLK}$
0001: 2x $t_{PCLK}$
... 1111: 16x $t_{PCLK}$
*Note: These bits must not be modified when an acquisition is ongoing.*

Bits 27:24 **CTPL[3:0]**: Charge transfer pulse low
These bits are set and cleared by software. They define the duration of the low state of the charge transfer pulse (transfer of charge from $C_X$ to $C_S$).
0000: 1x $t_{PCLK}$
0001: 2x $t_{PCLK}$
... 1111: 16x $t_{PCLK}$
*Note: These bits must not be modified when an acquisition is ongoing.*
*Note: Some configurations are forbidden. Refer to the Section 47.3.4: Charge transfer acquisition sequence for details.*

Bits 23:17 **SSD[6:0]**: Spread spectrum deviation
These bits are set and cleared by software. They define the spread spectrum deviation which consists in adding a variable number of periods of the SSCLK clock to the charge transfer pulse high state.
0000000: 1x $t_{SSCLK}$
0000001: 2x $t_{SSCLK}$
... 1111111: 128x $t_{SSCLK}$
*Note: These bits must not be modified when an acquisition is ongoing.*

Bit 16 **SSE**: Spread spectrum enable
This bit is set and cleared by software to enable/disable the spread spectrum feature.
0: Spread spectrum disabled
1: Spread spectrum enabled
*Note: This bit must not be modified when an acquisition is ongoing.*

Bit 15 **SSPSC**: Spread spectrum prescaler
This bit is set and cleared by software. It selects the AHB clock divider used to generate the spread spectrum clock (SSCLK).
0: $f_{HCLK}$
1: $f_{HCLK}/2$
*Note: This bit must not be modified when an acquisition is ongoing.*
Bits 14:12 **PGPSC[2:0]:** Pulse generator prescaler
These bits are set and cleared by software. They select the AHB clock divider used to generate the pulse generator clock (PGCLK).
000: \( f_{HCLK} \)
001: \( f_{HCLK} /2 \)
010: \( f_{HCLK} /4 \)
011: \( f_{HCLK} /8 \)
100: \( f_{HCLK} /16 \)
101: \( f_{HCLK} /32 \)
110: \( f_{HCLK} /64 \)
111: \( f_{HCLK} /128 \)

*Note:* These bits must not be modified when an acquisition is ongoing.

*Note:* Some configurations are forbidden. Refer to the Section 47.3.4: Charge transfer acquisition sequence for details.

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:5 **MCV[2:0]:** Max count value
These bits are set and cleared by software. They define the maximum number of charge transfer pulses that can be generated before a max count error is generated.
000: 255
001: 511
010: 1023
011: 2047
100: 4095
101: 8191
110: 16383
111: reserved

*Note:* These bits must not be modified when an acquisition is ongoing.

Bit 4 **IODEF:** I/O Default mode
This bit is set and cleared by software. It defines the configuration of all the TSC I/Os when there is no ongoing acquisition. When there is an ongoing acquisition, it defines the configuration of all unused I/Os (not defined as sampling capacitor I/O or as channel I/O).
0: I/Os are forced to output push-pull low
1: I/Os are in input floating

*Note:* This bit must not be modified when an acquisition is ongoing.

Bit 3 **SYNCPOL:** Synchronization pin polarity
This bit is set and cleared by software to select the polarity of the synchronization input pin.
0: Falling edge only
1: Rising edge and high level
Bit 2 **AM**: Acquisition mode
This bit is set and cleared by software to select the acquisition mode.
0: Normal acquisition mode (acquisition starts as soon as START bit is set)
1: Synchronized acquisition mode (acquisition starts if START bit is set and when the
selected signal is detected on the SYNC input pin)

*Note: This bit must not be modified when an acquisition is ongoing.*

Bit 1 **START**: Start a new acquisition
This bit is set by software to start a new acquisition. It is cleared by hardware as soon as the
acquisition is complete or by software to cancel the ongoing acquisition.
0: Acquisition not started
1: Start a new acquisition

Bit 0 **TSCE**: Touch sensing controller enable
This bit is set and cleared by software to enable/disable the touch sensing controller.
0: Touch sensing controller disabled
1: Touch sensing controller enabled

*Note: When the touch sensing controller is disabled, TSC registers settings have no effect.*

- **Bit 1 MCEF**: Max count error flag  
  This bit is set by hardware as soon as an analog I/O group counter reaches the max count value specified. It is cleared by software writing 1 to the bit MCEIC of the TSC_ICR register.  
  0: No max count error (MCE) detected  
  1: Max count error (MCE) detected

- **Bit 0 EOAF**: End of acquisition flag  
  This bit is set by hardware when the acquisition of all enabled group is complete (all GxS bits of all enabled analog I/O groups are set or when a max count error is detected). It is cleared by software writing 1 to the bit EOAIC of the TSC_ICR register.  
  0: Acquisition is ongoing or not started  
  1: Acquisition is complete
47.6.5 TSC I/O hysteresis control register (TSC_IOHCR)

Address offset: 0x10
Reset value: 0xFFFF FFFF

Bits 31:0 **Gx_IOy**: Gx_IOy Schmitt trigger hysteresis mode

These bits are set and cleared by software to enable/disable the Gx_IOy Schmitt trigger hysteresis.

- **0**: Gx_IOy Schmitt trigger hysteresis disabled
- **1**: Gx_IOy Schmitt trigger hysteresis enabled

**Note**: These bits control the I/O Schmitt trigger hysteresis whatever the I/O control mode is (even if controlled by standard GPIO registers).

</tbody>
</table>

Bits 31:0  **Gx_IOy**: Gx_IOy sampling mode

These bits are set and cleared by software to configure the Gx_IOy as a sampling capacitor I/O. Only one I/O per analog I/O group must be defined as sampling capacitor.

- 0: Gx_IOy unused
- 1: Gx_IOy used as sampling capacitor

*Note*: These bits must not be modified when an acquisition is ongoing.

During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC_IOSCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.

47.6.8  TSC I/O channel control register (TSC_IOCCR)

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **GxS**: Analog I/O group x status

These bits are set by hardware when the acquisition on the corresponding enabled analog I/O group x is complete. They are cleared by hardware when a new acquisition is started.

0: Acquisition on analog I/O group x is ongoing or not started
1: Acquisition on analog I/O group x is complete

*Note*: When a max count error is detected the remaining GxS bits of the enabled analog I/O groups are not set.

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **GxE**: Analog I/O group x enable

These bits are set and cleared by software to enable/disable the acquisition (counter is counting) on the corresponding analog I/O group x.

0: Acquisition on analog I/O group x disabled
1: Acquisition on analog I/O group x enabled

47.6.10  TSC I/O group x counter register (TSC_IOGxCr)

x represents the analog I/O group number.

Address offset: 0x30 + 0x04 * x, (x = 1 to 8)
Reset value: 0x0000 0000

48 True random number generator (RNG)

48.1 Introduction

The RNG is a true random number generator that provides full entropy outputs to the application as 32-bit samples. It is composed of a live entropy source (analog) and an internal conditioning component.

The RNG is a NIST SP 800-90B compliant entropy source that can be used to construct a nondeterministic random bit generator (NDRBG).

The RNG true random number generator has been precertified NIST SP800-90B. It has also been tested using the German BSI statistical tests of AIS-31 (T0 to T8).

48.2 RNG main features

- The RNG delivers 32-bit true random numbers, produced by an analog entropy source conditioned by a NIST SP800-90B approved conditioning stage.
- It can be used as the entropy source to construct a nondeterministic random bit generator (NDRBG).
- In the NIST configuration, it produces four 32-bit random samples every 412 AHB clock cycles if \( f_{\text{AHB}} < f_{\text{threshold}} \) (256 RNG clock cycles otherwise).
- It embeds startup and NIST SP800-90B approved continuous health tests (repetition count and adaptive proportion tests), associated with specific error management.
- It can be disabled to reduce power consumption, or enabled with an automatic low power mode (default configuration).
- It has an AMBA® AHB slave peripheral, accessible through 32-bit word single accesses only (else an AHB bus error is generated, and the write accesses are ignored).

</tbody>
</table>
48.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals.

Within its boundary RNG integrates all the required NIST components depicted on Figure 451. Those components are an analog noise source, a digitization stage, a conditioning algorithm, a health monitoring block and two interfaces that are used to interact with the entropy source: GetEntropy and HealthTest.

Figure 451. NIST SP800-90B entropy source model

The components pictured above are detailed hereafter.

Noise source

The noise source is the component that contains the non-deterministic, entropy-providing activity that is ultimately responsible for the uncertainty associated with the bitstring output by the entropy source. This noise source provides 1-bit samples. It is composed of:

- Multiple analog noise sources (x6), each based on three XORed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in Section 48.3.8: RNG low-power use.
- The XORing of all the noise sources into a single analog output.
- A sampling stage of this output clocked by a dedicated clock input (rng_clk with integrated divider), delivering a 1-bit raw data output.

This noise source sampling is independent to the AHB interface clock frequency (rng_hclk), with a possibility for the software to decrease the sampling frequency by using the integrated divider.

Note: In Section 48.6: RNG entropy source validation the recommended RNG clock frequencies and associated divider value are given.
Post processing

In the NIST configuration no post-processing is applied to the sampled noise source. In non-NIST configuration B (as defined in Section 48.6.2) a normalization debiasing is applied, that is half of the bits are taken from the sampled noise source, half of the bits are taken from the inverted sampled noise source.

Conditioning

The conditioning component in the RNG is a deterministic function that increases the entropy rate of the resulting fixed-length bitstrings output (128-bit). The NIST SP800-90B target is full entropy on the output (128-bit).

The times required between two random number generations, and between the RNG initialization and availability of first sample are described in Section 48.5: RNG processing time.

Output buffer

A data output buffer can store up to four 32-bit words that have been output from the conditioning component. When four words have been read from the output FIFO through the RNG_DR register, the content of the 128-bit conditioning output register is pushed into the output FIFO, and a new conditioning round is automatically started. Four new words are added to the conditioning output register after a number of clock cycles specified in Section 48.5: RNG processing time.

Whenever a random number is available through the RNG_DR register, the DRDY flag changes from 0 to 1. This flag remains high until the output buffer becomes empty after reading four words from the RNG_DR register.

Note: When interrupts are enabled an interrupt is generated when this data ready flag transitions from 0 to 1. Interrupt is then cleared automatically by the RNG as explained above.
Health checks

This component ensures that the entire entropy source (with its noise source) starts then operates as expected, obtaining assurance that failures are caught quickly and with a high probability and reliability.

The RNG implements the following health check features in accordance with NIST SP800-90B. The described thresholds correspond to the value recommended for register RNG_HTCR (configuration A in Section 48.6.2).

1. Startup health tests, performed after reset and before the first use of the RNG as entropy source:
   - Repetition count test, flagging an error when the noise source has provided more than 38 consecutive bits at a constant value (0 or 1).
   - Adaptive proportion test running on a window of 1024 consecutive bits: the RNG verifies that the first bit on the outputs of the noise source is not repeated more than 686 times.
   - Known-answer tests, to verify the conditioning stage.

2. Continuous health tests, running indefinitely on the outputs of the noise source:
   - Repetition count test, similar to the one running in startup tests.
   - Adaptive proportion test, similar to the one running in startup tests.

3. Vendor specific continuous tests
   - Transition count test, flagging an error when the noise source has delivered more than 32 consecutive occurrences of 2-bit patterns (01 or 10).
   - Real-time “too slow” sampling clock detector, flagging an error when one RNG clock cycle (before divider) is smaller than AHB clock cycle divided by 32.

4. On-demand test of digitized noise source (raw data)
   - Supported by restarting the entropy source and rerunning the startup tests (see software reset sequence in Section 48.3.4: RNG initialization). Other kinds of on-demand testing (software based) are not supported.

The CECS and SECS status bits in the RNG_SR register indicate when an error condition is detected, as detailed in Section 48.3.7: Error management.

Note: An interrupt can be generated when an error is detected.

Above the health test thresholds are modified by changing the value in the RNG_HTCR register. See Section 48.6: RNG entropy source validation for details.
48.3.4 RNG initialization

The RNG simplified state machine is pictured on Figure 452.

After enabling the RNG (RNGEN = 1 in RNG_CR), the following chain of events occurs:

1. The analog noise source is enabled, and by default the RNG waits 16 cycles of RNG clock cycles (before divider) before starting to sample the analog output and filling the 128-bit conditioning shift register.
2. The conditioning hardware initializes, automatically triggering startup behavior test on the raw data samples and known-answer tests.
3. When startup health tests are completed. During this time, three 128-bit noise source samples are used.
4. The conditioning stage internal input data buffer is filled again with 128-bit and a number of conditioning rounds defined by the RNG configuration (NIST or non-NIST) is performed. The output buffer is then filled with the post processing result.
5. The output buffer is refilled automatically according to the RNG usage.

The associated initialization time can be found in Section 48.5: RNG processing time.

Figure 452. RNG initialization overview
Figure 452 also highlights a possible software reset sequence, implemented by:
1. Writing bits RNGEN = 0 and CONDRST = 1 in the RNG_CR register with the same
   RNG configuration and a new CLKDIV if needed.
2. Then writing RNGEN = 1 and CONDRST = 0 in the RNG_CR register.
3. Wait for random number to be ready, after initialization completes.

Note: When the RNG peripheral is reset through RCC (hardware reset), the RNG configuration for
optimal randomness is lost in the RNG registers. Software reset with CONFIGLOCK set
preserves the RNG configuration.

48.3.5 RNG operation

Normal operations
To run the RNG using interrupts, the following steps are recommended:
1. Consult Section 48.6: RNG entropy source validation and verify if a specific RNG
   configuration is required for the application.
   – If it is the case, write in the RNG_CR register the bit CONDRST = 1 together with
     the correct RNG configuration. Then perform a second write to the RNG_CR
     register with the bit CONDRST = 0, the interrupt enable bit IE = 1 and the RNG
     enable bit RNGEN = 1.
   – If it is not the case perform a write to the RNG_CR register with the interrupt
     enable bit IE = 1 and the RNG enable bit RNGEN = 1.
2. An interrupt is now generated when a random number is ready or when an error
   occurs. Therefore, at each interrupt, check that:
   – No error occurred. The SEIS and CEIS bits must be set to 0 in the RNG_SR
     register.
   – A random number is ready. The DRDY bit must be set to 1 in the RNG_SR
     register.
   – If the above two conditions are true the content of the RNG_DR register can be
     read up to four consecutive times. If valid data is available in the conditioning
     output buffer, four additional words can be read by the application (in this case the
     DRDY bit is still high). If one or both of the above conditions are false, the
     RNG_DR register must not be read. If an error occurred, the error recovery
     sequence described in Section 48.3.7 must be used.

To run the RNG in polling mode following steps are recommended:
1. Consult Section 48.6: RNG entropy source validation and verify if a specific RNG
   configuration is required for the application.
   – If it is the case write in the RNG_CR register the bit CONDRST = 1 together with
     the correct RNG configuration. Then perform a second write to the RNG_CR
     register with the bit CONDRST = 0 and the RNG enable bit RNGEN = 1.
   – If it is not the case only enable the RNG by setting the RNGEN bit to 1 in the
     RNG_CR register.
2. Read the RNG_SR register and check that:
   – No error occurred (the SEIS and CEIS bits must be set to 0)
   – A random number is ready (the DRDY bit must be set to 1)
3. If above conditions are true read the content of the RNG_DR register up to four
   consecutive times. If valid data is available in the conditioning output buffer four
additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, the error recovery sequence described in Section 48.3.7 must be used.

**Note:** When data is not ready (DRDY = 0) RNG_DR returns zero.
It is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

If the random number generation period is a concern to the application and if NIST compliance is not required it is possible to select a faster RNG configuration by using the RNG configuration “B”, described in Section 48.6: RNG entropy source validation. The gain in random number generation speed is summarized in Section 48.5: RNG processing time.

**Low-power operations**
If the power consumption is a concern to the application, low-power strategies can be used, as described in Section 48.3.8: RNG low-power use.

**Software post-processing**
No specific software post-processing/conditioning is expected to meet the AIS-31 or NIST SP800-90B approvals.

Built-in health check functions are described in Section 48.3.3: Random number generation.

**48.3.6 RNG clocking**
The RNG runs on two different clocks: the AHB bus clock and a dedicated RNG clock. The AHB clock is used to clock the AHB banked registers and conditioning component. The RNG clock, coupled with a programmable divider (see CLKDIV bitfield in the RNG_CR register) is used for noise source sampling. Recommended clock configurations are detailed in Section 48.6: RNG entropy source validation.

**Note:** When the CED bit in the RNG_CR register is set to 0, the RNG clock frequency before the internal divider must be higher than the AHB clock frequency divided by 32, otherwise the clock checker always flags a clock error (CECS = 1 in the RNG_SR register).

See Section 48.3.1: RNG block diagram for details (AHB and RNG clock domains).

**48.3.7 Error management**
In parallel to random number generation a health check block verifies the correct noise source behavior and the frequency of the RNG source clock as detailed in this section. Associated error state is also described.

**Clock error detection**
When the clock error detection is enabled (CED = 0) and if the RNG clock frequency is too low, the RNG sets to 1 both the CEIS and CECS bits to indicate that a clock error occurred. In this case, the application must check that the RNG clock is configured correctly (see Section 48.3.6: RNG clocking) and then it must clear the CEIS bit interrupt flag. The CECS bit is automatically cleared when the clocking condition is normal.
Note: The clock error has no impact on generated random numbers that is the application can still read the RNG_DR register.

CEIS is set only when CECS is set to 1 by RNG.

Noise source error detection

When a noise source (or seed) error occurs, the RNG stops generating random numbers and sets to 1 both SEIS and SECS bits to indicate that a seed error occurred. If a value is available in the RNG_DR register, it must not be used as it may not have enough entropy.

The following sequence must be used to fully recover from a seed error:

1. Software reset by writing CONDRST at 1 and at 0 (see bitfield description for details). This step is needed only if SECS is set. Indeed, when SEIS is set and SECS is cleared it means RNG performed the reset automatically (auto-reset). In this case application must clear the SEIS bit interrupt flag.
2. If SECS was set in step 1 (no auto-reset) wait for CONDRST to be cleared in the RNG_CR register, then confirm that SEIS is cleared in the RNG_SR register. Otherwise, just clear the SEIS bit in the RNG_SR register.
3. If SECS was set in step 1 (no auto-reset), wait for SECS to be cleared by RNG. The random number generation is now back to normal.

Note: After a seed error RNG restarts generating random numbers when SECS is cleared.

When the application sets the ARDIS bit in the RNG_CR register, the auto-reset is disabled. CONDRST must be used in step 1.

RNG tamper errors

When an unexpected error is found by the RNG an internal tamper event is triggered in the TAMP peripheral, and the RNG stops delivering random data.

When this event occurs, the secure application needs to reset the RNG peripheral either using the central reset management or the global SoC reset. Then a proper initialization of the RNG is required, again.

48.3.8 RNG low-power use

If power consumption is a concern, the RNG can be disabled as soon as the DRDY bit is set to 1 by setting the RNGEN bit to 0 in the RNG_CR register. As the post-processing logic and the output buffer remain operational while RNGEN = 0 following features are available to the software:

- If there are valid words in the output buffer four random numbers can still be read from the RNG_DR register.
- If there are valid bits in the conditioning output internal register four additional random numbers can be still be read from the RNG_DR register. If it is not the case RNG must be reenabled by the application until the expected new noise source bits threshold is reached (128-bit in NIST mode) and a complete conditioning round is done. Four new random words are then available only if the expected number of conditioning round is reached (two if NISTC = 0). The overall time can be found in Section 48.5: RNG processing time on page 1905.

When disabling the RNG the user deactivates all the analog seed generators, whose power consumption is given in the datasheet electrical characteristics section. The user also gates
all the logic clocked by the RNG clock. Note that this strategy is adding latency before a random sample is available on the RNG_DR register, because of the RNG initialization time.

If the RNG block is disabled during initialization (that is well before the DRDY bit rises for the first time), the initialization sequence resumes from where it was stopped when RNGEN bit is set to 1, unless the application resets the conditioning logic using CONDRST bit in the RNG CR register.

When the application wants to gate the RNG clock it is recommended to wait two RNG kernel clock cycles between clearing the RNGEN bit and gating the RNG kernel clock using the RCC.

Also, when application needs to enter a power mode where RNG is de-activated, it is recommended to wait two RNG kernel clock cycles between clearing the RNGEN bit and entering the low power mode using the PWR.

In the two cases above, to avoid unexpected consumption when RNG analog oscillators stay active, application can set the bit 13 in RNG CR register. Setting this bit adds some marginal power consumption while RNGEN bit is set (RNG activated).

**Note:** The power modes where RNG is deactivated (that is retained or not available) can be found in the PWR section.

### 48.4 RNG interrupts

In the RNG an interrupt can be produced on the following events:

- Data ready flag
- Seed error, see Section 48.3.7: Error management
- Clock error, see Section 48.3.7: Error management

Dedicated interrupt enable control bits are available as shown in Table 459.

**Table 459. RNG interrupt requests**

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
</tr>
</thead>
<tbody>
<tr>
<td>RNG</td>
<td>Data ready flag</td>
<td>DRDY</td>
<td>IE</td>
<td>None (automatic)</td>
</tr>
<tr>
<td></td>
<td>Seed error flag</td>
<td>SEIS</td>
<td>IE</td>
<td>Write 0 to SEIS or write CONDRST to 1 then to 0</td>
</tr>
<tr>
<td></td>
<td>Clock error flag</td>
<td>CEIS</td>
<td>IE</td>
<td>Write 0 to CEIS</td>
</tr>
</tbody>
</table>

The user can enable or disable the above interrupt sources individually by changing the mask bits or the general interrupt control bit IE in the RNG CR register. The status of the individual interrupt sources can be read from the RNG SR register.

**Note:** Interrupts are generated only when RNG is enabled.
48.5 RNG processing time

In recommended configuration A described in Table 460, the time between two sets of four 32-bit data is either:

- 206 x N AHB cycles if f_{AHB} < f_{threshold} (conditioning stage is limiting), or
- 128 x N RNG cycles f_{AHB} ≥ f_{threshold} (noise source stage is limiting).

With f_{threshold} = 1.6 x f_{RNG}, for instance 77 MHz if f_{RNG} = 48 MHz. Value N is 2.

Note: When CLKDIV is different from zero, f_{RNG} must take into account the internal divider ratio.

If configuration B is selected the performance figures become:

- 206 AHB cycles if f_{AHB} < f_{threshold} or
- 32 RNG cycles f_{AHB} ≥ f_{threshold}

with f_{threshold} = 6.5 x f_{RNG}.

48.6 RNG entropy source validation

48.6.1 Introduction

In order to assess the amount of entropy available from the RNG, STMicroelectronics has tested the peripheral using the German BSI AIS-31 statistical tests (T0 to T8), and NIST SP800-90B test suite. The results can be provided on demand or the customer can reproduce the tests.

48.6.2 Validation conditions

STMicroelectronics has tested the RNG true random number generator in the following conditions:

- RNG clock rng_clk = 48 MHz
- RNG configurations described in Table 460: RNG configurations. Note that only configuration A can be certified NIST SP800-90B.

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>

</tr>
</tbody>
</table>

1. For NIST certification the noise source sampling must be 750 kHz or less. Hence, if the RNG clock is different from 48 MHz, this value of CLKDIV must be adapted. See the CLKDIV bitfield description in Section 48.7.1 for details.
2. 0x1 value is recommended when RNG power consumption is critical. See the end of Section 48.3.8: RNG low-power use for details.
3. Corresponds to 38 for repetition tests and 686 for adaptive tests. See Health checks on page 1899 for details.
48.6.3 Data collection

In order to run statistical tests, it is required to collect samples from the entropy source at the raw data level as well as at the output of the entropy source. For details on data collection and the running of statistical test suites refer to “STM32 microcontrollers random number generation validation using NIST statistical test suite” application note (AN4230) available from www.st.com.

Contact STMicroelectronics if the above samples need to be retrieved for the product.

48.7 RNG registers

The RNG is associated with a control register, a data register and a status register.

48.7.1 RNG control register (RNG_CR)

Address offset: 0x000
Reset value: 0x0080 0D00

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>CONFIGLOCK: RNG Config lock</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Writes to the RNG_HTCR and RNG_CR configuration bits [29:4] are allowed.</td>
</tr>
<tr>
<td>1</td>
<td>Writes to the RNG_HTCR and RNG_CR configuration bits [29:4] are ignored until the next RNG reset.</td>
</tr>
<tr>
<td></td>
<td>This bitfield is set once: if this bit is set it can only be reset to 0 if RNG is reset.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit 30</th>
<th>CONDRST: Conditioning soft reset</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Write 1 and then write 0 to reset the conditioning logic, clear all the FIFOs and start a new RNG initialization process, with RNG_SR cleared. Registers RNG_CR and RNG_HTCR are not changed by CONDRST.</td>
</tr>
<tr>
<td></td>
<td>This bit must be set to 1 in the same access that set any configuration bits [29:4]. In other words, when CONDRST bit is set to 1 correct configuration in bits [29:4] must also be written.</td>
</tr>
<tr>
<td></td>
<td>When CONDRST is set to 0 by the software, its value goes to 0 when the reset process is done. It takes about 2 AHB clock cycles + 2 RNG clock cycles.</td>
</tr>
</tbody>
</table>

Bits 29:26 Reserved, must be kept at reset value.

<table>
<thead>
<tr>
<th>Bits 25:20</th>
<th>RNG_CONFIG1[5:0]: RNG configuration 1</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Reserved to the RNG configuration (bitfield 1). Must be initialized using the recommended value documented in Section 48.6: RNG entropy source validation.</td>
</tr>
<tr>
<td></td>
<td>Writing any bit of RNG_CONFIG1 is taken into account only if the CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.</td>
</tr>
</tbody>
</table>
Bits 19:16 **CLKDIV[3:0]**: Clock divider factor

This value used to configure an internal programmable divider (from 1 to 16) acting on the incoming RNG clock. These bits can be written only when the core is disabled (RNGEN = 0).

- 0x0: Internal RNG clock after divider is similar to incoming RNG clock.
- 0x1: two RNG clock cycles per internal RNG clock.
- 0x2: \(2^2 = 4\) RNG clock cycles per internal RNG clock.
- ...
- 0xF: \(2^{15}\) RNG clock cycles per internal clock (for example, an incoming 48 MHz RNG clock becomes a 1.5 kHz internal RNG clock)

Writing these bits is taken into account only if the CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 15:13 **RNG_CONFIG2[2:0]**: RNG configuration 2

Reserved to the RNG configuration (bitfield 2). Bit 13 can be set when RNG power consumption is critical. See Section 48.3.8: RNG low-power use. Refer to the RNG_CONFIG1 bitfield for details.

Bit 12 **NISTC**: NIST custom

- 0: Hardware default values for NIST compliant RNG. In this configuration, per 128-bit output two conditioning loops are performed and 256 bits of noise source are used.
- 1: Custom values for NIST compliant RNG. See Section 48.6: RNG entropy source validation for proposed configuration.

Writing this bit is taken into account only if CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 11:8 **RNG_CONFIG3[3:0]**: RNG configuration 3

Reserved to the RNG configuration (bitfield 3). If the NISTC bit is cleared in this register RNG_CONFIG3 bitfield values are ignored by RNG.

Bit 7 **ARDIS**: Auto reset disable

- 0: When a noise source error occurs RNG performs an automatic reset to clear the SECS bit.
- 1: When a noise source error occurs the application must reset RNG by writing CONDRST to 1 then to 0, in order to restart random number generation.

When auto-reset is enabled the application still need to clear the SEIS bit after a noise source error.

Writing this bit is taken into account only if CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CED**: Clock error detection

- 0: Clock error detection enabled
- 1: Clock error detection is disabled

The clock error detection cannot be enabled nor disabled on-the-fly when the RNG is enabled, that is to enable or disable CED, the RNG must be disabled.

Writing this bit is taken into account only if the CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **IE**: Interrupt enable

- 0: RNG interrupt is disabled
- 1: RNG interrupt is enabled. An interrupt is pending as soon as DRDY = 1, SEIS = 1 or CEIS = 1 in the RNG_SR register.
Bit 2 **RNGEN**: True random number generator enable
0: True random number generator is disabled. Analog noise sources are powered off and logic clocked by the RNG clock is gated.
1: True random number generator is enabled.

Bits 1:0 Reserved, must be kept at reset value.
48.7.2  RNG status register (RNG_SR)

Address offset: 0x004
Reset value: 0x0000 0000

<p>| | | | | | | | | | | | | | | | |</p>

</table>

Bits 31:7  Reserved, must be kept at reset value.

Bit 6  **SEIS**: Seed error interrupt status

This bit is set at the same time as SECS. It is cleared by writing 0 (unless CONDRST is used). Writing 1 has no effect.
0: No faulty sequence detected
1: At least one faulty sequence is detected. See SECS bit description for details.

An interrupt is pending if IE = 1 in the RNG_CR register.

Bit 5  **CEIS**: Clock error interrupt status

This bit is set at the same time as CECS. It is cleared by writing 0. Writing 1 has no effect.
0: The RNG clock is correct ($f_{RNGCLK} > f_{HCLK}/32$)
1: The RNG clock before the internal divider is detected too slow ($f_{RNGCLK} < f_{HCLK}/32$)

An interrupt is pending if IE = 1 in the RNG_CR register.

Bits 4:3  Reserved, must be kept at reset value.

Bit 2  **SECS**: Seed error current status

0: No faulty sequence has currently been detected. If the SEIS bit is set, this means that a faulty sequence was detected and the situation has been recovered.
1: At least one of the following faulty sequences has been detected:
   – Runtime repetition count test failed (noise source has provided more than 24 consecutive bits at a constant value 0 or 1, or more than 32 consecutive occurrence of two bits patterns 01 or 10)
   – Startup or continuous adaptive proportion test on noise source failed.
   – Startup post-processing/conditioning sanity check failed.

Bit 1  **CECS**: Clock error current status

0: The RNG clock is correct ($f_{RNGCLK} > f_{HCLK}/32$). If the CEIS bit is set, this means that a slow clock was detected and the situation has been recovered.
1: The RNG clock is too slow ($f_{RNGCLK} < f_{HCLK}/32$).

**Note:** CECS bit is valid only if the CED bit in the RNG_CR register is set to 0.

Bit 0  **DRDY**: Data ready

0: The RNG_DR register is not yet valid, no random data is available.
1: The RNG_DR register contains valid random data.

Once the output buffer becomes empty (after reading the RNG_DR register), this bit returns to 0 until a new random value is generated.

**Note:** The DRDY bit can rise when the peripheral is disabled (RNGEN = 0 in the RNG_CR register).

If IE=1 in the RNG_CR register, an interrupt is generated when DRDY = 1.
48.7.3  RNG data register (RNG_DR)

Address offset: 0x008
Reset value: 0x0000 0000

The RNG_DR register is a read-only register that delivers a 32-bit random value when read. The content of this register is valid when the DRDY = 1 and the value is not 0x0, even if RNGEN = 0.

Bits 31:0  RNDATA[31:0]: Random data
32-bit random data, which are valid when DRDY = 1. When DRDY = 0, the RNDATA value is zero.
When DRDY is set, it is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

48.7.4  RNG health test control register (RNG_HTCR)

Address offset: 0x010
Reset value: 0x0000 72AC

Writing in RNG_HTCR is taken into account only if the CONDRST bit is set, and the CONFIGLOCK bit is cleared in the RNG_CR. Writing to this register is ignored if CONFIGLOCK=1.

Refer to Section 2.3 for the register boundary addresses.
49 AES hardware accelerator (AES)

This section only applies to STM32U545/585/5Ax/5Gx devices.

49.1 Introduction

The AES hardware accelerator (AES) encrypts or decrypts data, using an algorithm and implementation fully compliant with the advanced encryption standard (AES) defined in Federal information processing standards (FIPS) publication 197.

The peripheral supports CTR, GCM, GMAC, CCM, ECB, and CBC chaining modes for key sizes of 128 or 256 bits.

AES is an AMBA AHB slave peripheral accessible through 32-bit single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels required).

49.2 AES main features

- Compliance with NIST “Advanced encryption standard (AES), FIPS publication 197” from November 2001
- 128-bit data block processing
- Support for cipher key lengths of 128-bit and 256-bit
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- 51 or 75 clock cycle latency in ECB mode for processing one 128-bit block of data with, respectively, 128-bit or 256-bit key
- Integrated round key scheduler to compute the last round key for ECB/CBC decryption
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only
- 256-bit write-only register for storing the cryptographic key (eight 32-bit registers)
- 128-bit register for storing initialization vector (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control with support of single-transfer direct memory access (DMA) using two channels (one for incoming data, one for processed data)
- Data-swapping logic to support 1-, 8-, 16- or 32-bit data
- Possibility for software to suspend a message if AES needs to process another message with a higher priority, then resume the original message
- Hardware key sharing with side-channel resistant SAES peripheral (Shared-key mode), controlled by SAES
49.3 **AES implementation**

The devices have one AES and one SAES peripheral, implemented as shown in the following table.

\[^{1}\] X = supported.
49.4.3 AES cryptographic core

Overview

The AES cryptographic core consists of the following components:

- AES core algorithm (AEA)
- multiplier over a binary Galois field (GF2mul)
- key input
- initialization vector (IV) input
- chaining algorithm logic (XOR, feedback/counter, mask)

The AES core works on 128-bit data blocks (four words) with 128-bit or 256-bit key length. Depending on the chaining mode, the AES requires zero or one 128-bit initialization vector IV.

The AES features the following modes of operation:

- **Mode 1:** Plaintext encryption using a key stored in the AES_KEYRx registers
- **Mode 2:** ECB or CBC decryption key preparation. It must be used prior to selecting Mode 3 with ECB or CBC chaining modes. The key prepared for decryption is stored automatically in the AES_KEYRx registers. Now the AES peripheral is ready to switch to Mode 3 for executing data decryption.
- **Mode 3:** Ciphertext decryption using a key stored in the AES_KEYRx registers. When ECB and CBC chaining modes are selected, the key must be prepared beforehand, through Mode 2.

**Note:** **Mode 2 is only used when performing ECB and CBC decryption.**

The operating mode is selected by programming the MODE[1:0] bitfield of the AES_CR register. It may be done only when the AES peripheral is disabled.

Special key operation is selected using the KMOD[1:0] bitfield of the AES_CR register. See *Section 49.4.13* for details.

</tr>
</tbody>
</table>
Typical data processing

Typical usage of the AES is described in *Section 49.4.4: AES procedure to perform a cipher operation on page 1919.*

**Note:** The outputs of the intermediate AEA stages are never revealed outside the cryptographic boundary, with the exclusion of the IV bitfield.

Chaining modes

The following chaining modes are supported by AES, selected through the CHMOD[2:0] bitfield of the AES_CR register:

- Electronic code book (ECB)
- Cipher block chaining (CBC)
- Counter (CTR)
- Galois counter mode (GCM)
- Galois message authentication code (GMAC)
- Counter with CBC-MAC (CCM)

**Note:** The chaining mode may be changed only when AES is disabled (bit EN of the AES_CR register cleared).

Principle of each AES chaining mode is provided in the following subsections.

Detailed information is in dedicated sections, starting from *Section 49.4.8: AES basic chaining modes (ECB, CBC).*

**Electronic codebook (ECB) mode**

*Figure 454. ECB encryption and decryption principle*
ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately.

Note: For decryption, a special key scheduling is required before processing the first block.

Cipher block chaining (CBC) mode

In CBC mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing.

Note: For decryption, a special key scheduling is required before processing the first block.
Counter (CTR) mode

The CTR mode uses the AES core to generate a key stream. The keys are then XOR-ed with the plaintext to obtain the ciphertext as specified in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.

Note: Unlike with ECB and CBC modes, no key scheduling is required for the CTR decryption, since in this chaining scheme the AES core is always used in encryption mode for producing the key stream, or counter blocks.
Galois/counter mode (GCM)

In Galois/counter mode (GCM), the plaintext message is encrypted while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and its MAC (also known as authentication tag). It is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. It requires an initial value and a particular 128-bit block at the end of the message.

Galois message authentication code (GMAC) principle

Galois message authentication code (GMAC) allows authenticating a message and generating the corresponding message authentication code (MAC). It is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.
GMAC is similar to GCM, except that it is applied on a message composed only by plaintext authenticated data (that is, only header, no payload).

### Counter with CBC-MAC (CCM) principle

**Figure 459. CCM encryption and authentication principle**

In Counter with cipher block chaining-message authentication code (CCM) mode, the plaintext message is encrypted while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and the corresponding MAC (also known as tag). It is described by NIST in *Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*.

CCM mode is based on AES in counter mode for confidentiality and it uses CBC for computing the message authentication code. It requires an initial value.

Like GCM, the CCM chaining mode can be applied on a message composed only by plaintext authenticated data (that is, only header, no payload). Note that this way of using CCM is not called CMAC (it is not similar to GCM/GMAC), and its use is not recommended by NIST.

#### 49.4.4 AES procedure to perform a cipher operation

**Introduction**

A typical cipher operation is explained below. Detailed information is provided in sections starting from *Section 49.4.8: AES basic chaining modes (ECB, CBC)*.
**Initialization of AES**

To initialize AES, first disable it by clearing the EN bit of the AES_CR register. Then perform the following steps in any order:

- Configure the AES mode, by programming the MODE[1:0] bitfield of the AES_CR register.
  - For encryption, select Mode 1 (MODE[1:0] = 00).
  - For decryption, select Mode 3 (MODE[1:0] = 10), unless ECB or CBC chaining modes are used. In this latter case, perform an initial key derivation of the encryption key, as described in Section 49.4.5: AES decryption round key preparation.
- Select the chaining mode, by programming the CHMOD[2:0] bitfield of the AES_CR register.
- Configure the data type (1-, 8-, 16- or 32-bit), with the DATATYPE[1:0] bitfield in the AES_CR register.
- When it is required (for example in CBC or CTR chaining modes), write the initialization vector into the AES_IVRx registers.
- Configure the key size (128-bit or 256-bit), with the KEYSIZE bitfield of the AES_CR register. This step must be done before writing into key registers.
- Write a symmetric key into the AES_KEYRx registers (4 or 8 registers depending on the key size).

**Note:** AES sets KEYVALID in AES_SR when key information defined by KEYSIZE is loaded in AES_KEYRx.

**Data append**

This section describes different ways of appending data for processing, where the size of data to process is not a multiple of 128 bits when KMOD[1:0] = 00. For other KMOD[1:0] values refer to Section 49.4.13.

For ECB or CBC mode, refer to Section 49.4.6: AES ciphertext stealing and data padding. The last block management in these cases is more complex than in the sequence described in this section.

**Data append through polling**

This method uses flag polling to control the data append through the following sequence:

1. Enable the AES peripheral by setting the EN bit of the AES_CR register.
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the AES_DINR register.
   b) Wait until the status flag CCF is set in the AES_SR, then read the four data words from the AES_DOUTR register.
   c) Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
   d) If the data block just processed is the second-last block of the message and the significant data in the last block to process is inferior to 128 bits, pad the remainder of the last block with zeros and, in case of GCM payload encryption or CCM payload decryption, specify the number of non-valid bytes, using the NPBLB bitfield of the AES_CR register, for AES to compute a correct tag.
3. As it is the last block, discard the data that is not part of the data, then disable the AES peripheral by clearing the EN bit of the AES_CR register.
**Note:** Up to three wait cycles are automatically inserted between two consecutive writes to the AES_DINR register, to allow sending the key to the AES processor.

NPBLB bits are not used in header phase of GCM, GMAC and CCM chaining modes.

### Data append using interrupt

The method uses interrupt from the AES peripheral to control the data append, through the following sequence:

1. Enable interrupts from AES by setting the CCFIE bit of the AES_IER register.
2. Enable the AES peripheral by setting the EN bit of the AES_CR register.
3. Write first four input data words into the AES_DINR register.
4. Handle the data in the AES interrupt service routine, upon interrupt:
   a) Read four output data words from the AES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCF bit of the AES_ICR register.
   c) If the data block just processed is the second-last block of a message and the significant data in the last block to process is inferior to 128 bits, pad the remainder of the last block with zeros and, in case of GCM payload encryption or CCM payload decryption, specify the number of non-valid bytes, using the NPBLB bitfield of the AES_CR register, for AES to compute a correct tag. Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, discard the data that is not part of the data, then disable the AES peripheral by clearing the EN bit of the AES_CR register and quit the interrupt service routine.
   e) Write next four input data words into the AES_DINR register and quit the interrupt service routine.

**Note:** AES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two AES computations. NPBLB bits are not used in header phase of GCM, GMAC and CCM chaining modes.

### Data append using DMA

With this method, all the transfers and processing are managed by DMA and AES. To use the method, proceed as follows:

1. Prepare the last four-word data block (if the data to process does not fill it completely), by padding the remainder of the block with zeros.
2. Configure the DMA controller so as to transfer the data to process from the memory to the AES peripheral input and the processed data from the AES peripheral output to the memory, as described in Section 49.4.17: AES DMA interface. Configure the DMA controller so as to generate an interrupt on transfer completion. In case of GCM payload encryption or CCM payload decryption, DMA transfer must not include the last four-word block if padded with zeros. The sequence described in Data append through polling must be used instead for this last block, because NPBLB bits must be setup before processing the block, for AES to compute a correct tag.
3. Enable the AES peripheral by setting the EN bit of the AES_CR register
4. Enable DMA requests by setting the DMAINEN and DMAOUTEN bits of the AES_CR register.
5. Upon DMA interrupt indicating the transfer completion, get the AES-processed data from the memory.
Note: The CCF flag has no use with this method, because the reading of the AES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.

NPBLB bits are not used in header phase of GCM, GMAC, and CCM chaining modes.

### 49.4.5 AES decryption round key preparation

Internal key schedule is used to generate AES round keys. In AES encryption, the round 0 key is the one stored in the key registers. AES decryption must start using the last round key. As the encryption key is stored in memory, a special key scheduling must be performed to obtain the decryption key. This key scheduling is only required for AES decryption in ECB and CBC modes.

Recommended method is to select the Mode 2 by setting to 01 the MODE[1:0] bitfield of the AES_CR (key process only), then proceed with the decryption by setting MODE[1:0] to 10 (Mode 3, decryption only). Mode 2 usage is described below:

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select Mode 2 by setting to 01 the MODE[1:0] bitfield of the AES_CR. The CHMOD[2:0] bitfield is not significant in this case because this key derivation mode is independent of the chaining algorithm selected. Select normal key mode by setting KMOD[1:0] to 00. For decryption with other KMOD[1:0] values, refer to Section 49.4.13.
3. Set key length to 128 or 256 bits, via KEYSIZE bit of AES_CR register.
4. Write the AES_KEYRx registers (128 or 256 bits) with encryption key. Writes to the AES_IVRx registers have no effect.
5. Enable the AES peripheral, by setting the EN bit of the AES_CR register.
6. Wait until the CCF flag is set in the AES_SR register.
7. Clear the CCF flag. Derived key is available in AES core, ready to use for decryption.

Note: The AES is disabled by hardware when the derivation key is available.
To restart a derivation key computation, repeat steps 4, 5, 6, and 7.

Note: The operation of the key preparation lasts 59 or 82 clock cycles, depending on the key size (128- or 256-bit).

### 49.4.6 AES ciphertext stealing and data padding

When using AES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (128 bits), ciphertext stealing techniques are used, such as those described in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode. Since the AES peripheral does not support such techniques, the application must complete the last block of input data using data from the second last block.

Note: Ciphertext stealing techniques are not documented in this reference manual.

Similarly, when AES is used in other modes than ECB or CBC, an incomplete input data block (that is, block with input data shorter than 128 bits) must be padded with zeros prior to encryption (that is, extra bits must be appended to the trailing end of the data string). After decryption, the extra bits must be discarded. As AES does not implement automatic data padding operation to the last block, the application must follow the recommendation given...
in Section 49.4.4: AES procedure to perform a cipher operation on page 1919 to manage messages the size of which is not a multiple of 128 bits.

Note: Padding data are swapped in a similar way as normal data, according to the DATATYPE[1:0] field of the AES_CR register (see Section 49.4.14: AES data registers and data swapping for details).

49.4.7 AES task suspend and resume

A message can be suspended if another message with a higher priority must be processed. When this highest priority message is sent, the suspended message can resume in both encryption or decryption mode.

Suspend/resume operations do not break the chaining operation and the message processing can resume as soon as AES is enabled again to receive the next data block. Figure 460 gives an example of suspend/resume operation: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

Figure 460. Example of suspend mode management

A detailed description of suspend/resume operations is in the sections dedicated to each AES mode.

49.4.8 AES basic chaining modes (ECB, CBC)

Overview

This section gives a brief explanation of the four basic operation modes provided by the AES core: ECB encryption, ECB decryption, CBC encryption and CBC decryption. For detailed information, refer to the FIPS publication 197 from November 26, 2001.
Figure 461 illustrates the electronic codebook (ECB) encryption.

**Figure 461. ECB encryption**

In ECB encrypt mode, the 128-bit plaintext input data block \( P_x \) in the AES_DINR register first goes through bit/byte/half-word swapping. The swap result \( I_x \) is processed with the AES core set in encrypt mode, using a 128- or 256-bit key. The encryption result \( O_x \) goes through bit/byte/half-word swapping, then is stored in the AES_DOUTR register as 128-bit ciphertext output data block \( C_x \). The ECB encryption continues in this way until the last complete plaintext block is encrypted.

**Figure 462 illustrates the electronic codebook (ECB) decryption.**

To perform an AES decryption in the ECB mode, the secret key has to be prepared by collecting the last-round encryption key (which requires to first execute the complete key schedule for encryption), and using it as the first-round key for the decryption of the ciphertext. This preparation is supported by the AES core.

In ECB decrypt mode, the 128-bit ciphertext input data block \( C_1 \) in the AES_DINR register first goes through bit/byte/half-word swapping. The keying sequence is reversed compared to that of the ECB encryption. The swap result \( I_1 \) is processed with the AES core set in decrypt mode, using the formerly prepared decryption key. The decryption result goes through bit/byte/half-word swapping, then is stored in the AES_DOUTR register as 128-bit plaintext output data block \( P_1 \). The ECB decryption continues in this way until the last complete ciphertext block is decrypted.
Figure 463 illustrates the cipher block chaining (CBC) encryption.

**Figure 463. CBC encryption**

In CBC encrypt mode, the first plaintext input block, after bit/byte/half-word swapping (P1'), is XOR-ed with a 128-bit IVI bitfield (initialization vector and counter), producing the I1 input data for encrypt with the AES core, using a 128- or 256-bit key. The resulting 128-bit output block O1, after swapping operation, is used as ciphertext C1. The O1 data is then XOR-ed with the second-block plaintext data P2' to produce the I2 input data for the AES core to produce the second block of ciphertext data. The chaining of data blocks continues in this way until the last plaintext block in the message is encrypted.

If the message size is not a multiple of 128 bits, the final partial data block is encrypted in the way explained in Section 49.4.6: AES ciphertext stealing and data padding.

**Figure 464 illustrates the cipher block chaining (CBC) decryption.**

In CBC decrypt mode, like in ECB decrypt mode, the secret key must be prepared to perform an AES decryption.

After the key preparation process, the decryption goes as follows: the first 128-bit ciphertext block (after the swap operation) is used directly as the AES core input block I1 for decrypt operation, using the 128-bit or 256-bit key. Its output O1 is XOR-ed with the 128-bit IVI field (that must be identical to that used during encryption) to produce the first plaintext block P1.
The second ciphertext block is processed in the same way as the first block, except that the I1 data from the first block is used in place of the initialization vector.

The decryption continues in this way until the last complete ciphertext block is decrypted.

If the message size is not a multiple of 128 bits, the final partial data block is decrypted in the way explained in Section 49.4.6: AES ciphertext stealing and data padding.

For more information on data swapping, refer to Section 49.4.14: AES data registers and data swapping.

**ECB/CBC encryption sequence**

The sequence of events to perform an ECB/CBC encryption (more detail in Section 49.4.4):

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select the Mode 1 by setting to 00 the MODE[1:0] bitfield of the AES_CR register and select ECB or CBC chaining mode by setting the CHMOD[2:0] bitfield of the AES_CR register to 000 or 001, respectively. Data type can also be defined, using DATATYPE[1:0] bitfield. Select normal key mode by setting KMOD[1:0] to 00. For encryption with other KMOD[1:0] values, refer to Section 49.4.13.
3. Select 128- or 256-bit key length through the KEYSIZE bit of the AES_CR register.
4. Write the AES_KEYRx registers (128 or 256 bits) with encryption key. Fill the AES_IVRx registers with the initialization vector data if CBC mode has been selected.
5. Enable the AES peripheral by setting the EN bit of the AES_CR register.
6. Write the AES_DINR register four times to input the plaintext (MSB first), as shown in Figure 465.
7. Wait until the CCF flag is set in the AES_SR register.
8. Read the AES_DOUTR register four times to get the ciphertext (MSB first) as shown in Figure 465. Then clear the CCF flag by setting the CCF bit of the AES_ICR register.
9. Repeat steps 6-7-8 to process all the blocks with the same encryption key.

**Figure 465. ECB/CBC encryption (Mode 1)**

**ECB/CBC decryption sequence**

The sequence of events to perform an AES ECB/CBC decryption is as follows (More detail in Section 49.4.4). Select normal key mode by setting KMOD[1:0] to 00. For decryption with other KMOD[1:0] values, refer to Section 49.4.13.
1. Follow the steps described in Section 49.4.5: AES decryption round key preparation, in order to prepare the decryption key in AES core.

2. Select the Mode 3 by setting to 10 the MODE[1:0] bitfield of the AES_CR register and select ECB or CBC chaining mode by setting the CHMOD[2:0] bitfield of the AES_CR register to 000 or 001, respectively. Data type can also be defined, using DATATYPE[1:0] bitfield. KEYSIZE bitfield must be kept as-is.

3. Write the AES_IVRx registers with the initialization vector (required in CBC mode only).

4. Enable AES by setting the EN bit of the AES_CR register.

5. Write the AES_DINR register four times to input the cipher text (MSB first), as shown in Figure 466.

6. Wait until the CCF flag is set in the AES_SR register.

7. Read the AES_DOUTR register four times to get the plain text (MSB first), as shown in Figure 466. Then clear the CCF flag by setting the CCF bit of the AES_ICR register.

8. Repeat steps 5-6-7 to process all the blocks encrypted with the same key.

**Suspend/resume operations in ECB/CBC modes**

To suspend the processing of a message, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the AES_CR register.

2. If DMA is not used, read four times the AES_DOUTR register to save the last processed block. If DMA is used, wait until the CCF flag is set in the AES_SR register then stop the DMA transfers from the OUT FIFO by clearing the DMAOUTEN bit of the AES_CR register.

3. If DMA is not used, poll the CCF flag of the AES_SR register until it becomes 1 (computation completed).

4. Clear the CCF flag by setting the CCF bit of the AES_ICR register.

5. Save initialization vector registers (only required in CBC mode as AES_IVRx registers are altered during the data processing).

6. Disable the AES peripheral by clearing the bit EN of the AES_CR register.

7. Save the AES_CR register and clear the key registers if they are not needed, to process the higher priority message.

8. If DMA is used, save the DMA controller status (pointers for IN and OUT data transfers, number of remaining bytes, and so on).
To resume the processing of a message, proceed as follows:
1. If DMA is used, configure the DMA controller so as to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
3. Restore AES_CR register (with correct KEYSIZE) then restore AES_KEYRx registers.
4. Prepare the decryption key as described in Section 49.4.5: AES decryption round key preparation (only required for ECB or CBC decryption).
5. Restore AES_IVRx registers using the saved configuration (only required in CBC mode).
6. Enable the AES peripheral by setting the EN bit of the AES_CR register.
7. If DMA is used, enable AES DMA transfers by setting the DMAINEN and DMAOUTEN bits of the AES_CR register.

49.4.9 AES counter (CTR) mode

Overview

The counter mode (CTR) uses AES as a key-stream generator. The generated keys are then XOR-ed with the plaintext to obtain the ciphertext.

CTR chaining is defined in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation. A typical message construction in CTR mode is given in Figure 467.

Figure 467. Message construction in CTR mode

The structure of this message is:
- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - Initialization vector (IV): a 96-bit value that must be unique for each encryption cycle with a given key.
  - Counter: a 32-bit big-endian integer that is incremented each time a block processing is completed. The initial value of the counter must be set to 1.
- The plaintext \( P \) is encrypted as ciphertext \( C \), with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.
CTR encryption and decryption

*Figure 468* and *Figure 469* describe the CTR encryption and decryption process, respectively, as implemented in the AES peripheral. The CTR mode is selected by writing 010 to the CHMOD[2:0] bitfield of AES_CR register.

*Figure 468. CTR encryption*

In CTR mode, the cryptographic core output (also called keystream) Ox is XOR-ed with relevant input block (P'x for encryption, Cx' for decryption), to produce the correct output block (Cx' for encryption, P'x for decryption). Initialization vectors in AES must be initialized as shown in *Table 464*.

*Table 464. CTR mode initialization vector definition*

<table>
<thead>
<tr>
<th>AES_IVR3[31:0]</th>
<th>AES_IVR2[31:0]</th>
<th>AES_IVR1[31:0]</th>
<th>AES_IVR0[31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>32-bit counter = 0x0001</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Unlike in CBC mode that uses the AES_IVRx registers only once when processing the first data block, in CTR mode AES_IVRx registers are used for processing each data block, and the AES peripheral increments the counter bits of the initialization vector (leaving the nonce bits unchanged).

CTR decryption does not differ from CTR encryption, since the core always encrypts the current counter block to produce the key stream that is then XOR-ed with the plaintext (CTR encryption) or ciphertext (CTR decryption) input. In CTR mode, the MODE[1:0] bitfield setting 01 (key derivation) is forbidden and all the other settings default to encryption mode.

The sequence of events to perform an encryption or a decryption in CTR chaining mode:

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select CTR chaining mode by setting to 010 the CHMOD[2:0] bitfield of the AES_CR register. Set MODE[1:0] bitfield to any value other than 01.
3. Initialize the AES_KEYRx registers, and load the AES_IVRx registers as described in Table 464.
4. Set the EN bit of the AES_CR register, to start encrypting the current counter (EN is automatically reset when the calculation finishes).
5. If it is the last block, pad the data with zeros to have a complete block, if needed.
6. Append data in AES, and read the result. The three possible scenarios are described in Section 49.4.4: AES procedure to perform a cipher operation.
7. Repeat the previous step till the second-last block is processed. For the last block, apply the two previous steps and discard the bits that are not part of the payload (if the size of the significant data in the last input block is less than 16 bytes).

Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher priority message, and resume the message that was interrupted. Detailed CBC suspend/resume sequence is described in Section 49.4.8: AES basic chaining modes (ECB, CBC).

Note: Like for CBC mode, the AES_IVRx registers must be reloaded during the resume operation.

49.4.10 AES Galois/counter mode (GCM)

Overview

The AES Galois/counter mode (GCM) allows encrypting and authenticating a plaintext message into the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, GCM algorithm is based on AES counter mode. It uses a multiplier over a fixed finite field to generate the tag.

GCM chaining is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC. A typical message construction in GCM mode is given in Figure 470.
The message has the following structure:

- **16-byte initial counter block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV)**: a 96-bit value that must be unique for each encryption cycle with a given key. Note that the GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.

- **Authenticated header AAD** (also knows as additional authentication data) has a known length Len(A) that may be a non-multiple of 16 bytes, and must not exceed $2^{64} - 1$ bits. This part of the message is only authenticated, not encrypted.

- **Plaintext message P** is both authenticated and encrypted as ciphertext C, with a known length Len(P) that may be non-multiple of 16 bytes, and cannot exceed $2^{32} - 2$ 128-bit blocks.

- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in Table 465.

The GCM standard specifies that ciphertext C has the same bit length as the plaintext P. When a part of the message (AAD or P) has a length that is a non-multiple of 16-bytes a special padding scheme is required.

**Table 465. GCM last block definition**

GCM processing

*Figure 471* describes the GCM implementation in the AES peripheral. The GCM is selected by writing 011 to the CHMOD[2:0] bitfield of the AES_CR register.

The mechanism for the confidentiality of the plaintext in GCM mode is similar to that in the Counter mode, with a particular increment function (denoted 32-bit increment) that generates the sequence of input counter blocks.

AES_IVRx registers keeping the **counter block** of data are used for processing each data block. The AES peripheral automatically increments the Counter[31:0] bitfield. The first counter block (CB1) is derived from the initial counter block ICB by the application software (see *Table 466*).

*Table 466. Initialization of AES_IVRx registers in GCM mode*

<td></td>
</tr>
</tbody>
</table>

Note: In this mode, the setting 01 of the MODE[1:0] bitfield (key derivation) is forbidden.
The authentication mechanism in GCM mode is based on a hash function called \textit{GF2mul} that performs multiplication by a fixed parameter, called hash subkey (H), within a binary Galois field.

A GCM message is processed through the following phases, further described in next subsections:

- **Init phase**: AES prepares the GCM hash subkey (H).
- **Header phase**: AES processes the additional authenticated data (AAD), with hash computation only.
- **Payload phase**: AES processes the plaintext (P) with hash computation, counter block encryption and data XOR-ing. It operates in a similar way for ciphertext (C).
- **Final phase**: AES generates the authenticated tag (T) using the last block of the message.

**GCM init phase**

During this first step, the GCM hash subkey (H) is calculated and saved internally, to be used for processing all the blocks. The recommended sequence is:

1. Disable the AES peripheral by clearing the EN bit of the AES\_CR register.
2. Select GCM chaining mode, by setting to 011 the CHMOD[2:0] bitfield of the AES\_CR register, and optionally, set the DATATYPE[1:0] bitfield.
3. Indicate the Init phase, by setting to 00 the GCMPH[1:0] bitfield of the AES\_CR register.
4. Set the MODE[1:0] bitfield of the AES\_CR register to 00 or 10. Although the bitfield is only used in payload phase, it is recommended to set it in the Init phase and keep it unchanged in all subsequent phases.
5. Initialize the AES\_KEYRx registers with a key, and initialize AES\_IVRx registers with the information as defined in \textit{Table 466}.
6. Start the calculation of the hash key, by setting to 1 the EN bit of the AES\_CR register (EN is automatically reset when the calculation finishes).
7. Wait until the end of computation, indicated by the CCF flag of the AES\_SR transiting to 1. Alternatively, use the corresponding interrupt.
8. Clear the CCF flag of the AES\_SR register, by setting the CCF bit of the AES\_ICR register.

**GCM header phase**

This phase coming after the GCM Init phase must be completed before the payload phase. The sequence to execute, identical for encryption and decryption, is:

1. Indicate the header phase, by setting to 01 the GCMPH[1:0] bitfield of the AES\_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
2. Enable the AES peripheral by setting the EN bit of the AES\_CR register.
3. If it is the last block and the AAD size in the block is inferior to 128 bits, pad the remainder of the block with zeros. Then append the data block into AES in one of ways described in \textit{Section 49.4.4: AES procedure to perform a cipher operation}. No data is read during this phase.
4. Repeat the step 3 until the last additional authenticated data block is processed.

\textit{Note}: The header phase can be skipped if there is no AAD, that is, Len(A) = 0.
GCM payload phase

This phase, identical for encryption and decryption, is executed after the GCM header phase. During this phase, the encrypted/decrypted payload is stored in the AES_DOUTR register. The sequence to execute is:

1. Indicate the payload phase, by setting to 10 the GCMPH[1:0] bitfield of the AES_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
2. If the header phase was skipped, enable the AES peripheral by setting the EN bit of the AES_CR register.
3. If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in the block is inferior to 128 bits, pad the remainder of the block with zeros.
4. Append the data block into AES in one of ways described in Section 49.4.4: AES procedure to perform a cipher operation on page 1919, and read the result.
5. Repeat the previous step till the second-last plaintext block is encrypted or till the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), execute the two previous steps. For the last block, discard the bits that are not part of the payload when the last block size is less than 16 bytes.

Note: The payload phase can be skipped if there is no payload data, that is, Len(C) = 0 (see GMAC mode).

GCM final phase

In this last phase, the AES peripheral generates the GCM authentication tag and stores it in the AES_DOUTR register. The sequence to execute is:

1. Indicate the final phase, by setting to 11 the GCMPH[1:0] bitfield of the AES_CR register.
2. Compose the data of the block, by concatenating the AAD bit length and the payload bit length, as shown in Table 465. Write the block into the AES_DINR register.
3. Wait until the end of computation, indicated by the CCF flag of the AES_SR transiting to 1.
4. Get the GCM authentication tag, by reading the AES_DOUTR register four times.
5. Clear the CCF flag of the AES_SR register, by setting the CCF bit of the AES_ICR register.
6. Disable the AES peripheral, by clearing the bit EN of the AES_CR register. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message.

Note: In the final phase, data is written to AES_DINR normally (no swapping), while swapping is applied to tag data read from AES_DOUTR.

When transiting from the header or the payload phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.
Suspend/resume operations in GCM mode

To suspend the processing of a message, proceed as follows:
1. If DMA is used, stop the AES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the AES_CR register. If DMA is not used, make sure that the current computation is completed, which is indicated by the CCF flag of the AES_SR register set to 1.
2. In the payload phase, if DMA is not used, read four times the AES_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag is set in the AES_SR register then stop the DMA transfers from the OUT FIFO by clearing the DMAOUTEN bit of the AES_CR register.
3. Clear the CCF flag of the AES_SR register, by setting the CCF bit of the AES_ICR register.
4. Save the AES_SUSPxR registers in the memory, where x is from 0 to 7.
5. In the payload phase, save the AES_IVRx registers as, during the data processing, they changed from their initial values. In the header phase, this step is not required.
6. Disable the AES peripheral, by clearing the EN bit of the AES_CR register.
7. Save the current AES configuration in the memory, excluding the initialization vector registers AES_IVRx. Key registers do not need to be saved as the original key value is known by the application.
8. If DMA is used, save the DMA controller status (pointers for IN data transfers, number of remaining bytes, and so on). In the payload phase, pointers for OUT data transfers must also be saved.

To resume the processing of a message, proceed as follows:
1. If DMA is used, configure the DMA controller in order to complete the rest of the FIFO IN transfers. In the payload phase, the rest of the FIFO OUT transfers must also be configured in the DMA controller.
2. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
3. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPxR registers, where x is from 0 to 7.
4. In the payload phase, write the initialization vector register values, previously saved in the memory, back into their corresponding AES_IVRx registers. In the header phase, write initial setting values back into the AES_IVRx registers.
5. Restore the initial setting values in the AES_CR and AES_KEYRx registers.
6. Enable the AES peripheral by setting the EN bit of the AES_CR register.

If DMA is used, enable AES DMA requests by setting the DMAINEN bit (and DMAOUTEN bit if in payload phase) of the AES_CR register.

49.4.11 AES Galois message authentication code (GMAC)

Overview

The Galois message authentication code (GMAC) allows the authentication of a plaintext, generating the corresponding tag information (also known as message authentication code). It is based on GCM algorithm, as defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.
A typical message construction for GMAC is given in Figure 472.

**Figure 472. Message construction in GMAC mode**

The GMAC algorithm corresponds to the GCM algorithm applied on a message only containing a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.
Suspend/resume operations in GMAC

In GMAC mode, the sequence described for the GCM applies except that only the header phase can be interrupted.

49.4.12 AES counter with CBC-MAC (CCM)

Overview

The AES counter with cipher block chaining-message authentication code (CCM) algorithm allows encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES in counter mode. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve this CBC-MAC as an authentication mode outside the context of the CCM specification.

CCM chaining is specified in NIST Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality. A typical message construction for CCM is given in Figure 474.

Figure 474. Message construction in CCM mode

The structure of the message is:

- **16-byte first authentication block (B0),** composed of three distinct fields:
  - **Q:** a bit string representation of the octet length of P (Len(P))
  - **Nonce (N):** a single-use value (that is, a new nonce must be assigned to each new communication) of Len(N) size. The sum Len(N) + Len(P) must be equal to 15 bytes.
  - **Flags:** most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values t (MAC length expressed in bytes) and Q (plaintext length such that Len(P) < 2^q bytes). The counter blocks range associated to Q is equal to 2^{8Q-4}, that is, if the maximum value of Q is 8, the counter blocks used in cipher must be on 60 bits.

- **16-byte blocks (B) associated to the Associated Data (A).**

This part of the message is only authenticated, not encrypted. This section has a
known length \( \text{Len}(A) \) that can be a non-multiple of 16 bytes (see Figure 474). The standard also states that, on MSB bits of the first message block (B1), the associated data length expressed in bytes (a) must be encoded as follows:
- If \( 0 < a < 2^{16} - 2^8 \), then it is encoded as \([a]_{16}\), that is, on two bytes.
- If \( 2^{16} - 2^8 < a < 2^{32} \), then it is encoded as \(0xff \| 0xfe \| [a]_{32}\), that is, on six bytes.
- If \( 2^{32} < a < 2^{64} \), then it is encoded as \(0xff \| 0xff \| [a]_{64}\), that is, on ten bytes.

- **16-byte blocks (B)** associated to the plaintext message P, which is both authenticated and encrypted as ciphertext C, with a known length \( \text{Len}(P) \). This length can be a non-multiple of 16 bytes (see Figure 474).

- **Encrypted MAC (T)** of length \( \text{Len}(T) \) appended to the ciphertext C of overall length \( \text{Len}(C) \).

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a special padding scheme is required.

**Note:** CCM chaining mode can also be used with associated data only (that is, no payload).

As an example, the C.1 section in NIST Special Publication 800-38C gives the following values (hexadecimal numbers):

- \( N: 10111213 \ 141516 \) (\( \text{Len}(N) = 56 \text{ bits or 7 bytes} \))
- \( A: 00010203 \ 04050607 \) (\( \text{Len}(A) = 64 \text{ bits or 8 bytes} \))
- \( P: 20212223 \) (\( \text{Len}(P) = 32 \text{ bits or 4 bytes} \))
- \( T: 6084341B \) (\( \text{Len}(T) = 32 \text{ bits or } t = 4 \))
- \( B0: 4F101112 \ 13141516 \ 00000000 \ 00000004 \)
- \( B1: 00080001 \ 02030405 \ 06070000 \ 00000000 \)
- \( B2: 20212223 \ 00000000 \ 00000000 \ 00000000 \)
- \( CTR0: 0710111213 \ 141516 \ 00000000 \ 00000000 \)
- \( CTR1: 0710111213 \ 141516 \ 00000000 \ 00000001 \)

Generation of formatted input data blocks \( Bx \) (especially \( B0 \) and \( B1 \)) must be managed by the application.
CCM processing

*Figure 475* describes the CCM implementation within the AES peripheral (encryption example). This mode is selected by writing 100 into the CHMOD[2:0] bitfield of the AES_CR register.

The data input to the generation-encryption process are a valid nonce, a valid payload string, and a valid associated data string, all properly formatted. The CBC chaining mechanism is applied to the formatted plaintext data to generate a MAC, with a known length. Counter mode encryption that requires a sufficiently long sequence of counter blocks as input, is applied to the payload string and separately to the MAC. The resulting ciphertext C is the output of the generation-encryption process on plaintext P.

AES_IVRx registers are used for processing each data block, AES automatically incrementing the CTR counter with a bit length defined by the first block B0. *Table 467* shows how the application must load the B0 data.

### Note:
The AES peripheral in CCM mode supports counters up to 64 bits, as specified by NIST.
A CCM message is processed through the following phases, further described in next subsections:

- **Init phase**: AES processes the first block and prepares the first counter block.
- **Header phase**: AES processes associated data (A), with tag computation only.
- **Payload phase**: IP processes plaintext (P), with tag computation, counter block encryption, and data XOR-ing. It works in a similar way for ciphertext (C).
- **Final phase**: AES generates the message authentication code (MAC).

### CCM Init phase

In this phase, the first block B0 of the CCM message is written into the AES_IVRx register. The AES_DOUTR register does not contain any output data. The recommended sequence is:

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select CCM chaining mode, by setting to 100 the CHMOD[2:0] bitfield of the AES_CR register, and optionally, set the DATATYPE[1:0] bitfield.
3. Indicate the Init phase, by setting to 00 the GCMPH[1:0] bitfield of the AES_CR register.
4. Set the MODE[1:0] bitfield of the AES_CR register to 00 or 10. Although the bitfield is only used in payload phase, it is recommended to set it in the Init phase and keep it unchanged in all subsequent phases.
5. Initialize the AES_KEYRx registers with a key, and initialize AES_IVRx registers with B0 data as described in Table 467.
6. Start the calculation of the counter, by setting to 1 the EN bit of the AES_CR register (EN is automatically reset when the calculation finishes).
7. Wait until the end of computation, indicated by the CCF flag of the AES_SR transiting to 1. Alternatively, use the corresponding interrupt.
8. Clear the CCF flag in the AES_SR register, by setting to 1 the CCF bit of the AES_ICR register.

### CCM header phase

This phase coming after the GCM Init phase must be completed before the payload phase. During this phase, the AES_DOUTR register does not contain any output data. The sequence to execute, identical for encryption and decryption, is:

1. Indicate the header phase, by setting to 01 the GCMPH[1:0] bitfield of the AES_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
2. Enable the AES peripheral by setting the EN bit of the AES_CR register.
3. If it is the last block and the AAD size in the block is inferior to 128 bits, pad the remainder of the block with zeros. Then append the data block into AES in one of ways described in Section 49.4.4: AES procedure to perform a cipher operation. No data is read during this phase.
4. Repeat the step 3 until the last additional authenticated data block is processed.

**Note:** The header phase can be skipped if there is no associated data, that is, Len(A) = 0. The first block of the associated data (B1) must be formatted by software, with the associated data length.
CCM payload phase (encryption or decryption)

This phase, identical for encryption and decryption, is executed after the CCM header phase. During this phase, the encrypted/decrypted payload is stored in the AES_DOUTR register. The sequence to execute is:

1. Indicate the payload phase, by setting to 10 the GCMPH[1:0] bitfield of the AES_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
2. If the header phase was skipped, enable the AES peripheral by setting the EN bit of the AES_CR register.
3. If it is the last data block to encrypt and the plaintext size in the block is inferior to 128 bits, pad the remainder of the block with zeros.
4. Append the data block into AES in one of ways described in Section 49.4.4: AES procedure to perform a cipher operation on page 1919, and read the result.
5. Repeat the previous step till the second-last plaintext block is encrypted or till the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), apply the two previous steps. For the last block, discard the data that is not part of the payload when the last block size is less than 16 bytes.

Note: The payload phase can be skipped if there is no payload data, that is, Len(P) = 0 or Len(C) = Len(T).

Remove LSB_{Len(T)}(C) encrypted tag information when decrypting ciphertext C.

CCM final phase

In this last phase, the AES peripheral generates the GCM authentication tag and stores it in the AES_DOUTR register. The sequence to execute is:

1. Indicate the final phase, by setting to 11 the GCMPH[1:0] bitfield of the AES_CR register.
2. Wait until the end-of-computation flag CCF of the AES_SR register is set.
3. Read four times the AES_DOUTR register: the output corresponds to the CCM authentication tag.
4. Clear the CCF flag of the AES_SR register by setting the CCF bit of the AES_ICR register.
5. Disable the AES peripheral, by clearing the EN bit of the AES_CR register.
6. For authenticated decryption, compare the generated encrypted tag with the encrypted tag padded in the ciphertext.

Note: In this final phase, swapping is applied to tag data read from AES_DOUTR register.

When transiting from the header phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.

Application must mask the authentication tag output with tag length to obtain a valid tag.

Suspend/resume operations in CCM mode

To suspend the processing of a message in header or payload phase, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the AES_CR register. If DMA is not used, make sure that the current computation is completed, which is indicated by the CCF flag of the AES_SR register set to 1.
2. In the payload phase, if DMA is not used, read four times the AES_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag is set in the...
AES_SR register then stop the DMA transfers from the OUT FIFO by clearing the DMAOUTEN bit of the AES_CR register.

3. Clear the CCF flag of the AES_SR register, by setting to 1 the CCF bit of the AES_ICR register.

4. Save the AES_SUSPXR registers (where x is from 0 to 7) in the memory.

5. Save the AES_IVRx registers as, during the data processing, they changed from their initial values.

6. Disable the AES peripheral, by clearing the EN bit of the AES_CR register.

7. Save the current AES configuration in the memory, excluding the initialization vector registers AES_IVRx. Key registers do not need to be saved as the original key value is known by the application.

8. If DMA is used, save the DMA controller status (pointers for IN data transfers, number of remaining bytes, and so on). In the payload phase, pointers for OUT data transfers must also be saved.

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller in order to complete the rest of the FIFO IN transfers. In the payload phase, the rest of the FIFO OUT transfers must also be configured in the DMA controller.

2. Disable the AES peripheral by clearing the EN bit of the AES_CR register.

3. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPXR registers (where x is from 0 to 7).

4. Write the initialization vector register values, previously saved in the memory, back into their corresponding AES_IVRx registers.

5. Restore the initial setting values in the AES_CR and AES_KEYRx registers.

6. Enable the AES peripheral by setting the EN bit of the AES_CR register.

7. If DMA is used, enable AES DMA requests by setting to 1 the DMAINEN bit (and DMAOUTEN bit if in payload phase) of the AES_CR register.

49.4.13 AES operation with shared keys

The AES peripheral can use the SAES peripheral as security co-processor. In this case, secure application prepares the key in the robust SAES peripheral. When ready, the AES application can load this prepared key through a dedicated hardware key bus.

Recommended sequences are described below and in SAES peripheral section Section 50.4.10: SAES operation with shared keys.

1. In SAES peripheral application encrypts the key to be shared, once, in Shared-key mode (KMOD[1:0] = 10).

2. Each time shared key is needed in AES peripheral application needs to decrypt it in SAES peripheral, selecting the same Shared-key mode (KMOD[1:0] = 10).

3. Once the shared key is decrypted and loaded in SAES_KEYRx registers it can be shared with the AES peripheral. Indeed, when shared key must be loaded in AES peripheral, application sets correct KEYSIZE and write KMOD[1:0] = 10 in AES_CR register. When KEYVALID is cleared, the key information is automatically transferred by hardware into AES_KEYRx, with BUSY set in AES_SR.

4. Once transfer is completed BUSY bit is cleared and KEYVALID bit is set in AES_SR register. If KEYVALID is not set when BUSY bit is cleared, or if a key error flag (KEIF) is set it means that an unexpected event occurred during the transfer (for example
hardware fault) or the KEYVALID bit in SAES_SR was cleared before the end of the transfer. When such errors occur, the whole SAES key sharing process must be restarted through the IPRST bits of control registers in both SAES and AES peripherals (see Section 49.4.18 for details).

At that point AES is initialized with a valid, shared key. Application can proceed with the processing of data, setting KMOD[1:0] to 00.

Note: While KMOD[1:0] = 10 and BUSY = 1, if KEYSIZE in AES peripheral is different from the KEYSIZE in SAES peripheral the key sharing fails and KEIF is set in both peripherals.

49.4.14 AES data registers and data swapping

Data input and output

A 128-bit data block is entered into the AES peripheral with four successive 32-bit word writes into the AES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 128-bit data block is retrieved from the AES peripheral with four successive 32-bit word reads from the AES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The 32-bit data word for AES_DINR register or from AES_DOUTR register is organized in big endian order, that is:

- the most significant byte of a word to write into AES_DINR must be put on the lowest address out of the four adjacent memory locations keeping the word to write, or
- the most significant byte of a word read from AES_DOUTR goes to the lowest address out of the four adjacent memory locations receiving the word

For using DMA for input data block write into AES, the four words of the input block must be stored in the memory consecutively and in big-endian order, that is, the most significant word on the lowest address. See Section 49.4.17: AES DMA interface.

Data swapping

The AES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the AES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the AES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through the DATATYPE[1:0] bitfield of the AES_CR register. The selection applies both to the input and the output of the AES core.

For different data swap types, Figure 476 shows the construction of AES processing core input buffer data P127 to P0, from the input data entered through the AES_DINR register, or the construction of the output data available through the AES_DOUTR register, from the AES processing core output buffer data P127 to P0.
Figure 476. 128-bit block construction with respect to data swap

DATATYPE[1:0] = 00: no swapping

DATATYPE[1:0] = 01: 16-bit (half-word) swapping

DATATYPE[1:0] = 10: 8-bit (byte) swapping

DATATYPE[1:0] = 11: bit swapping

Note: The data in AES key registers (AES_KEYRx) and initialization registers (AES_IVRx) are not sensitive to the swap mode selection.

Data padding

Figure 476 also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 48 message bits, with DATATYPE[1:0] = 01
- 56 message bits, with DATATYPE[1:0] = 10
- 34 message bits, with DATATYPE[1:0] = 11
**49.4.15 AES key registers**

The AES_KEYRx write-only registers store the encryption or decryption key bitfield KEY[127:0] or KEY[255:0]. The data to write to each register is organized in the memory in little-endian order, that is, with most significant byte on the highest address (reads are not allowed for security reason).

The key is spread over eight registers as shown in Table 468.

<table>
<thead>
<tr>
<th>AES_KEYR7 [31:0]</th>
<th>AES_KEYR6 [31:0]</th>
<th>AES_KEYR5 [31:0]</th>
<th>AES_KEYR4 [31:0]</th>
<th>AES_KEYR3 [31:0]</th>
<th>AES_KEYR2 [31:0]</th>
<th>AES_KEYR1 [31:0]</th>
<th>AES_KEYR0 [31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>KEY[127:96]</td>
<td>KEY[95:64]</td>
<td>KEY[63:32]</td>
<td>KEY[31:0]</td>
</tr>
</tbody>
</table>

Note: Initiating the key-loading sequence sets the BUSY flag and clears the KEYVALID flag. Once the amount of bits defined by KEYSIZE is transferred to the AES_KEYRx registers, BUSY is cleared, KEYVALID set and the EN bit becomes writable. If an error occurs, BUSY and KEYVALID are cleared and KEIF set (see Section 49.4.18: AES error management for details). For additional information on key modes, refer to Section 49.4.13.

**49.4.16 AES initialization vector registers**

The four AES_IVRx registers keep the initialization vector input bitfield IV[127:0]. The data to write to or to read from each register is organized in the memory in little-endian order, that is, with most significant byte on the highest address. The registers are also ordered from lowest address (AES_IVR0) to highest address (AES_IVR3).

The significance of data in the bitfield depends on the chaining mode selected. When used, the bitfield is updated upon each computation cycle of the AES core.

Write operations to the AES_IVRx registers when the AES peripheral is enabled have no effect to the register contents. For modifying the contents of the AES_IVRx registers, the EN bit of the AES_CR register must first be cleared.

Reading the AES_IVRx registers returns the latest counter value (useful for managing suspend mode).

The AES_IVRx registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield of the AES_CR register.
49.4.17 AES DMA interface

The AES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the AES_CR register.

Data input using DMA

Setting the DMAINEN bit of the AES_CR register enables DMA writing into AES. The AES peripheral then initiates a DMA request during the input phase each time it requires to write a 128-bit block (quadruple word) to the AES_DINR register, as shown in Figure 477.

Note: According to the algorithm and the mode selected, special padding / ciphertext stealing might be required. For example, in case of AES GCM encryption or AES CCM decryption, a DMA transfer must not include the last block. For details, refer to Section 49.4.4: AES procedure to perform a cipher operation.

Data output using DMA

Setting the DMAOUTEN bit of the AES_CR register enables DMA reading from AES. The AES peripheral then initiates a DMA request during the Output phase each time it requires to read a 128-bit block (quadruple word) to the AES_DINR register, as shown in Figure 478.

Note: According to the message size, extra bytes might need to be discarded by application in the last block.
DMA operation in different operating modes

DMA operations are usable when Mode 1 (encryption) or Mode 3 (decryption) are selected via the MODE[1:0] bitfield of the register AES_CR. As in Mode 2 (key derivation) the AES_KEYR[x] registers must be written by software, enabling the DMA transfer through the DMAINEN and DMAOUTEN bits of the AES_CR register have no effect in that mode.

DMA single requests are generated by AES until it is disabled. So, after the data output phase at the end of processing of a 128-bit data block, AES switches automatically to a new data input phase for the next data block, if any.

When the data transferring between AES and memory is managed by DMA, the CCF flag has no use because the reading of the AES_DOUTR register is managed by DMA automatically at the end of the computation phase. The CCF flag must only be cleared when transiting back to data transferring managed by software. See Section 49.4.4: AES procedure to perform a cipher operation, subsection Data append, for details.

49.4.18 AES error management

AES configuration can be changed at any moment by clearing the EN bit of the AES_CR register.

Read error flag (RDERR)

Unexpected read attempt of the AES_DOUTR register sets the RDERR flag of the AES_SR register and the RWEIF flag of the AES_ISR register, and returns zero.

RDERR is triggered during the computation phase or during the input phase.

Note: AES is not disabled upon a RDERR error detection and continues processing.

An interrupt is generated if the RWEIE bit of the AES_IER register is set. For more details, refer to Section 49.5: AES interrupts.

The RDERR and RWEIF flag is cleared by setting the RWEIE bit of the AES_ICR register.

Write error flag (WDERR)

Unexpected write attempt of the AES_DINR register sets the WRERR flag of the AES_SR register and the RWEIF flag of the AES_ISR register, and has no effect on the AES_DINR register. The WRERR is triggered during the computation phase or during the output phase.
Note:  
\textit{AES is not disabled after a WRERR error detection and continues processing.}\n
An interrupt is generated if the RWEIE bit of the AES_IER register is set. For more details, refer to \textit{Section 49.5: AES interrupts}.  

The WRERR and RWEIF flag is cleared by setting the RWEIF bit of the AES_ICR register.

\textbf{Key error interrupt flag (KEIF)}

Failure to load a key into key registers, sets the KEIF flag of the AES_ISR register and clears the KEYVALID bit of the AES_SR register.

The KEIF flag is cleared with corresponding bit of the AES_ICR register. An interrupt is generated if the KEIE bit of the AES_IER register is set. For more details, refer to \textit{Section 49.5: AES interrupts}.

The possible sources of key errors are:

- Key writing sequence error: an incorrect sequence has been detected when writing key registers. See \textit{Section 49.4.15: AES key registers} for details.
- Key sharing size mismatch: error is triggered when KMOD[1:0] = 10 and application sets a KEYSIZE information in AES peripheral that does not match the KEYSIZE stored in SAES peripheral.
- Key sharing error: the copy of key registers from SAES peripheral to AES failed. See \textit{Section 49.4.13: AES operation with shared keys} for details.

Upon a key sharing error, reset both AES and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

\textit{Note: For any key error, clear KEIF flag prior to re-configuring AES.}

\textbf{49.5 AES interrupts}

Individual maskable interrupt sources generated by the AES peripheral signal the following events:

- computation completed
- read error
- write error
- key error

These sources are combined into a common interrupt signal from the AES peripheral that connects to the Arm® Cortex® interrupt controller. Each can individually be enabled/disabled, by setting/clearing the corresponding enable bit of the AES_IER register, and cleared by setting the corresponding bit of the AES_ICR register.

The status of each can be read from the AES_SR and AES_ISR registers. \textit{Table 469} gives a summary of the interrupt sources, their event flags and enable bits.
The tables below summarize the latency to process a 128-bit block for each mode of operation.

### Table 469. AES interrupt requests

1. Data insertion can include wait states forced by AES on the AHB bus (maximum 3 cycles, typical 1 cycle).
49.7 AES registers

49.7.1 AES control register (AES_CR)

Address offset: 0x00
Reset value: 0x0000 0000

|-------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-----|----|----|----|----|----|

Bit 31 **IPRST**: AES peripheral software reset

Setting the bit resets the AES peripheral, putting all registers to their default values, except the IPRST bit itself. Hence, any key-relative data is lost. For this reason, it is recommended to set the bit before handing over the AES to a less secure application.

The bit must be low while writing any configuration registers.

Bits 30:26 Reserved, must be kept at reset value.

Bits 25:24 **KMOD[1:0]**: Key mode selection

The bitfield defines how the AES key can be used by the application:

- 00: Normal key
- 10: Shared key from SAES co-processor
- Others: Reserved

With normal key selection, the key registers are freely usable, no specific usage or protection applies to AES_DIN and AES_DOUT registers.

With selection of shared key from SAES co-processor, the AES peripheral automatically loads its key registers with the data stored in the key registers of the SAES peripheral. The key value is available in key registers when BUSY bit is cleared and KEYVALID is set in the AES_SR register. Key error flag KEIF is set otherwise in the AES_ISR register.

The bitfield must be set only when KEYSIZE is correct, and when a shared key decryption sequence has been successfully completed in SAES co-processor.

Attempts to write the bitfield are ignored when the BUSY flag of AES_SR register is set, as well as when the EN bit of the AES_CR register is set before the write access and it is not cleared by that write access.

Bits 23:20 **NPBLB[3:0]**: Number of padding bytes in last block

The bitfield sets the number of padding bytes in last block of payload:

- 0000: All bytes are valid (no padding)
- 0001: Padding for one least-significant byte of last block
- ...
- 1111: Padding for 15 least-significant bytes of last block

Bit 19 Reserved, must be kept at reset value.
Bit 18 **KEYSIZE**: Key size selection
   This bitfield defines the length of the key used in the AES cryptographic core, in bits:
   0: 128
   1: 256
   Attempts to write the bit are ignored when the BUSY flag of AES_SR register is set, as well as when
   the EN bit of the AES_CR register is set before the write access and it is not cleared by that write
   access.

Bit 17 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bits 14:13 **GCMPH[1:0]**: GCM or CCM phase selection
   This bitfield selects the phase of GCM, GMAC or CCM algorithm:
   00: Init phase
   01: Header phase
   10: Payload phase
   11: Final phase
   The bitfield has no effect if other than GCM, GMAC or CCM algorithms are selected (through the
   ALGOMODE bitfield).

Bit 12 **DMAOUTEN**: DMA output enable
   This bit enables/disables data transferring with DMA, in the output phase:
   0: Disable
   1: Enable
   When the bit is set, DMA requests are automatically generated by AES during the output data
   phase. This feature is only effective when Mode 1 or Mode 3 is selected through the MODE[1:0]
   bitfield. It is not effective for Mode 2 (key derivation).

Bit 11 **DMAINEN**: DMA input enable
   This bit enables/disables data transferring with DMA, in the input phase:
   0: Disable
   1: Enable
   When the bit is set, DMA requests are automatically generated by AES during the input data phase.
   This feature is only effective when Mode 1 or Mode 3 is selected through the MODE[1:0] bitfield. It is
   not effective for Mode 2 (key derivation).

Bits 10:7 Reserved, must be kept at reset value.

Bits 16, 6:5 **CHMOD[2:0]**: Chaining mode selection
   This bitfield selects the AES chaining mode:
   000: Electronic codebook (ECB)
   001: Cipher-block chaining (CBC)
   010: Counter mode (CTR)
   011: Galois counter mode (GCM) and Galois message authentication code (GMAC)
   100: Counter with CBC-MAC (CCM)
   others: Reserved
   Attempts to write the bitfield are ignored when the BUSY flag of AES_SR register is set, as well as when
   the EN bit of the AES_CR register is set before the write access and it is not cleared by that write access.
49.7.2 AES status register (AES_SR)

Address offset: 0x04
Reset value: 0x0000 0000

Bits 31:8 Reserved, must be kept at reset value.
Bit 7 **KEYVALID**: Key Valid flag

This bit is set by hardware when the amount of key information defined by KEYSIZE in AES_CR has been loaded in AES_KEYx key registers.

0: No valid key information is available in key registers. EN bit in AES_CR cannot be set.
1: Valid key information, defined by KEYSIZE in AES_CR, is loaded in key registers.

In normal mode when KEYSEL equals to zero, the application must write the key registers in the correct sequence, otherwise the KEIF flag of the AES_ISR register is set and KEYVALID stays at zero.

When KEYSEL is different from zero the BUSY flag is automatically set by AES. When key is loaded successfully, the BUSY flag is cleared and KEYVALID set. Upon an error, the KEIF flag of the AES_ISR register is set, the BUSY flag cleared and KEYVALID kept at zero.

When the KEIF flag is set, the application must clear it through the AES_ICR register, otherwise KEYVALID cannot be set. See the KEIF bit description for more details.

For more information on key loading, refer to Section 49.4.15: AES key registers.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **BUSY**: Busy

This flag indicates whether AES is idle or busy during GCM payload encryption phase:

0: Idle
1: Busy

When the flag indicates “idle”, the current GCM encryption processing may be suspended to process a higher-priority message. In other chaining modes, or in GCM phases other than payload encryption, the flag must be ignored for the suspend process.

The flag is set when transferring a shared key from SAES peripheral.

Bit 2 **WRERR**: Write error

This flag indicates the detection of an unexpected write operation to the AES_DINR register (during computation or data output phase):

0: Not detected
1: Detected

The flag is set by hardware. It is cleared by software upon setting the RWEIF bit of the AES_ICR register.

Upon the flag setting, an interrupt is generated if enabled through the RWEIE bit of the AES_ICR register.

The flag setting has no impact on the AES operation. Unexpected write is ignored.

Bit 1 **RDERR**: Read error flag

This flag indicates the detection of an unexpected read operation from the AES_DOUTR register (during computation or data input phase):

0: Not detected
1: Detected

The flag is set by hardware. It is cleared by software upon setting the RWEIF bit of the AES_ICR register.

Upon the flag setting, an interrupt is generated if enabled through the RWEIE bit of the AES_ICR register.

The flag setting has no impact on the AES operation. Unexpected read returns zero.

Bit 0 **CCF**: Computation completed flag

This bit mirrors the CCF bit of the AES_ISR register.
49.7.3 AES data input register (AES_DINR)

Address offset: 0x08
Reset value: 0x0000 0000
Only 32-bit write access type is supported.

Bits 31:0 \textbf{DIN}[31:0]: Input data word

A four-fold sequential write to this bitfield during the input phase results in writing a complete 128-bit block of input data to the AES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 128-bit input buffer.

The data signification of the input data block depends on the AES operating mode:
- \textbf{Mode 1} (encryption): plaintext
- \textbf{Mode 2} (key derivation): the bitfield is not used (AES\_KEYRx registers used for input)
- \textbf{Mode 3} (decryption): ciphertext

The data swap operation is described in Section 49.4.14: AES data registers and data swapping on page 1943.

49.7.4 AES data output register (AES_DOUTR)

Address offset: 0x0C
Reset value: 0x0000 0000
Only 32-bit read access type is supported.
Bits 31:0 **DOUT[31:0]: Output data word**

This read-only bitfield fetches a 32-bit output buffer. A four-fold sequential read of this bitfield, upon the computation completion (CCF set), virtually reads a complete 128-bit block of output data from the AES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield. Data weights from the first to the fourth read operation are: [127:96], [95:64], [63:32], and [31:0]. The data signification of the output data block depends on the AES operating mode:

- **Mode 1** (encryption): ciphertext
- **Mode 2** (key derivation): the bitfield is not used
- **Mode 3** (decryption): plaintext

The data swap operation is described in Section 49.4.14: AES data registers and data swapping on page 1943.

### 49.7.5 AES key register 0 (AES_KEYR0)

**Address offset:** 0x10  
**Reset value:** 0x0000 0000

</tbody>
</table>

**Bits 31:0 **KEY[31:0]: Cryptographic key, bits [31:0]**

This write-only bitfield contains the bits [31:0] of the AES encryption or decryption key, depending on the operating mode:

- In **Mode 1** (encryption), **Mode 2** (key derivation): the value to write into the bitfield is the encryption key.
- In **Mode 3** (decryption): the value to write into the bitfield is the encryption key to be derived before being used for decryption.

The AES_KEYRx registers may be written only when KEYSIZE value is correct and when the AES peripheral is disabled (EN bit of the AES_CR register cleared). A special writing sequence is also required, as described in KEYVALID bit of the AES_SR register. Note that, if KMOD[1:0] = 10 (shared key), the key is directly loaded from SAES peripheral to AES_KEYRx registers (hence writes to key register is ignored and KEIF is set).

Refer to Section 49.4.15: AES key registers on page 1945 for more details.

**Note:** The key registers from 4 to 7 are used only when the key length of 256 bits is selected. They have no effect when the key length of 128 bits is selected (only key registers 0 to 3 are used in that case).

49.7.17 **AES suspend registers (AES_SUSPxR)**

Address offset: 0x040 + 0x4 * x, (x = 0 to 7)  
Reset value: 0x0000 0000

These registers contain the complete internal register states of the AES processor when the AES processing of the current task is suspended to process a higher-priority task.  
Upon suspend, the software reads and saves the AES_SUSPxR register contents (where x is from 0 to 7) into memory, before using the AES processor for the higher-priority task. Upon completion, the software restores the saved contents back into the corresponding suspend registers, before resuming the original task.

**Note:** These registers are used only when GCM, GMAC, or CCM chaining mode is selected.  
These registers can be read only when AES is enabled. Reading these registers while AES is disabled returns 0x0000 0000.

Bits 31:3 Reserved, must be kept at reset value.

- **KEIE**: Key error interrupt enable
  - This bit enables or disables (masks) the AES interrupt generation when KEIF (key error flag) is set.
  - 0: Disabled (masked)
  - 1: Enabled (not masked)

- **RWEIE**: Read or write error interrupt enable
  - This bit enables or disables (masks) the AES interrupt generation when RWEIF (read and/or write error flag) is set.
  - 0: Disabled (masked)
  - 1: Enabled (not masked)

- **CCFIE**: Computation complete flag interrupt enable
  - This bit enables or disables (masks) the AES interrupt generation when CCF (computation complete flag) is set.
  - 0: Disabled (masked)
  - 1: Enabled (not masked)

49.7.19 AES interrupt status register (AES_ISR)

<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 31:3 Reserved, must be kept at reset value.
Bit 2 **KEIF**: Key error interrupt flag
This read-only bit is set by hardware when key information failed to load into key registers.
0: No key error detected
1: Key information failed to load into key registers
Setting the corresponding bit of the AES_ICR register clears the KEIF and generates interrupt if the KEIE bit of the AES_IER register is set.
KEIF is triggered upon any of the following errors:
– AES_KEYRx register write does not respect the correct order. (For KEYSIZE = 0, AES_KEYR0 then AES_KEYR1 then AES_KEYR2 then AES_KEYR3 register, or reverse. For KEYSIZE = 1, AES_KEYR0 then AES_KEYR1 then AES_KEYR2 then AES_KEYR3 then AES_KEYR4 then AES_KEYR5 then AES_KEYR6 then AES_KEYR7, or reverse). KEIF must be cleared by the application software, otherwise KEYVALID cannot be set.

Bit 1 **RWEIF**: Read or write error interrupt flag
This read-only bit is set by hardware when a RDERR or a WRERR error flag is set in the AES_SR register.
0: No read or write error detected
1: Read or write error detected (see AES_SR register for details)
RWEIF bit is cleared when application sets the corresponding bit of AES_ICR register. An interrupt is generated if the RWEIE bit has been previously set in the AES_IER register.
This flags has no meaning when key derivation mode is selected.

Bit 0 **CCF**: Computation complete flag
This flag indicates whether the computation is completed:
0: Not completed
1: Completed
The flag is set by hardware upon the completion of the computation. It is cleared by software, upon setting the CCF bit of the AES_ICR register.
Upon the flag setting, an interrupt is generated if enabled through the CCFIE bit of the AES_IER register.
The flag is significant only when the DMAOUTEN bit is 0. It may stay high when DMA_EN is 1.

### 49.7.20 AES interrupt clear register (AES_ICR)

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF**: Key error interrupt flag clear
- Setting this bit clears the KEIF status bit of the AES_ISR register.

Bit 1 **RWEIF**: Read or write error interrupt flag clear
- Setting this bit clears the RWEIF status bit of the AES_ISR register, and both RDERR and WRERR flags in the AES_SR register.

Bit 0 **CCF**: Computation complete flag clear
- Setting this bit clears the CCF status bit of the AES_SR and AES_ISR registers.

Refer to Section 2.3 on page 139 for the register boundary addresses.
50 Secure AES coprocessor (SAES)

This section only applies to STM32U545/585/5Ax/5Gx devices.

50.1 Introduction

The secure AES coprocessor (SAES) encrypts or decrypts data, using an algorithm and implementation fully compliant with the advanced encryption standard (AES) defined in Federal information processing standards (FIPS) publication 197. It incorporates a protection against side-channel attacks (SCA), including differential power analysis (DPA), certified SESIP and PSA security assurance level 3.

The peripheral supports ECB, and CBC chaining modes for key sizes of 128 or 256 bits, as well as special modes such as hardware secret key encryption/decryption (Wrapped-key mode) and key sharing with faster AES peripheral (Shared-key mode).

SAES has the possibility to load by hardware STM32 hardware secret keys (boot hardware key BHK and derived hardware unique key DHUK), usable but not readable by application. SAES is an AMBA AHB slave peripheral accessible through 32-bit single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels required). It is hardware-linked with the true random number generator (TRNG) and with the AES peripheral.
50.2 SAES main features

- Compliance with NIST "Advanced encryption standard (AES), FIPS publication 197" from November 2001
- 128-bit data block processing
- Support for cipher key lengths of 128-bit and 256-bit
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
- 528 or 743 clock cycle latency in ECB mode for processing one 128-bit block of data with, respectively, 128-bit or 256-bit key
- Integrated round key scheduler to compute the last round key for ECB/CBC decryption
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only
- 256-bit write-only register for storing the cryptographic key (eight 32-bit registers)
  - Optional hardware loading of two hardware secret keys (BHK, DHUK) that can be XOR-ed together
- 128-bit register for storing initialization vector (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control with support of single-transfer direct memory access (DMA) using two channels (one for incoming data, one for processed data)
- Data-swapping logic to support 1-, 8-, 16- or 32-bit data
- Possibility for software to suspend a message if SAES needs to process another message with a higher priority, then resume the original message
- Security context enforcement for keys
- Hardware secret key encryption/decryption (Wrapped-key mode)
- Protection against side-channel attacks (SCA), incl. differential power analysis (DPA), certified SESIP and PSA security assurance level 3
- Hardware key sharing with faster AES peripheral (Shared-key mode), controlled by SAES

50.3 SAES implementation

The devices have one SAES and one AES peripheral, implemented as shown in the following table.

</tbody>
</table>
The SAES cryptographic core consists of the following components:

- AES core algorithm (AEA)
- key input
- initialization vector (IV) input
- chaining algorithm logic (XOR)

The SAES core works on 128-bit data blocks (four words) with 128-bit or 256-bit key length. Depending on the chaining mode, the SAES requires zero or one 128-bit initialization vector IV.

The SAES features the following modes of operation:

- **Mode 1:** Plaintext encryption using a key stored in the SAES_KEYRx registers or read using a dedicated hardware bus.
- **Mode 2:** ECB or CBC decryption key preparation. It must be used prior to selecting Mode 3 with ECB or CBC chaining modes. The key prepared for decryption is stored automatically in the SAES_KEYRx registers. Now the SAES peripheral is ready to switch to Mode 3 for executing data decryption.
- **Mode 3:** Ciphertext decryption using a key stored in the SAES_KEYRx registers. When ECB and CBC chaining modes are selected, the key must be prepared beforehand, through Mode 2.

**Note:** Mode 2 is only used when performing ECB and CBC decryption.

The operating mode is selected by programming the MODE[1:0] bitfield of the SAES_CR register. It may be done only when the SAES peripheral is disabled.
Secure AES coprocessor (SAES)

Special key operation is selected using the KMOD[1:0] bitfield of the SAES_CR register. See Section 50.4.10 and Section 50.4.9 for details.

Typical data processing

Typical usage of the SAES is described in Section 50.4.4: SAES procedure to perform a cipher operation on page 1969.

Note: The outputs of the intermediate AEA stages are never revealed outside the cryptographic boundary, with the exclusion of the IVI bitfield.

Chaining modes

The following chaining modes are supported by SAES, selected through the CHMOD[2:0] bitfield of the SAES_CR register:

- Electronic code book (ECB)
- Cipher block chaining (CBC)

Note: The chaining mode may be changed only when SAES is disabled (bit EN of the SAES_CR register cleared).

Principle of each SAES chaining mode is provided in the following subsections.

Detailed information is in dedicated sections, starting from Section 50.4.8: SAES basic chaining modes (ECB, CBC).

Electronic codebook (ECB) mode

Figure 480. ECB encryption and decryption principle

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately.
Note: For decryption, a special key scheduling is required before processing the first block.

Cipher block chaining (CBC) mode

Figure 481. CBC encryption and decryption principle

In CBC mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing.

Note: For decryption, a special key scheduling is required before processing the first block.

50.4.4 SAES procedure to perform a cipher operation

Introduction

A typical cipher operation is explained below. Detailed information is provided in sections starting from Section 50.4.8: SAES basic chaining modes (ECB, CBC).
Initialization of SAES

To initialize SAES, first disable it by clearing the EN bit of the SAES_CR register. Then perform the following steps in any order (except KEYSIZE):

- Verify that BUSY = 0 in SAES_SR (no RNG random number fetch in progress), and RNGEIF = 0 in SAES_ISR (no random number fetching error flagged).
- Configure the SAES mode, by programming the MODE[1:0] bitfield of the SAES_CR register.
  - For encryption, select Mode 1 (MODE[1:0] = 00).
  - For decryption, select Mode 2 (MODE[1:0] = 01) then Mode 3 (MODE[1:0] = 10), as described in Section 50.4.8: SAES basic chaining modes (ECB, CBC).
- Select the chaining mode, by programming the CHMOD[2:0] bitfield of the SAES_CR register. Select normal key mode by setting KMOD[1:0] to 00. For the other KMOD[1:0] values, refer to Section 50.4.9 and Section 50.4.10.
- Configure the data type (1-, 8-, 16- or 32-bit), with the DATATYPE[1:0] bitfield in the SAES_CR register.
- When it is required (for example in CBC chaining mode), write the initialization vector into the SAES_IVRx registers.
- Configure the key size (128-bit or 256-bit), with the KEYSIZE bitfield of the SAES_CR register. This step must be done before writing into key registers or selecting a different key source using KEYSEL. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit of the SAES_CR register must also be set.
- Write a symmetric key into the SAES_KEYRx registers (4 or 8 registers depending on the key size). Alternatively, select a key source different from the key registers by setting KEYSEL[2:0] to a value different from 0x0. See Section 50.4.12 for details.

Note: SAES sets KEYVALID in SAES_SR when key information defined by KEYSIZE is loaded in SAES_KEYRx.

Data append

This section describes different ways of appending data for processing, where the size of data to process is not a multiple of 128 bits when KMOD[1:0] = 00. For other KMOD[1:0] values refer to Section 50.4.10 and Section 50.4.9.

Data append through polling

This method uses flag polling to control the data append through the following sequence:

1. Enable the SAES peripheral by setting the EN bit of the SAES_CR register.
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the SAES_DINR register.
   b) Wait until the status flag CCF is set in the SAES_SR, then read the four data words from the SAES_DOUTR register.
   c) Clear the CCF flag, by setting the CCF bit of the SAES_ISR register.
   d) If the data block just processed is the second-last block of the message and the significant data in the last block to process is inferior to 128 bits, refer to Section 50.4.6: SAES ciphertext stealing and data padding.
3. As it is the last block, follow the instructions in Section 50.4.6: SAES ciphertext stealing and data padding, then disable the SAES peripheral by clearing the EN bit of the SAES_CR register.
Note:  Up to three wait cycles are automatically inserted between two consecutive writes to the SAES_DINR register, to allow sending the key to the AES co-processor.

Data append using interrupt

The method uses interrupt from the SAES peripheral to control the data append, through the following sequence:
1. Enable interrupts from SAES by setting the CCFIE bit of the SAES_IER register.
2. Enable the SAES peripheral by setting the EN bit of the SAES_CR register.
3. Write first four input data words into the SAES_DINR register.
4. Handle the data in the SAES interrupt service routine, upon interrupt:
   a) Read four output data words from the SAES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCF bit of the SAES_ISR register.
   c) If the data block just processed is the second-last block of a message and the significant data in the last block to process is inferior to 128 bits, refer to Section 50.4.6: SAES ciphertext stealing and data padding. Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, follow if needed Section 50.4.6: SAES ciphertext stealing and data padding, then disable the SAES peripheral by clearing the EN bit of the SAES_CR register and quit the interrupt service routine.
   e) Write next four input data words into the SAES_DINR register and quit the interrupt service routine.

Note:  SAES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two SAES computations.

Data append using DMA

With this method, all the transfers and processing are managed by DMA and SAES. To use the method, proceed as follows:
1. If the last block to process is inferior to 128 bits, refer to Section 50.4.6: SAES ciphertext stealing and data padding to prepare the last four-word data block.
2. Configure the DMA controller so as to transfer the data to process from the memory to the SAES peripheral input and the processed data from the SAES peripheral output to the memory, as described in Section 50.4.14: SAES DMA interface. Configure the DMA controller so as to generate an interrupt on transfer completion.
3. Enable the SAES peripheral by setting the EN bit of the SAES_CR register
4. Enable DMA requests by setting the DMAINEN and DMAOUTEN bits of the SAES_CR register.
5. Upon DMA interrupt indicating the transfer completion, get the SAES-processed data from the memory.

Note:  The CCF flag has no use with this method, because the reading of the SAES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.
50.4.5 **SAES decryption round key preparation**

Internal key schedule is used to generate AES round keys. In AES encryption, the round 0 key is the one stored in the key registers. AES decryption must start using the last round key. As the encryption key is stored in memory, a special key scheduling must be performed to obtain the decryption key.

Recommended method is to select the Mode 2 by setting to 01 the MODE[1:0] bitfield of the SAES_CR (key process only), then proceed with the decryption by setting MODE[1:0] to 10 (Mode 3, decryption only). Mode 2 usage is described below:

1. Verify that BUSY = 0 in SAES_SR (no RNG random number fetch in progress).
2. Disable the SAES peripheral by clearing the EN bit of the SAES_CR register.
3. Select Mode 2 by setting to 01 the MODE[1:0] bitfield of the SAES_CR. The CHMOD[2:0] bitfield is not significant in this case because this key derivation mode is independent of the chaining algorithm selected. Select normal key mode by setting KMOD[1:0] to 00. For decryption with other KMOD[1:0] values, refer to Section 50.4.10 and Section 50.4.9.
4. Set key length to 128 or 256 bits, via KEYSIZE bit of SAES_CR register. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit of the SAES_CR register must also be set.
5. Write the SAES_KEYRx registers (128 or 256 bits) with encryption key, or, alternatively, select a key source different from the key registers, through KEYSEL[2:0]. Refer to Section 50.4.12: SAES key registers for details. Writes to the SAES_IVRx registers have no effect.
6. Enable the SAES peripheral, by setting the EN bit of the SAES_CR register.
7. Wait until the CCF flag is set in the SAES_SR register.
8. Clear the CCF flag. Derived key is available in AES core, ready to use for decryption.

**Note:** The SAES is disabled by hardware when the derivation key is available. To restart a derivation key computation, repeat steps 5, 6, 7, and 8.

**Note:** The operation of the key preparation lasts 200 or 324 clock cycles, depending on the key size (128- or 256-bit).

50.4.6 **SAES ciphertext stealing and data padding**

When using SAES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (128 bits), ciphertext stealing techniques are used, such as those described in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode. Since the SAES peripheral does not support such techniques, the application must complete the last block of input data using data from the second last block.

**Note:** Ciphertext stealing techniques are not documented in this reference manual.

**Note:** Padding data are swapped in a similar way as normal data, according to the DATATYPE[1:0] field of the SAES_CR register (see Section 50.4.11: SAES data registers and data swapping for details).
50.4.7 SAES task suspend and resume

A message can be suspended if another message with a higher priority must be processed. When this highest priority message is sent, the suspended message can resume in both encryption or decryption mode.

Suspend/resume operations do not break the chaining operation and the message processing can resume as soon as SAES is enabled again to receive the next data block. Figure 482 gives an example of suspend/resume operation: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

**Figure 482. Example of suspend mode management**

A detailed description of suspend/resume operations is in the sections dedicated to each SAES mode.

50.4.8 SAES basic chaining modes (ECB, CBC)

**Overview**

This section gives a brief explanation of the four basic operation modes provided by the SAES core: ECB encryption, ECB decryption, CBC encryption and CBC decryption. For detailed information, refer to the FIPS publication 197 from November 26, 2001.
Figure 483 illustrates the electronic codebook (ECB) encryption.

**Figure 483. ECB encryption**

In ECB encrypt mode, the 128-bit plaintext input data block \( P_x \) in the SAES_DINR register first goes through bit/byte/half-word swapping. The swap result \( I_x \) is processed with the AES core set in encrypt mode, using a 128- or 256-bit key. The encryption result \( O_x \) goes through bit/byte/half-word swapping, then is stored in the SAES_DOUTR register as 128-bit ciphertext output data block \( C_x \). The ECB encryption continues in this way until the last complete plaintext block is encrypted.

Figure 484 illustrates the electronic codebook (ECB) decryption.

**Figure 484. ECB decryption**

To perform an AES decryption in the ECB mode, the secret key has to be prepared by collecting the last-round encryption key (which requires to first execute the complete key schedule for encryption), and using it as the first-round key for the decryption of the ciphertext. This preparation is supported by the AES core.

In ECB decrypt mode, the 128-bit ciphertext input data block \( C_1 \) in the SAES_DINR register first goes through bit/byte/half-word swapping. The keying sequence is reversed compared to that of the ECB encryption. The swap result \( I_1 \) is processed with the AES core set in decrypt mode, using the formerly prepared decryption key. The decryption result goes through bit/byte/half-word swapping, then is stored in the SAES_DOUTR register as 128-bit plaintext output data block \( P_1 \). The ECB decryption continues in this way until the last complete ciphertext block is decrypted.
Figure 485 illustrates the cipher block chaining (CBC) encryption.

**Figure 485. CBC encryption**

In CBC encrypt mode, the first plaintext input block, after bit/byte/half-word swapping (P1'), is XOR-ed with a 128-bit IVI bitfield (initialization vector and counter), producing the I1 input data for encrypt with the AES core, using a 128- or 256-bit key. The resulting 128-bit output block O1, after swapping operation, is used as ciphertext C1. The O1 data is then XOR-ed with the second-block plaintext data P2' to produce the I2 input data for the AES core to produce the second block of ciphertext data. The chaining of data blocks continues in this way until the last plaintext block in the message is encrypted.

If the message size is not a multiple of 128 bits, the final partial data block is encrypted in the way explained in *Section 50.4.6: SAES ciphertext stealing and data padding.*

Figure 486 illustrates the cipher block chaining (CBC) decryption.

**Figure 486. CBC decryption**

In CBC decrypt mode, like in ECB decrypt mode, the secret key must be prepared to perform an AES decryption.

After the key preparation process, the decryption goes as follows: the first 128-bit ciphertext block (after the swap operation) is used directly as the AES core input block I1 for decrypt operation, using the 128-bit or 256-bit key. Its output O1 is XOR-ed with the 128-bit IVI field (that must be identical to that used during encryption) to produce the first plaintext block P1.
The second ciphertext block is processed in the same way as the first block, except that the I1 data from the first block is used in place of the initialization vector.

The decryption continues in this way until the last complete ciphertext block is decrypted. If the message size is not a multiple of 128 bits, the final partial data block is decrypted in the way explained in Section 50.4.6: SAES ciphertext stealing and data padding.

For more information on data swapping, refer to Section 50.4.11: SAES data registers and data swapping.

ECB/CBC encryption sequence

The sequence of events to perform an ECB/CBC encryption (more detail in Section 50.4.4):
1. Verify that BUSY = 0 in SAES_SR (no RNG random number fetch in progress).
2. Disable the SAES peripheral by clearing the EN bit of the SAES_CR register.
3. Select the Mode 1 by setting to 00 the MODE[1:0] bitfield of the SAES_CR register and select ECB or CBC chaining mode by setting the CHMOD[2:0] bitfield of the SAES_CR register to 000 or 001, respectively. Data type can also be defined, using DATATYPE[1:0] bitfield. Select normal key mode by setting KMOD[1:0] to 00. For encryption with other KMOD[1:0] values, refer to Section 50.4.10 and Section 50.4.9.
4. Select 128- or 256-bit key length through the KEYSIZE bit of the SAES_CR register. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit of the SAES_CR register must also be set.
5. Write the SAES_KEYRx registers (128 or 256 bits) with encryption key. Alternatively, select a key source different from the key registers, through KEYSEL[2:0]. Refer to Section 50.4.12: SAES key registers for details. Fill the SAES_IVRx registers with the initialization vector data if CBC mode has been selected.
6. Enable the SAES peripheral by setting the EN bit of the SAES_CR register.
7. Write the SAES_DINR register four times to input the plaintext (MSB first), as shown in Figure 487.
8. Wait until the CCF flag is set in the SAES_SR register.
9. Read the SAES_DOUTR register four times to get the ciphertext (MSB first) as shown in Figure 487. Then clear the CCF flag by setting the CCF bit of the SAES_ISR register.
10. Repeat steps 7-8-9 to process all the blocks with the same encryption key.

Figure 487. ECB/CBC encryption (Mode 1)

Input phase
4 write operations into AES_DINR[31:0]

Computation phase
Wait until flag CCF = 1

Output phase
4 read operations of AES_DOUTR[31:0]

PT = plaintext = 4 words (PT3, … , PT0)
CT = ciphertext = 4 words (CT3, … , CT0)
**ECB/CBC decryption sequence**

The sequence of events to perform an AES ECB/CBC decryption is as follows (More detail in *Section 50.4.4*). Select normal key mode by setting KMOD[1:0] to 00. For decryption with other KMOD[1:0] values, refer to *Section 50.4.10* and *Section 50.4.9*.

1. Follow the steps described in *Section 50.4.5: SAES decryption round key preparation*, in order to prepare the decryption key in AES core.
2. Select the Mode 3 by setting to 10 the MODE[1:0] bitfield of the SAES_CR register and select ECB or CBC chaining mode by setting the CHMOD[2:0] bitfield of the SAES_CR register to 000 or 001, respectively. Data type can also be defined, using DATATYPE[1:0] bitfield. KEYSIZE and KMOD[1:0] bitfields must be kept as-is.
3. Write the SAES_IVRx registers with the initialization vector (required in CBC mode only).
4. Enable SAES by setting the EN bit of the SAES_CR register.
5. Write the SAES_DINR register four times to input the cipher text (MSB first), as shown in *Figure 488*.
6. Wait until the CCF flag is set in the SAES_SR register.
7. Read the SAES_DOUTR register four times to get the plain text (MSB first), as shown in *Figure 488*. Then clear the CCF flag by setting the CCF bit of the SAES_ISR register.
8. Repeat steps 5-6-7 to process all the blocks encrypted with the same key.

**Figure 488. ECB/CBC decryption (Mode 3)**

Suspend/resume operations in ECB/CBC modes

The following sequences are valid for normal key mode (KMOD[1:0] = 00).

**To suspend the processing of a message**, proceed as follows:

1. If DMA is used, stop the SAES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the SAES_CR register.
2. If DMA is not used, read four times the SAES_DOUTR register to save the last processed block. If DMA is used, wait until the CCF flag is set in the SAES_SR register then stop the DMA transfers from the OUT FIFO by clearing the DMAOUTEN bit of the SAES_CR register.
3. If DMA is not used, poll the CCF flag of the SAES_SR register until it becomes 1 (computation completed).
4. Clear the CCF flag by setting the CCF bit of the SAES_ISR register.
5. Save initialization vector registers (only required in CBC mode as SAES_IVRx registers are altered during the data processing).

6. Disable the SAES peripheral by clearing the bit EN of the SAES_CR register.

7. Save the SAES_CR register and clear the key registers if they are not needed, to process the higher priority message.

8. If DMA is used, save the DMA controller status (pointers for IN and OUT data transfers, number of remaining bytes, and so on).

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller so as to complete the rest of the FIFO IN and FIFO OUT transfers.

2. Disable the SAES peripheral by clearing the EN bit of the SAES_CR register.

3. Restore SAES_CR register (with correct KEYSIZE) then restore SAES_KEYRx registers. Alternatively, select a key source different from key registers, using KEYSEL[2:0]. Refer to Section 50.4.12: SAES key registers for details.

4. Prepare the decryption key as described in Section 50.4.5: SAES decryption round key preparation (only required for ECB or CBC decryption).

5. Restore SAES_IVRx registers using the saved configuration (only required in CBC mode).

6. Enable the SAES peripheral by setting the EN bit of the SAES_CR register.

7. If DMA is used, enable SAES DMA transfers by setting the DMAINEN and DMAOUTEN bits of the SAES_CR register.

50.4.9 SAES operation with wrapped keys

SAES peripheral can wrap (encrypt) and unwrap (decrypt) application keys using hardware-secret key DHUK, XOR-ed or not with application key BHK. With this feature, AES keys can be made usable by application software without being exposed in clear-text (unencrypted).

Wrapped key sequences are too small to be suspended/resumed. SAES cannot unwrap a key using an unwrapped key.

Figure 489 summarizes the operation with wrapped keys. To protect the wrapped key, select DHUK by setting KEYSEL[2:0] to 001 or 100. Alternatively, select BHK by setting KEYSEL to 010 if the corresponding registers are read/write-locked in the TAMP peripheral.
### Encryption in Wrapped-key mode

Recommended sequence to wrap (that is, encrypt) a key is described below:

1. Verify that BUSY = 0 in SAES_SR (no RNG random number fetch in progress).
2. Disable the SAES peripheral by clearing the EN bit of the SAES_CR register.
3. In SAES_CR register, select the Mode 1 (encryption) by setting to 00 the MODE[1:0] bitfield, and select ECB or CBC chaining mode by setting CHMOD[2:0] bitfield to 000 or 001, respectively. Data type can be defined as 32-bit, with DATATYPE[1:0] bitfield set to 00. Key size must be properly configured using KEYSIZE bit, and KMOD[1:0] bitfield must be set as 01 (wrapped key). The KEYSIZE information is used both for the encryption key and for the key to be encrypted.
4. Write the SAES_IVRx registers with the initialization vector if CBC mode has been selected in previous step.
5. Select the DHUK by setting the KEYSEL[2:0] bitfield of the SAES_CR register to 001 or 100. Upon successful key loading BUSY bit is cleared and KEYVALID bit is set in SAES_SR register. Refer to Section 50.4.12: SAES key registers for detail on KEYSEL = 100 usage.
6. Enable SAES by setting the EN bit of the SAES_CR register.
7. Write the SAES_DINR register four times to input the key to encrypt (MSB first, see Table 475 on page 1985).
8. Wait until the CCF flag is set in the SAES_SR register.
9. Get the encrypted key (MSB first) by reading the SAES_DOUTR register four times. Then clear the CCF flag by setting the CCF bit in SAES_ICR register.
10. Repeat steps 6 to 8 if KEYSIZE is 256 bits.

**Note:** Encryption in Wrapped-key mode is only supported when ECB or CBC is selected through CHMOD[2:0].
Decryption in Wrapped-key mode

Recommended sequence to unwrap (i.e. decrypt) a wrapped key is described below:

1. Verify that BUSY = 0 in SAES_SR (no RNG random number fetch in progress).
2. Disable the SAES peripheral by clearing the EN bit of the SAES_CR register.
3. SAES_CR register, select the Mode 2 by setting to 01 the MODE[1:0] bitfield, and select ECB or CBC chaining mode by setting CHMOD[2:0] to 000 or 001, respectively. Key size must be properly configured using KEYSIZE bit, and KMOD[1:0] bitfield must be set as 01 (wrapped key). Data type selection with DATATYPE[1:0] bitfield must be the same as the one used during encryption (that is, 0x0). The KEYSIZE information is used both for the decryption key and for the key to be decrypted.

   If the decrypted key is not to share with a different security context (different security attribute), the KEYPROT bit of the SAES_CR register must also be set.

4. Select the DHUK by setting the KEYSEL[2:0] bitfield of the SAES_CR register to 001 or 100. Upon successful key loading, the SAES_SR register BUSY bit is cleared and KEYVALID bit set. Refer to Section 50.4.12: SAES key registers for detail on KEYSEL = 100 usage.
5. Enable SAES by setting the EN bit of the SAES_CR register.
6. Wait until the CCF flag is set in the SAES_SR register.
7. Clear the CCF flag. Decryption key is available in AES core, and SAES is disabled automatically.
8. In SAES_CR register select the Mode 3 by setting to 10 the MODE[1:0] bitfield.
9. Write the SAES_IVRx registers with the initialization vector if CBC mode has been selected in previous step.
10. Enable SAES by setting the EN bit of the SAES_CR register.
11. Write the SAES_DINR register four times to input the encrypted random key (MSB first, see Table 475 on page 1985).
12. Wait until the CCF flag is set in the SAES_SR register.
13. Clear the CCF flag, then repeat steps 10 and 11 if KEYSIZE is 256 bits.

When the decrypted key is loaded in key registers, KEYSEL[2:0] of the SAES_CR register is automatically cleared. Hence, after this sequence, the decrypted wrapped key is available in SAES_KEYRx registers, immediately usable by the application software for any AES operation (normal key mode).

Decrypted wrapped key can be shared with an application running in a different security context (different security attribute) if KEYPROT bit was cleared during step 2.

**Note:**

When KMOD[1:0] = 01 (wrapped key) and MODE[1:0] = 10 (decryption) a read access to SAES_DOUTR register triggers a read error (RDERR).

When KEYSEL[2:0] = 001 (DHUK) or 100 (DHUK XOR BHK), the application software must use the same privilege, security, KMOD[1:0], CHMOD[2:0] and KEYSIZE context for encryption and decryption. Otherwise, the result is incorrect.
50.4.10 SAES operation with shared keys

SAES peripheral can share application keys wrapped with hardware-secret key DHUK, XOR-ed or not with application key BHK. With this feature, the application software can make the AES keys available to the AES peripheral, without exposing them in clear-text (unencrypted).

Shared key sequences are too small to be suspended/resumed. SAES cannot unwrap a shared key using an unwrapped key.

Note: When a key stored in SAES is shared with AES, the protection given by KEYPROT bit is lost. The protection is detailed in Section 50.4.12: SAES key registers.

Figure 490 summarizes how to use Shared-key mode. To protect the shared key, DHUK must be selected, by setting KEYSEL[2:0] to 001 or 100. Alternatively, select BHK by setting KEYSEL to 010 if the corresponding registers are read/write-locked in the TAMP peripheral.

**Figure 490. Usage of Shared-key mode**

**Key:**
- Pink: hardware secret (not readable by application)
- DHUK value depends on privilege, KMOD[1:0], KSHAREID, KEYSEL, CHMOD[2:0], and on whether SAES peripheral is secure or nonsecure.
- In the step 3, AES represents the AES peripheral.

**Encryption in Shared-key mode**

Before SAES can share a key with the AES peripheral, the key must be encrypted once. The encryption sequence of a shared key is the same as for a wrapped key, with KMOD[1:0] set to 10 (shared key) and KSHAREID[1:0] kept at 00 in the step 3 in Figure 490. See Encryption in Wrapped-key mode for details.

**Note:** Encryption in Shared-key mode is only supported when ECB or CBC is selected through CHMOD[2:0].
Decryption in Shared-key mode

Each time SAES needs to share a key with the AES peripheral, shared encrypted key must be decrypted in SAES, then loaded by the AES. The overall sequence is described next.

Sequence in the SAES peripheral

The decryption sequence of a shared key is the same as for a wrapped key, with KMOD[1:0] set to 10 (shared key) and KSHAREID[1:0] kept at 00 in the step 3 in Figure 490. See Decryption in Wrapped-key mode for details.

Note: Instead of being shared, a decrypted shared key can be used directly in SAES as the KEYSEL[2:0] bitfield is automatically cleared. In this case, KMOD[1:0] must be set to 00 (normal key mode).

Sequence in the AES peripheral

Once the shared key is decrypted in SAES key registers, it can be shared with the AES peripheral, while SAES peripheral remains in key sharing state, that is, with KMOD[1:0] = 10 and KEYVALID = 1 in the SAES_SR register. The sequence in the AES key share target peripheral is as follows:

1. Initialize the AES processor to process some data
2. When the key must be loaded, set the same KEYSIZE as for the SAES peripheral and write the KMOD[1:0] bitfield of the AES_CR register to 10 (shared key). If the previous sequence in the SAES peripheral completed successfully, with KMOD[1:0] kept at 10 and KSHAREID[1:0] kept at 00, the SAES_KEYRx registers are automatically copied into the AES_KEYRx registers, with BUSY set in AES_SR.
3. Once the transfer is completed, the BUSY flag is cleared and KEYVALID set in the AES_SR register. If KEYVALID is not set when BUSY bit is cleared, or if a key error flag (KEIF) is set an unexpected event occurred during the transfer, such as a DPA error, a tamper event or the KEYVALID SAES flag was cleared before the end of the transfer. When such errors occur, the whole key sharing process starting from the SAES peripheral must be restarted, through the IPRST bits of both control registers.
4. As KEYVALID is set, the key share target peripheral is initialized with a valid, shared key. The application can proceed with the data processing of data, setting KMOD[1:0] to 00.

This sequence can be run multiple times (for example, to manage a suspend/resume situation), as long as SAES is unused and duly remains in key sharing state.

Note: in SAES peripheral, when KMOD[1:0] = 10 (shared key) and MODE[1:0] = 10 (decryption), a read access to the SAES_DOUTR register triggers a read error (RDERR).

When KEYSEL[2:0] = 001 (DHUK) or 100 (DHUK XOR BHK), the application software must use the same privilege, security, KMOD[1:0] / KSHAREID[1:0], CHMOD[2:0], and KEYSIZE context for encryption and decryption. Otherwise, the result is incorrect.

When KMOD[1:0] = 10 and BUSY = 1 in the AES peripheral and KEYSIZE value of AES and SAES differs, the key sharing fails and the KEIF flag is raised in both peripherals.
50.4.11 SAES data registers and data swapping

Data input and output

A 128-bit data block is entered into the SAES peripheral with four successive 32-bit word writes into the SAES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 128-bit data block is retrieved from the SAES peripheral with four successive 32-bit word reads from the SAES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The 32-bit data word for SAES_DINR register or from SAES_DOUTR register is organized in big endian order, that is:

- the most significant byte of a word to write into SAES_DINR must be put on the lowest address out of the four adjacent memory locations keeping the word to write, or
- the most significant byte of a word read from SAES_DOUTR goes to the lowest address out of the four adjacent memory locations receiving the word

For using DMA for input data block write into SAES, the four words of the input block must be stored in the memory consecutively and in big-endian order, that is, the most significant word on the lowest address. See Section 50.4.14: SAES DMA interface.

Data swapping

The SAES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the SAES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the SAES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through the DATATYPE[1:0] bitfield of the SAES_CR register. The selection applies both to the input and the output of the AES core.

For different data swap types, Figure 491 shows the construction of AES processing core input buffer data P127 to P0, from the input data entered through the SAES_DINR register, or the construction of the output data available through the SAES_DOUTR register, from the AES processing core output buffer data P127 to P0.
The data in SAES key registers (SAES_KEYRx) and initialization registers (SAES_IVR Rx) are not sensitive to the swap mode selection.

Data padding

Figure 491 also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 48 message bits, with DATATYPE[1:0] = 01
- 56 message bits, with DATATYPE[1:0] = 10
- 34 message bits, with DATATYPE[1:0] = 11
50.4.12 SAES key registers

The SAES_KEYRx write-only registers store the encryption or decryption key bitfield KEY[127:0] or KEY[255:0]. The data to write to each register is organized in the memory in little-endian order, that is, with most significant byte on the highest address (reads are not allowed for security reason).

The key is spread over eight registers as shown in Table 475.

Table 475. Key endianness in SAES_KEYRx registers (128- or 256-bit key length)

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>KEY[127:96]</td>
<td>KEY[95:64]</td>
<td>KEY[63:32]</td>
<td>KEY[31:0]</td>
</tr>
</tbody>
</table>

The key for encryption or decryption may be written into these registers when the SAES peripheral is disabled, by clearing the EN bit and the KEYSEL[2:0] bitfield of the SAES_CR register.

The key registers are not affected by the data swapping controlled by DATATYPE[1:0] bitfield of the SAES_CR register.

The entire key must be written before starting an AES computation. In normal key mode (KMOD[1:0] = 00), with KEYSEL[2:0] = 000, the SAES_KEYRx (x = 0 to 3 for KEYSIZE = 0, x = 0 to 7 for KEYSIZE = 1) registers must always be written in either ascending or descending order.

With KEYSEL[2:0] set to 001, a derived hardware unique key (DHUK), computed inside the SAES engine from a non-volatile OTP-based root hardware unique key, is loaded directly into key registers, based on KEYSIZE information.

With KEYSEL[2:0] set to 010, the boot hardware key (BHK), stored in tamper-resistant secure backup registers, is entirely transferred into key registers upon a secure application performing a single read of all TAMP_BKPxR registers (x = 0 to 3 for KEYSIZE = 0, x = 0 to 7 for KEYSIZE = 1) in either ascending or descending order. Refer to Table 475.

With KEYSEL[2:0] set to 100, the XOR combination of DHUK and BHK is entirely transferred into key registers upon a secure application performing a single read of all TAMP_BKPxR registers (x = 0 to 3 for KEYSIZE = 0, x = 0 to 7 for KEYSIZE = 1) in either ascending or descending order. Refer to Table 475.

Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK or BHK if KEYVALID = 0. The recommended method to clear KEYVALID is to set the IPRST bit in the SAES_CR register. Such method is required for example when switching from ECB decryption to ECB encryption, selecting the same BHK (KEYSEL[2:0] = 010).
The KEYPROT bit of SAES_CR register must be set if the key to load in key registers must not be shared with an application executing in a different security context (that is, different security attribute). Setting KEYPROT and KEYVALID makes KEIF flag an error upon SAES access attempts by an application executing in a different security context than the one that loaded the key, as shown in Figure 492.

Note: KEYSEL[2:0] values different from zero (normal key) automatically protect the key registers.

DHUK, BHK and their XOR combination are not readable by any software (even secure).
Secure SAES uses secure DHUK. Nonsecure SAES uses nonsecure DHUK.

Figure 492. Key protection mechanisms

Note: Initiating the key-loading sequence sets the BUSY flag and clears the KEYVALID flag. Once the amount of bits defined by KEYSIZE is transferred to the SAES_KEYRx registers, BUSY is cleared, KEYVALID set and the EN bit becomes writable. If an error occurs, BUSY and KEYVALID are cleared and KEIF set (see Section 50.4.15: SAES error management for details). This holds for all KEYSEL values.
For additional information on key modes, refer to Section 50.4.10 and Section 50.4.9.

50.4.13 SAES initialization vector registers

The four SAES_IVRx registers keep the initialization vector input bitfield IVI[127:0]. The data to write to or to read from each register is organized in the memory in little-endian order, that is, with most significant byte on the highest address. The registers are also ordered from lowest address (SAES_IVR0) to highest address (SAES_IVR3).

The signification of data in the bitfield depends on the chaining mode selected. When used, the bitfield is updated upon each computation cycle of the AES core.

Write operations to the SAES_IVRx registers when the SAES peripheral is enabled have no effect to the register contents. For modifying the contents of the SAES_IVRx registers, the EN bit of the SAES_CR register must first be cleared.
Reading the SAES_IVRx registers returns the latest counter value (useful for managing suspend mode).

The SAES_IVRx registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield of the SAES_CR register.

### 50.4.14 SAES DMA interface

The SAES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the SAES_CR register.

#### Data input using DMA

Setting the DMAINEN bit of the SAES_CR register enables DMA writing into SAES. The SAES peripheral then initiates a DMA request during the input phase each time it requires to write a 128-bit block (quadruple word) to the SAES_DINR register, as shown in Figure 493.

**Note:** According to the algorithm and the mode selected, special padding / ciphertext stealing might be required. For details, refer to Section 50.4.6: SAES ciphertext stealing and data padding.

**Figure 493. DMA transfer of a 128-bit data block during input phase**

#### Data output using DMA

Setting the DMAROUTEN bit of the SAES_CR register enables DMA reading from SAES. The SAES peripheral then initiates a DMA request during the Output phase each time it requires to read a 128-bit block (quadruple word) to the SAES_DINR register, as shown in Figure 494.

**Note:** According to the message size, extra bytes might need to be discarded by application in the last block.
DMA operation in different operating modes

DMA operations are usable when Mode 1 (encryption) or Mode 3 (decryption) are selected via the MODE[1:0] bitfield of the register SAES_CR. As in Mode 2 (key derivation) the SAES_KEYRx registers must be written by software, enabling the DMA transfer through the DMAINEN and DMAOUTEN bits of the SAES_CR register have no effect in that mode.

DMA single requests are generated by SAES until it is disabled. So, after the data output phase at the end of processing of a 128-bit data block, SAES switches automatically to a new data input phase for the next data block, if any.

When the data transferring between SAES and memory is managed by DMA, the CCF flag has no use because the reading of the SAES_DOUTR register is managed by DMA automatically at the end of the computation phase. The CCF flag must only be cleared when transiting back to data transferring managed by software. See Section 50.4.4: SAES procedure to perform a cipher operation, subsection Data append, for details.

50.4.15 SAES error management

Unless indicated otherwise, SAES configuration can be changed at any moment by clearing the EN bit of the SAES_CR register.

Read error flag (RDERR)

Unexpected read attempt of the SAES_DOUTR register sets the RDERR flag of the SAES_SR register and the RWEIF flag of the SAES_ISR register, and returns zero.

RDERR is triggered during the computation phase or during the input phase.

Note: Unless indicated otherwise, SAES is not disabled upon a RDERR error detection and continues processing.

An interrupt is generated if the RWEIE bit of the SAES_IER register is set. For more details, refer to Section 50.5: SAES interrupts.

The RDERR and RWEIF flag is cleared by setting the RWEIE bit of the SAES_ISR register.

Write error flag (WDERR)

Unexpected write attempt of the SAES_DINR register sets the WRERR flag of the SAES_SR register and the RWEIF flag of the SAES_ISR register, and has no effect on the
SAES_DINR register. The WRERR is triggered during the computation phase or during the output phase.

Note: Unless indicated otherwise, SAES is not disabled after a WRERR error detection and continues processing.

An interrupt is generated if the RWEIE bit of the SAES_IER register is set. For more details, refer to Section 50.5: SAES interrupts.

The WRERR and RWEIF flag is cleared by setting the RWEIF bit of the SAES_ISR register.

**Key error interrupt flag (KEIF)**

Failure to load a key into key registers, or attempt to load a key while the key is protected, sets the KEIF flag of the SAES_ISR register and clears the KEYVALID bit of the SAES_SR register.

The KEIF flag is cleared with corresponding bit of the SAES_ISR register. An interrupt is generated if the KEIE bit of the SAES_IER register is set. For more details, refer to Section 50.5: SAES interrupts.

The possible sources of key errors are:

- Key protection error: while KEYVALID is set, if KEYPROT = 1 or KEYSEL is different from zero this error is triggered when an application executing in a security context different from the one used to load the key is detected accessing the SAES (that is, different security attribute).

- Key writing sequence error: an incorrect sequence has been detected when writing key registers. See Section 50.4.12: SAES key registers for details.

- Key sharing size mismatch: error is triggered when KMOD[1:0] = 10 and application sets a KEYSIZE information in AES peripheral that does not match the KEYSIZE stored in SAES peripheral

- Key sharing error: the copy of key registers from SAES peripheral to AES failed. See Section 50.4.10: SAES operation with shared keys for details.

- Hardware secret key loading error: the DHUK or BHK failed to load into SAES. KEYSEL = 001 (DHUK), 010 (BHK) or 100 (DHUK XOR BHK) is not functional.

Upon a key sharing error, reset both AES and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

Upon a key selection error, clearing the KEIF flag automatically restarts the key selection process. Persisting problems (for example, RHUK load failing) may require a power-on reset.

Note: For any key error, clear KEIF flag prior to re-configuring SAES.

**RNG error interrupt flag (RNGEIF)**

SAES fetches random numbers from the RNG peripheral automatically after an IP reset triggered in the RCC. SAES cannot be used when RNGEIF is set.

An error detected while fetching a random number from RNG peripheral (due to, for example, bad entropy) sets the RNGEIF flag of the SAES_ISR register. The flag is cleared by setting the corresponding bit of the SAES_ISR register. An interrupt is generated if the
RNGEIE bit of the SAES_IER register is set. For more details, refer to Section 50.5: SAES interrupts.

Upon an RNG error:
- Verify that the RNG peripheral AHB clock is enabled and no noise source (or seed) error is pending in this peripheral.
- Clear the RNGEIF bit of the SAES_ISR register, or reset the peripheral by setting the IPRST bit of the SAES_CR register. The clearance of the BUSY flag in the SAES_SR register then indicates the completion of the random number fetch from RNG.

Note: To avoid RNGEIF errors, it is recommended to activate the RNG AHB clock each time SAES AHB clock is activated.

About DPA errors
An unexpected error triggers an SAES internal tamper event in the TAMP peripheral, and stops any SAES co-processor processing.

To resume normal operation, application must reset the SAES peripheral through RCC or global reset.

50.5 SAES interrupts

Individual maskable interrupt sources generated by the SAES peripheral signal the following events:
- computation completed
- read error
- write error
- key error
- RNG error

These sources are combined into a common interrupt signal from the SAES peripheral that connects to the Arm® Cortex® interrupt controller. Each can individually be enabled/disabled, by setting/clearing the corresponding enable bit of the SAES_IER register, and cleared by setting the corresponding bit of the SAES_ISR register.

The status of each can be read from the SAES_SR and SAES_ISR registers.

Table 476 gives a summary of the interrupt sources, their event flags and enable bits.

</thead>
<tbody>
<tr>
<td>Setting the bit resets the SAES peripheral, putting all registers to their default values, except the IPRST bit itself and the SAES_DPACFG register. Hence, any key-relative data is lost. For this reason, it is recommended to set the bit before handing over the SAES to a less secure application. The bit must be low while writing any configuration registers.</td>
</tr>
</tbody>
</table>
Bits 30:28 **KEYSEL[2:0]**: Key selection

The bitfield defines the source of the key information to use in the AES cryptographic core.

- **000**: Software key, loaded in key registers SAES_KEYX
- **001**: Derived hardware unique key (DHUK)
- **010**: Boot hardware key (BHK)
- **100**: XOR of DHUK and BHK
- **111**: Test mode key (256-bit hardware constant 0xA5A5...A5A5)
- Others: Reserved (if used, unfreeze SAES with IPRST)

When KEYSEL is different from zero, selected key value is available in key registers when BUSY bit is cleared and KEYVALID is set in the SAES_SR register. Otherwise, the key error flag KEIF is set. Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK or BHK if KEYVALID = 0.

When the application software changes the key selection by writing the KEYSEL[2:0] bitfield, the key registers are immediately erased and the KEYVALID flag cleared.

At the end of the decryption process, if KMOD[1:0] is other than zero, KEYSEL[2:0] is cleared.

With the bitfield value other than zero and KEYVALID set, the application cannot transfer the ownership of SAES with a loaded key to an application running in another security context (such as secure, nonsecure). More specifically, when security of an access to any register does not match the information recorded by SAES, the KEIF flag is set.

Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

Bits 27:26 **KSHAREID[1:0]**: Key share identification

This bitfield defines, at the end of a decryption process with KMOD[1:0] = 10 (shared key), which target can read the SAES key registers using a dedicated hardware bus.

- **00**: AES peripheral
- Others: Reserved

Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

Bits 25:24 **KMOD[1:0]**: Key mode selection

The bitfield defines how the SAES key can be used by the application:

- **00**: Normal key
- **01**: Wrapped key
- **10**: Shared key
- Others: Reserved

With normal key selection, the key registers are freely usable, no specific usage or protection applies to SAES_DIN and SAES_DOUT registers.

With wrapped key selection, the key loaded in key registers can only be used to encrypt or decrypt AES keys. Hence, when a decryption is selected in Wrapped-key mode read-as-zero SAES_DOUT register is automatically loaded into SAES key registers after a successful decryption process.

With shared key selection, after a successful decryption process, SAES key registers are shared with the peripheral described in KSHAREID[1:0] bitfield. This sharing is valid only while KMOD[1:0] = 10 and KEYVALID = 1. When a decryption is selected, read-as-zero SAES_DOUT register is automatically loaded into SAES key registers after a successful decryption process.

With KMOD[1:0] other than zero, any attempt to configure the SAES peripheral for use by an application belonging to a different security domain (secure or nonsecure) results in automatic key erasure and setting of the KEIF flag.

Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

Bits 23:20 **Reserved**, must be kept at reset value.
Bit 19  **KEYPROT**: Key protection
When set, hardware-based key protection is enabled.
0: When KEYVALID is set and KEYSEL = 0 application can transfer the ownership of the SAES, with its loaded key, to an application running in another security context (such as nonsecure, secure).
1: When KEYVALID is set, key error flag (KEIF) is set when an access to any registers is detected, this access having a security context (for example, secure, nonsecure) that does not match the one of the application that loaded the key.
Attempts to write the bit are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

Bit 18  **KEYSIZE**: Key size selection
This bitfield defines the length of the key used in the SAES cryptographic core, in bits:
0: 128
1: 256
When KMOD[1:0] = 01 or 10 KEYSIZE also defines the length of the key to encrypt or decrypt.
Attempts to write the bit are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

Bit 17  Reserved, must be kept at reset value.

Bit 16  Reserved, must be kept at reset value.

Bits 15:13  Reserved, must be kept at reset value.

Bit 12  **DMAOUTEN**: DMA output enable
This bit enables/disables data transferring with DMA, in the output phase:
0: Disable
1: Enable
When the bit is set, DMA requests are automatically generated by SAES during the output data phase. This feature is only effective when Mode 1 or Mode 3 is selected through the MODE[1:0] bitfield. It is not effective for Mode 2 (key derivation).

Bit 11  **DMAINEN**: DMA input enable
This bit enables/disables data transferring with DMA, in the input phase:
0: Disable
1: Enable
When the bit is set, DMA requests are automatically generated by SAES during the input data phase. This feature is only effective when Mode 1 or Mode 3 is selected through the MODE[1:0] bitfield. It is not effective for Mode 2 (key derivation).

Bits 10:7  Reserved, must be kept at reset value.

Bit 6  Reserved, must be kept at reset value.

Bits 16, 6:5  **CHMOD[2:0]**: Chaining mode selection
This bitfield selects the AES chaining mode:
000: Electronic codebook (ECB)
001: Cipher-block chaining (CBC)
others: Reserved
Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.
50.7.2 **SAES status register (SAES_SR)**

</tbody>
</table>

Bits 31:8 Reserved, must be kept at reset value.
Bit 7 KEYVALID: Key Valid flag
This bit is set by hardware when the amount of key information defined by KEYSIZE in SAES_CR has been loaded in SAES_KEYx key registers.
0: No valid key information is available in key registers. EN bit in SAES_CR cannot be set.
1: Valid key information, defined by KEYSIZE in SAES_CR, is loaded in key registers.
In normal mode when KEYSEL equals to zero, the application must write the key registers in the correct sequence, otherwise the KEIF flag of the SAES_ISR register is set and KEYVALID stays at zero.
When KEYSEL is different from zero the BUSY flag is automatically set by SAES. When key is loaded successfully, the BUSY flag is cleared and KEYVALID set. Upon an error, the KEIF flag of the SAES_ISR register is set, the BUSY flag cleared and KEYVALID kept at zero.
When the KEIF flag is set, the application must clear it through the SAES_ICR register, otherwise KEYVALID cannot be set. See the KEIF bit description for more details.
For more information on key loading, refer to Section 50.4.12: SAES key registers.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 BUSY: Busy
This flag indicates whether SAES is idle or busy during GCM payload encryption phase:
0: Idle
1: Busy
The flag is also set upon SAES initialization, upon fetching random number from the RNG, or upon transferring a shared key to a target peripheral.

Bit 2 WRERR: Write error
This flag indicates the detection of an unexpected write operation to the SAES_DINR register (during computation or data output phase):
0: Not detected
1: Detected
The flag is set by hardware. It is cleared by software upon setting the RWEIF bit of the SAES_ISR register.
Upon the flag setting, an interrupt is generated if enabled through the RWEIE bit of the SAES_ISR register.
The flag setting has no impact on the SAES operation. Unexpected write is ignored.

Bit 1 RDERR: Read error flag
This flag indicates the detection of an unexpected read operation from the SAES_DOUTR register (during computation or data input phase):
0: Not detected
1: Detected
The flag is set by hardware. It is cleared by software upon setting the RWEIF bit of the SAES_ISR register.
Upon the flag setting, an interrupt is generated if enabled through the RWEIE bit of the SAES_ISR register.
The flag setting has no impact on the SAES operation. Unexpected read returns zero.

Bit 0 CCF: Computation completed flag
This bit mirrors the CCF bit of the SAES_ISR register.
50.7.3 **SAES data input register (SAES_DINR)**

Bits 31:0 **DIN[31:0]: Input data word**

A four-fold sequential write to this bitfield during the input phase results in writing a complete 128-bit block of input data to the SAES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 128-bit input buffer.

The data signification of the input data block depends on the SAES operating mode:
- **Mode 1** (encryption): plaintext
- **Mode 2** (key derivation): the bitfield is not used (SAES_KEYRx registers used for input if KEYSEL = 0)
- **Mode 3** (decryption): ciphertext

The data swap operation is described in [Section 50.4.11: SAES data registers and data swapping on page 1983](#).

50.7.4 **SAES data output register (SAES_DOUTR)**

Address offset: 0x0C  
Reset value: 0x0000 0000  
Only 32-bit read access type is supported. Read when KMOD[1:0] = 01 or 10 while MODE[1:0] = 10 and EN = 1 triggers a read error.

50.7.5 SAES key register 0 (SAES_KEYR0)

Address offset: 0x10
Reset value: 0x0000 0000

Bits 31:0 **KEY[31:0]**: Cryptographic key, bits [31:0]
This write-only bitfield contains the bits [31:0] of the AES encryption or decryption key, depending on the operating mode:
- In **Mode 1** (encryption), **Mode 2** (key derivation): the value to write into the bitfield is the encryption key.
- In **Mode 3** (decryption): the value to write into the bitfield is the encryption key to be derived before being used for decryption.

The SAES_KEYRx registers may be written only when KEYSIZE value is correct and when the SAES peripheral is disabled (EN bit of the SAES_CR register cleared). A special writing sequence is also required, as described in KEYVALID bit of the SAES_SR register. Note that, if KEYSEL is different from 0 and KEYVALID = 0, the key is directly loaded to SAES_KEYRx registers (hence writes to key register is ignored and KEIF is set).

Refer to Section 50.4.12: SAES key registers on page 1985 for more details.

50.7.6 SAES key register 1 (SAES_KEYR1)

Address offset: 0x14
Reset value: 0x0000 0000

Bits 31:0 **KEY[63:48]**: Output data word
This read-only bitfield fetches a 32-bit output buffer. A four-fold sequential read of this bitfield, upon the computation completion (CCF set), virtually reads a complete 128-bit block of output data from the SAES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield.

Data weights from the first to the fourth read operation are: [127:96], [95:64], [63:32], and [31:0].

The data significanion of the output data block depends on the SAES operating mode:
- **Mode 1** (encryption): ciphertext
- **Mode 2** (key derivation): the bitfield is not used
- **Mode 3** (decryption): plaintext

The data swap operation is described in Section 50.4.11: SAES data registers and data swapping on page 1983.
Bits 31:0  **KEY[63:32]**: Cryptographic key, bits [63:32]
Refer to the SAES_KEYR0 register for description of the KEY[255:0] bitfield.

### 50.7.7  SAES key register 2 (SAES_KEYR2)

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:4  Reserved, must be kept at reset value.

**Bit 3 RNGEIF**: RNG error interrupt flag

This read-only bit is set by hardware when an error is detected on RNG bus interface (e.g. bad entropy).
- 0: RNG bus is functional
- 1: Error detected on RNG bus interface (random seed fetching error)

RNGEIF bit is cleared when application sets the corresponding bit of SAES_ICR register. An interrupt is generated if the RNGEIF bit has been previously set in the SAES_IER register. Clearing this bit triggers the reload of a new random number from RNG peripheral.

**Bit 2 KEIF**: Key error interrupt flag

This read-only bit is set by hardware when key information failed to load into key registers or key register usage is forbidden.
- 0: No key error detected
- 1: Key information failed to load into key registers, or key register use is forbidden

Setting the corresponding bit of the SAES_ICR register clears the KEIF and generates interrupt if the KEIF bit of the SAES_IER register is set.

KEIF is triggered upon any of the following errors:
- SAES fails to load the DHUK (KEYSEL = 001 or 100).
- SAES fails to load the BHK (KEYSEL = 010 or 100) respecting the correct order.
- AES fails to load the key shared by SAES peripheral (KMOD = 10).
- When KEYVALID = 1 and (KEYPROT = 1 or KEYSEL is not 0x0), the security context of the application that loads the key (secure or nonsecure) does not match the security attribute of the access to SAES_CR or SAES_DOUT. In this case, KEYVALID and EN bits are cleared.
- SAES_KEYRx register write does not respect the correct order. (For KEYSIZE = 0, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 then SAES_KEYR4 then SAES_KEYR5 then SAES_KEYR6 then SAES_KEYR7, or reverse. For KEYSIZE = 1, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 then SAES_KEYR4 then SAES_KEYR5 then SAES_KEYR6 then SAES_KEYR7, or reverse).

KEIF must be cleared by the application software, otherwise KEYVALID cannot be set.
Bit 1  **RWEIF**: Read or write error interrupt flag

This read-only bit is set by hardware when a RDERR or a WRERR error flag is set in the SAES_SR register.
0: No read or write error detected
1: Read or write error detected (see SAES_SR register for details)

RWEIF bit is cleared when application sets the corresponding bit of SAES_ICR register. An interrupt is generated if the RWEIF bit has been previously set in the SAES_IER register.

This flag has no meaning when key derivation mode is selected.

Bit 0  **CCF**: Computation complete flag

This flag indicates whether the computation is completed:
0: Not completed
1: Completed

The flag is set by hardware upon the completion of the computation. It is cleared by software, upon setting the CCF bit of the SAES_ISR register.

Upon the flag setting, an interrupt is generated if enabled through the CCFIE bit of the SAES_IER register.

The flag is significant only when the DMAOUTEN bit is 0. It may stay high when DMA_EN is 1.

### 50.7.19  **SAES interrupt clear register (SAES_ICR)**

Address offset: 0x308
Reset value: 0x0000 0000

Bits 31:4  **Reserved**, must be kept at reset value.

Bit 3  **RNGEIF**: RNG error interrupt flag clear

Application must set this bit to clear the RNGEIF status bit in SAES_ISR register.

Bit 2  **KEIF**: Key error interrupt flag clear

Setting this bit clears the KEIF status bit of the SAES_ISR register.

Bit 1  **RWEIF**: Read or write error interrupt flag clear

Setting this bit clears the RWEIF status bit of the SAES_ISR register, and both RDERR and WRERR flags in the SAES_SR register.

Bit 0  **CCF**: Computation complete flag clear

Setting this bit clears the CCF status bit of the SAES_SR and SAES_ISR registers.

51 Hash processor (HASH)

51.1 Introduction

The hash processor is a fully compliant implementation of the secure hash algorithm (SHA-1, SHA2-224, SHA2-256), the MD5 (message-digest algorithm 5) hash algorithm and the HMAC (keyed-hash message authentication code) algorithm. HMAC is suitable for applications requiring message authentication.

The hash processor computes FIPS (Federal Information Processing Standards) approved digests of length of 160, 224, 256 bits, for messages of up to \(2^{64} - 1\) bits. It also computes 128-bit digests for the MD5 algorithm.

51.2 HASH main features

- Suitable for data authentication applications, compliant with:
  - Federal Information Processing Standards Publication FIPS PUB 180-4, Secure Hash Standard (SHA-1 and SHA-2 family)
  - Federal Information Processing Standards Publication FIPS PUB 186-4, Digital Signature Standard (DSS)
  - Internet Engineering Task Force (IETF) Request For Comments RFC 1321, MD5 Message-Digest Algorithm
- Fast computation of SHA-1, SHA2-224, SHA2-256, and MD5
  - 82 (respectively 66) clock cycles for processing one 512-bit block of data using SHA-1 (respectively SHA2-256) algorithm
  - 66 clock cycles for processing one 512-bit block of data using MD5 algorithm
- Corresponding 32-bit words of the digest from consecutive message blocks are added to each other to form the digest of the whole message
  - Automatic 32-bit words swapping to comply with the internal little-endian representation of the input bit-string
  - Word swapping supported: bits, bytes, half-words and 32-bit words
- Automatic padding to complete the input bit string to fit digest minimum block size of 512 bits (16 \times 32 bits)
- Single 32-bit input register associated to an internal input FIFO, corresponding to one block size
- AHB slave peripheral, accessible through 32-bit word accesses only (else an AHB error is generated)
- 8 \times 32-bit words (H0 to H7) for output message digest
- Automatic data flow control with support of direct memory access (DMA) using one channel.
- Single or fixed DMA burst transfers of four words
• Interruptible message digest computation, on a per-block basis
  – Re-loadable digest registers
  – Hashing computation suspend/resume mechanism, including DMA

51.3 HASH implementation
The devices have a single instance of HASH peripheral.

51.4 HASH functional description

51.4.3 About secure hash algorithms

The hash processor is a fully compliant implementation of the secure hash algorithm defined by FIPS PUB 180-4 standard and the IETF RFC1321 publication (MD5).

With each algorithm, the HASH computes a condensed representation of a message or data file. More specifically, when a message of any length below $2^{64}$ bits is provided on input, the HASH processing core produces respectively a fixed-length output string called a message digest, defined as follows:

- For MD5 digest size is 128-bit
- For SHA-1 digest size is 160-bit
- For SHA2-224 and SHA2-256, the digest size is 224 bits and 256 bits, respectively

The message digest can then be processed with a digital signature algorithm in order to generate or verify the signature for the message.

Signing the message digest rather than the message often improves the efficiency of the process because the message digest is usually much smaller in size than the message. The verifier of a digital signature has to use the same hash algorithm as the one used by the creator of the digital signature.

The SHA-2 functions supported by the hash processor are qualified as “secure” by NIST because it is computationally infeasible to find a message that corresponds to a given message digest, or to find two different messages that produce the same message digest (SHA-1 does not qualify as secure since February 2017). Any change to a message in transit, with very high probability, results in a different message digest, and the signature fails to verify.

51.4.4 Message data feeding

The message (or data file) to be processed by the HASH is considered as a bit string. Per FIPS PUB 180-4 standard this message bit string grows from left to right, with hexadecimal words expressed in “big-endian” convention, so that within each word, the most significant bit is stored in the left-most bit position. For example message string “abc” with a bit string representation of “01100001 01100010 01100011” is represented by a 32-bit word 0x00636261, and 8-bit words 0x61626300.

Data are entered into the HASH one 32-bit word at a time, by writing them into the HASH_DIN register. The current contents of the HASH_DIN register are transferred to the 16 words input FIFO each time the register is written with new data. Hence HASH_DIN and the FIFO form a seventeen 32-bit words length FIFO (named the IN buffer).
In accordance to the kind of data to be processed (e.g. byte swapping when data are ASCII text stream) there must be a bit, byte, half-word or no swapping operation to be performed on data from the input FIFO before entering the little-endian hash processing core. 

*Figure 496* shows how the hash processing core 32-bit data block M0…31 is constructed from one 32-bit words popped into input FIFO by the driver, according to the DATATYPE bitfield in the HASH control register (HASH_CR).

HASH_DIN data endianness when bit swapping is disabled (DATATYPE = 00) can be described as following: the least significant bit of the message has to be at MSB position in the first word entered into the hash processor, the 32nd bit of the bit string has to be at MSB position in the second word entered into the hash processor and so on.

*Figure 496. Message data swapping feature*
51.4.5 **Message digest computing**

The hash processor sequentially processes several blocks when computing the message digest. For MD5, SHA1 and SHA2, the block size is 512 bits.

Each time the DMA or the CPU writes a block to the hash processor, the HASH automatically starts computing the message digest. This operation is known as partial digest computation.

As described in Section 51.4.4: Message data feeding, the message to be processed is entered into the HASH 32-bit word at a time, writing to the HASH_DIN register to fill the input FIFO.

In order to perform the hash computation on this data below sequence must be used by the application:

1. Initialize the hash processor using the HASH_CR register:
   a) Select the right algorithm using the ALGO bitfield. If needed program the correct swapping operation on the message input words using DATATYPE bitfield in HASH_CR.
   b) When the HMAC mode is required, set the MODE bit, as well as the LKEY bit if the HMAC key size is greater than the known block size of the algorithm (else keep LKEY cleared). Refer to Section 51.4.7: HMAC operation for details.
   c) Update NBLW[4:0] to define the number of valid bits in last word of the message if it is different from 32 bits. NBLW[4:0] information are used to correctly perform the automatic message padding before the final message digest computation.

2. Complete the initialization by setting to 1 the INIT bit in HASH_CR. Also set the bit DMAE to 1 if data are transferred via DMA.

**Caution:** When programming step 2, it is important to set up before or at the same time the correct configuration values (ALGO, DATATYPE, HMAC mode, key length, NBLW[4:0]).

3. Start filling data by writing to HASH_DIN register, unless data are automatically transferred via DMA. Note that the processing of a block can start only once the last value of the block has entered the input FIFO. The way the partial or final digest computation is managed depends on the way data are fed into the processor:
   a) When data are filled by software:
      - Partial digest computation are triggered each time the application writes the first word of the next block, the block size being defined the NBWE bit of HASH_CR. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write new data to HASH_DIN. This mechanism avoids the introduction of wait states by the HASH.
      - The final digest computation is triggered when the last block is entered and the software writes the DCAL bit to 1. If the message length is not an exact multiple of the block size, the NBLW[4:0] bitfield in HASH_STR register must be written prior to writing DCAL bit (see Section 51.4.6 for details).
   b) When data are filled by DMA as a single DMA transfer (MDMAT bit = 0):
      - Partial digest computations are triggered automatically each time the FIFO is full. The final digest computation is triggered automatically when the last block has been transferred to the HASH_DIN register (DCAL bit is set to 1 by hardware). If the message length is not an exact multiple of the block size, the NBLW[4:0] field
in HASH_STR register must be written prior to enabling the DMA (see Section 51.4.6 for details).

c) When data are filled by DMA using multiple DMA transfers (MDMAT bit = 1):
   - Partial digest computations are triggered as for single DMA transfers. However the final digest computation is not triggered automatically when the last block has been transferred by DMA to the HASH_DIN register (DCAL bit is not set to 1 by hardware). It allows the hash processor to receive a new DMA transfer as part of this digest computation. To launch the final digest computation, the software must set MDMAT bit to 0 before the last DMA transfer in order to trigger the final digest computation as it is done for single DMA transfers (see description before).

4. Once the digest computation is complete (DCIS = 1), the resulting digest can be read from the output registers as described in Table 480.

For more information about HMAC detailed instructions, refer to Section 51.4.7: HMAC operation.

51.4.6 Message padding

Overview

When computing a condensed representation of a message, the process of feeding data into the hash processor (with automatic partial digest computation every block transfer) loops until the last bits of the original message are written to the HASH_DIN register.

As the length (number of bits) of a message can be any integer value, the last word written to the hash processor may have a valid number of bits between 1 and 32. This number of valid bits in the last word, NBLW[4:0], has to be written to the HASH_STR register, so that message padding is correctly performed before the final message digest computation.

Padding processing

Detailed padding sequences with DMA enabled or disabled are described in Section 51.4.5: Message digest computing.

Padding example

As specified by Federal Information Processing Standards PUB 180-4, the message padding consists in appending a “1” followed by k “0”s, itself followed by a 64-bit integer that is equal to the length L in bits of the message. These three padding operations generate a padded message of length \( L + 1 + k + 64 \), which by construction is a multiple of 512 bits.

For the hash processor, the “1” is added to the last word written to the HASH_DIN register at the bit position defined by the NBLW[4:0] bitfield, and the remaining upper bits are cleared (“0”s).
Example from FIPS PUB180-4

Let us assume that the original message is the ASCII binary-coded form of “abc”, of length \( L = 24 \):

\[
\begin{array}{cccc}
\text{byte 0} & \text{byte 1} & \text{byte 2} & \text{byte 3} \\
01100001 & 01100010 & 01100011 & \underbrace{\text{UUU} \cdots \text{UUU}} \\
\end{array}
\]

\( \leftarrow \, 1\text{st word written to HASH_DIN} \rightarrow \)

\( \text{NBLW}[4:0] \) has to be loaded with the value 24: a “1” is appended at bit location 24 in the bit string (starting counting from left to right in the above bit string), which corresponds to bit 31 in the HASH_DIN register (little-endian convention):

\[
\begin{array}{cccc}
01100001 & 01100010 & 01100011 & \underbrace{\text{iUUU} \cdots \text{iUUU}} \\
\end{array}
\]

Since \( L = 24 \), the number of bits in the above bit string is 25, and 423 “0” bits are appended, making now 448 bits.

This gives in hexadecimal (byte words in big-endian format):

\[
\begin{array}{cccc}
61 & 62 & 63 & 80 \\
00 & 00 & 00 & 00 \\
00 & 00 & 00 & 00 \\
00 & 00 & 00 & 00 \\
00 & 00 & 00 & 00 \\
00 & 00 & 00 & 00 \\
00 & 00 & 00 & 00 \\
00 & 00 & 00 & 00 \\
\end{array}
\]

The message length value, \( L \), in two-word format (that is 00000000 00000018) is appended.

Hence the final padded message in hexadecimal (byte words in big-endian format):

\[
\begin{array}{cccc}
61 & 62 & 63 & 80 \\
00 & 00 & 00 & 00 \\
00 & 00 & 00 & 00 \\
00 & 00 & 00 & 00 \\
00 & 00 & 00 & 00 \\
00 & 00 & 00 & 00 \\
00 & 00 & 00 & 00 \\
00 & 00 & 00 & 00 \\
00 & 00 & 00 & 00 \\
\end{array}
\]

If the hash processor is programmed to swap byte within HASH_DIN input register (DATATYPE = 10 in HASH_CR), the above message has to be entered by following the below sequence:

1. \( 0\text{xUU}636261 \) is written to the HASH_DIN register (where ‘U’ means don’t care).
2. \( 0\text{x18} \) is written to the HASH_STR register (the number of valid bits in the last word written to the HASH_DIN register is 24, as the original message length is 24 bits).
3. \( 0\text{x10} \) is written to the HASH_STR register to start the message padding (described above) and then perform the digest computation.
4. The hash computing is complete with the message digest available in the HASH_HRx registers \( (x = 0 \ldots 4) \) for the SHA-1 algorithm. For this FIPS example, the expected value is as follows:

\[
\begin{array}{l}
\text{HASH_HR0} = 0\text{xA9993E36} \\
\text{HASH_HR1} = 0\text{x4706816A} \\
\text{HASH_HR2} = 0\text{xBA3E2571} \\
\text{HASH_HR3} = 0\text{x7850C26C} \\
\text{HASH_HR4} = 0\text{x9CD0D89D} \\
\end{array}
\]
51.4.7 HMAC operation

Overview
As specified by Internet Engineering Task Force RFC2104 and NIST FIPS PUB 198-1, the HMAC algorithm is used for message authentication by irreversibly binding the message being processed to a key chosen by the user. The algorithm consists of two nested hash operations:

\[
\text{HMAC}(\text{message}) = \text{Hash}((\text{Key} | \text{pad}) \text{ XOR} \text{ opad} | \text{Hash}((\text{Key} | \text{pad}) \text{ XOR} \text{ ipad} | \text{message}))
\]

where:
- \text{opad} = \[0x5C\]_n (outer pad) and \text{ipad} = \[0x36\]_n (inner pad)
- \[X\]_n represents a repetition of \(X\) \(n\) times, where \(n\) equal to the size of the underlying hash function data block (\(n = 64\) for 512-bit blocks).
- \text{pad} is a sequence of zeroes needed to extend the key to the length \(n\) defined above. If the key length is greater than \(n\), the application must first hash the key using \text{Hash()} function and then use the resultant byte string as the actual key to HMAC.
- \(|\) represents the concatenation operator.

Note: HMAC mode of the hash processor can be used with all supported algorithms.

HMAC processing
Four different steps are required to compute the HMAC:
1. The software writes the INIT bit to 1 with the MODE bit at 1 and the ALGO bits set to the value corresponding to the desired algorithm. The LKEY bit must also be set to 1 if the key being used is longer than 64 bytes. In this case, as required by HMAC specifications, the hash processor uses the hash of the key instead of the real key.
2. The software provides the key to be used for the inner hash function, using the same mechanism as the message string loading, that is writing the key data into HASH_DIN register then completing the transfer by writing DCAL bit to 1 and the correct NBLW[4:0] to HASH_STR register.

Note: Endianness details can be found in Section 51.4.4: Message data feeding.
3. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write the message string to HASH_DIN. When the last word of the last block is entered and the software writes DCAL bit to 1 in HASH_STR register, the NBLW[4:0] bitfield must be written at the same time to a value different from zero if the message length is not an exact multiple of the block size. Note that the DMA can also be used to feed the message string, as described in Section 51.4.4: Message data feeding.
4. Once the processor is ready again (DINIS = 1 in HASH_SR), the software provides the key to be used for the outer hash function, writing the key data into HASH_DIN register then completing the transfer by writing DCAL bit to 1 and the correct NBLW[4:0] to HASH_STR register. The HMAC result can be found in the valid output registers (HASH_HRx) as soon as DCIS bit is set to 1.

Note: The computation latency of the HMAC primitive depends on the lengths of the keys and message, as described in Section 51.6: HASH processing time.

HMAC example
Below is an example of HMAC SHA-1 algorithm (ALGO = 00 and MODE = 1 in HASH_CR) as specified by NIST.
Let us assume that the original message is the ASCII binary-coded form of "Sample message for keylen = blocklen", of length L = 34 bytes. If the HASH is programmed in no swapping mode (DATATYPE = 00 in HASH_CR), the following data must be loaded sequentially into HASH_DIN register:

1. **Inner hash key** input (length = 64, that is no padding), specified by NIST. As key length = 64, LKEY bit is set to 0 in HASH_CR register

   00010203 04050607 08090A0B 0C0D0E0F 10111213 14151617
   18191A1B 1C1D1E1F 20212223 24252627 28292A2B 2C2D2E2F
   30313233 34353637 38393A3B 3C3D3E3F

2. **Message** input (length = 34, that is padding required). HASH_STR must be set to 0x20 to start message padding and inner hash computation (see 'U' as don't care)

   53616D70 6C65206D 65737361 67652066 6F72206B 65796C65
   6E3D626C 6F636B6C 6EUUUU

3. **Outer hash key** input (length = 64, that is no padding). A key identical to the inner hash key is entered here.

4. **Final outer hash computing** is then performed by the HASH. The HMAC-SHA1 digest result is available in the HASH_HRx registers (x = 0 to 4), as shown below:

   \begin{align*}
   \text{HASH}_HR0 &= 0x5FD596EE \\
   \text{HASH}_HR1 &= 0x78D5553C \\
   \text{HASH}_HR2 &= 0x8FF4E72D \\
   \text{HASH}_HR3 &= 0x266DFD19 \\
   \text{HASH}_HR4 &= 0x2366DA29
   \end{align*}
51.4.8 HASH suspend/resume operations

Overview

It is possible to interrupt a hash/HMAC operation to perform another processing with a higher priority. The interrupted process completes later when the higher-priority task has been processed, as shown in Figure 497.

Figure 497. HASH suspend/resume mechanism

To do so, the context of the interrupted task must be saved from the HASH registers to memory, and then be restored from memory to the HASH registers.

The procedures where the data flow is controlled by software or by DMA are described hereafter.
Data loaded by software

When the DMA is not used to load the message into the hash processor, the context can be saved only when no block processing is ongoing.

To suspend the processing of a message, proceed as follows after writing the number of words defined in NBWE:

1. In Polling mode, wait for BUSY = 0, then poll if the DINIS status bit is set to 1.
   In Interrupt mode, implement the next step in DINIS interrupt handler (recommended).
2. Store the contents of the following registers into memory:
   - HASH.IMR
   - HASH.STR
   - HASH.CR
   - HASH.CSR0 to HASH.CSR37. HASH.CSR38 to HASH.CSR53 registers must also be saved if an HMAC operation was ongoing.

To resume the processing of a message, proceed as follows:

1. Write the following registers with the values saved in memory: HASH.IMR, HASH.STR and HASH.CR.
2. Initialize the hash processor by setting the INIT bit in the HASH.CR register.
3. Write the HASH.CSRx registers with the values saved in memory.
4. Restart the processing from the point where it has been interrupted.

Data loaded by DMA

When the DMA is used to load the message into the hash processor, it is recommended to suspend and then restore a secure digest computing is described below. In this sequence the DMA channel allocated to the hash peripheral remains allocated to the processing of message 1 (see Figure 497).

To suspend the processing of a message using DMA, proceed as follows:

1. Clear the DMAE bit to disable the DMA interface. The hash peripheral automatically fetches enough data using the DMA to complete the current input block and launch a hash process.
2. Wait until the last DMA transfer is complete (DMAS = 0 in HASH_SR).
3. Disable the DMA channel.
4. In Polling or Interrupt mode (recommended), wait until the hash processor is ready (no block is being processed), that is wait for DINIS = 1 in HASH_SR. If DCIS is also set in this register the hash result is available and the context swapping is useless. Else go to step 5.
5. Save HASH.IMR, HASH.STR, HASH.CR, and HASH.CSR0 to HASH.CSR37 registers. HASH.CSR38 to HASH.CSR53 registers must also be saved if an HMAC operation was ongoing.
To resume the processing of a message using DMA, proceed as follows:

1. Reconfigure the DMA controller so that it proceeds with the transfer of the message up to the end if it is not interrupted again.
2. Program the values saved in memory to HASH_IMR, HASH_STR and HASH_CR registers.
3. Initialize the hash processor by setting the INIT bit in the HASH_CR register.
4. Program the values saved in memory to the HASH_CSRx registers.
5. Restart the processing from the point where it was interrupted by setting the DMAE bit.

51.4.9 HASH DMA interface

The HASH supports both single and fixed DMA burst transfers of four words.

The hash processor provides an interface to connect to the DMA controller. This DMA can be used to write data to the HASH by setting the DMAE bit in the HASH_CR register. When this bit is set, the HASH initiates a DMA request each time a block has to be written to the HASH_DIN register.

Once four 32-bit words have been received, the HASH automatically triggers a new request to the DMA. For more information refer to Section 51.4.5: Message digest computing.

Before starting the DMA transfer, the software must program the number of valid bits in the last word that is copied into HASH_DIN register. This is done by writing in HASH_STR register the following value:

\[ NBLW[4:0] = \text{Len}(\text{Message}) \mod 32 \]

where “x\mod 32” gives the remainder of x divided by 32.

The DMAS bit of the HASH_SR register provides information on the DMA interface activity. This bit is set with DMAE and cleared when DMAE is cleared and no DMA transfer is ongoing.

Note: No interrupt is associated to DMAS bit.

When MDMAT is set, the size of the transfer must be a multiple of four words.

51.4.10 HASH error management

No error flags are generated by the hash processor.

51.5 HASH interrupts

Two individual maskable interrupt sources are generated by the hash processor to signal the following events:

- Digest calculation completion (DCIS)
- Data input buffer ready (DINIS)

Both interrupt sources are connected to the same global interrupt request signal (hash_it), which is in turn connected to the NVIC (nested vectored interrupt controller). Each interrupt source can individually be enabled or disabled by changing the mask bits in the HASH_IMR register. Setting the appropriate mask bit to 1 enables the interrupt.

The status of each maskable interrupt source can be read from the HASH_SR register. Table 481 gives a summary of the available features.
51.6 HASH processing time

Table 482 summarizes the time required to process an intermediate block for each mode of operation.

<table>
<thead>
<tr>
<th>Mode of operation</th>
<th>FIFO load(1)</th>
<th>Computation phase</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD5</td>
<td>16</td>
<td>50</td>
<td>66</td>
</tr>
<tr>
<td>SHA-1</td>
<td>16</td>
<td>66</td>
<td>82</td>
</tr>
<tr>
<td>SHA2-224</td>
<td>16</td>
<td>50</td>
<td>66</td>
</tr>
<tr>
<td>SHA2-256</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1. Add the time required to load the block into the processor.

The time required to process the last block of a message (or of a key in HMAC) can be longer. This time depends on the length of the last block and the size of the key (in HMAC mode).

Compared to the processing of an intermediate block, it can be increased by the factor below:

- **1 to 2.5** for a hash message
- **~2.5** for an HMAC input-key
- **1 to 2.5** for an HMAC message
- **~2.5** for an HMAC output key in case of a short key
- **3.5 to 5** for an HMAC output key in case of a long key
## 51.7 HASH registers

The HASH core is associated with several control and status registers and several message digest registers. All these registers are accessible through 32-bit word accesses only, else an AHB error is generated.

### 51.7.1 HASH control register (HASH_CR)

Address offset: 0x00  
Reset value: 0x0000 0000

| Bit 31:19 | Reserved, must be kept at reset value. |
| Bit 18:17 | **ALGO[1:0]**: Algorithm selection |
|           | These bits select the hash algorithm. |
|           | 00: SHA-1 |
|           | 01: MD5 |
|           | 10: SHA2-224 |
|           | 11: SHA2-256 |
|           | This selection is only taken into account when the INIT bit is set. Changing this bitfield during a computation has no effect. |
|           | When ALGO bitfield is updated and INIT bit is set, NBWE in HASH_SR is automatically updated to 0x11. |
| Bit 16    | **LKEY**: Long key selection |
|           | This bit selects between short key (≤ 64 bytes) or long key (> 64 bytes) in HMAC mode. |
|           | 0: the HMAC key is shorter or equal to 64 bytes. The actual key value written to HASH_DIN is used during the HMAC computation. |
|           | 1: the HMAC key is longer than 64 bytes. The hash of the key is used instead of the real key during the HMAC computation. |
|           | This selection is only taken into account when the INIT and MODE bits are both set. Changing this bit during a computation has no effect. |
| Bit 15    | Reserved, must be kept at reset value. |
| Bit 14    | Reserved, must be kept at reset value. |
| Bit 13    | **MDMAT**: Multiple DMA transfers |
|           | This bit is set when hashing large files when multiple DMA transfers are needed. |
|           | 0: DCAL is automatically set at the end of a DMA transfer. |
|           | 1: DCAL is not automatically set at the end of a DMA transfer. |
| Bit 12    | **DINNE**: DIN not empty |
|           | Refer to DINNE bit of HASH_SR for the description. |
|           | This bit is read-only. |
51.7.2 HASH data input register (HASH_DIN)

Address offset: 0x04
Reset value: 0x0000 0000

HASH_DIN is the data input register. It is 32-bit wide. This register is used to enter the message by blocks. When the HASH_DIN register is programmed, the value presented on the AHB databus is ‘pushed’ into the hash core and the register takes the new value presented on the AHB databus. To get a correct message format, the DATATYPE bits must have been previously configured in the HASH_CR register.

When a complete block has been written to the HASH_DIN register, an intermediate digest calculation is launched:
• by writing new data into the HASH_DIN register (the first word of the next block) if the DMA is not used (intermediate digest calculation),
• automatically if the DMA is used.

When the last block has been written to the HASH_DIN register, the final digest calculation (including padding) is launched by writing the DCAL bit to 1 in the HASH_STR register (final digest calculation). This operation is automatic if the DMA is used and MDMAT bit is set to 0.

Reading the HASH_DIN register returns zeros.

Note: When the HASH is busy, a write access to the HASH_DIN register might stall the AHB bus if the digest calculation (intermediate or final) is not complete.

---

**51.7.3 HASH start register (HASH_STR)**

Address offset: 0x08

Reset value: 0x0000 0000

The HASH_STR register has two functions:

• It is used to define the number of valid bits in the last word of the message entered in the hash processor (that is the number of valid least significant bits in the last data written to the HASH_DIN register).
• It is used to start the processing of the last block in the message by writing the DCAL bit to 1.
These registers contain the message digest result named as follows:

- **HASH_HR0**, **HASH_HR1**, **HASH_HR2**, **HASH_HR3** and **HASH_HR4** registers return the SHA-1 digest result.
- **HASH_HR0**, **HASH_HR1**, **HASH_HR2** and **HASH_HR3** registers return A, B, C and D (respectively), as defined by MD5.
- **HASH_HR0** to **HASH_HR6** registers return the SHA2-224 digest result.
- **HASH_HR0** to **HASH_HR7** registers return the SHA2-256 digest result.

In all cases, the digest most significant bit is stored in HASH_H0[31] and unused **HASH_HRx** registers are read as zeros.

If a read access to one of these registers is performed while the hash core is calculating an intermediate digest or a final message digest (DCIS bit equals 0), then the read operation returns zeros.

**Note:** When starting a digest computation for a new message (by writing the INIT bit to 1), **HASH_HRx** registers are forced to their reset values. **HASH_HR0** to **HASH_HR4** registers can be accessed through two different addresses.
HASH aliased digest register x (HASH_HRAx)

Address offset: 0x0C + 0x4 * x, (x = 0 to 4)
Reset value: 0x0000 0000

The content of the HASH_HRAx registers is identical to the one of the HASH_HRx registers located at address offset 0x310.

</tr>
</tbody>
</table>

Bits 31:21 Reserved, must be kept at reset value.

- **Bits 20:16 NBWE[4:0]**: Number of words expected
  - This bitfield reflects the number of words in the message that must be pushed into the FIFO to trigger a partial computation. NBWE is decremented by 1 when a write access is performed to the HASH_DIN register.
  - NBWE is set to the expected block size +1 in words (0x11) when INIT bit is set in HASH_CR, and it is set to the expected block size when partial digest calculation ends.

- **Bit 15 DINNE**: DIN not empty
  - This bit is set when the HASH_DIN register holds valid data (that is after being written at least once). It is cleared when either the INIT bit (initialization) or the DCAL bit (completion of the previous message processing) is written to 1.
  - 0: No data are present in the data input buffer
  - 1: The input buffer contains at least one word of data

- **Bit 14 Reserved, must be kept at reset value.**
51.7.7 HASH context swap registers

These registers contain the complete internal register states of the hash processor. They are useful when a suspend/resume operation has to be performed because a high-priority task needs to use the hash processor while it is already used by another task.

When such an event occurs, the HASH_CSRx registers have to be read and the read values have to be saved in the system memory space. Then the hash processor can be used by the preemptive task, and when the hash computation is complete, the saved context can be read from memory and written back into the HASH_CSRx registers.

HASH_CSRx registers can be read only when DINIS equals to 1, otherwise zeros are returned.
**HASH context swap register x (HASH_CSRx)**

Address offset: 0x0F8 + x * 0x4, (x = 0 to 53)
Reset value: 0x0000 0002 (HASH_CSR0)
Reset value: 0x0000 0000 (HASH_CSR1 to 53)

Refer to Section 2.3 on page 139 for the register boundary addresses.
On-the-fly decryption engine (OTFDEC)

This section only applies to STM32U545/585/5Ax/5Gx devices.

52.1 Introduction

OTFDEC allows on-the-fly decryption of the AHB traffic based on the read request address information. Four independent and non-overlapping encrypted regions can be defined in OTFDEC.

OTFDEC uses AES-128 in counter mode to achieve the lowest possible latency. As a consequence, each time the content of one encrypted region is changed, the entire region must be re-encrypted with a different cryptographic context (key or initialization vector). This constraint makes OTFDEC suitable to decrypt read-only data or code, stored in external NOR flash.

Note: When OTFDEC is used in conjunction with OCTOSPI, it is mandatory to access the flash memory using the memory-mapped mode of the flash memory controller.

When security is enabled in the product, OTFDEC can be programmed only by a secure host.

52.2 OTFDEC main features

- On-the-fly 128-bit decryption during the OCTOSPI Memory-mapped read operations (single or multiple).
  - Use of AES in counter (CTR) mode, with two 128-bit keystream buffers
  - Support for any read size
  - Physical address of the reads used for the encryption/decryption
- Up to four independent encrypted regions
  - Granularity of the region definition: 4096 bytes
  - Region configuration write-locking mechanism
  - Each region has its own 128-bit key, two bytes firmware version, and eight bytes application-defined nonce. At least one of those must be changed each time an encryption is performed by the application.
- Encryption keys confidentiality and integrity protection
  - Write-only registers, with software locking mechanism
  - Availability of 8-bit CRC as public key information
- Support for OCTOSPI pre-fetching mechanism
- Possibility to select an enhanced encryption mode to add a proprietary layer of protection on top of AES stream cipher (execute only)
- Privileged-aware AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
- Secure only programming if TrustZone security is enabled in the product
- Encryption mode

- TZEN = 0: TrustZone security is disabled in the product.

## 52.3.3 OTFDEC on-the-fly decryption

### Introduction

Typical usage for OTFDEC is shown on Figure 499.

![Figure 499. Typical OTFDEC use in a SoC](image)

Original purpose of OTFDEC is to protect the confidentiality of read-only firmware libraries stored in external SPI NOR flash devices.

A special locking scheme is available in OTFDEC in order to protect the integrity of the decryption keys and also to protect the other configurations against software denial of services attacks. OTFDEC access to most registers can be made privileged-only by setting PRIV bit in OTFDEC_PRIVCFGR register. OTFDEC is only writeable by TrustZone CPU, when TrustZone security is activated.

When OTFDEC is used in conjunction with OCTOSPI, it is mandatory to read the flash memory using the Memory-mapped mode of the flash controller.

On top of decrypting on-the-fly, OTFDEC can also encrypt 32-bit word at a time (see Section 52.5.3: Encrypting for OTFDEC for more details).

### OTFDEC architecture

OTFDEC analyzes all AHB read transfers on the associated AHB bus. If the read request is within one of the four regions programmed in OTFDEC, the control logic triggers a keystream computation based on AES algorithm in counter mode. This keystream is then used to decrypt on-the-fly the data present in the read transfer from the OCTOSPI AHB master, tying low the HREADYOUT signal of this master while the keystream information is being computed (this takes up to 11 cycles). Any accesses outside the enabled OTFDEC regions belong to a non-encrypted region.

Each OTFDEC region is programmed through OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR, OTFDEC_RxNONCER and
OTFDEC_RxKEYR registers, where x = 1 to 4. In OTFDEC_RxCFGR, the MODE bits define the OTFDEC operating mode (standard or enhanced encryption).

Granularity for the region determination is 4096 bytes.

Note: Although OTFDEC does not prevent region overlapping, it is not a valid programming and it must be avoided by application software.

OTFDEC can decrypt incremental or wrap bursts only if they do not cross the 4096-byte aligned address boundaries.

52.3.4 OTFDEC usage of AES in counter mode decryption

Figure 500 shows how OTFDEC uses industry standard Advanced Encryption Standard (AES) algorithm in counter chaining mode. This mode is specified by NIST in Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.

![Figure 500. AES CTR decryption flow](image)

Every 128-bit data block, a special keystream information is computed using AES block cipher, as defined below:

- initialization vector AES_IV[127:0] = RxNONCER1[31:0] || RxNONCER0[31:0] || 0b0000 0000 0000 0000 || RxCFGR[31:16] || 0b00 || (x-1) || ReadAddress[31:4]
- key material AES_KEY[127:0] = RxKEYR3[31:0] || RxKEYR2[31:0] || RxKEYR1[31:0] || RxKEYR0[31:0]

Note: Above x is the RegionID of the selected encrypted region (x=1 to 4). ReadAddress is the AHB address of the encrypted data block, modulo 128-bit.

Resulting 128-bit keystream is XORed with 128-bit cipher text data to produce the 128-bit clear text data.

- AES_DIN and AES_DOUT data blocks are constructed following the rule below ("||" represents a binary concatenation):
  AES_Dx[127:0]= AHB_word(@ | 0xC)[31:0] | AHB_word(@ | 0x8)[31:0] | AHB_word(@ | 0x4)[31:0] || AHB_word(@ | 0x0)[31:0], where @ is the hexadecimal address used to compute the keystream (ReadAddress[31:4] above).
When the read request is not within an encrypted region, or the decryption is not enabled in this region, the AHB data is not changed.

**Note:** When the application sets the MODE bitfield to 11 in OTFDEC_RxCFGR, an additional layer of protection is added on top of the AES stream cipher. This enhanced encryption mode can only be used with instructions (execute-only region).

### 52.3.5 Flow control management

*Figure 501* shows how OTFDEC manages one INCR4 AHB burst that corresponds to one 128-bit AES data block.

**Figure 501. OTFDEC flow control overview (dual burst read request)**

with the following notes:

1. OTFDEC enforces HREADY signal from the AHB master low as it is not ready to decrypt data (keystream computation).
2. Thanks to the keystream buffer, OTFDEC can be ready to process a new batch of data within 12 cycles in this configuration (120 MHz AHB clock, 104 MHz SPI bus delivering 2 bytes per SPI clock).

### 52.3.6 OTFDEC error management

OTFDEC automatically manages errors defined as below:

- Illegal read to OTFDEC_RxKEYR registers
- Illegal write to OTFDEC_RxKEYR registers while CONFIGLOCK or KEYLOCK = 1 in OTFDEC_RxCFGR, while the access is secure. If the security is disabled in the product, the same error occurs when the access is nonsecure.
- Illegal write to OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR or OTFDEC_RxNONCER registers while CONFIGLOCK = 1 in OTFDEC_RxCFGR (x = 1 to 4), while the access is secure. If the security is disabled in the product the same error occurs when the access is nonsecure.
- Illegal read to an execute-only region (MODE[1:0] = 11). Such illegal request returns 0x0, without bus error.
- Execution request to a region while encryption is enabled (ENC = 1). The request returns 0x0, without bus error.
- Key error: read request to an encrypted region while its key registers are null or not properly initialized (KEYCRC = 0x0). Source of the error can be an incorrect key loading sequence (see KEYCRC in OTFDEC_RxCFGR) or it can be an abort event.
(tamper detection, unauthorized debug connection, untrusted boot, RDP level regression). Such read request returns 0x0, without bus error.

- Write to any registers while the access is nonsecure, if TrustZone security is enabled in the product.

  This last error is managed and cleared through TrustZone interrupt controller, as described in the GTZC section of the product reference manual.

For these errors (except the last one), an interrupt can be generated if the SEIE, XONEIE or KEIE bit is set in OTFDEC_IER register (see Section 52.4).

Note: After a key error, OTFDEC keys must be properly initialized again, and a reset of OTFDEC may be needed if registers are locked.

52.4 OTFDEC interrupts

There are three independent maskable interrupt sources generated by the OTFDEC, signaling following security events:

- Illegal read or write access to keys (SEIF flag), see Section 52.3.6
- Illegal write to a region configuration while CONFIGLOCK = 1 (SEIF flag), see Section 52.3.6
- Read access to an execute-only region (MODE[1:0] = 11), triggering the XONEIF flag
- Executing while encryption is enabled (XONEIF flag)
- Key error (encrypted regions read as zero) triggering the KEIF flag, see Section 52.3.6.

Interrupt sources are connected to the same global interrupt request signal.

OTFDEC interrupt sources can be enabled/disabled by setting the corresponding SEIE, XONEIE or KEIE bit in OTFDEC_IER, as described in Table 485. Status of the interrupt event is found in OTFDEC_ISR, and this event can be cleared using OTFDEC_ICR.

52.5 OTFDEC application information

52.5.1 OTFDEC initialization process

Introduction

One key aspect of OTFDEC is the trusted initialization of its registers, as it involves secret keys. Two trusted initialization schemes are recommended here below.
Note: Those sequences are for production code, as during firmware development, it is not always recommended to lock the key or the region configuration.

Writes to configuration registers are effective when the configuration locks allow it, even if the region is enabled.

Initialization scheme 1: one key for all regions

In this scheme, one entity owns the secret key used to decrypt the four protected regions. The recommended OTFDEC configuration sequence is described below:

1. For \( x = 1 \) to 4, write the correct MODE[1:0] value in OTFDEC_RxCFGR.
2. For \( x = 1 \) to 4, program OTFDEC_RxKEYR registers using the sequence described in KEYCRC (to have a valid CRC). Warning as key registers are write only.
3. For \( x = 1 \) to 4, check the key CRC. If OK, set KEYLOCK bit in OTFDEC_RxCFGR. This bit cannot be cleared (key registers in this region \( x \) are no more writable).
4. To do to decrypt a region \( x \) (task that does not necessarily have to be performed by the entity that owns the decryption keys):
   a) Verify if the key CRC corresponds to the encrypted binary stored in the region.
   b) Fill the detailed information corresponding to this binary (nonce, start address, end address, version number).
   c) Enable decryption of this region using REG_EN.
   d) Set CONFIGLOCK bit in OTFDEC_RxCFGR. This bit cannot be cleared (the region configuration is no more writable).

Caution: For a given region, when MODE bits are changed, the key registers and associated CRC are cleared by hardware. As a consequence, step 1 above must be done before step 2, and MODE bits must not be modified after step 2.

Initialization scheme 2: one key per region

In this scheme, one entity can own the secret used to decrypt one (or more) protected region. The recommended OTFDEC configuration sequence is described below:

1. To do to decrypt a region \( x \) (this task must be performed by the entity that owns the corresponding key):
   a) Write the correct MODE[1:0] value in OTFDEC_RxCFGR.
   b) Program OTFDEC_RxKEYR registers using the sequence described in KEYCRC (to have a valid CRC). Warning as key registers are write only.
   c) Check the key CRC. If OK, set KEYLOCK bit in OTFDEC_RxCFGR. This bit cannot be cleared (key registers are no more writable).
   d) Fill the detailed information corresponding to the protected firmware (nonce, start address, end address, version number).
   e) Enable decryption of this region using REG_EN.
   f) Set CONFIGLOCK bit in OTFDEC_RxCFGR. This bit cannot be cleared (the region configuration is no more writable).

Caution: For a given region, when MODE bits are changed, the key registers and associated CRC are cleared by hardware. As a consequence step a) above must be done before step b), and MODE bits must not be modified after step b).
52.5.2 OTFDEC and power management

Each time OTFDEC is reset, the correct key loading sequence described in Section 52.5.1 must be performed (in this case KEYCRC = 0 in OTFDEC_RxCFGR).

It is recommended for application software to verify this point each time OTFDEC is reset by hardware.

52.5.3 Encrypting for OTFDEC

Code and data standard encryption

OTFDEC uses standard AES in counter mode when processing a binary stored in a protected region with MODE[1:0] = 10. When this mode is selected, any AES compatible hardware accelerator or library can be used to encrypt those protected libraries. OTFDEC can be used as well, as described in enhanced encryption section below (with MODE[1:0] = 10).

Definition and endianness of the AES inputs and outputs are defined in Section 52.3.4: OTFDEC usage of AES in counter mode decryption.

Enhanced encryption with OTFDEC

OTFDEC uses a proprietary layer of protection on top of the standard AES in counter mode when processing a code stored in a protected region with MODE[1:0] = 11.

Enhanced encryption mode can be used to increase the robustness against tampering.

Recommended sequence to encrypt using OTFDEC is described below:

1. The application in charge of the encryption sets the ENC bit in OTFDEC_CR. This application must run in TrustZone secure mode when TrustZone security is enabled in the product. If PRIV bit is set in OTFDEC_PRIVCFGR, this application must be privileged.

2. Encryption application initializes OTFDEC as described in Section 52.5.1: OTFDEC initialization process. OCTOSPI must also be properly clocked, so that OTFDEC is fully functional in encryption mode. This step can also be done before step 1.

3. Encryption application writes 32-bit of clear-text data at the expected protected address, then reads it back encrypted at the same address to store it in RAM. Note that this data stays inside the device, as it is intercepted by OTFDEC in encryption mode.

4. Encryption application goes back to previous step (changing the address) until the whole binary is processed.

5. Encryption application clears the ENC bit in OTFDEC_CR. Another application can then take the encrypted binary and flash it to the correct address in external flash.

There are few important notes about this procedure:

- Encryption granularity is 32-bit (single 32-bit access is mandatory).
- While ENC bit is set, reads to non-encrypted regions return normal data (such as no encryption nor decryption). While in encryption mode, no access to OCTOSPI (including registers) must be done. This is because the OTFDEC cuts the communication with OCTOSPI while ENC bit is set.
- OTFDEC does not support execution while ENC = 1 (only encrypted data reads). Upon illegal execution detection a XONEIF flag is raised and zero is returned.
52.5.4 OTFDEC key CRC source code

Below is the CRC source code that can be used to compare with the result of the computation provided by OTFDEC in KEYCRC bitfield after loading the keys in OTFDEC_RxKEYR registers.

```c
uint8_t getCRC(uint32_t * keyin)
{
    const uint8_t CRC7_POLY = 0x7;
    const uint32_t key_strobe[4] = {0xAA55AA55, 0x3, 0x18, 0xC0};
    uint8_t  i, j, k, crc = 0x0;
    uint32_t  keyval;

    for (j = 0; j < 4; j++)
    {
        keyval = *(keyin+j);
        if (j == 0)
        {
            keyval ^= key_strobe[0];
        }
        else
        {
            keyval ^= (key_strobe[j] << 24) | (crc << 16) | (key_strobe[j] << 8) | crc;
        }
        for (i = 0, crc = 0; i < 32; i++)
        {
            k = (((crc >> 7) ^ (keyval >> (31-i))&0xF)) & 1;
            crc <<= 1;
            if (k)
            {
                crc ^= CRC7_POLY;
            }
        }
        crc ^= 0x55;
    }
    return crc;
}
```
52.6 OTFDEC registers

52.6.1 OTFDEC control register (OTFDEC_CR)

<table>
<thead>
<tr>
<th>Address offset: 0x0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reset value: 0x0000 0000</td>
</tr>
</tbody>
</table>

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **ENC:** Encryption mode bit

- When this bit is set, OTFDEC is used in encryption mode, during which application can write clear text data then read back encrypted data. When this bit is cleared (default), OTFDEC is used in decryption mode, during which application only read back decrypted data. For both modes, cryptographic context (keys, nonces, firmware versions) must be properly initialized.
- When this bit is set, only data accesses are allowed (zeros are returned otherwise, and XONEIF is set). When MODE = 11, enhanced encryption mode is automatically selected.

0: OTFDEC working in decryption mode
1: OTFDEC working in encryption mode

**Note:** When **ENC** bit is set, no access to OCTOSPI must be done (registers and Memory-mapped region).
### 52.6.2 OTFDEC privileged access control configuration register (OTFDEC_PRIVCFGR)

Address offset: 0x10
Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Bits 31:1 Reserved, must be kept at reset value.

- **Bit 0 PRIV**: Privileged access protection.
  - 0: No additional protection is added on OTFDEC register accesses.
  - 1: An additional protection is added when accessing all registers except OTFDEC_PRIVCFGR:
    - Unprivileged read accesses to registers return zeros
    - Unprivileged write accesses to registers are ignored.

  **Note**: This bit can only be written in privileged mode. There is no limitations on reads.

### 52.6.3 OTFDEC region x configuration register (OTFDEC_RxCFGFR)

Address offset: 0x20 + 0x30 * (x - 1), (x = 1 to 4)
Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Writes are ignored if CONFIGLOCK bit is set to 1.

- **KEYCRC[7:0]**
- **MODE[1:0]**
- **KEYLOCK**
- **CONFIGLOCK**
- **REG_EN**
Bits 31:16 **REG\_VERSION[15:0]**: region firmware version

This 16-bit bitfield must be correctly initialized before the region corresponding REG\_EN bit is set in OTFDEC\_RxCFGR.

Bits 15:8 **KEYCRC[7:0]**: region key 8-bit CRC

When KEYLOCK = 0, KEYCRC bitfield is automatically computed by hardware while loading the key of this region in this exact sequence: KEYR0 then KEYR1 then KEYR2 then finally KEYR3 (all written once). A new computation starts as soon as a new valid sequence is initiated, and KEYCRC is read as zero until a valid sequence is completed.

When KEYLOCK = 1, KEYCRC remains unchanged until the next reset.

CRC computation is an 8-bit checksum using the standard CRC-8-CCITT algorithm $X^8 + X^2 + X + 1$ (according the convention). Source code is available in Section 52.5.4. This field is read only.

Note: CRC information is updated only after the last bit of the key has been written.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **MODE[1:0]**: operating mode

This bitfield selects the OTFDEC operating mode for this region:
- 10: All read accesses are decrypted (instruction or data).
- 11: Enhanced encryption mode is activated, and only instruction accesses are decrypted
- Others: Reserved

When MODE $\neq 11$, the standard AES encryption mode is activated.

When either of the MODE bits are changed, the region key and associated CRC are zeroed.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **KEYLOCK**: region key lock

0: Writes to this region KEYR$\text{x}$ registers are allowed.
1: Writes to this region KEYR$\text{x}$ registers are ignored until next OTFDEC reset. KEYCRC bitfield is locked.

Note: This bit is set once: if this bit is set, it can only be reset to 0 if the OTFDEC is reset.

Bit 1 **CONFIGLOCK**: region config lock

0: Writes to this region OTFDEC\_RxCFGR, OTFDEC\_RxSTARTADDR, OTFDEC\_RxENDADDR and OTFDEC\_RxNONCERy registers are allowed.
1: Writes to this region OTFDEC\_RxCFGR, OTFDEC\_RxSTARTADDR, OTFDEC\_RxENDADDR and OTFDEC\_RxNONCERy registers are ignored until next OTFDEC reset.

Note: This bit is set once. If this bit is set, it can only be reset to 0 if OTFDEC is reset. Setting this bit forces KEYLOCK bit to 1.

Bit 0 **REG\_EN**: region on-the-fly decryption enable

0: On-the-fly decryption is disabled for this region.
1: On-the-fly decryption is enabled for this region. Data are XORed with the corresponding keystream.

Note: Garbage is decrypted if region context (version, key, nonce) is not valid when this bit is set.
52.6.4 OTFDEC region x start address register (OTFDEC_RxSTARTADDR)

Address offset: 0x24 + 0x30 * (x - 1), (x = 1 to 4)
Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Bits 31:0 REG_START_ADDR[31:0]: Region AHB start address
This register must be written before the region corresponding REG_EN bit in the OTFDEC_RxCFGR register is set.
Writing to this register is discarded if performed while the region CONFIGLOCK bit in the OTFDEC_RxCFGR register is set.

Note: When determining the region the first 12 bits (LSB) and the last 4 bits (MSB) are ignored.
When this register is accessed in read the 4 MSB bits and the 12 LSB bits return zeros.

52.6.5 OTFDEC region x end address register (OTFDEC_RxENDADDR)

Address offset: 0x28 + 0x30 * (x - 1), (x = 1 to 4)
Reset value: 0x0000 0FFF

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

REG_END_ADDR[31:16]

REG_END_ADDR[15:0]
Bits 31:0 REG_ADDR[31:0]: Region AHB end address
This register must be written before the region corresponding REG_EN bit in the OTFDEC_RxCFGR register is set, and OTFDEC_RxENDADDR must be strictly greater than OTFDEC_RxSTARTADDR to be valid.
Writing to this register is discarded if performed while the region CONFIGLOCK bit in OTFDEC_RxCFGR is set.

Note: When determining the region the first 12 bits (LSB) and the last 4 bits (MSB) are ignored.
When this register is accessed in read the 4 MSB bits return zeros and the 12 LSB bits return ones.

52.6.6 OTFDEC region x nonce register 0 (OTFDEC_RxNONCER0)
Address offset: 0x2C + 0x30 * (x - 1), (x = 1 to 4)
Reset value: 0x0000 0000
Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.
Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

</thead>
</table>

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF**: Key error interrupt flag status
This bit is set by hardware and read only by application. The bit is set when a read access occurs on an encrypted region, while its key registers is null or not properly initialized (KEYCRC = 0x0).
This bit is cleared when the application sets in OTFDEC_ICR the corresponding bit to 1.
0: OTFDEC operates properly.
1: Read access detected on an enabled encrypted region with its key registers null or not properly initialized (KEYCRC = 0x0). OTFDEC returns a zeroed value for the read, and an optional interrupt is generated if bit KEIE is set to 1 in OTFDEC_IER.
After KEIF is set any subsequent read to the region with bad key registers returns a zeroed value. This state remains until those key registers are properly initialized (KEYCRC not zero).
Bit 1 **XONEIF**: Execute-only execute-never error interrupt flag status

This bit is set by hardware and read only by application. This bit is set when a read access and not an instruction fetch is detected on any encrypted region with MODE bits set to 11. Lastly, XONEIF is also set when an execute access is detected while encryption mode is enabled.

This bit is cleared when application sets in OTFDEC_ICR the corresponding bit to 1.

0: No execute-only error status. No interrupt pending.

1: Read access detected on one region with MODE bits set to 11 or execute access detected while ENC = 1. OTFDEC returns a zeroed value for the illegal access, and an optional interrupt is generated if bit XONEIE is set to 1 in OTFDEC_IER.

Bit 0 **SEIF**: Security error interrupt flag status

This bit is set by hardware and read only by application. This bit is set when at least one security error has been detected.

This bit is cleared when application sets in OTFDEC_ICR the corresponding bit to 1.

0: No security error status. No interrupt pending.

1: Security error flag status, with interrupt pending. Actual interrupt generation is dependent on OTFDEC_IER corresponding bit SEIE.

### 52.6.13 OTFDEC interrupt clear register (OTFDEC_ICR)

Address offset: 0x304

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.
Bit 2 \textbf{KEIF}: Key error interrupt flag clear
This bit is written by application, and always read as 0.
0: KEIF flag status is not affected.
1: KEIF flag status is cleared in OTFDEC_ISR.
\textit{Note:} Clearing KEIF does not solve the source of the problem (bad key registers). To be able to access again any encrypted region, OTFDEC key registers must be properly initialized again.

Bit 1 \textbf{XONEIF}: Execute-only execute-never error interrupt flag clear
This bit is written by application, and always read as 0.
0: XONEIF flag status is not affected.
1: XONEIF flag status is cleared in OTFDEC_ISR.

Bit 0 \textbf{SEIF}: Security error interrupt flag clear
This bit is written by application, and always read as 0.
0: SEIF flag status is not affected.
1: SEIF flag status is cleared in OTFDEC_ISR.

52.6.14 \textbf{OTFDEC interrupt enable register (OTFDEC_IER)}
Address offset: 0x308
Reset value: 0x0000 0000
Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.
Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

53 Public key accelerator (PKA)

This section only applies to STM32U545/585/5Ax/5Gx devices.

53.1 Introduction

PKA (public key accelerator) is intended for the computation of cryptographic public key primitives, specifically those related to RSA, Diffie-Hellmann or ECC (elliptic curve cryptography) over GF(p) (Galois fields). To achieve high performance at a reasonable cost, these operations are executed in the Montgomery domain.

For a given operation, all needed computations are performed within the accelerator, so no further hardware/software elaboration is needed to process the inputs or the outputs.

When manipulating secrets, the PKA incorporates a protection against side-channel attacks (SCA), including differential power analysis (DPA), certified SESIP and PSA security assurance level 3.

53.2 PKA main features

- Acceleration of RSA, DH and ECC over GF(p) operations, based on the Montgomery method for fast modular multiplications. More specifically:
  - RSA modular exponentiation, RSA chinese remainder theorem (CRT) exponentiation
  - ECC scalar multiplication, point on curve check, complete addition, double base ladder, projective to affine
  - ECDSA signature generation and verification
- Capability to handle operands up to 4160 bits for RSA/DH and 640 bits for ECC
- When manipulating secrets: protection against side-channel attacks (SCA), including differential power analysis (DPA), certified SESIP and PSA security assurance level 3
  - Applicable to modular exponentiation, ECC scalar multiplication and ECDSA signature generation
- Arithmetic and modular operations such as addition, subtraction, multiplication, modular reduction, modular inversion, comparison, and Montgomery multiplication
- Built-in Montgomery domain inward and outward transformations
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)

<td>PKA internal tamper event signal to TAMP (XOR-ed), triggered when an unexpected fault occurs while PKA manipulates secrets, or when the programmed input point is not found on the input curve (ECDSA signature and ECC scalar multiplication only). This signal is asserted as soon as a fault is detected. When asserted, read access to PKA registers are reset to 0 and writes are ignored. The signal is de-asserted when PKA memory is cleared.</td>
</tr>
</tbody>
</table>

53.3.3 PKA reset and clocks

PKA is clocked on the AHB bus clock. When the PKA peripheral reset signal is released PKA_RAM is cleared automatically, taking 667 clock cycles. During this time the setting of bit EN in PKA_CR register is ignored.

According to the security policy applied to the device, PKA RAM can also be reset following a tamper event. Refer to *Tamper detection and response* in the System security section (if applicable to this product).
53.3.4 PKA public key acceleration

Overview

Public key accelerator (PKA) is used to accelerate Rivest, Shamir and Adleman (RSA),
Diffie-Hellman (DH) as well as ECC over prime field operations. Supported operand sizes is
up to 4160 bits for RSA and DH, and up to 640 bits for ECC.

The PKA supports all non-singular elliptic curves defined over prime fields, that can be
described with a short Weierstrass equation $y^2 = x^3 + ax + b \pmod{p}$. More information can
be found in Section 53.5.1: Supported elliptic curves.

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

A memory of 5336 bytes (667 words of 64 bits) called PKA RAM is used to provide initial
data to the PKA, and to hold the results after computation is completed. Access is done
though the PKA AHB interface.

PKA operating modes

The list of operations the PKA can perform is detailed in Table 488 and Table 489,
respectively, for integer arithmetic functions and prime field (Fp) elliptic curve functions.

</tbody>
</table>

Each of these operating modes has an associated code that has to be written to the MODE field in the PKA_CR register. If the application selects any value that is not documented below the write to MODE bitfield is ignored, and an operation error (OPERRF) is triggered. When this happens, a new operation must be selected after the error is cleared.

Some operations in Table 488 and Table 489 are indicated as protected. Those operations are used when manipulating secret keys (modular exponentiation for RSA decryption, scalar multiplication and signature for ECC). Those secrets (protected against side channel attacks) are automatically erased from PKA RAM at the end of the protected operations (BUSY goes low). They are also protected against side channel attacks.

**Caution:** For security reason it is very important to select protected modular exponentiation (MODE = 0x3) when performing RSA decryption.

**Montgomery space and fast mode operations**

For efficiency reason the PKA internally performs modular multiply operations in the Montgomery domain, automatically performing inward and outward transformations.

As Montgomery parameter computation is time consuming the application can decide to use a faster mode of operation, during which the precomputed Montgomery parameter is supplied before starting the operation. Performance improvement is detailed in Section 53.5.2: Computation times.

The only operation using fast mode is modular exponentiation (MODE = 0x02).

**53.3.5 Typical applications for PKA**

**Introduction**

The PKA can be used to accelerate a number of public key cryptographic functions. In particular:

- RSA encryption and decryption
- RSA key finalization
- CRT-RSA decryption
- DSA and ECDSA signature generation and verification
- DH and ECDH key agreement
Specifications of the above functions are given in following publications:

- FIPS PUB 186-4, Digital Signature Standard (DSS), July 2013 by NIST
- PKCS #1, RSA Cryptography Standard, v1.5, v2.1 and v2.2. by RSA Laboratories

The principles of the main functions are described in this section, for a more detailed description refer to the above cited documents.

### RSA key pair

For the following RSA operations a public key and a private key information are defined as below:

- Alice transmits her public key \((n, e)\) to Bob. Numbers \(n\) and \(e\) are very large positive integers.
- Alice keeps secret her private key \(d\), also a very large positive integer. Alternatively this private key can also be represented by a quintuple \((p, q, dp, dq, qInv)\).

For more information on the above representations refer to the RSA specification.

### RSA encryption/decryption principle

As recommended by the PKCS#1 specification, Bob, to encrypt message \(M\) using Alice’s public key \((n, e)\) must go through the following steps:

1. Compute the encoded message \(EM = ENCODE(M)\), where ENCODE is an encoding method.
2. Turn \(EM\) into an integer \(m\), with \(0 \leq m < n\) and \((m, n)\) being coprimes.
3. Compute ciphertext \(c = m^e \mod n\).
4. Convert the integer \(c\) into a string ciphertext \(C\).

Alice, to decrypt ciphertext \(c\) using her private key \(d\), follows the steps indicated below:

1. Convert the ciphertext \(C\) to an integer ciphertext representative \(c\).
2. If necessary, retrieve the prime factors \((p, q)\) using \((n, e, d)\) information, then compute \(\phi = (p - 1) * (q - 1)\). Refer to NIST SP800-56B Appendix C for details.
3. Recover plaintext \(m = c^d \mod n = (m^p)^d \mod n\). If the private key is the quintuple \((p, q, dp, dq, qInv)\), then plaintext \(m\) is obtained by performing the operations:
   
   a) \(m_1 = c^{dp} \mod p\)
   
   b) \(m_2 = c^{dq} \mod q\)
   
   c) \(h = qInv (m_1 - m_2) \mod p\)
   
   d) \(m = m_2 + h q\)
4. Convert the integer message representative \(m\) to an encoded message \(EM\).
5. Recover message \(M = DECODE(EM)\), where DECODE is a decoding method.

Above operations can be accelerated by PKA using **Modular exponentiation** \(A^e \mod n\) if the private key is \(d\), or **RSA CRT exponentiation** if the private key is the quintuple \((p, q, dp, dq, qInv)\).

**Note:** The decoding operation and the conversion operations between message and integers are specified in PKCS#1 standard.
Note: For the decryption process protected version of modular exponentiation (MODE = 0x3) is strongly recommended for security reason. For encryption process MODE = 0x3 cannot be used, as it requires the knowledge of the private key.

Elliptic curve selection

For following ECC operations curve parameters are defined as below:
- Curve corresponds to the elliptic curve field agreed among actors (Alice and Bob). Supported curves parameters are summarized in Section 53.5.1: Supported elliptic curves.
- G is the chosen elliptic curve base point (also known as generator), with a large prime order n (i.e. \( n \times G = \text{identity element O} \)).

ECDSA message signature generation

ECDSA (elliptic curve digital signature algorithm) signature generation function principle is the following: Alice, to sign a message \( m \) using her private key integer \( d_A \), goes through the following steps.
1. Calculate \( e = \text{HASH}(m) \), where \( \text{HASH} \) is a cryptographic hash function.
2. Let \( z \) be the \( L_n \) leftmost bits of \( e \), where \( L_n \) is the bit length of the group order \( n \).
3. Select a cryptographically secure random integer \( k \) where \( 0 < k < n \).
4. Calculate the curve point \( (x_1, y_1) = k \times G \).
5. Calculate \( r = x_1 \mod n \). If \( r = 0 \) go back to step 3.
6. Calculate \( s = k^{-1} (z + rd_A) \mod n \). If \( s = 0 \) go back to step 3.
7. The signature is the pair \( (r, s) \).

Steps 4 to 7 are accelerated by PKA using:
- \textit{ECDSA sign} or
- All of the operations below:
  - \textit{ECC Fp scalar multiplication} \( k \times P \)
  - \textit{Modular reduction} \( A \mod n \)
  - \textit{Modular inversion} \( A^{-1} \mod n \)
  - \textit{Modular addition} and \textit{Modular and Montgomery multiplication}

ECDSA signature verification

ECDSA (elliptic curve digital signature algorithm) signature verification function principle is the following: Bob, to authenticate Alice's signature, must have a copy of her public key curve point \( Q_A \).

Bob can verify that \( Q_A \) is a valid curve point going through the following steps:
1. check that \( Q_A \) is not equal to the identity element \( O \)
2. check that \( Q_A \) is on the agreed curve
3. check that \( n \times Q_A = O \).

Then Bob follows the procedure detailed below:
1. verify that \( r \) and \( s \) are integer in \([1, n-1]\)
2. calculate \( e = \text{HASH}(m) \), where HASH is the agreed cryptographic hash function
3. let \( z \) be the \( L_n \) leftmost bits of \( e \)
4. calculate \( w = s^{-1} \mod n \)
5. calculate \( u_1 = zw \mod n \) and \( u_2 = rw \mod n \)
6. calculate the curve point \((x_1, y_1) = u_1 \times G + u_2 \times Q_A\)
7. the signature is valid if \( r = x_1 \mod n \), it is invalid otherwise.

Steps 4 to 7 are accelerated by PKA using **ECDSA verification**.

### 53.3.6 PKA procedure to perform an operation

**Enabling/disabling PKA**

Setting the EN bit to 1 in PKA\_CR register enables the PKA peripheral. The PKA becomes available when INITOK bit is set in PKA\_SR. When EN = 0, the PKA peripheral is kept under reset, with PKA memory still accessible by the application through the AHB interface.

*Note:* When PKA is in the process of clearing its memory EN bit cannot be set.

*Note:* When setting EN bit in PKA\_CR make sure that the value of MODE bitfield corresponds to an authorized PKA operation (see OPERRF in Section 53.3.7).

Clearing EN bit to 0 while a calculation is in progress causes the operation to be aborted. In this case, the content of the PKA memory is not guaranteed, with the exception of the PKA modes 0x03, 0x20 and 0x24. For these operations, the PKA memory is cleared after abort, making the memory unavailable for 667 cycles. During this clearing time only PKA registers can be accessed, with writes to EN bits ignored.

If INITOK bit stays at 0, make sure that the RNG peripheral is clocked and properly initialized, then try to enable PKA again.

**Data formats**

The format of the input data and the results in the PKA RAM are specified, for each operation, in Section 53.4.

**Executing a PKA operation**

Each of the supported PKA operation is executed using the following procedure:

1. Load initial data into the PKA internal RAM, which is located at address offset 0x400.
2. Write in the MODE field of PKA\_CR register, specifying the operation which is to be executed and then assert the START bit, also in PKA\_CR register.
3. Wait until the PROCENDF bit in the PKA\_SR register is set to 1, indicating that the computation is complete.
4. Read the result data from the PKA internal RAM, then clear PROCENDF bit by setting PROCENDFC bit in PKA\_CLRFR.

*Note:* When PKA is busy (BUSY = 1) any access by the application to PKA RAM is ignored, and the flag RAMERRF is set in PKA\_SR.

Selecting an illegal or unknown operation in step 2 triggers an OPERRF error, and step 3 (PROCENDF = 1) never happens. See Section 53.3.7 for details.
Using precomputed Montgomery parameters (PKA Fast mode)

As explained in Section 53.3.4, when computing many operations with the same modulus it can be beneficial for the application to compute only once the corresponding Montgomery parameter (see, for example, Section 53.4.5). This is known as “Fast mode”.

To manage the usage of Fast mode it is recommended to follow the procedure described below:

1. Load in PKA RAM the modulus size and value information. Such information is compiled in Section 53.5.1.
2. Program in PKA_CR register the PKA in Montgomery parameter computation mode (MODE=“0x1”) then assert the START bit.
3. Wait until the PROCENDF bit in the PKA_SR register is set to 1, then read back from PKA memory the corresponding Montgomery parameter, and then clear PROCENDF bit by setting PROCENDFC bit in PKA_CLRFR.
4. Proceed with the required PKA operation, loading on top of regular input data the Montgomery information R2 mod m. All addresses are indicated in Section 53.4.

53.3.7 PKA error management

When PKA is used some errors can occur:

- The access to PKA RAM falls outside the expected range. In this case the Address Error flag (ADDRERRF) is set in the PKA_SR register.
- An AHB access to the PKA RAM occurred while the PKA core was using it. In this case the RAM Error Flag (RAMERRF) is set in the PKA_SR register, reads to PKA RAM return zero, while writes are ignored.
- The selected operating mode using MODE bitfield is not listed in PKA operating modes (or in bitfield description). In this case the operation error flag (OPERRF) is set in the PKA_SR register, and write to MODE bitfield is ignored.

For each error flag above PKA generates an interrupt if the application sets the corresponding bit in PKA_CR register (see Section 53.6 for details).

ADDRERRF, OPERRF and RAMERRF errors are cleared by setting the corresponding bit in PKA_CLRFR.

The PKA can be re-initialized at any moment by resetting the EN bit in the PKA_CR register.

OPERRF error must be cleared using OPERRFC bit in PKA_CLRFR before a new operation is written in PKA_CR register.

53.4 PKA operating modes

53.4.1 Introduction

The various operations supported by PKA are described in the following subsections, defining the format of the input data and of the results, both stored in the PKA RAM.

---

**Warning:** The validity of all input parameters to the PKA must be checked before starting any operation, as PKA assumes that...
all of them are valid and consistent with each other. Input parameters must not exceed the operand size specified in the operation tables.

The following information applies to all PKA operations.

- PKA core processes 64-bit words in its RAM. Hence hereafter all word size is 64-bit.
- When an element is written as input in the PKA RAM, an additional word with all bits equal to zero has to be added after the most significant input word. This rule does not apply if the operand has a fixed size of 1.
- All reported RAM storage addresses refer to the least significant word of the data, and to obtain the actual address to use application must add to the indicated offset the base address of the PKA.
- Supported operand “Size” are:
  - ROS (RSA operand Size): data size is (rsa_size / 64 + 1) words, with rsa_size equal to the chosen modulus length in bits. For example, when computing RSA with an operand size of 1024 bits, ROS is equal to 17 words, or 1088 bits.
  - EOS (ECC operand Size): data size is (ecc_size / 64 + 1) words, with ecc_size equal to the chosen prime modulus length in bits. For example, when computing ECC with an operand size of 192 bits, EOS is equal to 4 words, or 256 bits.
  - ROS and EOS values include the required additional all 0 word.
- Unless indicated otherwise, all operands in the tables are integers.

Note: Fractional results for above formulas must be rounded up to the nearest integer since PKA core processes 64-bit words.

Note: The maximum ROS is 66 words (4160-bit max exponent size), while the maximum EOS is 11 words (640-bit max operand size).

As a first example (and to better understand the endianess in PKA memory), to prepare the operation ECC Fp scalar multiplication, when the application writes the x coordinate of point P for an ECC P256 curve (EOS = 5 words), the least significant bit must be placed in bit 0 at address offset 0x578, and the most significant bit in bit 63 at address offset 0x590. Then, as mentioned above, the application must write the empty word 0x0000000000000000 at address offset 0x598.

As a second example, still to prepare the operation ECC Fp scalar multiplication, when the application need to write the information a = -3, on a curve with a modulus length of 224 bits (i.e. four 64-bit words, rounded up, plus one) following data must be written in PKA memory:

```
@RAM+410 0x0000000000000001 /* curve coefficient 'a' sign without extra word */
@RAM+418 0x0000000000000011 /* value of |a| LSB */
@RAM+420 0x0000000000000000 ... 
@RAM+428 0x0000000000000000 ... 
@RAM+430 0x0000000000000000 value of |a| MSB */
@RAM+438 0x0000000000000000 /* additional all 0 word */
```
53.4.2 Montgomery parameter computation

This function is used to compute the Montgomery parameter \( (R^2 \mod n) \) used by PKA to convert operands into the Montgomery residue system representation. This operation can be very useful when fast mode operation is used, because in this case the Montgomery parameter is passed as input, saving the time for its computation.

*Note:* *This operation can also be used with ECC curves. In this case prime modulus length and EOS size must be used.*

Operation instructions for Montgomery parameter computation are summarized in *Table 490*.

</tbody>
</table>

Table 491. Modular addition

53.4.4 Modular subtraction

Modular subtraction operation consists in the following computations:

- If \(A \geq B\) result equals \(A - B \mod n\)
- If \(A < B\) result equals \(A + n - B \mod n\)

Operation instructions are summarized in *Table 492*.
To be more efficient when performing a sequence of multiplications the PKA accelerates multiplication which has at least one input in the Montgomery domain. The two main uses of this operation are:

- Map a value from natural domain to Montgomery domain and vice-versa
- Perform a modular multiplication $A \times B \mod n$

The method to perform above operations are described below. Note that “x” function is this operation, and $A$, $B$, $C$ operands are in the natural domain.

1. Inward (or outward) conversion into (or from) Montgomery domain
   a) Let us assume $A$ is an integer in the natural domain
      Compute $r_2 \mod n$ using Montgomery parameter computation
      Result $AR = A \times r_2 \mod n$ is $A$ in the Montgomery domain
   b) Let us assume $BR$ is an integer in the Montgomery domain
      Result $B = BR \times 1 \mod n$ is $B$ in the natural domain
      Similarly, above value $AR$ computed in a) can be converted into the natural domain by computing $A = AR \times 1 \mod n$

2. Simple modular multiplication $A \times B \mod n$
   a) Compute $r_2 \mod n$ using Montgomery parameter computation
   b) Compute $AR = A \times r_2 \mod n$. Output is in the Montgomery domain
   c) Compute $AB = AR \times B \mod n$. Output is in natural domain

3. Multiple modular multiplication $A \times B \times C \mod n$
   a) Compute $r_2 \mod n$ using Montgomery parameter computation
   b) Compute $AR = A \times r_2 \mod n$. Output is in the Montgomery domain
   c) Compute $BR = B \times r_2 \mod n$. Output is in the Montgomery domain
   d) Compute $ABR = AR \times BR \mod n$. Output is in the Montgomery domain
   e) Compute $CR = C \times r_2 \mod n$. Output is in the Montgomery domain
   f) Compute $ABCR = ABR \times CR \mod n$. Output is in the Montgomery domain
   g) (optional) Repeat the two steps above if more operands need to be multiplied
   h) Compute $ABC = ABCR \times 1 \mod n$ to retrieve the result in natural domain

Operation instructions for Montgomery multiplication are summarized in Table 493.

### 53.4.5 Modular and Montgomery multiplication

To be more efficient when performing a sequence of multiplications the PKA accelerates multiplication which has at least one input in the Montgomery domain. The two main uses of this operation are:

- Map a value from natural domain to Montgomery domain and vice-versa
- Perform a modular multiplication $A \times B \mod n$

The method to perform above operations are described below. Note that “x” function is this operation, and $A$, $B$, $C$ operands are in the natural domain.

1. Inward (or outward) conversion into (or from) Montgomery domain
   a) Let us assume $A$ is an integer in the natural domain
      Compute $r_2 \mod n$ using Montgomery parameter computation
      Result $AR = A \times r_2 \mod n$ is $A$ in the Montgomery domain
   b) Let us assume $BR$ is an integer in the Montgomery domain
      Result $B = BR \times 1 \mod n$ is $B$ in the natural domain
      Similarly, above value $AR$ computed in a) can be converted into the natural domain by computing $A = AR \times 1 \mod n$

2. Simple modular multiplication $A \times B \mod n$
   a) Compute $r_2 \mod n$ using Montgomery parameter computation
   b) Compute $AR = A \times r_2 \mod n$. Output is in the Montgomery domain
   c) Compute $AB = AR \times B \mod n$. Output is in natural domain

3. Multiple modular multiplication $A \times B \times C \mod n$
   a) Compute $r_2 \mod n$ using Montgomery parameter computation
   b) Compute $AR = A \times r_2 \mod n$. Output is in the Montgomery domain
   c) Compute $BR = B \times r_2 \mod n$. Output is in the Montgomery domain
   d) Compute $ABR = AR \times BR \mod n$. Output is in the Montgomery domain
   e) Compute $CR = C \times r_2 \mod n$. Output is in the Montgomery domain
   f) Compute $ABCR = ABR \times CR \mod n$. Output is in the Montgomery domain
   g) (optional) Repeat the two steps above if more operands need to be multiplied
   h) Compute $ABC = ABCR \times 1 \mod n$ to retrieve the result in natural domain

Operation instructions for Montgomery multiplication are summarized in Table 493.
Modular exponentiation

Modular exponentiation operation is commonly used to perform a single-step RSA operation. It consists in the computation of $A^e \mod n$.

RSA operation involving public information (RSA encryption) can use the normal or fast mode detailed on Table 494 and Table 495. RSA operation involving secret information (RSA decryption) must use the protected mode detailed on Table 496, for security reason.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware.

Note: When $MODE = 0x03$, if the error output is different from $0xD60D$ all the memory content is cleared by PKA to avoid leaking information about the private key.

Operation instructions for modular exponentiation are summarized in Table 494 (normal mode), Table 495 (fast mode) and in Table 496 (protected mode). Fast mode usage is explained in Section 53.3.6.

53.4.7 Modular inversion

Modular inversion operation consists in the computation of multiplicative inverse $A^{-1} \mod n$. If the modulus $n$ is prime, for all values of $A$ ($1 \leq A < n$) modular inversion output is valid. If the modulus $n$ is not prime, $A$ has an inverse only if the greatest common divisor between $A$ and $n$ is 1.

If the operand $A$ is a divisor of the modulus $n$ the result is a multiple of a factor of $n$.

Operation instructions for modular inversion are summarized in Table 497.
53.4.8 Modular reduction

Modular reduction operation consists in the computation of the remainder of A divided by n. Operation instructions are summarized in Table 498.

</tr>
</tbody>
</table>

Table 499. Arithmetic addition

53.4.10 Arithmetic subtraction

Arithmetic subtraction operation consists in the following computations:
- If \(A \geq B\) result equals \(A - B\)
- If \(A < B\) and \(M/32\) residue is \(> 0\) result equals \(A + 2^{\text{int}(M/32)\times 32} + 1 - B\)
- If \(A < B\) and \(M/32\) residue is \(0\) result equals \(A + 2^{\text{int}(M/32)\times 32} - B\)
For the last two bullets the 32-bit word following the most significant word of the output equals 0xFFFF FFFF, as result is negative.

Operation instructions are summarized in Table 500.

53.4.13 RSA CRT exponentiation

For efficiency many popular crypto libraries like OpenSSL RSA use the following optimization for decryption and signing based on the chinese remainder theorem (CRT):

- $p$ and $q$ are precomputed primes, stored as part of the private key
- $d_P = d \mod (p-1)$
- $d_Q = d \mod (q-1)$ and
- $q_{inv} = q^{-1} \mod p$

These values allow the recipient to compute the exponentiation $m = A^d \mod pq$ more efficiently as follows:

- $m_1 = A^{d_P} \mod p$
- $m_2 = A^{d_Q} \mod p$
- $h = q_{inv} (m_1 - m_2) \mod p$, with $m_1 > m_2$
- $m = m_2 + h q$

Operation instructions for computing CRT exponentiation $A^d \mod pq$ are summarized in Table 503.

<td>RAM@0x410</td>
<td></td>
</tr>
</tbody>
</table>

When this operation completes with errors due to unexpected hardware events, a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware. PKA tamper is also triggered when the programmed input point is not found on the input ECC curve. PKA operation "Point on elliptic curve" can be used to avoid this.
When performing this operation the following special cases must be noted:

- For \( k = 0 \) this function returns a point at infinity \((0, 0)\) if curve parameter \( b \) is nonzero, \((0, 1)\) otherwise. For \( k \) different from 0 it might happen that a point at infinity is returned. When the application detects this behavior a new computation must be carried out.

- For \( k < 0 \) (i.e. a negative scalar multiplication is required) multiplier absolute value \( k = |-k| \) must be provided to the PKA. After the computation completion, the formula \(-P = (x, -y)\) can be used to compute the \( y \) coordinate of the effective final result (the \( x \) coordinate remains the same).

Note: If the error output is different from 0xD60D all the memory content is cleared by PKA to avoid leaking information about the private key.

### 53.4.16 ECDSA sign

ECDSA signing operation (outlined in Section 53.3.5) is summarized in Table 506 (input parameters) and in Table 507 (output parameters).

The application has to check if the output error is equal to 0xD60D, if it is different a new \( k \) must be generated and the ECDSA sign operation must be repeated.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware. PKA tamper is also triggered when the programmed input point is not found on the input ECC curve. PKA operation "Point on elliptic curve" can be used to avoid this.

| Error \( k \times P \) | – No errors: 0xD60D  
– Errors: 0xCBC9 | RAM@0x680 | 64 bits |

**Note:** If the error output is different from 0xD60D all the memory content is cleared by PKA to avoid leaking information about the private key.
Note: If the error output equals 0xD60D or 0xBC9 all the memory content is cleared by PKA to avoid leaking information about the private key. If error output equals 0xA3B7 or 0xF946 PKA memory content is partially erased, keeping the error code readable.

**Extended ECDSA support**

PKA also supports extended ECDSA signature, for which the inputs and the outputs are the same as ECDSA signature (Table 506 and Table 507, respectively), with the addition of the coordinates of the point kG. This extra output is defined in Table 508.

---

1. Padding with zeroes or hash truncation must be used to have the hash parameter size equal to the curve prime order n length.
### 53.4.18 ECC complete addition

ECC complete addition computes the addition of two given points on an elliptic curve.

Operation instructions are summarized in Table 511.

**Note:** The two input points and the resulting point are represented in Jacobian coordinates \((X,Y,Z)\). To input a point in affine coordinates \((x,y)\) conversion \((X,Y,Z) = (x,y,1)\) can be used. To convert resulting point to Jacobian coordinates conversion \((x,y)=(X/Z^2,Y/Z^3)\) can be used.

<table>

### 53.4.19 ECC double base ladder

ECC double base ladder operation consists in the computation of \(k^*P + m^*Q\), where \((P,Q)\) are two points on an elliptic curve and \((k,m)\) are two scalars. Operation instructions are summarized in Table 512.

If the resulting point is the point at infinity (error code 0xA3B7), resulting coordinate equals \((0,0)\).
The two input points are represented in Jacobian coordinates \((X, Y, Z)\). To input a point in affine coordinates \((x, y)\), conversion \((X, Y, Z) = (x, y, 1)\) can be used. The result is represented in affine coordinates \((x, y)\).

                   – Point at infinity: 0xA3B7 | RAM@0x520    | 64 bits|

### 53.4.20 ECC projective to affine

ECC projective to affine operation computes the conversion between the representation of a point \(P\) in homogeneous projective coordinates and the representation of the point \(P\) in affine coordinates. Namely, if the point is represented by the triple \((X, Y, Z)\), it computes the affine coordinates \((x, y) = (X/Y, Y/Z)\).

All the operations are performed modulo the modulus \(p\) of the curve, which the point belongs to. If the resulting point is the point at infinity (error code 0xA3B7), resulting coordinate equals \((0,0)\).

Operation instructions are summarized in Table 513.
53.5 Example of configurations and processing times

53.5.1 Supported elliptic curves

The PKA supports all non-singular elliptic curves defined over prime fields. Those curves can be described with a short Weierstrass equation, \( y^2 = x^3 + ax + b \pmod{p} \).

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA. The maximum supported operand size for ECC operations is 640 bits.

When publishing the ECC domain parameters of those elliptic curves, standard bodies define the following parameters:
- the prime integer \( p \), used as the modulus for all point arithmetic in the finite field \( \mathbb{GF}(p) \)
- the (usually prime) integer \( n \), the order of the group generated by \( G \), defined below
- the base point of the curve \( G \), defined by its coordinates \((G_x, G_y)\)
- the integers \( a \) and \( b \), coefficients of the short Weierstrass equation.

For the last bullet, when standard bodies define \( a \) as negative, PKA supports two representations:
1. **a defined as \( p-|a| \)** in the finite field \( \mathbb{GF}(p) \), for example \( p-3 \):
   - Curve coefficient \( p = \text{FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF} \)
   - Curve coefficient a sign= 0x0 (positive)
   - Curve coefficient a = \text{FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF}
   - Curve coefficient a sign= 0x1 (negative)
   - Curve coefficient a = \text{FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF}

2. **a defined as negative**, for example \(-3\):
   - Curve coefficient \( p = \text{FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF} \)
   - Curve coefficient a sign= 0x1 (negative)
   - Curve coefficient a = \text{FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF}
Table 514 summarizes the family of curves supported by PKA for ECC operations.

</table>

1. These values are average execution times of random moduli of given length, as they depend upon the length and the value of the modulus.
2. The execution time for the moduli that define the finite field of NIST elliptic curves is shorter than that needed for the moduli used for Brainpool elliptic curves or for random moduli of the same size.

</table>
There are four individual maskable interrupt sources generated by the public key accelerator, signaling the following events:

1. PKA unsupported operation error (OPERRF), see Section 53.3.7
2. Access to unmapped address (ADDRERRF), see Section 53.3.7
3. PKA RAM access while PKA operation is in progress (RAMERRF), see Section 53.3.7
4. PKA end of operation (PROCENDF)

The interrupt sources are connected to the same global interrupt request signal pka_it.

The user can enable or disable above interrupt sources individually by changing the mask bits in the PKA control register (PKA_CR). Setting the appropriate mask bit to 1 enables the interrupt. The status of the individual interrupt events can be read from the PKA status register (PKA_SR), and it is cleared in PKA_CLRFR register.

Table 524 gives a summary of the available features.

### Table 523. Montgomery parameters average computation times\(^{(1)}\)

<table>
<thead>
<tr>
<th>Modulus length (in bits)</th>
<th>192</th>
<th>256</th>
<th>320</th>
<th>512</th>
<th>1024</th>
<th>2048</th>
<th>3072</th>
<th>4096</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>8600</td>
<td>8710</td>
<td>11870</td>
<td>17000</td>
<td>102000</td>
<td>410000</td>
<td>506000</td>
<td>822000</td>
</tr>
</tbody>
</table>

1. The computation times depend upon the length and the value of the modulus, hence these values are average execution times of random moduli of given length.

</tr>
</tbody>
</table>

Bits 31:22  Reserved, must be kept at reset value.

Bit 21 **OPERRIE**: Operation error interrupt enable

- 0: No interrupt is generated when OPERRF flag is set in PKA_SR.
- 1: An interrupt is generated when OPERRF flag is set in PKA_SR.

Bit 20 **ADDRERRIE**: Address error interrupt enable

- 0: No interrupt is generated when ADDRERRF flag is set in PKA_SR.
- 1: An interrupt is generated when ADDRERRF flag is set in PKA_SR.

Bit 19 **RAMERRIE**: RAM error interrupt enable

- 0: No interrupt is generated when RAMERRF flag is set in PKA_SR.
- 1: An interrupt is generated when RAMERRF flag is set in PKA_SR.

Bit 18  Reserved, must be kept at reset value.

Bit 17 **PROCENDIE**: End of operation interrupt enable

- 0: No interrupt is generated when PROCENDF flag is set in PKA_SR.
- 1: An interrupt is generated when PROCENDF flag is set in PKA_SR.

Bits 16:14  Reserved, must be kept at reset value.
Bits 13:8  **MODE[5:0]:** PKA operation code
- 000000: Montgomery parameter computation then modular exponentiation
- 000001: Montgomery parameter computation only
- 000010: Modular exponentiation only (Montgomery parameter must be loaded first)
- 000011: Modular exponentiation (protected, used when manipulating secrets)
- 100000: Montgomery parameter computation then ECC scalar multiplication (protected)
- 100100: ECDSA sign (protected)
- 100110: ECDSA verification
- 101000: Point on elliptic curve Fp check
- 001011: RSA CRT exponentiation
- 001000: Modular inversion
- 001010: Arithmetic addition
- 001011: Arithmetic subtraction
- 001100: Arithmetic comparison
- 001101: Modular reduction
- 001110: Modular addition
- 001111: Modular subtraction
- 010000: Montgomery multiplication
- 100111: ECC complete addition
- 101111: ECC projective to affine

When an operation not listed here is written by the application with EN bit set, OPERRF bit is set in PKA_SR register, and the write to MODE bitfield is ignored.

Bits 7:2  Reserved, must be kept at reset value.

**Bit 1 START:** start the operation
Writing 1 to this bit starts the operation which is selected by MODE[5:0], using the operands and data already written to the PKA RAM. This bit is always read as 0.
When an illegal operation is selected while START bit is set no operation is started, and OPERRF bit is set in PKA_SR.

Note:  **START is ignored if PKA is busy.**

**Bit 0 EN:** PKA enable
0: Disable PKA
1: Enable PKA. PKA becomes functional when INITOK is set by hardware in PKA_SR.
When an illegal operation is selected while EN = 1, OPERRF bit is set in PKA_SR. See PKA_CR.MODE bitfield for details.

Note:  **When EN = 0, PKA RAM can still be accessed by the application.**
53.7.2 PKA status register (PKA_SR)

Address offset: 0x04
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>

<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **OPERRF**: Operation error flag
0: No event error
1: An illegal or unknown operation has been selected in PKA_CR register
This bit is cleared using OPERRFC bit in PKA_CLRFR.

Bit 20 **ADDRERRF**: Address error flag
0: No address error
1: Address access is out of range (unmapped address)
This bit is cleared using ADDRERRFC bit in PKA_CLRFR.

Bit 19 **RAMERRF**: PKA RAM error flag
0: No PKA RAM access error
1: An AHB access to the PKA RAM occurred while the PKA core was computing and using its internal RAM (AHB PKA_RAM access are not allowed while PKA operation is in progress).
This bit is cleared using RAMERRFC bit in PKA_CLRFR.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDF**: PKA end of operation flag
0: Operation in progress
1: PKA operation is completed. This flag is set when the BUSY bit is deasserted.

Bit 16 **BUSY**: Busy flag
This bit is set whenever a PKA operation is in progress (START = 1 in PKA_CR). It is automatically cleared when the computation is complete, making PKA RAM accessible again.
0: No operation is in progress (default)
1: An operation is in progress
If PKA is started with a wrong opcode, it stays busy for a couple of cycles, then it aborts automatically the operation and goes back to ready (BUSY = 0).

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **INITOK**: PKA initialization OK
This bit is asserted when PKA initialization is complete. When RNG is not able to output proper random numbers INITOK stays at 0.
0: PKA is not initialized correctly. START bit cannot be set.
1: PKA is initialized correctly and can be used normally.
53.7.3 PKA clear flag register (PKA_CLRFR)

Address offset: 0x08
Reset value: 0x0000 0000

<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>

*Note:* Reading PKA_CLRFR returns all 0s.

53.7.4 PKA RAM

The PKA RAM is mapped at the offset address of 0x0400 compared to the PKA base address. Only 32-bit word single accesses are supported, through PKA_AHB interface.

RAM size is 5336 bytes (max word offset: 0x14D0)

*Note:* PKA RAM cannot be used just after a PKA reset or a product reset, as described in Section 53.3.3: PKA reset and clocks.
### 53.7.5 PKA register map

#### Table 525. PKA register map and reset values

| Offset | Register name | Offset | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Refer to Section 2.3 on page 139 for the register boundary addresses.
Advanced-control timers (TIM1/TIM8)

54.1 TIM1/TIM8 introduction

The advanced-control timers (TIM1/TIM8) consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1/TIM8) and general-purpose (TIMy) timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 54.3.30: Timer synchronization.

54.2 TIM1/TIM8 main features

TIM1/TIM8 timer features include:

- 16-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency either by any factor between 1 and 65536.
- Up to 6 independent channels for:
  - Input capture (but channels 5 and 6)
  - Output compare
  - PWM generation (Edge and Center-aligned Mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- 2 break inputs to put the timer’s output signals in a safe user selectable configuration.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and Hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management
54.3 TIM1/TIM8 functional description

54.3.1 Block diagram

Figure 503. Advanced-control timer block diagram

Notes:
- Preload registers transferred to active registers on UEV event according to control bit
- Event
- Interrupt & DMA output

1. This feature is not available on all timers, refer to Section 54.3.2: TIM1/TIM8 pins and internal signals.
2. See Figure 550: Break and Break2 circuitry overview for details.
## 54.3.2 TIM1/TIM8 pins and internal signals

The tables in this section summarize the TIM inputs and outputs.

### Table 526. TIM input/output pins

<table>

54.3.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software, even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the
TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note: The counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler divides the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 504 and Figure 505 give some examples of the counter behavior when the prescaler ratio is changed on the fly.

**Figure 504. Counter timing diagram with prescaler division change from 1 to 2**

![Counter timing diagram with prescaler division change from 1 to 2](MSv50998V1)
54.3.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

**Figure 506. Counter timing diagram, internal clock divided by 1**
Figure 507. Counter timing diagram, internal clock divided by 2

Figure 508. Counter timing diagram, internal clock divided by 4
Figure 509. Counter timing diagram, internal clock divided by N

Figure 510. Counter timing diagram, update event when ARPE=0 (TIMx_ARR not preloaded)

Write a new value in TIMx_ARR
**Downcounting mode**

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter underflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

**Figure 512. Counter timing diagram, internal clock divided by 1**
Figure 513. Counter timing diagram, internal clock divided by 2

Figure 514. Counter timing diagram, internal clock divided by 4
Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-
reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.
1. Here, center-aligned mode 1 is used (for more details refer to Section 54.6: TIM1/TIM8 registers).

**Figure 517. Counter timing diagram, internal clock divided by 1, TIMx_ARR = 0x6**

Update interrupt flag (UIF)
Figure 521. Counter timing diagram, update event with ARPE=1 (counter underflow)
54.3.5 Repetition counter

Section 54.3.3: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented:
- At each counter overflow in upcounting mode,
- At each counter underflow in downcounting mode,
- At each counter overflow and at each counter underflow in center-aligned mode.

Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is 2xTck, due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 523). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
In Center aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was launched: if the RCR was written before launching the counter, the UEV occurs on the underflow. If the RCR was written after launching the counter, the UEV occurs on the overflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event depending on when the RCR was written.

Figure 523. Update rate examples depending on mode and TIMx_RCR register settings

54.3.6 External trigger input

The timer features an external trigger input tim_etr_in. It can be used as:
- external clock (external clock mode 2, see Section 54.3.7)
- trigger for the slave mode (see Section 54.3.30)
- PWM reset input for cycle-by-cycle current regulation (see Section 54.3.9)

Figure 524 below describes the tim_etr_in input conditioning. The input polarity is defined with the ETP bit in TIMxSMCR register. The trigger can be prescaled with the divider programmed by the ETPS[1:0] bitfield and digitally filtered with the ETF[3:0] bitfield. The resulting signal (tim_etrf) is available for three purposes: as an external clock, to condition
the output (typically to reset a PWM output for a current limitation), and as a trigger for the Slave mode controller.

Figure 524. External trigger input block

The tim_etr_in input comes from multiple sources: input pins (default configuration), or internal sources. The selection is done with the ETRSEL[3:0] bitfield in the TIMx_AF1 register.

Refer to Section 54.3.2: TIM1/TIM8 pins and internal signals for the list of sources connected to the etr_in input in the product.

54.3.7 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2)
- External clock mode2: external trigger input (tim_etr_in)
- Encoder mode

Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 525 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
**External clock source mode 1**

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

1. Codes ranging from 01000 to 11111 are reserved.
For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the tim_ti2 input by writing CC2S = '01' in the TIMx_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
3. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
5. Select tim_ti2 as the trigger input source by writing TS=00110 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

**Note:** The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set. The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to the resynchronization circuit on tim_ti2 input.

![Figure 527. Control circuit in external clock mode 1](MSv62319V1)

**External clock source mode 2**

This mode is selected by writing ECE=1 in the TIMx_SMCR register.

The counter counts at each rising or falling edge on the external trigger input tim_etr_in. The **Figure 528** gives an overview of the external trigger input block.
For example, to configure the upcounter to count each 2 rising edges on tim_etr_in, use the following procedure:

1. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register.
3. Select rising edge detection on the tim_etr_in input by writing ETP=0 in the TIMx_SMCR register.
4. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 tim_etr_in rising edges.

The delay between the rising edge on tim_etr_in and the actual clock of the counter is due to the resynchronization circuit on the tim_etrp signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most \( \frac{1}{4} \) of tim_ker_ck frequency. When the ETRP signal is faster, the user must apply a division of the external signal by a proper ETPS prescaler setting.
54.3.8 Capture/compare channels

Each capture/compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

*Figure 530* to *Figure 533* give an overview of one capture/compare channel.

The input stage samples the corresponding \textit{tim\_tix} input to generate a filtered signal \textit{tim\_tixf}. Then, an edge detector with polarity selection generates a signal \textit{(tim\_tixfpy)} which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (\textit{ICxPS}).

*Figure 530. Capture/compare channel (example: channel 1 input stage)*
The output stage generates an intermediate waveform which is then used for reference: `tim_oxref` (active high). The polarity acts at the end of the chain.

**Figure 531. Capture/compare channel 1 main circuit**
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.
In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 54.3.9 Input capture mode

In Input capture mode, the capture/compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_t1 input rises. To do this, use the following procedure:

- Select the active input: TIMx_CCR1 must be linked to the tim_t1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
- Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_t1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
- Select the edge of the active transition on the tim_t1 channel by writing CC1P and CC1NP bits to 0 in the TIMx_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.
Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

54.3.10 PWM input mode

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIM_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges)

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same tim_tixfp1 input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two tim_tixfp signals is selected as trigger input and the slave mode controller is configured in reset mode.

The period and the pulsewidth of a PWM signal applied on tim_t1 can be measured using the following procedure:

- Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_t1 selected).
- Select the active polarity for tim_t1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
- Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_t1 selected).
- Select the active polarity for tim_t1fp2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to CC2P/CC2NP=’10’ (active on falling edge).
- Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_t1fp1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the TIMx_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.
54.3.11 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx/tim_ocxn) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, user just needs to write 0101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP = 0 (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 0100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

54.3.12 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 4 can be output, while channel 5 and 6 are only available inside the microcontroller (for instance, for compound waveform generation or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCXM=0000), be set...
active (OCxM=0001), be set inactive (OCxM=0010) or can toggle (OCxM=0011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 0011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 535.
54.3.13 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing ‘0110’ (PWM mode 1) or ‘0111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.
PWM edge-aligned mode

- Upcounting configuration
  
  Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to the Upcounting mode on page 2092.

  In the following example, we consider PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then tim_ocxref is held at ‘1’. If the compare value is 0 then tim_ocxref is held at ‘0’. Figure 536 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

  **Figure 536. Edge-aligned PWM waveforms (ARR=8)**

- Downcounting configuration
  
  Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to the Downcounting mode on page 2096.

  In PWM mode 1, the reference signal tim_ocxref is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then tim_ocxref is held at ‘1’. 0% PWM is not possible in this mode.

PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00’ (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit

Counter register | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 0 | 1
--- | --- | --- | --- | --- | --- | --- | --- | --- | --- | --- | ---
CCRx=4 tim_ocxref | | | | | | | | | | | |
CCRx=4 CCxIF |
CCRx=8 tim_ocxref | | | | | | | | | | | |
CCRx=8 CCxIF |
CCRx>8 tim_ocxref | '1' | '1' | '1' | '1' | '1' | '1' | '1' | '1' | '1' | '1' | '1'
CCRx>8 CCxIF |
CCRx=0 tim_ocxref | '0' | '0' | '0' | '0' | '0' | '0' | '0' | '0' | '0' | '0' | '0'
CCRx=0 CCxIF |
(DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to the Center-aligned mode (up/down counting) on page 2099.

Figure 537 shows some center-aligned PWM waveforms in an example where:
- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

Hints on using center-aligned mode:
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit.
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT > TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

**Dithering mode**

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The Figure 538 below presents the dithering principle applied to 4 consecutive PWM cycles.

![Figure 538. Dithering principle](image)

When the dithering mode is enabled, the register coding is changed as follows (see Figure 539 for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value
**Note:** The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The DITHEN bit must be reset
3. The CCIF flags must be cleared
4. The CEN bit can be set (eventually with ARPE = 1).

**Figure 539. Data format and register coding in dithering mode**

Base compare value is 20 during 16 periods Additional 6 cycles are spread over the 16 periods

The minimum frequency is given by the following formula:

\[
\text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{\text{MaxResolution}}
\]

Dithering mode disabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65536} \)

Dithering mode enabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}} \)

**Note:** The maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on the **Figure 540** below, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.
The duty cycle and/or period changes are spread over 16 consecutive periods, as described in the Figure 541 below.
The auto-reload and compare values increments are spread following specific patterns described in the Table 539 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

The dithering mode is also available in center-aligned PWM mode (CMS bits in TIMx_CR1 register are not equal to '00'). In this case, the dithering pattern is applied over 8 consecutive PWM periods, considering the up and down counting phases as shown in the Figure 542 below.

Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx register. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channel (one tim_ocx output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an tim_oc1refc signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the tim_oc2refc signal on channel 2, or an tim_oc2refc signal resulting from asymmetric PWM mode 1.

Figure 543 represents an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 2). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.
54.3.15 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 544 represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1.
54.3.16 Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The tim_oc5ref signal is used to define the resulting combined signal. The 3-bits GC5C[3:1] in the TIMx_CCR5 allow selection on which reference signal the tim_oc5ref is combined. The resulting signals, tim_ocxrefc, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, tim_oc1refc is controlled by TIMx_CCR1 and TIMx_CCR5
- If GC5C2 is set, tim_oc2refc is controlled by TIMx_CCR2 and TIMx_CCR5
- If GC5C3 is set, tim_oc3refc is controlled by TIMx_CCR3 and TIMx_CCR5

Combined 3-phase PWM mode can be selected independently on channels 1 to 3 by setting at least one of the 3-bits GC5C[3:1].
54.3.17 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1/TIM8) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...).

The polarity of the outputs (main output tim_ocx or complementary tim_ocxn) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals tim_ocx and tim_ocxn are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 548: Output control bits for complementary tim_ocx and tim_ocxn channels with break feature on page 2201 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel.
reference waveform tim_ocxref, it generates 2 outputs tim_ocx and tim_ocxn. If tim_ocx and tim_ocxn are active high:

- The tim_ocx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The tim_ocxn output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (tim_ocx or tim_ocxn) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal tim_ocxref. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 546. Complementary output with symmetrical dead-time insertion**

The DTAE bit in the TIMx_DTR2 is used to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on **Figure 547**.

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIMx_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIMx_DTR2 register. The DTAE bit must be written before enabling the counter and must not be modified while CEN=1.

It is possible to have the deadtime value updated on-the-fly during pwm operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set, in the TIMx_DTR2 register. The preload value is loaded in the active register on the next update event.

**Note:** If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 54.6.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8) for delay calculation.
Re-directing \textit{tim\_ocxref} to \textit{tim\_ocx} or \textit{tim\_ocxn}

In output mode (forced, output compare or PWM), \textit{tim\_ocxref} can be re-directed to the \textit{tim\_ocx} output or to \textit{tim\_ocxn} output by configuring the CCxE and CCxNE bits in the TIMx\_CCER register.

This is used to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

\textit{Note:} When only \textit{tim\_ocxn} is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as \textit{tim\_ocxref} is high. For example, if CCxNP=0 then \textit{tim\_ocxn}=\textit{tim\_ocxref}. On the other hand, when both \textit{tim\_ocx} and \textit{tim\_ocxn} are enabled (CCxE=CCxNE=1) \textit{tim\_ocx} becomes active when \textit{tim\_ocxref} is high whereas \textit{tim\_ocxn} is complemented and becomes active when \textit{tim\_ocxref} is low.

54.3.18 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The two break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state. A number of internal MCU events can also be selected to trigger an output shut-down.

The break features two channels. A break channel which gathers both system-level fault (clock failure, ECC / parity errors,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration. A break2 channel which only includes application faults and is able to force the outputs to an inactive state.

The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx\_BDTR register is used to enable /disable the outputs by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx\_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx\_CR2 register which are setting the output shut-down level, either active or inactive. The \textit{tim\_ocx} and \textit{tim\_ocxn} outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 548: Output control bits for complementary \textit{tim\_ocx} and \textit{tim\_ocxn} channels with break feature on page 2201 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break functions can be enabled by setting the BKE and BK2E bits in the TIMx\_BDTR register. The break input polarities can be selected by configuring the BKP and BK2P bits in the same register. BKEx and BKPx can be modified at the same time. When the BKEx and BKPx bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx\_BDTR register). It results in some delays between the asynchronous
and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay
must be inserted (dummy instruction) before reading it correctly. This is because the write
acts on the asynchronous signal whereas the read reflects the synchronous signal.

The sources for break (tim_brk) channel are:

- External sources connected to one of the TIMx_BKIN pin (as per selection done in the
  GPIO alternate function selection registers), with polarity selection and optional digital
  filtering
- Internal sources:
  - coming from a tim_brk_cmpx input (refer to Section 54.3.2: TIM1/TIM8 pins and
    internal signals for product specific implementation)
  - coming from a system break request (refer to Section 54.3.2: TIM1/TIM8 pins and
    internal signals for product specific implementation)

The sources for break2 (tim_brk2) are:

- External sources connected to one of the TIMx_BKIN2 pin (as per selection done in the
  GPIO alternate function selection registers), with polarity selection and optional digital
  filtering
- Internal sources coming from a tim_brk2_cmpx input (refer to Section 54.3.2: TIM1/TIM8 pins and internal signals for product specific implementation)

Break events can also be generated by software using BG and B2G bits in the TIMx_EGR
register.

All sources are ORed before entering the timer tim_brk or tim_brk2 inputs, as per
Figure 550 below.
An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When one of the breaks occurs (selected level on one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO controller (selected by the OSSI bit). This feature is enabled even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO controller), otherwise the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_ocz and tim_oczxn cannot be driven to
their active level together. Note that because of the resynchronization on MOE, the dead-time duration is slightly longer than usual (around 2 tim_ker_ck clock cycles).

- If OSSI=0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state), otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.

- The break status flag (SBIF, BIF and B2IF bits in the TIMx_SR register) is set. An interrupt is generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.

- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event (UEV). As an example, this can be used to perform a regulation. Otherwise, MOE remains low until the application sets it to ‘1’ again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

**Note:** If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSI value. If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIMx_CR2 register.

**Note:** The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It is used to freeze the configuration of several parameters (dead-time duration, tim_ocx/tim_ocxn polarities and state when disabled, OCxM configurations, break enable and polarity). The application can choose from 3 levels of protection selected by the LOCK bits in the TIMx_BDTR register. Refer to [Section 54.6.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8)](#). The LOCK bits can be written only once after an MCU reset.

*Figure 551* shows an example of behavior of the outputs in response to a break.
The two break inputs have different behaviors on timer outputs:

- The tim_brk input can either disable (inactive state) or force the PWM outputs to a predefined safe state.
- tim_brk2 can only disable (inactive state) the PWM outputs.
The tim_brk has a higher priority than tim_brk2 input, as described in Table 541.

**Note:** tim_brk2 must only be used with OSSR = OSSI = 1.

**Table 541. Behavior of timer outputs versus tim_brk/tim_brk2 inputs**

**Figure 552** gives an example of tim_ocx and tim_ocxn output behavior in case of active signals on tim_brk and tim_brk2 inputs. In this case, both outputs have active high polarities (CCxP = CCxNP = 0 in TIMx_CCER register).

**Figure 552. PWM output state following tim_brk and tim_brk2 assertion (OSSI=1)**
54.3.19 Bidirectional break inputs

The TIM1/TIM8 are featuring bidirectional break I/Os, as represented on Figure 554.

This provides support for:

- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged

The tim_brk and tim_brk2 inputs are configured in bidirectional mode using the BKBID and BK2BID bits in the TIMxBDTR register. The BKBID programming bits can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode is available for both the tim_brk and tim_brk2 inputs, and require the I/O to be configured in open-drain mode with active low polarity (using BKINP, BK2INP and BK2P bits). Any break request coming either from system (for example CSS), from on-chip peripherals or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software events (BG and B2G) also cause the break I/O to be forced to '0' to indicate to the external components that the timer is entered in break state. However, this is valid only if the break is enabled (BKE or B2KE = 1). When a software break event is generated with BKE or B2KE = 0), the outputs are put in safe state and the break flag is set, but there is no effect on the TIMx_BKIN and TIMx_BKIN2 I/Os.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the BKDSRM (BK2DSRM) bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:

- The break input path is always active: a break event is active even if the BKDSRM (BK2DSRM) bit is set and the open drain control is released. This prevents the PWM output to be re-started as long as the break condition is present.
- The BKDSRM (BK2DSRM) bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see Table 542).
Arming and re-arming break circuitry

The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).

The following procedure must be followed to re-arm the protection after a break (break2) event:

- The BKDSRM (BK2DSRM) bit must be set to release the output control
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before re-arming)
- The software must poll the BKDSRM (BK2DSRM) bit until it is cleared by hardware (when the application break condition disappears)

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

54.3.20 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocxref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM
cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode. tim_ocref_clr_int input can be selected between the tim_ocref_clr input and tim_etrf (tim_etrf_in after the filter) by configuring the OCCS bit in the TIMx_SMCR register.

The tim_ocref_clr input can be selected among several inputs, using the OCRSEL[2:0] bitfield in the TIMx_AF2 register, as shown on the Figure 555 below. Refer to Section 54.3.2: TIM1/TIM8 pins and internal signals for a list of sources available in the product.

Figure 555. tim_ocref_clr input selection multiplexer

When tim_etrf is chosen, tim_etrf_in must be configured as follows:
1. The External Trigger Prescaler must be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to '00'.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to '0'.
3. The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to application needs (as per polarity of the source connected to the trigger and eventual need to remove noise using the filter).

Figure 556 shows the behavior of the tim_ocxref signal when the tim_etrf Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.
### 54.3.21 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, OCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on tim_trgi rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The Figure 557 describes the behavior of the tim_ocx and tim_ocxn outputs when a COM event occurs, in 3 different examples of programmed configurations.

**Note:** In case of a PWM with a 100% duty cycle (if CCRx>ARR), then tim_ocxref is enabled again at the next counter overflow.
54.3.22 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: CNT < CCRx ≤ ARR (in particular, 0 < CCRx)
- In downcounting: CNT > CCRx
For example one may want to generate a positive pulse on `tim_oc1` with a length of `tPULSE` and after a delay of `tDELAY` as soon as a positive edge is detected on the `tim_ti2` input pin. Let's use `tim_ti2fp2` as trigger 1:

- Map `tim_ti2fp2` to `tim_ti2` by writing `CC2S='01'` in the `TIMx_CCMR1` register.
- `tim_ti2fp2` must detect a rising edge, write `CC2P='0'` and `CC2NP='0'` in the `TIMx_CCER` register.
- Configure `tim_ti2fp2` as trigger for the slave mode controller (`tim_trgi`) by writing `TS=00110` in the `TIMx_SMCR` register.
- `tim_ti2fp2` is used to start the counter by writing `SMS='110'` in the `TIMx_SMCR` register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The `tDELAY` is defined by the value written in the `TIMx_CCR1` register.
- The `tPULSE` is defined by the difference between the auto-reload value and the compare value (`TIMx_ARR - TIMx_CCR1`).
- Let's say one want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing `OC1M=111` in the `TIMx_CCMR1` register. Optionally the preload registers can be enabled by writing `OC1PE='1'` in the `TIMx_CCMR1` register and `ARPE` in the `TIMx_CR1` register. In this case one has to write the compare value in the `TIMx_CCR1` register, the auto-reload value in the `TIMx_ARR` register, generate an update by setting the `UG` bit and wait for external trigger event on `tim_ti2`. `CC1P` is written to '0' in this example.

In our example, the `DIR` and `CMS` bits in the `TIMx_CR1` register must be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the `TIMx_CR1` register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the `TIMx_CR1` register is set to '0', so the Repetitive Mode is selected.
Particular case: tim_ocx fast enable:

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 54.3.23 Retriggerable One-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one-pulse mode described in Section 54.3.22:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ’1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ’1000’ or ’1001’ for retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

**Note:** The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

**Figure 559. Retriggerable one-pulse mode**
54.3.24 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulsewidth generated when the counter value equals a given compare value, for debugging or synchronization purposes.

This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on the Figure 560 below.

Figure 560. Pulse generator circuitry

The Figure 561 below shows how the pulse is generated for edge-aligned and encoder operating modes.
This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bit fields in TIMx_CCMR2 register.

The pulsewidth is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

\[ t_{PW} = PW[7:0] \times t_{PWG} \]

where \( t_{PWG} = \left(2^{(PWPRSC[2:0])}\right) \times t_{tim\_ker\_ck} \).

This gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

**Note:** If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the 1st arriving trigger is extended (because of the re-trigger), while the pulse width of the last arriving trigger is correct (as shown on the Figure 562 below).
54.3.25 Encoder interface mode

Quadrature encoder

To select Encoder Interface mode write SMS='0001' in the TIMx_SMCR register if the counter is counting on tim_t1 edges only, SMS='0010' if it is counting on tim_t2 edges only and SMS='0011' if it is counting on both tim_t1 and tim_t2 edges.

Select the tim_t1 and tim_t2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs tim_t1 and tim_t2 are used to interface to an quadrature encoder. Refer to Table 543. The counter is clocked by each valid transition on tim_t1fp1 or tim_t2fp2 (tim_t1 and tim_t2 after input filter and polarity selection, tim_t1fp1=tim_t1 if not filtered and not inverted, tim_t2fp2=tim_t2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1’). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_t1 or tim_t2), whatever the counter is counting on tim_t1 only, tim_t2 only or both tim_t1 and tim_t2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_t1 and tim_t2 do not switch at the same time.
A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicates the mechanical zero position, may be connected to the external trigger input and trigger a counter reset.

The Figure 563 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S='01' (TIMx_CCMR1 register, tim_ti1fp1 mapped on tim_ti1).
- CC2S='01' (TIMx_CCMR2 register, tim_ti1fp2 mapped on tim_ti2).
- CC1P='0' and CC1NP='0' (TIMx_CCER register, tim_ti1fp1 non-inverted, tim_ti1fp1=tim_ti1).
- CC2P='0' and CC2NP='0' (TIMx_CCER register, tim_ti1fp2 non-inverted, tim_ti1fp2=tim_ti2).
- SMS='0011' (TIMx_SMCR register, both inputs are active on both rising and falling edges).
- CEN='1' (TIMx_CR1 register, Counter enabled).

Table 543. Counting direction versus encoder signals (CC1P = CC2P = 0)
Figure 563. Example of counter operation in encoder interface mode.

Figure 564 gives an example of counter behavior when tim_ti1fp1 polarity is inverted (same configuration as above except CC1P='1').

Figure 564. Example of encoder interface mode with tim_ti1fp1 polarity inverted.

The Figure 565 below shows the timer counter value during a speed reversal, for various counting modes.
The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register’s bit 31 (TIMx_CNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

**Clock plus direction encoder mode**

In addition to the quadrature encoder mode, the timer offers support other types of encoders.

In the “clock plus direction” mode shown on Figure 566, the clock is provided on a single line, on \texttt{tim\_ti2}, while the direction is forced using the \texttt{tim\_ti1} input.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- 1010: \texttt{x2} mode, the counter is updated on both rising and falling edges of the clock
- 1011: \texttt{x1} mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity
The polarity of the direction signal on `tim_ti1` is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when `tim_ti1` is high and down-counting when `tim_ti1` is low) and CC1P = 1 corresponds to negative polarity (up-counting when `tim_ti1` is low).

**Index Input**

The counter can be reset by an index signal coming from the encoder, indicating an absolute reference position. The Index signal must be connected to the tim__etr_in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMX_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0001, 0010, 011, 1010, 1011, 1100, 1101, 1110, 1111.
Commercially available encoders are proposed with several options for index pulse conditioning, as per the Figure 569 below:

- gated with A and B: the pulsewidth is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulsewidth is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulsewidth is up to one channel period, without any alignment to the edges

![Figure 569. Index gating options](image1)

The circuitry tolerates jitter on index signal, whatever the gating mode, as show on Figure 570 below.

In ungated mode, the signal must be strictly below 2 encoder periods. If the pulsewidth is greater or equal to 2 encoder period, the counter is reset multiple times.

![Figure 570. Jittered Index signals](image2)

The timer supports the 3 gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (i.e. channel A and channel B...
state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIMx_ECR register.

The Index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:

- The counter is reset during up-counting (DIR bit = 0).
- The counter is set to TIMx_ARR when down counting.

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. The Figure 571 below shows at which position is the index generated, for a simplistic example (an encoder providing 4 edges per mechanical rotation).

**Figure 571. Index generation for IPOS[1:0] = 11**

![Index generation diagram]

The Figure 572 below presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is ‘11’ (ChA=1, ChB=1), when up-counting (DIR bit = 0).
- Counter set to TIMx_ARR when exiting the ‘11’ state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.
Figure 572. Counter reading with index gated on channel A (IPOS[1:0] = 11)

The Figure 573. below presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.

Figure 573. Counter reading with index ungated (IPOS[1:0] = 00)

The Figure 574. below shows how the ‘gated on A & B’ mode is handled, for various pulse alignment scenario. The arrows are indicating on which transition is the index event generated.
The *Figure 575* and *Figure 576* detail the case where the subsequent index pulse may be narrower than one quarter of the encoder clock period.
Figure 575. Encoder mode behavior in case of narrow index pulse (IPOS[1:0] = 11)

Index leading state transition

Index delayed versus state transition
The Figure 577 below shows how the index is managed in x1 and x2 modes.
Figure 577. Index behavior in x1 and x2 mode (IPOS[1:0] = 01)

Directional index sensitivity

The IDIR[1:0] bitfield in the TIMx_ECR register allows the index to be active only in a selected counting direction.

The Figure 578 below shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

Figure 578. Directional index sensitivity
Special first index event management

The FIDX bit in the TIMx_ECR register allows the Index to be taken only once, as shown on the Figure 579 below. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be re-armed by writing the FIDX bit to 0 and setting it again to 1.

Figure 579. Counter reset as function of FIDX bit setting

Index blanking

The Index event can be blanked using the tim_ti3 or tim_ti4 inputs. During the blanking window, the index events are no longer resetting the counter, as shown on the Figure 580 below.

This mode is enabled using the IBLK[1:0] bitfield in the TIMx_ECR register, as following:
- IBLK[1:0] = 00: Index signal always active
- IBLK[1:0] = 01: Index signal blanking on tim_ti3 input
- IBLK[1:0] = 10: Index signal blanking on tim_ti4 input

Figure 580. Index blanking
Index management in non-quadrature mode

The Figure 581 and Figure 582 below detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[3:0] bitfield is equal to 1010, 1011, 1100, 1101.

For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:

- IPOS[0] = 0: Index is detected on clock low level
- IPOS[0] = 1: Index is detected on clock high level

The IPOS[1] bit is not-significant.

Figure 581. Index behavior in clock + direction mode, IPOS[0] = 1

Figure 582. Index behavior in directional clock mode, IPOS[0] = 1

Encoder error management

For encoder configurations where 2 quadrature signals are available, it is possible to detect transition errors. The reading on the 2 inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on the Figure 583. below. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIMx_SR status.
A transition error interrupt is generated if the TERRIE bit is set in the TIMx_DIER register.

**Figure 583. State diagram for quadrature encoded signals**

For an encoder having an Index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The Index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIMx_ARR to 0 or decremented from 0 to TIMx_ARR value without any index event, this is reported as an Index position error.

The overflow threshold is programmed using the TIMx_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIMx_ARR = 3999 + 1 = 4000.
The error assertion is delayed to the transition 0 to 1 when in up-counting. This is cope with narrow index pulses in gated A and B mode, as shown on Figure 584 below.

**Figure 584. Up-counting encoder error detection**

[Diagram showing up-counting encoder error detection]

Error detected  
Abort (index detection)  
Error asserted
In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on Figure 585 below, to avoid any false error detection in case the encoder dithers between TIMx_ARR and 0 immediately after the index detection.

**Figure 585. Down-counting encode error detection**

An index error sets the IERRF interrupt flag in the TIMx_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIMx_DIER register.

**Functional encoder Interrupts**

The following interrupts are also available in encoder mode:

- **Direction change:** any change of the counting direction in encoder mode causes the DIR bit in the TIMx_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIMx_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIMx_DIER register.
- **Index event:** the Index event sets the IDXF interrupt flag in the TIMx_SR status register. An Index interrupt is generated if the IDXIE bit is set in the TIMx_DIER register.
Slave mode selection preload for run-time encoder mode update

It may be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the Update interrupt rate, by switching from x4 to x2 to x1 mode, as show on the Figure 586 below.

For this purpose, the SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value can be selected with the SMPS bit in the TIMx_SMCR register.

- SMSPS = 0: the transfer is triggered by the update event (UEV) occurring when the counter overflows when upcounting, and underflows when downcounting.
- SMSPS = 1: the transfer is triggered by the Index event.

Figure 586. Encoder mode change with preload transferred on update (SMSPS = 0)

Encoder clock output

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIMx_CR2 register. It is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

54.3.26 Direction bit output

It is possible to output a direction signal out of the timer, on the tim_oc3n and tim_oc4 output signals (copy of the DIR bit in the TIMx_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bit field to 1011 in the TIMx_CCMR2 register.
This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

54.3.27 UIF bit remapping

The UIFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register’s bit 31 (TIMx_CNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the UIF and UIFCPY flags assertion.

54.3.28 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per Figure 587 below.

**Figure 587. Measuring time interval between edges on 3 signals**

54.3.29 Interfacing with Hall sensors

This is done using the advanced-control timers to generate PWM signals to drive the motor and another timer TIMx referred to as “interfacing timer” in Figure 588. The “interfacing timer” captures the 3 timer input pins (tim_ti1, tim_ti2 and tim_ti3) connected through a XOR to the tim_ti1 input channel (selected by setting the TI1S bit in the TIMx_CR2 register).

The slave mode controller is configured in reset mode; the slave input is tim_ti1f_ed. Thus, each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is tim_trc (See Figure 530: Capture/compare channel (example: channel 1
input stage) on page 2110). The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (by triggering a COM event). The advanced-control timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer through the tim_trgo output.

Example: one wants to change the PWM configuration of the advanced-control timer after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure 3 timer inputs ORed to the tim_ti1 input channel by writing the TI1S bit in the TIMx_CR2 register to ‘1’,
- Program the time base: write the TIMx_ARR to the max value (the counter must be cleared by the tim_ti1 change. Set the prescaler to get a maximum counter period longer than the time between 2 changes on the sensors,
- Program the channel 1 in capture mode (tim_trc selected): write the CC1S bits in the TIMx_CCMR1 register to ‘01’. The digital filter can also be programmed if needed,
- Program the channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to ‘111’ and the CC2S bits to ‘00’ in the TIMx_CCMR1 register,
- Select tim_oc2ref as trigger output on tim_trgo: write the MMS bits in the TIMx_CR2 register to ‘101’,

In the advanced-control timer, the right tim_itrx input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC=1 in the TIMx_CR2 register) and the COM event is controlled by the trigger input (CCUS=1 in the TIMx_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of tim_oc2ref).

The Figure 588 describes this example.
54.3.30 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 55.4.23: Timer synchronization for details. They can be synchronized in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.
In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

- Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect rising edges only).

- Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

- Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

**Figure 589. Control circuit in reset mode**

---

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_ti1 input is low:

- Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect low level only).

- Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

- Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).
The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.

**Slide mode: Trigger mode**

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

- Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.
Slave mode: Combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for One-pulse mode.

Slave mode: Combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode: external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_trgi occurs:
1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on tim_etr_in and ECE=1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on T1:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP=’0’ in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

A rising edge on tim_ti1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.

**Figure 592. Control circuit in external clock mode 2 + trigger mode**

---

**Note:**
The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
54.3.31 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events. It is also possible to generate a pulse issued by internal edge detectors, such as:

- Rising and falling edges of OC4ref
- Rising edge on OC5ref or falling edge on OC6ref

The triggers are issued on the tim_trgo2 internal line which is redirected to the ADC. There is a total of 16 possible events, which can be selected using the MMS2[3:0] bits in the TIMx_CR2 register.

An example of an application for 3-phase motor drives is given in Figure 545 on page 2128.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Note: The clock of the ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the timer.

54.3.32 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR register define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:

00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

The DBSS[3:0] bits in the TIMx_DCR register defines the interrupt source that triggers the DMA burst transfers (see Section 54.6.29: TIMx DMA control register (TIMx_DCR)(x = 1, 8) for details).

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:
1. Configure the corresponding DMA channel as follows:
   – DMA channel peripheral address is the DMAR register address.
   – DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   – Number of data to transfer = 3 (see note below).
   – Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   DBL = 3 transfers, DBA = 0xE and DBSS = 1.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx.
5. Enable the DMA channel.

This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

*Note:* A null value can be written to the reserved registers.

### 54.3.33 TIM1/TIM8 DMA requests

The TIM1/TIM8 can generate a DMA request, as shown in the table below.

<table>

### 54.3.34 Debug mode

When the microcontroller enters debug mode (Cortex®-M33 core halted), the TIMx counter can either continue to work normally or stop, depending on DBG_TIMx_STOP configuration bit in DBG module.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0), typically to force a Hi-Z.
For more details, refer to section Debug support (DBG).

### 54.4 TIM1/TIM8 low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>

54.6 TIM1/TIM8 registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

54.6.1 TIMx control register 1 (TIMx_CR1)(x = 1, 8)

Address offset: 0x000
Reset value: 0x0000

| Bit 15:13 | Reserved, must be kept at reset value. |
| Bit 12   | DITHEN: Dithering enable |
| 0:       | Dithering disabled |
| 1:       | Dithering enabled |
| Note:    | The DITHEN bit can only be modified when CEN bit is reset. |
| Bit 11   | UIFREMAP: UIF status bit remapping |
| 0:       | No remapping. UIF status bit is not copied to TIMx_CNT register bit 31. |
| 1:       | Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31. |
| Bit 10   | Reserved, must be kept at reset value. |
| Bits 9:8 | CKD[1:0]: Clock division |
| 00:      | tDTS=tim_ker_ck |
| 01:      | tDTS=2*tim_ker_ck |
| 10:      | tDTS=4*tim_ker_ck |
| 11:      | Reserved, do not program this value |
| Bit 7    | ARPE: Auto-reload preload enable |
| 0:       | TIMx_ARR register is not buffered |
| 1:       | TIMx_ARR register is buffered |
| Bits 6:5 | CMS[1:0]: Center-aligned mode selection |
| 00:      | Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR). |
| 01:      | Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down. |
| 10:      | Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up. |
| 11:      | Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down. |
| Note:    | It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1) |
**54.6.2 TIMx control register 2 (TIMx_CR2)(x = 1, 8)**

Address offset: 0x004

Reset value: 0x0000 0000

| Bit 32 | Bit 31 | Bit 30 | Bit 29 | Bit 28 | Bit 27 | Bit 26 | Bit 25 | Bit 24 | Bit 23 | Bit 22 | Bit 21 | Bit 20 | Bit 19 | Bit 18 | Bit 17 | Bit 16 |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
|        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |

**Bit 4** \( \text{DIR} \): Direction

- 0: Counter used as upcounter
- 1: Counter used as downcounter

*Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.*

**Bit 3** \( \text{OPM} \): One-pulse mode

- 0: Counter is not stopped at update event
- 1: Counter stops counting at the next update event (clearing the bit \( \text{CEN} \))

**Bit 2** \( \text{URS} \): Update request source

- This bit is set and cleared by software to select the UEV event sources.
- 0: Any of the following events generate an update interrupt or DMA request if enabled.
- 1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

**Bit 1** \( \text{UDIS} \): Update disable

- This bit is set and cleared by software to enable/disable UEV event generation.
- 0: UEV enabled. The Update (UEV) event is generated by one of the following events:
  - Counter overflow/underflow
  - Setting the UG bit
  - Update generation through the slave mode controller
- 1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

**Bit 0** \( \text{CEN} \): Counter enable

- 0: Counter disabled
- 1: Counter enabled

*Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*
RM0456 Advanced-control timers (TIM1/TIM8)

Bits 31:26  Reserved, must be kept at reset value.

Bit 24  Reserved, must be kept at reset value.

Bits 23:20  **MMS2[3:0]**: Master mode selection 2

These bits allow the information to be sent to ADC for synchronization (tim_trgo2) to be selected. The combination is as follows:

0000:  **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo2).
       If the reset is generated by the trigger input (slave mode controller configured in reset mode), the signal on tim_trgo2 is delayed compared to the actual reset.

0001:  **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo2). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between the CEN control bit and the trigger input when configured in Gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo2, except if the Master/Slave mode is selected (see the MSM bit description in TIMx_SMCR register).

0010:  **Update** - the update event is selected as trigger output (tim_trgo2). For instance, a master timer can then be used as a prescaler for a slave timer.

0011:  **Compare pulse** - the trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or compare match occurs (tim_trgo2).

0100:  **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo2)

0101:  **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo2)

0110:  **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo2)

0111:  **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo2)

1000:  **Compare** - tim_oc5refc signal is used as trigger output (tim_trgo2)

1001:  **Compare** - tim_oc6refc signal is used as trigger output (tim_trgo2)

1010:  **Compare Pulse** - tim_oc4refc rising or falling edges generate pulses on tim_trgo2

1011:  **Compare pulse** - tim_oc6refc rising or falling edges generate pulses on tim_trgo2

1100:  **Compare pulse** - tim_oc4refc or tim_oc6refc rising edges generate pulses on tim_trgo2

1101:  **Compare pulse** - tim_oc4refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

1110:  **Compare pulse** - tim_oc5refc or tim_oc6refc rising edges generate pulses on tim_trgo2

1111:  **Compare pulse** - tim_oc5refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

*Note:* The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 19  Reserved, must be kept at reset value.

Bit 18  **OIS6**: Output idle state 6 (tim_oc6 output)
       Refer to OIS1 bit

Bit 17  Reserved, must be kept at reset value.

Bit 16  **OIS5**: Output idle state 5 (tim_oc5 output)
       Refer to OIS1 bit

Bit 15  **OIS4N**: Output idle state 4 (tim_oc4n output)
       Refer to OIS1N bit

Bit 14  **OIS4**: Output idle state 4 (tim_oc4 output)
       Refer to OIS1 bit
Bit 13 **OIS3N**: Output idle state 3 (tim_oc3n output)
Refer to OIS1N bit

Bit 12 **OIS3**: Output idle state 3 (tim_oc3n output)
Refer to OIS1 bit

Bit 11 **OIS2N**: Output idle state 2 (tim_oc2n output)
Refer to OIS1N bit

Bit 10 **OIS2**: Output idle state 2 (tim_oc2 output)
Refer to OIS1 bit

Bit 9 **OIS1N**: Output idle state 1 (tim_oc1n output)
0: tim_oc1n=0 after a dead-time when MOE=0
1: tim_oc1n=1 after a dead-time when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 8 **OIS1**: Output idle state 1 (tim_oc1 output)
0: tim_oc1=0 (after a dead-time) when MOE=0
1: tim_oc1=1 (after a dead-time) when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 7 **TI1S**: tim_ti1 selection
0: The tim_ti1_in[15:0] multiplexer output is connected to tim_ti1 input
1: tim_ti1_in[15:0], tim_ti2_in[15:0] and tim_ti3_in[15:0] multiplexers outputs are XORed and connected to the tim_ti1 input
Bits 25, 6:4 **MMS[3:0]**: Master mode selection

These bits select the information to be sent in master mode to slave timers for synchronization (tim\_trgo). The combination is as follows:

0000: **Reset** - the UG bit from the TIMx\_EGR register is used as trigger output (tim\_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim\_trgo is delayed compared to the actual reset.

0001: **Enable** - the Counter Enable signal CNT\_EN is used as trigger output (tim\_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim\_trgo, except if the master/slave mode is selected (see the MSM bit description in TIMx\_SMCR register).

0010: **Update** - The update event is selected as trigger output (tim\_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

0011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (tim\_trgo).

0100: **Compare** - tim\_oc1refc signal is used as trigger output (tim\_trgo)

0101: **Compare** - tim\_oc2refc signal is used as trigger output (tim\_trgo)

0110: **Compare** - tim\_oc3refc signal is used as trigger output (tim\_trgo)

0111: **Compare** - tim\_oc4refc signal is used as trigger output (tim\_trgo)

1000: **Encoder Clock output** - The encoder clock signal is used as trigger output (tim\_trgo). This code is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

Other codes reserved

*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only
1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on tim\_trgi

*Note: This bit acts only on channels that have a complementary output.*

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

0: CCxE, CCxNE and OCxM bits are not preloaded
1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on tim\_trgi, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*
54.6.3 TIMx slave mode control register (TIMx_SMCR)(x = 1, 8)

Address offset: 0x008
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address offset: 0x008</th>
<th>Reset value: 0x0000 0000</th>
</tr>
</thead>
</table>

| Bit 31:26 Reserved, must be kept at reset value. |  |
| Bit 25 SMSPS: SMS preload source |  |
| This bit selects whether the events that triggers the SMS[3:0] bitfield transfer from preload to active |  |
| 0: The transfer is triggered by the Timer's Update event |  |
| 1: The transfer is triggered by the Index event |  |
| Bit 24 SMSPE: SMS preload enable |  |
| This bit selects whether the SMS[3:0] bitfield is preloaded |  |
| 0: SMS[3:0] bitfield is not preloaded |  |
| 1: SMS[3:0] preload is enabled |  |
| Bits 23:22 Reserved, must be kept at reset value. |  |
| Bits 21:20 TS[4:3]: Trigger selection - bit 4:3 |  |
| Refer to TS[2:0] description - bits 6:4 |  |
| Bits 19:17 Reserved, must be kept at reset value. |  |
| Bit 15 ETP: External trigger polarity |  |
| This bit selects whether tim_eetr_in or tim_etr_in is used for trigger operations |  |
| 0: tim_eetr_in is non-inverted, active at high level or rising edge. |  |
| 1: tim_eetr_in is inverted, active at low level or falling edge. |  |
| Bit 14 ECE: External clock enable |  |
| This bit enables External clock mode 2. |  |
| 0: External clock mode 2 disabled |  |
| 1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_eetr signal. |  |
| Note: Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_eetr (SMS=111 and TS=00111). |  |
| It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_eetr in this case (TS bits must not be 0011). |  |
| If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_eetr. |  |
Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal `tim_etrp` frequency must be at most 1/4 of `TIMxCLK` frequency. A prescaler can be enabled to reduce `tim_etrp` frequency. It is useful when inputting fast external clocks on `tim_etr_in`.

- **00**: Prescaler OFF
- **01**: `tim_etr_in` frequency divided by 2
- **10**: `tim_etr_in` frequency divided by 4
- **11**: `tim_etr_in` frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample `tim_etrp` signal and the length of the digital filter applied to `tim_etrp`. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- **0000**: No filter, sampling is done at `fDTS`
- **0001**: `fSAMPLING=tim_ker_ck`, N=2
- **0010**: `fSAMPLING=tim_ker_ck`, N=4
- **0011**: `fSAMPLING=tim_ker_ck`, N=8
- **0100**: `fSAMPLING=fDTS/2`, N=6
- **0101**: `fSAMPLING=fDTS/2`, N=8
- **0110**: `fSAMPLING=fDTS/4`, N=6
- **0111**: `fSAMPLING=fDTS/4`, N=8
- **1000**: `fSAMPLING=fDTS/8`, N=6
- **1001**: `fSAMPLING=fDTS/8`, N=8
- **1010**: `fSAMPLING=fDTS/16`, N=5
- **1011**: `fSAMPLING=fDTS/16`, N=6
- **1100**: `fSAMPLING=fDTS/16`, N=8
- **1101**: `fSAMPLING=fDTS/16`, N=8
- **1110**: `fSAMPLING=fDTS/32`, N=6
- **1111**: `fSAMPLING=fDTS/32`, N=8

Bit 7 **MSM**: Master/slave mode

- **0**: No action
- **1**: The effect of an event on the trigger input (`tim_trgi`) is delayed to allow a perfect synchronization between the current timer and its slaves (through `tim_trgo`). It is useful if we want to synchronize several timers on a single external event.
Bits 6:4 **TS[2:0]: Trigger selection**

This bitfield is combined with TS[4:3] bits. This bit-field selects the trigger input to be used to synchronize the counter.

- 00000: Internal Trigger 0 (tim_itr0)
- 00001: Internal Trigger 1 (tim_itr1)
- 00010: Internal Trigger 2 (tim_itr2)
- 00011: Internal Trigger 3 (tim_itr3)
- 00100: tim_ti1 Edge Detector (tim_ti1f_ed)
- 00101: Filtered Timer Input 1 (tim_ti1fp1)
- 00110: Filtered Timer Input 2 (tim_ti2fp2)
- 00111: External Trigger input (tim_etrf)
- 01000: Internal Trigger 4 (tim_itr4)
- 01001: Internal Trigger 5 (tim_itr5)
- 01010: Internal Trigger 6 (tim_itr6)
- 01011: Internal Trigger 7 (tim_itr7)
- 01100: Internal Trigger 8 (tim_itr8)
- 01101: Internal Trigger 9 (tim_itr9)
- 01110: Internal Trigger 10 (tim_itr10)
- 01111: Internal trigger 11 (tim_itr11)
- 10000: Internal trigger 12 (tim_itr12)
- 10001: Internal trigger 13 (tim_itr13)
- 10010: Internal trigger 14 (tim_itr14)
- 10011: Internal trigger 15 (tim_itr15)
- Others: Reserved

See Table 532: Internal trigger connection for more details on tim_itrx meaning for each Timer.

**Note:** These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3 **OCCS: OCREF clear selection**

This bit is used to select the OCREF clear source.

- 0: tim_ocref_clr_int is connected to the tim_ocref_clr input
- 1: tim_ocref_clr_int is connected to tim_etrf
Bits 16, 2:0 **SMS[3:0]: Slave mode selection**

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.

0001: Quadrature encoder mode 1, x2 mode- Counter counts up/down on tim_ti1fp1 edge depending on tim_ti2fp2 level.

0010: Quadrature encoder mode 2, x2 mode - Counter counts up/down on tim_ti2fp2 edge depending on tim_ti1fp1 level.

0011: Quadrature encoder mode 3, x4 mode - Counter counts up/down on both tim_ti1fp2 and tim_ti2fp2 edges depending on the level of the other input.

0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

1010: Encoder mode: Clock plus direction, x2 mode.

1011: Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by CC2P

1100: Encoder mode: Directional Clock, x2 mode.

1101: Encoder mode: Directional Clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity is set by CC1P and CC2P.

1110: Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge sensitivity is set by CC1P.

1111: Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge sensitivity is set by CC2P.

**Note:** The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS=00100). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on Ti1F, whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Bits 31:24  Reserved, must be kept at reset value.

Bit 23  **TERRF**: Transition error interrupt flag
This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to '0'.
0: No encoder transition error has been detected.
1: An encoder transition error has been detected

Bit 22  **IERRF**: Index error interrupt flag
This flag is set by hardware when an index error is detected. It is cleared by software by writing it to '0'.
0: No index error has been detected.
1: An index error has been detected

Bit 21  **DIRF**: Direction change interrupt flag
This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIMx_CR is changing). It is cleared by software by writing it to '0'.
0: No direction change
1: Direction change

Bit 20  **IDXF**: Index interrupt flag
This flag is set by hardware when an index event is detected. It is cleared by software by writing it to '0'.
0: No index event occurred.
1: An index event has occurred

Bits 19:18  Reserved, must be kept at reset value.

Bit 17  **CC6IF**: Compare 6 interrupt flag
Refer to CC1IF description
*Note: Channel 6 can only be configured as output.*

Bit 16  **CC5IF**: Compare 5 interrupt flag
Refer to CC1IF description
*Note: Channel 5 can only be configured as output.*

Bits 15:14  Reserved, must be kept at reset value.

Bit 13  **SBIF**: System break interrupt flag
This flag is set by hardware as soon as the system break input goes active. It can be cleared by software if the system break input is not active.
This flag must be reset to re-start PWM operation.
0: No break event occurred.
1: An active level has been detected on the system break input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 12  **CC4OF**: Capture/compare 4 overcapture flag
Refer to CC1OF description

Bit 11  **CC3OF**: Capture/compare 3 overcapture flag
Refer to CC1OF description

Bit 10  **CC2OF**: Capture/compare 2 overcapture flag
Refer to CC1OF description
Bit 9  **CC1OF**: Capture/compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bit 8  **B2IF**: Break 2 interrupt flag
This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active.
0: No break event occurred.
1: An active level has been detected on the break 2 input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 7  **BIF**: Break interrupt flag
This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
0: No break event occurred.
1: An active level has been detected on the break input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 6  **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred.
1: Trigger interrupt pending.

Bit 5  **COMIF**: COM interrupt flag
This flag is set by hardware on COM event (when capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.
0: No COM event occurred.
1: COM interrupt pending.

Bit 4  **CC4IF**: Capture/compare 4 interrupt flag
Refer to CC1IF description

Bit 3  **CC3IF**: Capture/compare 3 interrupt flag
Refer to CC1IF description
Bit 2 **CC2IF**: Capture/compare 2 interrupt flag  
Refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag  
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).  
0: No compare match / No input capture occurred  
1: A compare match or an input capture occurred  

**If channel CC1 is configured as output**: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.  

**If channel CC1 is configured as input**: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCRER).

Bit 0 **UIF**: Update interrupt flag  
This bit is set by hardware on an update event. It is cleared by software.  
0: No update occurred.  
1: Update interrupt pending. This bit is set by hardware when the registers are updated:  
– At overflow or underflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx_CR1 register.  
– When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.  
– When CNT is reinitialized by a trigger event (refer to Section 54.6.3: TIMx slave mode control register (TIMx_SMCR)(x = 1, 8)), if URS=0 and UDIS=0 in the TIMx_CR1 register.

54.6.6 **TIMx event generation register (TIMx_EGR)(x = 1, 8)**

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **B2G**: Break 2 generation  
This bit is set by software in order to generate an event, it is automatically cleared by hardware.  
0: No action  
1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled.

Bit 7 **BG**: Break generation  
This bit is set by software in order to generate an event, it is automatically cleared by hardware.  
0: No action  
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.
Bit 6 **TG**: Trigger generation
   This bit is set by software in order to generate an event, it is automatically cleared by
   hardware.
   0: No action
   1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if
      enabled.

Bit 5 **COMG**: Capture/compare control update generation
   This bit can be set by software, it is automatically cleared by hardware
   0: No action
   1: CCxE, CCxNE and OCxM bits update (providing CCPC bit is set)
   *Note*: This bit acts only on channels having a complementary output.

Bit 4 **CC4G**: Capture/compare 4 generation
   Refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation
   Refer to CC1G description

Bit 2 **CC2G**: Capture/compare 2 generation
   Refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation
   This bit is set by software in order to generate an event, it is automatically cleared by
   hardware.
   0: No action
   1: A capture/compare event is generated on channel 1:
      **If channel CC1 is configured as output:**
      CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
      **If channel CC1 is configured as input:**
      The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set,
      the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the
      CC1IF flag was already high.

Bit 0 **UG**: Update generation
   This bit can be set by software, it is automatically cleared by hardware.
   0: No action
   1: Reinitialize the counter and generates an update of the registers. Note that the prescaler
      counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if
      the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload
      value (TIMx_ARR) if DIR=1 (downcounting).

54.6.7 TIMx capture/compare mode register 1 (TIMx_CCMR1) 
(x = 1, 8)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare
mode (next section). The direction of a channel is defined by configuring the corresponding
CCxS bits. All the other bits of this register have a different function for input capture and for
output compare modes. It is possible to combine both modes independently (for example
channel 1 in input capture mode and channel 2 in output compare mode).
## Input capture mode:

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:12  **IC2F[3:0]**: Input capture 2 filter

Bits 11:10  **IC2PSC[1:0]**: Input capture 2 prescaler

<table>
<thead>
<tr>
<th>bits</th>
<th>name</th>
<th>description</th>
</tr>
</thead>
</table>
| 9:8  | **CC2S[1:0]** | Capture/compare 2 selection  
This bit-field defines the direction of the channel (input/output) as well as the used input.  
00: CC2 channel is configured as output  
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2  
10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1  
11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)  
Note: **CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).**  

Note: **CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).**
Bits 7:4 IC1F[3:0]: Input capture 1 filter
This bit-field defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:
0000: No filter, sampling is done at fDTS
0001: fSAMPLING=ftim_ker_ck, N=2
0010: fSAMPLING=ftim_ker_ck, N=4
0011: fSAMPLING=ftim_ker_ck, N=8
0100: fSAMPLING=fDTS/2, N=6
0101: fSAMPLING=fDTS/2, N=8
0110: fSAMPLING=fDTS/4, N=6
0111: fSAMPLING=fDTS/4, N=8
1000: fSAMPLING=fDTS/8, N=6
1001: fSAMPLING=fDTS/8, N=8
1010: fSAMPLING=fDTS/16, N=5
1011: fSAMPLING=fDTS/16, N=6
1100: fSAMPLING=fDTS/32, N=5
1101: fSAMPLING=fDTS/32, N=6
1110: fSAMPLING=fDTS/32, N=8
1111: fSAMPLING=fDTS/32, N=8

Bits 3:2 IC1PSC[1:0]: Input capture 1 prescaler
This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).
00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0 CC1S[1:0]: Capture/compare 1 Selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC1 channel is configured as output
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).

54.6.8 TIMx capture/compare mode register 1 [alternate]
(TIMx_CCMR1)(x = 1, 8)
Address offset: 0x018
Reset value: 0x0000 0000
The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).
### Output compare mode:

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15  **OC2CE**: Output compare 2 clear enable

Bit 24, 14:12  **OC2M[3:0]**: Output compare 2 mode

Bit 11  **OC2PE**: Output compare 2 preload enable

Bit 10  **OC2FE**: Output compare 2 fast enable

Bits 9:8  **CC2S[1:0]**: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
11: CC2 channel is configured as input, tim_ic2 is mapped on tim_itr. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

**Note:** CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).

Bit 7  **OC1CE**: Output compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr_int signal
1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)
Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal `tim_oc1ref` from which `tim_oc1` and `tim_oc1n` are derived. `tim_oc1ref` is active high whereas `tim_oc1` and `tim_oc1n` active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register `TIMx_CCR1` and the counter `TIMx_CNT` has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. `tim_oc1ref` signal is forced high when the counter `TIMx_CNT` matches the capture/compare register 1 (`TIMx_CCR1`).

0010: Set channel 1 to inactive level on match. `tim_oc1ref` signal is forced low when the counter `TIMx_CNT` matches the capture/compare register 1 (`TIMx_CCR1`).

0011: Toggle - `tim_oc1ref` toggles when `TIMx_CNT=TIMx_CCR1`.

0100: Force inactive level - `tim_oc1ref` is forced low.

0101: Force active level - `tim_oc1ref` is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as `TIMx_CNT<TIMx_CCR1` else inactive. In downcounting, channel 1 is inactive (`tim_oc1ref='0'`) as long as `TIMx_CNT>TIMx_CCR1` else active (`tim_oc1ref='1'`).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as `TIMx_CNT<TIMx_CCR1` else active. In downcounting, channel 1 is active as long as `TIMx_CNT>TIMx_CCR1` else inactive.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - `tim_oc1ref` has the same behavior as in PWM mode 1. `tim_oc1refc` is the logical OR between `tim_oc1ref` and `tim_oc2ref`.

1101: Combined PWM mode 2 - `tim_oc1ref` has the same behavior as in PWM mode 2. `tim_oc1refc` is the logical AND between `tim_oc1ref` and `tim_oc2ref`.

1110: Asymmetric PWM mode 1 - `tim_oc1ref` has the same behavior as in PWM mode 1. `tim_oc1refc` outputs `tim_oc1ref` when the counter is counting up, `tim_oc2ref` when it is counting down.

1111: Asymmetric PWM mode 2 - `tim_oc1ref` has the same behavior as in PWM mode 2. `tim_oc1refc` outputs `tim_oc1ref` when the counter is counting up, `tim_oc2ref` when it is counting down.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

**Note:** In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

**Note:** On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.
Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

*Note*: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1

10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2

11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note*: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).

### 54.6.9 TIMx capture/compare mode register 2 (TIMx_CCMR2)

*(x = 1, 8)*

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 3 in input capture mode and channel 4 in output compare mode).
Bits 31:16  Reserved, must be kept at reset value.

Bits 15:12  **IC4F[3:0]**: Input capture 4 filter

Bits 11:10  **IC4PSC[1:0]**: Input capture 4 prescaler

Bits 9:8  **CC4S[1:0]**: Capture/compare 4 selection

- This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC4 channel is configured as output
- 01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
- 10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
- 11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx_CCER).*

Bits 7:4  **IC3F[3:0]**: Input capture 3 filter

Bits 3:2  **IC3PSC[1:0]**: Input capture 3 prescaler

Bits 1:0  **CC3S[1:0]**: Capture/compare 3 selection

- This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC3 channel is configured as output
- 01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
- 10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4
- 11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = '0' in TIMx_CCER).*

### 54.6.10 TIMx capture/compare mode register 2 [alternate]

**TIMx_CCMR2**(x = 1, 8)

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 3 in input capture mode and channel 4 in output compare mode).

**Output compare mode**

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15  **OC4CE**: Output compare 4 clear enable
Bits 24, 14:12 **OC4M[3:0]**: Output compare 4 mode  
Refer to OC3M[3:0] bit description

Bit 11 **OC4PE**: Output compare 4 preload enable

Bit 10 **OC4FE**: Output compare 4 fast enable

Bits 9:8 **CC4S[1:0]**: Capture/compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC4 channel is configured as output
- 01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
- 10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
- 11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note**: CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx_CCER).

Bit 7 **OC3CE**: Output compare 3 clear enable
Bits 16, 6:4 **OC3M[3:0]:** Output compare 3 mode

These bits define the behavior of the output reference signal `tim_oc3ref` from which `tim_oc3` and `tim_oc3n` are derived. `tim_oc3ref` is active high whereas `tim_oc3` and `tim_oc3n` active level depends on CC3P and CC3NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR3 and the counter TIMx_CNT has no effect on the outputs. (This mode is used to generate a timing base).

0001: Set channel 3 to active level on match. `tim_oc3ref` signal is forced high when the counter TIMx_CNT matches the capture/compare register 3 (TIMx_CCR3).

0010: Set channel 3 to inactive level on match. `tim_oc3ref` signal is forced low when the counter TIMx_CNT matches the capture/compare register 3 (TIMx_CCR3).

0011: Toggle - `tim_oc3ref` toggles when TIMx_CNT=TIMx_CCR3.

0100: Force inactive level - `tim_oc3ref` is forced low.

0101: Force active level - `tim_oc3ref` is forced high.

0110: PWM mode 1 - In upcounting, channel 3 is active as long as TIMx_CNT<TIMx_CCR3 else inactive. In downcounting, channel 3 is inactive (`tim_oc3ref=’0’`) as long as TIMx_CNT>TIMx_CCR3 else active (`tim_oc3ref=’1’`).

0111: PWM mode 2 - In upcounting, channel 3 is inactive as long as TIMx_CNT<TIMx_CCR3 else active. In downcounting, channel 3 is active as long as TIMx_CNT>TIMx_CCR3 else inactive.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TIM_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TIM_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TIM_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TIM_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Pulse on compare: a pulse is generated on `tim_oc3ref` upon CCR3 match event, as per PWPRSC[2:0] and PW[7:0] bitfields programming in TIMxECR.

1011: Direction output. The `tim_oc3ref` signal is overridden by a copy of the DIR bit.

1100: Combined PWM mode 1 - `tim_oc3ref` has the same behavior as in PWM mode 1. `tim_oc3refc` is the logical OR between `tim_oc3ref` and `tim_oc4ref`.

1101: Combined PWM mode 2 - `tim_oc3ref` has the same behavior as in PWM mode 2. `tim_oc3refc` is the logical AND between `tim_oc3ref` and `tim_oc4ref`.

1110: Asymmetric PWM mode 1 - `tim_oc3ref` has the same behavior as in PWM mode 1. `tim_oc3refc` outputs `tim_oc3ref` when the counter is counting up, `tim_oc4ref` when it is counting down.

1111: Asymmetric PWM mode 2 - `tim_oc3ref` has the same behavior as in PWM mode 2. `tim_oc3refc` outputs `tim_oc3ref` when the counter is counting up, `tim_oc4ref` when it is counting down.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output).

**Note:** In PWM mode, the OCRF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC3M active bits take the new value from the preloaded bits only when a COM event is generated.
### 54.6.11 TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)

Bits 31:22 Reserved, must be kept at reset value.

- Bit 21 **CC6P**: Capture/compare 6 output polarity  
  Refer to CC1P description

- Bit 20 **CC6E**: Capture/compare 6 output enable  
  Refer to CC1E description

Bits 19:18 Reserved, must be kept at reset value.

- Bit 17 **CC5P**: Capture/compare 5 output polarity  
  Refer to CC1P description

- Bit 16 **CC5E**: Capture/compare 5 output enable  
  Refer to CC1E description

- Bit 15 **CC4NP**: Capture/compare 4 complementary output polarity  
  Refer to CC1NP description

- Bit 14 **CC4NE**: Capture/compare 4 complementary output enable  
  Refer to CC1NE description

- Bit 13 **CC4P**: Capture/compare 4 output polarity  
  Refer to CC1P description

- Bit 12 **CC4E**: Capture/compare 4 output enable  
  Refer to CC1E description

- Bit 11 **CC3NP**: Capture/compare 3 complementary output polarity  
  Refer to CC1NP description
Bit 10 **CC3NE**: Capture/compare 3 complementary output enable  
Refer to CC1NE description

Bit 9 **CC3P**: Capture/compare 3 output polarity  
Refer to CC1P description

Bit 8 **CC3E**: Capture/compare 3 output enable  
Refer to CC1E description

Bit 7 **CC2NP**: Capture/compare 2 complementary output polarity  
Refer to CC1NP description

Bit 6 **CC2NE**: Capture/compare 2 complementary output enable  
Refer to CC1NE description

Bit 5 **CC2P**: Capture/compare 2 output polarity  
Refer to CC1P description

Bit 4 **CC2E**: Capture/compare 2 output enable  
Refer to CC1E description

Bit 3 **CC1NP**: Capture/compare 1 complementary output polarity

**CC1 channel configured as output:**
0: tim_oc1n active high.  
1: tim_oc1n active low.  

**CC1 channel configured as input:**
This bit is used in conjunction with CC1P to define the polarity of tim_t1fp1 and tim_t2fp1.  
Refer to CC1P description.

*Note:* This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=“00” (channel configured as output).

*Note:* On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 2 **CC1NE**: Capture/compare 1 complementary output enable  
0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSS1, OIS1, OSSR, OIS1N and CC1E bits.  
1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSS1, OSSR, OIS1, OIS1N and CC1E bits.  

*Note:* On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NE active bit takes the new value from the preloaded bit only when a Commutation event is generated.
Bit 1 **CC1P**: Capture/compare 1 output polarity

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

- **CC1NP=0, CC1P=0**: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).
- **CC1NP=0, CC1P=1**: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).
- **CC1NP=1, CC1P=1**: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.
- **CC1NP=1, CC1P=0**: the configuration is reserved, it must not be used.

*Note:* This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0 **CC1E**: Capture/compare 1 output enable

0: Capture mode disabled / OC1 is not active (see below)
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

*When CC1 channel is configured as output*, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to Table 548 for details.

*Note:* On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a Commutation event is generated.

1. When both outputs of a channel are not used (control taken over by GPIO), the OISx, OISxN, CCxP, and CCxNP bits must be kept cleared.

**Note:** The state of the external I/O pins connected to the complementary tim\_ocx and tim\_ocxn channels depends on the tim\_ocx and tim\_ocxn channel state and the GPIO registers.

<td></td>
<td></td>
</tr>
</tbody>
</table>
54.6.14 TIMx auto-reload register (TIMx_ARR)(x = 1, 8)

Address offset: 0x02C
Reset value: 0x0000 FFFF

| Bits 31:20 | Reserved, must be kept at reset value. |
| Bits 19:0 | ARR[19:0]: Auto-reload value |
| ARR is the value to be loaded in the actual auto-reload register. |
| Refer to the Section 54.3.3: Time-base unit on page 2090 for more details about ARR update and behavior. |
| The counter is blocked while the auto-reload value is null. |
| Non-dithering mode (DITHEN = 0) |
| The register holds the auto-reload value. |
| Dithering mode (DITHEN = 1) |
| The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part. |

54.6.15 TIMx repetition counter register (TIMx_RCR)(x = 1, 8)

Address offset: 0x030
Reset value: 0x0000

| Bits 15:0 | REP[15:0]: Repetition counter reload value |
| This bitfield defines the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable. It also defines the update interrupt generation rate, if this interrupt is enable. |
| When the repetition down-counter reaches zero, an update event is generated and it restarts counting from REP value. As the repetition counter is reloaded with REP value only at the repetition update event UEV, any write to the TIMx_RCR register is not taken in account until the next repetition update event. |
| It means in PWM mode (REP+1) corresponds to: |
| – the number of PWM periods in edge-aligned mode |
| – the number of half PWM period in center-aligned mode |
54.6.16  TIMx capture/compare register 1 (TIMx_CCR1)(x = 1, 8)

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR1[19:0]:** Capture/compare 1 value

- **If channel CC1 is configured as output:** CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
  
  It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

  The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

  - **Non-dithering mode (DITHEN = 0)**
    
    The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.

  - **Dithering mode (DITHEN = 1)**
    
    The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

- **If channel CC1 is configured as input:** CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

  - **Non-dithering mode (DITHEN = 0)**
    
    The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.

  - **Dithering mode (DITHEN = 1)**
    
    The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

54.6.17  TIMx capture/compare register 2 (TIMx_CCR2)(x = 1, 8)

- **If channel CC1 is configured as output:** CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

- **If channel CC1 is configured as input:** CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR2[19:0]: Capture/compare 2 value**

If channel CC2 is configured as output: CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

**Non-dithering mode (DITHEN = 0)**
The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

**Dithering mode (DITHEN = 1)**
The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

If channel CC2 is configured as input: CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

**Non-dithering mode (DITHEN = 0)**
The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.

**Dithering mode (DITHEN = 1)**
The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

---

2206/3637  RM0456 Rev 5
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR4[19:0]: Capture/compare value**

*If channel CC4 is configured as output:* CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on tim_oc4 output.

*Non-dithering mode (DITHEN = 0)*

The register holds the compare value in CCR4[15:0]. The CCR4[19:16] bits are reset.

*Dithering mode (DITHEN = 1)*

The register holds the integer part in CCR4[19:4]. The CCR4[3:0] bitfield contains the dithered part.

*If channel CC4 is configured as input:* CCR4 is the counter value transferred by the last input capture 4 event (tim_ic4). The TIMx_CCR4 register is read-only and cannot be programmed.

*Non-dithering mode (DITHEN = 0)*

The register holds the capture value in CCR4[15:0]. The CCR4[19:16] bits are reset.

*Dithering mode (DITHEN = 1)*

The register holds the capture in CCR4[19:4]. The CCR4[3:0] bits are reset.

### 54.6.20  TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8)

Address offset: 0x044

*Note:* As the bits BK2BID/BK2ID/BK2P, BK2E, BK2F[3:0], BK[3:0], AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx_BDTR register.
Bits 31:30  Reserved, must be kept at reset value.

Bit 29  **BK2BID**: Break2 bidirectional
Refer to BK2BID description

Bit 28  **BK2BID**: Break bidirectional
0: Break input tim_brk in input mode
1: Break input tim_brk in bidirectional mode
In the bidirectional mode (BK2BID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27  **BK2DSRM**: Break2 disarm
Refer to BK2DSRM description

Bit 26  **BKDSRM**: Break disarm
0: Break input tim_brk is armed
1: Break input tim_brk is disarmed
This bit is cleared by hardware when no break source is active.
The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled it until it is reset by hardware, indicating that the fault condition has disappeared.

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 25  **BK2P**: Break 2 polarity
0: Break input tim_brk2 is active low
1: Break input tim_brk2 is active high

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 24  **BK2E**: Break 2 enable
This bit enables the complete break 2 protection (including all sources connected to bk_acth and BKIN sources, as per Figure 550: Break and Break2 circuitry overview).
0: Break2 function disabled
1: Break2 function enabled

*Note:* The BK2IN2 must only be used with OSSR = OSSI = 1.

*Note:* This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bits 23:20  **BK2F[3:0]**: Break 2 filter

This bit-field defines the frequency used to sample tim_brk2 input and the length of the digital filter applied to tim_brk2. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, tim_brk2 acts asynchronously
0001: $f_{SAMPLING} = f_{tim\_ker\_ck}$, N=2
0010: $f_{SAMPLING} = f_{tim\_ker\_ck}$, N=4
0011: $f_{SAMPLING} = f_{tim\_ker\_ck}$, N=8
0100: $f_{SAMPLING} = f_{DTS}/2$, N=6
0101: $f_{SAMPLING} = f_{DTS}/2$, N=8
0110: $f_{SAMPLING} = f_{DTS}/4$, N=6
0111: $f_{SAMPLING} = f_{DTS}/4$, N=8
1000: $f_{SAMPLING} = f_{DTS}/8$, N=6
1001: $f_{SAMPLING} = f_{DTS}/8$, N=8
1010: $f_{SAMPLING} = f_{DTS}/16$, N=6
1011: $f_{SAMPLING} = f_{DTS}/16$, N=8
1100: $f_{SAMPLING} = f_{DTS}/32$, N=5
1101: $f_{SAMPLING} = f_{DTS}/32$, N=6
1110: $f_{SAMPLING} = f_{DTS}/32$, N=8

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 19:16  **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample tim_brk input and the length of the digital filter applied to tim_brk. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, tim_brk acts asynchronously
0001: $f_{SAMPLING} = f_{tim\_ker\_ck}$, N=2
0010: $f_{SAMPLING} = f_{tim\_ker\_ck}$, N=4
0011: $f_{SAMPLING} = f_{tim\_ker\_ck}$, N=8
0100: $f_{SAMPLING} = f_{DTS}/2$, N=6
0101: $f_{SAMPLING} = f_{DTS}/2$, N=8
0110: $f_{SAMPLING} = f_{DTS}/4$, N=6
0111: $f_{SAMPLING} = f_{DTS}/4$, N=8
1000: $f_{SAMPLING} = f_{DTS}/8$, N=6
1001: $f_{SAMPLING} = f_{DTS}/8$, N=8
1010: $f_{SAMPLING} = f_{DTS}/16$, N=6
1011: $f_{SAMPLING} = f_{DTS}/16$, N=8
1100: $f_{SAMPLING} = f_{DTS}/32$, N=5
1101: $f_{SAMPLING} = f_{DTS}/32$, N=6
1110: $f_{SAMPLING} = f_{DTS}/32$, N=8

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as one of the break inputs is active (tim_brk or tim_brk2). It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

- 0: In response to a break 2 event. OC and OCN outputs are disabled
- 1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register).

See OC/OCN enable description for more details (Section 54.6.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)).

Bit 14 **AOE**: Automatic output enable

- 0: MOE can be set only by software
- 1: MOE can be set by software or automatically at the next update event (if none of the break inputs tim_brk and tim_brk2 is active)

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 **BKP**: Break polarity

- 0: Break input tim_brk is active low
- 1: Break input tim_brk is active high

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Note**: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 **BKE**: Break enable

This bit enables the complete break protection (including all sources connected to bk_acth and BKIN sources, as per Figure 550: Break and Break2 circuitry overview).

- 0: Break function disabled
- 1: Break function enabled

**Note**: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Note**: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (Section 54.6.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)).

- 0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic, which forces a Hi-Z state).
- 1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

**Note**: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 10  **OSSI**: Off-state selection for idle mode

This bit is used when MOE=0 due to a break event or by a software write, on channels configured as outputs.

See OC/OCN enable description for more details (Section 54.6.11: TIMx capture/compare enable register (TIMx_CCRer)(x = 1, 8)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic and which imposes a Hi-Z state).

1: When inactive, OC/OCN outputs are first forced with their inactive level then forced to their idle level after the deadtime. The timer maintains its control over the output.

**Note**: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8  **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected.

01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKBIID/BK2BID/BKBE/BKPAOE bits in TIMx_BDTR register can no longer be written.

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCRer register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

**Note**: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0  **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5]=0xx => DT=DTG[7:0]x t_{drg} with t_{drg}=1_{DTS}.

DTG[7:5]=10x => DT=(64+DTG[5:0])x t_{drg} with T_{drg}=2x_{DTS}.

DTG[7:5]=110 => DT=(32+DTG[4:0])x t_{drg} with T_{drg}=8x_{DTS}.

DTG[7:5]=111 => DT=(32+DTG[4:0])x t_{drg} with T_{drg}=16x_{DTS}.

Example if T_{DTS}=125ns (8MHz), dead-time possible values are:

0 to 15875 ns by 125 ns steps,

16 us to 31750 ns by 250 ns steps,

32 us to 63us by 1 us steps,

64 us to 126 us by 2 us steps

**Note**: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

STI
Bit 31 **GC5C3**: Group channel 5 and channel 3  
Distortion on channel 3 output:  
0: No effect of tim_oc5ref on tim_oc3refc  
1: tim_oc3refc is the logical AND of tim_oc3ref and tim_oc5ref  
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR2).  
*Note: it is also possible to apply this distortion on combined PWM signals.*

Bit 30 **GC5C2**: Group channel 5 and channel 2  
Distortion on channel 2 output:  
0: No effect of tim_oc5ref on tim_oc2refc  
1: tim_oc2refc is the logical AND of tim_oc2ref and tim_oc5ref  
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).  
*Note: it is also possible to apply this distortion on combined PWM signals.*

Bit 29 **GC5C1**: Group channel 5 and channel 1  
Distortion on channel 1 output:  
0: No effect of oc5ref on oc1refc  
1: oc1refc is the logical AND of oc1ref and oc5ref  
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).  
*Note: it is also possible to apply this distortion on combined PWM signals.*

Bits 28:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR5[19:0]**: Capture/compare 5 value  
CCR5 is the value to be loaded in the actual capture/compare 5 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC5PE). Else the preload value is copied in the active capture/compare 5 register when an update event occurs.  
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc5 output.  
**Non-dithering mode (DITHEN = 0)**  
The register holds the compare value in CCR5[15:0]. The CCR5[19:16] bits are reset.  
**Dithering mode (DITHEN = 1)**  
The register holds the integer part in CCR5[19:4]. The CCR5[3:0] bitfield contains the dithered part.

</tbody>
</table>
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  `CCR6[19:0]`: Capture/compare 6 value

CCR6 is the value to be loaded in the actual capture/compare 6 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register
(bit OC6PE). Else the preload value is copied in the active capture/compare 6 register when
an update event occurs.
The active capture/compare register contains the value to be compared to the counter
TIMx_CNT and signaled on tim_oc6 output.

Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR6[15:0]. The CCR6[19:16] bits are reset.

Dithering mode (DITHEN = 1)
The register holds the integer part in CCR6[19:4]. The CCR6[3:0] bitfield contains the
dithered part.

54.6.23  **TIMx capture/compare mode register 3 (TIMx_CCMR3)**

(x = 1, 8)

Address offset: 0x050
Reset value: 0x0000 0000

Refer to the above CCMR1 register description. Channels 5 and 6 can only be configured in
output.

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15  `OC6CE`: Output compare 6 clear enable

Bits 24, 14:12  `OC6M[3:0]`: Output compare 6 mode

Bit 11  `OC6PE`: Output compare 6 preload enable

Bit 10  `OC6FE`: Output compare 6 fast enable

Bits 9:8  Reserved, must be kept at reset value.

Bit 7  `OC5CE`: Output compare 5 clear enable

Bits 16, 6:4  `OC5M[3:0]`: Output compare 5 mode

Bit 3  `OC5PE`: Output compare 5 preload enable

Bit 2  `OC5FE`: Output compare 5 fast enable

Bits 1:0  Reserved, must be kept at reset value.
54.6.24  TIMx timer deadtime register 2 (TIMx_DTR2) (x = 1, 8)

Address offset: 0x054
Reset value: 0x0000 0000

Bits 31:18  Reserved, must be kept at reset value.

Bit 17  **DTPE**: Deadtime preload enable
       0: Deadtime value is not preloaded
       1: Deadtime value preload is enabled

*Note*: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 16  **DTAE**: Deadtime asymmetric enable
       0: Deadtime on rising and falling edges are identical, and defined with DTG[7:0] register
       1: Deadtime on rising edge is defined with DTG[7:0] register and deadtime on falling edge is
       defined with DTGF[7:0] bits.

*Note*: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **DTGF[7:0]**: Dead-time falling edge generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs, on the falling edge.

- DTGF[7:5]=0xx => DTF=DTGF[7:0]x DT_{DG} with DT_{DG}=T_{DTS}.
- DTGF[7:5]=10x => DTF=(64+DTGF[5:0])x DT_{DG} with DT_{DG}=8xT_{DTS}.
- DTGF[7:5]=110 => DTF=(32+DTGF[4:0])x DT_{DG} with DT_{DG}=16xT_{DTS}.
- DTGF[7:5]=111 => DTF=(32+DTGF[4:0])x DT_{DG} with DT_{DG}=32xT_{DTS}.

Example if T_{DTS}=125ns (6MHz), dead-time possible values are:
- 0 to 15875 ns by 125 ns steps,
- 16 us to 31750 ns by 250 ns steps,
- 32 us to 63us by 1 us steps,
- 64 us to 126 us by 2 us steps

*Note*: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 14:9 Reserved, must be kept at reset value.

Bits 8:3 Reserved, must be kept at reset value.

Bits 2:0 Reserved, must be kept at reset value.
Bits 4:3  **IBLK[1:0]:** Index blanking
This bit indicates if the Index event is conditioned by the tim_ti3 or tim_ti4 input
00: Index always active
01: Index disabled when tim_ti3 input is active, as per CC3P bitfield
10: Index disabled when tim_ti4 input is active, as per CC4P bitfield
11: Reserved

Bits 2:1  **IDIR[1:0]:** Index direction
This bit indicates in which direction the Index event resets the counter.
00: Index resets the counter whatever the direction
01: Index resets the counter when up-counting only
10: Index resets the counter when down-counting only
11: Reserved

Bit 0  **IE:** Index enable
This bit indicates if the Index event resets the counter.
0: Index disabled
1: Index enabled

| 1111: tim_etrt |
| Refer to Section 54.3.2: TIM1/TIM8 pins and internal signals for product specific implementation. |

**Note:** These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 BKCMP4P: tim_brk_cmp4 input polarity

This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp4 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)

1: tim_brk_cmp4 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 12 **BKCMP3P**: tim_brk_cmp3 input polarity

This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp3 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim_brk_cmp3 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 11 **BKCMP2P**: tim_brk_cmp2 input polarity

This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp2 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim_brk_cmp2 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 10 **BKCMP1P**: tim_brk_cmp1 input polarity

This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp1 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim_brk_cmp1 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 9 **BKINP**: TIMx_BKIN input polarity

This bit selects the TIMx_BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

0: TIMx_BKIN input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: TIMx_BKIN input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 8 **BKCMP8E**: tim_brk_cmp8 enable

This bit enables the tim_brk_cmp8 for the timer’s tim_brk input. tim_brk_cmp8 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp8 input disabled
1: tim_brk_cmp8 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 7 **BKCMP7E**: tim_brk_cmp7 enable

This bit enables the tim_brk_cmp7 for the timer’s tim_brk input. tim_brk_cmp7 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp7 input disabled
1: tim_brk_cmp7 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 6 **BKCMP6E**: tim_brk_cmp6 enable

This bit enables the tim_brk_cmp6 for the timer’s tim_brk input. tim_brk_cmp6 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp6 input disabled
1: tim_brk_cmp6 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
Bit 5 BKCMP5E: tim_brk_cmp5 enable
This bit enables the tim_brk_cmp5 for the timer's tim_brk input. tim_brk_cmp5 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp5 input disabled
1: tim_brk_cmp5 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 4 BKCMP4E: tim_brk_cmp4 enable
This bit enables the tim_brk_cmp4 for the timer's tim_brk input. tim_brk_cmp4 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp4 input disabled
1: tim_brk_cmp4 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 3 BKCMP3E: tim_brk_cmp3 enable
This bit enables the tim_brk_cmp3 for the timer's tim_brk input. tim_brk_cmp3 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp3 input disabled
1: tim_brk_cmp3 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 2 BKCMP2E: tim_brk_cmp2 enable
This bit enables the tim_brk_cmp2 for the timer's tim_brk input. tim_brk_cmp2 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp2 input disabled
1: tim_brk_cmp2 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 1 BKCMP1E: tim_brk_cmp1 enable
This bit enables the tim_brk_cmp1 for the timer's tim_brk input. tim_brk_cmp1 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp1 input disabled
1: tim_brk_cmp1 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 0 BKINE: TIMx_BKIN input enable
This bit enables the TIMx_BKIN alternate function input for the timer's tim_brk input. TIMx_BKIN input is 'ORed' with the other tim_brk sources.
0: TIMx_BKIN input disabled
1: TIMx_BKIN input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Refer to Section 54.3.2: TIM1/TIM8 pins and internal signals for product specific implementation.

---

2222/3637  RM0456 Rev 5
Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **DBSS[3:0]: DMA burst source selection**
This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).
- 0000: Reserved
- 0001: Update
- 0010: CC1
- 0011: CC2
- 0100: CC3
- 0101: CC4
- 0110: COM
- 0111: Trigger
- Others: reserved

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]: DMA burst length**
This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).
- 00000: 1 transfer
- 00001: 2 transfers
- 00010: 3 transfers
- ...
- 11010: 26 transfers

**Example:** Let us consider the following transfer: DBL = 7 bytes & DBA = TIM2_CR1.

- If DBL = 7 bytes and DBA = TIM2_CR1 represents the address of the byte to be transferred, the address of the transfer is given by the following equation:
  \[(TIMx\_CR1\text{ address}) + DBA + \text{(DMA index)}\], where DMA index = DBL

In this example, 7 bytes are added to \((TIMx\_CR1\text{ address}) + DBA\), which gives us the address from/to which the data are copied. In this case, the transfer is done to 7 registers starting from the following address: \((TIMx\_CR1\text{ address}) + DBA\)

According to the configuration of the DMA Data Size, several cases may occur:

- If the DMA Data Size is configured in half-words, 16-bit data are transferred to each of the 7 registers.
- If the DMA Data Size is configured in bytes, the data are also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on.

So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]: DMA base address**
This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

**Example:**
- 00000: TIMx_CR1
- 00001: TIMx_CR2
- 00010: TIMx_SMCR
- ...

RM0456 Advanced-control timers (TIM1/TIM8)
54.6.30  TIMx DMA address for full transfer (TIMx_DMAR)(x = 1, 8)

Address offset: 0x3E0
Reset value: 0x0000 0000

Bits 31:0  DMAB[31:0]: DMA register for burst accesses
A read or write operation to the DMAR register accesses the register located at the address
(TIMx_CR1 address) + (DBA + DMA index) x 4
where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base
address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA
transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).

54.6.31  TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

55 General-purpose timers (TIM2/TIM3/TIM4/TIM5)

55.1 TIM2/TIM3/TIM4/TIM5 introduction

The general-purpose timers consist of a 16-bit or 32-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare and PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 55.4.23: Timer synchronization.

55.2 TIM2/TIM3/TIM4/TIM5 main features

General-purpose TIMx timer features include:

• 16-bit or 32-bit up, down, up/down auto-reload counter.
• 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
• Up to 4 independent channels for:
  – Input capture
  – Output compare
  – PWM generation (Edge- and Center-aligned modes)
  – One-pulse mode output
• Synchronization circuit to control the timer with external signals and to interconnect several timers.
• Interrupt/DMA generation on the following events:
  – Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  – Trigger event (counter start, stop, initialization or count by internal/external trigger)
  – Input capture
  – Output compare
• Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
• Trigger input for external clock or cycle-by-cycle current management

### 55.4.3 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC):
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.
The counter is clocked by the prescaler output `tim_cnt_ck`, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the actual counter enable signal CNT_EN is set 1 clock cycle after CEN.

**Prescaler description**

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 594* and *Figure 595* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

*Figure 594. Counter timing diagram with prescaler division change from 1 to 2*
55.4.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Write a new value in TIMx_ARR
**Downcounting mode**

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generated at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

**Figure 602. Counter timing diagram, internal clock divided by 1**

![Counter timing diagram, internal clock divided by 1](image-url)
Figure 603. Counter timing diagram, internal clock divided by 2

Figure 604. Counter timing diagram, internal clock divided by 4
Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-
reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the direction bit (DIR from TIMx_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupt when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

55.4.5 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2)
- External clock mode2: external trigger input (tim_etr_in)
- Internal trigger inputs (tim_itr): using one timer as prescaler for another timer, for example, Timer 1 can be configured to act as a prescaler for Timer 2. Refer to: Using one timer as prescaler for another timer on page 2298 for more details.

Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS=000 in the TIMx_SMCR register), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 613 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
General-purpose timers (TIM2/TIM3/TIM4/TIM5)

Figure 613. Control circuit in normal mode, internal clock divided by 1

External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 614. tim_ti2 external clock connection example

1. Codes ranging from 01000 to 11111: tim_itr[15:0].

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:
1. Select the proper `tim_ti2_in[15:0]` source (internal or external) with the `TI2SEL[3:0]` bits in the `TIMx_TISEL` register.
2. Configure channel 2 to detect rising edges on the `tim_ti2` input by writing `CC2S= '01` in the `TIMx_CCMR1` register.
3. Configure the input filter duration by writing the `IC2F[3:0]` bits in the `TIMx_CCMR1` register (if no filter is needed, keep `IC2F=0000`).

*Note:* The capture prescaler is not used for triggering, so it does not need to be configured.
4. Select rising edge polarity by writing `CC2P=0` and `CC2NP=0` and `CC2NP=0` in the `TIMx_CCER` register.
5. Configure the timer in external clock mode 1 by writing `SMS=111` in the `TIMx_SMCR` register.
6. Select `tim_ti2` as the input source by writing `TS=00110` in the `TIMx_SMCR` register.
7. Enable the counter by writing `CEN=1` in the `TIMx_CR1` register.

When a rising edge occurs on `tim_ti2`, the counter counts once and the TIF flag is set.

The delay between the rising edge on `tim_ti2` and the actual clock of the counter is due to the resynchronization circuit on `tim_ti2` input.

**Figure 615. Control circuit in external clock mode 1**

---

**External clock source mode 2**

This mode is selected by writing `ECE=1` in the `TIMx_SMCR` register.

The counter can count at each rising or falling edge on the external trigger input `tim_etr_in`.

*Figure 616* gives an overview of the external trigger input block.
For example, to configure the upcounter to count each 2 rising edges on tim_etr_in, use the following procedure:

1. Select the proper tim_etr_in source (internal or external) with the ETRSEL[3:0] bits in the TIMx_AF1 register.
2. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
3. Set the prescaler by writing ETPS\[1:0\]=01 in the TIMx_SMCR register.
4. Select rising edge detection on the tim_etr_in by writing ETP=0 in the TIMx_SMCR register.
5. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 tim_etr_in rising edges.

The delay between the rising edge on tim_etr_in and the actual clock of the counter is due to the resynchronization circuit on the tim_etrp signal. As a consequence, the maximum frequency that can be correctly captured by the counter is at most ¼ of TIMxCLK frequency. When the ETRP signal is faster, the user must apply a division of the external signal by a proper ETPS prescaler setting.
55.4.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of one Capture/Compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfpy) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

Figure 619. Capture/compare channel 1 main circuit

Figure 620. Output stage of capture/compare channel (channel 1, idem ch.2, 3 and 4)

1. Available on some instances only. If not available, tim_etrf is directly connected to tim_ocref_clr_int.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.
In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

55.4.7 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

1. Select the proper tim_tix_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.

2. Select the active input: TIMx_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.

3. Program the needed input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at least 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_ti1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.

4. Select the edge of the active transition on the tim_ti1 channel by writing the CC1P and CC1NP bits to 00 in the TIMx_CCER register (rising edge in this case).

5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).

6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.

7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.
55.4.8 **PWM input mode**

This mode is used to measure both the period and the duty cycle of a PWM signal connected to a single TIMx input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges).
- The TIM_CCR2 register holds the pulse width (interval between two consecutive rising and falling edges).

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same TIMx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

The period and the pulse width of a PWM signal applied on TIMx can be measured using the following procedure:

1. Select the proper TIMx_in[15:0] source (internal or external) with the Ti1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TIMx selected).
3. Select the active polarity for TIMx_CCR1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P to ‘0’ and the CC1NP bit to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TIMx selected).
5. Select the active polarity for TIMx_CCR2 (used for capture in TIMx_CCR2): write the CC2P bit to ‘1’ and the CC2NP bit to ‘0’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (TIMx selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.
55.4.9 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP=0 (tim_ocx active high) => tim_ocx is forced to high level.

tim_ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the Output Compare Mode section.

55.4.10 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP
bit in the TIMx_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example:
   a) Write OCxM = 0011 to toggle tim_ocx output pin when CNT matches CCRx
   b) Write OCxPE = 0 to disable preload register
   c) Write CCxP = 0 to select active high polarity
   d) Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 622.
55.4.11 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per TIM_ocx output) by writing 110 (PWM mode 1) or ‘111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx \leq TIMx_CNT or TIMx_CNT \leq TIMx_CCRx (depending on the direction of the counter). The tim_ocref_clr can be cleared by an external event through the tim_etr_in or the tim_ocref_clr signals. In this case the tim_ocref_clr signal is asserted only:

- After a compare match event
- When the output compare mode (OCxM bits in TIMx_CCMRx register) switches from the “frozen” configuration (no comparison, OCxM=’000) to one of the PWM modes (OCxM=’110 or ’111). This forces the PWM by software while the timer is running.

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.
PWM edge-aligned mode

Upcounting configuration

Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to Upcounting mode on page 2236.

In the following example, we consider PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then tim_ocxref is held at ‘1’. If the compare value is 0 then tim_ocxref is held at ‘0’. Figure 623 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

Downcounting configuration

Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to Downcounting mode on page 2240.

In PWM mode 1, the reference signal tim_ocxref is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then tim_ocxref is held at 100%. PWM is not possible in this mode.

PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00’ (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit
(DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to *Center-aligned mode (up/down counting)* on page 2243.

*Figure 624* shows some center-aligned PWM waveforms in an example where:
- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

**Figure 624. Center-aligned PWM waveforms (ARR=8)**

Hints on using center-aligned mode:
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit.
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

**Dithering mode**

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The **Figure 625** below presents the dithering principle applied to 4 consecutive PWM cycles.

**Figure 625. Dithering principle**

![Dithering principle](MS0456_rev5.png)

When the dithering mode is enabled, the register coding is changed as following (see **Figure 626** for example):

- The 4 LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted by 4 places and are coding for the base value. In 16-bit mode, the 16-bit format is maintained.
Note: The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset.
2. The DITHEN bit must be reset.
3. The CCIF flags must be cleared.
4. The CEN bit can be set (eventually with ARPE = 1).

Figure 626. Data format and register coding in dithering mode

The minimum frequency is given by the following formula:

\[
\text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{\text{Max Resolution}}
\]

Dithering mode disabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65536} \)

Dithering mode (16-bit timer): \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}} \)

Dithering mode (32-bit timer): \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{268435454 + \frac{15}{16}} \)

Note: For 16-bit timers, the maximum TIMx.ARR and TIMx.CCRy values are limited to 0xFFFEEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).
For 32-bit timers, the maximum TIMx.ARR and TIMx.CCRy values are limited to...
0xFFFFFFFF in dithering mode (corresponds to 264435454 for the integer part and 15 for the dithered part).

As shown on the Figure 627 and Figure 628 below, the dithering mode is used to increase the PWM resolution.

Figure 627. PWM resolution vs frequency (16-bit mode)

![Figure 627](image1)

Figure 628. PWM resolution vs frequency (32-bit mode)

![Figure 628](image2)

The duty cycle and/or period changes are spread over 16 consecutive periods, as described in the Figure 629 below.
The auto-reload and compare values increments are spread following specific patterns described in the Table 561 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.
The dithering mode is also available in center-aligned PWM mode (CMS bits in TIMx_CR1 register are not equal to '00'). In this case, the dithering pattern is applied over 8 consecutive PWM periods, considering the up and down counting phases as shown in the Figure 630 below.

Table 562 below shows how the dithering pattern is added in center-aligned PWM mode.

**Figure 630. Dithering effect on duty cycle in center-aligned PWM mode**

Table 562 below shows how the dithering pattern is added in center-aligned PWM mode.

[MSv50904V1]
55.4.12 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx registers. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- `tim_oc1refc` (or `tim_oc2refc`) is controlled by TIMx_CCR1 and TIMx_CCR2
- `tim_oc3refc` (or `tim_oc4refc`) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channels (one `tim_ocx` output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its secondary channel can also be used. For instance, if an `tim_oc1refc` signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the `tim_oc2ref` signal on channel 2, or an `tim_oc2refc` signal resulting from asymmetric PWM mode 2.
Figure 631 shows an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 2).

Figure 631. Generation of 2 phase-shifted PWM signals with 50% duty cycle

| Counter register | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 1 |
| tim_oc1refc      |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| CCR1=0           |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| CCR2=8           |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| tim_oc3refc      |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| CCR3=3           |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| CCR4=5           |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

55.4.13 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

– tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
– tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its secondary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 632 shows an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1
55.4.14 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocxref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The tim_ocxref_clr_int source depends on the OCREF clear selection feature implementation, refer to Section 55.3: TIM2/TIM3/TIM4/TIM5 implementation.

If the OCREF clear selection feature is implemented, the tim_ocxref_clr_int can be selected between the tim_ocxref_clr input and the tim_etrf input (tim_etrf_in after the filter) by configuring the OCCS bit in the TIMx_SMCR register. The tim_ocxref_clr input can be selected among several tim_ocxref_clr[7:0] inputs, using the OCRSEL[2:0] bitfield in the TIMx_AF2 register, as shown in Figure 633 below.
If the OCREF clear selection feature is not implemented, the tim_ocref_clr_int input is directly connected to the tim_etrf input.

For example, the tim_ocref_clr_int signal can be connected to the output of a comparator to be used for current handling. In this case, tim_etrf_in must be configured as follows:

1. The external trigger prescaler must be kept off: bits ETPS[1:0] in the TIMx_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application’s needs.

*Figure 634* shows the behavior of the tim_ocxref signal when the tim_etrf input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.
55.4.15 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- CNT<CCRx ≤ ARR (in particular, 0<CCRx),

For example one may want to generate a positive pulse on tim_oc1 with a length of tPULSE and after a delay of tDELAY as soon as a positive edge is detected on the tim_ti2 input pin.

Let’s use tim_ti2fp2 as trigger 1:

1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map tim_ti2fp2 on tim_ti2 by writing CC2S=01 in the TIMx_CCMR1 register.
3. tim_ti2fp2 must detect a rising edge, write CC2P=0 and CC2NP='0' in the TIMx_CCER register.
4. Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS=00110 in the TIMx_SMCR register.
5. tim_ti2fp2 is used to start the counter by writing SMS to ‘110 in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The \( t_{\text{DELAY}} \) is defined by the value written in the TIMx_CCR1 register.
- The \( t_{\text{PULSE}} \) is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let’s say one want to build a waveform with a transition from ‘0 to ‘1 when a compare match occurs and a transition from ‘1 to ‘0 when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=1 in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to ‘0 in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register must be low. Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to ‘0’, so the Repetitive Mode is selected.

**Particular case: tim_ocx fast enable:**

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay \( t_{\text{DELAY \ min}} \) we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 55.4.16 Retriggerable one-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one-pulse mode described in Section 55.4.15:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode CCRx must be above or equal to ARR.

*Note:* In Retriggerable one-pulse mode, the CCxIF flag is not significant.

The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

*This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.*
55.4.17 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulse width generated when the counter value equals a given compare value, for debugging or synchronization purposes.

This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on the Figure 637 below.

The Figure 638 below shows how the pulse is generated for edge-aligned and encoder operating modes.
This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bit fields in TIMx_CCMR2 register.

The pulse width is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

\[ t_{PW} = PW[7:0] \times t_{PWG} \]

where \( t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim\_ker\_ck} \).

This gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

**Note:** If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the 1st arriving trigger is extended (because of the re-trigger), while the pulse width of the last arriving trigger is correct (as shown on the Figure 639 below).
55.4.18 Encoder interface mode

Quadrature encoder

To select Encoder Interface mode write SMS=’0001 in the TIMx_SMCR register if the counter is counting on tim_ti1 edges only, SMS=’0010 if it is counting on tim_ti2 edges only and SMS=’0011 if it is counting on both tim_ti1 and tim_ti2 edges.

Select the tim_ti1 and tim_ti2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. CC1NP and CC2NP must be kept cleared. When needed, the input filter can be programmed as well.

The two inputs tim_ti1 and tim_ti2 are used to interface to an incremental encoder. Refer to Table 563. The counter is clocked by each valid transition on tim_ti1fp1 or tim_ti2fp2 (tim_ti1 and tim_ti2 after input filter and polarity selection, tim_ti1fp1=tim_ti1 if not filtered and not inverted, tim_ti2fp2=tim_ti2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_ti1 or tim_ti2), whatever the counter is counting on tim_ti1 only, tim_ti2 only or both tim_ti1 and tim_ti2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the-quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_ti1 and tim_ti2 do not switch at the same time.
A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to the external trigger input and trigger a counter reset.

*Figure 640* gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S = 01 (TIMx_CCMR1 register, tim_ti1fp1 mapped on tim_ti1)
- CC2S = 01 (TIMx_CCMR2 register, tim_ti2fp2 mapped on tim_ti2)
- CC1P and CC1NP = ‘0’ (TIMx_CCER register, tim_ti1fp1 noninverted, tim_ti1fp1=tim_ti1)
- CC2P and CC2NP = ‘0’ (TIMx_CCER register, tim_ti2fp2 noninverted, tim_ti2fp2=tim_ti2)
- SMS = 0011 (TIMx_SMCR register, both inputs are active on both rising and falling edges)
- CEN = 1 (TIMx_CR1 register, Counter is enabled)
Figure 640. Example of counter operation in encoder interface mode

Figure 641 gives an example of counter behavior when tim_ti1fp1 polarity is inverted (same configuration as above except CC1P=1).

Figure 641. Example of encoder interface mode with tim_ti1fp1 polarity inverted
The figure below shows the timer counter value during a speed reversal, for various counting modes.

**Figure 642. Quadrature encoder counting modes**

The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register’s bit 31 (TIMx_CNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

**Clock plus direction encoder mode**

In addition to the quadrature encoder mode, the timer offers support other types of encoders.

In the “clock plus direction” mode shown on Figure 643, the clock is provided on a single line, on tim_t1, while the direction is forced using the tim_t2 input.
This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- 1010: x2 mode, the counter is updated on both rising and falling edges of the clock
- 1011: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity

The polarity of the direction signal on tim_ti1 is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when tim_ti1 is high and down-counting when tim_ti1 is low) and CC1P = 1 corresponds to negative polarity (up-counting when tim_ti1 is low).

**Figure 643. Direction plus clock encoder mode**

**Directional Clock encoder mode**

In the “directional clock” mode on Figure 644, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- 1100: x2 mode, the counter is updated on both rising and falling edges of any of the two clock line. The CC1P and CC2P bits are coding for the clock idle state. CCxP = 0 corresponds to high-level idle state (refer to Figure 644 below) and CCxP = 1 corresponds to low-level idle state (refer to Figure 645 below).
- 1101: x1 mode, the counter is updated on a single clock edge, as per CC1P and CC2P bit value. CCxP = 0 corresponds to falling edge sensitivity and high-level idle state (refer to Figure 644 below), CCxP = 1 corresponds to rising edge sensitivity and low-level idle state (refer to Figure 645 below).
The Table 564 here-below details how the directional clock mode operates, for any input transition.
The counter can be reset by an Index signal coming from the encoder, indicating an absolute reference position. The Index signal must be connected to the tim_etr_in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMx_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0000, 0001, 0010, 011, 1001, 1010, 1011, 1100, 1101, 1111.

Commercially available encoders are proposed with several options for index pulse conditioning, as per the Figure 646 below:

- gated with A and B: the pulse width is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulse width is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulse width is up to one channel period, without any alignment to the edges

### Index Input

The counter can be reset by an Index signal coming from the encoder, indicating an absolute reference position. The Index signal must be connected to the tim_etr_in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMx_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0000, 0001, 0010, 011, 1001, 1010, 1011, 1100, 1101, 1111.

Commercially available encoders are proposed with several options for index pulse conditioning, as per the Figure 646 below:

- gated with A and B: the pulse width is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulse width is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulse width is up to one channel period, without any alignment to the edges
The circuitry tolerates jitter on index signal, whatever the gating mode, as show on Figure 647 below.

In ungated mode, the signal must be strictly below 2 encoder periods. If the pulse width is greater or equal to 2 encoder period, the counter is reset multiple times.

The timer supports the 3 gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (i.e., channel A and channel B state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIMx_ECR register.

The Index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:

- The counter is reset during up-counting (DIR bit = 0)
- The counter is set to TIMx_ARR when down counting

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. The Figure 648 below shows at which position is the index generated, for a simplistic example (an encoder providing 4 edges per mechanical rotation).
The Figure 648 below presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is ‘11’ (ChA=1, ChB=1), when up-counting (DIR bit = 0).
- Counter set to TIMx_ARR when exiting the ‘11’ state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.

The Figure 649 below presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.
The Figure 651 below shows how the ‘gated on A & B’ mode is handled, for various pulse alignment scenario. The arrows are indicating on which transition is the index event generated.

The Figure 652 and Figure 653 detail the case where the subsequent index pulse may be narrower than one quarter of the encoder clock period.
Figure 652. Encoder mode behavior in case of narrow index pulse (IPOS[1:0] = 11)
The Figure 654 below shows how the index is managed in x1 and x2 modes.
### Directional index sensitivity

The IDIR[1:0] bitfield in the TIMx_ECR register allows the index to be active only in a selected counting direction.

The *Figure 655* below shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

#### Figure 654. Index behavior in x1 and x2 mode (IPOS[1:0] = 01)

Special first index event management

The FIDX bit in the TIMx_ECR register allows the Index to be taken only once, as shown on the Figure 656 below. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be re-armed by writing the FIDX bit to 0 and setting it again to 1.

Figure 656. Counter reset as function of FIDX bit setting

Index blanking

The Index event can be blanked using the tim_ti3 or tim_ti4 inputs. During the blanking window, the index events are no longer resetting the counter, as shown on the Figure 657 below.

This mode is enabled using the IBLK[1:0] bitfield in the TIMx_ECR register, as following:
- IBLK[1:0] = 00: Index signal always active
- IBLK[1:0] = 01: Index signal blanking on tim_ti3 input
- IBLK[1:0] = 10: Index signal blanking on tim_ti4 input

Figure 657. Index blanking
Index management in non-quadrature mode

The Figure 658 and Figure 659 below detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[3:0] bitfield is equal to 1010, 1011, 1100, 1101.

For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:
- IPOS[0] = 0: Index is detected on clock low level
- IPOS[0] = 1: Index is detected on clock high level

The IPOS[1] bit is not-significant.

**Figure 658. Index behavior in clock + direction mode, IPOS[0] = 1**

![Index behavior in clock + direction mode, IPOS[0] = 1](image1)

**Figure 659. Index behavior in directional clock mode, IPOS[0] = 1**

![Index behavior in directional clock mode, IPOS[0] = 1](image2)

Encoder error management

For encoder configurations where 2 quadrature signals are available, it is possible to detect transition errors. The reading on the 2 inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on the Figure 660. below. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIMx_SR status.
register. A transition error interrupt is generated if the TERRIE bit is set in the TIMx_DIER register.

Figure 660. State diagram for quadrature encoded signals

For encoder having an Index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The Index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIMx_ARR to 0 or decremented from 0 to TIMxARR value without any index event, this is reported as an Index position error.

The overflow threshold is programmed using the TIMx.ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIMx_ARR = 3999 + 1 = 4000.
The error assertion is delayed to the transition 0 to 1 when in up-counting. This is cope with narrow index pulses in gated A and B mode, as shown on Figure 661 below.

**Figure 661. Up-counting encoder error detection**

<table>
<thead>
<tr>
<th>Channel A</th>
<th>Channel B</th>

<th>Counter</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>5 6 7 0 1 2 3</td>
</tr>
</tbody>
</table>
In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on Figure 662 below, to avoid any false error detection in case the encoder dithers between TIMx_ARR and 0 immediately after the index detection.

**Figure 662. Down-counting encode error detection**

An index error sets the IERRF interrupt flag in the TIMx_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIMx_DIER register.

### Functional encoder Interrupts

The following interrupts are also available in encoder mode:

- **Direction change**: any change of the counting direction in encoder mode causes the DIR bit in the TIMx_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIMx_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIMx_DIER register.

- **Index event**: the Index event sets the IDXF interrupt flag in the TIMx_SR status register. An Index interrupt is generated if the IDXIE bit is set in the TIMx_DIER register.
Slave mode selection preload for run-time encoder mode update

It may be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the Update interrupt rate, by switching from x4 to x2 to x1 mode, as show on the Figure 663 below.

For this purpose, the SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value can be selected with the SMSPS bit in the TIMx_SMCR register.

- SMPS = 0: the transfer is triggered by the update event (UEV) occurring when the counter overflows when upcounting, and underflows when downcounting.
- SMPS = 1: the transfer is triggered by the Index event.

**Figure 663. Encoder mode change with preload transferred on update (SMPS = 0)**

Encoder clock output

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIMx_CR2 register. It is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

55.4.19 Direction bit output

It is possible to output a direction signal out of the timer, on the tim_oc3 and tim_oc4 output signals (copy of the DIR bit in the TIMx_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bit field to 1011 in the TIMx_CCMR2 register.
This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

55.4.20 UIF bit remapping

The IUFRERMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into bit 31 of the timer counter register’s bit 31 (TIMx_CNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFRERMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

55.4.21 Timer input XOR function

The TI1S bit in the TIM1xx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3. The XOR output can be used with all the timer input functions such as trigger or input capture.

An example of this feature used to interface Hall sensors is given in Section 54.3.29: Interfacing with Hall sensors on page 2165.

55.4.22 Timers and external trigger synchronization

The TIMx Timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

1. Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the
trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

**Figure 664. Control circuit in reset mode**

![Control circuit in reset mode](image)

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_ti1 input is low:

1. Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.
Note: The configuration “CCxP=CCxNP=1” (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

**Slave mode: Trigger mode**

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

1. Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. CC2S bits are selecting the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.
Slave mode selection preload for run-time encoder mode update

The SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value is the update event (UEV) occurring when the counter overflows.

Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

Slave mode – combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode – external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_ti1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on tim_etr_in and ECE=1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

A rising edge on tim_ti1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.
55.4.23 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.

*Figure 668 and Figure 669* show examples of master/slave timer connections.
Note: The timers with one channel only (see Figure 669) do not feature a master mode. However, the tim_oc1 output signal can serve as trigger for slave timer (see TIMx internal trigger connection table in Section 55.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals). The tim_oc1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger. For instance, if the destination timer tim_ker_ck clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

**Using one timer as prescaler for another timer**

For example, TIM_mstr can be configured to act as a prescaler for TIM_slv. Refer to Figure 668. To do this:

1. Configure TIM_mstr in master mode so that it outputs a periodic trigger signal on each update event UEV. If MMS=010 is written in the TIM_mstr_CR2 register, a rising edge is output on tim_trgo each time an update event is generated.

2. To connect the tim_trgo output of TIM_mstr to TIM_slv, TIM_slv must be configured in slave mode using ITR2 as internal trigger. This is selected through the TS bits in the TIM_slv_SMCR register (writing TS=00010).

3. Then the slave mode controller must be put in external clock mode 1 (write SMS=111 in the TIM_slv_SMCR register). This causes TIM_slv to be clocked by the rising edge of the periodic TIM_mstr trigger signal (which correspond to the TIM_mstr counter overflow).

4. Finally both timers must be enabled by setting their respective CEN bits (TIMx_CR1 register).

*Note:* If tim_ocx is selected on TIM_mstr as the trigger output (MMS=1xx), its rising edge is used to clock the counter of TIM_slv.

**Using one timer to enable another timer**

In this example, we control the enable of TIM_slv with the output compare 1 of TIM_mstr. Refer to Figure 668 for connections. TIM_slv counts on the divided internal clock only when tim_oc1ref of TIM_mstr is high. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck ($f_{tim_cnt_ck} = f_{tim_ker_ck}/3$).
1. Configure TIM_mstr master mode to send its Output Compare 1 Reference (tim_oc1ref) signal as trigger output (MMS=100 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr tim_oc1ref waveform (TIM_mstr_CCMR1 register).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in gated mode (SMS=101 in TIM_slv_SMCR register).
5. Enable TIM_slv by writing '1 in the CEN bit (TIM_slv_CR1 register).
6. Start TIM_mstr by writing '1 in the CEN bit (TIM_mstr_CR1 register).

**Note:** The slave timer counter clock is not synchronized with the master timer counter clock, this mode only affects the TIM_slv counter enable signal.

In the example in Figure 670, the TIM_slv counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting TIM_mstr. Then any value can be written in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx_EGR registers.

In the next example (refer to Figure 671), we synchronize TIM_mstr and TIM_slv. TIM_mstr is the master and starts from 0. TIM_slv is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. TIM_slv stops when TIM_mstr is disabled by writing '0 to the CEN bit in the TIM_mstr_CR1 register.
1. Configure TIM_mstr master mode to send its Output Compare 1 Reference (tim_oc1ref) signal as trigger output (MMS=100 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr tim_oc1ref waveform (TIM_mstr_CCMR1 register).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in gated mode (SMS=101 in TIM_slv_SMCR register).
5. Reset TIM_mstr by writing ‘1’ in UG bit (TIM_mstr_EGR register).
6. Reset TIM_slv by writing ‘1’ in UG bit (TIM_slv_EGR register).
7. Initialize TIM_slv to 0xE7 by writing ‘0xE7’ in the TIM_slv counter (TIM_slv_CNT).
8. Enable TIM_slv by writing ‘1’ in the CEN bit (TIM_slv_CR1 register).
9. Start TIM_mstr by writing ‘1’ in the CEN bit (TIM_mstr_CR1 register).
10. Stop TIM_mstr by writing ‘0’ in the CEN bit (TIM_mstr_CR1 register).

**Figure 671. Gating TIM_slv with Enable of TIM_mstr**

![Diagram showing gating of TIM_slv with Enable of TIM_mstr](MSv62377V1)

### Using one timer to start another timer

In this example, we set the enable of TIM_slv with the update event of TIM_mstr. Refer to Figure 668 for connections. TIM_slv starts counting from its current value (which can be non-zero) on the divided internal clock as soon as the update event is generated by TIM_mstr. When TIM_slv receives the trigger signal its CEN bit is automatically set and the counter counts until we write ‘0’ to the CEN bit in the TIM_slv_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck \( f_{tim_cnt_ck} = \frac{f_{tim_ker_ck}}{3} \).

1. Configure TIM_mstr master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr period (TIM_mstr_ARR registers).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in trigger mode (SMS=110 in TIM_slv_SMCR register).
5. Start TIM_mstr by writing ‘1’ in the CEN bit (TIM_mstr_CR1 register).
As in the previous example, both counters can be initialized before starting counting. *Figure 673* shows the behavior with the same configuration as in *Figure 672* but in trigger mode instead of gated mode (SMS=110 in the TIM_slv_SMCR register).

**Starting 2 timers synchronously in response to an external trigger**

In this example, we set the enable of TIM_mstr when its tim_ti1 input rises, and the enable of TIM_slv with the enable of TIM_mstr. Refer to *Figure 668* for connections. To ensure the counters are aligned, TIM_mstr must be configured in Master/Slave mode (slave with respect to tim_ti1, master with respect to TIM_slv):
1. Configure TIM_mstr master mode to send its Enable as trigger output (MMS=001 in the TIM_mstr_CR2 register).
2. Configure TIM_mstr slave mode to get the input trigger from tim_ti1 (TS=00100 in the TIM_mstr_SMCR register).
3. Configure TIM_mstr in trigger mode (SMS=110 in the TIM_mstr_SMCR register).
4. Configure the TIM_mstr in Master/Slave mode by writing MSM=1 (TIM_mstr_SMCR register).
5. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00000 in the TIM_slv_SMCR register).
6. Configure TIM_slv in trigger mode (SMS=110 in the TIM_slv_SMCR register).

When a rising edge occurs on tim_ti1 (TIM_mstr), both counters start counting synchronously on the internal clock and both TIF flags are set.

**Note:** In this example both timers are initialized before starting (by setting their respective UG bits). Both counters starts from 0, but an offset can easily be inserted between them by writing any of the counter registers (TIMx_CNT). One can see that the master/slave mode insert a delay between CNT_EN and CK_PSC on TIM_mstr.

**Figure 674. Triggering TIM_mstr and TIM_slv with TIM_mstr tim_ti1 input**

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

### 55.4.24 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

**Note:** The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
55.4.25 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:

00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

The DBSS[3:0] bits in the TIMx_DCR register defines the interrupt source that triggers the DMA burst transfers (see Section 55.5.23: TIMx DMA control register (TIMx_DCR)(x = 2 to 5) for details).

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   - DBL = 3 transfers, DBA = 0xE and DBSS = 1.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register has to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.
Note: A null value can be written to the reserved registers.

55.4.26 TIM2/TIM3/TIM4/TIM5 DMA requests

The TIM2/TIM3/TIM4/TIM5 can generate a DMA requests, as shown in Table 565.

Table 565. DMA request

<table>
<thead>

</tbody>
</table>

Note: Some timer's DMA requests may not be connected to the DMA controller. Refer to the DMA section(s) for more details.

55.4.27 Debug mode

When the microcontroller enters debug mode (Cortex®-M33 core halted), the TIMx counter can either continues to work normally or stops.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to section Debug support (DBG).

55.4.28 TIM2/TIM3/TIM4/TIM5 low-power modes

```

Bits 15:13  Reserved, must be kept at reset value.

Bit 12  **DITHEN**: Dithering Enable
   0: Dithering disabled
   1: Dithering enabled

   **Note**: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11  **UIFREMAP**: UIF status bit remapping
   0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
   1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10  Reserved, must be kept at reset value.

Bits 9:8  **CKD[1:0]**: Clock division
   This bit-field indicates the division ratio between the timer clock (tim_ker_ck) frequency and
   sampling clock used by the digital filters (tim_etr_in, tim_tix),
   00: \( t_{DTS} = t_{\text{tim_ker_ck}} \)
   01: \( t_{DTS} = 2 \times t_{\text{tim_ker_ck}} \)
   10: \( t_{DTS} = 4 \times t_{\text{tim_ker_ck}} \)
   11: Reserved

Bit 7  **ARPE**: Auto-reload preload enable
   0: TIMx.ARR register is not buffered
   1: TIMx.ARR register is buffered

Bits 6:5  **CMS[1:0]**: Center-aligned mode selection
   00: Edge-aligned mode. The counter counts up or down depending on the direction bit
   (DIR).
   01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare
   interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set
   only when the counter is counting down.
   10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare
   interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set
   only when the counter is counting up.
   11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare
   interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set
   both when the counter is counting up or down.

   **Note**: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as
   the counter is enabled (CEN=1)
55.5.2 TIMx control register 2 (TIMx_CR2)(x = 2 to 5)

Address offset: 0x004
Reset value: 0x0000 0000
Bits 31:26  Reserved, must be kept at reset value.

Bits 24:8  Reserved, must be kept at reset value.

Bit 7  **TI1S**: tim_ti1 selection
0: The `tim_ti1_in[15:0]` multiplexer output is to `tim_ti1` input
1: The `tim_ti1_in[15:0]`, `tim_ti2_in[15:0]` and `tim_ti3_in[15:0]` multiplexers outputs are XORed and connected to the `tim_ti1` input. See also Section 54.3.29: Interfacing with Hall sensors on page 2165.

Bits 25, 6, 5, 4  **MMS[3:0]**: Master mode selection
These bits are used to select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

- **0000**: `Reset` - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.
- **0001**: `Enable` - the Counter enable signal, CNT_EN, is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).
- **0010**: `Update` - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.
- **0011**: `Compare Pulse` - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (tim_trgo).
- **0100**: `Compare` - `tim_oc1refc` signal is used as trigger output (tim_trgo)
- **0101**: `Compare` - `tim_oc2refc` signal is used as trigger output (tim_trgo)
- **0110**: `Compare` - `tim_oc3refc` signal is used as trigger output (tim_trgo)
- **0111**: `Compare` - `tim_oc4refc` signal is used as trigger output (tim_trgo)
- **1000**: `Encoder Clock output` - The encoder clock signal is used as trigger output (tim_trgo). This code is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

Others: Reserved

Note: *The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 3  **CCDS**: Capture/compare DMA selection
0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bits 2:0  Reserved, must be kept at reset value.
### 55.5.3 TIMx slave mode control register (TIMx_SMCR)(x = 2 to 5)

**Address offset:** 0x008  
**Reset value:** 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:26</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bit 25 | **SMSPS**: SMS preload source  
0: The transfer is triggered by the Timer’s Update event  
1: The transfer is triggered by the Index event |
| Bit 24 | **SMSPE**: SMS preload enable  
0: SMS[3:0] bitfield is not preloaded  
1: SMS[3:0] preload is enabled |
| Bit 23:22 | Reserved, must be kept at reset value. |
| Bit 19:17 | Reserved, must be kept at reset value. |
| Bit 15 | **ETP**: External trigger polarity  
This bit selects whether tim_etr_in or tim_etr_in is used for trigger operations  
0: tim_etr_in is non-inverted, active at high level or rising edge  
1: tim_etr_in is inverted, active at low level or falling edge |
| Bit 14 | **ECE**: External clock enable  
This bit enables External clock mode 2.  
0: External clock mode 2 disabled  
1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_etrf signal.  
**Note:** Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_etrf (SMS=111 and TS=00111).  
It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etrf in this case (TS bits must not be 00111).  
If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etrf. |
| Bit 13:12 | **ETPS[1:0]**: External trigger prescaler  
External trigger signal tim_etrp frequency must be at most 1/4 of tim_ker_ck frequency. A prescaler can be enabled to reduce tim_etrp frequency. It is useful when inputting fast external clocks on tim_etr_in.  
00: Prescaler OFF  
01: tim_etrp frequency divided by 2  
10: tim_etrp frequency divided by 4  
11: tim_etrp frequency divided by 8 |
Bits 11:8  **ETF[3:0]:** External trigger filter

This bit-field then defines the frequency used to sample tim_etrp signal and the length of the
digital filter applied to tim_etrp. The digital filter is made of an event counter in which N
consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at fDTS
- 0001: fSAMPLING=fTim_ker_ck, N=2
- 0010: fSAMPLING=fTim_ker_ck, N=4
- 0011: fSAMPLING=fTim_ker_ck, N=8
- 0100: fSAMPLING=fDTS/2, N=6
- 0101: fSAMPLING=fDTS/2, N=8
- 0110: fSAMPLING=fDTS/4, N=6
- 0111: fSAMPLING=fDTS/4, N=8
- 1000: fSAMPLING=fDTS/8, N=6
- 1001: fSAMPLING=fDTS/8, N=8
- 1010: fSAMPLING=fDTS/16, N=5
- 1011: fSAMPLING=fDTS/16, N=6
- 1100: fSAMPLING=fDTS/16, N=8
- 1101: fSAMPLING=fDTS/32, N=5
- 1110: fSAMPLING=fDTS/32, N=6
- 1111: fSAMPLING=fDTS/32, N=8

Bit 7  **MSM:** Master/Slave mode

- 0: No action
- 1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect
  synchronization between the current timer and its slaves (through tim_trgo). It is useful if we
  want to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4  **TS[4:0]**: Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

- 00000: Internal trigger 0 (tim_itr0)
- 00001: Internal trigger 1 (tim_itr1)
- 00010: Internal trigger 2 (tim_itr2)
- 00011: Internal trigger 3 (tim_itr3)
- 00100: tim_ti1 edge detector (tim_ti1f_ed)
- 00101: Filtered timer input 1 (tim_ti1fp1)
- 00110: Filtered timer input 2 (tim_ti2fp2)
- 00111: External trigger input (tim_etr)
- 01000: Internal trigger 4 (tim_itr4)
- 01001: Internal trigger 5 (tim_itr5)
- 01010: Internal trigger 6 (tim_itr6)
- 01110: Internal trigger 10 (tim_itr10)
- 01111: Internal trigger 11 (tim_itr11)
- 10000: Internal trigger 12 (tim_itr12)
- 10001: Internal trigger 13 (tim_itr13)
- 10010: Internal trigger 14 (tim_itr14)
- 10011: Internal trigger 15 (tim_itr15)
- Others: Reserved

See [Section 55.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals](#) for product specific implementation details.

**Note:** These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3  **OCCS**: OCREF clear selection

This bit is used to select the OCREF clear source

- 0: tim_ocref_clr_int is connected to the tim_ocref_clr input
- 1: tim_ocref_clr_int is connected to tim_etr

**Note:** If the OCREF clear selection feature is not supported, this bit is reserved and forced by hardware to 0. [Section 55.3: TIM2/TIM3/TIM4/TIM5 implementation](#).
Bits 16, 2, 1, 0  **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = `1 then the prescaler is clocked directly by the internal clock.

0001: Encoder mode 1 - Counter counts up/down on tim_ti1fp1 edge depending on tim_ti2fp2 level.

0010: Encoder mode 2 - Counter counts up/down on tim_ti2fp2 edge depending on tim_ti1fp1 level.

0011: Encoder mode 3 - Counter counts up/down on both tim_ti1fp1 and tim_ti2fp2 edges depending on the level of the other input.

0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

1010: Encoder mode: Clock plus direction, x2 mode.

1011: Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by CC2P.

1100: Encoder mode: Directional Clock, x2 mode.

1101: Encoder mode: Directional Clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity is set by CC1P and CC2P.

1110: Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge sensitivity is set by CC1P.

1111: Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge sensitivity is set by CC2P.

**Note:** The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS=00100). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on tim_ti1f, whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave peripherals (timer, ADC, …) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

55.5.5  TIMx status register (TIMx_SR)(x = 2 to 5)

Address offset: 0x010
Reset value: 0x0000 0000

Bit 7  Reserved, must be kept at reset value.

Bit 6  **TIE**: Trigger interrupt enable
       0: Trigger interrupt disabled.
       1: Trigger interrupt enabled.

Bit 5  Reserved, must be kept at reset value.

Bit 4  **CC4IE**: Capture/Compare 4 interrupt enable
       0: CC4 interrupt disabled.
       1: CC4 interrupt enabled.

Bit 3  **CC3IE**: Capture/Compare 3 interrupt enable
       0: CC3 interrupt disabled.
       1: CC3 interrupt enabled.

Bit 2  **CC2IE**: Capture/Compare 2 interrupt enable
       0: CC2 interrupt disabled.
       1: CC2 interrupt enabled.

Bit 1  **CC1IE**: Capture/Compare 1 interrupt enable
       0: CC1 interrupt disabled.
       1: CC1 interrupt enabled.

Bit 0  **UIE**: Update interrupt enable
       0: Update interrupt disabled.
       1: Update interrupt enabled.

Bits 31:24  Reserved, must be kept at reset value.

Bit 23  **TERRF**: Transition error interrupt flag

This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to ‘0’.

0: No encoder transition error has been detected.
1: An encoder transition error has been detected

Bit 22  **IERRF**: Index error interrupt flag

This flag is set by hardware when an index error is detected. It is cleared by software by writing it to ‘0’.

0: No index error has been detected.
1: An index error has been detected
Bit 21 **DIRF**: Direction change interrupt flag
This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIMx_CR is changing). It is cleared by software by writing it to ‘0’.
0: No direction change
1: Direction change

Bit 20 **IDXF**: Index interrupt flag
This flag is set by hardware when an index event is detected. It is cleared by software by writing it to ‘0’.
0: No index event occurred.
1: An index event has occurred

Bits 19:13 Reserved, must be kept at reset value.

Bit 12 **CC4OF**: Capture/Compare 4 overcapture flag
Refer to CC1OF description

Bit 11 **CC3OF**: Capture/Compare 3 overcapture flag
Refer to CC1OF description

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag
Refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred.
1: Trigger interrupt pending.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag
Refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag
Refer to CC1IF description
55.5.6 TIMx event generation register (TIMx_EGR)(x = 2 to 5)

55.5.7 **TIMx capture/compare mode register 1 (TIMx_CCMR1)** (x = 2 to 5)

Address offset: 0x018  
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

**Input capture mode**

Bits 31:16: Reserved, must be kept at reset value.

Bits 15:12: **IC2F[3:0]**: Input capture 2 filter

Bits 11:10: **IC2PSC[1:0]**: Input capture 2 prescaler
Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC2 channel is configured as output.
- 01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2.
- 10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1.
- 11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register).

**Note:** *CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).*

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:
- 0000: No filter, sampling is done at f\_DTS
- 0001: f\_SAMPLING=\*f\_tim\_ker\_ck, N=2
- 0010: f\_SAMPLING=\*f\_tim\_ker\_ck, N=4
- 0011: f\_SAMPLING=\*f\_tim\_ker\_ck, N=8
- 0100: f\_SAMPLING=\*f\_DTS/2, N=6
- 0101: f\_SAMPLING=\*f\_DTS/2, N=8
- 0110: f\_SAMPLING=\*f\_DTS/4, N=6
- 0111: f\_SAMPLING=\*f\_DTS/4, N=8
- 1000: f\_SAMPLING=\*f\_DTS/8, N=6
- 1001: f\_SAMPLING=\*f\_DTS/8, N=8
- 1010: f\_SAMPLING=\*f\_DTS/16, N=5
- 1011: f\_SAMPLING=\*f\_DTS/16, N=6
- 1100: f\_SAMPLING=\*f\_DTS/16, N=8
- 1101: f\_SAMPLING=\*f\_DTS/32, N=5
- 1110: f\_SAMPLING=\*f\_DTS/32, N=6
- 1111: f\_SAMPLING=\*f\_DTS/32, N=8

**Note:** *CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E=0 (TIMx_CCER register).
- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
- 10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
- 11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)
TIMx capture/compare mode register 1 [alternate]  
(TIMx_CCMR1)(x = 2 to 5)

Address offset: 0x018
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

### Output compare mode

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC2CE**: Output compare 2 clear enable

Bits 24, 14:12 **OC2M[3:0]**: Output compare 2 mode

Refer to **OC1M** description on bits 6:4

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

Note: **CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).**

Bit 7 **OC1CE**: Output compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr_int input
1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int input
Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 is derived. tim_oc1ref is active high whereas tim_oc1 active level depends on CC1P bit.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - tim_oc1ref toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - tim_oc1ref is forced low.

0101: Force active level - tim_oc1ref is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (tim_oc1ref=0) as long as TIMx_CNT>TIMx_CCR1 else active (tim_oc1ref=1).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved.

1011: Reserved.

1100: Combined PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc is the logical OR between tim_oc1ref and tim_oc2ref.

1101: Combined PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc is the logical AND between tim_oc1ref and tim_oc2ref.

1110: Asymmetric PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

1111: Asymmetric PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

**Note:** In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from "frozen" mode to "PWM" mode and when the output compare mode switches from "force active/inactive" mode to "PWM" mode.
Bit 3 **OC1PE**: Output compare 1 preload enable
0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

Bit 2 **OC1FE**: Output compare 1 fast enable
This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.
0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC1 channel is configured as output.
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1.
10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2.
11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).

### 55.5.9 **TIMx capture/compare mode register 2 (TIMx_CCMR2)**(x = 2 to 5)

Address offset: 0x01C
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

### Output compare mode

- Bits 31:25 Reserved, must be kept at reset value.
- Bits 23:17 Reserved, must be kept at reset value.
- Bit 15 **OC4CE**: Output compare 4 clear enable
- Bits 24, 14:12 **OC4M[3:0]**: Output compare 4 mode
  Refer to OC1M description (bits 6:4 in TIMx_CCMR1 register)
- Bit 11 **OC4PE**: Output compare 4 preload enable
- Bit 10 **OC4FE**: Output compare 4 fast enable
55.5.11 TIMx capture/compare enable register (TIMx_CCER)(x = 2 to 5)

Address offset: 0x020
Reset value: 0x0000

| Bit 15 | CC4NP: Capture/Compare 4 output Polarity. Refer to CC1NP description |
| Bit 14 | Reserved, must be kept at reset value. |
| Bit 13 | CC4P: Capture/Compare 4 output Polarity. Refer to CC1P description |
| Bit 12 | CC4E: Capture/Compare 4 output enable. Refer to CC1E description |
| Bit 11 | CC3NP: Capture/Compare 3 output Polarity. Refer to CC1NP description |
| Bit 10 | Reserved, must be kept at reset value. |
| Bit 9 | CC3P: Capture/Compare 3 output Polarity. Refer to CC1P description |
| Bit 8 | CC3E: Capture/Compare 3 output enable. Refer to CC1E description |

| Bit 7 | OC3CE: Output compare 3 clear enable |
| Bits 6, 5 | OC3M[3:0]: Output compare 3 mode Refer to OC1M description (bits 6:4 in TIMx_CCMR1 register) |
| Bit 3 | OC3PE: Output compare 3 preload enable |
| Bit 2 | OC3FE: Output compare 3 fast enable |
| Bits 1:0 | CC3S[1:0]: Capture/Compare 3 selection | 

This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC3 channel is configured as output
01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
10: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)
11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC3E bits are writable only when the channel is OFF (CC3E = 0 in TIMx_CCER).

| Bit 9 | CC4S[1:0]: Capture/Compare 4 selection |

This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC4 channel is configured as output
01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
10: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)
11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC4E bits are writable only when the channel is OFF (CC4E = 0 in TIMx_CCER).
Bit 7  **CC2NP**: Capture/Compare 2 output Polarity.
Refer to CC1NP description

Bit 6  Reserved, must be kept at reset value.

Bit 5  **CC2P**: Capture/Compare 2 output Polarity.
refer to CC1P description

Bit 4  **CC2E**: Capture/Compare 2 output enable.
Refer to CC1E description

Bit 3  **CC1NP**: Capture/Compare 1 output Polarity.

**CC1 channel configured as output**: CC1NP must be kept cleared in this case.

**CC1 channel configured as input**: This bit is used in conjunction with CC1P to define tim_ti1fp1/tim_ti2fp1 polarity. refer to CC1P description.

Bit 2  Reserved, must be kept at reset value.

Bit 1  **CC1P**: Capture/Compare 1 output Polarity.

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

CC1NP=1, CC1P=1: non-inverted/both edges. The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

CC1NP=1, CC1P=0: this configuration is reserved, it must not be used.

Bit 0  **CC1E**: Capture/Compare 1 output enable.

0: Capture mode disabled / OC1 is not active
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

<table>
<thead>
<tr>
<th>CCxE bit</th>
<th>tim_ocx output state</th>

</table>

**Note:** The state of the external IO pins connected to the standard tim_ocx channels depends only on the GPIO registers when CCxE=0.
55.5.12 TIMx counter (TIMx_CNT)(x = 2 to 5)

Address offset: 0x024
Reset value: 0x0000 0000

Bit 31 **UIFCPY_CNT[31]**: Value depends on IUFREMAP in TIMx_CR1.
  - If IUFREMAP = 0
    - **CNT[31]**: Most significant bit of counter value
  - If IUFREMAP = 1
    - **UIFCPY**: UIF Copy
      This bit is a read-only copy of the UIF bit of the TIMx_ISR register

Bits 30:0 **CNT[30:0]**: Least significant part of counter value
  - **Non-dithering mode (DITHEN = 0)**
    - The register holds the counter value.
  - **Dithering mode (DITHEN = 1)**
    - The register holds the non-dithered part in CNT[30:0]. The fractional part is not available.

55.5.13 TIMx prescaler (TIMx_PSC)(x = 2 to 5)

Address offset: 0x028
Reset value: 0x0000

Bits 15:0 **PSC[15:0]**: Prescaler value
  - The counter clock frequency \( t_{im\_cnt\_ck} \) is equal to \( f_{tim\_psc\_ck} / (PSC[15:0] + 1) \).
  - PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in "reset mode").
55.5.14 TIMx auto-reload register (TIMx_ARR)(x = 2 to 5)

Address offset: 0x02C
Reset value: 0xFFFF FFFF

Bits 31:0 ARR[31:0]: Auto-reload value
ARR is the value to be loaded in the actual auto-reload register.
Refer to the Section 55.4.3: Time-base unit on page 2234 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
Non-dithering mode (DITHEN = 0)
The register holds the auto-reload value.
Dithering mode (DITHEN = 1)
The register holds the integer part in ARR[31:4]. The ARR[3:0] bitfield contains the dithered part.

55.5.15 TIMx capture/compare register 1 (TIMx_CCR1)(x = 2 to 5)

Address offset: 0x034
Reset value: 0x0000 0000
Bits 31:0 **CCR1[31:0]**: Capture/compare 1 value

If channel CC1 is configured as output:
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

Non-dithering mode (DITHEN = 0)
The register holds the compare value.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR1[31:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input:
CCR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)
The register holds the capture value.
Dithering mode (DITHEN = 1)
The register holds the capture in CCR1[31:0]. The CCR1[3:0] bits are reset.

55.5.16 **TIMx capture/compare register 2 (TIMx_CCR2)(x = 2 to 5)**
Address offset: 0x038
Reset value: 0x0000 0000

Bits 31:0  **CCR2[31:0]**: Capture/compare 2 value

**If channel CC2 is configured as output:**
CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

- **Non-dithering mode (DITHEN = 0)**
The register holds the compare value.

- **Dithering mode (DITHEN = 1)**
The register holds the integer part in CCR2[31:4]. The CCR2[3:0] bitfield contains the dithered part.

**If channel CC2 is configured as input:**
CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

- **Non-dithering mode (DITHEN = 0)**
The register holds the capture value.

- **Dithering mode (DITHEN = 1)**
The register holds the capture in CCR2[31:0]. The CCR2[3:0] bits are reset.

### 55.5.17 TIMx capture/compare register 3 (TIMx_CCR3)(x = 2 to 5)

Bits 31:0 CCR3[31:0]: Capture/compare 3 value

If channel CC3 is configured as output:
CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc3 output.

Non-dithering mode (DITHEN = 0)
The register holds the compare value.

Dithering mode (DITHEN = 1)
The register holds the integer part in CCR3[31:4]. The CCR3[3:0] bitfield contains the dithered part.

If channel CC3 is configured as input:
CCR3 is the counter value transferred by the last input capture 3 event (tim_ic3). The TIMx_CCR3 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)
The register holds the capture value.

Dithering mode (DITHEN = 1)
The register holds the capture in CCR3[31:0]. The CCR3[3:0] bits are reset.
Bits 31:0 **CCR4[31:0]**: Capture/compare 4 value

**If channel CC4 is configured as output:**
CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR4 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc4 output.

- **Non-dithering mode (DITHEN = 0)**
The register holds the compare value.
- **Dithering mode (DITHEN = 1)**
The register holds the integer part in CCR4[31:4]. The CCR4[3:0] bitfield contains the dithered part.

**If channel CC4 is configured as input:**
CCR4 is the counter value transferred by the last input capture 4 event (tim_ic4). The TIMx_CCR4 register is read-only and cannot be programmed.

- **Non-dithering mode (DITHEN = 0)**
The register holds the capture value.
- **Dithering mode (DITHEN = 1)**
The register holds the capture in CCR4[31:0]. The CCR4[3:0] bits are reset.

### 55.5.19 TIMx timer encoder control register (TIMx_ECR)(x = 2 to 5)

</tbody>
</table>

- **Bits 31:27** Reserved, must be kept at reset value.
- **Bits 26:24** **PWPRSC[2:0]**: Pulse width prescaler  
This bitfield sets the clock prescaler for the pulse generator, as following:
\[ t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim.ker.clk} \]
- **Bits 23:16** **PW[7:0]**: Pulse width  
This bitfield defines the pulse duration, as following:
\[ t_{PW} = PW[7:0] \times t_{PWG} \]
- **Bits 15:8** Reserved, must be kept at reset value.
Bits 7:6 **IPOS[1:0]**: Index positioning

In quadrature encoder mode (SMS[3:0] = 0001, 0010, 0011, 1110, 1111), this bit indicates in which AB input configuration the Index event resets the counter.
- 00: Index resets the counter when AB = 00
- 01: Index resets the counter when AB = 01
- 10: Index resets the counter when AB = 10
- 11: Index resets the counter when AB = 11

In directional clock mode or clock plus direction mode (SMS[3:0] = 1010, 1011, 1100, 1101), these bits indicates on which level the Index event resets the counter. In bidirectional clock mode, this applies for both clock inputs.
- 00: Index resets the counter when clock is 0
- 01: Index resets the counter when clock is 1

*Note: IPOS[1] bit is not significant*

Bit 5 **FDX**: First index

This bit indicates if the first index only is taken into account
- 0: Index is always active
- 1: the first Index only resets the counter

Bits 4:3 **IBLK[1:0]**: Index blanking

This bit indicates if the Index event is conditioned by the tim_ti3 input
- 00: Index always active
- 01: Index disabled hen tim_ti3 input is active, as per CC3P bitfield
- 10: Index disabled when tim_ti4 input is active, as per CC4P bitfield
- 11: Reserved

Bits 2:1 **IDIR[1:0]**: Index direction

This bit indicates in which direction the Index event resets the counter.
- 00: Index resets the counter whatever the direction
- 01: Index resets the counter when up-counting only
- 10: Index resets the counter when down-counting only
- 11: Reserved

Bit 0 **IE**: Index enable

This bit indicates if the Index event resets the counter.
- 0: Index disabled
- 1: Index enabled

Bits 31:19  Reserved, must be kept at reset value.

Bits 18:16  OCRSEL[2:0]: ocref_clr source selection

These bits select the ocref_clr input source.

000: tim_ocref_clr0
001: tim_ocref_clr1
...
111: tim_ocref_clr7
Refer to Section 55.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals for product specific implementation.

Bits 15:0  Reserved, must be kept at reset value.
55.5.23  **TIMx DMA control register (TIMx_DCR)(x = 2 to 5)**

Address offset: 0x3DC  
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   | 16 |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |   |   |   |   |   |   |   |   |   |
| 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |   |   |   |   |   |   |   |   |   |

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:16 **DBSS[3:0]**: DMA burst source selection  
This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).

0000: Reserved  
0001: Update  
0010: CC1  
0011: CC2  
0100: CC3  
0101: CC4  
0110: COM  
0111: Trigger  
Others: reserved

Bits 15:13  Reserved, must be kept at reset value.
Bits 12:8 **DBL[4:0]: DMA burst length**

This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

- 00000: 1 transfer
- 00001: 2 transfers
- 00010: 3 transfers
- ...
- 11010: 26 transfers

**Example:** Let us consider the following transfer: DBL = 7 bytes & DBA = TIM2_CR1.

- If DBL = 7 bytes and DBA = TIM2_CR1 represents the address of the byte to be transferred, the address of the transfer is given by the following equation:

  \[(TIMx_CR1\text{ address}) + DBA + (DMA\ index)\]

  Where DMA index = DBL

  In this example, 7 bytes are added to (TIMx_CR1 address) + DBA, which gives us the address from/to which the data are copied. In this case, the transfer is done to 7 registers starting from the following address: (TIMx_CR1 address) + DBA

  According to the configuration of the DMA Data Size, several cases may occur:

  - If the DMA Data Size is configured in half-words, 16-bit data are transferred to each of the 7 registers.
  - If the DMA Data Size is configured in bytes, the data are also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on.

So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]: DMA base address**

This 5-bit vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

**Example:**

- 00000: TIMx_CR1, 00001: TIMx_CR2, 00010: TIMx_SMCR, ...

### 55.5.24 TIMx DMA address for full transfer (TIMx_DMAR)(x = 2 to 5)

Address offset: 0x3E0

Reset value: 0x0000 0000

<table>
<thead>
<tr>

<td>DMAB[15:0]</td>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>
Bits 31:0  **DMAB[31:0]**: DMA register for burst accesses
A read or write operation to the DMAR register accesses the register located at the address
(TIMx_CR1 address) + (DBA + DMA index) x 4
where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).
### 55.5.25 TIMx register map

TIMx registers are mapped as described in the table below.

Refer to Section 2.3 on page 139 for the register boundary addresses.
56 General purpose timers (TIM15/TIM16/TIM17)

56.1 TIM15/TIM16/TIM17 introduction

The TIM15/TIM16/TIM17 timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM15/TIM16/TIM17 timers are completely independent, and do not share any resources. TIM15 can be synchronized as described in Section 56.4.26: Timer synchronization (TIM15 only).

56.2 TIM15 main features

TIM15 includes the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535

- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge mode)
  - One-pulse mode output

- Complementary outputs with programmable dead-time (for channel 1 only)

- Synchronization circuit to control the timer with external signals and to interconnect several timers together

- Repetition counter to update the timer registers only after a given number of cycles of the counter

- Break input to put the timer’s output signals in the reset state or a known state

- Interrupt/DMA generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
  - Break input (interrupt request)
56.3 TIM16/TIM17 main features

The TIM16/TIM17 timers include the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- One channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow
  - Input capture
  - Output compare
  - Break input

### 56.4.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be
generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

**Prescaler description**

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 677* and *Figure 678* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

**Figure 677. Counter timing diagram with prescaler division change from 1 to 2**
56.4.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Write a new value in TIMx_ARR
56.4.5 Repetition counter

Section 56.4.3: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented at each counter overflow.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 685). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
Clock selection

The counter clock can be provided by the following clock sources:
- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_t1 or tim_t12, if available)
- Internal trigger inputs (tim_itr) (only for TIM15): using one timer as the prescaler for another timer, for example, TIM1 can be configured to act as a prescaler for TIM15. Refer to Using one timer to enable another timer for more details.

Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS=000), then the CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed.
only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

*Figure 686* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

*Figure 686. Control circuit in normal mode, internal clock divided by 1*

![Control circuit diagram](image)

**External clock source mode 1**

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

*Figure 687. tim_ti2 external clock connection example*

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:
1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the tim_ti2 input by writing CC2S = '01' in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
4. Select rising edge polarity by writing CC2P=0 in the TIMx_CCRER register.
5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
6. Select tim_ti2 as the trigger input source by writing TS=00110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set.
The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 688. Control circuit in external clock mode 1

56.4.7 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

Figure 689 to Figure 692 give an overview of one Capture/Compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfpy) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: \textit{tim\_ocxref} (active high). The polarity acts at the end of the chain.

**Figure 689. Capture/compare channel (example: channel 1 input stage)**

**Figure 690. Capture/compare channel 1 main circuit**
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

56.4.8 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding tim_icx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was
already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

1. Select the proper tim_ti1_in[15:1] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at least 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_ti1 when 8 consecutive samples with the new level have been detected (sampled at f_{DTS} frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the tim_ti1 channel by writing CC1P bit to 0 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.
56.4.9 PWM input mode (only for TIM15)

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIMx_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges)

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two tim_icx signals are mapped on the same tim_tix input.
- These 2 tim_icx signals are active on edges with opposite polarity.
- One of the two tim_tixfpy signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on tim_ti1 using the following procedure (depending on tim_ker_ck frequency and prescaler value):

1. Select the proper tim_ti1_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_ti1 selected).
3. Select the active polarity for tim_ti1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_ti1 selected).
5. Select the active polarity for tim_ti1fp2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to ‘10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_ti1fp1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.
56.4.10 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx/tim_ocxn) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP=0 (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

56.4.11 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP...
bit in the TIMx_CCER register). The output pin can keep its level (OCXM=000), be set active (OCXM=001), be set inactive (OCXM=010) or can toggle (OCXM=011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

**Procedure**

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 694.
56.4.12 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing ‘110’ (PWM mode 1) or ‘111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The TIM15/TIM16/TIM17 are capable of upcounting only. Refer to Upcounting mode on page 2348.
In the following example, we consider PWM mode 1. The reference PWM signal `tim_ocxref` is high as long as `TIMx_CNT < TIMx_CCRx` else it becomes low. If the compare value in `TIMx_CCRx` is greater than the auto-reload value (in `TIMx_ARR`) then `tim_ocxref` is held at ‘1’. If the compare value is 0 then `tim_ocxref` is held at ‘0’. Figure 695 shows some edge-aligned PWM waveforms in an example where `TIMx_ARR=8`.

**Figure 695. Edge-aligned PWM waveforms (ARR=8)**

![Diagram of edge-aligned PWM waveforms (ARR=8)](image)

**Dithering mode**

The PWM mode effective resolution can be increased by enabling the dithering mode, using the `DITHEN` bit in the `TIMx_CR1` register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The **Figure 696** below presents the dithering principle applied to 4 consecutive PWM cycles.
When the dithering mode is enabled, the register coding is changed as following (see Figure 697 for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- the MSBs are left-shifted to the bits 19:4 and are coding for the base value.

**Note:** The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The ARR[3:0] bits must be reset
3. The CCIF flags must be cleared
4. The CEN bit can be set (eventually with ARPE = 1).

The minimum frequency is given by the following formula:

\[
\text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{pwmMin}} = \frac{F_{\text{TimMax}}}{\text{Resolution}}
\]
The maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFFE in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on the Figure 698 below, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

![Figure 698. PWM resolution vs frequency](image)

The duty cycle and/or period changes are spread over 16 consecutive periods, as described in the Figure 699 below.
The auto-reload and compare values increments are spread following specific patterns described in the Table 578 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

Combined PWM mode (TIM15 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 700 represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
56.4.14 Complementary outputs and dead-time insertion

The TIM15/TIM16/TIM17 general-purpose timers can output one complementary signal and manage the switching-off and switching-on of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

The polarity of the outputs (main output tim\_ocx or complementary tim\_ocxn) can be selected independently for each output. This is done by writing to the CCnP and CCxNP bits in the TIMx\_CCER register.

The complementary signals tim\_ocx and tim\_ocxn are activated by a combination of several control bits: the CCxEx and CCxNE bits in the TIMx\_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx\_BDTR and TIMx\_CR2 registers. Refer to Table 585: Output control bits for complementary tim\_oc1 and tim\_oc1n channels with break feature (TIM16/TIM17) on page 2429 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

msv62330v1
Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a reference waveform tim_ocxref, it generates 2 outputs tim_ocx and tim_ocxn. If tim_ocx and tim_ocxn are active high:

- The tim_ocx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The tim_ocxn output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (tim_ocx or tim_ocxn) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal tim_ocxref. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 701. Complementary output with symmetrical dead-time insertion.**

<table>
<thead>
<tr>

<th>tim_ocx</th>
<th>tim_ocxn</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\text{delay})</td>
<td>(\text{delay})</td>
<td></td>
</tr>
</tbody>
</table>

The DTAE bit in the TIMx_DTR2 is used to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on **Figure 702**.

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIMx_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIMx_DTR2 register. The DTAE bit must be written before enabling the counter and must not be modified while CEN = 1.

It is possible to have the deadtime value updated on-the-fly during pwm operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set, in the TIMX_DTR2 register. The preload value is loaded in the active register on the next update event.

**Note:** If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 56.8.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17) on page 2433 for delay calculation.
Re-directing tim_ocxref to tim_ocx or tim_ocxn

In output mode (forced, output compare or PWM), tim_ocxref can be re-directed to the tim_ocx output or to tim_ocxn output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This is used to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

Note: When only tim_ocxn is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as tim_ocxref is high. For example, if CCxNP=0 then tim_ocxn=tim_ocxref. On the other hand, when both tim_ocx and tim_ocxn are enabled (CCxE=CCxNE=1) tim_ocx becomes active when tim_ocxref is high whereas tim_ocxn is complemented and becomes active when tim_ocxref is low.

56.4.15 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The break input is usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state.

The break channel gathers both system-level fault (clock failure, ECC / parity errors,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration.

The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx_BDTR register is used to enable /disable the outputs by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shutdown level, either active or inactive. The tim_ocx and tim_ocxn outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 585: Output control bits for complementary tim_oc1 and tim_oc1n channels with break feature (TIM16/TIM17) on page 2429 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break function is enabled by setting the BKE bit in the TIMx_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. When the BKE and BKP bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.
The break is generated by the tim_brk inputs which have:

- Programmable polarity (BKP bit in the TIMx_BDTR register)
- Programmable enable bit (BKE bit in the TIMx_BDTR register)
- Programmable filter (BKF[3:0] bits in the TIMx_BDTR register) to avoid spurious events.

The break can be generated from multiple sources which can be individually enabled and with programmable edge sensitivity, using the TIMx_AF1 register.

The sources for break (tim_brk) channel are:

- External sources connected to one of the TIM_BKIN pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources:
  - coming from a tim_brk_cmpx input (refer to Section 56.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation)
  - coming from a system break request on the tim_sys_brk inputs (refer to Section 56.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation)

Break events can also be generated by software using BG bit in the TIMx_EGR register. All sources are ORed before entering the timer tim_brk inputs, as per Figure 705 below.

**Figure 705. Break circuitry overview**

Caution: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example, using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.
When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO (selected by the OSSI bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO) else the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_ocx and tim_ocxn cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2 tim_ker_ck clock cycles).
  - If OSSI=0 then the timer releases the enable outputs (taken over by the GPIO which forces a Hi-Z state) else the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.
- The break status flag (BIF bit in the TIMx_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.
- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance. Else, MOE remains low until it is written with 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSI value. If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIMx_CR2 register.

Note: The break inputs is acting on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF cannot be cleared.

The break can be generated by the tim_brk input which has a programmable polarity and an enable bit BKE in the TIMx_BDTR Register.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It is used to freeze the configuration of several parameters (dead-time duration, tim_ocx/tim_ocxn polarities and state when disabled, OCxM configurations, break enable and polarity). The protection can be selected among 3 levels with the LOCK bits in the TIMx_BDTR register. Refer to Section 56.8.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17). The LOCK bits can be written only once after an MCU reset.

The Figure 706 shows an example of behavior of the outputs in response to a break.

56.4.16 Bidirectional break input

The TIM15/TIM16/TIM17 are featuring bidirectional break I/Os, as represented on Figure 707.

They are used to have:
- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged

The `tim_brk` input is configured in bidirectional mode using the `BKBID` bit in the TIMxBDTR register. The `BKBID` programming bit can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode requires the I/O to be configured in open-drain mode with active low polarity (using BKINP and BKP bits). Any break request coming either from system (for example CSS), from on-chip peripherals or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software event (triggered by setting the BG bit) also causes the break I/O to be forced to '0' to indicate to the external components that the timer has entered in break state. However, this is valid only if the break is enabled (BKE = 1). When a software break event is generated with BKE = 0, the outputs are put in safe state and the break flag is set, but there is no effect on the TIM_BKIN I/O.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the `BKDSRM` bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:
- The break input path is always active: a break event is active even if the BKDSRM bit is set and the open drain control is released. This prevents the PWM output to be re-started as long as the break condition is present.
- The BKDSRM bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see Table 579)

Arming and re-arming break circuitry

The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).
The following procedure must be followed to re-arm the protection after a break event:

- The BKDSRM bit must be set to release the output control
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before re-arming)
- The software must poll the BKDSRM bit until it is cleared by hardware (when the application break condition disappears)

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

**Figure 707. Output redirection**

56.4.17 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocxref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The tim_ocxref_clr_int input can be selected among several inputs, as shown on **Figure 708** below.
56.4.18 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on tim_trgi rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The Figure 709 describes the behavior of the tim_ocx and tim_ocxn outputs when a COM event occurs, in 3 different examples of programmed configurations.

56.4.19 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- \( \text{CNT} < \text{CCRx} \leq \text{ARR} \) (in particular, 0 < CCRx)

![Figure 710. Example of one pulse mode.](image)

For example one may want to generate a positive pulse on tim_oc1 with a length of \( t_{\text{PULSE}} \) and after a delay of \( t_{\text{DELAY}} \) as soon as a positive edge is detected on the tim_ti2 input pin.

Let’s use tim_ti2fp2 as trigger 1:

1. Select the proper tim_ti2_in[15:1] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map tim_ti2fp2 to tim_ti2 by writing CC2S='01' in the TIMx_CCMR1 register.
3. tim_ti2fp2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
4. Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS='00110' in the TIMx_SMCR register.
5. tim_ti2fp2 is used to start the counter by writing SMS to ‘110’ in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value ($\text{TIMx_ARR} - \text{TIMx_CCR1}$).
- Let’s say one want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE='1' in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to ‘0’ in this example.

Since only 1 pulse is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0).

Particular case: tim_ocx fast enable

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY}}$ min we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

56.4.20 Retriggerable one pulse mode (TIM15 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in Section 56.4.19:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retrigerrable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

Note: The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.
56.4.21 UIF bit remapping

The UIFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

56.4.22 Timer input XOR function (TIM15 only)

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins tim_ti1 and tim_ti2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in Figure 712.

56.4.23 External trigger synchronization (TIM15 only)

The TIM timers are linked together internally for timer synchronization or chaining.
The TIM15 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TIM_TI1 input:

1. Configure the channel 1 to detect rising edges on TIM_TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P='0' and CC1NP='0' in the TIMx_CCER register to validate the polarity (and detect rising edges only).

2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TIM_TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TIM_TI1 rising edge. When TIM_TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TIM_TI1 and the actual reset of the counter is due to the resynchronization circuit on TIM_TI1 input.

**Figure 713. Control circuit in reset mode**

![Control circuit in reset mode](image)
Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_ti1 input is low:

1. Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP = '0' in the TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.

![Figure 714. Control circuit in gated mode](MSv62362V1)
Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

1. Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=’1’ and CC2NP=’0’ in the TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in the TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=00110 in the TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.

![Figure 715. Control circuit in trigger mode](MSv62363V1)

Slave mode selection preload for run-time update

The SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value is the update event (UEV) occurring when the counter overflows.

56.4.24 Slave mode – combined reset + trigger mode (TIM15 only)

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

56.4.25 Slave mode – combined reset + gated mode (TIM15 only)

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).
56.4.26 Timer synchronization (TIM15 only)

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 55.4.23: Timer synchronization for details.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

56.4.27 Using timer output as trigger for other timers (TIM16/TIM17 only)

The timers with one channel only do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any timer on the device to identify which timers can be targeted as slave.

The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger.

For instance, if the destination's timer CK_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

56.4.28 ADC triggers (TIM15 only)

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

56.4.29 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests on a single event. The main purpose is to be able to re-program several timer registers multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:
00000: TIMx_CR1,
00001: TIMx_CR2,
00010: TIMx_SMCR,
The DBSS[3:0] bits in the TIMx_DCR register define the interrupt source that triggers the DMA burst transfers (see Section 56.8.20: TIMx DMA control register (TIMx_DCR)(x = 16 to 17) for details).

For example, the timer DMA burst feature can be used to update the contents of the CCRx registers (x = 2, 3, 4) on an update event, with the DMA transferring half-words into the CCRx registers.

This is done in the following steps:
1. Configure the corresponding DMA channel as follows:
   – DMA channel peripheral address is the DMAR register address
   – DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into the CCRx registers.
   – Number of data to transfer = 3 (See note below).
   – Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   DBL = 3 transfers, DBA = 0xE and DBSS = 1.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register is to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

56.4.30 TIM15/TIM16/TIM17 DMA requests

The TIM15/TIM16/TIM17 can generate a DMA requests, as shown in Table 580.

<table>

1. Available for TIM15 only.

56.4.31 Debug mode

When the microcontroller enters debug mode (Cortex®-M33 core halted), the TIMx counter can either continue to work normally or stop.
The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0) to force them to Hi-Z.

For more details, refer to the debug section.

### 56.5 TIM15/TIM16/TIM17 low-power modes

Table 581. Effect of low-power modes on TIM15/TIM16/TIM17

</table>

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable

- 0: Dithering disabled
- 1: Dithering enabled

*Note: The DITHEN bit can only be modified when CEN bit is reset.*

Bit 11 **UIFREMAP**: UIF status bit remapping

- 0: No remapping. UIF status bit is not copied to TIM15_CNT register bit 31.
- 1: Remapping enabled. UIF status bit is copied to TIM15_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bitfield indicates the division ratio between the timer clock (tim_ker_ck) frequency and the dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters (tim_tix)

- 00: tDTS = tim_ker_ck
- 01: tDTS = 2*tim_ker_ck
- 10: tDTS = 4*tim_ker_ck
- 11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

- 0: TIM15_ARR register is not buffered
- 1: TIM15_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode

- 0: Counter is not stopped at update event
- 1: Counter stops counting at the next update event (clearing the bit CEN)
Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

- 0: Any of the following events generate an update interrupt if enabled. These events can be:
  - Counter overflow/underflow
  - Setting the UG bit
  - Update generation through the slave mode controller
- 1: Only counter overflow/underflow generates an update interrupt if enabled

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

- 0: UEV enabled. The Update (UEV) event is generated by one of the following events:
  - Counter overflow/underflow
  - Setting the UG bit
  - Update generation through the slave mode controller
  - Buffered registers are then loaded with their preload values.
- 1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

- 0: Counter disabled
- 1: Counter enabled

*Note*: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

### 56.7.2 TIM15 control register 2 (TIM15_CR2)

Address offset: 0x04

</tbody>
</table>

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **OIS2**: Output idle state 2 (TIM_OC2 output)

- 0: TIM_OC2=0 when MOE=0
- 1: TIM_OC2=1 when MOE=0

*Note*: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in the TIM15_BKR register).

Bit 9 **OIS1N**: Output Idle state 1 (TIM_OC1n output)

- 0: TIM_OC1n=0 after a dead-time when MOE=0
- 1: TIM_OC1n=1 after a dead-time when MOE=0

*Note*: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BKR register).

Bit 8 **OIS1**: Output Idle state 1 (TIM_OC1 output)

- 0: TIM_OC1=0 after a dead-time when MOE=0
- 1: TIM_OC1=1 after a dead-time when MOE=0

*Note*: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BKR register).
Bit 7 **TI1S**: tim_ti1 selection

- **0**: The tim_ti1_in[15:0] multiplexer output is connected to tim_ti1 input
- **1**: The tim_ti1_in[15:0] and tim_ti2_in[15:0] multiplexers output are connected to the tim_ti1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

- **000**: *Reset* - the UG bit from the TIM15_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.
- **001**: *Enable* - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIM15_SMCR register).
- **010**: *Update* - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.
- **011**: *Compare Pulse* - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (tim_trgo).
- **100**: *Compare* - tim_oc1refc signal is used as trigger output (tim_trgo).
- **101**: *Compare* - tim_oc2refc signal is used as trigger output (tim_trgo).

Bit 3 **CCDS**: Capture/compare DMA selection

- **0**: CCx DMA request sent when CCx event occurs
- **1**: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

- **0**: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
- **1**: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on tim_trgi.

*Note: This bit acts only on channels that have a complementary output.*

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

- **0**: CCxE, CCxNE and OCxM bits are not preloaded
- **1**: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on tim_trgi, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*
56.7.3 TIM15 slave mode control register (TIM15_SMCR)

- 10001: Internal trigger 13 (tim_itr13)
- 10010: Internal trigger 14 (tim_itr14)
- 10011: Internal trigger 15 (tim_itr15)

Others: Reserved

See \textit{Section 56.4.2: TIM15/TIM16/TIM17 pins and internal signals} for more details on tim_itrx meaning for each timer.

\textit{Note}: These bits must be changed only when they are not used (for example when SMS=000) to avoid wrong edge detections at the transition.

Bit 3  Reserved, must be kept at reset value.
Bits 16, 2, 1, 0 **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.

0001: Reserved

0010: Reserved

0011: Reserved

0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

Others: Reserved.

**Note:** The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS=’00100’). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on tim_ti1f, whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Bits 15:11  Reserved, must be kept at reset value.

Bit 10  CC2OF: Capture/Compare 2 overcapture flag
Refer to CC1OF description

Bit 9  CC1OF: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.
0: No overcapture has been detected
1: The counter value has been captured in TIM15_CCR1 register while CC1IF flag was already set

Bit 8  Reserved, must be kept at reset value.
Bit 7  **BIF**: Break interrupt flag
This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
0: No break event occurred
1: An active level has been detected on the break input

Bit 6  **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode, both edges in case gated mode is selected). It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred
1: Trigger interrupt pending

Bit 5  **COMIF**: COM interrupt flag
This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.
0: No COM event occurred
1: COM interrupt pending

Bits 4:3 Reserved, must be kept at reset value.

Bit 2  **CC2IF**: Capture/Compare 2 interrupt flag
refer to CC1IF description

Bit 1  **CC1IF**: Capture/Compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred

**If channel CC1 is configured as output**: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

**If channel CC1 is configured as input**: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0  **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
- At overflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIM15_CR1 register.
- When CNT is reinitialized by software using the UG bit in TIM15_EGR register, if URS=0 and UDIS=0 in the TIM15_CR1 register.
- When CNT is reinitialized by a trigger event (refer to Section 56.7.3: TIM15 slave mode control register (TIM15_SMCR)), if URS=0 and UDIS=0 in the TIM15_CR1 register.
56.7.6 TIM15 event generation register (TIM15_EGR)

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **BG**: Break generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 **TG**: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: The TIF flag is set in TIM15_SR register. Related interrupt or DMA transfer can occur if enabled

Bit 5 **COMG**: Capture/Compare control update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits
*Note*: This bit acts only on channels that have a complementary output.

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **CC2G**: Capture/Compare 2 generation
Refer to CC1G description

Bit 1 **CC1G**: Capture/Compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
   - **If channel CC1 is configured as output**: CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
   - **If channel CC1 is configured as input**: The current value of the counter is captured in TIM15_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected).
56.7.7 **TIM15 capture/compare mode register 1 (TIM15_CCMR1)**

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

### Input capture mode

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM15_SMCR register)

*Note:* **CC2S bits are writable only when the channel is OFF (CC2E = ‘0’ in TIM15_CCER).**
Bits 7:4  **IC1F[3:0]: Input capture 1 filter**

This bit-field defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at fDTS
- 0001: $f_{SAMPLING}=f_{tim_ker_ck}$, N=2
- 0010: $f_{SAMPLING}=f_{tim_ker_ck}$, N=4
- 0011: $f_{SAMPLING}=f_{tim_ker_ck}$, N=8
- 0100: $f_{SAMPLING}=f_{DTS}/2$, N=6
- 0101: $f_{SAMPLING}=f_{DTS}/2$, N=8
- 0110: $f_{SAMPLING}=f_{DTS}/4$, N=6
- 0111: $f_{SAMPLING}=f_{DTS}/4$, N=8
- 1000: $f_{SAMPLING}=f_{DTS}/8$, N=6
- 1001: $f_{SAMPLING}=f_{DTS}/8$, N=8
- 1010: $f_{SAMPLING}=f_{DTS}/16$, N=5
- 1011: $f_{SAMPLING}=f_{DTS}/16$, N=6
- 1100: $f_{SAMPLING}=f_{DTS}/16$, N=8
- 1101: $f_{SAMPLING}=f_{DTS}/32$, N=5
- 1110: $f_{SAMPLING}=f_{DTS}/32$, N=6
- 1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

Bits 3:2  **IC1PSC[1:0]: Input capture 1 prescaler**

This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E='0' (TIM15_CCER register).

- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 1:0  **CC1S[1:0]: Capture/Compare 1 selection**

This bit-field defines the direction of the channel (input/output) as well as the used input.

- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
- 10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
- 11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM15_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIM15_CCER).*

56.7.8  **TIM15 capture/compare mode register 1 [alternate]**

**(TIM15_CCMR1)**

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).
Output compare mode:

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15  OC2CE: Output compare 2 clear enable

Bits 24, 14:12  OC2M[3:0]: Output compare 2 mode

Bit 11  OC2PE: Output compare 2 preload enable

Bit 10  OC2FE: Output compare 2 fast enable

Bits 9:8  CC2S[1:0]: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output.
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2.
10: C2 channel is configured as input, tim_ic2 is mapped on tim_ti1.
11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIM15_SMCR register)

Note:  CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIM15_CCER).

Bit 7  OC1CE: Output compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr_int input.
1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int input.
Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal `tim_oc1ref` from which `tim_oc1` and `tim_oc1n` are derived. `tim_oc1ref` is active high whereas `tim_oc1` and `tim_oc1n` active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIM15_CCR1 and the counter TIM15_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. `tim_oc1ref` signal is forced high when the counter TIM15_CNT matches the capture/compare register 1 (TIM15_CCR1).

0010: Set channel 1 to inactive level on match. `tim_oc1ref` signal is forced low when the counter TIM15_CNT matches the capture/compare register 1 (TIM15_CCR1).

0011: Toggle - `tim_oc1ref` toggles when TIM15_CNT=TIM15_CCR1.

0100: Force inactive level - `tim_oc1ref` is forced low.

0101: Force active level - `tim_oc1ref` is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIM15_CNT<TIM15_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIM15_CNT<TIM15_CCR1 else active.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved

1011: Reserved

1100: Combined PWM mode 1 - `tim_oc1ref` has the same behavior as in PWM mode 1. `tim_oc1ref` is the logical OR between `tim_oc1ref` and `tim_oc2ref`.

1101: Combined PWM mode 2 - `tim_oc1ref` has the same behavior as in PWM mode 2. `tim_oc1ref` is the logical AND between `tim_oc1ref` and `tim_oc2ref`.

1110: Reserved

1111: Reserved

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM15_BDTR register) and CC1S='00' (the channel is configured in output).

In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

On channels that have a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIM15_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.
Bit 3 **OC1PE**: Output Compare 1 preload enable
0: Preload register on TIM15_CCR1 disabled. TIM15_CCR1 can be written at anytime, the new value is taken in account immediately.
1: Preload register on TIM15_CCR1 enabled. Read/Write operations access the preload register. TIM15_CCR1 preload value is loaded in the active register at each update event.

*Note: These bits cannot be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM15_BDTR register) and CC1S='00' (the channel is configured in output).*

Bit 2 **OC1FE**: Output Compare 1 fast enable
This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.
0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
1: An active edge on the trigger input acts like a compare match on CC1 output. Then, tim_ocx is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC1 channel is configured as output.
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1.
10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2.
11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM15_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIM15_CCER).*

56.7.9 **TIM15 capture/compare enable register (TIM15_CCER)**
Address offset: 0x20
Reset value: 0x0000

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **CC2NP**: Capture/Compare 2 complementary output polarity
Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output polarity
Refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable
Refer to CC1E description
Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity  
CC1 channel configured as output:
0: tim_oc1n active high  
1: tim_oc1n active low  
CC1 channel configured as input:
This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1 and tim_ti2fp1. Refer to CC1P description.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register) and CC1S="00" (the channel is configured in output). On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIM15_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable
0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.  
1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 **CC1P**: Capture/Compare 1 output polarity  
CC1 channel configured as output:
0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)  
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

*When CC1 channel is configured as input*, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.  
CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is not inverted (trigger operation in gated mode).  
CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is inverted (trigger operation in gated mode).  
CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is not inverted (trigger operation in gated mode).  
CC1NP=1, CC1P=0: this configuration is reserved, it must not be used.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register). On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIM15_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 0 **CC1E**: Capture/Compare 1 output enable
0: Capture mode disabled / OC1 is not active (see below)  
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

*When CC1 channel is configured as output*, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to *Table 583* for details.

1. When both outputs of a channel are not used (control taken over by GPIO controller), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

Note: The state of the external I/O pins connected to the complementary tim\_ocx and tim\_ocxn channels depends on the tim\_ocx and tim\_ocxn channel state and GPIO control and alternate function selection registers.
56.7.10 TIM15 counter (TIM15_CNT)

Bits 31:20 Reserved, must be kept at reset value.
Bits 19:0 **ARR[19:0]: Auto-reload value**
- ARR is the value to be loaded in the actual auto-reload register.
- Refer to the **Section 56.4.3: Time-base unit on page 2346** for more details about ARR update and behavior.
- The counter is blocked while the auto-reload value is null.
- Non-dithering mode (DITHEN = 0)
- The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reset.
- Dithering mode (DITHEN = 1)

56.7.13 TIM15 repetition counter register (TIM15_RCR)

</tbody>
</table>

Bits 15:8 Reserved, must be kept at reset value.
Bits 7:0 **Rep[7:0]: Repetition counter reload value**
- This bitfield defines the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable. It also defines the update interrupt generation rate, if this interrupt is enable.
- When the repetition down-counter reaches zero, an update event is generated and it restarts counting from REP value. As the repetition counter is reloaded with REP value only at the repetition update event UEV, any write to the TIM15_RCR register is not taken in account until the next repetition update event.
- It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode:
  - the number of PWM periods in edge-aligned mode
  - the number of half PWM period in center-aligned mode

</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 CCR1[19:0]: Capture/compare 1 value

If channel CC1 is configured as output:
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIM15_CCMR1 register
(bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when
an update event occurs.
The active capture/compare register contains the value to be compared to the counter
TIM15_CNT and signaled on tim_oc1 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the
dithered part.

If channel CC1 is configured as input:
CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The
TIMx_CCR1 register is read-only and cannot be programmed.
Non-dithering mode (DITHEN = 0)
The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.
56.7.15 TIM15 capture/compare register 2 (TIM15_CCR2)

</tr>
</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR2[19:0]**: Capture/compare 2 value

**If channel CC2 is configured as output:**

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIM15_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIM15_CNT and signalled on tim_oc2 output.

- **Non-dithering mode (DITHEN = 0)**:
  - The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.
  - Dithering mode (DITHEN = 1):
    - The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

**If channel CC2 is configured as input:**

CCR2 is the counter value transferred by the last input capture 1 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

- **Non-dithering mode (DITHEN = 0)**:
  - The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.
  - Dithering mode (DITHEN = 1):
    - The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

56.7.16 TIM15 break and dead-time register (TIM15_BDTR)

</tr>
</tbody>
</table>

**Note:**

As the BKBID, BKDSRM, BKF[3:0], AOE, BKP, BKE, OSSR, OSSI and DTG[7:0] bits may be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIM15_BDTR register.
Bits 31:29  Reserved, must be kept at reset value.

Bit 28  **BKBID**: Break bidirectional
- 0: Break input tim_brk in input mode
- 1: Break input tim_brk in bidirectional mode
In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.

*Note: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 27  Reserved, must be kept at reset value.

Bit 26  **BKDSRM**: Break disarm
- 0: Break input tim_brk is armed
- 1: Break input tim_brk is disarmed
This bit is cleared by hardware when no break source is active.
The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled until it is reset by hardware, indicating that the fault condition has disappeared.

*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bits 25:20  Reserved, must be kept at reset value.

Bits 19:16  **BKF[3:0]**: Break filter
This bit-field defines the frequency used to sample the tim_brk input signal and the length of the digital filter applied to tim_brk. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

- 0000: No filter, tim_brk acts asynchronously
- 0001: $f_{SAMPLING}=f_{tim\_ker\_ck}$, $N=2$
- 0010: $f_{SAMPLING}=f_{tim\_ker\_ck}$, $N=4$
- 0011: $f_{SAMPLING}=f_{tim\_ker\_ck}$, $N=8$
- 0100: $f_{SAMPLING}=f_{DTS}/2$, $N=6$
- 0101: $f_{SAMPLING}=f_{DTS}/2$, $N=8$
- 0110: $f_{SAMPLING}=f_{DTS}/4$, $N=6$
- 0111: $f_{SAMPLING}=f_{DTS}/4$, $N=8$
- 1000: $f_{SAMPLING}=f_{DTS}/8$, $N=6$
- 1001: $f_{SAMPLING}=f_{DTS}/8$, $N=8$
- 1010: $f_{SAMPLING}=f_{DTS}/16$, $N=5$
- 1011: $f_{SAMPLING}=f_{DTS}/16$, $N=6$
- 1100: $f_{SAMPLING}=f_{DTS}/16$, $N=8$
- 1101: $f_{SAMPLING}=f_{DTS}/32$, $N=5$
- 1110: $f_{SAMPLING}=f_{DTS}/32$, $N=6$
- 1111: $f_{SAMPLING}=f_{DTS}/32$, $N=8$

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*
Bit 15  **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as the tim_brk input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

- 0: tim_ocx and tim_ocxn outputs are disabled or forced to idle state depending on the OSSI bit.
- 1: tim_ocx and tim_ocxn outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIM15_CCER register)

See **tim_ocx/tim_ocxn enable description** for more details (Section 56.7.9: **TIM15 capture/compare enable register (TIM15_CCER)** on page 2401).

Bit 14  **AOE**: Automatic output enable

- 0: MOE can be set only by software
- 1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 13  **BKP**: Break polarity

- 0: Break input tim_brk is active low
- 1: Break input tim_brk is active high

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12  **BKE**: Break enable

- 0: Break inputs (tim_brk and tim_sys_brk clock failure event) disabled
- 1: Break inputs (tim_brk and tim_sys_brk clock failure event) enabled

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

**Note**: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11  **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See **tim_ocx/tim_ocxn enable description** for more details (Section 56.7.9: **TIM15 capture/compare enable register (TIM15_CCER)** on page 2401).

- 0: When inactive, tim_ocx/tim_ocxn outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state)
- 1: When inactive, tim_ocx/tim_ocxn outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

**Note**: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 10  **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See **tim_ocx/tim_ocxn enable description** for more details (Section 56.7.9: **TIM15 capture/compare enable register (TIM15_CCER)** on page 2401).

- 0: When inactive, tim_ocx/tim_ocxn outputs are disabled (tim_ocx/tim_ocxn enable output signal=0)
- 1: When inactive, tim_ocx/tim_ocxn outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. tim_ocx/tim_ocxn enable output signal=1)

**Note**: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIM15_BDTR register).
Bits 9:8  LOCK[1:0]: Lock configuration
These bits offer a write protection against software errors.
00: LOCK OFF - No bit is write protected
01: LOCK Level 1 = DTG bits in TIM15_BDTR register, OISx and OISxN bits in TIM15_CR2 register and BKID/BKE/BKP/AOEN bits in TIM15_BDTR register can no longer be written
10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIM15_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIM15_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

Note: The LOCK bits can be written only once after the reset. Once the TIM15_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0  DTG[7:0]: Dead-time generator setup
This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.
DTG[7:5]=0xx => DT=DTG[7:0]x tDTS
DTG[7:5]=10x => DT=(64+DTG[5:0])x tDTS
DTG[7:5]=110 => DT=(32+DTG[4:0])x tDTS
DTG[7:5]=111 => DT=(32+DTG[4:0])x tDTS
Example if T_{DTS}=125ns (8MHz), dead-time possible values are:
0 to 15875 ns by 125 ns steps,
16 µs to 31750 ns by 250 ns steps,
32 µs to 63 µs by 1 µs steps,
64 µs to 126 µs by 2 µs steps

Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).

56.7.17  TIM15 timer deadtime register 2 (TIM15_DTR2)
Address offset: 0x054
Reset value: 0x0000 0000

| Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9  | Bit 8  | Bit 7  | Bit 6  | Bit 5  | Bit 4  | Bit 3  | Bit 2  | Bit 1  | Bit 0 DTGF[7:0] |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|-----------------|

Bits 31:18 Reserved, must be kept at reset value.

Bit 17  DTPE: Deadtime preload enable
0: Deadtime value is not preloaded
1: Deadtime value preload is enabled

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).
Bit 16 **DTAE**: Deadtime asymmetric enable  
0: Deadtime on rising and falling edges are identical, and defined with DTG[7:0] register  
1: Deadtime on rising edge is defined with DTG[7:0] register and deadtime on falling edge is defined with DTGF[7:0] bits.  
*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).*

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **DTGF[7:0]**: Dead-time falling edge generator setup  
This bit-field defines the duration of the dead-time inserted between the complementary outputs, on the falling edge.  
- DTGF[7:5]=0x0 => DTF=DTGF[7:0]x tdtg with tdtg=tDTS.  
- DTGF[7:5]=0x10 => DTF=(64+DTGF[5:0])x tdtg with tdtg=2x tDTS.  
- DTGF[7:5]=0x110 => DTF=(32+DTGF[4:0])x tdtg with tdtg=8x tDTS.  
- DTGF[7:5]=0x111 => DTF=(32+DTGF[4:0])x tdtg with tdtg=16x tDTS.  
Example if tDTS=125ns (8MHz), dead-time possible values are:  
- 0 to 15875 ns by 125 ns steps,  
- 16 us to 31750 ns by 250 ns steps,  
- 32 us to 63us by 1 us steps,  
- 64 us to 126 us by 2 us steps  
*Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).*

Refer to Section 56.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **BKCMP4P**: tim_brk_cmp4 input polarity

This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp4 input is active high
1: tim_brk_cmp4 input is active low

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 12 **BKCMP3P**: tim_brk_cmp3 input polarity

This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp3 input is active high
1: tim_brk_cmp3 input is active low

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 11 **BKCMP2P**: tim_brk_cmp2 input polarity

This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp2 input is active high
1: tim_brk_cmp2 input is active low

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 10 **BKCMP1P**: tim_brk_cmp1 input polarity

This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp1 input is active high
1: tim_brk_cmp1 input is active low

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).
Bit 9 **Bkinp**: TIMx_BKIN input polarity
This bit selects the TIMx_BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.
0: TIMx_BKIN input is active high
1: TIMx_BKIN input is active low

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 8 **Bkcmp8e**: tim_brk_cmp8 enable
This bit enables the tim_brk_cmp8 for the timer’s tim_brk input. mdf_brkx output is ‘ORed’ with the other tim_brk sources.
0: tim_brk_cmp8 input disabled
1: tim_brk_cmp8 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 7 **Bkcmp7e**: tim_brk_cmp7 enable
This bit enables the tim_brk_cmp7 for the timer’s tim_brk input. COMP7 output is ‘ORed’ with the other tim_brk sources.
0: tim_brk_cmp7 input disabled
1: tim_brk_cmp7 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 6 **Bkcmp6e**: tim_brk_cmp6 enable
This bit enables the tim_brk_cmp6 for the timer’s tim_brk input. tim_brk_cmp6 output is ‘ORed’ with the other tim_brk sources.
0: tim_brk_cmp6 input disabled
1: tim_brk_cmp6 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 5 **Bkcmp5e**: tim_brk_cmp5 enable
This bit enables the tim_brk_cmp5 for the timer’s tim_brk input. tim_brk_cmp5 output is ‘ORed’ with the other tim_brk sources.
0: tim_brk_cmp5 input disabled
1: tim_brk_cmp5 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 4 **Bkcmp4e**: tim_brk_cmp4 enable
This bit enables the tim_brk_cmp4 for the timer’s tim_brk input. tim_brk_cmp4 output is ‘ORed’ with the other tim_brk sources.
0: tim_brk_cmp4 input disabled
1: tim_brk_cmp4 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 3 **Bkcmp3e**: tim_brk_cmp3 enable
This bit enables the tim_brk_cmp3 for the timer’s tim_brk input. tim_brk_cmp3 output is ‘ORed’ with the other tim_brk sources.
0: tim_brk_cmp3 input disabled
1: tim_brk_cmp3 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*
Bit 2 **BKCMP2E**: tim_brk_cmp2 enable
This bit enables the tim_brk_cmp2 for the timer’s tim_brk input. tim_brk_cmp2 output is ‘ORed’ with the other tim_brk sources.
0: tim_brk_cmp2 input disabled
1: tim_brk_cmp2 input enabled

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 1 **BKCMP1E**: tim_brk_cmp1 enable
This bit enables the tim_brk_cmp1 for the timer’s tim_brk input. tim_brk_cmp1 output is ‘ORed’ with the other tim_brk sources.
0: tim_brk_cmp1 input disabled
1: tim_brk_cmp1 input enabled

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 0 **BKINE**: TIMx_BKIN input enable
This bit enables the TIMx_BKIN alternate function input for the timer’s tim_brk input. TIMx_BKIN input is ‘ORed’ with the other tim_brk sources.
0: TIMx_BKIN input disabled
1: TIMx_BKIN input enabled

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **OCRSEL[2:0]**: ocref_clr source selection
These bits select the ocref_clr input source.
000: tim_ocref_clr0
001: tim_ocref_clr1
010: tim_ocref_clr2
011: tim_ocref_clr3
100: tim_ocref_clr4
101: tim_ocref_clr5
110: tim_ocref_clr6
111: tim_ocref_clr7

Refer to Section 56.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation.

*Note*: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).
56.7.21 TIM15 DMA control register (TIM15_DCR)

Address offset: 0x3DC
Reset value: 0x0000 0000

Bits 15:0 Reserved, must be kept at reset value.

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 DBSS[3:0]: DMA burst source selection

This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).
- 0000: Reserved
- 0001: Update
- 0010: CC1
- 0110: COM
- 0111: Trigger
- Other: reserved

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 DBL[4:0]: DMA burst length

This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIM15_DMAR address).
- 00000: 1 transfer,
- 00001: 2 transfers,
- 00010: 3 transfers,
  ...
- 10001: 18 transfers.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 DBA[4:0]: DMA base address

This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIM15_DMAR address). DBA is defined as an offset starting from the address of the TIM15_CR1 register.
Example:
- 00000: TIM15_CR1,
- 00001: TIM15_CR2,
- 00010: TIM15_SMCR,
  ...
56.7.22 TIM15 DMA address for full transfer (TIM15_DMAR)

Bits 31:0 DMAB[31:0]: DMA register for burst accesses
A read or write operation to the DMAR register accesses the register located at the address
(TIM15_CR1 address) + (DBA + DMA index) x 4
where TIM15_CR1 address is the address of the control register 1, DBA is the DMA base
address configured in TIM15_DCR register, DMA index is automatically controlled by the
DMA transfer, and ranges from 0 to DBL (DBL configured in TIM15_DCR).

56.7.23 TIM15 register map

TIM15 registers are mapped as 16-bit addressable registers as described in the table
below:

| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable
0: Dithering disabled
1: Dithering enabled

*Note: The DITHEN bit can only be modified when CEN bit is reset.*

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bit-field indicates the ratio between the timer clock (tim_ker_ck) frequency and the dead-time and sampling clock (tDTS) used by the dead-time generator and the digital filters (tim_tix),
- 00: tDTS = tim_ker_ck
- 01: tDTS = 2 * tim_ker_ck
- 10: tDTS = 4 * tim_ker_ck
- 11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable
0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled.
These events can be:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
1: nly counter overflow/underflow generates an update interrupt or DMA request if enabled.
56.8.2  TIMx control register 2 (TIMx_CR2)(x = 16 to 17)

Address offset: 0x04
Reset value: 0x0000

Bits 15:10  Reserved, must be kept at reset value.

Bit 9  **OIS1N**: Output Idle state 1 (tim_oc1n output)
0: tim_oc1n=0 after a dead-time when MOE=0
1: tim_oc1n=1 after a dead-time when MOE=0

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).

Bit 8  **OIS1**: Output Idle state 1 (tim_oc1 output)
0: tim_oc1=0 after a dead-time when MOE=0
1: tim_oc1=1 after a dead-time when MOE=0

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).

Bits 7:4  Reserved, must be kept at reset value.

Bit 3  **CCDS**: Capture/compare DMA selection
0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bit 2  **CCUS**: Capture/compare control update selection
0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when a rising edge occurs on tim_trgi (if available).

Note: This bit acts only on channels that have a complementary output.

Bit 1  Reserved, must be kept at reset value.
Bit 0 **CCPC**: Capture/compare preloaded control
0: CCxE, CCxNE and OCxM bits are not preloaded
1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when COM bit is set.

*Note: This bit acts only on channels that have a complementary output.*

</tbody>
</table>

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 CC1OF: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bit 8 Reserved, must be kept at reset value.

Bit 7 BIF: Break interrupt flag
This flag is set by hardware as soon as the tim_brk input goes active. It can be cleared by software if the break input is not active.
0: No break event occurred
1: An active level has been detected on the break input

Bit 6 Reserved, must be kept at reset value.

Bit 5 COMIF: COM interrupt flag
This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.
0: No COM event occurred
1: COM interrupt pending

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 CC1IF: Capture/Compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.
If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).
Bit 0 **UIF**: Update interrupt flag
   This bit is set by hardware on an update event. It is cleared by software.
   0: No update occurred.
   1: Update interrupt pending. This bit is set by hardware when the registers are updated:
      - At overflow regarding the repetition counter value (update if repetition counter = 0)
        and if the UDIS=0 in the TIMx_CR1 register.
      - When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if
        URS=0 and UDIS=0 in the TIMx_CR1 register.

56.8.5 **TIMx event generation register (TIMx_EGR)** (x = 16 to 17)

Address offset: 0x14

Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **BG**: Break generation
   This bit is set by software in order to generate an event, it is automatically cleared by
   hardware.
   0: No action.
   1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or
   DMA transfer can occur if enabled.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **COMG**: Capture/Compare control update generation
   This bit can be set by software, it is automatically cleared by hardware.
   0: No action
   1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits

   Note: This bit acts only on channels that have a complementary output.

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CC1G**: Capture/Compare 1 generation
   This bit is set by software in order to generate an event, it is automatically cleared by
   hardware.
   0: No action.
   1: A capture/compare event is generated on channel 1:

   If channel CC1 is configured as output:
   CC1IF flag is set. Corresponding interrupt or DMA request is sent if enabled.

   If channel CC1 is configured as input:
   The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the
   CC1IF flag was already high.

Bit 0 **UG**: Update generation
   This bit can be set by software, it is automatically cleared by hardware.
   0: No action.
   1: Reinitialize the counter and generates an update of the registers. Note that the prescaler
   counter is cleared too (anyway the prescaler ratio is not affected).
56.8.6 TIMx capture/compare mode register 1 (TIMx_CCMR1)
(x = 16 to 17)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare
mode (next section). The direction of a channel is defined by configuring the corresponding
CCxS bits. All the other bits of this register have a different function for input capture and for
output compare modes. It is possible to combine both modes independently (for example
channel 1 in input capture mode and channel 2 in output compare mode).

| Bit 3:2 | **IC1PSC[1:0]**: Input capture 1 prescaler |
|         | This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). |
|         | The prescaler is reset as soon as CC1E='0' (TIMx_CCER register). |
|         | 00: no prescaler, capture is done each time an edge is detected on the capture input. |
|         | 01: capture is done once every 2 events |
|         | 10: capture is done once every 4 events |
|         | 11: capture is done once every 8 events |
56.8.7 TIM\textsubscript{x} capture/compare mode register 1 [alternate] (TIM\textsubscript{x} CCMR1)(x = 16 to 17)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CC\textsubscript{x}S bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

### Bits 1:0 CC\textsubscript{1S}[1:0]: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- 00: CC\textsubscript{1} channel is configured as output
- 01: CC\textsubscript{1} channel is configured as input, tim\_ic1 is mapped on tim\_ti1
- Others: Reserved

Note: CC\textsubscript{1}S bits are writable only when the channel is OFF (CC\textsubscript{1}E = ‘0’ in TIM\textsubscript{x} CCER).

#### Output compare mode:

- Bits 31:17 Reserved, must be kept at reset value.
- Bits 15:8 Reserved, must be kept at reset value.

- Bit 7 OC\textsubscript{1}CE: Output Compare 1 clear enable
  - 0: tim\_oc1ref is not affected by the tim\_ocref\_clr input.
  - 1: tim\_oc1ref is cleared as soon as a High level is detected on tim\_ocref\_clr input.
Bits 16, 6:4 **OC1M[3:0]**: Output Compare 1 mode

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 and tim_oc1n are derived. tim_oc1ref is active high whereas tim_oc1 and tim_oc1n active level depends on CC1P and CC1NP bits.

- **0000**: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

- **0001**: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

- **0010**: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

- **0011**: Toggle - tim_oc1ref toggles when TIMx_CNT=TIMx_CCR1.

- **0100**: Force inactive level - tim_oc1ref is forced low.

- **0101**: Force active level - tim_oc1ref is forced high.

- **0110**: PWM mode 1 - Channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive.

- **0111**: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active.

Others: Reserved

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

Bit 3 **OC1PE**: Output Compare 1 preload enable

- 0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.

- 1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

- 0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

- 1: An active edge on the trigger input acts like a compare match on CC1 output. Then, tim_ocx is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- 00: CC1 channel is configured as output

- 01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1

Others: Reserved

Note: CC1S bits are writable only when the channel is OFF (CC1E = ‘0’ in TIMx_CCER).
56.8.8  TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17)

Address offset: 0x20
Reset value: 0x0000

<table>
<thead>
<tr>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:4  Reserved, must be kept at reset value.

Bit 3  **CC1NP**: Capture/Compare 1 complementary output polarity

CC1 channel configured as output:
0: tim_oc1n active high
1: tim_oc1n active low

CC1 channel configured as input:
This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1. Refer to the description of CC1P.

**Note:**  This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (the channel is configured in output).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a commutation event is generated.
Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable
- 0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
- 1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 **CC1P**: Capture/Compare 1 output polarity
- 0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
- 1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

*When CC1 channel is configured as input*, both CC1NP/CC1P bits select the active polarity of T11FP1 and T12FP1 for trigger or capture operations.
- CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to T1xFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), T1xFP1 is not inverted (trigger operation in gated mode).
- CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to T1xFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), T1xFP1 is inverted (trigger operation in gated mode).
- CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both T1xFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), T1xFP1 is not inverted (trigger operation in gated mode).
- CC1NP=1, CC1P=0: this configuration is reserved, it must not be used.

*Note:* This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

*On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 0 **CC1E**: Capture/Compare 1 output enable
- 0: Capture mode disabled / OC1 is not active (see below)
- 1: Capture mode enabled / OC1 signal is output on the corresponding output pin

*When CC1 channel is configured as output*, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to *Table 585* for details.

</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 CCR1[19:0]: Capture/Compare 1 value

If channel CC1 is configured as output:
- CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
- It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
- The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.
- Non-dithering mode (DITHEN = 0)
  - The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.
- Dithering mode (DITHEN = 1)
  - The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input:
- CCR1 is the counter value transferred by the last input capture 1 event (tim_ic1).
- Non-dithering mode (DITHEN = 0)
  - The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.
- Dithering mode (DITHEN = 1)
  - The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.
### 56.8.14 TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17)

<td>1: Break input tim_brk is disarmed</td>
</tr>
<tr>
<td></td>
<td>This bit is cleared by hardware when no break source is active.</td>
</tr>
<tr>
<td></td>
<td>The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled it until it is reset by hardware, indicating that the fault condition has disappeared.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.</td>
</tr>
</tbody>
</table>
Bits 25:20  Reserved, must be kept at reset value.

Bits 19:16  **BKF[3:0]:** Break filter

This bit-field defines the frequency used to sample tim_brk input and the length of the digital filter applied to tim_brk. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

- **0000:** No filter, tim_brk acts asynchronously
- **0001:** \( f_{SAMPLING} = f_{t\text{im ker ck}} \), \( N=2 \)
- **0010:** \( f_{SAMPLING} = f_{t\text{im ker ck}} \), \( N=4 \)
- **0011:** \( f_{SAMPLING} = f_{t\text{im ker ck}} \), \( N=8 \)
- **0100:** \( f_{SAMPLING} = f_{DTS/2} \), \( N=6 \)
- **0101:** \( f_{SAMPLING} = f_{DTS/2} \), \( N=8 \)
- **0110:** \( f_{SAMPLING} = f_{DTS/4} \), \( N=6 \)
- **0111:** \( f_{SAMPLING} = f_{DTS/4} \), \( N=8 \)
- **1000:** \( f_{SAMPLING} = f_{DTS/6} \), \( N=6 \)
- **1001:** \( f_{SAMPLING} = f_{DTS/6} \), \( N=8 \)
- **1010:** \( f_{SAMPLING} = f_{DTS/16} \), \( N=5 \)
- **1011:** \( f_{SAMPLING} = f_{DTS/16} \), \( N=6 \)
- **1100:** \( f_{SAMPLING} = f_{DTS/32} \), \( N=5 \)
- **1101:** \( f_{SAMPLING} = f_{DTS/32} \), \( N=6 \)
- **1110:** \( f_{SAMPLING} = f_{DTS/32} \), \( N=8 \)
- **1111:** \( f_{SAMPLING} = f_{DTS/32} \), \( N=8 \)

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 15  **MOE:** Main output enable

This bit is cleared asynchronously by hardware as soon as the tim_brk input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

- **0:** tim_oc1 and tim_oc1n outputs are disabled or forced to idle state depending on the OSSI bit.
- **1:** tim_oc1 and tim_oc1n outputs are enabled if their respective enable bits are set (CC1E, CC1NE in TIMx_CCER register)

See tim_oc1/tim_oc1n enable description for more details (*Section 56.8.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 2427*).

Bit 14  **AOE:** Automatic output enable

- **0:** MOE can be set only by software
- **1:** MOE can be set by software or automatically at the next update event (if the tim_brk input is not active)

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13  **BKP:** Break polarity

- **0:** Break input tim_brk is active low
- **1:** Break input tim_brk is active high

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12  **BKE:** Break enable

- **0:** Break inputs (tim_brk and tim_sys_brk event) disabled
- **1:** Break inputs (tim_brk and tim_sys_brk event) enabled

*Note:* This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See timer ocx1/tim ocx1n enable description for more details (Section 56.8.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 2427).

0: When inactive, timer ocx1/tim ocx1n outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state).

1: When inactive, timer ocx1/tim ocx1n outputs are enabled with their inactive level as soon as CC1E=1 or CC1NE=1 (the output is still controlled by the timer).

*Note: This bit cannot be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See timer ocx1/tim ocx1n enable description for more details (Section 56.8.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 2427).

0: When inactive, timer ocx1/tim ocx1n outputs are disabled (timer ocx1/tim ocx1n enable output signal=0).

1: When inactive, timer ocx1/tim ocx1n outputs are forced first with their idle level as soon as CC1E=1 or CC1NE=1. timer ocx1/tim ocx1n enable output signal=1).

*Note: This bit cannot be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected

01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKBD/BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.*

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

\[
\text{DTG}[7:5]=0xx \implies DT=\text{DTG}[7:0]\times t_dig \text{ with } t_dig=t_{DTS}
\]

\[
\text{DTG}[7:5]=10x \implies DT=(64+\text{DTG}[5:0])\times t_dig \text{ with } t_dig=2\times t_{DTS}
\]

\[
\text{DTG}[7:5]=110 \implies DT=(32+\text{DTG}[4:0])\times t_dig \text{ with } t_dig=8\times t_{DTS}
\]

\[
\text{DTG}[7:5]=111 \implies DT=(32+\text{DTG}[4:0])\times t_dig \text{ with } t_dig=16\times t_{DTS}
\]

Example if \(t_{DTS}=125\text{ns (8MHz)}\), dead-time possible values are:

0 to 15875 ns by 125 ns steps,

16 µs to 31750 ns by 250 ns steps,

32 µs to 63 µs by 1 µs steps,

64 µs to 126 µs by 2 µs steps

*Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*
56.8.15  **TIMx timer deadtime register 2 (TIMx_DTR2)(x = 16 to 17)**

**Bits 31:14** Reserved, must be kept at reset value.  
**Bit 13** **BKCMP4P:** tim_brk_cmp4 input polarity  
This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.  
0: tim_brk_cmp4 input is active high  
1: tim_brk_cmp4 input is active low  
**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 12 **BKCMP3P**: tim_brk_cmp3 input polarity
This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp3 input is active high
1: tim_brk_cmp3 input is active low
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 11 **BKCMP2P**: tim_brk_cmp2 input polarity
This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp2 input is active high
1: tim_brk_cmp2 input is active low
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10 **BKCMP1P**: tim_brk_cmp1 input polarity
This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp1 input is active high
1: tim_brk_cmp1 input is active low
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 9 **BKINP**: TIMx_BKIN input polarity
This bit selects the TIMx_BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.
0: TIMx_BKIN input is active high
1: TIMx_BKIN input is active low
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **BKCMP8E**: tim_brk_cmp8 enable
This bit enables the tim_brk_cmp8 for the timer’s tim_brk input. mdf_brkx output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp8 input disabled
1: tim_brk_cmp8 input enabled
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7 **BKCMP7E**: tim_brk_cmp7 enable
This bit enables the tim_brk_cmp7 for the timer’s tim_brk input. tim_brk_cmp7 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp7 input disabled
1: tim_brk_cmp7 input enabled
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 6 **BKCMP6E**: tim_brk_cmp6 enable
This bit enables the tim_brk_cmp6 for the timer’s tim_brk input. tim_brk_cmp6 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp6 input disabled
1: tim_brk_cmp6 input enabled
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 5 **BKCMP5E**: tim_brk_cmp5 enable
This bit enables the tim_brk_cmp5 for the timer's tim_brk input. tim_brk_cmp5 output is 'OREd' with the other tim_brk sources.
0: tim_brk_cmp5 input disabled
1: tim_brk_cmp5 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 4 **BKCMP4E**: tim_brk_cmp4 enable
This bit enables the tim_brk_cmp4 for the timer's tim_brk input. tim_brk_cmp4 output is 'OREd' with the other tim_brk sources.
0: tim_brk_cmp4 input disabled
1: tim_brk_cmp4 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 3 **BKCMP3E**: tim_brk_cmp3 enable
This bit enables the tim_brk_cmp3 for the timer's tim_brk input. tim_brk_cmp3 output is 'OREd' with the other tim_brk sources.
0: tim_brk_cmp3 input disabled
1: tim_brk_cmp3 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 2 **BKCMP2E**: tim_brk_cmp2 enable
This bit enables the tim_brk_cmp2 for the timer's tim_brk input. tim_brk_cmp2 output is 'OREd' with the other tim_brk sources.
0: tim_brk_cmp2 input disabled
1: tim_brk_cmp2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 1 **BKCMP1E**: tim_brk_cmp1 enable
This bit enables the tim_brk_cmp1 for the timer's tim_brk input. tim_brk_cmp1 output is 'OREd' with the other tim_brk sources.
0: tim_brk_cmp1 input disabled
1: tim_brk_cmp1 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 0 **BKINE**: TIMx_BKIN input enable
This bit enables the TIMx_BKIN alternate function input for the timer's tim_brk input.
TIMx_BKIN input is 'OREd' with the other tim_brk sources.
0: TIMx_BKIN input disabled
1: TIMx_BKIN input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
### 56.8.18 TIMx alternate function register 2 (TIMx_AF2)(x = 16 to 17)

Bits 31:19 Reserved, must be kept at reset value.

**Bits 18:16 OCRSEL[2:0]:** tim_ocref_clr source selection  
These bits select the tim_ocref_clr input source.  
000: tim_ocref_clr0  
001: tim_ocref_clr1  
010: tim_ocref_clr2  
011: tim_ocref_clr3  
100: tim_ocref_clr4  
101: tim_ocref_clr5  
110: tim_ocref_clr6  
111: tim_ocref_clr7  
Refer to Section 56.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation.

*Note:* These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 15:0 Reserved, must be kept at reset value.

### 56.8.19 TIMx option register 1 (TIMx_OR1)(x = 16 to 17)

</tr>
</tbody>
</table>

**Bits 31:0 DMAB[31:0]:** DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address

\[(TIMx\_CR1\text{ address}) + (DBA + DMA\text{ index}) \times 4\]

where TIMx\_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx\_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx\_DCR).
56.8.22 TIM16/TIM17 register map

TIM16/TIM17 registers are mapped as 16-bit addressable registers as described in the table below:

Table 586. TIM16/TIM17 register map and reset values

| Offset | Register name       | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|--------|---------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

Refer to Section 2.3 for the register boundary addresses.
57  Basic timers (TIM6/TIM7)

57.1 TIM6/TIM7 introduction

The basic timers TIM6/TIM7 consist in a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used as generic timers for time-base generation.

The basic timer can also be used for triggering the digital-to-analog converter. This is done with the trigger output of the timer.

The timers are completely independent, and do not share any resources.

57.2 TIM6/TIM7 main features

Basic timer (TIM6/TIM7) features include:

• 16-bit auto-reload upcounter
• 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
• Synchronization circuit to trigger the DAC
• Interrupt/DMA generation on the update event: counter overflow
57.3 TIM6/TIM7 functional description

57.3.1 TIM6/TIM7 block diagram

Figure 716. Basic timer block diagram

57.3.2 TIM6/TIM7 internal signals

The table in this section summarizes the TIM inputs and outputs.

</tbody>
</table>
57.3.3 TIM6/TIM7 clocks

The timer bus interface is clocked by the `tim_pclk` APB clock.

The counter clock `tim_ker_ck` is connected to the `tim_pclk` input.

The CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock `tim_ker_ck`.

Figure 717 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

Figure 717. Control circuit in normal mode, internal clock divided by 1

57.3.4 Time-base unit

The main block of the programmable timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. The preload register is accessed each time an attempt is made to write or read the auto-reload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the auto-reload preload enable bit (ARPE) in the TIMx_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.
The counter is clocked by the prescaler output `tim_cnt_ck`, which is enabled only when the counter enable bit (CEN) in the TIMx_CR1 register is set.

Note that the actual counter enable signal `tim_cnt_en` is set 1 clock cycle after CEN bit set.

**Prescaler description**

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as the TIMx_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 718* and *Figure 719* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

*Figure 718. Counter timing diagram with prescaler division change from 1 to 2*
57.3.5 Counting mode

The counter counts from 0 to the auto-reload value (contents of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generate at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been written to 0, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIMx_CR1 register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.
Figure 720. Counter timing diagram, internal clock divided by 1

Write a new value in TIMx_ARR
Dithering mode

The time base effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This affects the way the TIMx_ARR is behaving, and is useful for adjusting the average counter period when the timer is used as a trigger (typically for a DAC).

The operating principle is to have the actual ARR value slightly changed (adding or not one timer clock period) over 16 consecutive counting periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average counting period.

The Figure 726 below presents the dithering principle applied to 4 consecutive counting periods.
When the dithering mode is enabled, the register coding is changed as following (see Figure 727 for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value

**Note:** The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The ARR[3:0] bits must be reset
3. The DITHEN bit must be reset
4. The CEN bit can be set (eventually with ARPE = 1).

The minimum frequency is given by the following formula:
Resolution = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{\text{MaxResolution}}

\text{Dithering mode disabled: } F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65536}

\text{Dithering mode enabled: } F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}}

\textbf{Note:} The maximum TIMx_ARR value is limited to 0xFFFFE in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on the Figure 728 below, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

\textbf{Figure 728. } F_{\text{Cnt}} resolution vs frequency

\text{The period changes are spread over 16 consecutive periods, as described in the Figure 729 below.}

\textbf{Figure 729. } PWM dithering pattern

</tbody>
</table>

The auto-reload and compare values increments are spread following specific patterns described in the Table 588 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.
57.3.6 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register’s bit 31 (TIMx_CNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

57.3.7 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receiving events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

57.3.8 TIM6/TIM7 DMA requests

The TIM6/TIM7 can generate a single DMA request, as shown in Table 589.

<table>
<thead>
<tr>
<th>DMA acronym</th>
<th>DMA request</th>
<th>Enable control bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>tim_upd_dma</td>
<td>Update</td>
<td>UDE</td>
</tr>
</tbody>
</table>

57.3.9 Debug mode

When the microcontroller enters debug mode (Cortex®-M33 core halted), the TIMx counter can either continue to work normally or be stopped.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to section Debug support (DBG).

57.3.10 TIM6/TIM7 low-power modes

<table>
<thead>

</tbody>
</table>

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable

0: Dithering disabled
1: Dithering enabled

*Note: The DITHEN bit can only be modified when CEN bit is reset.*

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx_ARR register is not buffered.
1: TIMx_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the CEN bit).
Bit 2 **URS:** Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generates an update interrupt or DMA request if enabled.
These events can be:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS:** Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN:** Counter enable
0: Counter disabled
1: Counter enabled
CEN is cleared automatically in one-pulse mode, when an update event occurs.
57.4.2 TIMx control register 2 (TIMx_CR2)(x = 6 to 7)

</tbody>
</table>

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **MMS[2:0]**: Master mode selection
These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:
- 000: **Reset** - the UG bit from the TIMx_EGR register is used as a trigger output (tim_trgo).
- 001: **Enable** - the Counter enable signal, tim_cnt_en, is used as a trigger output (tim_trgo).
It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated when the CEN control bit is written.
- 010: **Update** - The update event is selected as a trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

**Note:** The clock of the slave timer or the peripheral receiving the tim_trgo must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bits 3:0 Reserved, must be kept at reset value.

57.4.3 TIMx DMA/Interrupt enable register (TIMx_DIER)(x = 6 to 7)

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency \( f_{\text{cnt\_ck}} \) is equal to \( f_{\text{puc\_ck}} / (\text{PSC}[15:0] + 1) \).
PSC contains the value to be loaded into the active prescaler register at each update event. (including when the counter is cleared through UG bit of TIMx_EGR register.

**57.4.8 TIMx auto-reload register (TIMx_ARR)(x = 6 to 7)**

Address offset: 0x2C

Reset value: 0x0000 FFFF

<table>
<thead>
<tr>
<th></th>
<th>ARR[19:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>rw rw rw rw</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>ARR[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]**: Auto-reload value

ARR is the value to be loaded into the actual auto-reload register.

Refer to *Section 57.3.4: Time-base unit on page 2447* for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

*Non-dithering mode (DITHEN = 0)*
The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reserved.

*Dithering mode (DITHEN = 1)*
The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.
### 57.4.9 TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

#### Table 592. TIMx register map and reset values

58 Low-power timer (LPTIM)

58.1 Introduction

The LPTIM is a 16-bit timer that benefits from the ultimate developments in power consumption reduction. Thanks to its diversity of clock sources, the LPTIM is able to keep running in all power modes except for Standby mode. Given its capability to run even with no internal clock source, the LPTIM can be used as a “Pulse Counter” which can be useful in some applications. Also, the LPTIM capability to wake up the system from low-power modes, makes it suitable to realize “Timeout functions” with extremely low power consumption.

The LPTIM introduces a flexible clock scheme that provides the needed functionalities and performance, while minimizing the power consumption.

58.2 LPTIM main features

- 16 bit upcounter
- 3-bit prescaler with 8 possible dividing factors (1,2,4,8,16,32,64,128)
- Selectable clock
  - Internal clock sources: configurable internal clock source (see RCC section)
  - External clock source over LPTIM input (working with no LP oscillator running, used by Pulse Counter application)
- 16 bit ARR autoreload register
- 16 bit capture/compare register
- Continuous/One-shot mode
- Selectable software/hardware input trigger
- Programmable Digital Glitch filter
- Configurable output: Pulse, PWM
- Configurable I/O polarity
- Encoder mode
- Repetition counter
- Up to 2 independent channels for:
  - Input capture
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Interrupt generation on 10 events
- DMA request generation on the following events:
  - Update event
  - Input capture
58.3 LPTIM implementation

The table below describes LPTIM implementation on STM32U5 Series devices. The full set of features is implemented in LPTIM1, LPTIM2 and LPTIM3. LPTIM4 supports a smaller set of features.

Table 593. STM32U5 Series LPTIM features

<table>
<thead>

</tbody>
</table>
The LPTIM can be clocked using several clock sources. It can be clocked using an internal clock signal which can be any configurable internal clock source selectable through the RCC (see RCC section for more details). Also, the LPTIM can be clocked using an external clock signal injected on its external Input1. When clocked with an external clock source, the LPTIM may run in one of these two possible configurations:

- The first configuration is when the LPTIM is clocked by an external signal but in the same time an internal clock signal is provided to the LPTIM from configurable internal clock source (see RCC section).
- The second configuration is when the LPTIM is solely clocked by an external clock source through its external Input1. This configuration is the one used to realize Timeout function or Pulse counter function when all the embedded oscillators are turned off after entering a low-power mode.

Programming the CKSEL and COUNTMODE bits allows controlling whether the LPTIM uses an external clock source or an internal one.

When configured to use an external clock source, the CKPOL bits are used to select the external clock signal active edge. If both edges are configured to be active ones, an internal edge is selected.
clock signal must also be provided (first configuration). In this case, the internal clock signal frequency must be at least four times higher than the external clock signal frequency.

58.4.5 Glitch filter

The LPTIM inputs, either external (mapped to GPIOs) or internal (mapped on the chip-level to other embedded peripherals), are protected with digital filters that prevent any glitches and noise perturbations to propagate inside the LPTIM. This is in order to prevent spurious counts or triggers.

Before activating the digital filters, an internal clock source must first be provided to the LPTIM. This is necessary to guarantee the proper operation of the filters.

The digital filters are divided into three groups:
- The first group of digital filters protects the LPTIM internal or external inputs. The digital filters sensitivity is controlled by the CKFLT bits.
- The second group of digital filters protects the LPTIM internal or external trigger inputs. The digital filters sensitivity is controlled by the TRGFLT bits.
- The third group of digital filters protects the LPTIM internal or external input captures. The digital filters sensitivity is controlled by the ICxF bits.

Note: The digital filters sensitivity is controlled by groups. It is not possible to configure each digital filter sensitivity separately inside the same group.

The filter sensitivity acts on the number of consecutive equal samples that is detected on one of the LPTIM inputs to consider a signal level change as a valid transition. Figure 732 shows an example of glitch filter behavior in case of a 2 consecutive samples programmed.

![Glitch filter timing diagram](image)

Note: In case no internal clock signal is provided, the digital filter must be deactivated by setting the CKFLT, ICxF and TRGFLT bits to ‘0’. In that case, an external analog filter may be used to protect the LPTIM external inputs against glitches.
58.4.6 Prescaler

The LPTIM 16-bit counter is preceded by a configurable power-of-2 prescaler. The prescaler division ratio is controlled by the PRESC[2:0] 3-bit field. The table below lists all the possible division ratios:

<table>

| 58.4.7 Trigger multiplexer |

The LPTIM counter may be started either by software or after the detection of an active edge on one of the 8 trigger inputs.

TRIGEN[1:0] is used to determine the LPTIM trigger source:

- When TRIGEN[1:0] equals ‘00’, The LPTIM counter is started as soon as one of the CNTSTRT or the SNGSTRT bits is set by software. The three remaining possible values for the TRIGEN[1:0] are used to configure the active edge used by the trigger inputs. The LPTIM counter starts as soon as an active edge is detected.
- When TRIGEN[1:0] is different than ‘00’, TRIGSEL[2:0] is used to select which of the 8 trigger inputs is used to start the counter.

The external triggers are considered asynchronous signals for the LPTIM. So after a trigger detection, a two-counter-clock period latency is needed before the timer starts running due to the synchronization.

If a new trigger event occurs when the timer is already started it is ignored (unless timeout function is enabled).

Note: The timer must be enabled before setting the SNGSTRT/CNTSTRT bits. Any write on these bits when the timer is disabled is discarded by hardware.

Note: When starting the counter by software (TRIGEN[1:0] = 00), there is a delay of 3 kernel clock cycles between the LPTIM_CR register update (set one of SNGSTRT or CNTSTRT bits) and the effective start of the counter.
58.4.8 Operating mode

The LPTIM features two operating modes:

- The Continuous mode: the timer is free running, the timer is started from a trigger event and never stops until the timer is disabled.
- One-shot mode: the timer is started from a trigger event and stops when an LPTIM update event is generated.

One-shot mode

To enable the one-shot counting, the SNGSTRT bit must be set.

A new trigger event re-starts the timer. Any trigger event occurring after the counter starts and before the next LPTIM update event, is discarded.

In case an external trigger is selected, each external trigger event arriving after the SNGSTRT bit is set, and after the repetition counter has stopped (after the update event), and if the repetition register content is different from zero, the repetition counter gets reloaded with the value already contained by the repetition register and a new one-shot counting cycle is started as shown in Figure 733.

![Figure 733. LPTIM output waveform, single counting mode configuration when repetition register content is different than zero (with PRELOAD = 1)](MSv47414V1_LPTIM_RCR_LPTIM_RCR)

- Set-once mode activated:

Note that when the WAVE bitfield in the LPTIM_CFGR register is set, the Set-once mode is activated. In this case, the counter is only started once following the first trigger, and any subsequent trigger event is discarded as shown in Figure 734.
In case of software start (TRIGEN[1:0] = ‘00’), the SNGSTRT setting starts the counter for one-shot counting.

**Continuous mode**

To enable the continuous counting, the CNTSTRT bit must be set.

In case an external trigger is selected, an external trigger event arriving after CNTSTRT is set, starts the counter for continuous counting. Any subsequent external trigger event is discarded as shown in Figure 735.

In case of software start (TRIGEN[1:0] = ‘00’), setting CNTSTRT starts the counter for continuous counting.

PNG Figure 734. LPTIM output waveform, Single counting mode configuration and Set-once mode activated (WAVE bit is set)

SNGSTRT and CNTSTRT bits can only be set when the timer is enabled (The ENABLE bit is set to ‘1’). It is possible to change “on the fly” from One-shot mode to Continuous mode.

If the Continuous mode was previously selected, setting SNGSTRT switches the LPTIM to the One-shot mode. The counter (if active) stops as soon as an LPTIM update event is generated.

If the One-shot mode was previously selected, setting CNTSTRT switches the LPTIM to the Continuous mode. The counter (if active) restarts as soon as it reaches ARR.
58.4.9 Timeout function

The detection of an active edge on one selected trigger input can be used to reset the LPTIM counter. This feature is controlled through the TIMOUT bit.

The first trigger event starts the timer, any successive trigger event resets the LPTIM counter and the repetition counter and the timer restarts.

A low-power timeout function can be realized. The timeout value corresponds to the compare value; if no trigger occurs within the expected time frame, the MCU is waked-up by the compare match event.

58.4.10 Waveform generation

Two 16-bit registers, the LPTIM_ARR (autoreload register) and LPTIM_CCRx (capture/compare register), are used to generate several different waveforms on LPTIM output.

The timer can generate the following waveforms:

- The PWM mode: the LPTIM output is set as soon as the counter value in LPTIM_CNT exceeds the compare value in LPTIM_CCRx. The LPTIM output is reset as soon as a match occurs between the LPTIM_ARR and the LPTIM_CNT register. For more details see Section 58.4.19: PWM mode.
- The One-pulse mode: the output waveform is similar to the one of the PWM mode for the first pulse, then the output is permanently reset
- The Set-once mode: the output waveform is similar to the One-pulse mode except that the output is kept to the last signal level (depends on the output configured polarity).

The above described modes require that the LPTIM_ARR register value be strictly greater than the LPTIM_CCRx register value.

The LPTIM output waveform can be configured through the WAVE bit as follow:

- Resetting the WAVE bit to ‘0’ forces the LPTIM to generate either a PWM waveform or a One pulse waveform depending on which bit is set: CNTSTRT or SNGSTRT.
- Setting the WAVE bit to ‘1’ forces the LPTIM to generate a Set-once mode waveform.

The WAVPOL/CCxP bit controls the LPTIM output polarity. The change takes effect immediately, so the output default value changes immediately after the polarity is re-configured, even before the timer is enabled.

Signals with frequencies up to the LPTIM clock frequency divided by 2 can be generated. Figure 736 below shows the three possible waveforms that can be generated on the LPTIM output. Also, it shows the effect of the polarity change using the WAVPOL/CCxP bit.
58.4.11 Register update

The LPTIM_ARR register, the LPTIM_RCR register and the LPTIM_CCRx register are updated immediately after the APB bus write operation or in synchronization with the next LPTIM update event if the timer is already started.

The PRELOAD bit controls how the LPTIM_ARR, the LPTIM_RCR and the LPTIM_CCRx registers are updated:

- When the PRELOAD bit is reset to ‘0’, the LPTIM_ARR, the LPTIM_RCR and the LPTIM_CCRx registers are immediately updated after any write access.
- When the PRELOAD bit is set to ‘1’, the LPTIM_ARR, the LPTIM_RCR and the LPTIM_CCRx registers are updated at next LPTIM update event, if the timer has been already started.

The LPTIM APB interface and the LPTIM kernel logic use different clocks, so there is some latency between the APB write and the moment when these values are available to the counter comparator. Within this latency period, any additional write into these registers must be avoided.

The ARROK flag, the REPOK flag and the CMPxOK flag in the LPTIM_ISR register indicate when the write operation is completed to respectively the LPTIM_ARR register, the LPTIM_RCR register and the LPTIM_CCRx register.

After a write to the LPTIM_ARR, the LPTIM_RCR or the LPTIM_CCRx register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before respectively the ARROK flag, the REPOK flag or the CMPxOK flag be set, leads to unpredictable results.
58.4.12 Counter mode

The LPTIM counter can be used to count external events on the LPTIM Input1 or it can be used to count internal clock cycles. The CKSEL and COUNTMODE bits control which source is used for updating the counter.

In case the LPTIM is configured to count external events on Input1, the counter can be updated following a rising edge, falling edge or both edges depending on the value written to the CKPOL[1:0] bits.

The count modes below can be selected, depending on CKSEL and COUNTMODE values:

- **CKSEL = 0**: the LPTIM is clocked by an internal clock source
  - **COUNTMODE = 0**: The LPTIM is configured to be clocked by an internal clock source and the LPTIM counter is configured to be updated following each internal clock pulse.
  - **COUNTMODE = 1**: The LPTIM external Input1 is sampled with the internal clock provided to the LPTIM.

Consequently, in order not to miss any event, the frequency of the changes on the external Input1 signal must never exceed the frequency of the internal clock provided to the LPTIM. Also, the internal clock provided to the LPTIM must not be prescaled (PRES[2:0] = 000).

- **CKSEL = 1**: the LPTIM is clocked by an external clock source
  COUNTMODE value is don’t care.

In this configuration, the LPTIM has no need for an internal clock source (except if the glitch filters are enabled). The signal injected on the LPTIM external Input1 is used as system clock for the LPTIM. This configuration is suitable for operation modes where no embedded oscillator is enabled.

For this configuration, the LPTIM counter can be updated either on rising edges or falling edges of the input1 clock signal but not on both rising and falling edges.

Since the signal injected on the LPTIM external Input1 is also used to clock the LPTIM kernel logic, there is some initial latency (after the LPTIM is enabled) before the counter is incremented. More precisely, the first five active edges on the LPTIM external Input1 (after LPTIM is enable) are lost.

58.4.13 Timer enable

The ENABLE bit located in the LPTIM.CR register is used to enable/disable the LPTIM kernel logic. After setting the ENABLE bit, a delay of two counter clock is needed before the LPTIM is actually enabled.

The LPTIM.CFGR register must be modified only when the LPTIM is disabled.
58.4.14 Timer counter reset

In order to reset the content of LPTIM_CNT register to zero, two reset mechanisms are implemented:

- The synchronous reset mechanism: the synchronous reset is controlled by the COUNTRST bit in the LPTIM_CR register. After setting the COUNTRST bitfield to ‘1’, the reset signal is propagated in the LPTIM kernel clock domain. So it is important to note that a few clock pulses of the LPTIM kernel logic elapse before the reset is taken into account. This makes the LPTIM counter count few extra pulses between the time when the reset is trigger and it become effective. Since the COUNTRST bit is located in the APB clock domain and the LPTIM counter is located in the LPTIM kernel clock domain, a delay of 3 clock cycles of the kernel clock is needed to synchronize the reset signal issued by the APB clock domain when writing ‘1’ to the COUNTRST bit.

- The asynchronous reset mechanism: the asynchronous reset is controlled by the RSTARE bit located in the LPTIM_CR register. When this bit is set to ‘1’, any read access to the LPTIM_CNT register resets its content to zero. Asynchronous reset must be triggered within a timeframe in which no LPTIM core clock is provided. For example when LPTIM Input1 is used as external clock source, the asynchronous reset must be applied only when there is enough insurance that no toggle occurs on the LPTIM Input1.

Note that to read reliably the content of the LPTIM_CNT register two successive read accesses must be performed and compared. A read access can be considered reliable when the value of the two read accesses is equal. Unfortunately when asynchronous reset is enabled there is no possibility to read twice the LPTIM_CNT register.

---

**Warning:** There is no mechanism inside the LPTIM that prevents the two reset mechanisms from being used simultaneously. So developer must make sure that these two mechanisms are used exclusively.

---

58.4.15 Encoder mode

This mode allows handling signals from quadrature encoders used to detect angular position of rotary elements. Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value programmed into the LPTIM_ARR register (0 up to ARR or ARR down to 0 depending on the direction). Therefore LPTIM_ARR must be configured before starting the counter. From the two external input signals, Input1 and Input2, a clock signal is generated to clock the LPTIM counter. The phase between those two signals determines the counting direction.

The Encoder mode is only available when the LPTIM is clocked by an internal clock source. The signals frequency on both Input1 and Input2 inputs must not exceed the LPTIM internal clock frequency divided by 4. This is mandatory in order to guarantee a proper operation of the LPTIM.

Direction change is signalized by the two Down and Up flags in the LPTIM_ISR register. Also, an interrupt can be generated for both direction change events if enabled through the DOWNIE bit.
To activate the Encoder mode the ENC bit has to be set to ‘1’. The LPTIM must first be configured in Continuous mode.

When Encoder mode is active, the LPTIM counter is modified automatically following the speed and the direction of the incremental encoder. Therefore, its content always represents the encoder’s position. The count direction, signaled by the Up and Down flags, correspond to the rotation direction of the encoder rotor.

According to the edge sensitivity configured using the CKPOL[1:0] bits, different counting scenarios are possible. The following table summarizes the possible combinations, assuming that Input1 and Input2 do not switch at the same time.

<table>
<thead>
<tr>
<th>Active edge</th>
<th>Level on opposite signal (Input1 for Input2, Input2 for Input1)</th>
<th>Input1 signal</th>
<th>Input2 signal</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Rising</td>
<td>Falling</td>
<td>Rising</td>
</tr>
<tr>
<td>Rising Edge</td>
<td>High</td>
<td>Down</td>
<td>No count</td>
</tr>
<tr>
<td></td>
<td>Low</td>
<td>Up</td>
<td>No count</td>
</tr>
<tr>
<td>Falling Edge</td>

<td>Down</td>
</tr>
<tr>
<td>Both Edges</td>
<td>High</td>
<td>Down</td>
<td>Up</td>
</tr>
<tr>
<td></td>
<td>Low</td>
<td>Up</td>
<td>Down</td>
</tr>
</tbody>
</table>

The following figure shows a counting sequence for Encoder mode where both-edge sensitivity is configured.

**Caution:** In this mode the LPTIM must be clocked by an internal clock source, so the CKSEL bit must be maintained to its reset value which is equal to ‘0’. Also, the prescaler division ratio must be equal to its reset value which is 1 (PRESC[2:0] bits must be ‘000’).
58.4.16 Repetition Counter

The LPTIM features a repetition counter that decrements by 1 each time an LPTIM counter overflow event occurs. A repetition counter underflow event is generated when the repetition counter contains zero and the LPTIM counter overflows. Next to each repetition counter underflow event, the repetition counter gets loaded with the content of the REP[7:0] bitfield which belongs to the repetition register LPTIM_RCR.

A repetition underflow event is generated on each and every LPTIM counter overflow when the REP[7:0] register is set to 0.

When PRELOAD = 1, writing to the REP[7:0] bitfield has no effect on the content of the repetition counter until the next repetition underflow event occurs. The repetition counter continues to decrement each LPTIM counter overflow event and only when a repetition underflow event is generated, the new value written into REP[7:0] is loaded into the repetition counter. This behavior is depicted in Figure 738.
A repetition counter underflow event is systematically associated with LPTIM preloaded registers update (refer to section "Register update" for more information).

Repetition counter underflow event is signaled to the software through the update event (UE) flag mapped into the LPTIM_ISR register. When set, the UE flag can trigger an LPTIM interrupt if its respective update event interrupt enable (UEIE) control bit, mapped to the LPTIM_DIER register, is set.

The repetition register LPTIM_RCR is located in the APB bus interface clock domain where the repetition counter itself is located in the LPTIM kernel clock domain. Each time a new value is written to the LPTIM_RCR register, that new content is propagated from the APB bus interface clock domain to the LPTIM kernel clock domain so that the new written value is loaded to the repetition counter immediately after a repetition counter underflow event. The synchronization delay for the new written content is four APB clock cycles plus three LPTIM kernel clock cycles and it is signaled by the REPOK flag located in the LPTIM_ISR register when it is elapsed. When the LPTIM kernel clock cycle is relatively slow, for instance when the LPTIM kernel is being clocked by the LSI clock source, it can be lengthy to keep polling on the REPOK flag by software to detect that the synchronization of the LPTIM_RCR register content is finished. For that reason, the REPOK flag, when set, can generate an interrupt if its associated REPOKIE control bit in the LPTIM_DIER register is set.

Note: After a write to the LPTIM_RCR register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before the REPOK flag is set, leads to unpredictable results.

Caution: When using repetition counter with PRELOAD = 0, LPTIM_RCR register must be changed at least five counter cycles before the autoreload match event, otherwise an unpredictable behavior may occur.
58.4.17 Capture/compare channels

Each capture/compare channel is built around a capture/compare register, an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control) for PWM.

Input stage

The input stage samples the corresponding LPTIx input to generate a filtered signal LPTIxF. Then, an edge detector with polarity selection generates ICx signal used as the capture command. It is prescaled to generate the capture command signal (ICxPS).

Output stage

The output stage generates an intermediate waveform which is then used for reference: OCxREF (active high). The polarity acts at the end of the chain.

58.4.18 Input capture mode

In input capture mode, the capture/compare registers (LPTIM_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. Assuming input capture is enabled on a channel x (CCxE set) and when a capture occurs, the corresponding CCxF flag (LPTIM_ISR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (LPTIM_ISR register) is set. CCxIF can be cleared by software by writing the CCxICF to 1 or by reading the captured data stored in the LPTIM_CCRx register. CCxOF is cleared by writing CCxOCF to 1.

Note: In DMA mode, the input capture channel have to be enabled (set CCxE bit) the last, after enabling the IC DMA request and after starting the counter. This is in order to prevent generating an input capture DMA request when the counter is not started yet.

Input capture Glitch filter latency

When a trigger event arrives on channel x input (LPTIx) and depending on the configured glitch filter (ICxF[1:0] field in CCMRx register) and on the kernel clock prescaler value
(PRESC[2:0] field in CFGR register), there is a variable latency that leads to a systematic offset (see Table 607) between the captured value stored in the CCRx register and the real value corresponding to the capture trigger.

This offset has no impact on pulse width measurement as it is systematic and compensated between two captures.

The real capture value corresponding to the input capture trigger can be calculated using the below formula:

Real capture value = captured(LPTIM_CCRx) - offset

The relevant offset must be used depending on the glitch filter and on the kernel clock prescaler value (PRESC field in CFGR register)

**Example:** determining the real capture value when PRESC[2:0] = 0x2 and ICxF = 0x3.

For this configuration (PRESC[2:0] = 0x2 and ICxF = 0x3) and according to the Table 607, the offset is 5.

Assuming that the captured value in CCRx is 9 (LPTIM_CNT = 9), this means that the capture trigger occurred when the LPTIM_CNT was equal to 9 - 5 = 4.

58.4.19 PWM mode

The PWM mode enables to generate a signal with a frequency determined by the value of the LPTIM_ARR register and a duty cycle determined by the value of the LPTIM_CCRx register. The LPTIM is able to generate PWM in edge-aligned mode.

OCx polarity is software programmable using the CCxP bit in the LPTIM_CCMRx register. It can be programmed as active high or active low. OCx output is enabled by the CCxE bit in the LPTIM_CCMRx register. Refer to the LPTIM_CCMRx register description for more details.

Figure 741 gives an example where the LPTIM channel 1 is configured in PWM mode with LPTIM_CCR1 = 6 then 1 and LPTIM_ARR=10.

In the following example the reference PWM signal OCxREF is low as long as LPTIM_CNT ≤ LPTIM_CCRx else it becomes high.
Figure 742 shows some edge-aligned PWM waveforms in an example where LPTIM_ARR = 8.

Figure 742. Edge-aligned PWM waveforms (ARR=8 and CCxP = 0)

PWM mode with immediate update PRELOAD = 0

The PWM mode with PRELOAD = 0 enables the early change of the output level within the current PWM cycle. Based on the immediate update (PRELOAD = 0) of the LPTIM_CCRx register and on the continuous comparison of LPTIM_CNT and LPTIM_CCRx registers, it permits to have a new duty cycle value applied as soon as possible within the current PWM cycle, without having to wait for the completion of the current PWM period.

When the (PRELOAD = 0), the OCxREF signal level can be changed on-the-fly by software (or DMA) by updating the compare value in the LPTIM_CCRx register.

Depending on the written compare value and on the current counter and compare values, the OCxREF level is re-assigned as illustrated below:

- If the new compare value does not exceed the current counter value and the current compare value exceeds the counter, OCxREF level is re-assigned high as soon as the new compare value is written.
- If the new compare value exceeds the counter value and the current compare value does not exceed the counter, OCxREF level is re-assigned low as soon as the new compare value is written.

The output reference signal OCxREF level is left unchanged when none of the new compare value and the current compare value exceed the counter. Figure 743 illustrates the behavior of the OCxREF signal level when PRELOAD = 0 and PRELOAD = 1.
Note: For both PWM modes, the compare match, auto-reload match and the update event flags are set one LPTIM counter cycle later after the corresponding event, the OCxREF level is also changed one LPTIM counter cycle later after the corresponding event. For instance when the LPTIM_CCRx is set to 3 the CCxIF is set when the LPTIM_CNT = 4. Figure 741 illustrates this behavior.

58.4.20 Autonomous mode

When clocked by oscillators available in this mode (refer to RCC), the LPTIM can operate in autonomous mode, permitting it to remain fully functional in Stop mode where the APB clock is stopped. The APB clock is requested by the peripheral each time a data must be transferred from or to the SRAM. Once the APB clock is received by the peripheral, either an interrupt or a DMA request is generated, depending on the LPTIM configuration.

In order to offload the CPU (in Run mode) or to avoid to wake it up when in Stop mode, it is possible to use LPTIM DMA requests to transfer the captured values when in input capture mode or to update LPTIM registers when in PWM mode.

When in Stop mode, the LPTIM counter can be automatically started after the detection of an active edge on one of its external input triggers.

Input capture mode

To operate autonomously in stop mode, the input capture DMA request must be enabled by setting the CCxDE bit in the LPTIM_DIER register.

Each time a counter value is captured and available in the LPTIM_CCRx register, the APB clock is requested by the peripheral and a DMA request is generated. The captured value is then transferred to the SRAM. The CCxIF flag is automatically cleared by hardware once the captured value is read by APB (can be any bus master like CPU or DMA).

PWM mode

The LPTIM can be configured to autonomously change, at each update event, the output waveform pulse width and/or the duty cycle without any CPU intervention. To enable this autonomous mode, the corresponding UEDE bit must be set in the LPTIM_DIER register.
At each update event, the APB clock is requested by the peripheral and a DMA request is generated. DMA direction must be configured as memory-to-peripheral which enables updating LPTIM registers, at each DMA request, with values stored in SRAM.

The UE flag is automatically cleared by hardware once the LPTIM_ARR register is written by any bus master like CPU or DMA. Thus, to enable automatic hardware clearing of UE flag, the application must configure the LPTIM_ARR register to be the last one to be written (at the end of list). For instance if LPTIM_CCR1 and LPTIM_RCR registers need to be updated in Stop mode by DMA, the update sequence must be: LPTIM_CCR1, LPTIM_RCR then LPTIM_ARR.

The UE flag can also be cleared over its corresponding clear bit UECF in the LPTIM_ICR register, this can be done by configuring the DMA to write the LPTIM_ICR register at the end of register update.

58.4.21 DMA requests

The LPTIM has the capability to generate two categories of DMA requests:

- DMA requests used to retrieve the input-capture counter values
- DMA update requests are used to re-program part of the LPTIMER, multiple times, at regular intervals, without software overhead.

Input capture DMA request

Each LPTIM channel has its dedicated input capture DMA request. A DMA request is generated (if CCxDE bit is set in LPTIM_DIER) and CCxIF is set each time a capture is ready in the CCRx register. The captured values in CCRx can then be transferred regularly by DMA to the desired memory destination. The CCxIF is automatically cleared by hardware when the captured value in CCRx register is read.

**Note:** The ICx DMA request signal lptim_icx_dma is reset in the following conditions:
- if the corresponding DMA request is disabled (clear CCxDE bit in the LPTIM_DIER register)
- or if the channel x is disabled (clear CCxE bit)
- or if the LPTIM is disabled (clear the ENABLE bit in the LPTIM_CR register)

Update event DMA request

A DMA request is generated (if UEDE is set in LPTIM_DIER) and the UE flag is set at each update event. DMA request can be used to regularly update the LPTIM_ARR, the LPTIM_RCR or the LPTIM_CCRx registers permitting to generate custom PWM waveforms.

The UE is automatically cleared by hardware upon any bus master (like CPU or DMA) write access to the LPTIM_ARR register.

**Note:** The UE DMA request signal lptim_ue_dma is reset in the following conditions:
- if the corresponding DMA request is disabled (clear UEDE bit in the LPTIM_DIER register)
- or if the LPTIM is disabled (clear the ENABLE bit in the LPTIM_CR register)

58.4.22 Debug mode

When the microcontroller enters debug mode (core halted), the LPTIM counter either continues to work normally or stops, depending on the DBG_LPTIM_STOP configuration bit in the DBG module.
58.5 LPTIM low-power modes

</tbody>
</table>

1. Only LPTIM1 and LPTIM3 support autonomous mode with wake-up capability in Stop 2 mode. LPTIM4 does not support autonomous mode but has wake-up capability in stop 2 mode. LPTIM2 must be disabled before entering Stop 2 mode.

58.6 LPTIM interrupts

The following events generate an interrupt/wake-up event, if they are enabled through the LPTIM_DIER register:

- Compare match
- Auto-reload match (whatever the direction if encoder mode)
- External trigger event
- Autoreload register write completed
- Compare register write completed
- Direction change (encoder mode), programmable (up / down / both).
- Update Event
- Repetition register update OK
- Input capture occurred
- Over-capture occurred
- Interrupt enable register update OK

**Note:** If any bit in the LPTIM_DIER register is set after that its corresponding flag in the LPTIM_ISR register (Status Register) is set, the interrupt is not asserted.

1. Each LPTIM event can wake up the device from Stop mode only if the LPTIM instance supports the wake-up from Stop mode feature. Refer to Section 58.3: LPTIM implementation.
2. If LPTIM does not implement any channel this event does not exist. Refer to Section 58.3: LPTIM implementation.
3. If LPTIM does not support encoder mode feature, this event does not exist. Refer to Section 58.3: LPTIM implementation.

58.7 LPTIM registers

Refer to Section 1.2: List of abbreviations for registers on page 126 for a list of abbreviations used in register descriptions.
The peripheral registers can only be accessed by words (32-bit).

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 DIEROK: Interrupt enable register update OK
DIEROK is set by hardware to inform application that the APB bus write operation to the LPTIM_DIER register has been successfully completed. DIEROK flag can be cleared by writing 1 to the DIEROKCF bit in the LPTIM_ICR register.

Bits 23:9 Reserved, must be kept at reset value.

Bit 8 REPOK: Repetition register update OK
REPOK is set by hardware to inform application that the APB bus write operation to the LPTIM_RCR register has been successfully completed. REPOK flag can be cleared by writing 1 to the REPOKCF bit in the LPTIM_ICR register.

Bit 7 UE: LPTIM update event occurred
UE is set by hardware to inform application that an update event was generated. UE flag can be cleared by writing 1 to the UECF bit in the LPTIM_ICR register.

Bit 6 DOWN: Counter direction change up to down
In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM_ICR register.

Note: **If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3: LPTIM implementation.**

Bit 5 UP: Counter direction change down to up
In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM_ICR register.

Note: **If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3: LPTIM implementation.**

Bit 4 ARROK: Autoreload register update OK
ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM_ICR register.

Bit 3 CMP1OK: Compare register 1 update OK
CMP1OK is set by hardware to inform application that the APB bus write operation to the LPTIM_CCR1 register has been successfully completed. CMP1OK flag can be cleared by writing 1 to the CMP1OKCF bit in the LPTIM_ICR register.
Bit 2 **EXTTRIG**: External trigger edge event
EXTTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTTRIG flag can be cleared by writing 1 to the EXTTRIGCF bit in the LPTIM_ICR register.

Bit 1 **ARRM**: Autoreload match
ARRM is set by hardware to inform application that LPTIM_CNT register’s value reached the LPTIM_ARR register’s value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM_ICR register.

Bit 0 **CC1IF**: Compare 1 interrupt flag
The CC1IF flag is set by hardware to inform application that LPTIM_CNT register value matches the compare register’s value. The CC1IF flag can be cleared by writing 1 to the CC1CF bit in the LPTIM_ICR register.

0: No match
1: The content of the counter LPTIM_CNT register value has matched the LPTIM_CCR1 register's value

---

**58.7.2 LPTIMx interrupt and status register [alternate] (LPTIMx_ISR) (x = 1 to 3)**

This description of the register can only be used for output compare mode. See next section for input capture mode.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DIEROK**: Interrupt enable register update OK
DIEROK is set by hardware to inform application that the APB bus write operation to the LPTIM_DIER register has been successfully completed. DIEROK flag can be cleared by writing 1 to the DIEROKCF bit in the LPTIM_ICR register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 Reserved, must be kept at reset value.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **CMP2OK**: Compare register 2 update OK
CMP2OK is set by hardware to inform application that the APB bus write operation to the LPTIM_CCR2 register has been successfully completed. CMP2OK flag can be cleared by writing 1 to the CMP2OKCF bit in the LPTIM_ICR register.

**Note**: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 58.3.

Bits 18:12 Reserved, must be kept at reset value.
Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC2IF**: Compare 2 interrupt flag

If channel CC2 is configured as output:
The CC2IF flag is set by hardware to inform application that LPTIM_CNT register value matches the compare register's value. CC2IF flag can be cleared by writing 1 to the CC2CF bit in the LPTIM_ICR register.
0: No match
1: The content of the counter LPTIM_CNT register value has matched the LPTIM_CCR2 register's value

*Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 58.3.*

Bit 8 **REPOK**: Repetition register update OK

REPOK is set by hardware to inform application that the APB bus write operation to the LPTIM_RCR register has been successfully completed. REPOK flag can be cleared by writing 1 to the REPOKCF bit in the LPTIM_ICR register.

Bit 7 **UE**: LPTIM update event occurred

UE is set by hardware to inform application that an update event was generated. The corresponding interrupt or DMA request is generated if enabled. UE flag can be cleared by writing 1 to the UECF bit in the LPTIM_ICR register. The UE flag is automatically cleared by hardware once the LPTIM_ARR register is written by any bus master like CPU or DMA.

Bit 6 **DOWN**: Counter direction change up to down

In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM_ICR register.

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3.*

Bit 5 **UP**: Counter direction change down to up

In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM_ICR register.

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3.*

Bit 4 **ARROK**: Autoreload register update OK

ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM_ICR register.

Bit 3 **CMP1OK**: Compare register 1 update OK

CMP1OK is set by hardware to inform application that the APB bus write operation to the LPTIM_CCR1 register has been successfully completed. CMP1OK flag can be cleared by writing 1 to the CMP1OKCF bit in the LPTIM_ICR register.
Bit 2 **EXTTRIG**: External trigger edge event

EXTTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTTRIG flag can be cleared by writing 1 to the EXTTRIGCF bit in the LPTIM_ICR register.

Bit 1 **ARRM**: Autoreload match

ARRM is set by hardware to inform application that LPTIM_CNT register's value reached the LPTIMARR register's value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM_ICR register.

Bit 0 **CC1IF**: Compare 1 interrupt flag

*If channel CC1 is configured as output:*

The CC1IF flag is set by hardware to inform application that LPTIM_CNT register value matches the compare register's value. CC1IF flag can be cleared by writing 1 to the CC1CF bit in the LPTIM_ICR register.

- 0: No match
- 1: The content of the counter LPTIM_CNT register value has matched the LPTIM_CCR1 register's value

### 58.7.3 LPTIMx interrupt and status register [alternate] (LPTIMx_ISR)

(x = 1 to 3)

This description of the register can only be used for input capture mode. See previous section for output compare mode.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DIEROK**: Interrupt enable register update OK

DIEROK is set by hardware to inform application that the APB bus write operation to the LPTIM_DIER register has been successfully completed. DIEROK flag can be cleared by writing 1 to the DIEROKCF bit in the LPTIM_ICR register.

Bits 23:16 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC2OF**: Capture 2 over-capture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing 1 to the CC2OCF bit in the LPTIM_ICR register.

- 0: No over-capture has been detected.
- 1: The counter value has been captured in LPTIM_CCR2 register while CC2IF flag was already set.

Note: *If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 58.3.*
Bit 12 CC1OF: Capture 1 over-capture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing 1 to the CC1OCF bit in the LPTIM_ICR register.
0: No over-capture has been detected.
1: The counter value has been captured in LPTIM_CCR1 register while CC1IF flag was already set.
   
   Note: If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 58.3.

Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 CC2IF: Capture 2 interrupt flag
If channel CC2 is configured as input:
CC2IF is set by hardware to inform application that the current value of the counter is captured in LPTIM_CCR2 register. The corresponding interrupt or DMA request is generated if enabled. The CC2OF flag is set if the CC2IF flag was already high.
0: No input capture occurred
1: The counter value has been captured in the LPTIM_CCR2 register. (An edge has been detected on IC2 which matches the selected polarity). The CC2IF flag is automatically cleared by hardware once the captured value is read (CPU or DMA). The CC2IF flag can be cleared by writing 1 to the CC2CF bit in the LPTIM_ICR register.
   
   Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 58.3.

Bit 8 REPOK: Repetition register update OK
REPOK is set by hardware to inform application that the APB bus write operation to the LPTIM_RCR register has been successfully completed. REPOK flag can be cleared by writing 1 to the REPOKCF bit in the LPTIM_ICR register.

Bit 7 UE: LPTIM update event occurred
UE is set by hardware to inform application that an update event was generated. UE flag can be cleared by writing 1 to the UECF bit in the LPTIM_ICR register.

Bit 6 DOWN: Counter direction change up to down
In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM_ICR register.
   
   Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3.

Bit 5 UP: Counter direction change down to up
In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM_ICR register.
   
   Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3.

Bit 4 ARROK: Autoreload register update OK
ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM_ICR register.

Bit 3 Reserved, must be kept at reset value.

Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 58.3.
Bit 8  **REPOKCF**: Repetition register update OK clear flag  
Writing 1 to this bit clears the REPOK flag in the LPTIM_ISR register.

Bit 7  **UECF**: Update event clear flag  
Writing 1 to this bit clears the UE flag in the LPTIM_ISR register.

Bit 6  **DOWNCF**: Direction change to down clear flag  
Writing 1 to this bit clears the DOWN flag in the LPTIM_ISR register.  
*Note*: *If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3.*

Bit 5  **UPCF**: Direction change to UP clear flag  
Writing 1 to this bit clears the UP flag in the LPTIM_ISR register.  
*Note*: *If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3.*

Bit 4  **ARROKCF**: Autoreload register update OK clear flag  
Writing 1 to this bit clears the ARROK flag in the LPTIM_ISR register.

Bit 3  **CMP1OKCF**: Compare register 1 update OK clear flag  
Writing 1 to this bit clears the CMP1OK flag in the LPTIM_ISR register.

Bit 2  **EXTTRIGCF**: External trigger valid edge clear flag  
Writing 1 to this bit clears the EXTTRIG flag in the LPTIM_ISR register.

Bit 1  **ARRMCF**: Autoreload match clear flag  
Writing 1 to this bit clears the ARRM flag in the LPTIM_ISR register.

Bit 0  **CC1CF**: Capture/compare 1 clear flag  
Writing 1 to this bit clears the CC1IF flag in the LPTIM_ISR register.

*Bits 31:25*  Reserved, must be kept at reset value.

**Bit 24  DIEROKCF**: Interrupt enable register update OK clear flag  
Writing 1 to this bit clears the DIEROK flag in the LPTIM_ISR register.

**Bits 23:16**  Reserved, must be kept at reset value.

**Bit 15**  Reserved, must be kept at reset value.

**Bit 14**  Reserved, must be kept at reset value.
Bit 13 **CC2OCF**: Capture/compare 2 over-capture clear flag
Writing 1 to this bit clears the CC2OF flag in the LPTIM_ISR register.
*Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 58.3.*

Bit 12 **CC1OCF**: Capture/compare 1 over-capture clear flag
Writing 1 to this bit clears the CC1OF flag in the LPTIM_ISR register.
*Note: If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 58.3.*

Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC2CF**: Capture/compare 2 clear flag
Writing 1 to this bit clears the CC2IF flag in the LPTIM_ISR register.
*Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 58.3.*

Bit 8 **REPOKCF**: Repetition register update OK clear flag
Writing 1 to this bit clears the REPOK flag in the LPTIM_ISR register.

Bit 7 **UECF**: Update event clear flag
Writing 1 to this bit clears the UE flag in the LPTIM_ISR register.

Bit 6 **DOWNCF**: Direction change to down clear flag
Writing 1 to this bit clears the DOWN flag in the LPTIM_ISR register.
*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3.*

Bit 5 **UPCF**: Direction change to UP clear flag
Writing 1 to this bit clears the UP flag in the LPTIM_ISR register.
*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3.*

Bit 4 **ARROKCF**: Autoreload register update OK clear flag
Writing 1 to this bit clears the ARROK flag in the LPTIM_ISR register.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **EXTTRIGCF**: External trigger valid edge clear flag
Writing 1 to this bit clears the EXTTRIG flag in the LPTIM_ISR register.

Bit 1 **ARRMCF**: Autoreload match clear flag
Writing 1 to this bit clears the ARRM flag in the LPTIM_ISR register.

Bit 0 **CC1CF**: Capture/compare 1 clear flag
Writing 1 to this bit clears the CC1IF flag in the LPTIM_ISR register.

### 58.7.7 LPTIM4 interrupt enable register (LPTIM4_DIER)

Address offset: 0x008
Reset value: 0x0000 0000

Caution: The LPTIMx_DIER register must only be modified when the LPTIM is enabled (ENABLE bit set to 1). After a write to the LPTIMx_DIER register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before the DIEROK flag is set, leads to unpredictable results.
58.7.8  LPTIMx interrupt enable register [alternate] (LPTIMx_DIER)  
(x = 1 to 3)

This description of the register can only be used for output compare mode. See next section for input capture compare mode.

Bits 31:28  Reserved, must be kept at reset value.
Bit 27  Reserved, must be kept at reset value.
Bit 26  Reserved, must be kept at reset value.
Bit 25  **CC2DE**: Capture/compare 2 DMA request enable
- 0: CC2 DMA request disabled. Writing '0' to the CC2DE bit resets the associated ic2_dma_req signal.
- 1: CC2 DMA request enabled
  
  *Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 58.3.*

Bit 24  Reserved, must be kept at reset value.
Bit 23  **UEDE**: Update event DMA request enable
- 0: UE DMA request disabled. Writing '0' to the UEDE bit resets the associated ue_dma_req signal.
- 1: UE DMA request enabled
  
  *Note: If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 58.3.*

Bits 22:17  Reserved, must be kept at reset value.
Bit 16  **CC1DE**: Capture/compare 1 DMA request enable
- 0: CC1 DMA request disabled. Writing '0' to the CC1DE bit resets the associated ic1_dma_req signal.
- 1: CC1 DMA request enabled
  
  *Note: If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 58.3.*

Bit 15  Reserved, must be kept at reset value.
Bit 14  Reserved, must be kept at reset value.
Bit 13  **CC2OIE**: Capture/compare 2 over-capture interrupt enable
- 0: CC2 over-capture interrupt disabled
- 1: CC2 over-capture interrupt enabled
  
  *Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 58.3.*

Bit 12  **CC1OIE**: Capture/compare 1 over-capture interrupt enable
- 0: CC1 over-capture interrupt disabled
- 1: CC1 over-capture interrupt enabled
  
  *Note: If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 58.3.*

Bit 11  Reserved, must be kept at reset value.
Bit 10  Reserved, must be kept at reset value.
Bit 9  **CC2IE**: Capture/compare 2 interrupt enable
- 0: Capture/compare 2 interrupt disabled
- 1: Capture/compare 2 interrupt enabled
  
  *Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 58.3.*

Bit 8  **REPOKIE**: Repetition register update OK interrupt Enable
- 0: Repetition register update OK interrupt disabled
- 1: Repetition register update OK interrupt enabled

Bit 7  **UEIE**: Update event interrupt enable
- 0: Update event interrupt disabled
- 1: Update event interrupt enabled
Bit 6  **DOWNIE**: Direction change to down Interrupt Enable  
0: DOWN interrupt disabled  
1: DOWN interrupt enabled  
*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3.*

Bit 5  **UPIE**: Direction change to UP Interrupt Enable  
0: UP interrupt disabled  
1: UP interrupt enabled  
*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3.*

Bit 4  **ARROKIE**: Autoreload register update OK Interrupt Enable  
0: ARROK interrupt disabled  
1: ARROK interrupt enabled  

Bit 3  Reserved, must be kept at reset value.

Bit 2  **EXTTRIGIE**: External trigger valid edge Interrupt Enable  
0: EXTTRIG interrupt disabled  
1: EXTTRIG interrupt enabled

Bit 1  **ARRMIE**: Autoreload match Interrupt Enable  
0: ARRM interrupt disabled  
1: ARRM interrupt enabled

**Caution:** The LPTIMx_DIER register must only be modified when the LPTIM is enabled (ENABLE bit set to 1). After a write to the LPTIMx_DIER register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before the DIEROK flag is set, leads to unpredictable results.

Bit 31:30  Reserved, must be kept at reset value.

Bit 29  Reserved, must be kept at reset value.

Bits 28:25  Reserved, must be kept at reset value.
Bit 24 **ENC**: Encoder mode enable
   The ENC bit controls the Encoder mode
   0: Encoder mode disabled
   1: Encoder mode enabled

   *Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3.*

Bit 23 **COUNTMODE**: counter mode enabled
   The COUNTMODE bit selects which clock source is used by the LPTIM to clock the counter:
   0: the counter is incremented following each internal clock pulse
   1: the counter is incremented following each valid clock pulse on the LPTIM external Input1

Bit 22 **PRELOAD**: Registers update mode
   The PRELOAD bit controls the LPTIM_ARR, LPTIM_RCR and the LPTIM_CCRx registers update modality
   0: Registers are updated after each APB bus write access
   1: Registers are updated at the end of the current LPTIM period

Bit 21 **WAVPOL**: Waveform shape polarity
   The WAVPOL bit controls the output polarity
   0: The LPTIM output reflects the compare results between LPTIM_CNT and LPTIM_CCRx registers
   1: The LPTIM output reflects the inverse of the compare results between LPTIM_CNT and LPTIM_CCRx registers

   *Note: If the LPTIM implements at least one capture/compare channel, this bit is reserved. Refer to Section 58.3.*

Bit 20 **WAVE**: Waveform shape
   The WAVE bit controls the output shape
   0: Deactivate Set-once mode
   1: Activate the Set-once mode

Bit 19 **TIMOUT**: Timeout enable
   The TIMOUT bit controls the Timeout feature
   0: A trigger event arriving when the timer is already started is ignored
   1: A trigger event arriving when the timer is already started resets and restarts the LPTIM counter and the repetition counter

Bits 18:17 **TRIGEN[1:0]**: Trigger enable and polarity
   The TRIGEN bits controls whether the LPTIM counter is started by an external trigger or not. If the external trigger option is selected, three configurations are possible for the trigger active edge:
   00: software trigger (counting start is initiated by software)
   01: rising edge is the active edge
   10: falling edge is the active edge
   11: both edges are active edges

Bit 16 Reserved, must be kept at reset value.
Bits 15:13 TRIGSEL[2:0]: Trigger selector
The TRIGSEL bits select the trigger source that serves as a trigger event for the LPTIM among the below 8 available sources:
000: lptim_ext_trig0
001: lptim_ext_trig1
010: lptim_ext_trig2
011: lptim_ext_trig3
100: lptim_ext_trig4
101: lptim_ext_trig5
110: lptim_ext_trig6
111: lptim_ext_trig7
See Section 58.4.3: LPTIM input and trigger mapping for details.

Bit 12 Reserved, must be kept at reset value.

Bits 11:9 PRESC[2:0]: Clock prescaler
The PRESC bits configure the prescaler division factor. It can be one among the following division factors:
000: /1
001: /2
010: /4
011: /8
100: /16
101: /32
110: /64
111: /128

Bit 8 Reserved, must be kept at reset value.

Bits 7:6 TRGFLT[1:0]: Configurable digital filter for trigger
The TRGFLT value sets the number of consecutive equal samples that are detected when a level change occurs on an internal trigger before it is considered as a valid level transition. An internal clock source must be present to use this feature
00: any trigger active level change is considered as a valid trigger
01: trigger active level change must be stable for at least 2 clock periods before it is considered as valid trigger.
10: trigger active level change must be stable for at least 4 clock periods before it is considered as valid trigger.
11: trigger active level change must be stable for at least 8 clock periods before it is considered as valid trigger.

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 CKFLT[1:0]: Configurable digital filter for external clock
The CKFLT value sets the number of consecutive equal samples that are detected when a level change occurs on an external clock signal before it is considered as a valid level transition. An internal clock source must be present to use this feature
00: any external clock signal level change is considered as a valid transition
01: external clock signal level change must be stable for at least 2 clock periods before it is considered as valid transition.
10: external clock signal level change must be stable for at least 4 clock periods before it is considered as valid transition.
11: external clock signal level change must be stable for at least 8 clock periods before it is considered as valid transition.
Bits 2:1 CKPOL[1:0]: Clock Polarity
When the LPTIM is clocked by an external clock source, CKPOL bits is used to configure the active edge or edges used by the counter:
00: the rising edge is the active edge used for counting.
01: the falling edge is the active edge used for counting.
10: both edges are active edges. When both external clock signal edges are considered active ones, the LPTIM must also be clocked by an internal clock source with a frequency equal to at least four times the external clock frequency.
11: not allowed
Refer to Section 58.4.15: Encoder mode for more details about Encoder mode sub-modes.

Bit 0 CKSEL: Clock selector
The CKSEL bit selects which clock source the LPTIM uses:
0: LPTIM is clocked by internal clock source (APB clock or any of the embedded oscillators)
1: LPTIM is clocked by an external clock source through the LPTIM external Input1

Caution: The LPTIM_CFGR register must only be modified when the LPTIM is disabled (ENABLE bit reset to '0').

</tbody>
</table>

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 RSTARE: Reset after read enable
This bit is set and cleared by software. When RSTARE is set to ‘1’, any read access to LPTIM_CNT register asynchronously resets LPTIM_CNT register content.
This bit can be set only when the LPTIM is enabled.

Bit 3 COUNTRST: Counter reset
This bit is set by software and cleared by hardware. When set to ‘1’ this bit triggers a synchronous reset of the LPTIM_CNT counter register. Due to the synchronous nature of this reset, it only takes place after a synchronization delay of 3 LPTimer core clock cycles (LPTimer core clock may be different from APB clock).
This bit can be set only when the LPTIM is enabled. It is automatically reset by hardware.

Caution: COUNTRST must never be set to ‘1’ by software before it is already cleared to ‘0’ by hardware. Software must consequently check that COUNTRST bit is already cleared to ‘0’ before attempting to set it to ‘1’.
Bit 2  **CNTSTRT:** Timer start in Continuous mode

This bit is set by software and cleared by hardware. In case of software start (TRIGEN[1:0] = '00'), setting this bit starts the LPTIM in Continuous mode. If the software start is disabled (TRIGEN[1:0] different than '00'), setting this bit starts the timer in Continuous mode as soon as an external trigger is detected. If this bit is set when a single pulse mode counting is ongoing, then the timer does not stop at the next match between the LPTIM.ARR and LPTIM.CNT registers and the LPTIM counter keeps counting in Continuous mode. This bit can be set only when the LPTIM is enabled. It is automatically reset by hardware.

Bit 1  **SNGSTRT:** LPTIM start in Single mode

This bit is set by software and cleared by hardware. In case of software start (TRIGEN[1:0] = '00'), setting this bit starts the LPTIM in single pulse mode. If the software start is disabled (TRIGEN[1:0] different than '00'), setting this bit starts the LPTIM in single pulse mode as soon as an external trigger is detected. If this bit is set when the LPTIM is in continuous counting mode, then the LPTIM stops at the following match between LPTIM.ARR and LPTIM.CNT registers. This bit can only be set when the LPTIM is enabled. It is automatically reset by hardware.

Bit 0  **ENABLE:** LPTIM enable

The ENABLE bit is set and cleared by software. 0: LPTIM is disabled. Writing '0' to the ENABLE bit resets all the DMA request signals (input capture and update event DMA requests). 1: LPTIM is enabled

58.7.12 LPTIM compare register 1 (LPTIM.CCR1)

</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0  **CCR1[15:0]:** Capture/compare 1 value

**If channel CC1 is configured as output:**

CCR1 is the value to be loaded in the capture/compare 1 register. Depending on the PRELOAD option, the CCR1 register is immediately updated if the PRELOAD bit is reset and updated at next LPTIM update event if PRELOAD bit is reset. The capture/compare register 1 contains the value to be compared to the counter LPTIM.CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**

CCR1 becomes read-only, it contains the counter value transferred by the last input capture 1 event. The LPTIM.CCR1 register is read-only and cannot be programmed.

**If LPTIM does not implement any channel:**

The compare register 1 contains the value to be compared to the counter LPTIM.CNT and signaled on LPTIM output.
Caution: The LPTIM_CCR1 register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’).

58.7.13 LPTIM autoreload register (LPTIM_ARR)

Address offset: 0x018
Reset value: 0x0000 0001

Caution: The LPTIM_ARR register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’).

58.7.14 LPTIM counter register (LPTIM_CNT)

Address offset: 0x01C
Reset value: 0x0000 0000

Caution: The LPTIM_ARR register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’).
58.7.15  LPTIM configuration register 2 (LPTIM_CFGR2)

Address offset: 0x024
Reset value: 0x0000 0000

| Bit 31:22 | Reserved, must be kept at reset value. |
| Bit 21:20 | ic2sel[1:0]: LPTIM input capture 2 selection |
| The IC2SEL bits control the LPTIM Input capture 2 multiplexer, which connects LPTIM Input capture 2 to one of the available inputs. |
| 00: lptim_ic2_mux0 |
| 01: lptim_ic2_mux1 |
| 10: lptim_ic2_mux2 |
| 11: lptim_ic2_mux3 |
| For connection details refer to Section 58.4.3: LPTIM input and trigger mapping. |
| Bit 19:18 | Reserved, must be kept at reset value. |
| Bit 17:16 | ic1sel[1:0]: LPTIM input capture 1 selection |
| The IC1SEL bits control the LPTIM Input capture 1 multiplexer, which connects LPTIM Input capture 1 to one of the available inputs. |
| 00: lptim_ic1_mux0 |
| 01: lptim_ic1_mux1 |
| 10: lptim_ic1_mux2 |
| 11: lptim_ic1_mux3 |
| For connection details refer to Section 58.4.3: LPTIM input and trigger mapping. |
| Bit 15:6 | Reserved, must be kept at reset value. |
| Bit 5:4 | in2sel[1:0]: LPTIM input 2 selection |
| The IN2SEL bits control the LPTIM input 2 multiplexer, which connects LPTIM input 2 to one of the available inputs. |
| 00: lptim_in2_mux0 |
| 01: lptim_in2_mux1 |
| 10: lptim_in2_mux2 |
| 11: lptim_in2_mux3 |
| For connection details refer to Section 58.4.3: LPTIM input and trigger mapping. |
| Bit 3:2 | Reserved, must be kept at reset value. |
| Bit 1:0 | in1sel[1:0]: LPTIM input 1 selection |
| The IN1SEL bits control the LPTIM input 1 multiplexer, which connects LPTIM input 1 to one of the available inputs. |
| 00: lptim_in1_mux0 |
| 01: lptim_in1_mux1 |
| 10: lptim_in1_mux2 |
| 11: lptim_in1_mux3 |
| For connection details refer to Section 58.4.3: LPTIM input and trigger mapping. |
58.7.16  LPTIM repetition register (LPTIM_RCR)

Address offset: 0x028  
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16|   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  2|  1|  0|   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  Rep[7:0]: Repetition register value

REP is the repetition value for the LPTIM.

Caution:  The LPTIM_RCR register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1`). When using repetition counter with PRELOAD = 0, LPTIM_RCR register must be changed at least five counter cycles before the auto reload match event, otherwise an unpredictable behavior may occur.

58.7.17  LPTIM capture/compare mode register 1 (LPTIM_CCMR1)

Address offset: 0x02C  
Reset value: 0x0000 0000

The channels can be used in input (capture mode) or in output (PWM mode). The direction of a channel is defined by configuring the corresponding CCxSEL bits.

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  2|  1|  0|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  IC2F[1:0]: Input capture on pin 2

IC2F is the input capture value for pin 2.

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  IC2PSC[1:0]: Input capture preload value

IC2PSC is the preload value for the input capture register.

Caution:  The LPTIM_CCMR1 register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1`). When using capture and preload counters with PRELOAD = 0, LPTIM_CCMR1 register must be changed at least five counter cycles before the auto reload match event, otherwise an unpredictable behavior may occur.
Bits 31:30  Reserved, must be kept at reset value.

Bits 29:28  **IC2F[1:0]:** Input capture 2 filter
            This bitfield defines the number of consecutive equal samples that are detected when a level change occurs on an external input capture signal before it is considered as a valid level transition. An internal clock source must be present to use this feature.
            00: any external input capture signal level change is considered as a valid transition
            01: external input capture signal level change must be stable for at least 2 clock periods before it is considered as valid transition.
            10: external input capture signal level change must be stable for at least 4 clock periods before it is considered as valid transition.
            11: external input capture signal level change must be stable for at least 8 clock periods before it is considered as valid transition.

Bits 27:26  Reserved, must be kept at reset value.

Bits 25:24  **IC2PSC[1:0]:** Input capture 2 prescaler
            This bitfield defines the ratio of the prescaler acting on the CC2 input (IC2).
            00: no prescaler, capture is done each time an edge is detected on the capture input
            01: capture is done once every 2 events
            10: capture is done once every 4 events
            11: capture is done once every 8 events

Bits 23:20  Reserved, must be kept at reset value.

Bits 19:18  **CC2P[1:0]:** Capture/compare 2 output polarity.
            **Condition: CC2 as output**
            Only bit2 is used to set polarity when output mode is enabled, bit3 is don't care.
            0: OC2 active high
            1: OC2 active low
            **Condition: CC2 as input**
            This field is used to select the IC2 polarity for capture operations.
            00: rising edge, circuit is sensitive to IC2 rising edge
            01: falling edge, circuit is sensitive to IC2 falling edge
            10: reserved, do not use this configuration.
            11: both edges, circuit is sensitive to both IC2 rising and falling edges.

Bit 17  **CC2E:** Capture/compare 2 output enable.
            **Condition: CC2 as output**
            0: Off - OC2 is not active. Writing '0' to the CC2E bit resets the ue_dma_req signal only if all the other LPTIM channels are disabled.
            1: On - OC2 signal is output on the corresponding output pin
            **Condition: CC2 as input**
            This bit determines if a capture of the counter value can actually be done into the input capture/compare register 2 (LPTIM_CCR2) or not.
            0: Capture disabled. Writing '0' to the CC2E bit resets the associated ic2_dma_req signal.
            1: Capture enabled.

Bit 16  **CC2SEL:** Capture/compare 2 selection
            This bitfield defines the direction of the channel, input (capture) or output mode.
            0: CC2 channel is configured in output PWM mode
            1: CC2 channel is configured in input capture mode

Bits 15:14  Reserved, must be kept at reset value.
Bits 13:12 **IC1F[1:0]**: Input capture 1 filter
This bitfield defines the number of consecutive equal samples that are detected when a level change occurs on an external input capture signal before it is considered as a valid level transition. An internal clock source must be present to use this feature.
00: any external input capture signal level change is considered as a valid transition
01: external input capture signal level change must be stable for at least 2 clock periods before it is considered as valid transition.
10: external input capture signal level change must be stable for at least 4 clock periods before it is considered as valid transition.
11: external input capture signal level change must be stable for at least 8 clock periods before it is considered as valid transition.

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **IC1PSC[1:0]**: Input capture 1 prescaler
This bitfield defines the ratio of the prescaler acting on the CC1 input (IC1).
00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:2 **CC1P[1:0]**: Capture/compare 1 output polarity.
Condition: **CC1 as output**
Only bit2 is used to set polarity when output mode is enabled, bit3 is don't care.
0: OC1 active high, the LPTIM output reflects the compare results between LPTIM_ARR and LPTIM_CCRx registers
1: OC1 active low, the LPTIM output reflects the inverse of the compare results between LPTIM_ARR and LPTIM_CCRx registers
Condition: **CC1 as input**
This field is used to select the IC1 polarity for capture operations.
00: rising edge, circuit is sensitive to IC1 rising edge
01: falling edge, circuit is sensitive to IC1 falling edge
10: reserved, do not use this configuration.
11: both edges, circuit is sensitive to both IC1 rising and falling edges.

Bit 1 **CC1E**: Capture/compare 1 output enable.
Condition: **CC1 as output**
0: Off - OC1 is not active. Writing '0' to the CC1E bit resets the ue_dma_req signal only if all the other LPTIM channels are disabled.
1: On - OC1 signal is output on the corresponding output pin
Condition: **CC1 as input**
This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (LPTIM_CCR1) or not.
0: Capture disabled. Writing '0' to the CC1E bit resets the associated ic1_dma_req signal.
1: Capture enabled.

Bit 0 **CC1SEL**: Capture/compare 1 selection
This bitfield defines the direction of the channel input (capture) or output mode.
0: CC1 channel is configured in output PWM mode
1: CC1 channel is configured in input capture mode

Caution: After a write to the LPTIM_CCMRx register, a new write operation to the same register can only be performed after a delay that must be equal or greater than the value of (PRES × 3)
kernel clock cycles, PRESC[2:0] being the clock decimal division factor (1, 2, 4,..128). Any successive write violating this delay, leads to unpredictable results.

**Caution:** The CCxSEL, ICxF[1:0], CCxP[1:0] and ICxPSC[1:0] fields must only be modified when the channel x is disabled (CCxE bit reset to 0).

*If LPTIM does not implement any channel this register is reserved. Refer to Section 58.3.*

### 58.7.18 LPTIM compare register 2 (LPTIM_CCR2)

**Address offset:** 0x034  
**Reset value:** 0x0000 0000

</tbody>
</table>

**Bits 31:16 Reserved, must be kept at reset value.**

**Bits 15:0 CCR2[15:0]: Capture/compare 2 value**

*If channel CC2 is configured as output:*

CCR2 is the value to be loaded in the capture/compare 2 register. Depending on the PRELOAD option, the CCR2 register is immediately updated if the PRELOAD bit is reset and updated at next LPTIM update event if PRELOAD bit is reset.

The capture/compare register 2 contains the value to be compared to the counter LPTIM_CNT and signaled on OC2 output.

*If channel CC2 is configured as input:*

CCR2 becomes read-only, it contains the counter value transferred by the last input capture 2 event. The LPTIM_CCR2 register is read-only and cannot be programmed.

**Caution:** The LPTIM_CCR2 register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1').

**Note:** If the LPTIM implements less than 2 channels this register is reserved. Refer to Section 58.3: LPTIM implementation.

### 58.7.19 LPTIM register map

The following table summarizes the LPTIM registers.

**Table 610. LPTIM register map and reset values**

| Offset  | Register name   | Bit 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|---------|----------------|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x000   | LPTIM4_ISR     |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|         | Reset value    | 0      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

**Note:** If the LPTIM implements less than 2 channels this register is reserved. Refer to Section 58.3: LPTIM implementation.
| Offset | Register name | 31  | 29  | 28  | 26  | 24  | 22  | 19  | 17  | 15  | 13  | 11  | 9   | 7   | 5   | 3   | 1   | 0   |
|--------|---------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 0x000  | LPTIMx_ISR   | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | (x = 1 to 3) |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | Output compare mode |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIMx_ISR   | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | (x = 1 to 3) |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | Input capture mode |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIMx_ICR  | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | (x = 1 to 3) |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | Output compare mode |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIMx_ICR  | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | (x = 1 to 3) |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | Input capture mode |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_DIER | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_ICR  | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_ICR  | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_DIER | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_DIER | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_DIER | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_ICR  | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_ICR  | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_DIER | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_DIER | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_ICR  | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_ICR  | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_DIER | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_DIER | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | LPTIM4_ICR  | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

1. If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 58.3: LPTIM implementation.
2. If LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 58.3: LPTIM implementation.
3. If the LPTIM implements at least one capture/compare channel, this bit is reserved. Refer to Section 58.3: LPTIM implementation.
4. If LPTIM does not implement any channel this register is reserved. Refer to Section 58.3: LPTIM implementation.
5. If the LPTIM implements less than 2 channels this register is reserved. Refer to Section 58.3: LPTIM implementation.

Refer to Section 2.3 on page 139 for the register boundary addresses.
59 Graphic timer (GFXTIM)

This section only applies to STM32U5Fx/5Gx devices.

59.1 Introduction

The graphic timer (GFXTIM) is a graphic oriented timer allowing smart management of graphical events for frame or line counting.

59.2 GFXTIM main features

- Integrated frame and line clock generation
- One absolute frame counter with one compare channel
- Two auto-reload relative frame counters
- One line timer with two compare channels
- External tearing-effect line management and synchronization
- Four programmable event generators with external trigger generation
- One watchdog counter

59.3 GFXTIM functional description

59.3.1 Block diagram

The graphic timer is split into six functional blocks

- Clock generator
- Absolute timers
- Relative timers
- Tearing-effect detection
- Event generators
- Watchdog timer
59.3.2 GFXTIM pins and internal signals

59.3.3 Clock generator

Two clocks are generated internally to feed the absolute and relative timers:

- the frame clock: clocking frame counters
- the line clock: clocking line counters

Internal counter for time base generation

The GFXTIM embeds a two-clock generation counter:

- a 22-bit auto-reload down-counter on the system clock
- a 12-bit auto-reload down-counter on selectable internal or external event
Line clock counter

The line clock counter is a 22-bit auto-reload down-counter on the system clock. The line clock counter is enabled selecting its clock source with LCCCS (line clock counter clock source) in GFXTIM_CGCR (clock generator control register).

The line clock counter can be reloaded automatically when one of the following event occurs:

- frame clock counter underflows
- VSYNC edge (with control of polarity)
- HSYNC edge (with control of polarity)
- TE edge (with control of polarity)

The hardware reload function and source can be selected with LCCHRS (line clock counter hardware reload source) in GFXTIM_CGCR (clock generator control register).

The line clock counter can be reloaded by software, setting LCCFR (line clock counter force reload) in GFXTIM_CGCR (clock generator control register).

The reload value is programmed in GFXTIM_LCCRR (line clock counter reload register).

Frame clock counter

The frame clock counter if an 12-bit auto-reload down-counter clocked by either, TE, HYSNC, VSYNC or a line clock counter underflow.

The frame clock counter is enabled selecting its clock source with FCCCS in GFXTIM_CGCR.

The frame clock counter can be reloaded automatically when one of the following event occurs:

- line clock counter underflow
- VSYNC edge (with control of polarity)
- HSYNC edge (with control of polarity)
- TE edge (with control of polarity)

The hardware reload function and source can be selected with FCCHRS in GFXTIM_CGCR.

The frame clock counter can be reloaded by software, setting FCCFR in GFXTIM_CGCR.
The reload value is programmed in GFXTIM_FCCRR.

**Clock generation**

The line clock source can be one of the following:
- underflow flag of the internal 22-bit down-counter
- underflow flag of the internal 12-bit down-counter
- HSYNC, VSYNC or TE pin (with control of polarity)

The frame clock source can be one of the following:
- underflow flag of the internal 22-bit down-counter
- underflow flag of the internal 12-bit down-counter
- HSYNC, VSYNC or TE pin (with control of polarity)

**Clock calibration output**

For calibration/debug purpose, the frame clock and line clock can be output on a specific I/O.

The frame clock calibration output is enabled by setting FCCOE (frame clock calibration output enable) in GFXTIM_CR (configuration register).

The line clock calibration output is enabled by setting LCCOE in GFXTIM_CR.

**Synchronization and tearing-effect sources**

The GFXTIM can be connected to peripherals providing HSYNC and/or VSYNC synchronization signals, like the LCD-TFT controller or the camera interface.

The source of HSYNC and/or VSYNC is selected through SYNCS (synchronization source) in GFXTIM_CR.

The tearing-effect source can be an external pin or can be provided by the MIPI® DSI Host on system embedding this interface. To extend the orthogonality versus the synchronization signals, the tearing-effect source can be also the selected HSYNC or VSYNC input.

The tearing-effect source can be selected with TES (TE source) in GFXTIM_CR.

### 59.3.4 Example of clock generator configuration

The clock generator can have several configuration to work:
- in standalone (without any external synchronization)
- with external HSYNC and VSYNC
- with external HSYNC only
- with external VSYNC only
- with external CSYNC (TE) only

The synchronization signals, HSYNC, VSYNC and TE, are symmetrical in the implementation and can be exchanged if needed.

The set of examples detailed below are given for reference, but other combinations can be programmed into the clock generator.
Standalone

In standalone configuration, the clock generator provides to the GFXTIM, the frame clock and the line clock without any external signals.

`Figure 746. Waveforms in standalone`

The LCCUF (line-clock counter underflow) event acts as line clock and the FCCUF (frame-clock counter underflow) acts as frame clock.

The clock generator can be synchronized by one of the following ways:
- by software reload, setting the FCCFR in GFXTIM_CGCR.
- by hardware reload on an external VSYNC (or TE)

`Figure 747. Active counters and signals in standalone`

External HSYNC and VSYNC

When using external HSYNC and VSYNC, the counters are not used for the line and frame clock generation. The clock generator copy directly HSYNC to the line clock and VSYNC to the frame clock.

`Figure 748. Waveforms with external HSYNC and VSYNC`
HSYNC acts as line clock and VSYNC acts as frame clock.

**External HSYNC only**

With external HSYNC only, the clock generator provides to the GFXTIM, the frame clock and the line clock based only on HSYNC.

![Diagram](image1)

HSYNC acts as line clock and FCCUF acts as frame clock.

The clock generator can be synchronized by one of the following ways:
- by software reload, setting FCCFR in GFXTIM_CGCR
- by hardware reload on an external VSYNC (or TE)

![Diagram](image2)

**External VSYNC only**

With external VSYNC only, the clock generator provides to the GFXTIM, the frame clock and the line clock based only on VSYNC.

![Diagram](image3)

LCCUF (line clock counter underflow) acts as line clock and VSYNC acts as frame clock.
The line clock counter generating the line clock is reloaded on VSYNC event.

**Figure 752. Active counters with external VSYNC only**

The line clock counter can also act as a prescaler for the frame clock counter to have a wider range of counting. FCCUF acts as line clock.

**Figure 753. Prescaling when external VSYNC only**

External CSYNC only

With external CSYNC only, the clock generator provides to the GFXTIM, the frame clock and the line clock based only on CSYNC (in the following figures, CSYNC is input on TE).

**Figure 754. Waveforms with external CSYNC only**

The CSYNC (on TE pin in this example) acts as line clock and LCCUF acts as frame clock.

The line clock counter generating the frame clock is reloaded on CSYNC event.
The line-clock counter can also act as a prescaler for the frame clock counter to have a wider range of counting. FCCUF acts as frame clock.

**59.3.5 Absolute timers**

**Absolute time**

The absolute time 32-bit value can be read directly in GFXTIM_ATR (absolute time register) to provide a global time and to generate absolute time accurate event to synchronize the graphical software.

The absolute time is generated by the combination of:
- the absolute frame counter
- the absolute line counter

**Absolute frame counter**

The absolute frame counter is a 20-bit free running up-counter with a software controlled reset.

It can be enabled by writing 1 in AFCEN (absolute-frame counter enable) of GFXTIM_TCR (timers configuration register).
The counter is incremented at each rising edge of the frame clock and is reset by setting FAFCR (force absolute-frame counter reset) in GFXTIM_TCR.

In case of overflow of the absolute frame counter, AFCOF (overflow flag) is set in GFXTIM_ISR (interrupt status register), and an interrupt is generated if AFCOIE (overflow interrupt enable) is set in (interrupt enable register).

A 20-bit compare register can generate an absolute-frame counter compare event when the counter value matches the compare value. When a compare event occurs, AFCC1F (compare 1 flag) is set in GFXTIM_ISR, and an interrupt is generated if AFCC1IE (compare 1 interrupt enable) is set in GFXTIM_IER.

The absolute frame counter can be disabled by writing 1 in AFCDIS (counter disable) of GFXTIM_TDR (timers disable register).

The status (enabled/disabled) can be monitored through AFCS (counter status) in GFXTIM_TSR (timers status register).

**Absolute line counter**

The absolute line counter is 12-bit free running-up counter with an hardware controlled reset.

It can be enabled by writing 1 in ALCEN of GFXTIM_TCR.

The counter is incremented at each rising edge of the line clock an is reset at each rising edge of the frame clock or setting FALCR in GFXTIM_TCR).

In case of overflow of the absolute line counter, ALCOF is set in GFXTIM_ISR, and an interrupt is generated if ALCOIE is set in GFXTIM_IER.

Two 12-bit compare registers can generate an absolute line counter compare events when the counter value matches the compare value. When a compare event occurs, ALCC1F or ALCC2F is set in GFXTIM_ISR, and an interrupt is generated if ALCC1IE or ALCC2IE is set in GFXTIM_IER.

The absolute line counter can be disabled writing 1 in ALCDIS of GFXTIM_TDR.

The status (enabled/disabled) can be monitored through ALCS in GFXTIM_TSR.

### 59.3.6 Relative timers

The relative timers can generate periodic events to synchronize the graphical tasks at frame level.

The relative frame counters are 12-bit down-counting auto-reload timers that are decremented at each rising edge of the frame clock. The counter is started by writing 1 in RFCxEN (relative frame counter x enable) of GFXTIM_TCR. The starting value is automatically loaded from GFXTIM_RFCxRR (relative frame counter x reload register).

The current relative frame counter value can be read directly in GFXTIM_RFCxR.

Once the counter reaches zero, it is automatically reloaded with the value of GFXTIM_RFCxRR. RFCxRF (reload flag) is set in GFXTIM_ISR is set, and an interrupt is generated if RFCxRIE (interrupt enable) is set in GFXTIM_IER.

Once the reload operation occurs, the timer can be disabled automatically or continue counting if RFCxCM (continuous mode) is set in GFXTIM_TCR.

The status (enabled/disabled) can be monitored through RFCxS in GFXTIM_TSR.
The counter can be reloaded on the fly by setting FRFCRx in GFXTIM_TCR. This force reload neither stop the timer (even if RFCxCM = 0 in GFXTIM_TCR), nor set RFCxRF (reload flag) in GFXTIM_ISR.

The relative frame counter can be disabled by setting RFCxDIS (disable) in GFXTIM_TDR.

59.3.7 Tearing-effect detection

A tearing-effect line can work in one of the two configurations shown in the figure below.

![Tearing-effect configurations](image)

A tearing-effect event can be generated on rising or falling edge depending on TEPOL (tearing-effect polarity) in GFXTIM_CR.

When a tearing-effect event is detected, TEF (tearing-event flag) is set in GFXTIM_ISR, and an interrupt is generated if TEIE (interrupt enable) is set in GFXTIM_IER.

59.3.8 Event generator

The event generator can combine timer events into complex events. Up to four combined events can be generated.

The events can be used for:
- interrupt generation
- watchdog clocking
- external trigger generation

A complex event is a combination between a frame event and a line event.

Once a frame event occurs, the GFXTIM waits for the line event to occur before generating the complex event.

The frame event is selected by the corresponding FESx (frame event selection x) in GFXTIM_EVSR (events selection y register). The line event is selected by the corresponding LESx in GFXTIM_EVSR.

The complex event generation is enabled by setting the corresponding EVxEN (event x enable) in GFXTIM_EVCR (event control register).

It is recommended to disable the event generation prior to any event configuration to avoid spurious complex event generation.

When a complex event occurs, the corresponding EVxF (event x flag) is set in GFXTIM_ISR, and an interrupt is generated if EVxIE (event x interrupt enable) is set in GFXTIM_IER.

Each of the events can be connected to another peripherals (such as DMA) to generate hardware triggers.
59.3.9 **Watchdog timer**

The watchdog timer is a 16-bit auto-reload down-counter with a programmable clock source.

**Figure 758. Watchdog timer**

![Watchdog timer diagram](image)

**Clock source**

The watchdog clock source can be selected through WDGCS (clock source) in GTXTIM_WDGTCR (watchdog timer configuration register), between one of the following:

- line clock
- frame clock
- HSYNC
- VSYNC
- TE
- event 1
- event 2
- event 3
- event 4

**Startup**

The watchdog is started by setting WDGEN in GFXTIM_WDGTCR and stops automatically when reaching 0.

On start, the watchdog counter is automatically loaded with the auto-reload value programmed in GFXTIM_WDGRR (watchdog reload register).

The current watchdog value can be read through GFXTIM_WDGCR.

**Auto-reload**

The auto-reload can be forced in one of the following ways:

- by software, setting FWDGR (force watchdog reload) in GTXTIM_WDGTCR (watchdog timer configuration register)
- by hardware through an external trigger (gfxtim_wrld signal)

The polarity of the trigger is configured by WDGHRC (watchdog hardware reload configuration) in GFXTIM_WDGTCR.
Event and interrupt generation

The watchdog can generate two events:

- an alarm when the watchdog down-counter reaches 0
  The watchdog counter is automatically stopped, and WDGAF (alarm flag) is set in GFXTIM_ISR. An interrupt is generated if WDGAIE (alarm interrupt enable) is set in GFXTIM_IER.
- a pre-alarm when the watchdog counter matches the pre-alarm register value in GFXTIM_WDGPAR (watchdog pre-alarm register)
  WDGPF (pre-alarm flag) is set in GFXTIM_ISR, and an interrupt is generated if WDGPIE (pre-alarm interrupt enable) is set in GFXTIM_IER.

59.4 GFXTIM interrupts

An interrupt can be produced on the following events:

- absolute frame counter compare event
- absolute frame counter overflow
- absolute line counter compare events
- absolute line counter overflow
- relative frame counter reload events
- external tearing effect
- combined events
- watchdog alarm event
- watchdog pre-alarm event

Separate interrupt enable bits are available for flexibility.

This bitfield defines the frame-event selection for complex event 1 generation.
000: No frame event
001: Absolute frame counter overflow
010: Absolute frame counter compare
100: Relative frame counter 1 reload
101: Relative frame counter 2 reload
Others: Reserved

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **LES1[2:0]**: Line-event selection 1
This bitfield defines the line-event selection for complex event 1 generation.
000: No line event
001: Absolute line counter overflow
010: Tearing effect
100: Absolute line counter 1 compare
101: Absolute line counter 2 compare
Others: Reserved

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **FWDGR**: Force watchdog reload
This bit forces the reload of the graphic watchdog.
0: No effect
1: Graphic watchdog reload forced

Bits 15:12 Reserved, must be kept at reset value.
Bits 11:8 **WDGCS[3:0]**: Watchdog clock source
   This bitfield selects the watchdog clock source.
   0000: Line clock
   0001: Frame clock
   0010: HSYNC rising edge
   0011: HSYNC falling edge
   0100: VSYNC rising edge
   0101: VSYNC falling edge
   0110: TE rising edge
   0111: TE falling edge
   1000: Event 1
   1001: Event 2
   1010: Event 3
   1011: Event 4
   Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **WDGHRC[1:0]**: Watchdog hardware reload configuration
   This bitfield configures the watchdog hardware reload.
   00: Watchdog hardware reload disabled
   01: Watchdog reloaded a rising edge of gfxtim wrld
   10: Watchdog reloaded a falling edge of gfxtim wrld
   11: Reserved

Bit 3 Reserved, must be kept at reset value.

Bit 2 **WDGS**: Watchdog status
   This bit returns the status of the graphic watchdog.
   0: Graphic watchdog disabled
   1: Graphic watchdog enabled

Bit 1 **WDGDIS**: Watchdog disable
   This bit disables the graphic watchdog.
   0: No effect
   1: Graphic watchdog disabled

Bit 0 **WDGEN**: Watchdog enable
   This bit enables the graphic watchdog.
   0: No effect
   1: Graphic watchdog enabled
59.5.8  **GFXTIM interrupt status register (GFXTIM_ISR)**

Bit 12 **RFC1RF**: Relative frame counter 1 reload flag
This bit indicates relative frame counter 1 has been reloaded.
0: No reload occurred on relative frame counter 1.
1: A reload on relative frame counter 1 occurred.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **ALCC2F**: Absolute line counter compare 2 flag
This bit indicates match on compare 2 of the absolute line counter.
0: No match occurred on compare 2 of the absolute line counter.
1: A match on compare 2 of the absolute line counter occurred.

Bit 8 **ALCC1F**: Absolute line counter compare 1 flag
This bit indicates match on compare 1 of the absolute line counter.
0: No match occurred on compare 1 of the absolute line counter.
1: A match on compare 1 of the absolute line counter occurred.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **AFCC1F**: Absolute frame counter compare 1 flag
This bit indicates match on compare 1 of the absolute frame counter.
0: No match occurred on compare 1 of the absolute frame counter.
1: A match on compare 1 of the absolute frame counter occurred.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TEF**: Tearing-effect flag
This bit indicates a tearing effect event occurred.
0: No tearing effect occurred.
1: A tearing effect occurred.

Bit 1 **ALCOF**: Absolute line counter overflow flag
This bit indicates an overflow occurred on the absolute line counter.
0: No overflow occurred on the absolute line counter.
1: An overflow on the absolute line counter occurred.

Bit 0 **AFCOF**: absolute frame counter overflow flag
This bit indicates an overflow occurred on the absolute frame counter.
0: No overflow occurred on the absolute frame counter.
1: An overflow on the absolute frame counter occurred.

Bits 31:26 Reserved, must be kept at reset value.
Bit 25 **CWDGPF**: Clear watchdog pre-alarm flag
   This bit clears WDGPF in GXFXTIM_ISR.
   0: No effect
   1: WDGPF cleared

Bit 24 **CWDGAF**: Clear watchdog alarm flag
   This bit clears WDGAF in GXFXTIM_ISR.
   0: No effect
   1: WDGAF cleared

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **CEV4F**: Clear event 4 flag
   This bit clears EV4F in GXFXTIM_ISR.
   0: No effect
   1: EV4F cleared

Bit 18 **CEV3F**: Clear event 3 flag
   This bit clears EV3F in GXFXTIM_ISR.
   0: No effect
   1: EV3F cleared

Bit 17 **CEV2F**: Clear event 2 flag
   This bit clears EV2F in GXFXTIM_ISR.
   0: No effect
   1: EV2F cleared

Bit 16 **CEV1F**: Clear event 1 flag
   This bit EV1F in GXFXTIM_ISR.
   0: No effect
   1: EV1F cleared

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **CRFC2RF**: Clear relative frame counter 2 reload flag
   This bit clears RFC2RF in GXFXTIM_ISR.
   0: No effect
   1: RFC2RF cleared

Bit 12 **CRFC1RF**: Clear relative frame counter 1 reload flag
   This bit clears RFC1RF in GXTIM_ISR.
   0: No effect
   1: RFC1RF cleared

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **CALCC2F**: Clear absolute line counter compare 2 flag
   This bit clears ALCC2F in GXTIM_ISR.
   0: No effect
   1: ALCC2F cleared

Bit 8 **CALCC1F**: Clear absolute line counter compare 1 flag
   This bit clears ALCC1F in GXTIM_ISR.
   0: No effect
   1: ALCC1F cleared

Bits 7:5 Reserved, must be kept at reset value.
Bit 4  **CAFCC1F**: Clear absolute frame counter compare 1 flag
This bit clears AFCC1F in GXTIM_ISR.
0: No effect
1: AFCC1F cleared

Bit 3  Reserved, must be kept at reset value.

Bit 2  **CTEF**: Clear tearing-effect flag
This bit clears TEF in GXTIM_ISR.
0: No effect
1: TEF cleared

Bit 1  **CALCOF**: Clear absolute line counter overflow flag
This bit clears ALCOF in GXTIM_ISR.
0: No effect
1: ALCOF cleared

Bit 0  **CAFCOF**: Clear absolute frame counter overflow flag
This bit clears AFCOF in GXTIM_ISR.
0: No effect
1: AFCOF cleared

Bits 31:26  Reserved, must be kept at reset value.

Bit 25  **WDGPIE**: Watchdog pre-alarm interrupt enable
This bit enables the watchdog pre-alarm interrupt generation.
0: Watchdog pre-alarm interrupt disabled
1: Watchdog pre-alarm interrupt enabled

Bit 24  **WDGAIE**: Watchdog alarm interrupt enable
This bit enables the watchdog alarm interrupt generation.
0: Watchdog alarm interrupt disabled
1: Watchdog alarm interrupt enabled

Bits 23:20  Reserved, must be kept at reset value.

Bit 19  **EV4IE**: Event 4 interrupt enable
This bit enables the complex event 4 interrupt generation.
0: Event 4 interrupt disabled
1: Event 4 interrupt enabled
Bit 18  **EV3IE**: Event 3 interrupt enable
This bit enables the complex event 3 interrupt generation.
- 0: Event 3 interrupt disabled
- 1: Event 3 interrupt enabled

Bit 17  **EV2IE**: Event 2 interrupt enable
This bit enables the complex event 2 interrupt generation.
- 0: Event 2 interrupt disabled
- 1: Event 2 interrupt enabled

Bit 16  **EV1IE**: Event 1 interrupt enable
This bit enables the complex event 1 interrupt generation.
- 0: Event 1 interrupt disabled
- 1: Event 1 interrupt enabled

Bits 15:14  Reserved, must be kept at reset value.

Bit 13  **RFC2RIE**: Relative frame counter 2 reload interrupt enable
This bit enables the relative frame counter 2 reload interrupt generation.
- 0: Relative frame counter 2 reload interrupt disabled
- 1: Relative frame counter 2 reload interrupt enabled

Bit 12  **RFC1RIE**: Relative frame counter 1 reload interrupt enable
This bit enables the relative frame counter 1 reload interrupt generation.
- 0: Relative frame counter 1 reload interrupt disabled
- 1: Relative frame counter 1 reload interrupt enabled

Bits 11:10  Reserved, must be kept at reset value.

Bit 9  **ALCC2IE**: Absolute line counter compare 2 interrupt enable
This bit enables the absolute line counter compare 2 interrupt generation.
- 0: Absolute line counter compare 2 interrupt disabled
- 1: Absolute line counter compare 2 interrupt enabled

Bit 8  **ALCC1IE**: Absolute line counter compare 1 interrupt enable
This bit enables the absolute line counter compare 1 interrupt generation.
- 0: Absolute line counter compare 1 interrupt disabled
- 1: Absolute line counter compare 1 interrupt enabled

Bits 7:5  Reserved, must be kept at reset value.

Bit 4  **AFCC1IE**: Absolute frame counter compare 1 interrupt enable
This bit enables the absolute frame counter compare interrupt generation.
- 0: Absolute frame counter compare 1 interrupt disabled
- 1: Absolute frame counter compare 1 interrupt enabled

Bit 3  Reserved, must be kept at reset value.

Bit 2  **TEIE**: Tearing-effect interrupt enable
This bit enables the Tearing Effect interrupt generation.
- 0: Tearing-effect interrupt disabled
- 1: Tearing-effect interrupt enabled

Bit 1  **ALCOIE**: Absolute line counter overflow interrupt enable
This bit enables the absolute line counter overflow interrupt generation.
- 0: Absolute line counter overflow interrupt disabled
- 1: Absolute line counter overflow interrupt enabled
Bit 0  **AFCOIE**: Absolute frame counter overflow interrupt enable
   This bit enables the absolute frame counter overflow interrupt generation.
   0: Absolute frame counter overflow interrupt disabled
   1: Absolute frame counter overflow interrupt enabled

- 0x058: GFXTIM_ALCR
- 0x05C: Reserved
Refer to Section 2.3 for the register boundary addresses.
Infrared interface (IRTIM)

An infrared interface (IRTIM) for remote control is available on the device. It can be used with an infrared LED to perform remote control functions.

It uses internal connections with TIM16 and TIM17 as shown in Figure 759.

To generate the infrared remote control signals, the IR interface must be enabled and TIM16 channel 1 (TIM16_OC1) and TIM17 channel 1 (TIM17_OC1) must be properly configured to generate correct waveforms.

The infrared receiver can be implemented easily through a basic input capture mode.

All standard IR pulse modulation modes can be obtained by programming the two timer output compare channels.

TIM17 is used to generate the high frequency carrier signal, while TIM16 generates the modulation envelope.

The infrared function is output on the IR_OUT pin. The activation of this function is done through the GPIOx_AFRx register by enabling the related alternate function bit.

The high sink LED driver capability (only available on the PB9 pin) can be activated through the PB9_FMP bit in the SYSCFG_CGR1 register and used to sink the high current needed to directly control an infrared LED.
61  Independent watchdog (IWDG)

61.1  Introduction

The independent watchdog (IWDG) peripheral offers a high safety level, thanks to its capability to detect malfunctions due to software or hardware failures.

The IWDG is clocked by an independent clock, and stays active even if the main clock fails.

In addition, the watchdog function is performed in the VDD voltage domain, allowing the IWDG to remain functional even in low-power modes. Refer to Section 61.3 to check the capability of the IWDG in this product.

The IWDG is best suited for applications that require the watchdog to run as a totally independent process outside the main application, making it very reliable to detect any unexpected behavior.

61.2  IWDG main features

- 12-bit down-counter
- Dual voltage domain, thus enabling operation in low-power modes
- Independent clock
- Early wake-up interrupt generation
- Reset generation
  - In case of timeout
  - In case of refresh outside the expected window

61.3  IWDG implementation

<td>X</td>
</tr>
</tbody>
</table>

1. ‘X’ = supported, ‘-’ = not supported.
2. Refer to the RCC section for additional information.
3. Wake-up from Stop with interrupt is supported only in Stop 0, Stop 1, and Stop 2 modes for STM32U575/585, and in Stop 0, Stop 1, Stop 2, and Stop 3 modes for STM32U535/545/59x/5Ax/5Fx/5Gx.

4. Controlled via DBG_IWDG_STOP in DBG section.

5. Controlled via the option byte IWDG_STOP in FLASH section.

6. Controlled via the option byte IWDG_STDBY in FLASH section.

7. Controlled via the option byte IWDG_SW in FLASH section.

### 61.4 IWDG functional description

#### 61.4.1 IWDG block diagram

*Figure 760* shows the functional blocks of the independent watchdog module.

*Figure 760. Independent watchdog block diagram*

The register and IRQ interfaces are located into the VCORE voltage domain. The watchdog function itself is located into the VDD voltage domain to remain functional in low-power modes. See *Section 61.3* for IWDG capabilities.

The register and IRQ interfaces are mainly clocked by the APB clock (iwdg_pclk), while the watchdog function is clocked by a dedicated kernel clock (iwdg_ker_ck). A synchronization mechanism makes the data exchange between the two domains possible. Note that most of the registers located in the register interface are shadowed into the VDD voltage domain.

The IWDG down-counter (IWDCNT) is clocked by the prescaled clock (presc_ck). The prescaled clock is generated from the kernel clock iwdg_ker_ck divided by the prescaler, according to PR[3:0] bitfield.
61.4.2 IWDG internal signals

The list of IWDG internal signals is detailed in Table 617.

<table>
<thead>

</table>

61.4.3 Software and hardware watchdog modes

The watchdog modes allow the application to select the way the IWDG is enabled, either by software commands (Software watchdog mode), or automatically (Hardware watchdog mode). All other functions work similarly for both Software and Hardware modes.

The Software watchdog mode is the default working mode. The independent watchdog is started by writing the value 0x0000 CCCC into the IWDG key register (IWDG_KR), and the IWDCNT starts counting down from the reset value (0xFFF).

In the Hardware watchdog mode the independent watchdog is started automatically at power-on, or every time it is reset (via iwdg_in_rst). The IWDCNT down-counter starts counting down from the reset value 0xFFF. The hardware watchdog mode feature is enabled through the device option bits, see Section 61.3 for details.

When the IWDCNT reaches 0x000, a reset signal is generated (iwdg_out_rst asserted).

Whenever the key value 0x0000 AAAA is written in the IWDG key register (IWDG_KR), the IWDG_RLR value is reloaded into the IWDCNT, and the watchdog reset is prevented.

Due to re-synchronization delays, the IWDG must be refreshed before the IWDCNT down-counter reaches 1.

Once started, the IWDG can be stopped only when it is reset (iwdg_in_rst asserted).

As shown in Figure 761, when the refresh command is executed, one period of presc_ck later, the IWDCNT is reloaded with the content of RL[11:0].
1. If window option activated.

If the IWDG is not refreshed before the IWDCNT reaches 1, then the IWDG generates a reset (i.e. iwdg_out_rst asserted). In return, the RCC resets the IWDG (assertion of iwdg_in_rst) to clear the reset source.

61.4.4 Window option

The IWDG can also work as a window watchdog by setting the appropriate window in the IWDG window register (IWDG_WINR).

If the reload operation is performed while the counter is greater than WIN[11:0] + 1 a reset is generated. WIN[11:0] is located in the IWDG window register (IWDG_WINR). As shown in Figure 762, the reset is generated one period of presc_ck after the unexpected refresh command.

The default value of the IWDG window register (IWDG_WINR) is 0x0000 0FFF, so, if not updated, the window option is disabled.

As soon as the window value changes, the down-counter (IWDCNT) is reloaded with the RL[11:0] value to ease the estimation for where the next refresh must take place.
Figure 762. Reset timing due to refresh in the not allowed area

**Configuring the IWDG when the window option is enabled**

1. Enable the IWDG by writing 0x0000 CCCC in the *IWDG key register (IWDG_KR)*.
2. Enable register access by writing 0x0000 5555 in the *IWDG key register (IWDG_KR)*.
3. Write the IWDG prescaler by programming the *IWDG prescaler register (IWDG_PR)*.
4. Write the *IWDG reload register (IWDG_RLR)*.
5. If needed, enable the early wake-up interrupt, and program the early wake-up comparator, by writing the proper values into the *IWDG early wake-up interrupt register (IWDG_EWCR)*.
6. Write to the *IWDG window register (IWDG_WINR)*. This automatically reloads the IWDCNT down-counter with the RL[11:0] value.
7. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
8. Write 0x0000 0000 into *IWDG key register (IWDG_KR)* to write-protect registers.

*Note:* Step 7 can be skipped if the application does not intend to disable the APB clock after the completion of this sequence.

**Configuring the IWDG when the window option is disabled**

When the window option it is not used, the IWDG can be configured as follows:
1. Enable the IWDG by writing 0x0000 CCCC in the IWDG key register (IWDG_KR).
2. Enable register access by writing 0x0000 5555 in the IWDG key register (IWDG_KR).
3. Write the prescaler by programming the IWDG prescaler register (IWDG_PR).
4. Write the IWDG reload register (IWDG_RLR).
5. If needed, enable the early wake-up interrupt, and program the early wake-up comparator, by writing the proper values into the IWDG early wake-up interrupt register (IWDG_EWCR).
6. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
7. Refresh the counter with RL[11:0] value, and write-protect registers by writing 0x0000 AAAA into IWDG key register (IWDG_KR).

**Updating the window comparator**

It is possible to update the window comparator when the IWDG is already running. The IWDCNT is reloaded as well. The following sequence can be performed to update the window comparator:

1. Enable register access by writing 0x0000 5555 in the IWDG key register (IWDG_KR).
2. Write to the IWDG window register (IWDG_WINR). This automatically reloads the IWDCNT down-counter with RL[11:0] value.
3. Wait for WVU = 0
4. Lock registers by writing IWDG_KR to 0x0000 0000

Step 3 can be skipped if the application does not intend to disable the APB clock after the completion of this sequence.

### 61.4.5 Debug

When the processor enters into Debug mode (core halted), the IWDCNT down-counter either continues to work normally or stops, depending on debug capability of the product. Refer to Section 61.3 for details on the capabilities of this product.

### 61.4.6 Register access protection

Write accesses to IWDG prescaler register (IWDG_PR), IWDG reload register (IWDG_RLR), IWDG early wake-up interrupt register (IWDG_EWCR) and IWDG window register (IWDG_WINR) are protected. To modify them, first write 0x0000 5555 in the IWDG key register (IWDG_KR). A write access to this register with a different value breaks the sequence and register access is protected again. This is the case of the reload operation (writing 0x0000 AAAA).

A status register is available to indicate that an update of the prescaler or the down-counter reload value or the window value is ongoing.

### 61.5 IWDG low-power modes

Depending on option bytes configuration, the IWDG can continue counting or not during the low-power modes. Refer to Section 61.3 for details.
The IWDG offers the possibility to generate an early interrupt depending on the value of the down-counter. The early interrupt is enabled by setting the EWIE bit of the IWDG early wake-up interrupt register (IWDG_EWCR) to 1.

A comparator value (EWIT[11:0]) allows the application to define at which position the early interrupt must be generated.

When the IWDCNT down-counter reaches the value of EWIT[11:0] - 1, the iwdg_wkup is activated, making it possible for the system to exit from low-power mode if needed.

When the APB clock is available, the iwdg_it is activated as well.

In addition the flag EWIF of the IWDG status register (IWDG_SR) is set to 1.

The EWI interrupt is acknowledged by writing ‘1’ to the EWIC bit in the IWDG early wake-up interrupt register (IWDG_EWCR).

Writing into the IWDG_EWCR register also triggers a refresh of the down-counter (IWDCNT) with the reload value RL[11:0].
The early wake-up interrupt (EWI) can be used if specific safety operations or data logging must be performed before the watchdog reset is generated.

**Changing the early wake-up comparator value**

It is possible to change the early wake-up comparator value or to enable/disable the interrupt generation at any time, by performing the following sequence:

1. Enable register access by writing 0x0000 5555 in the IWDG key register (IWDG_KR).
2. Enable or disable the early wake-up interrupt, and/or program the early wake-up comparator, by writing the proper values into the IWDG early wake-up interrupt register (IWDG_EWCR).
3. Wait for EWU = '0', EWU is located into the IWDG status register (IWDG_SR).
4. Write-protect registers by writing 0x0000 0000 to IWDG key register (IWDG_KR).

Step 3 can be skipped if the application does not intend to disable the APB clock after the completion of this sequence.

*Table 619* summarizes the IWDG interrupt request.

<table>
<thead>
<tr>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Interrupt clear method</th>
<th>Interrupt enable control bit</th>
<th>Activated interrupt</th>
</tr>
</thead>
<tbody>
<tr>
<td>IWDG_CNT reaches EWIT value</td>

<td>iwdg_it, iwdg_wkup_it</td>
</tr>
</tbody>
</table>

1. Generated when a clock is present on iwdg_pclk input.
2. Generated when a clock is present on iwdg_ker_ck input.

61.7 IWDG registers

Refer to Section 1.2 on page 126 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

Most of the registers located into the register interface are shadowed into the VDD voltage domain. When the iwdg_in_rst is asserted, the watchdog logic and the shadow registers located into the VDD voltage domain are reset.

When the application reads back a watchdog register, the hardware transfers the value of the corresponding shadow register to the register interface.

When the application writes a watchdog register, the hardware updates the corresponding shadow register.

61.7.1 IWDG key register (IWDG_KR)

Address offset: 0x00

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **KEY[15:0]**: Key value (write only, read 0x0000)

These bits can be used for several functions, depending upon the value written by the application:

- 0xAAAA: reloads the RL[11:0] value into the IWDCNT down-counter (watchdog refresh), and write-protects registers. This value must be written by software at regular intervals, otherwise the watchdog generates a reset when the counter reaches 0.
- 0x5555: enables write-accesses to the registers.
- 0xCCCC: enables the watchdog (except if the hardware watchdog option is selected) and write-protects registers.
- values different from 0x5555: write-protects registers.

Note that only IWDG_PR, IWDG_RLR, IWDG_EWCR and IWDG_WINR registers have a write-protection mechanism.
### 61.7.2 IWDG prescaler register (IWDG_PR)

Address offset: 0x04  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:4 Reserved, must be kept at reset value.

**Bits 3:0 PR[3:0]: Prescaler divider**

These bits are write access protected, see Section 61.4.6. They are written by software to select the prescaler divider feeding the counter clock. PVU bit of the IWDG status register (IWDG_SR) must be reset to be able to change the prescaler divider.

- 0000: divider / 4
- 0001: divider / 8
- 0010: divider / 16
- 0011: divider / 32
- 0100: divider / 64
- 0101: divider / 128
- 0110: divider / 256
- 0111: divider / 512
- Others: divider / 1024

**Note:** Reading this register returns the prescaler value from the V_DD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the PVU bit in the IWDG status register (IWDG_SR) is reset.

### 61.7.3 IWDG reload register (IWDG_RLR)

Address offset: 0x08  
Reset value: 0x0000 0FFF

<table>

<td>r</td>
</tr>
</tbody>
</table>

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 EWIF: Watchdog early interrupt flag
This bit is set to ‘1’ by hardware in order to indicate that an early interrupt is pending. This bit must be cleared by the software by writing the bit EWIC of IWDG_EWCR register to ‘1’.

Bits 13:4 Reserved, must be kept at reset value.

Bit 3 EWU: Watchdog interrupt comparator value update
This bit is set by hardware to indicate that an update of the interrupt comparator value (EWIT[11:0]) or an update of the EWIE is ongoing. It is reset by hardware when the update operation is completed in the VDD voltage domain (takes up to three periods of the IWDG kernel clock iwdg_ker_ck).
The EWIT[11:0] and EWIE fields can be updated only when EWU bit is reset.

Bit 2 WVU: Watchdog counter window value update
This bit is set by hardware to indicate that an update of the window value is ongoing. It is reset by hardware when the reload value update operation is completed in the VDD voltage domain (takes up to three periods of the IWDG kernel clock iwdg_ker_ck).
The window value can be updated only when WVU bit is reset.
This bit is generated only if generic “window” = 1.

Bit 1 RVU: Watchdog counter reload value update
This bit is set by hardware to indicate that an update of the reload value is ongoing. It is reset by hardware when the reload value update operation is completed in the VDD voltage domain (takes up to three periods of the IWDG kernel clock iwdg_ker_ck).
The reload value can be updated only when RVU bit is reset.
Bit 0  **PVU**: Watchdog prescaler value update
This bit is set by hardware to indicate that an update of the prescaler value is ongoing. It is
reset by hardware when the prescaler update operation is completed in the VDD voltage
domain (takes up to three periods of the IWDG kernel clock iwdg_ker_ck).
The prescaler value can be updated only when PVU bit is reset.

**Note:** If several reload, prescaler, early interrupt position or window values are used by the
application, it is mandatory to wait until RVU bit is reset before changing the reload value, to
wait until PVU bit is reset before changing the prescaler value, to wait until WVU bit is reset
before changing the window value, and to wait until EWU bit is reset before changing the
early interrupt position value. After updating the prescaler and/or the reload/window/early
interrupt value, it is not necessary to wait until RVU or PVU or WVU or EWU is reset before
continuing code execution, except in case of low-power mode entry.

### 61.7.5 IWDG window register (IWDG_WINR)

Address offset: 0x10

Reset value: 0x0000 0FFF

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  **WIN[11:0]**: Watchdog counter window value
These bits are write access protected, see Section 61.4.6. They contain the high limit of the
window value to be compared with the downcounter.

To prevent a reset, the IWDCNT downcounter must be reloaded when its value is lower than
WIN[11:0] + 1 and greater than 1.

The WVU bit in the **IWDG status register (IWDG_SR)** must be reset to be able to change the
reload value.

**Note:** Reading this register returns the reload value from the VDD voltage domain. This value
may not be valid if a write operation to this register is ongoing. For this reason the value
read from this register is valid only when the WVU bit in the **IWDG status register (IWDG_SR)** is reset.
### 61.7.6 IWDG early wake-up interrupt register (IWDG_EWCR)

Address offset: 0x14  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 16</th>
<th>Bit 15</th>
<th>Bit 14</th>
<th>Bit 13-12</th>
<th>Bit 11-0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>EWIE</td>
<td>EWIC</td>
<td>EWIT[11:0]</td>
<td></td>
</tr>
<tr>
<td>rw</td>
<td>w</td>
<td>rw</td>
<td>rw</td>
<td></td>
</tr>
</tbody>
</table>

**Bits 31:16** Reserved, must be kept at reset value.

**Bit 15** **EWIE**: Watchdog early interrupt enable  
Set and reset by software.  
0: The early interrupt interface is disabled.  
1: The early interrupt interface is enabled.  
The EWU bit in the **IWDG status register (IWDG_SR)** must be reset to be able to change the value of this bit.

**Bit 14** **EWIC**: Watchdog early interrupt acknowledge  
The software must write a 1 into this bit in order to acknowledge the early wake-up interrupt and to clear the EWIF flag. Writing 0 has no effect, reading this flag returns a 0.

**Bits 13:12** Reserved, must be kept at reset value.

**Bits 11:0** **EWIT[11:0]**: Watchdog counter window value  
These bits are write access protected (see **Section 61.4.6**). They are written by software to define at which position of the IWDCNT down-counter the early wake-up interrupt must be generated. The early interrupt is generated when the IWDCNT is lower or equal to EWIT[11:0] - 1.  
EWIT[11:0] must be bigger than 1.  
An interrupt is generated only if EWIE = 1.  
The EWU bit in the **IWDG status register (IWDG_SR)** must be reset to be able to change the reload value.

**Note**: Reading this register returns the Early wake-up comparator value and the Interrupt enable bit from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing, hence the value read from this register is valid only when the EWU bit in the **IWDG status register (IWDG_SR)** is reset.
### 61.7.7 IWDG register map

Refer to Section 2.3 on page 139 for the register boundary addresses.

62 System window watchdog (WWDG)

62.1 Introduction

The system window watchdog (WWDG) is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence.

The watchdog circuit generates a reset on expiry of a programmed time period, unless the program refreshes the contents of the down-counter before the T6 bit is cleared. A reset is also generated if the 7-bit down-counter value (in the control register) is refreshed before the down-counter reaches the window register value. This implies that the counter must be refreshed in a limited window.

The WWDG clock is prescaled from the APB clock and has a configurable time-window that can be programmed to detect abnormally late or early application behavior.

The WWDG is best suited for applications requiring the watchdog to react within an accurate timing window.

62.2 WWDG main features

- Programmable free-running down-counter
- Conditional reset
  - Reset (if watchdog activated) when the down-counter value becomes lower than 0x40
  - Reset (if watchdog activated) if the down-counter is reloaded outside the window (see Figure 765)
- Early wake-up interrupt (EWI): triggered (if enabled and the watchdog activated) when the down-counter is equal to 0x40

62.3 WWDG implementation

<table>
<thead>
<tr>

</tr>
<tr>
<td>Capability to be frozen when the microcontroller enters in Debug mode$^{(3)}$</td>
<td>X</td>
</tr>
<tr>
<td>Option bytes to control the Hardware mode$^{(4)}$</td>
<td>X</td>
</tr>
</tbody>
</table>

1. "X" = supported, "-" = not supported.
2. Refer to the RCC section for additional information.
3. Controlled via DBG_WWDG_STOP in DBG block.
4. Controlled via the option byte WWDG_SW. When WWDG_SW is set in HW mode the WWDG is running as soon as the CPU is in Run or Sleep modes.

62.4 WWDG functional description

If the watchdog is activated (the WDGA bit is set in the WWDG_CR register), and when the 7-bit down-counter (T[6:0] bits) is decremented from 0x40 to 0x3F (T6 becomes cleared), it initiates a reset. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

The application program must write in the WWDG_CR register at regular intervals during normal operation to prevent a reset. This operation can take place only when the counter value is lower than or equal to the window register value, and higher than 0x3F. The value to be stored in the WWDG_CR register must be between 0xFF and 0xC0.

Refer to Figure 764 for the WWDG block diagram.

62.4.1 WWDG block diagram

Figure 764. Watchdog block diagram

62.4.2 WWDG internal signals

Table 622 gives the list of WWDG internal signals.

<table>
<thead>
<tr>

<td>WWDG reset signal output</td>
</tr>
<tr>
<td>wwdg_it</td>
<td>Digital output</td>
<td>WWDG early interrupt output</td>
</tr>
</tbody>
</table>
62.4.3 Enabling the watchdog

When the user option WWDG_SW selects “Software window watchdog”, the watchdog is always disabled after a reset. It is enabled by setting the WDGA bit in the WWDG_CR register, then it cannot be disabled again, except by a reset.

When the user option WWDG_SW selects “Hardware window watchdog”, the watchdog is always enabled after a reset, it cannot be disabled.

62.4.4 Controlling the down-counter

This down-counter is free-running, counting down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset.

The T[5:0] bits contain the number of increments that represent the time delay before the watchdog produces a reset. The timing varies between a minimum and a maximum value, due to the unknown status of the prescaler when writing to the WWDG_CR register (see Figure 765). The WWDG configuration register (WWDG_CFR) contains the high limit of the window: to prevent a reset, the down-counter must be reloaded when its value is lower than or equal to the window register value, and greater than 0x3F. Figure 765 describes the window watchdog process.

Note: The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

62.4.5 How to program the watchdog timeout

Use the formula in Figure 765 to calculate the WWDG timeout.

---

Warning: When writing to the WWDG_CR register, always write 1 in the T6 bit to avoid generating an immediate reset.
The formula to calculate the timeout value is given by:

\[ t_{\text{WWDG}} = t_{\text{PCLK}} \times 4096 \times 2^{W\text{DGTB}[2:0]} \times (T[5:0] + 1) \, (\text{ms}) \]

where:
- \( t_{\text{WWDG}} \): WWDG timeout
- \( t_{\text{PCLK}} \): APB clock period measured in ms
- 4096: value corresponding to internal divider

As an example, if APB frequency is 48 MHz, WDGTB[2:0] is set to 3 and T[5:0] is set to 63:

\[ t_{\text{WWDG}} = \left(\frac{1}{48000}\right) \times 4096 \times 2^3 \times (63 + 1) = 43.69 \text{ms} \]

Refer to the datasheet for the minimum and maximum values of \( t_{\text{WWDG}} \).

### 62.4.6 Debug mode

When the device enters debug mode (processor halted), the WWDG counter either continues to work normally or stops, depending on the configuration bit in DBG module. For more details, refer to *Section 75: Debug support (DBG)*.
62.5 **WWDG interrupts**

The early wake-up interrupt (EWI) can be used if specific safety operations or data logging must be performed before the reset is generated. To enable the early wake-up interrupt, the application must:

- Write EWIF bit of WWDG_SR register to 0, to clear unwanted pending interrupt
- Write EWI bit of WWDG_CFR register to 1, to enable interrupt

When the down-counter reaches the value 0x40, a watchdog interrupt is generated, and the corresponding interrupt service routine (ISR) can be used to trigger specific actions (such as communications or data logging), before resetting the device.

In some applications, the EWI interrupt can be used to manage a software system check and/or system recovery/graceful degradation, without generating a WWDG reset. In this case the corresponding ISR must reload the WWDG counter to avoid the WWDG reset, then trigger the required actions.

The watchdog interrupt is cleared by writing '0' to the EWIF bit in the WWDG_SR register.

*Note:* When the watchdog interrupt cannot be served (for example due to a system lock in a higher priority task), the WWDG reset is eventually generated.

### Table 623. WWDG interrupt requests

<table>
<thead>
<tr>

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:11 **WDGTB[2:0]**: Timer base

The timebase of the prescaler can be modified as follows:
- 000: CK counter clock (PCLK div 4096) div 1
- 001: CK counter clock (PCLK div 4096) div 2
- 010: CK counter clock (PCLK div 4096) div 4
- 011: CK counter clock (PCLK div 4096) div 8
- 100: CK counter clock (PCLK div 4096) div 16
- 101: CK counter clock (PCLK div 4096) div 32
- 110: CK counter clock (PCLK div 4096) div 64
- 111: CK counter clock (PCLK div 4096) div 128

Bit 10 Reserved, must be kept at reset value.

Bit 9 **EWI**: Early wake-up interrupt enable

Set by software and cleared by hardware after a reset. When set, an interrupt occurs whenever the counter reaches the value 0x40.

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:0 **W[6:0]**: 7-bit window value

These bits contain the window value to be compared with the down-counter.
62.6.3 WWDG status register (WWDG_SR)

</table>

Refer to Section 2.3 on page 139 for the register boundary addresses.
63  Real-time clock (RTC)

63.1  Introduction

The RTC provides an automatic wake-up to manage all low-power modes.

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar with programmable alarm interrupts.

As long as the supply voltage remains in the operating range, the RTC never stops, regardless of the device status (Run mode, low-power mode or under reset).

The RTC is functional in $V_{BAT}$ mode.

63.2  RTC main features

The RTC supports the following features (see Figure 766: RTC block diagram):

- Calendar with subseconds, seconds, minutes, hours (12 or 24 format), week day, date, month, year, in BCD (binary-coded decimal) format.
- Binary mode with 32-bit free-running counter.
- Automatic correction for 28, 29 (leap year), 30, and 31 days of the month.
- Two programmable alarms.
- On-the-fly correction from 1 to 32767 RTC clock pulses. This can be used to synchronize it with a master clock.
- Reference clock detection: a more precise second source clock (50 or 60 Hz) can be used to enhance the calendar precision.
- Digital calibration circuit with 0.95 ppm resolution, to compensate for quartz crystal inaccuracy.
- Timestamp feature which can be used to save the calendar content. This function can be triggered by an event on the timestamp pin, or by a tamper event, or by a switch to $V_{BAT}$ mode.
- 17-bit auto-reload wake-up timer (WUT) for periodic events with programmable resolution and period.
- TrustZone support:
  - RTC fully securable
  - Alarm A, alarm B, wake-up Timer and timestamp individual secure or nonsecure configuration
- Alarm A, alarm B, wake-up Timer and timestamp individual privilege protection

The RTC is supplied through a switch that takes power either from the $V_{DD}$ supply when present or from the $V_{BAT}$ pin.

The RTC is functional in $V_{BAT}$ mode and in all low-power modes when it is clocked by the LSE.

All RTC events (Alarm, wake-up Timer, Timestamp) can generate an interrupt and wake-up the device from the low-power modes.
63.3 RTC functional description

63.3.1 RTC block diagram
Figure 766. RTC block diagram
63.3.2 RTC pins and internal signals

Table 625. RTC input/output pins

<table>
<thead>
<tr>
<th>Pin name</th>

</tr>
<tr>
<td>RTC_OUT2</td>
<td>Output</td>
<td>RTC output 2</td>
</tr>
</tbody>
</table>

RTC_OUT1 and RTC_OUT2 which select one of the following two outputs:
- **CALIB**: 512 Hz or 1 Hz clock output (with an LSE frequency of 32.768 kHz). This output is enabled by setting the COE bit in the RTC_CR register.
- **TAMPALRM**: This output is the OR between rtc_tamp_evt and ALARM signals. ALARM is enabled by configuring the OSEL[1:0] bits in the RTC_CR register which select the alarm A, alarm B or wake-up outputs. rtc_tamp_evt is enabled by setting the TAMPOE bit in the RTC_CR register which selects the tamper event outputs.

Table 626. RTC internal input/output signals

<table>

<td>RTC calendar overflow: this signal is generated when the RTC calendar reaches its maximum value, on the 31st of December 99, at 23:59:59. The calendar is then frozen and cannot overflow.</td>
</tr>
</tbody>
</table>

The RTC kernel clock is usually the LSE at 32.768 kHz although it is possible to select other clock sources in the RCC (refer to RCC for more details). Some functions are not available in some low-power modes or VBAT when the selected clock is not LSE. Refer to Section 63.4: RTC low-power modes for more details.
The TZEN option bit is used to activate TrustZone in the device.
TZEN = 1: TrustZone activated.
TZEN = 0: TrustZone disabled.
When TrustZone is disabled, the APB access to the RTC registers are nonsecure.
The triggers outputs can be used as triggers for other peripherals.

63.3.3 GPIOs controlled by the RTC and TAMP

The GPIOs included in the Battery Backup Domain (V_{BAT}) are directly controlled by the
peripherals providing functions on these I/Os, whatever the GPIO configuration.

RTC_OUT1, RTC_TS, TAMP_IN1 and TAMP_OUT2 are mapped on the same pin (PC13).
The RTC and TAMP functions mapped on PC13 are available in all low-power modes and in
V_{BAT} mode.
The output mechanism follows the priority order shown in Table 628.

1. OD: open drain; PP: push-pull.
2. In this configuration the GPIO must be configured in input.

In addition, it is possible to output RTC_OUT2 on PB2 pin thanks to OUT2EN bit. The different functions are mapped on RTC_OUT1 or on RTC_OUT2 depending on OSEL, COE and OUT2EN configuration, as shown in table **Table 629**.
63.3.4 RTC secure protection modes

By default after a backup domain power-on reset, all RTC registers can be read or written in both secure and nonsecure modes, except for the RTC secure configuration register (RTC_SECCFGR) which can be written in secure mode only. The RTC protection configuration is not affected by a system reset.

When the SEC bit is set in the RTC_SECCFGR register:
- Writing the RTC registers is possible only in secure mode.
- Reading RTC_SECCFGR, RTC_PRIVCFGR, RTC_MISR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER and RTC_CALR is always possible in secure and nonsecure modes. All the other RTC registers can be read only in secure mode.

When the SEC bit is cleared, it is still possible to protect some of the registers by setting dedicated INITSEC, CALSEC, TSSEC, WUTSEC, ALRASEC or ALRBSEC control bits. If all these bits are also set, all the RTC registers can be read and written in secure and nonsecure mode.
- When INITSEC is set:
  - RTC_TR, RTC_DR, RTC_PRER registers, plus INIT, BIN and BCDU in RTC_ICSR, FMT control bits in RTC_CR and INITPRIV in the RTC_PRIVCFGR can be written only in secure mode.
  - These registers and control bits can be read in secure and nonsecure mode.
- When CALSEC is set:
  - RTC_SHIFTR and RTC_CALR registers, plus ADD1H, SUB1H and REFCKON control bits in the RTC_CR and CALPRIV in the RTC_PRIVCFGR can be written only in secure mode.
  - These registers and control bits can be read in secure and nonsecure mode.
- When ALRASEC is set:
  - RTC_ALRMAR, RTC_ALRMASSR and RTC_ALRABINR registers, plus ALRAE, ALRAFCLR, ALRAIE and SSRUIE in the RTC_CR, CALRAF and CSSRUF in the

</table>
RTC_SCR, ALRAF and SSRUF in RTC_SR, and ALRAMF and SSRUMF in RTC_SMISR can be read and written only in secure mode.

- ALRAPRIV in the RTC_PRIVCFGR can be written only in secure mode.

- When ALRBSEC is set:
  - RTC_ALRMBR, RTC_ALRMBSSR and RTC_ALRBBINR registers, plus ALRBE ALRBFCLR, ALRBE in the RTC_CR, CALRBF in the RTC_SCR, ALRBF in RTC_SR, and ALRBMF in RTC_SMISR can be read and written only in secure mode.
  - ALRBPRIV in the RTC_PRIVCFGR can be written only in secure mode.

- When WUTSEC is set:
  - RTC_WUTR register, plus WUTE, WUTIE and WUCKSEL control bits in the RTC_CR, CWUTF in the RTC_SCR, WUTF in RTC_SR, and WUTMF in RTC_SMISR can be read and written only in secure mode.
  - WUTPRIV in the RTC_PRIVCFGR can be written only in secure mode.

- When TSSEC is set:
  - RTC_TSTR, RTC_TSDR and RTC_TSSSR registers, plus TAMPTS, ITSE, TSE, TSIE, TSEDGE control bits in the RTC_CR, CITSF, CTSOVF and CTSF bits in the RTC_SCR, TSF, TSOVF and ITSF in RTC_SR, and TSMF, TSOVMF and ITSMF in RTC_SMISR can be read and written only in secure mode.
  - TSPRIV in the RTC_PRIVCFGR can be written only in secure mode.

A nonsecure access to a secure-protected register is denied:

- There is no bus error generated.
- In case the register has a global protection: a notification is generated through a flag/interrupt in the TZIC (TrustZone illegal access controller). In case only a few bits of the register are protected (for registers with mixed features such as RTC_CR...), no notification is generated.
- When write protected, the bits are not written.
- When read protected they are read as 0.

As soon as at least one function is configured to be secured, the RTC reset and clock control is also secured in the RCC.

### 63.3.5 RTC privilege protection modes

By default after a backup domain power-on reset, all RTC registers can be read or written in both privileged and non-privileged modes, except for the RTC privilege mode control register (RTC_PRIVCFGR) which can be written in privilege mode only. The RTC protection configuration is not affected by a system reset.

When the PRIV bit is set in the RTC_PRIVCFGR register:

- Writing the RTC registers is possible only in privileged mode.
- Reading the RTC_SECCFG, RTC_PRIVCFGR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER and RTC_CALR is always possible in privilege and non-privileged modes.
All the other RTC registers can be read only in privilege mode.

When the PRIV bit is cleared, it is still possible to protect some of the registers by setting dedicated INITPRIV, CALPRIV, TSPRIV, WUTPRIV, ALRAPRIV or ALRBPRIV control bits.
all these bits are also cleared, all the RTC registers can be read or written in privilege and non-privileged modes.

- When INITPRIV is set:
  - RTC_TR, RTC_DR, RTC_PRER registers, plus INIT, BIN and BCDU in RTC_ICSR and FMT control bits in RTC_CR, plus INITSEC in the RTC_SECCFGFR can be written only in privilege mode.
  - These registers and control bits can be read in privilege and non-privileged mode.

- When CALPRIV is set:
  - RTC_SHIFTR and RTC_CALR registers, plus ADD1H, SUB1H and REFCKON control bits in the RTC_CR, plus CALDSEC in the RTC_SECCFGFR can be written only in privilege mode.
  - These registers and control bits can be read in privilege and non-privileged mode.

- When ALRAPRIV is set:
  - RTC_ALRMAR, RTC_ALRMASSR and RTC_ALRABINR registers, plus ALRAE ALRAFCLR, ALRAIE and SSRUIE in the RTC_CR, and CALRAF and CSSRUF in the RTC_SCR, ALRAF and SSRUF in RTC_SR, and ALRAMF and SSRUMF in RTC_MISR and RTC_SMISR can be read and written only in privilege mode.
  - ALRASEC in the RTC_SECCFGFR can be written only in privilege mode.

- When ALRBPRI is set:
  - RTC_ALRMBR, RTC_ALRMBSSR and RTC_ALRBBINR registers, plus ALRBE ALRBFCLR, ALRBIE in the RTC_CR, and CALRBF in the RTC_SCR, ALRBF in RTC_SR, and ALRBMF in RTC_MISR and RTC_SMISR can be read and written only in privilege mode.
  - ALRBSEC in the RTC_SECCFGFR can be written only in privilege mode.

- When WUTPRIV is set:
  - RTC_WUTR register, plus WUTE, WUTIE and WUCKSEL control bits in the RTC_CR, and CWUTF in the RTC_SCR, WUTF in RTC_SR, and WUTMF in RTC_MISR and RTC_SMISR can be read and written only in privilege mode.
  - WUTSEC in the RTC_SECCFGFR can be written only in privilege mode.

- When TSPRIV is set:
  - RTC_TSTR, RTC_TSDR and RTC_TSSSR registers, plus TAMPTS, ITSE, TSE, TSIE, TSEDGE control bits in the RTC_CR, CITSF, CTSOVF and CTSF bits in the RTC_SCR, TSF, TSOVF and ITSF in RTC_SR, and TSMF, TSOVMF and ITSF in RTC_MISR and RTC_SMISR can be read and written only in privilege mode.
  - TSSEC in the RTC_SECCFGFR can be written only in privilege mode.

A non-privileged access to a privileged-protected register is denied:

- There is no bus error generated.
- When write protected, the bits are not written.
- When read protected they are read as 0.

### 63.3.6 Clock and prescalers

For more information on the RTC clock (RTCCLK) source configuration, refer to “Reset and clock control (RCC)”. 
Real-time clock (RTC)

BCD mode (BIN=00)

A programmable prescaler stage generates a 1 Hz clock which is used to update the calendar. To minimize power consumption, the prescaler is split into 2 programmable prescalers (see Figure 766: RTC block diagram):

- A 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register.
- A 15-bit synchronous prescaler configured through the PREDIV_S bits of the RTC_PRER register.

Note: When both prescalers are used, it is recommended to configure the asynchronous prescaler to a high value to minimize consumption.

The asynchronous prescaler division factor is set to 128, and the synchronous division factor to 256, to obtain an internal clock frequency of 1 Hz (ck_spre) with an LSE frequency of 32.768 kHz.

The minimum division factor is 1 and the maximum division factor is $2^{22}$.

This corresponds to a maximum input frequency of around 4 MHz.

$\text{f}_{\text{ck}, \text{apre}}$ is given by the following formula:

$$\text{f}_{\text{CK}, \text{APRE}} = \frac{\text{f}_{\text{RTCCLK}}}{\text{PREDIV}_A + 1}$$

The $\text{ck}_{\text{apre}}$ clock is used to clock the binary RTC_SSR subsecond downcounter. When it reaches 0, RTC_SSR is reloaded with the content of PREDIV_S.

$\text{f}_{\text{ck}, \text{spre}}$ is given by the following formula:

$$\text{f}_{\text{CK}, \text{SPRE}} = \frac{\text{f}_{\text{RTCCLK}}}{(\text{PREDIV}_S + 1) \times (\text{PREDIV}_A + 1)}$$

The $\text{ck}_{\text{spre}}$ clock can be used either to update the calendar or as timebase for the 16-bit wake-up auto-reload timer. To obtain short timeout periods, the 16-bit wake-up auto-reload timer can also run with the RTCCLK divided by the programmable 4-bit asynchronous prescaler (see Section 63.3.10: Periodic auto-wake-up for details).

Binary mode (BIN=01)

The SSR binary down-counter is extended to 32-bit length and is free running. The time and date calendar BCD registers are not functional.

This down-counter is clocked by $\text{ck}_{\text{apre}}$: the output of the 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register.

PREDIV_S value is don’t care.

Mixed mode (BIN=10 or 11)

The SSR binary down-counter is extended to 32-bit length and is free running. The time and date calendar BCD registers are also available.

This down-counter is clocked by $\text{ck}_{\text{apre}}$: the output of the 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register. The bits BCDU[2:0] are
used to define when the calendar is incremented by 1 second, using the SSR least significant bits.

63.3.7 Real-time clock and calendar

The RTC calendar time and date registers are accessed through shadow registers which are synchronized with PCLK (APB clock). They can also be accessed directly in order to avoid waiting for the synchronization duration.

- RTC_SSR for the subseconds
- RTC_TR for the time
- RTC_DR for the date

Every RTCCLK periods, the current calendar value is copied into the shadow registers, and the RSF bit of RTC_ICSR register is set (see Section 63.6.12: RTC shift control register (RTC_SHIFTR)). The copy is not performed in Stop and Standby mode. When exiting these modes, the shadow registers are updated after up to 4 RTCCLK periods.

When the application reads the calendar registers, it accesses the content of the shadow registers. It is possible to make a direct access to the calendar registers by setting the BYPSHAD control bit in the RTC_CR register. By default, this bit is cleared, and the user accesses the shadow registers.

When reading the RTC_SSR, RTC_TR or RTC_DR registers in BYPSHAD = 0 mode, the frequency of the APB clock (fAPB) must be at least 7 times the frequency of the RTC clock (fRTCCLK).

The shadow registers are reset by system reset.

63.3.8 Calendar ultra-low power mode

It is possible to reduce drastically the RTC power consumption by setting the LPCAL bit in the RTC_CALR register. In this configuration, the whole RTC is clocked by ck_apre only instead of both RTCCLK and ck_apre. Consequently, some flags delays are longer, and the calibration window is longer (refer to Section : RTC ultra-low-power mode).

The LPCAL bit is ignored (assumed to be 0) when asynchronous prescaler division factor (PREDIV_A+1) is not a power of 2.

Switching from LPCAL=0 to LPCAL=1 or from LPCAL=1 to LPCAL=0 is not immediate and requires a few ck_apre periods to complete.

63.3.9 Programmable alarms

The RTC unit provides programmable alarm: alarm A and alarm B. The description below is given for alarm A, but can be translated in the same way for alarm B.

The programmable alarm function is enabled through the ALRAE bit in the RTC_CR register.

The ALRAF is set to 1 if the calendar subseconds, seconds, minutes, hours, date or day match the values programmed in the alarm registers RTC_ALRMASSR and RTC_ALRMAR. Each calendar field can be independently selected through the MSKx bits of the RTC_ALRMAR register, and through the MASKSSx bits of the RTC_ALRMASSR register.
When the binary mode is used, the subsecond field can be programmed in the alarm binary register RTC_ALRABINR.

The alarm interrupt is enabled through the ALRAIE bit in the RTC_CR register.

In case the Alarm is used to generate a trigger event for another peripheral, the ALRAF can be automatically cleared by hardware by configuring the ALRAFCLR bit at 1 in the RTC_CR register. In this configuration there is no need for software intervention if the only purpose is clearing the ALRAF flag.

**Caution:** If the seconds field is selected (MSK1 bit reset in RTC_ALRMAR), the synchronous prescaler division factor set in the RTC_PRER register must be at least 3 to ensure correct behavior.

Alarm A and alarm B (if enabled by bits OSEL[1:0] in RTC_CR register) can be routed to the TAMPALRM output. TAMPALRM output polarity can be configured through bit POL the RTC_CR register.

### 63.3.10 Periodic auto-wake-up

The periodic wake-up flag is generated by a 16-bit programmable auto-reload down-counter. The wake-up timer range can be extended to 17 bits.

The wake-up function is enabled through the WUTE bit in the RTC_CR register.

The wake-up timer clock input ck_wut can be:

- RTC clock (RTCCLK) divided by 2, 4, 8, or 16.
  
  When RTCCLK is LSE (32.768 kHz), this permits the wake-up interrupt period to be configured from 122 µs to 32 s, with a resolution down to 61 µs.

- ck_spre (usually 1 Hz internal clock) in BCD mode, or the clock used to update the calendar as defined by BCDU in binary or mixed (BCD-binary) modes.
  
  When ck_spre frequency is 1 Hz, a wake-up time from 1 s to around 36 hours can be achieved with one-second resolution. This large programmable time range is divided in 2 parts:
  
  - from 1 s to 18 hours when WUCKSEL [2:1] = 10
  
  - and from around 18 h to 36 h when WUCKSEL[2:1] = 11. In this last case $2^{16}$ is added to the 16-bit counter current value. When the initialization sequence is complete (see *Programming the wake-up timer on page 2589*), the timer starts counting down. When the wake-up function is enabled, the down-counting remains active in low-power modes. In addition, when it reaches 0, the WUTF flag is set in the RTC_SR register, and the wake-up counter is automatically reloaded with its reload value (RTC_WUTR register value).

Depending on WUTOCLR in the RTC_WUTR register, the WUTF flag must either be cleared by software (WUTOCLR = 0x0000), or the WUTF is automatically cleared by hardware when the auto-reload down counter reaches WUTOCLR value (0x0000 < WUTOCLR ≤ WUT).

The wake-up flag is output on an internal signal rtc_wut that can be used by other peripherals (refer to section *Section 63.3.1: RTC block diagram*).

When the periodic wake-up interrupt is enabled by setting the WUTIE bit in the RTC_CR register, it can exit the device from low-power modes.
The periodic wake-up flag can be routed to the TAMPALRM output provided it has been enabled through bits OSEL[1:0] of RTC_CR register. TAMPALRM output polarity can be configured through the POL bit in the RTC_CR register.

System reset, as well as low-power modes (Sleep, Stop, and Standby) have no influence on the wake-up timer.

63.3.11 RTC initialization and configuration

RTC Binary, BCD or Mixed mode

By default the RTC is in BCD mode (BIN = 00 in the RTC_ICSR register): the RTC_SSR register contains the subsecond field SS[15:0], clocked by ck_apre, allowing to generate a 1 Hz clock to update the calendar registers in BCD format (RTC_TR and RTC_DR).

When the RTC is configured in binary mode (BIN = 01 in the RTC_ICSR register): the RTC_SSR register contains the binary counter SS[31:0], clocked by ck_apre. The calendar registers in BCD format (RTC_TR and RTC_DR) are not used.

When the RTC is configured in mixed mode (BIN = 10 or 11 in the RTC_ICSR register): the RTC_SSR register contains the binary counter SS[31:0], clocked by ck_apre. The calendar is updated (1 second increment) each time the SSR[BCDU+7:0] reaches 0.

RTC register write protection

After system reset, the RTC registers are protected against parasitic write access by the DBP bit in the power control peripheral (refer to the PWR power control section). DBP bit must be set in order to enable RTC registers write access.

After Backup domain reset, some of the RTC registers are write-protected: RTC_TR, RTC_DR, RTC_PRER, RTC_CALR, RTC_SHIFTR, the bits INIT, BIN and BCDU in RTC_ICSR and the bits FMT, SUB1H, ADD1H, REFCKON in RTC_CR.

The following steps are required to unlock the write protection on the protected RTC registers.

1. Write 0xCA into the RTC_WPR register.
2. Write 0x53 into the RTC_WPR register.

Writing a wrong key reactivates the write protection.

The protection mechanism is not affected by system reset.

The registers protected by INITPRIV are write-protected by the INIT KEY.

The registers protected by CALDPRIV are write-protected by the CAL KEY.

In case PRIV or INITPRIV is set in the RTC_PRIVCFGR, and/or SEC or INITSEC is set in the RTC_SECCFGR: the INIT KEY is unlocked and locked only if the write accesses into the RTC_WPR register are done in the privilege and security mode defined by PRIV, INITPRIV, SEC, INITSEC configuration.

In case PRIV or CALPRIV is set in the RTC_PRIVCFGR, and/or SEC or CALSEC is set in the RTC_SECCFGR: the CAL KEY is unlocked and locked only if the write accesses into the RTC_WPR register are done in the privilege and security mode defined by PRIV, CALPRIV, SEC, CALSEC configuration.
Calendar initialization and configuration

To program the initial time and date calendar values, including the time format and the prescaler configuration, the following sequence is required:

1. Set INIT bit to 1 in the RTC_ICSR register to enter initialization mode. In this mode, the calendar counter is stopped and its value can be updated.

2. Poll INITF bit of in the RTC_ICSR register. The initialization phase mode is entered when INITF is set to 1.
   - If LPCAL=0: INITF is set around 2 RTCCLK cycles after INIT bit is set.
   - If LPCAL=1: INITF is set up to 2 ck_apre cycle after INIT bit is set.

3. To generate a 1 Hz clock for the calendar counter, program both the prescaler factors in RTC_PRER register, plus BIN and BCDU in the RTC_ICSR register.

4. Load the initial time and date values in the shadow registers (RTC_TR and RTC_DR), and configure the time format (12 or 24 hours) through the FMT bit in the RTC_CR register.

5. Exit the initialization mode by clearing the INIT bit. The actual calendar counter value is then automatically loaded.
   - If LPCAL=0: the counting restarts after 4 RTCCLK clock cycles.
   - If LPCAL=1: the counting restarts after up to 2 RTCCLK + 1 ck_apre.

When the initialization sequence is complete, the calendar starts counting. The RTC_SSR content is initialized with:

- PREDIV_S in BCD mode (BIN=00)
- 0xFFFF FFFF in binary or mixed (BCD-binary) modes (BIN=01, 10 or 11).

In BCD mode, RTC_SSR contains the value of the synchronous prescaler counter. This enables one to calculate the exact time being maintained by the RTC down to a resolution of 1 / (PREDIV_S + 1) seconds. As a consequence, the resolution can be improved by increasing the synchronous prescaler value (PREDIV_S[14:0]). The maximum resolution allowed (30.52 μs with a 32768 Hz clock) is obtained with PREDIV_S set to 0x7FFF.

However, increasing PREDIV_S means that PREDIV_A must be decreased in order to maintain the synchronous prescaler output at 1 Hz. In this way, the frequency of the asynchronous prescaler output increases, which may increase the RTC dynamic consumption. The RTC dynamic consumption is optimized for PREDIV_A+1 being a power of 2.

**Note:** After a system reset, the application can read the INITS flag in the RTC_ICSR register to check if the calendar has been initialized or not. If this flag equals 0, the calendar has not been initialized since the year field is set at its Backup domain reset default value (0x00).

**Note:** To read the calendar after initialization, the software must first check that the RSF flag is set in the RTC_ICSR register.

Daylight saving time

The daylight saving time management is performed through bits SUB1H, ADD1H, and BKP of the RTC_CR register.

Using SUB1H or ADD1H, the software can subtract or add one hour to the calendar in one single operation without going through the initialization procedure.

In addition, the software can use the BKP bit to memorize this operation.
Programming the alarm

A similar procedure must be followed to program or update the programmable alarms. The procedure below is given for alarm A but can be translated in the same way for alarm B.

1. Clear ALRAE in RTC_CR to disable alarm A.
2. Program the alarm A registers (RTC_ALRMASSR/RTC_ALRMAR or RTC_ALRABINR).
3. Set ALRAE in the RTC_CR register to enable alarm A again.

Note: Each change of the RTC_CR register is taken into account after around 2 RTCCLK clock cycles due to clock synchronization.

Programming the wake-up timer

The following sequence is required to configure or change the wake-up timer auto-reload value (WUT[15:0] in RTC_WUTR):

1. Clear WUTE in RTC_CR to disable the wake-up timer.
2. Poll WUTWF until it is set in RTC_ICSR to make sure the access to wake-up auto-reload counter and to WUCKSEL[2:0] bits is allowed. This step must be skipped in calendar initialization mode.
   - If WUCKSEL[2] = 0: WUTWF is set around 1 ck_wut + 1 RTCCLK cycles after WUTE bit is cleared.
   - If WUCKSEL[2] = 1: WUTWF is set up to 1 ck_apre + 1 RTCCLK cycles after WUTE bit is cleared.
3. Program the wake-up auto-reload value WUT[15:0], WUTOCLR[15:0] and the wake-up clock selection (WUCKSEL[2:0] bits in RTC_CR). Set WUTE in RTC_CR to enable the timer again. The wake-up timer restarts down-counting.
   - If WUCKSEL[2] = 0: WUTWF is cleared around 1 ck_wut + 1 RTCCLK cycles after WUTE bit is set.
   - If WUCKSEL[2] = 1: WUTWF is cleared up to 1 ck_apre + 1 RTCCLK cycles after WUTE bit is set.

63.3.12 Reading the calendar

When BYPSHAD control bit is cleared in the RTC_CR register

To read the RTC calendar registers (RTC_SSR, RTC_TR and RTC_DR) properly, the APB clock frequency (fPCLK) must be equal to or greater than seven times the RTC clock frequency (fRTCCLK). This ensures a secure behavior of the synchronization mechanism.

If the APB clock frequency is less than seven times the RTC clock frequency, the software must read the calendar time and date registers twice. If the second read of the RTC_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done. In any case the APB clock frequency must never be lower than the RTC clock frequency.

The RSF bit is set in RTC_ICSR register each time the calendar registers are copied into the RTC_SSR, RTC_TR and RTC_DR shadow registers. The copy is performed every RTCCCLK cycle. To ensure consistency between the 3 values, reading either RTC_SSR or RTC_TR locks the values in the higher-order calendar shadow registers until RTC_DR is read. In case the software makes read accesses to the calendar in a time interval smaller than 1 RTCCCLK periods: RSF must be cleared by software after the first calendar read, and
then the software must wait until RSF is set before reading again the RTC_SSR, RTC_TR and RTC_DR registers.

After waking up from low-power mode (Stop or Standby), RSF must be cleared by software. The software must then wait until it is set again before reading the RTC_SSR, RTC_TR and RTC_DR registers.

The RSF bit must be cleared after wake-up and not before entering low-power mode.

After a system reset, the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers. Indeed, a system reset resets the shadow registers to their default values.

After an initialization (refer to Calendar initialization and configuration on page 2588): the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

After synchronization (refer to Section 63.3.14: RTC synchronization): the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

When the BYPSHAD control bit is set in the RTC_CR register (bypass shadow registers)

Reading the calendar registers gives the values from the calendar counters directly, thus eliminating the need to wait for the RSF bit to be set. This is especially useful after exiting from low-power modes (Stop or Standby), since the shadow registers are not updated during these modes.

When the BYPSHAD bit is set to 1, the results of the different registers might not be coherent with each other if an RTCCCLK edge occurs between two read accesses to the registers. Additionally, the value of one of the registers may be incorrect if an RTCCCLK edge occurs during the read operation. The software must read all the registers twice, and then compare the results to confirm that the data is coherent and correct. Alternatively, the software can just compare the two results of the least-significant calendar register.

Note: While BYPSHAD = 1, instructions which read the calendar registers require one extra APB cycle to complete.

63.3.13 Resetting the RTC

The calendar shadow registers (RTC_SSR, RTC_TR and RTC_DR) and some bits of the RTC status register (RTC_ICSR) are reset to their default values by all available system reset sources.

On the contrary, the following registers are reset to their default values by a Backup domain reset and are not affected by a system reset: the RTC current calendar registers, the RTC control register (RTC_CR), the prescaler register (RTC_PRER), the RTC calibration register (RTC_CALR), the RTC shift register (RTC_SHIFTR), the RTC timestamp registers (RTC_TSSSR, RTC_TSTR and RTC_TSDR), the wake-up timer register (RTC_WUTR), the alarm A and alarm B registers (RTC_ALRMASSR/RTC_ALRMAR/RTC_ALRABINR and RTC_ALRMBSSR/RTC_ALRMBR/RTC_ALRBBINR).

In addition, when clocked by LSE, the RTC keeps on running under system reset if the reset source is different from the Backup domain reset one (refer to RCC for details about RTC clock sources not affected by system reset). When a Backup domain reset occurs, the RTC is stopped and all the RTC registers are set to their reset values.
63.3.14 RTC synchronization

The RTC can be synchronized to a remote clock with a high degree of precision. After reading the subsecond field (RTC_SSR or RTC_TSSSR), a calculation can be made of the precise offset between the times being maintained by the remote clock and the RTC. The RTC can then be adjusted to eliminate this offset by “shifting” its clock by a fraction of a second using RTC_SHIFTR.

The RTC can be finely adjusted using the RTC shift control register (RTC_SHIFTR). Writing to RTC_SHIFTR can shift (either delay or advance) the clock with a resolution of 1 ck_apre period.

The shift operation consists in adding the SUBFS[14:0] value to the synchronous prescaler counter SS[15:0]: this delays the clock.

If at the same time the ADD1S bit is set in BCD or mixed mode, this results in adding one second and at the same time subtracting a fraction of second, so this advances the clock. ADD1S has no effect in binary mode.

As soon as a shift operation is initiated by a write to the RTC_SHIFTR register, the SHPF flag is set by hardware to indicate that a shift operation is pending. This bit is cleared by hardware as soon as the shift operation has completed.

Caution: In mixed mode (BIN=10 or 11), the SUBFS[14:BCDU+8] must be written with 0.

Caution: Before initiating a shift operation in BCD mode, the user must check that SS[15] = 0 in order to ensure that no overflow occurs. In mixed mode, the user must check that the bit SS[BCDU+8] = 0.

Caution: This synchronization feature is not compatible with the reference clock detection feature: firmware must not write to RTC_SHIFTR when REFCKON = 1.

63.3.15 RTC reference clock detection

This feature is available only in BCD mode (BIN=00).

The update of the RTC calendar can be synchronized to a reference clock, RTC_REFIN, which is usually the mains frequency (50 or 60 Hz). The precision of the RTC_REFIN reference clock should be higher than the 32.768 kHz LSE clock. When the RTC_REFIN detection is enabled (REFCKON bit of RTC_CR set to 1), the calendar is still clocked by the LSE, and RTC_REFIN is used to compensate for the imprecision of the calendar update frequency (1 Hz).

Each 1 Hz clock edge is compared to the nearest RTC_REFIN clock edge (if one is found within a given time window). In most cases, the two clock edges are properly aligned. When the 1 Hz clock becomes misaligned due to the imprecision of the LSE clock, the RTC shifts the 1 Hz clock a bit so that future 1 Hz clock edges are aligned. Thanks to this mechanism, the calendar becomes as precise as the reference clock.

The RTC detects if the reference clock source is present by using the 256 Hz clock (ck_apre) generated from the 32.768 kHz quartz. The detection is performed during a time window around each of the calendar updates (every 1 s). The window equals 7 ck_apre periods when detecting the first reference clock edge. A smaller window of 3 ck_apre periods is used for subsequent calendar updates.

Each time the reference clock is detected in the window, the asynchronous prescaler which outputs the ck_spre clock is forced to reload. This has no effect when the reference clock and the 1 Hz clock are aligned because the prescaler is being reloaded at the same
moment. When the clocks are not aligned, the reload shifts future 1 Hz clock edges a little for them to be aligned with the reference clock.

If the reference clock halts (no reference clock edge occurred during the 3 ck_apre window), the calendar is updated continuously based solely on the LSE clock. The RTC then waits for the reference clock using a large 7 ck_apre period detection window centered on the ck_spre edge.

When the RTC_REFIN detection is enabled, PREDIV_A and PREDIV_S must be set to their default values:
- PREDIV_A = 0x007F
- PREVID_S = 0x00FF

**Note:** RTC_REFIN clock detection is not available in Standby mode.

### 63.3.16 RTC smooth digital calibration

The RTC frequency can be digitally calibrated with a resolution of about 0.954 ppm with a range from -487.1 ppm to +488.5 ppm. The correction of the frequency is performed using series of small adjustments (adding and/or subtracting individual ck_cal pulses).

If LPCAL=0: ck_cal = RTCCLK

If LPCAL=1: ck_cal = ck_apre

These adjustments are fairly well distributed so that the RTC is well calibrated even when observed over short durations of time.

### RTC ultra-low-power mode

The RTC consumption can be reduced by setting the LPCAL bit in the RTC calibration register (RTC_CALR). In this case, the calibration mechanism is applied on ck_apre instead of RTCCLK. The resulting accuracy is the same, but the calibration is performed during a calibration cycle of about $2^{20} \times$ PREDIV_A $\times$ RTCCLK pulses instead of $2^{20}$ RTCCLK pulses when LPCAL=0.

### Smooth calibration mechanism

The smooth calibration register (RTC_CALR) specifies the number of ck_cal clock cycles to be masked during the calibration cycle:
- Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the calibration cycle.
- Setting CALM[1] to 1 causes two additional cycles to be masked
- Setting CALM[2] to 1 causes four additional cycles to be masked
- and so on up to CALM[8] set to 1 which causes 256 clocks to be masked.

**Note:** CALM[8:0] (RTC_CALR) specifies the number of ck_cal pulses to be masked during the calibration cycle. Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the calibration cycle at the moment when cal_cnt[19:0] is 0x80000; CALM[1] = 1 causes two other cycles to be masked (when cal_cnt is 0x40000 and 0xC0000); CALM[2] = 1 causes four other cycles to be masked (cal_cnt = 0x20000/0x60000/0xA0000/0xE0000); and so on up to CALM[8] = 1 which causes 256 clocks to be masked (cal_cnt = 0xXX800).

While CALM permits the RTC frequency to be reduced by up to 487.1 ppm with fine resolution, the bit CALP can be used to increase the frequency by 488.5 ppm. Setting CALP...
to 1 effectively inserts an extra \( \text{ck}_\text{cal} \) pulse every \( 2^{11} \) \( \text{ck}_\text{cal} \) cycles, which means that 512 clocks are added during every calibration cycle.

Using CALM together with CALP, an offset ranging from -511 to +512 \( \text{ck}_\text{cal} \) cycles can be added during the calibration cycle, which translates to a calibration range of -487.1 ppm to +488.5 ppm with a resolution of about 0.954 ppm.

The formula to calculate the effective calibrated frequency (\( F_{\text{CAL}} \)) given the input frequency (\( F_{\text{RTCCLK}} \)) is as follows:

\[
F_{\text{CAL}} = F_{\text{RTCCLK}} \times \left[ 1 + \frac{(\text{CALP} \times 512 - \text{CALM})}{(2^{20} + \text{CALM} - \text{CALP} \times 512)} \right]
\]

**Caution:** PREDIV_A must be greater or equal to 3.

**Calibration when PREDIV_A < 3**

The CALP bit can not be set to 1 when the asynchronous prescaler value (PREDIV_A bits in RTC_PRER register) is less than 3. If CALP was already set to 1 and PREDIV_A bits are set to a value less than 3, CALP is ignored and the calibration operates as if CALP was equal to 0.

It is however possible to perform a calibration with PREDIV_A less than 3 in BCD mode, the synchronous prescaler value (PREDIV_S) should be reduced so that each second is accelerated by 8 \( \text{ck}_\text{cal} \) clock cycles, which is equivalent to adding 256 clock cycles every calibration cycle. As a result, between 255 and 256 clock pulses (corresponding to a calibration range from 243.3 to 244.1 ppm) can effectively be added during each calibration cycle using only the CALM bits.

With a nominal RTCCLK frequency of 32768 Hz, when PREDIV_A equals 1 (division factor of 2), PREDIV_S should be set to 16379 rather than 16383 (4 less). The only other interesting case is when PREDIV_A equals 0, PREDIV_S should be set to 32759 rather than 32767 (8 less).

If PREDIV_S is reduced in this way, the formula given the effective frequency of the calibrated input clock is as follows:

\[
F_{\text{CAL}} = F_{\text{RTCCLK}} \times \left[ 1 + \frac{(256 - \text{CALM})}{(2^{20} + \text{CALM} - 256)} \right]
\]

In this case, \( \text{CALM}[7:0] \) equals 0x100 (the midpoint of the CALM range) is the correct setting if RTCCLK is exactly 32768.00 Hz.

**Verifying the RTC calibration**

It is recommended to verify the RTC calibration with LPCAL = 0, in order to have a 32-second calibration cycle.

RTC precision is ensured by measuring the precise frequency of RTCCLK and calculating the correct CALM value and CALP values. An optional 1 Hz output is provided to allow applications to measure and verify the RTC precision.

Measuring the precise frequency of the RTC over a limited interval can result in a measurement error of up to 2 RTCCLK clock cycles over the measurement period, depending on how the digital calibration cycle is aligned with the measurement period.
However, this measurement error can be eliminated if the measurement period is the same length as the calibration cycle period. In this case, the only error observed is the error due to the resolution of the digital calibration.

- By default, the calibration cycle period is 32 seconds.
  
  Using this mode and measuring the accuracy of the 1 Hz output over exactly 32 seconds guarantees that the measure is within 0.477 ppm (0.5 RTCCLK cycles over 32 seconds, due to the limitation of the calibration resolution).

- CALW16 bit of the RTC_CALR register can be set to 1 to force a 16-second calibration cycle period.

  In this case, the RTC precision can be measured during 16 seconds with a maximum error of 0.954 ppm (0.5 RTCCLK cycles over 16 seconds). However, since the calibration resolution is reduced, the long term RTC precision is also reduced to 0.954 ppm: CALM[0] bit is stuck at 0 when CALW16 is set to 1.

- CALW8 bit of the RTC_CALR register can be set to 1 to force a 8-second calibration cycle period.

  In this case, the RTC precision can be measured during 8 seconds with a maximum error of 1.907 ppm (0.5 RTCCLK cycles over 8 s). The long term RTC precision is also reduced to 1.907 ppm: CALM[1:0] bits are stuck at 00 when CALW8 is set to 1.

**Re-calibration on-the-fly**

The calibration register (RTC_CALR) can be updated on-the-fly while RTC_ICSR/INITF = 0, by using the follow process:

1. Poll the RTC_ICSR/RECALPF (re-calibration pending flag).
2. If it is set to 0, write a new value to RTC_CALR, if necessary. RECALPF is then automatically set to 1
3. Within three ck_apre cycles after the write operation to RTC_CALR, the new calibration settings take effect.

### 63.3.17 Timestamp function

Timestamp is enabled by setting the TSE or ITSE bits of RTC_CR register to 1.

When TSE is set:

The calendar is saved in the timestamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when a timestamp event is detected on the RTC_TS pin.

When TAMPTS is set:

The calendar is saved in the timestamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when an internal or external tamper event is detected. Refer to **RTC control register (RTC_CR)** and refer to Section: Timestamp on tamper event.

When ITSE is set:

The calendar is saved in the timestamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when an internal timestamp event is detected. The internal timestamp event is generated by the switch to the VBAT supply.

When a timestamp event occurs, due to internal or external event, the timestamp flag bit (TSF) in RTC_SR register is set. In case the event is internal, the ITSF flag is also set in RTC_SR register.
By setting the TSIE bit in the RTC_CR register, an interrupt is generated when a timestamp event occurs.

If a new timestamp event is detected while the timestamp flag (TSF) is already set, the timestamp overflow flag (TSOVF) flag is set and the timestamp registers (RTC_TSTR and RTC_TSDR) maintain the results of the previous event.

**Note:** TSF is set up to 2 ck_apre cycles after the timestamp event from RTC_TS pin or from rtc its internal signal occurs due to synchronization process. TSF is set up to 3 ck_apre cycles after tamper flags.

TSOVF is set up to only 1 ck_apre cycle after the event occurs. This means that if two timestamp events are close together, TSOVF can be seen as ‘1’ while TSF is still ‘0’. As a consequence, it is recommended to poll TSOVF only after TSF has been set.

**Caution:** If a timestamp event occurs immediately after the TSF bit is supposed to be cleared, then both TSF and TSOVF bits are set. To avoid masking a timestamp event occurring at the same moment, the application must not write 0 into TSF bit unless it has already read it to 1.

### 63.3.18 Calibration clock output

When the COE bit is set to 1 in the RTC_CR register, a reference clock is provided on the CALIB device output.

If the COSEL bit in the RTC_CR register is reset and PREDIV_A = 0x7F, the CALIB frequency is \( f_{RTCCLK/64} \). This corresponds to a calibration output at 512 Hz for an RTCCCLK frequency at 32.768 kHz. The CALIB duty cycle is irregular: there is a light jitter on falling edges. It is therefore recommended to use rising edges.

When COSEL is set and “PREDIV_S+1” is a non-zero multiple of 256 (i.e: PREDIV_S[7:0] = 0xFF), the CALIB frequency is \( f_{RTCCLK/(256 \times (PREDIV_A+1))} \). This corresponds to a calibration output at 1 Hz for prescaler default values (PREDIV_A = 0x7F, PREDIV_S = 0xFF), with an RTCCCLK frequency at 32.768 kHz.

**Note:** When COSEL is cleared, the CALIB output is the output of the 6th stage of the asynchronous prescaler. If LPCAL is changed from 0 to 1, the output can be irregular (glitch...) during the LPCAL switch. If LPCAL = 1 this output is always available. If LPCAL = 0, no output is present if PREDIV_A is < 0x20.

When COSEL is set, the CALIB output is the output of the 8th stage of the synchronous prescaler.

### 63.3.19 Tamper and alarm output

The OSEL[1:0] control bits in the RTC_CR register are used to activate the alarm output TAMPALRM, and to select the function which is output. These functions reflect the contents of the corresponding flags in the RTC_SR register.

When the TAMPOE control bit is set in the RTC_CR, all external and internal tamper flags are ORed and routed to the TAMPALRM output. If OSEL = 00 the TAMPALRM output reflects only the tampers flags. If OSEL ≠ 00, the signal on TAMPALRM provides both tamper flags and alarm A, B, or wake-up flag.

The polarity of the TAMPALRM output is determined by the POL control bit in RTC_CR so that the opposite of the selected flags bit is output when POL is set to 1.
TAMPALRM output

The TAMPALRM pin can be configured in output open drain or output push-pull using the control bit TAMPALRM_TYPE in the RTC_CR register. It is possible to apply the internal pull-up in output mode thanks to TAMPALRM_PU in the RTC_CR.

Note: Once the TAMPALRM output is enabled, it has priority over CALIB on RTC_OUT1. In case the TAMPALRM is configured open-drain in the RTC, the RTC_OUT1 GPIO must be configured as input.

63.4 RTC low-power modes

Table 630. Effect of low-power modes on RTC

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect RTC interrupts cause the device to exit the Sleep mode.</td>

1. The event flags are in the RTC_SR register.
2. The interrupt masked flags (resulting from event flags AND enable control bits) are in the RTC_SMISR register.
3. When the RTC is clocked by an oscillator functional in the low-power mode.
63.6 RTC registers
Refer to Section 1.2 of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

63.6.1 RTC time register (RTC_TR)
The RTC_TR is the calendar time shadow register. This register must be written in initialization mode only. Refer to Calendar initialization and configuration on page 2588 and Reading the calendar on page 2589.

This register is write protected. The write access procedure is described in RTC register write protection on page 2587.

This register can be write-protected against nonsecure access. Refer to Section 63.3.4: RTC secure protection modes.

This register can be write-protected against non-privileged access. Refer to Section 63.3.5: RTC privilege protection modes.

63.6.2 RTC date register (RTC_DR)

The RTC_DR is the calendar date shadow register. This register must be written in initialization mode only. Refer to Calendar initialization and configuration on page 2588 and Reading the calendar on page 2589.

This register is write protected. The write access procedure is described in RTC register write protection on page 2587.

This register can be write-protected against nonsecure access. Refer to Section 63.3.4: RTC secure protection modes.

This register can be write-protected against non-privileged access. Refer to Section 63.3.5: RTC privilege protection modes.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **DT[1:0]**: Date tens in BCD format

Bits 3:0 **DU[3:0]**: Date units in BCD format

**Note:** The calendar is frozen when reaching the maximum value, and can’t roll over.
63.6.3 RTC subsecond register (RTC_SSR)

Address offset: 0x08
Backup domain reset value: 0x0000 0000
System reset value: 0x0000 0000 (when BYPSSHAD = 0, not affected when BYPSSHAD = 1)

### 63.6.4 RTC initialization control and status register (RTC_ICSR)

This register is write protected. The write access procedure is described in RTC register write protection on page 2587.

This register can be globally protected, or each bit of this register can be individually protected against nonsecure access. Refer to Section 63.3.4: RTC secure protection modes.

This register can be globally protected, or each bit of this register can be individually protected against non-privileged access. Refer to Section 63.3.5: RTC privilege protection modes.

Address offset: 0x0C

Backup domain reset value: 0x0000 0007

System reset: not affected except INIT, INITF, and RSF bits which are cleared to 0

| Bit 31:17 Reserved, must be kept at reset value. |
| Bit 16 **RECALPF**: Recalibration pending Flag |
| The RECALPF status flag is automatically set to 1 when software writes to the RTC_CALR register, indicating that the RTC_CALR register is blocked. When the new calibration settings are taken into account, this bit returns to 0. Refer to Re-calibration on-the-fly. |
| Bits 15:13 Reserved, must be kept at reset value. |
| Bits 12:10 **BCDU[2:0]**: BCD update (BIN = 10 or 11) |
| In mixed mode when both BCD calendar and binary extended counter are used (BIN = 10 or 11), the calendar second is incremented using the SSR Least Significant Bits. |
| 0x0: 1s calendar increment is generated each time SS[7:0] = 0 |
| 0x1: 1s calendar increment is generated each time SS[8:0] = 0 |
| 0x2: 1s calendar increment is generated each time SS[9:0] = 0 |
| 0x3: 1s calendar increment is generated each time SS[10:0] = 0 |
| 0x4: 1s calendar increment is generated each time SS[11:0] = 0 |
| 0x5: 1s calendar increment is generated each time SS[12:0] = 0 |
| 0x6: 1s calendar increment is generated each time SS[13:0] = 0 |
| 0x7: 1s calendar increment is generated each time SS[14:0] = 0 |
| Bits 9:8 **BIN[1:0]**: Binary mode |
| 00: Free running BCD calendar mode (Binary mode disabled). |
| 01: Free running Binary mode (BCD mode disabled) |
| 10: Free running BCD calendar and Binary modes |
| 11: Free running BCD calendar and Binary modes |
Bit 7 **INIT**: Initialization mode
   0: Free running mode
   1: Initialization mode used to program time and date register (RTC_TR and RTC_DR), and
      prescaler register (RTC_PRER), plus BIN and BCDU fields. Counters are stopped and start
      counting from the new value when INIT is reset.

Bit 6 **INITF**: Initialization flag
   When this bit is set to 1, the RTC is in initialization state, and the time, date and prescaler
   registers can be updated.
   0: Calendar registers update is not allowed
   1: Calendar registers update is allowed

Bit 5 **RSF**: Registers synchronization flag
   This bit is set by hardware each time the calendar registers are copied into the shadow
   registers (RTC_SSR, RTC_TR and RTC_DR). This bit is cleared by hardware in initialization
   mode, while a shift operation is pending (SHPF = 1), or when in bypass shadow register
   mode (BYPSHAD = 1). This bit can also be cleared by software.
   It is cleared either by software or by hardware in initialization mode.
   0: Calendar shadow registers not yet synchronized
   1: Calendar shadow registers synchronized

Bit 4 **INITS**: Initialization status flag
   This bit is set by hardware when the calendar year field is different from 0 (Backup domain
   reset state).
   0: Calendar has not been initialized
   1: Calendar has been initialized

Bit 3 **SHPF**: Shift operation pending
   This flag is set by hardware as soon as a shift operation is initiated by a write to the
   RTC_SHIFTR register. It is cleared by hardware when the corresponding shift operation has
   been executed. Writing to the SHPF bit has no effect.
   0: No shift operation is pending
   1: A shift operation is pending

Bit 2 **WUTWF**: Wake-up timer write flag
   This bit is set by hardware when WUT value can be changed, after the WUTE bit has been
   set to 0 in RTC_CR.
   It is cleared by hardware in initialization mode.
   0: Wake-up timer configuration update not allowed except in initialization mode
   1: Wake-up timer configuration update allowed

Bits 1:0 Reserved, must be kept at reset value.
63.6.5 RTC prescaler register (RTC_PRER)

This register must be written in initialization mode only. The initialization must be performed in two separate write accesses. Refer to Calendar initialization and configuration on page 2588.

This register is write protected. The write access procedure is described in RTC register write protection on page 2587.

This register can be write-protected against nonsecure access. Refer to Section 63.3.4: RTC secure protection modes.

This register can be write-protected against non-privileged access. Refer to Section 63.3.5: RTC privilege protection modes.

Address offset: 0x10

Backup domain reset value: 0x007F 00FF

System reset: not affected

| Bit 31:23 Reserved, must be kept at reset value. |
| Bits 22:16 **PREDIV_A[6:0]**: Asynchronous prescaler factor |
| This is the asynchronous division factor: ck_apre frequency = RTCCLK frequency/(PREDIV_A+1) |
| Bit 15 Reserved, must be kept at reset value. |
| Bits 14:0 **PREDIV_S[14:0]**: Synchronous prescaler factor |
| This is the synchronous division factor: ck_spre frequency = ck_apre frequency/(PREDIV_S+1) |
63.6.6   RTC wake-up timer register (RTC_WUTR)

This register can be written only when WUTF is set to 1 in RTC_ICSR.
This register can be protected against nonsecure access. Refer to Section 63.3.4: RTC secure protection modes.
This register can be protected against non-privileged access. Refer to Section 63.3.5: RTC privilege protection modes.

Address offset: 0x14
Backup domain reset value: 0x0000 FFFF
System reset: not affected

<table>
<thead>
<tr>
<th>WUTOCLR[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>WUT[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 31:16  **WUTOCLR[15:0]:** Wake-up auto-reload output clear value
When WUTOCLR[15:0] is different from 0x0000, WUTF is set by hardware when the auto-reload down-counter reaches 0 and is cleared by hardware when the auto-reload downcounter reaches WUTOCLR[15:0].
When WUTOCLR[15:0] = 0x0000, WUTF is set by hardware when the WUT down-counter reaches 0 and is cleared by software.

Bits 15:0  **WUT[15:0]:** Wake-up auto-reload value bits
When the wake-up timer is enabled (WUTE set to 1), the WUTF flag is set every (WUT[15:0] + 1) ck_wut cycles. The ck_wut period is selected through WUCKSEL[2:0] bits of the RTC_CR register.
When WUCKSEL[2] = 1, the wake-up timer becomes 17-bits and WUCKSEL[1] effectively becomes WUT[16] the most-significant bit to be reloaded into the timer.
The first assertion of WUTF occurs between WUT and (WUT + 2) ck_wut cycles after WUTE is set. Setting WUT[15:0] to 0x0000 with WUCKSEL[2:0] = 011 (RTCCLK/2) is forbidden.

63.6.7   RTC control register (RTC_CR)

This register is write protected. The write access procedure is described in RTC register write protection on page 2587.
This register can be globally protected, or each bit of this register can be individually protected against non-secure access. Refer to Section 63.3.4: RTC secure protection modes.

This register can be globally protected, or each bit of this register can be individually protected against non-privileged access. Refer to Section 63.3.5: RTC privilege protection modes.

Address offset: 0x18

Backup domain reset value: 0x0000 0000

System reset: not affected

Bit 31 **OUT2EN**: RTC_OUT2 output enable

With this bit set, the RTC outputs can be remapped on RTC_OUT2 as follows:

- **OUT2EN = 0**: RTC output 2 disable
  - If OSEL ≠ 00 or TAMPOE = 1: TAMPALRM is output on RTC_OUT1
  - If OSEL = 00 and TAMPOE = 0 and COE = 1: CALIB is output on RTC_OUT1
- **OUT2EN = 1**: RTC output 2 enable
  - If (OSEL ≠ 00 or TAMPOE = 1) and COE = 0: TAMPALRM is output on RTC_OUT2
  - If OSEL = 00 and TAMPOE = 0 and COE = 1: CALIB is output on RTC_OUT2
  - If (OSEL ≠ 00 or TAMPOE = 1) and COE = 1: CALIB is output on RTC_OUT2 and TAMPALRM is output on RTC_OUT1.

Bit 30 **TAMPALRM_TYPE**: TAMPALRM output type

- 0: TAMPALRM is push-pull output
- 1: TAMPALRM is open-drain output

Bit 29 **TAMPALRM_PU**: TAMPALRM pull-up enable

- 0: No pull-up is applied on TAMPALRM output
- 1: A pull-up is applied on TAMPALRM output

Bit 28 **ALRBFCLR**: Alarm B flag automatic clear

- 0: Alarm B event generates a trigger event and ALRBF must be cleared by software to allow next alarm event.
- 1: Alarm B event generates a trigger event. ALRBF is automatically cleared by hardware after 1 ck_apre cycle.

Bit 27 **ALRAFCLR**: Alarm A flag automatic clear

- 0: Alarm A event generates a trigger event and ALRAF must be cleared by software to allow next alarm event.
- 1: Alarm A event generates a trigger event. ALRAF is automatically cleared by hardware after 1 ck_apre cycle.
Bit 26 **TAMPOE**: Tamper detection output enable on TAMPALRM
0: The tamper flag is not routed on TAMPALRM
1: The tamper flag is routed on TAMPALRM, combined with the signal provided by OSEL and with the polarity provided by POL.

Bit 25 **TAMPTS**: Activate timestamp on tamper detection event
0: Tamper detection event does not cause a RTC timestamp to be saved
1: Save RTC timestamp on tamper detection event
TAMPTS is valid even if TSE = 0 in the RTC_CR register. Timestamp flag is set up to 3 ck_apre cycles after the tamper flags.

*Note*: **TAMPTS must be cleared before entering RTC initialization mode.**

Bit 24 **ITSE**: timestamp on internal event enable
0: Internal event timestamp disabled
1: Internal event timestamp enabled

Bit 23 **COE**: Calibration output enable
This bit enables the CALIB output
0: Calibration output disabled
1: Calibration output enabled

Bits 22:21 **OSEL[1:0]**: Output selection
These bits are used to select the flag to be routed to TAMPALRM output.
00: Output disabled
01: Alarm A output enabled
10: Alarm B output enabled
11: Wake-up output enabled

Bit 20 **POL**: Output polarity
This bit is used to configure the polarity of TAMPALRM output.
0: The pin is high when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]), or when a TAMPxF/ITAMPxF is asserted (if TAMPOE = 1).
1: The pin is low when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]), or when a TAMPxF/ITAMPxF is asserted (if TAMPOE = 1).

Bit 19 **COSEL**: Calibration output selection
When COE = 1, this bit selects which signal is output on CALIB.
0: Calibration output is 512 Hz
1: Calibration output is 1 Hz
These frequencies are valid for RTCCLK at 32.768 kHz and prescalers at their default values (PREDIV_A = 127 and PREDIV_S = 255). Refer to Section 63.3.18: Calibration clock output.

Bit 18 **BKP**: Backup
This bit can be written by the user to memorize whether the daylight saving time change has been performed or not.

Bit 17 **SUB1H**: Subtract 1 hour (winter time change)
When this bit is set outside initialization mode, 1 hour is subtracted to the calendar time if the current hour is not 0. This bit is always read as 0.
Setting this bit has no effect when current hour is 0.
0: No effect
1: Subtracts 1 hour to the current time. This can be used for winter time change.
Bit 16  **ADD1H**: Add 1 hour (summer time change)  
When this bit is set outside initialization mode, 1 hour is added to the calendar time. This bit is always read as 0.  
0: No effect  
1: Adds 1 hour to the current time. This can be used for summer time change

Bit 15  **TSIE**: Timestamp interrupt enable  
0: Timestamp interrupt disable  
1: Timestamp interrupt enable

Bit 14  **WUTIE**: Wake-up timer interrupt enable  
0: Wake-up timer interrupt disabled  
1: Wake-up timer interrupt enabled

Bit 13  **ALRBIE**: Alarm B interrupt enable  
0: Alarm B interrupt disable  
1: Alarm B interrupt enable

Bit 12  **ALRAIE**: Alarm A interrupt enable  
0: Alarm A interrupt disabled  
1: Alarm A interrupt enabled

Bit 11  **TSE**: timestamp enable  
0: timestamp disable  
1: timestamp enable

Bit 10  **WUTE**: Wake-up timer enable  
0: Wake-up timer disabled  
1: Wake-up timer enabled  
*Note: When the wake-up timer is disabled, wait for WUTWF = 1 before enabling it again.*

Bit 9  **ALRBE**: Alarm B enable  
0: Alarm B disabled  
1: Alarm B enabled

Bit 8  **ALRAE**: Alarm A enable  
0: Alarm A disabled  
1: Alarm A enabled

Bit 7  **SSRUIE**: SSR underflow interrupt enable  
0: SSR underflow interrupt disabled  
1: SSR underflow interrupt enabled

Bit 6  **FMT**: Hour format  
0: 24 hour/day format  
1: AM/PM hour format

Bit 5  **BYPShAD**: Bypass the shadow registers  
0: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken from the shadow registers, which are updated once every two RTCCLK cycles.  
1: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken directly from the calendar counters.  
*Note: If the frequency of the APB clock is less than seven times the frequency of RTCCLK, BYPSHAD must be set to 1.*
Bit 4  **REFCKON**: RTC\_REFIN reference clock detection enable (50 or 60 Hz)  
0: RTC\_REFIN detection disabled  
1: RTC\_REFIN detection enabled  

**Note**: BIN must be 0x00 and PREDIV\_S must be 0x00FF.

Bit 3  **TSEDGE**: Timestamp event active edge  
0: RTC\_TS input rising edge generates a timestamp event  
1: RTC\_TS input falling edge generates a timestamp event  

TSE must be reset when TSEDGE is changed to avoid unwanted TSF setting.

Bits 2:0  **WUCKSEL[2:0]**: ck\_wut wake-up clock selection  
000: RTC/16 clock is selected  
001: RTC/8 clock is selected  
010: RTC/4 clock is selected  
011: RTC/2 clock is selected  
10x: ck\_spre (usually 1 Hz) clock is selected in BCD mode. In binary or mixed mode, this is the clock selected by BCDU.  
11x: ck\_spre (usually 1 Hz) clock is selected in BCD mode. In binary or mixed mode, this is the clock selected by BCDU. Furthermore, 2^{16} is added to the WUT counter value.

**Note**: Bits 6 and 4 of this register can be written in initialization mode only (RTC\_ICSR/INITF = 1).  
WUT = wake-up unit counter value. WUT = (0x0000 to 0xFFFF) + 0x10000 added when WUCKSEL[2:1 = 11].  

Bits 2 to 0 of this register can be written only when RTC\_CR WUTE bit = 0 and RTC\_ICSR WUTF bit = 1.  

*It is recommended not to change the hour during the calendar hour increment as it may mask the incrementation of the calendar hour.  
ADD1H and SUB1H changes are effective in the next second.*

### 63.6.8 RTC privilege mode control register (RTC\_PRIVCFGR)

This register can be written only when the APB access is privileged. This register can be write-protected, or each bit of this register can be individually write-protected against nonsecure access depending on the RTC\_SECCFGR configuration (refer to Section 63.3.5: RTC privilege protection modes).

Address offset: 0x1C  
Backup domain reset value: 0x0000 0000  
System reset: not affected
Bits 31:16  Reserved, must be kept at reset value.

Bit 15  **PRIV:** RTC privilege protection
0: All RTC registers can be written when the APB access is privileged or non-privileged, except the registers protected by other privilege protection bits.
1: All RTC registers can be written only when the APB access is privileged.

Bit 14  **INITPRIV:** Initialization privilege protection
0: RTC Initialization mode, calendar and prescalers registers can be written when the APB access is privileged or non-privileged.
1: RTC Initialization mode, calendar and prescalers registers can be written only when the APB access is privileged.

Bit 13  **CALPRIV:** Shift register, Delight saving, calibration and reference clock privilege protection
0: Shift register, Delight saving, calibration and reference clock can be written when the APB access is privileged or non-privileged.
1: Shift register, Delight saving, calibration and reference clock can be written only when the APB access is privileged.

Bits 12:4  Reserved, must be kept at reset value.

Bit 3  **TSPRIV:** Timestamp privilege protection
0: RTC Timestamp configuration and interrupt clear can be written when the APB access is privileged or non-privileged.
1: RTC Timestamp configuration and interrupt clear can be written only when the APB access is privileged.

Bit 2  **WUTPRIV:** Wake-up timer privilege protection
0: RTC wake-up timer configuration and interrupt clear can be written when the APB access is privileged or non-privileged.
1: RTC wake-up timer configuration and interrupt clear can be written only when the APB access is privileged.

Bit 1  **ALRBPRIV:** Alarm B privilege protection
0: RTC Alarm B configuration and interrupt clear can be written when the APB access is privileged or non-privileged.
1: RTC Alarm B configuration and interrupt clear can be written only when the APB access is privileged.

Bit 0  **ALRAPRIV:** Alarm A and SSR underflow privilege protection
0: RTC Alarm A and SSR underflow configuration and interrupt clear can be written when the APB access is privileged or non-privileged.
1: RTC Alarm A and SSR underflow configuration and interrupt clear can be written only when the APB access is privileged.

*Note:*  Refer to Section 63.3.5: RTC privilege protection modes for details on the read protection.
63.6.9 RTC secure configuration register (RTC_SECCFGR)

This register can be written only when the APB access is secure.

This register can be globally write-protected, or each bit of this register can be individually write-protected against non-privileged access depending on the RTC_PRIVCFGR configuration (refer to Section 63.3.5: RTC privilege protection modes).

Address offset: 0x20
Backup domain reset value: 0x0000 0000
System reset: not affected

| Bit 31:16 Reserved, must be kept at reset value. |
| Bit 15 SEC: RTC global protection |
| 0: All RTC registers can be written when the APB access is secure or non-secure, except the registers protected by other secure protection bits. |
| 1: All RTC registers can be written only when the APB access is secure. |
| Bit 14 INITSEC: Initialization protection |
| 0: RTC Initialization mode, calendar and prescalers registers can be written when the APB access is secure or nonsecure. |
| 1: RTC Initialization mode, calendar and prescalers registers can be written only when the APB access is secure. |
| Bit 13 CALSEC: Shift register, daylight saving, calibration and reference clock protection |
| 0: Shift register, daylight saving, calibration and reference clock can be written when the APB access is secure or nonsecure. |
| 1: Shift register, daylight saving, calibration and reference clock can be written only when the APB access is secure. |
| Bit 12:4 Reserved, must be kept at reset value. |
| Bit 3 TSSEC: Timestamp protection |
| 0: RTC timestamp configuration and interrupt clear can be written when the APB access is secure or nonsecure. |
| 1: RTC timestamp configuration and interrupt clear can be written only when the APB access is secure. |
Bit 2  **WUTSEC**: Wake-up timer protection
0: RTC wake-up timer configuration and interrupt clear can be written when the APB access is secure or nonsecure.
1: RTC wake-up timer configuration and interrupt clear can be written only when the APB access is secure.

Bit 1  **ALRBSEC**: Alarm B protection
0: RTC alarm B configuration and interrupt clear can be written when the APB access is secure or nonsecure.
1: RTC alarm B configuration and interrupt clear can be written only when the APB access is secure.

Bit 0  **ALRASEC**: Alarm A and SSR underflow protection
0: RTC alarm A and SSR underflow configuration and interrupt clear can be written when the APB access is secure or nonsecure.
1: RTC alarm A and SSR underflow configuration and interrupt clear can be written only when the APB access is secure.

**Note:** Refer to *Section 63.3.4: RTC secure protection modes* for details on the read protection.

### 63.6.10 RTC write protection register (RTC_WPR)

**Address offset:** 0x24  
**Reset value:** 0x0000 0000

**Bits 31:8**  Reserved, must be kept at reset value.

**Bits 7:0**  **KEY[7:0]**: Write protection key
This byte is written by software.
Reading this byte always returns 0x00.
Refer to *RTC register write protection* for a description of how to unlock RTC register write protection.
63.6.11 RTC calibration register (RTC_CALR)

This register is write protected. The write access procedure is described in RTC register write protection on page 2587.

This register can be write-protected against nonsecure access. Refer to Section 63.3.4: RTC secure protection modes.

This register can be write-protected against non-privileged access. Refer to Section 63.3.5: RTC privilege protection modes.

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 CALP: Increase frequency of RTC by 488.5 ppm
0: No RTCCCLK pulses are added.
1: One RTCCCLK pulse is effectively inserted every $2^{11}$ pulses (frequency increased by 488.5 ppm).
This feature is intended to be used in conjunction with CALM, which lowers the frequency of the calendar with a fine resolution. If the input frequency is 32768 Hz, the number of RTCCCLK pulses added during a 32-second window is calculated as follows:
$(512 \times \text{CALP}) - \text{CALM}$.
Refer to Section 63.3.16: RTC smooth digital calibration.

Bit 14 CALW8: Use an 8-second calibration cycle period
When CALW8 is set to 1, the 8-second calibration cycle period is selected.

Note: CALM[1:0] are stuck at 00 when CALW8 = 1. Refer to Section 63.3.16: RTC smooth digital calibration.

Bit 13 CALW16: Use a 16-second calibration cycle period
When CALW16 is set to 1, the 16-second calibration cycle period is selected. This bit must not be set to 1 if CALW8 = 1.

Note: CALM[0] is stuck at 0 when CALW16 = 1. Refer to Section 63.3.16: RTC smooth digital calibration.
Bit 12 **LPCAL**: RTC low-power mode
0: Calibration window is $2^{20}$ RTCLK, which is a high-consumption mode. This mode must be set only when less than 32s calibration window is required.
1: Calibration window is $2^{20}$ ck_apre, which is the required configuration for ultra-low consumption mode.

Bits 11:9 Reserved, must be kept at reset value.

Bits 8:0 **CALM[8:0]**: Calibration minus
The frequency of the calendar is reduced by masking CALM out of $2^{20}$ RTCLK pulses (32 seconds if the input frequency is 32768 Hz). This decreases the frequency of the calendar with a resolution of 0.9537 ppm.
To increase the frequency of the calendar, this feature should be used in conjunction with CALP. See Section 63.3.16: RTC smooth digital calibration on page 2592.

### 63.6.12 RTC shift control register (RTC_SHIFTR)

This register is write protected. The write access procedure is described in RTC register write protection on page 2587.

This register can be protected against nonsecure access. Refer to Section 63.3.4: RTC secure protection modes.

This register can be protected against non-privileged access. Refer to Section 63.3.5: RTC privilege protection modes.

**ADD1S**: 31-0

**SUBFS[14:0]**
Real-time clock (RTC)

Bit 31 **ADD1S**: Add one second
0: No effect
1: Add one second to the clock/calendar
This bit is write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF = 1, in RTC_ICSR).
This function is intended to be used with SUBFS (see description below) in order to effectively add a fraction of a second to the clock in an atomic operation.

Bits 30:15 Reserved, must be kept at reset value.

Bits 14:0 **SUBFS[14:0]**: Subtract a fraction of a second
These bits are write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF = 1, in RTC_ICSR).
The value which is written to SUBFS is added to the synchronous prescaler counter. Since this counter counts down, this operation effectively subtracts from (delays) the clock by:
Delay (seconds) = SUBFS / (PREDIV_S + 1)
A fraction of a second can effectively be added to the clock (advancing the clock) when the ADD1S function is used in conjunction with SUBFS, effectively advancing the clock by:
Advance (seconds) = (1 - (SUBFS / (PREDIV_S + 1))).
In mixed BCD-binary mode (BIN=10 or 11), the SUBFS[14:BCDU+8] must be written with 0.
**Note**: Writing to SUBFS causes RSF to be cleared. Software can then wait until RSF = 1 to be sure that the shadow registers have been updated with the shifted time.

### 63.6.13 RTC timestamp time register (RTC_TSTR)

The content of this register is valid only when TSF is set to 1 in RTC_SR. It is cleared when TSF bit is reset.

This register can be protected against nonsecure access. Refer to Section 63.3.4: RTC secure protection modes.

This register can be protected against non-privileged access. Refer to Section 63.3.5: RTC privilege protection modes.

**SSCLR**: Clear synchronous counter on alarm (Binary mode only)
0: The synchronous binary counter (SS[31:0] in RTC_SSR) is free-running.
1: The synchronous binary counter (SS[31:0] in RTC_SSR) is running from 0xFFFF FFFF to RTC_ALRBBINR.SS[31:0] value and is automatically reloaded with 0xFFFF FFFF one clock_apre cycle after reaching RTC_ALRBBINR.SS[31:0].

*Note*: **SSCLR** must be kept to 0 when BCD or mixed mode is used (BIN = 00, 10 or 11).

Bit 30 **Reserved**, must be kept at reset value.
Bits 29:24 **MASKSS[5:0]**: Mask the most-significant bits starting at this bit

0: No comparison on subseconds for Alarm B. The alarm is set when the seconds unit is incremented (assuming that the rest of the fields match).
1: SS[31:1] are don’t care in Alarm B comparison. Only SS[0] is compared.
2: SS[31:2] are don’t care in Alarm B comparison. Only SS[1:0] are compared.
...
31: SS[31] is don’t care in Alarm B comparison. Only SS[30:0] are compared.

*Note:* In BCD mode (BIN=00) the overflow bits of the synchronous counter (bits 15) is never compared. This bit can be different from 0 only after a shift operation.

Bits 23:15 Reserved, must be kept at reset value.

Bits 14:0 **SS[14:0]**: Subseconds value

This value is compared with the contents of the synchronous prescaler counter to determine if alarm B is to be activated. Only bits 0 up to MASKSS-1 are compared.

This field is the mirror of SS[14:0] in the RTC_ALRBBINR, and so can also be read or written through RTC_ALRBINR.

### 63.6.20 RTC status register (RTC_SR)

This register can be globally protected, or each bit of this register can be individually protected against non-secure access. Refer to Section 63.3.4: RTC secure protection modes.

This register can be globally protected, or each bit of this register can be individually protected against non-privileged access. Refer to Section 63.3.5: RTC privilege protection modes.

Bit 6 **SSR UF**: SSR underflow flag

This flag is set by hardware when the SSR rolls under 0. SSRUF is not set when SSCLR=1.

Bit 5 **ITSF**: Internal timestamp flag

This flag is set by hardware when a timestamp on the internal event occurs.
Bit 4  **TSOVF**: Timestamp overflow flag
This flag is set by hardware when a timestamp event occurs while TSF is already set.
It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise,
an overflow might not be noticed if a timestamp event occurs immediately before the TSF bit
is cleared.

Bit 3  **TSF**: Timestamp flag
This flag is set by hardware when a timestamp event occurs.
If ITSF flag is set, TSF must be cleared together with ITSF.

*Note*: TSF is not set if TAMPTS = 1 and the tamper flag is read during the 3 ck_apre cycles
following tamper event. Refer to Timestamp on tamper event for more details.

Bit 2  **WUTF**: Wake-up timer flag
This flag is set by hardware when the wake-up auto-reload counter reaches 0.
If WUTOCLR[15:0] is different from 0x0000, WUTF is cleared by hardware when the wake-
up auto-reload counter reaches WUTOCLR value.
If WUTOCLR[15:0] is 0x0000, WUTF must be cleared by software.
This flag must be cleared by software at least 1.5 RTCLK periods before WUTF is set to 1
again.

Bit 1  **ALRBF**: Alarm B flag
This flag is set by hardware when the time/date registers (RTC_TR and RTC_DR) match the
alarm B register (RTC_ALRMBR).

Bit 0  **ALRAF**: Alarm A flag
This flag is set by hardware when the time/date registers (RTC_TR and RTC_DR) match the
alarm A register (RTC_ALRMAR).

*Note*: The bits of this register are cleared 2 APB clock cycles after setting their corresponding
clear bit in the RTC_SCR register.

### 63.6.21 RTC nonsecure masked interrupt status register (RTC_MISR)
This register can be globally protected, or each bit of this register can be individually
protected against non-privileged access. Refer to Section 63.3.5: RTC privilege protection
modes.

Address offset: 0x54
Backup domain reset value: 0x0000 0000
System reset: not affected
63.6.22 RTC secure masked interrupt status register (RTC_SMISR)

This register can be globally protected, or each bit of this register can be individually protected against nonsecure access. Refer to Section 63.3.4: RTC secure protection modes.

This register can be globally protected, or each bit of this register can be individually protected against non-privileged access. Refer to Section 63.3.5: RTC privilege protection modes.

Address offset: 0x58
Backup domain reset value: 0x0000 0000
System reset: not affected
Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **SSRUMF**: SSR underflow secure masked flag
This flag is set by hardware when the SSR underflow secure interrupt occurs.

Bit 5 **ITSMF**: Internal timestamp interrupt secure masked flag
This flag is set by hardware when a timestamp on the internal event occurs and timestamp secure interrupt is raised.

Bit 4 **TSOVMF**: Timestamp overflow interrupt secure masked flag
This flag is set by hardware when a timestamp secure interrupt occurs while TSMF is already set.
It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a timestamp event occurs immediately before the TSF bit is cleared.

Bit 3 **TSMF**: Timestamp interrupt secure masked flag
This flag is set by hardware when a timestamp secure interrupt occurs.
If ITSF flag is set, TSF must be cleared together with ITSF.

Bit 2 **WUTMF**: Wake-up timer interrupt secure masked flag
This flag is set by hardware when the wake-up timer secure interrupt occurs.
This flag must be cleared by software at least 1.5 RTCCLK periods before WUTF is set to 1 again.

Bit 1 **ALRBMF**: Alarm B interrupt secure masked flag
This flag is set by hardware when the alarm B secure interrupt occurs.

Bit 0 **ALRAMF**: Alarm A interrupt secure masked flag
This flag is set by hardware when the alarm A secure interrupt occurs.

### 63.6.23 RTC status clear register (RTC_SCR)

This register can be globally protected, or each bit of this register can be individually protected against nonsecure access. Refer to [Section 63.3.4: RTC secure protection modes](#).

This register can be globally protected, or each bit of this register can be individually protected against non-privileged access. Refer to [Section 63.3.5: RTC privilege protection modes](#).

Bits 31:7  Reserved, must be kept at reset value.

Bit 6  **CSSRUF**: Clear SSR underflow flag
   Writing ‘1’ in this bit clears the SSRUF in the RTC_SR register.

Bit 5  **CITSF**: Clear internal timestamp flag
   Writing 1 in this bit clears the ITSF bit in the RTC_SR register.

Bit 4  **CTSOVF**: Clear timestamp overflow flag
   Writing 1 in this bit clears the TSOVF bit in the RTC_SR register.
   It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a timestamp event occurs immediately before the TSF bit is cleared.

Bit 3  **CTSF**: Clear timestamp flag
   Writing 1 in this bit clears the TSF bit in the RTC_SR register.
   If ITSF flag is set, TSF must be cleared together with ITSF by setting CRSF and CITSF.

Bit 2  **CWUTF**: Clear wake-up timer flag
   Writing 1 in this bit clears the WUTF bit in the RTC_SR register.

Bit 1  **CALRBF**: Clear alarm B flag
   Writing 1 in this bit clears the ALRBF bit in the RTC_SR register.

Bit 0  **CALRAF**: Clear alarm A flag
   Writing 1 in this bit clears the ALRAF bit in the RTC_SR register.

### 63.6.24 RTC alarm A binary mode register (RTC_ALRABINR)

This register can be written only when ALRAE is reset in RTC_CR register, or in initialization mode.

This register can be protected against nonsecure access. Refer to Section 63.3.4: RTC secure protection modes.

This register can be protected against non-privileged access. Refer to Section 63.3.5: RTC privilege protection modes.

Refer to Section 2.3 for the register boundary addresses.
64  Tamper and backup registers (TAMP)

64.1  Introduction

The anti-tamper detection circuit is used to protect sensitive data from external attacks. 32 32-bit backup registers are retained in all low-power modes and also in $V_{\text{BAT}}$ mode. The backup registers, as well as other secrets in the device, are protected by this anti-tamper detection circuit with 8 tamper pins and 11 internal tampers. The external tamper pins can be configured for edge detection, or level detection with or without filtering, or active tamper which increases the security level by auto checking that the tamper pins are not externally opened or shorted.
64.2 TAMP main features

- A tamper detection can optionally erase the backup registers, backup SRAM, SRAM2, caches and cryptographic peripherals. The device resources protected by tamper are named “device secrets”.
- 32 32-bit backup registers:
  - The backup registers (TAMP_BKPxR) are implemented in the backup domain that remains powered-on by V_BAT when the V_DD power is switched off.
- Up to 8 tamper pins for 8 external tamper detection events:
  - Active tamper mode: continuous comparison between tamper output and input to protect from physical open-short attacks.
  - Flexible active tamper I/O management: from 4 meshes (each input associated to its own exclusive output) to 7 meshes (single output shared for up to 7 tamper inputs)
  - Passive tampers: ultra-low power edge or level detection with internal pull-up hardware management.
  - Configurable digital filter.
- 11 internal tamper events to protect against transient or environmental perturbation attacks
- Each tamper can be configured in two modes:
  - Confirmed mode: immediate erase of secrets on tamper detection, including backup registers erase
  - Potential mode: most of the secrets erase following a tamper detection are launched by software
- Any tamper detection can generate a RTC timestamp event.
- TrustZone support:
  - Tamper secure or nonsecure configuration.
  - Backup registers configuration in 3 configurable-size areas:
    1 read/write secure area.
    1 write secure/read nonsecure area.
    1 read/write nonsecure area.
  - Boot hardware key for secure AES, stored in backup registers, protected against read and write access.
- Tamper configuration and backup registers privilege protection
- Monotonic counter.

64.3 TAMP implementation

STM32U575/585 rev. X devices do not implement the active tamper prescaler extension. This feature is implemented in all other STM32U575/585 revisions, and in the other STM32U5 Series devices.
64.4 TAMP functional description

64.4.1 TAMP block diagram

</tbody>
</table>

1. This monitoring must be enabled by setting MONEN in PWR backup domain control register 1 (PWR_BDCR1).
2. This monitoring must be enabled by setting LSECSSON in RCC backup domain control register (RCC_BDCR).
3. This signal is generated in the TAMP peripheral.

The TZEN option bit is used to activate TrustZone in the device.

TZEN = 1: TrustZone activated.
TZEN = 0: TrustZone disabled.
When TrustZone is disabled, the APB access to the TAMP registers are nonsecure.

### 64.4.3 GPIOs controlled by the RTC and TAMP

Refer to Section 63.3.3: GPIOs controlled by the RTC and TAMP.

### 64.4.4 TAMP register write protection

After system reset, the TAMP registers (including backup registers) are protected against parasitic write access by the DBP bit in the power control peripheral (refer to the PWR power control section). DBP bit must be set in order to enable TAMP registers write access.

### 64.4.5 TAMP secure protection modes

By default after a backup domain power-on reset, all TAMP registers can be read or written in both secure and nonsecure modes, except for the TAMP secure configuration register (TAMP_SECCFGR) which can be written in secure mode only. The TAMP protection configuration is not affected by a system reset.

- When the TAMPSEC bit is set in the TAMP_SECCFGR register:
  - Writing the TAMP registers is possible only in secure mode, except for the backup registers which have their own protection setting.
  - Reading TAMP_SECCFGR, TAMP_PRIVCFGR and TAMP_MISR is always possible in secure and nonsecure modes. All the other TAMP registers can be read only in secure mode, except for the backup registers and monotonic counters which have their own protection setting.
- When the CNT1SEC bit is set in the TAMP_SECCFGR register: the TAMP_COUNT1R can be read and written only in secure mode.

A nonsecure access to a secure-protected register is denied:

- There is no bus error generated.
- A notification is generated through a flag/interrupt in the TZIC (TrustZone illegal access controller).
- When write protected, the bits are not written.
- When read protected they are read as 0.

As soon as at least one function is configured to be secured, the TAMP reset and clock control is also secured in the RCC.
64.4.6 Backup registers protection zones

The backup registers protection is configured thanks to BKPRWSEC[7:0] and BKPWSEC[7:0] (refer to the figure below):

**Figure 768. Backup registers protection zones**

1. \( l \) = last backup register index

In case TZEN = 1, the bits BKPWPRIV and BKPRWPRIV in the TAMP_PRIVCFGR can be written only in secure mode.

64.4.7 TAMP privilege protection modes

By default after a backup domain power-on reset, all TAMP registers can be read or written in both privileged and non-privileged modes, except for the TAMP privilege configuration register (TAMP_PRIVCFGR) which can be written in privilege mode only. The TAMP protection configuration is not affected by a system reset.

When the TAMPPRIV bit is set in the TAMP_PRIVCFGR register:

- Writing the TAMP registers is possible only in privilege mode, except for the backup registers and the monotonic counters which have their own protection setting.
- When the CNT1PRIV bit is set in the TAMP_PRIVCFGR register: the TAMP_COUNT1R can be read and written only in privilege mode.
- Reading TAMP_SECCFGR, TAMP_PRIVCFGR is always possible in privilege and non-privileged modes. All the other TAMP registers can be read only in privileged mode, except for the backup registers and the monotonic counters which have their own protection setting.

The backup registers protection is configured thanks to BKPRWSEC[7:0] and BKPRWPRIV for the protection zone 1, and thanks to BKPRWSEC[7:0], BKPWSEC[7:0] and BKPWPRIV for the protection zone 2 (refer to Figure 768). The BHKLOCK bit can be written only in privileged mode when the BKPRWPRIV bit is set.

A non-privileged access to a privileged-protected register is denied:

- There is no bus error generated.
- When write protected, the bits are not written.
- When read protected they are read as 0.
64.4.8 Boot hardware key (BHK)

The eight first backup registers from TAMP_BKP0R to TAMP_BKP7R can be used to store a boot hardware key for the secure AES.

For this purpose, these registers must belong to the Protection Zone 1: BKPRWSEC must be greater or equal to 8.

Once the backup registers are written with the boot hardware key, the BHKLOCK bit must be set in the TAMP_SECCFGR register. Once BHKLOCK is set, the 8 backup registers cannot be accessed anymore by software: they are read as 0 and write to these registers is ignored. BHKLOCK cannot be cleared by software, and is cleared by hardware following a tamper event or when the readout protection (RDP) is disabled. It is also cleared with BKERASE command (in all cases the backup registers are also erased).

Refer to section secure AES co-processor (SAES) for details on procedure to download the boot hardware key in the SAES.

64.4.9 Tamper detection

The tamper detection main purpose is to protect the device secrets from device external attacks. The detection is made on events on TAMP_INx (x = pin index) I/Os, or on internal monitors detecting out-of-range device conditions.

The tamper detection can be configured for the following purposes:

- erase the backup registers and other device secrets stored in SRAMs or peripherals listed in Table 637: TAMP interconnection
- block the read/write access to the backup registers and other device secrets stored in SRAMs or peripherals listed in Table 637: TAMP interconnection
- generate an interrupt, capable to wake-up from low-power modes
- generate a hardware trigger for the low-power timers, or a RTC timestamp event

The external I/Os tamper detection supports 2 main configurations:

- Passive mode: TAMP_INx I/Os are monitored and a tamper is detected either on edge or on level.
- Active mode: TAMP_INx (x = pin index) is continuously compared with TAMP_OUTy (y = pin index) allowing open-short detection.

A digital filter can be applied on external tamper detection to avoid false detection. In addition, it is possible to configure each tamper source in potential mode, so that the secrets erase is not launched by hardware on tamper detection. The secrets erase can then be launched by software after software checks.

64.4.10 TAMP backup registers and other device secrets erase

The backup registers (TAMP_BKPxR) are not reset by system reset or when the device wakes up from Standby mode.

The backup registers and the other device secrets are not reset when the corresponding mask is set (TAMPxMSK=1 in the TAMP_CR2 register).

**Note:** The backup registers are also erased when the readout protection of the flash is changed from level 1 to level 0.
**Tamper detection – confirmed mode**

The confirmed mode is selected for TAMPx (external tamper x) when TAMPxNOER = 0 in the TAMP_CR2 register. The confirmed mode is selected for ITAMPx (internal tamper x) when ITAMPxNOER = 0 in the TAMP_CR3 register. The effects of a tamper detection in confirmed mode are described with tamp_confirmed and tamp_confirmed_ercfgx signals in the Table 637: TAMP interconnection.

This mode is selected to erase automatically the device secrets when the tamper is detected.

**Tamper detection – potential mode**

The potential mode is selected for TAMPx (external tamper x) when TAMPxNOER = 1 in the TAMP_CR2 register. The potential tamper mode is selected for ITAMPx (internal tamper x) when ITAMPxNOER = 1 in the TAMP_CR3 register. The effects of a tamper detection in potential mode are described with tamp_potential and tamp_potential_ercfgx signals in the Table 637: TAMP interconnection.

This mode is selected to avoid irreversible erasure of some device secrets when the tamper is detected. In this mode, some device secrets are not erased when the corresponding tamper event is detected. In addition, the read and write accesses to these device secrets are blocked as soon as the tamper detection flag is set in potential mode, until this flag is cleared by setting the corresponding clear flag in the TAMP_SCR register. Therefore the software can perform some checks to discriminate false from true tamperers, and decide to launch secrets erase only in case of the potential tamper is confirmed to be a true tamper. The device secrets are erased by software by setting the BKERASE bit in the TAMP_CR2 register.

**Potential tamper to confirmed tamper timeout**

Some internal tampers generate a tamper event if the independent watchdog reset occurs when another tamper flag is set (refer to Table 637: TAMP interconnection). The IWDG tamper must be configured with ITAMPxNOER = 0. This permits the erasure of device secrets to be forced by hardware after a timeout, in case the previous tamper event was in potential mode. This is equivalent to change the “potential tamper” into “confirmed tamper” if a watchdog reset occurs before any software decision following the potential tamper event.

**Device resources protection configuration**

Some device resources can be configured in order to be included to the list of the device secrets protected by tamper detection.

When ERCFGz = 0 in the TAMP_ERCFGR, the device resource associated to ERCFGz is not protected by the TAMP peripheral:

- It is not affected by tamper detection (whatever confirmed or potential mode)
- It is not affected by BKERASE software command
- It is not affected by BKBLOCK software command

When ERCFGz = 1 in the TAMP_ERCFGR, the device resource associated to ERCFGz is protected by the TAMP peripheral:

- It is affected by confirmed tamper detection and BKERASE software command, as described with tamp_confirmed_ercfgz signal in Table 637: TAMP interconnection
- It is affected by potential tamper detection and BKBLOCK software command, as described with tamp_potential_ercfgz signal in Table 637: TAMP interconnection
Device secrets access blocked by software

By default, the device secrets can be accessed by the application, except if a tamper event flag is detected: the device secrets access is not possible as long as a tamper flag is set.

It is possible to block the access to the device secrets by software, by setting the BKBLOCK bit of the TAMP_CR2 register. The device secrets access is possible only when BKBLOCK = 0 and no tamper flag is set.

64.4.11 Tamper detection configuration and initialization

Each input can be enabled by setting the corresponding TAMPxE bits to 1 in the TAMP_CR register.

Each TAMP_INx tamper detection input is associated with a flag TAMPxF in the TAMP_SR register.

By setting the TAMPxIE bit in the TAMP_IER register, an interrupt is generated when a tamper detection event occurs (when TAMPxF is set). Setting TAMPxIE is not allowed when the corresponding TAMPxMSK is set.

Trigger output generation on tamper event

The tamper event detection can be used as trigger input by the low-power timers.

When TAMPxMSK bit is cleared in TAMP_CR register, the TAMPxF flag must be cleared by software in order to allow a new tamper detection on the same pin.

When TAMPxMSK bit is set, the TAMPxF flag is masked, and kept cleared in TAMP_SR register. This configuration permits the low-power timers to be triggered automatically in Stop mode, without requiring the system wake-up to perform the TAMPxF clearing. In this case, the backup registers are not cleared.

This feature is available only when the tamper is configured in the Level detection with filtering on tamper inputs (passive mode) mode (TAMPFLT ≠ 00 and active mode is not selected).

Timestamp on tamper event

With TAMPTS set to 1 in the RTC_CR, any internal or external tamper event causes a timestamp to occur. In case a timestamp occurs due to tamper event, either the TSF bit or the TSOVF bit is set in RTC_SR, in the same manner as if a normal timestamp event occurs.

Note: TSF is set up to 3 ck_apre cycles after TAMPxF flags. TSF is not set if RTCCCLK is stopped (it is set when RTCCCLK restarts).
Note: If TAMPxF is cleared before the expected rise of TSF, TSF is not set. Consequently, in case TAMPTS = 1, the software should either wait for timestamp flag before clearing the tamper flag, or should read the RTC counters values in the TAMP interrupt routine.

Edge detection on tamper inputs (passive mode)

If the TAMPFLT bits are 00, the TAMP_INx pins generate tamper detection events when either a rising edge or a falling edge is observed depending on the corresponding TAMPxTRG bit. The internal pull-up resistors on the TAMP_INx inputs are deactivated when edge detection is selected.

Caution: When TAMPFLT = 00 and TAMPxTRG = 0 (rising edge detection), a tamper event may be detected by hardware if the tamper input is already at high level before enabling the tamper detection.

After a tamper event has been detected and cleared, the TAMP_INx should be disabled and then re-enabled (TAMPxE set to 1) before re-programming the backup registers (TAMP_BKPxR). This prevents the application from writing to the backup registers while the TAMP_INx input value still indicates a tamper detection. This is equivalent to a level detection on the TAMP_INx input.

Note: Tamper detection is still active when VDD power is switched off. To avoid unwanted resetting of the backup registers, the pin to which the TAMPx is mapped should be externally tied to the correct level.

Level detection with filtering on tamper inputs (passive mode)

Level detection with filtering is performed by setting TAMPFLT to a non-zero value. A tamper detection event is generated when either 2, 4, or 8 (depending on TAMPFLT) consecutive samples are observed at the level designated by the TAMPxTRG bits.

The TAMP_INx inputs are precharged through the I/O internal pull-up resistance before its state is sampled, unless disabled by setting TAMPPUDIS to 1. The duration of the precharge is determined by the TAMPPRCH bits, allowing for larger capacitances on the TAMP_INx inputs.

The trade-off between tamper detection latency and power consumption through the pull-up can be optimized by using TAMPFREQ to determine the frequency of the sampling for level detection.

Note: Refer to the microcontroller datasheet for the electrical characteristics of the pull-up resistors.

Active tamper detection

When the TAMPxAM bit is set in the TAMP_ATCR, the tamper events are configured in active mode, which is based on a comparison between a TAMP_OUTy pin and a TAMP_INx pin. By default (ATOSHARE = 0) the comparison is made between TAMP_INx and TAMP_OUTx (y = x). When ATOSHARE bit is set, the same output can be used for several tamper inputs. The TAMP_OUTy function is enabled on the I/O as soon as it is selected for comparison with an active tamper input TAMP_INx (TAMPxEN = TAMPxAM = 1), thanks to ATOSHARE and ATOSELx bits. Refer to ATOSHARE and ATOSELx bits descriptions in the TAMP_ATCRx (x = 1, 2) registers.

Every two CK_ATPER cycles (CK_ATPER = 2ATPER × CK_ATPRE), TAMP_OUTy output pin provides a value provided by a pseudo random number generator (PRNG). After outputting this value, the TAMP_OUTy pin outputs its opposite value one CK_ATPER cycle after.
PRNG is consumed by the selected tamper outputs at a different frequency depending on the number of selected tamper outputs. The number of selected outputs depends on TAMPxAM, TAMPxE, ATOSEL and ATOSHAPE.

- When only 1 output is selected: PRNG is consumed every 16 CK_ATPER periods.
- When 2 outputs are selected: PRNG is consumed every 8 CK_ATPER periods.
• When 3 or 4 outputs are selected: PRNG is consumed every 4 CK_ATPER periods.
• When 5 or more outputs are selected: PRNG is consumed every 2 CK_ATPER periods

The PRNG needs minimum 9 CK_ATPRE cycles to output a new value. Consequently the minimum ATPER values for correct functionality are provided in the table below:

<table>
<thead>
<tr>
<th>Number of selected outputs</th>
<th>Minimum ATPER</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3 or 4</td>
<td>2</td>
</tr>
<tr>
<td>5 or more</td>
<td>3</td>
</tr>
</tbody>
</table>

The TAMP_INx pin is externally connected to TAMP_OUTy pin. The comparison is made between TAMP_OUTy output value and TAMP_INx received value, every CK_ATPRE cycle. In case a comparison mismatch occurs, the TAMPxF bit is set in the TAMP_SR register.

As an example, TAMP_OUT1 can be used for comparison with TAMP_IN1 and TAMP_IN2 by configuring and enabling both TAMP1 and TAMP2 in active mode, with ATOSHARE = 1, ATOSEL1 = 000 and ATOSEL2 = 000.

The active tamper can be combined with input filtering when FLTEN = 1. In this case, the tamper is detected only when 2 comparisons are false, in 4 consecutive comparison samples.

As illustrated in Figure 769, if FLTEN = 0, any mismatch between the TAMP_OUTy output and the associated TAMP_INx input when the latter is sampled generates a tamper. This is the case in all three examples (a), (b) and (c).

If FLTEN = 1, example (a) does not generate a tamper, since only one mismatch is detected in four consecutive comparisons. In example (b), a tamper is generated since two successive mismatches are detected. Example (c) also generates a tamper, since two mismatches occur in four consecutive comparisons, even though the mismatches do not occur on successive samples.
Setting FLTEN = 1 avoids unwanted detection of tampers due to glitches, bounce or transitory states on the TAMP_INx inputs, by ignoring single pulses which are shorter than one period of CK_ATPRE, programmed in the ATCKSEL field of the TAMP_ATCR1 register. The minimum filtered pulse width is listed in Table 641 for each possible setting of ATCKSEL, assuming fRTCCLK = 32.768 kHz.

</tbody>
</table>

1. These values are supported only when the active tamper prescaler extension is supported. Refer to Section 64.3: TAMP implementation.
2. This setting requires that (PREDIV_A+1) = 128 and (PREDIV_S+1) is a multiple of 16.

**Note:** Multiple pulses which are shorter than one CK_ATPRE period may nevertheless cause a tamper if they result in two mismatches in four consecutive comparisons.

**Caution:** Entering RTC initialization mode stops CK_ATPRE and CK_ATPER clocks when ATCKSEL[3] = 1. Therefore, TAMP_OUTy pin stops toggling until INIT mode exit.

Refer to section Section 64.3: Calendar initialization and configuration.

Refer also to RTC alarm A subsecond register (RTC_ALRMASSR), RTC alarm B subsecond register (RTC_ALRMBSSR), RTC alarm A binary mode register (RTC_ALRABINR) and RTC alarm B binary mode register (RTC_ALRBBINR) in case RTC binary mode is used in conjunction with ATCKSEL[3] = 1.

**Caution:** Caution: The active tamper detection is no more functional in case of calendar overflow when ATCKSEL[3] = 1. It is mandatory to enable the internal tamper 5 on calendar overflow to ensure tamper protection.

The pseudo-random generator must be initialized with a seed. This is done by writing consecutively four 32-bit random values in the TAMP_ATSEEDR register. Programming the seed automatically sends it to the PRNG. As long as the new seed is transferred and elaborated by the PRNG, the SEEDF bit is set in the TAMP_ATOR and it is not allowed to switch off the TAMP APB clock. The duration of the elaboration is up to 184 APB clock cycles after the forth seed is written. Consequently, after writing a new seed, the user must wait until SEEDF is cleared before entering low-power modes.

The active tamper outputs are activated only after the first seed is written and the elaboration is completed. Then new seeds can be written and elaborated during active tamper activity.
Active tamper initialization

Here is the software procedure to initialize the active tampers after system reset:

Read INITS in TAMP_ATOR register.

- If INITS = 0x0 (initialization was not done):
  
  a) Write TAMP_ATCR to configure Active tamper clock, filter and output sharing if any, and active mode.
  
  b) Write TAMP_CR1 to enable tampers (all the needed tampers must be enabled in the same write access).
  
  c) Write SEED by writing four times in the TAMP_ATSEEDR.
  
  d) Wait until SEEDF = 0 in TAMP_ATOR. Backup registers are then protected by active tamper.

- If INITS = 0x1 (initialization already done):
  
  No initialization. To increase randomness a new SEED should be provided regularly. When a new SEED is provided, wait until SEEDF = 0 before entering a low-power mode which switches off the TAMP APB clock.

- In case the tampers are disabled by software, and re-enabled afterwards, the SEED must be written after enabling tampers:
  
  a) Write TAMP_CR1 to enable tampers (all the needed tampers must be enabled in the same write access).
  
  b) Write SEED by writing four times in the TAMP_ATSEEDR.
  
  c) Wait until SEEDF = 0 in TAMP_ATOR. Backup registers are then protected by active tamper.

64.5 TAMP low-power modes

Table 642. Effect of low-power modes on TAMP

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. TAMP interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>No effect on all features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>No effect on all features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Standby mode.</td>
</tr>
<tr>
<td>Shutdown</td>
<td>No effect on all features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE. Tamper events cause the device to exit the Shutdown mode.</td>
</tr>
</tbody>
</table>

Table 643. TAMP pins functionality over modes

<td>Write 1 in CITAMPxF</td>
<td>Yes(3)</td>
</tr>
</tbody>
</table>

1. The event flags are in the TAMP_SR register.
2. The number of tampers and internal tampers events depend on products.
3. Refer to Table 642: Effect of low-power modes on TAMP for more details about available features in the low-power modes.

64.7 TAMP registers

Refer to Section 1.2 of the reference manual for a list of abbreviations used in register descriptions. The peripheral registers can be accessed by words (32-bit).

64.7.1 TAMP control register 1 (TAMP_CR1)

This register can be protected against nonsecure access. Refer to Section 64.4.5: TAMP secure protection modes.

This register can be protected against non-privileged access. Refer to Section 64.4.7: TAMP privilege protection modes.

- 0: If TAMPFLT ≠ 00 tamper 2 input staying low triggers a tamper detection event.
- If TAMPFLT = 00 tamper 2 input rising edge triggers a tamper detection event.
- 1: If TAMPFLT ≠ 00 tamper 2 input staying high triggers a tamper detection event.
- If TAMPFLT = 00 tamper 2 input falling edge triggers a tamper detection event.

Bit 24 **TAMP1TRG**: Active level for tamper 1 input
- 0: If TAMPFLT ≠ 00 tamper 1 input staying low triggers a tamper detection event.
- If TAMPFLT = 00 tamper 1 input rising edge triggers a tamper detection event.
- 1: If TAMPFLT ≠ 00 tamper 1 input staying high triggers a tamper detection event.
- If TAMPFLT = 00 tamper 1 input falling edge triggers a tamper detection event.

Bit 23 **BKERASE**: Backup registers and device secrets\(^{(1)}\) erase
- Writing “1” to this bit reset the backup registers and device secrets\(^{(1)}\). Writing 0 has no effect.
- This bit is always read as 0.

Bit 22 **BKBLOCK**: Backup registers and device secrets\(^{(1)}\) access blocked
- 0: backup registers and device secrets\(^{(1)}\) can be accessed if no tamper flag is set
- 1: backup registers and device secrets\(^{(1)}\) cannot be accessed

Bits 21:19 Reserved, must be kept at reset value.
Bit 18 **TAMP3MSK**: Tamper 3 mask

0: Tamper 3 event generates a trigger event and TAMP3F must be cleared by software to allow next tamper event detection.
1: Tamper 3 event generates a trigger event. TAMP3F is masked and internally cleared by hardware. The backup registers and device secrets(1) are not erased.

*The tamper 3 interrupt must not be enabled when TAMP3MSK is set.*

Bit 17 **TAMP2MSK**: Tamper 2 mask

0: Tamper 2 event generates a trigger event and TAMP2F must be cleared by software to allow next tamper event detection.
1: Tamper 2 event generates a trigger event. TAMP2F is masked and internally cleared by hardware. The backup registers and device secrets(1) are not erased.

*The tamper 2 interrupt must not be enabled when TAMP2MSK is set.*

Bit 16 **TAMP1MSK**: Tamper 1 mask

0: Tamper 1 event generates a trigger event and TAMP1F must be cleared by software to allow next tamper event detection.
1: Tamper 1 event generates a trigger event. TAMP1F is masked and internally cleared by hardware. The backup registers and device secrets(1) are not erased.

*The tamper 1 interrupt must not be enabled when TAMP1MSK is set.*

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TAMP8NOER**: Tamper 8 no erase

0: Tamper 8 event detection is in confirmed mode(1).
1: Tamper 8 event detection is in potential mode(2).

Bit 6 **TAMP7NOER**: Tamper 7 no erase

0: Tamper 7 event detection is in confirmed mode(1).
1: Tamper 7 event detection is in potential mode(2).

Bit 5 **TAMP6NOER**: Tamper 6 no erase

0: Tamper 6 event detection is in confirmed mode(1).
1: Tamper 6 event detection is in potential mode(2).

Bit 4 **TAMP5NOER**: Tamper 5 no erase

0: Tamper 5 event detection is in confirmed mode(1).
1: Tamper 5 event detection is in potential mode(2).

Bit 3 **TAMP4NOER**: Tamper 4 no erase

0: Tamper 4 event detection is in confirmed mode(1).
1: Tamper 4 event detection is in potential mode(2).

Bit 2 **TAMP3NOER**: Tamper 3 no erase

0: Tamper 3 event detection is in confirmed mode(1).
1: Tamper 3 event detection is in potential mode(2).

Bit 1 **TAMP2NOER**: Tamper 2 no erase

0: Tamper 2 event detection is in confirmed mode(1).
1: Tamper 2 event detection is in potential mode(2).

Bit 0 **TAMP1NOER**: Tamper 1 no erase

0: Tamper 1 event detection is in confirmed mode(1).
1: Tamper 1 event detection is in potential mode(2).

---

1. The effects of tamper detection in confirmed mode is described with tamp_confirmed and tamp_confirmed_ercfgx signals in Table 637: TAMP interconnection.
2. The effects of tamper detection in potential mode is described with tamp_potential and tamp_potential_ercfgx signals in Table 637: TAMP interconnection.
64.7.3 **TAMP control register 3 (TAMP_CR3)**

This register can be protected against nonsecure access. Refer to *Section 64.4.5: TAMP secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 64.4.7: TAMP privilege protection modes*.

</tbody>
</table>

Bit 31  **FLTEN**: Active tamper filter enable
- 0: Active tamper filtering disable
- 1: Active tamper filtering enable: a tamper event is detected when 2 comparison mismatches occur out of 4 consecutive samples.

Bit 30  **ATOSHARE**: Active tamper output sharing
- 0: Each active tamper input TAMP_INi is compared with its dedicated output TAMP_OUTi
- 1: Each active tamper input TAMP_INi is compared with TAMPOUTSELi defined by ATOSELi bits.

Bits 29:27 Reserved, must be kept at reset value.

Bits 26:24  **ATPER[2:0]**: Active tamper output change period
The tamper output is changed every CK_ATPER = (2^ATPER x CK_ATPRE) cycles. Refer to Table 640: Minimum ATPER value.

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16  **ATCKSEL[3:0]**: Active tamper RTC asynchronous prescaler clock selection
These bits select the RTC asynchronous prescaler stage output. The selected clock is CK_ATPRE. ATCKSEL[3] is reserved, read only, and tied to 0 when the active tamper prescaler extension is not implemented.
- 0000: RTCCLK is selected
- 0001: RTCCLK/2 is selected
- 0010: RTCCLK/4 is selected
- 0011: RTCCLK/8 is selected
- 0100: RTCCLK/16 is selected
- 0101: RTCCLK/32 is selected
- 0110: RTCCLK/64 is selected
- 0111: RTCCLK/128 is selected
- 1011: RTCCLK/2048 is selected when (PREDIV_A+1) = 128 and (PREDIV_S+1) is a multiple of 16. This value is supported only when the active tamper prescaler extension is supported. Refer to Section 64.3: TAMP implementation.

Others: Reserved

**Note**: These bits can be written only when all active tampers are disabled. The write protection remains for up to 1.5 CK_ATPRE cycles after all the active tampers are disabled.
Bits 15:14 **ATOSEL4[1:0]**: Active tamper shared output 4 selection
- 00: TAMPOUTSEL4 = TAMP_OUT1
- 01: TAMPOUTSEL4 = TAMP_OUT2
- 10: TAMPOUTSEL4 = TAMP_OUT3
- 11: TAMPOUTSEL4 = TAMP_OUT4
If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bits 13:12 **ATOSEL3[1:0]**: Active tamper shared output 3 selection
- 00: TAMPOUTSEL3 = TAMP_OUT1
- 01: TAMPOUTSEL3 = TAMP_OUT2
- 10: TAMPOUTSEL3 = TAMP_OUT3
- 11: TAMPOUTSEL3 = TAMP_OUT4
If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bits 11:10 **ATOSEL2[1:0]**: Active tamper shared output 2 selection
- 00: TAMPOUTSEL2 = TAMP_OUT1
- 01: TAMPOUTSEL2 = TAMP_OUT2
- 10: TAMPOUTSEL2 = TAMP_OUT3
- 11: TAMPOUTSEL2 = TAMP_OUT4
If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bits 9:8 **ATOSEL1[1:0]**: Active tamper shared output 1 selection
- 00: TAMPOUTSEL1 = TAMP_OUT1
- 01: TAMPOUTSEL1 = TAMP_OUT2
- 10: TAMPOUTSEL1 = TAMP_OUT3
- 11: TAMPOUTSEL1 = TAMP_OUT4
If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bit 7 **TAMP8AM**: Tamper 8 active mode
- 0: Tamper 8 detection mode is passive.
- 1: Tamper 8 detection mode is active.

Bit 6 **TAMP7AM**: Tamper 7 active mode
- 0: Tamper 7 detection mode is passive.
- 1: Tamper 7 detection mode is active.

Bit 5 **TAMP6AM**: Tamper 6 active mode
- 0: Tamper 6 detection mode is passive.
- 1: Tamper 6 detection mode is active.

Bit 4 **TAMP5AM**: Tamper 5 active mode
- 0: Tamper 5 detection mode is passive.
- 1: Tamper 5 detection mode is active.

Bit 3 **TAMP4AM**: Tamper 4 active mode
- 0: Tamper 4 detection mode is passive.
- 1: Tamper 4 detection mode is active.
Bit 2 **TAMP3AM**: Tamper 3 active mode  
0: Tamper 3 detection mode is passive.  
1: Tamper 3 detection mode is active.  

Bit 1 **TAMP2AM**: Tamper 2 active mode  
0: Tamper 2 detection mode is passive.  
1: Tamper 2 detection mode is active.  

Bit 0 **TAMP1AM**: Tamper 1 active mode  
0: Tamper 1 detection mode is passive.  
1: Tamper 1 detection mode is active.  

**Note:** Changing the active tampers configuration in this register is not allowed when a TAMPxAM bit is set, unless the corresponding TAMPxE bits are all cleared in the TAMP_CR1 register.  
All tampers configured in active mode must be enabled at the same time (by setting all related TAMPxE in the same TAMP_CR1 write).  
All tampers configured in active mode must be disabled at the same time (by clearing all related TAMPxE in the same TAMP_CR1 write).  
A minimum duration of 1 CK_ATPRE period must be waited for after disabling the active tampers and before re-enabling them.  

### 64.7.6 TAMP active tamper seed register (TAMP_ATSEEDR)  
This register can be protected against nonsecure access. Refer to Section 64.4.5: **TAMP secure protection modes**.  
This register can be protected against non-privileged access. Refer to Section 64.4.7: **TAMP privilege protection modes**.  
Address offset: 0x14  
Backup domain reset value: 0x0000 0000  
System reset: not affected

Bits 31:0 **SEED[31:0]**: Pseudo-random generator seed value  
This register must be written four times with 32-bit values to provide the 128-bit seed to the PRNG. Writing to this register automatically sends the seed value to the PRNG.
### 64.7.7 TAMPER active tamper output register (TAMP_ATOR)

This register can be protected against nonsecure access. Refer to *Section 64.4.5: TAMPER secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 64.4.7: TAMPER privilege protection modes*.

Address offset: 0x18

Backup domain reset value: 0x0000 0000

System reset: not affected, except for SEEDF which is reset to 0.

Bits 31:29  **ATOSEL8[2:0]**: Active tamper shared output 8 selection

000: TAMPOUTSEL8 = TAMP_OUT1
001: TAMPOUTSEL8 = TAMP_OUT2
010: TAMPOUTSEL8 = TAMP_OUT3
011: TAMPOUTSEL8 = TAMP_OUT4
100: TAMPOUTSEL8 = TAMP_OUT5
101: TAMPOUTSEL8 = TAMP_OUT6
110: TAMPOUTSEL8 = TAMP_OUT7
111: TAMPOUTSEL8 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bits 28:26  **ATOSEL7[2:0]**: Active tamper shared output 7 selection

000: TAMPOUTSEL7 = TAMP_OUT1
001: TAMPOUTSEL7 = TAMP_OUT2
010: TAMPOUTSEL7 = TAMP_OUT3
011: TAMPOUTSEL7 = TAMP_OUT4
100: TAMPOUTSEL7 = TAMP_OUT5
101: TAMPOUTSEL7 = TAMP_OUT6
110: TAMPOUTSEL7 = TAMP_OUT7
111: TAMPOUTSEL7 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bits 25:23  **ATOSEL6[2:0]**: Active tamper shared output 6 selection

000: TAMPOUTSEL6 = TAMP_OUT1
001: TAMPOUTSEL6 = TAMP_OUT2
010: TAMPOUTSEL6 = TAMP_OUT3
011: TAMPOUTSEL6 = TAMP_OUT4
100: TAMPOUTSEL6 = TAMP_OUT5
101: TAMPOUTSEL6 = TAMP_OUT6
110: TAMPOUTSEL6 = TAMP_OUT7
111: TAMPOUTSEL6 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.
Bits 22:20 **ATOSEL5[2:0]**: Active tamper shared output 5 selection
- 000: TAMPOUTSEL5 = TAMP_OUT1
- 001: TAMPOUTSEL5 = TAMP_OUT2
- 010: TAMPOUTSEL5 = TAMP_OUT3
- 011: TAMPOUTSEL5 = TAMP_OUT4
- 100: TAMPOUTSEL5 = TAMP_OUT5
- 101: TAMPOUTSEL5 = TAMP_OUT6
- 110: TAMPOUTSEL5 = TAMP_OUT7
- 111: TAMPOUTSEL5 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bits 19:17 **ATOSEL4[2:0]**: Active tamper shared output 4 selection
- 000: TAMPOUTSEL4 = TAMP_OUT1
- 001: TAMPOUTSEL4 = TAMP_OUT2
- 010: TAMPOUTSEL4 = TAMP_OUT3
- 011: TAMPOUTSEL4 = TAMP_OUT4
- 100: TAMPOUTSEL4 = TAMP_OUT5
- 101: TAMPOUTSEL4 = TAMP_OUT6
- 110: TAMPOUTSEL4 = TAMP_OUT7
- 111: TAMPOUTSEL4 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bits 18:17 are the mirror of ATOSEL2[1:0] in the TAMP_ATCR1, and so can also be read or written through TAMP_ATCR1.

Bits 16:14 **ATOSEL3[2:0]**: Active tamper shared output 3 selection
- 000: TAMPOUTSEL3 = TAMP_OUT1
- 001: TAMPOUTSEL3 = TAMP_OUT2
- 010: TAMPOUTSEL3 = TAMP_OUT3
- 011: TAMPOUTSEL3 = TAMP_OUT4
- 100: TAMPOUTSEL3 = TAMP_OUT5
- 101: TAMPOUTSEL3 = TAMP_OUT6
- 110: TAMPOUTSEL3 = TAMP_OUT7
- 111: TAMPOUTSEL3 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bits 15:14 are the mirror of ATOSEL3[1:0] in the TAMP_ATCR1, and so can also be read or written through TAMP_ATCR1.
Bits 13:11 **ATOSEL2[2:0]**: Active tamper shared output 2 selection

- 000: TAMPOUTSEL2 = TAMP_OUT1
- 001: TAMPOUTSEL2 = TAMP_OUT2
- 010: TAMPOUTSEL2 = TAMP_OUT3
- 011: TAMPOUTSEL2 = TAMP_OUT4
- 100: TAMPOUTSEL2 = TAMP_OUT5
- 101: TAMPOUTSEL2 = TAMP_OUT6
- 110: TAMPOUTSEL2 = TAMP_OUT7
- 111: TAMPOUTSEL2 = TAMP_OUT8

If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bits 12:11 are the mirror of ATOSEL2[1:0] in the TAMP_ATCR1, and so can also be read or written through TAMP_ATCR1.

Bits 10:8 **ATOSEL1[2:0]**: Active tamper shared output 1 selection

- 000: TAMPOUTSEL1 = TAMP_OUT1
- 001: TAMPOUTSEL1 = TAMP_OUT2
- 010: TAMPOUTSEL1 = TAMP_OUT3
- 011: TAMPOUTSEL1 = TAMP_OUT4
- 100: TAMPOUTSEL1 = TAMP_OUT5
- 101: TAMPOUTSEL1 = TAMP_OUT6
- 110: TAMPOUTSEL1 = TAMP_OUT7
- 111: TAMPOUTSEL1 = TAMP_OUT8

If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bits 9:8 are the mirror of ATOSEL1[1:0] in the TAMP_ATCR1, and so can also be read or written through TAMP_ATCR1.

Bits 7:0 Reserved, must be kept at reset value.

**Note:** Changing the active tampers configuration in this register is not allowed when a TAMPxAM bit is set, unless the corresponding TAMPxE bits are all cleared in the TAMP_CR1 register.

All tampers configured in active mode must be enabled at the same time (by setting all related TAMPxE in the same TAMP_CR1 write).

All tampers configured in active mode must be disabled at the same time (by clearing all related TAMPxE in the same TAMP_CR1 write).

A minimum duration of 1 CK_ATPRE period must be waited for after disabling the active tampers and before re-enabling them.

### 64.7.9 TAMP secure configuration register (TAMP_SECCFGR)

If TZEN = 1, this register can be written only when the APB access is secure. If TZEN = 0, BKPRWSEC[7:0], BKPWSEC[7:0] and BHKLOCK can be written with nonsecure APB access, and TAMPSEC, CNT1SEC cannot be written.

This register can be globally write-protected, or each bit of this register can be individually write-protected against non-privileged access depending on the TAMP_PRIVCFGR configuration (refer to Section 64.4.7: TAMP privilege protection modes).
Bit 31  **TAMPSEC**: Tamper protection (excluding monotonic counters and backup registers)

0: Tamper configuration and interrupt can be written when the APB access is secure or nonsecure.
1: Tamper configuration and interrupt can be written only when the APB access is secure.

 **Note**: Refer to Section 64.4.5: **TAMP secure protection modes** for details on the read protection.

Bit 30  **BHKLOCK**: Boot hardware key lock

This bit can be read and can only be written to 1 by software. It is cleared by hardware together with the backup registers following a tamper detection event or when the readout protection (RDP) is disabled.

0: The Backup registers from TAMP_BKP0R to TAMP_BKP7R can be accessed according to the Protection zone they belong to.
1: The backup registers from TAMP_BKP0R to TAMP_BKP7R cannot be accessed neither in read nor in write (they are read as 0 and write ignore).

Bits 29:24 Reserved, must be kept at reset value.

Bits 23:16  **BKPWSEC[7:0]**: Backup registers write protection offset

**BKPWSEC** value must be from 0 to 32.

Protection zone 2 is defined for backup registers from TAMP_BKPyR (y = BKPWSEC) to TAMP_BKPzR (z = BKPWSEC-1, with BKPWSEC > BKPWSEC):

- if TZEN=1, these backup registers can be written only with secure access.
- They can be read with secure or nonsecure access.

If BKPWSEC = 0 or if BKPWSEC ≤ BKPWSEC: there is no protection zone 2.

Protection zone 3 is defined for backup registers from TAMP_BKPtR (t = BKPWSEC if BKPWSEC ≥ BKPWSEC, else t = BKPWSEC):

They can be read or written with secure or nonsecure access.

If BKPWSEC = 32: there is no protection zone 3.

Refer to Figure 768: **Backup registers protection zones**.

**Note**: If TZEN=0: the protection zone 2 can be read and written with nonsecure access.

**Note**: If BKPWPRIV is set, BKPWSEC[7:0] can be written only in privileged mode.
Bit 15  **CNT1SEC**: Monotonic counter 1 secure protection
   0: Monotonic counter 1 (TAMP_COUNT1R) can be read and written when the APB access is secure or nonsecure.
   1: Monotonic counter 1 (TAMP_COUNT1R) can be read and written only when the APB access is secure.

Bits 14:8 Reserved, must be kept at reset value.

Bits 7:0  **BKPRWSEC[7:0]**: Backup registers read/write protection offset

**Protection zone 1** is defined for backup registers from TAMP_BKP0R to TAMP_BKPxR (x = BKPRWSEC-1, with BKPRWSEC ≥ 1).
   – if TZEN=1, these backup registers can be read and written only with secure access.
   If BKPRWSEC = 0: there is no protection zone 1.

Refer to  **Figure 768: Backup registers protection zones**.

Note: If TZEN=0: the protection zone 1 can be read and written with nonsecure access.

Note: If BKPRWPRIV is set, BKPRWSEC[7:0] can be written only in privileged mode.

### 64.7.10 TAMP privilege configuration register (TAMP_PRIVCFGR)

This register can be written only when the APB access is privileged.

When TZEN = 1, this register can be write-protected, or each bit of this register can be individually write-protected against nonsecure access depending on the TAMP_SECCFGR configuration (refer to  **Section 64.4.5: TAMP secure protection modes**).

Address offset: 0x24

Backup domain reset value: 0x0000 0000

System reset: not affected
Tamper and backup registers (TAMP)

Bit 31 **TAMPPRIV**: Tamper privilege protection (excluding backup registers)
- 0: Tamper configuration and interrupt can be written with privileged or unprivileged access.
- 1: Tamper configuration and interrupt can be written only with privileged access.

*Note: Refer to Section 64.4.7: TAMP privilege protection modes for details on the read protection.*

Bit 30 **BKPWPRIV**: Backup registers zone 2 privilege protection
- 0: Backup registers zone 2 can be written with privileged or unprivileged access.
- 1: Backup registers zone 2 can be written only with privileged access.

Bit 29 **BKPRWPRIV**: Backup registers zone 1 privilege protection
- 0: Backup registers zone 1 can be read and written with privileged or unprivileged access.
- 1: Backup registers zone 1 can be read and written only with privileged access

Bits 28:16 Reserved, must be kept at reset value.

Bit 15 **CNT1PRIV**: Monotonic counter 1 privilege protection
- 0: Monotonic counter 1 (TAMP_COUNT1R) can be read and written when the APB access is privileged or non-privileged.
- 1: Monotonic counter 1 (TAMP_COUNT1R) can be read and written only when the APB access is privileged.

Bits 14:0 Reserved, must be kept at reset value.

### 64.7.11 TAMP interrupt enable register (TAMP_IER)

This register can be protected against nonsecure access. Refer to *Section 64.4.5: TAMP secure protection modes.*

This register can be protected against non-privileged access. Refer to *Section 64.4.7: TAMP privilege protection modes.*

Address offset: 0x2C

Bit 27 **ITAMP12F**: Internal tamper 12 flag  
This flag is set by hardware when a tamper detection event is detected on the internal tamper 12.
Bit 26 **ITAMP11F**: Internal tamper 11 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 11.

Bit 25 Reserved, must be kept at reset value.

Bit 24 **ITAMP9F**: Internal tamper 9 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 9.

Bit 23 **ITAMP8F**: Internal tamper 8 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 8.

Bit 22 **ITAMP7F**: Internal tamper 7 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 7.

Bit 21 **ITAMP6F**: Internal tamper 6 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 6.

Bit 20 **ITAMP5F**: Internal tamper 5 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 5.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **ITAMP3F**: Internal tamper 3 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 3.

Bit 17 **ITAMP2F**: Internal tamper 2 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 2.

Bit 16 **ITAMP1F**: Internal tamper 1 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 1.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TAMP8F**: TAMP8 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP8 input.

Bit 6 **TAMP7F**: TAMP7 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP7 input.

Bit 5 **TAMP6F**: TAMP6 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP6 input.

Bit 4 **TAMP5F**: TAMP5 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP5 input.

Bit 3 **TAMP4F**: TAMP4 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP4 input.
Bit 2  **TAMP3F**: TAMP3 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP3 input.

Bit 1  **TAMP2F**: TAMP2 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP2 input.

Bit 0  **TAMP1F**: TAMP1 detection flag
This flag is set by hardware when a tamper detection event is detected on the TAMP1 input.

### 64.7.13  TAMP nonsecure masked interrupt status register (TAMP_MISR)
This register can be protected against non-privileged access. Refer to **Section 64.4.7: TAMP privilege protection modes**.

This flag is set by hardware when the internal tamper 8 nonsecure interrupt is raised.

Bit 22  **ITAMP7MF**: Internal tamper 7 tamper nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 7 nonsecure interrupt is raised.

Bit 21  **ITAMP6MF**: Internal tamper 6 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 6 nonsecure interrupt is raised.

Bit 20  **ITAMP5MF**: Internal tamper 5 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 5 nonsecure interrupt is raised.
Bit 19 Reserved, must be kept at reset value.

Bit 18 **ITAMP3MF**: Internal tamper 3 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 3 nonsecure interrupt is raised.

Bit 17 **ITAMP2MF**: Internal tamper 2 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 2 nonsecure interrupt is raised.

Bit 16 **ITAMP1MF**: Internal tamper 1 nonsecure interrupt masked flag
This flag is set by hardware when the internal tamper 1 nonsecure interrupt is raised.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TAMP8MF**: TAMP8 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 8 nonsecure interrupt is raised.

Bit 6 **TAMP7MF**: TAMP7 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 7 nonsecure interrupt is raised.

Bit 5 **TAMP6MF**: TAMP6 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 6 nonsecure interrupt is raised.

Bit 4 **TAMP5MF**: TAMP5 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 5 nonsecure interrupt is raised.

Bit 3 **TAMP4MF**: TAMP4 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 4 nonsecure interrupt is raised.

Bit 2 **TAMP3MF**: TAMP3 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 3 nonsecure interrupt is raised.

Bit 1 **TAMP2MF**: TAMP2 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 2 nonsecure interrupt is raised.

Bit 0 **TAMP1MF**: TAMP1 nonsecure interrupt masked flag
This flag is set by hardware when the tamper 1 nonsecure interrupt is raised.

### 64.7.14 TAMPER secure masked interrupt status register (**TAMP_SMISR**)

This register can be protected against nonsecure access. Refer to Section 64.4.5: TAMPER secure protection modes.

This register can be protected against non-privileged access. Refer to Section 64.4.7: TAMPER privilege protection modes.

Bit 20  CITAMP5F: Clear ITAMP5 detection flag
Writing 1 in this bit clears the ITAMP5F bit in the TAMP_SR register.

Bit 19  Reserved, must be kept at reset value.

Bit 18  CITAMP3F: Clear ITAMP3 detection flag
Writing 1 in this bit clears the ITAMP3F bit in the TAMP_SR register.

Bit 17  CITAMP2F: Clear ITAMP2 detection flag
Writing 1 in this bit clears the ITAMP2F bit in the TAMP_SR register.

Bit 16  CITAMP1F: Clear ITAMP1 detection flag
Writing 1 in this bit clears the ITAMP1F bit in the TAMP_SR register.

Bits 15:8  Reserved, must be kept at reset value.

Bit 7  CTAMP8F: Clear TAMP8 detection flag
Writing 1 in this bit clears the TAMP8F bit in the TAMP_SR register.

Bit 6  CTAMP7F: Clear TAMP7 detection flag
Writing 1 in this bit clears the TAMP7F bit in the TAMP_SR register.

Bit 5  CTAMP6F: Clear TAMP6 detection flag
Writing 1 in this bit clears the TAMP6F bit in the TAMP_SR register.

Bit 4  CTAMP5F: Clear TAMP5 detection flag
Writing 1 in this bit clears the TAMP5F bit in the TAMP_SR register.

Bit 3  CTAMP4F: Clear TAMP4 detection flag
Writing 1 in this bit clears the TAMP4F bit in the TAMP_SR register.

Bit 2  CTAMP3F: Clear TAMP3 detection flag
Writing 1 in this bit clears the TAMP3F bit in the TAMP_SR register.

Bit 1  CTAMP2F: Clear TAMP2 detection flag
Writing 1 in this bit clears the TAMP2F bit in the TAMP_SR register.

Bit 0  CTAMP1F: Clear TAMP1 detection flag
Writing 1 in this bit clears the TAMP1F bit in the TAMP_SR register.
64.7.16  **TAMP monotonic counter 1 register (TAMP_COUNT1R)**

This register can be protected against nonsecure access. Refer to **Section 64.4.5: TAMP secure protection modes.**

This register can be protected against non-privileged access. Refer to **Section 64.4.7: TAMP privilege protection modes.**

65 Inter-integrated circuit (I2C) interface

65.1 Introduction

The I²C (inter-integrated circuit) bus interface handles communications between the microcontroller and the serial I²C bus. It provides multimaster capability, and controls all I²C bus-specific sequencing, protocol, arbitration and timing. It supports Standard-mode (Sm), Fast-mode (Fm) and Fast-mode Plus (Fm+).

It is also SMBus (system management bus) and PMBus® (power management bus) compatible.

DMA can be used to reduce CPU overload.

65.2 I2C main features

- **I²C bus specification rev03 compatibility:**
  - Slave and master modes
  - Multimaster capability
  - Standard-mode (up to 100 kHz)
  - Fast-mode (up to 400 kHz)
  - Fast-mode Plus (up to 1 MHz)
  - 7-bit and 10-bit addressing mode
  - Multiple 7-bit slave addresses (2 addresses, 1 with configurable mask)
  - All 7-bit addresses acknowledge mode
  - General call
  - Programmable setup and hold times
  - Easy to use event management
  - Optional clock stretching
  - Software reset
- **1-byte buffer with DMA capability**
- **Programmable analog and digital noise filters**

The following additional features are also available, depending on the product implementation (see Section 65.3):

- SMBus specification rev 3.0 compatibility:
  - Hardware PEC (packet error checking) generation and verification with ACK control
  - Command and data acknowledge control
  - Address resolution protocol (ARP) support
  - Host and device support
  - SMBus alert
  - Timeouts and idle condition detection
- PMBus rev 1.3 standard compatibility
- Independent clock: a choice of independent clock sources allowing the I²C communication speed to be independent from the i²c_pclk reprogramming
Wake-up from stop mode
Autonomous functionality in Stop mode

### 65.4 I2C functional description

In addition to receiving and transmitting data, this interface converts them from serial to parallel format and vice versa. The interrupts are enabled or disabled by software. The interface is connected to the I²C bus by a data pin (SDA) and by a clock pin (SCL). It can be connected with a standard (up to 100 kHz), Fast-mode (up to 400 kHz) or Fast-mode Plus (up to 1 MHz) I²C bus.

This interface can also be connected to an SMBus with data (SDA) and clock (SCL) pins. If the SMBus feature is supported, the optional SMBus Alert pin (SMBA) is also available.

65.4.3 I2C clock requirements

The I2C kernel is clocked by i2c_ker_ck.

The i2c_ker_ck period tI2CCLK must respect the following conditions:
- \( t_{I2CCLK} < \frac{(t_{LOW} - t_{filters})}{4} \)
- \( t_{I2CCLK} < t_{HIGH} \)

with:
- \( t_{LOW} \): SCL low time and \( t_{HIGH} \): SCL high time
- \( t_{filters} \): when enabled, sum of the delays brought by the analog and by the digital filters.
- The digital filter delay is \( DNF \times t_{I2CCLK} \).

The i2c_pclk clock period \( t_{PCLK} \) must respect the condition:
- \( t_{PCLK} < \frac{4}{3} t_{SCL} \) (\( t_{SCL} \): SCL period)

Caution: When the I2C kernel is clocked by i2c_pclk, this clock must respect the conditions for \( t_{I2CCLK} \).
65.4.4 Mode selection

The interface can operate in one of the four following modes:

- Slave transmitter
- Slave receiver
- Master transmitter
- Master receiver

By default, it operates in slave mode. The interface automatically switches from slave to master when it generates a START condition, and from master to slave if an arbitration loss or a STOP generation occurs, allowing multimaster capability.

Communication flow

In master mode, the I2C interface initiates a data transfer and generates the clock signal. A serial data transfer always begins with a START condition and ends with a STOP condition. Both START and STOP conditions are generated in master mode by software.

In slave mode, the interface is capable of recognizing its own addresses (7- or 10-bit), and the general call address. The general call address detection can be enabled or disabled by software. The reserved SMBus addresses can also be enabled by software.

Data and addresses are transferred as 8-bit bytes, MSB first. The first byte(s) following the START condition contains the address (one in 7-bit mode, two in 10-bit mode). The address is always transmitted in master mode.

A ninth clock pulse follows the eight clock cycles of a byte transfer, during which the receiver must send an acknowledge bit to the transmitter (see Figure 771).

Figure 771. I2C bus protocol

![I2C bus protocol diagram](MS19854V1)

Acknowledge can be enabled or disabled by software. The I2C interface addresses can be selected by software.

65.4.5 I2C initialization

Enabling and disabling the peripheral

The I2C peripheral clock must be configured and enabled in the clock controller, then the I2C can be enabled by setting the PE bit in the I2C_CR1 register.
When the I2C is disabled (PE = 0), the I2C performs a software reset. Refer to *Section 65.4.6* for more details.

**Noise filters**

Before enabling the I2C peripheral by setting the PE bit in I2C_CR1 register, the user must configure the noise filters, if needed. By default, an analog noise filter is present on the SDA and SCL inputs. This filter is compliant with the I2C specification, which requires the suppression of spikes with pulse width up to 50 ns in Fast-mode and Fast-mode Plus. The user can disable this analog filter by setting the ANOFF bit, and/or select a digital filter by configuring the DNF[3:0] bit in the I2C_CR1 register.

When the digital filter is enabled, the level of the SCL or the SDA line is internally changed only if it remains stable for more than DNF x i2c_ker_ck periods. This allows spikes with a programmable length of 1 to 15 i2c_ker_ck periods to be suppressed.

**Table 652. Comparison of analog vs. digital filters**

<td>Functionality in Stop mode is not supported when digital filter is enabled.</td>
</tr>
</tbody>
</table>

**Caution:** The filter configuration cannot be changed when the I2C is enabled.

**I2C timings**

The timings must be configured to guarantee correct data hold and setup times, in master and slave modes. This is done by programming the PRESC[3:0], SCLDEL[3:0] and SDADEL[3:0] bits in the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C configuration window.
When the SCL falling edge is internally detected, a delay ($t_{SDADEL}$, impacting the hold time $t_{HD;DAT}$) is inserted before sending SDA output: $t_{SDADEL} = SDADEL \times t_{PRESC} + t_{I2CCLK}$, where $t_{PRESC} = (PRESC + 1) \times t_{I2CCLK}$.

The total SDA output delay is:

$$t_{SYNC1} + \{[SDADEL \times (PRESC + 1) + 1] \times t_{I2CCLK}\}$$

$t_{SYNC1}$ duration depends upon:

- SCL falling slope
- When enabled, input delay brought by the analog filter: $t_{AF(min)} < t_{AF} < t_{AF(max)}$
- When enabled, input delay brought by the digital filter: $t_{DNF} = DNF \times t_{I2CCLK}$
- Delay due to SCL synchronization to i2c_ker_ck clock (two to three i2c_ker_ck periods)

To bridge the undefined region of the SCL falling edge, the user must program SDADEL in such a way that:

$$\frac{(t_f(\text{max}) + t_{HD;DAT}(\text{min}) - t_{AF(\text{min})} - [(DNF + 3) \times t_{I2CCLK}]) / ((PRESC + 1) \times t_{I2CCLK})}{t_{SYNC1}} \leq SDADEL$$
Inter-integrated circuit (I2C) interface RM0456

\[
SDADEL \leq \left\{ t_{HD;DAT} \text{ (max)} - t_{AF\text{ (max)}} \right\} \cdot \left\{ (DFN + 4) \times t_{I2CCLK} \right\} / \left\{ (PRESC + 1) \times t_{I2CCLK} \right\}
\]

**Note:**  
\( t_{AF\text{ (min)}} / t_{AF\text{ (max)}} \) are part of the equation only when the analog filter is enabled. Refer to the device datasheet for \( t_{AF} \) values.

The maximum \( t_{HD;DAT} \) can be, respectively, 3.45, 0.9, and 0.45 \( \mu s \) for Standard-mode, Fast-mode, and Fast-mode Plus. It must be lower than the maximum of \( t_{VD;DAT} \) by a transition time. This maximum must only be met if the device does not stretch the LOW period (\( t_{LOW} \)) of the SCL signal. If the clock stretches the SCL, the data must be valid by the set-up time before it releases the clock.

The SDA rising edge is usually the worst case. In this case the previous equation becomes:

\[
SDADEL \leq \left\{ t_{VD;DAT} \text{ (max)} - t_r \text{ (max)} - t_{AF\text{ (max)}} - \left\{ (DFN + 4) \times t_{I2CCLK} \right\} / \left\{ (PRESC + 1) \times t_{I2CCLK} \right\}
\]

**Note:** This condition can be violated when \( \text{NOSTRETCH} = 0 \), because the device stretches SCL low to guarantee the set-up time, according to the SCLDEL value.

Refer to Table 653 for \( t_r \), \( t_{HD;DAT} \), and \( t_{VD;DAT} \) standard values.

- After \( t_{SDADEL} \), or after sending SDA output when the slave had to stretch the clock because the data was not yet written in I2C_TXDR register, SCL line is kept at low level during the setup time. This setup time is \( t_{SCLDEL} = (SCLDEL+ 1) \times t_{PRESC} \) where \( t_{PRESC} = (PRESC+ 1) \times t_{I2CCLK} \). \( t_{SCLDEL} \) impacts the setup time \( t_{SU;DAT} \).

To bridge the undefined region of the SDA transition (rising edge usually worst case), the user must program SCLDEL in such a way that:

\[
\frac{t_r \text{ (max)} + t_{SU;DAT} \text{ (min)}}{(PRESC+ 1) \times t_{I2CCLK}} - 1 \leq SCLDEL
\]

Refer to Table 653 for \( t_r \) and \( t_{SU;DAT} \) standard values.

The SDA and SCL transition time values to use are the ones in the application. Using the maximum values from the standard increases the constraints for the SDADEL and SCLDEL calculation, but ensures the feature, whatever the application.

**Note:** At every clock pulse, after SCL falling edge detection, the I2C master or slave stretches SCL low during at least \((\text{SDADEL} + \text{SCLDEL} + 1) \times (\text{PRESC} + 1) \times t_{I2CCLK} \) in both transmission and reception modes. In transmission mode, if the data is not yet written in I2C_TXDR when SDADEL counter is finished, the I2C keeps on stretching SCL low until the next data is written. Then new data MSB is sent on SDA output, and SCLDEL counter starts, continuing stretching SCL low to guarantee the data setup time.

If \( \text{NOSTRETCH} = 1 \) in slave mode, the SCL is not stretched. Consequently the SDADEL must be programmed so that it guarantees a sufficient setup time.

### Table 653. I2C-SMBus specification data setup and hold times

</tr>
</tbody>
</table>
Additionally, in master mode, the SCL clock high and low levels must be configured by programming the PRESC[3:0], SCLH[7:0] and SCLL[7:0] bit fields in the I2C_TIMINGR register.

- When the SCL falling edge is internally detected, a delay is inserted before releasing the SCL output. This delay is \( t_{SCLL} = (SCLL + 1) \times t_{PRESC} \) where \( t_{PRESC} = (PRESC + 1) \times t_{I2CCLK} \). \( t_{SCLL} \) impacts the SCL low time \( t_{LOW} \).
- When the SCL rising edge is internally detected, a delay is inserted before forcing the SCL output to low level. This delay is \( t_{SCHL} = (SCHL + 1) \times t_{PRESCH} \), where \( t_{PRESCH} = (PRESCH + 1) \times t_{I2CCLK} \). \( t_{SCHL} \) impacts the SCL high time \( t_{HIGH} \).

Refer to [I2C master initialization](#) for more details.

**Caution:** Changing the timing configuration is not allowed when the I2C is enabled.

The I2C slave NOSTRETCH mode must also be configured before enabling the peripheral. Refer to [I2C slave initialization](#) for more details.

**Caution:** Changing the NOSTRETCH configuration is not allowed when the I2C is enabled.

65.4.6 Software reset

A software reset can be performed by clearing the PE bit in the I2C_CR1 register. In that case I2C lines SCL and SDA are released. Internal states machines are reset and communication control bits, as well as status bits come back to their reset value. The configuration registers are not impacted.

Here is the list of impacted register bits:
1. I2C_CR2 register: START, STOP, NACK
2. I2C_ISR register: BUSY, TXE, TXIS, RXNE, ADDR, NACKF, TCR, TC, STOPF, BERR, ARLO, OVR

and in addition when the SMBus feature is supported:
1. I2C_CR2 register: PECBYTE
2. I2C_ISR register: PECERR, TIMEOUT, ALERT

PE must be kept low during at least three APB clock cycles in order to perform the software reset. This is ensured by writing the following software sequence:
1. Write PE = 0
2. Check PE = 0
3. Write PE = 1
65.4.7 Data transfer

The data transfer is managed through transmit and receive data registers and a shift register.

Reception

The SDA input fills the shift register. After the eighth SCL pulse (when the complete data byte is received), the shift register is copied into I2C_RXDR register if it is empty (RXNE = 0). If RXNE = 1, meaning that the previous received data byte has not yet been read, the SCL line is stretched low until I2C_RXDR is read. The stretch is inserted between the eighth and ninth SCL pulse (before the acknowledge pulse).

Figure 774. Data reception
Transmission

If the I2C_TXDR register is not empty (TXE = 0), its content is copied into the shift register after the ninth SCL pulse (the acknowledge pulse). Then the shift register content is shifted out on SDA line. If TXE = 1, meaning that no data is written yet in I2C_TXDR, SCL line is stretched low until I2C_TXDR is written. The stretch is done after the ninth SCL pulse.

Figure 775. Data transmission

Hardware transfer management

The I2C has a byte counter embedded in hardware in order to manage byte transfer and to close the communication in various modes such as:

- NACK, STOP and ReSTART generation in master mode
- ACK control in slave receiver mode
- PEC generation/checking when SMBus feature is supported

The byte counter is always used in master mode. By default it is disabled in slave mode, but it can be enabled by software by setting the SBC (slave byte control) bit in the I2C_CR1 register.

The number of bytes to be transferred is programmed in the NBYTES[7:0] bit field in the I2C_CR2 register. If the number of bytes to be transferred (NBYTES) is greater than 255, or if a receiver wants to control the acknowledge value of a received data byte, the reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this mode, the TCR flag is set when the number of bytes programmed in NBYTES is transferred, and an interrupt is generated if TCIE is set. SCL is stretched as long as TCR flag is set. TCR is cleared by software when NBYTES is written to a non-zero value.

When the NBYTES counter is reloaded with the last number of bytes, RELOAD bit must be cleared.
When RELOAD = 0 in master mode, the counter can be used in two modes:

- **Automatic end mode** (AUTOEND = ‘1’ in the I2C_CR2 register). In this mode, the master automatically sends a STOP condition once the number of bytes programmed in the NBYTES[7:0] bit field is transferred.

- **Software end mode** (AUTOEND = ‘0’ in the I2C_CR2 register). In this mode, software action is expected once the number of bytes programmed in the NBYTES[7:0] bit field is transferred; the TC flag is set and an interrupt is generated if the TCIE bit is set. The SCL signal is stretched as long as the TC flag is set. The TC flag is cleared by software when the START or STOP bit is set in the I2C_CR2 register. This mode must be used when the master wants to send a RESTART condition.

**Caution:** The AUTOEND bit has no effect when the RELOAD bit is set.

#### 65.4.8 I2C slave mode

**I2C slave initialization**

To work in slave mode, the user must enable at least one slave address. Registers I2C_OAR1 and I2C_OAR2 are available to program the slave own addresses OA1 and OA2.

- OA1 can be configured either in 7-bit mode (by default) or in 10-bit addressing mode by setting the OA1MODE bit in the I2C_OAR1 register.
  
- OA1 is enabled by setting the OA1EN bit in the I2C_OAR1 register.

- If additional slave addresses are required, the second slave address OA2 can be configured. Up to 7 OA2 LSB can be masked by configuring the OA2MSK[2:0] bits in the I2C_OAR2 register. Therefore for OA2MSK configured from 1 to 6, only OA2[7:2], OA2[7:3], OA2[7:4], OA2[7:5], OA2[7:6] or OA2[7] are compared with the received address. As soon as OA2MSK is not equal to 0, the address comparator for OA2 excludes the I2C reserved addresses (0000 XXX and 1111 XXX), which are not acknowledged. If OA2MSK = 7, all received 7-bit addresses are acknowledged (except reserved addresses). OA2 is always a 7-bit address.

  These reserved addresses can be acknowledged if they are enabled by the specific enable bit, if they are programmed in the I2C_OAR1 or I2C_OAR2 register with OA2MSK = 0.

  OA2 is enabled by setting the OA2EN bit in the I2C_OAR2 register.

- The general call address is enabled by setting the GCEN bit in the I2C_CR1 register.

  When the I2C is selected by one of its enabled addresses, the ADDR interrupt status flag is set, and an interrupt is generated if the ADDRIE bit is set.

  By default, the slave uses its clock stretching capability, which means that it stretches the SCL signal at low level when needed, to perform software actions. If the master does not
support clock stretching, the I2C must be configured with NOSTRETCH = 1 in the I2C_CR1 register.

After receiving an ADDR interrupt, if several addresses are enabled the user must read the ADDCODE[6:0] bits in the I2C_ISR register in order to check which address matched. DIR flag must also be checked in order to know the transfer direction.

**Slave clock stretching (NOSTRETCH = 0)**

In default mode, the I2C slave stretches the SCL clock in the following situations:

- When the ADDR flag is set: the received address matches with one of the enabled slave addresses. This stretch is released when the ADDR flag is cleared by software setting the ADDRCF bit.
- In transmission, if the previous data transmission is completed and no new data is written in I2C_TXDR register, or if the first data byte is not written when the ADDR flag is cleared (TXE = 1). This stretch is released when the data is written to the I2C_TXDR register.
- In reception when the I2C_RXDR register is not read yet and a new data reception is completed. This stretch is released when I2C_RXDR is read.
- When TCR = 1 in Slave Byte Control mode, reload mode (SBC = 1 and RELOAD = 1), meaning that the last data byte has been transferred. This stretch is released when then TCR is cleared by writing a non-zero value in the NBYTES[7:0] field.
- After SCL falling edge detection, the I2C stretches SCL low during 
\[ (SDADEL + SCLDEL + 1) \times (PRESC+1) + 1 \] \times t_{I2CCLK}.

**Slave without clock stretching (NOSTRETCH = 1)**

When NOSTRETCH = 1 in the I2C_CR1 register, the I2C slave does not stretch the SCL signal.

- The SCL clock is not stretched while the ADDR flag is set.
- In transmission, the data must be written in the I2C_TXDR register before the first SCL pulse corresponding to its transfer occurs. If not, an underrun occurs, the OVR flag is set in the I2C_ISR register and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register. The OVR flag is also set when the first data transmission starts and the STOPF bit is still set (has not been cleared). Therefore, if the user clears the STOPF flag of the previous transfer only after writing the first data to be transmitted in the next transfer, he ensures that the OVR status is provided, even for the first data to be transmitted.
- In reception, the data must be read from the I2C_RXDR register before the ninth SCL pulse (ACK pulse) of the next data byte occurs. If not an overrun occurs, the OVR flag is set in the I2C_ISR register and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.
Slave byte control mode

In order to allow byte ACK control in slave reception mode, the Slave byte control mode must be enabled by setting the SBC bit in the I2C_CR1 register. This is required to be compliant with SMBus standards.

The Reload mode must be selected in order to allow byte ACK control in slave reception mode (RELOAD = 1). To get control of each byte, NBYTES must be initialized to 0x1 in the ADDR interrupt subroutine, and reloaded to 0x1 after each received byte. When the byte is received, the TCR bit is set, stretching the SCL signal low between the eighth and ninth SCL pulses. The user can read the data from the I2C_RXDR register, and then decide to acknowledge it or not by configuring the ACK bit in the I2C_CR2 register. The SCL stretch is released by programming NBYTES to a non-zero value: the acknowledge or not-acknowledge is sent and next byte can be received.

NBYTES can be loaded with a value greater than 0x1, and in this case, the reception flow is continuous during NBYTES data reception.

Note: The SBC bit must be configured when the I2C is disabled, or when the slave is not addressed, or when ADDR = 1.

The RELOAD bit value can be changed when ADDR = 1, or when TCR = 1.

Caution: The Slave byte control mode is not compatible with NOSTRETCH mode. Setting SBC when NOSTRETCH = 1 is not allowed.

Figure 776. Slave initialization flow

*SBC must be set to support SMBus features
Slave transmitter

A transmit interrupt status (TXIS) is generated when the I2C_TXDR register becomes empty. An interrupt is generated if the TXIE bit is set in the I2C_CR1 register.

The TXIS bit is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

When a NACK is received, the NACKF bit is set in the I2C_ISR register and an interrupt is generated if the NACKIE bit is set in the I2C_CR1 register. The slave automatically releases the SCL and SDA lines in order to let the master perform a STOP or a RESTART condition. The TXIS bit is not set when a NACK is received.

When a STOP is received and the STOPIE bit is set in the I2C_CR1 register, the STOPF flag is set in the I2C_ISR register and an interrupt is generated. In most applications, the SBC bit is usually programmed to ‘0’. In this case, if TXE = 0 when the slave address is received (ADDR = 1), the user can choose either to send the content of the I2C_TXDR register as the first data byte, or to flush the I2C_TXDR register by setting the TXE bit in order to program a new data byte.

In Slave byte control mode (SBC = 1), the number of bytes to be transmitted must be programmed in NBYTES in the address match interrupt subroutine (ADDR = 1). In this case, the number of TXIS events during the transfer corresponds to the value programmed in NBYTES.

Caution: When NOSTRETCH = 1, the SCL clock is not stretched while the ADDR flag is set, so the user cannot flush the I2C_TXDR register content in the ADDR subroutine, in order to program the first data byte. The first data byte to be sent must be previously programmed in the I2C_TXDR register:

- This data can be the data written in the last TXIS event of the previous transmission message.
- If this data byte is not the one to be sent, the I2C_TXDR register can be flushed by setting the TXE bit in order to program a new data byte. The STOPF bit must be cleared only after these actions, in order to guarantee that they are executed before the first data transmission starts, following the address acknowledge.

If STOPF is still set when the first data transmission starts, an underrun error is generated (the OVR flag is set).

If a TXIS event is needed, (transmit interrupt or transmit DMA request), the user must set the TXIS bit in addition to the TXE bit, in order to generate a TXIS event.

65.4.9 I2C master mode

I2C master initialization

Before enabling the peripheral, the I2C master clock must be configured by setting the SCLH and SCLL bits in the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C Configuration window.

A clock synchronization mechanism is implemented in order to support multi-master environment and slave clock stretching.

In order to allow clock synchronization:

- The low level of the clock is counted using the SC LL counter, starting from the SCL low level internal detection.
- The high level of the clock is counted using the SCLH counter, starting from the SCL high level internal detection.

The I2C detects its own SCL low level after a \( t_{SYNC1} \) delay depending on the SCL falling edge, SCL input noise filters (analog + digital) and SCL synchronization to the I2CxCLK clock. The I2C releases SCL to high level once the SC LL counter reaches the value programmed in the SC LL[7:0] bits in the I2C_TIMINGR register.

The I2C detects its own SCL high level after a \( t_{SYNC2} \) delay depending on the SCL rising edge, SCL input noise filters (analog + digital) and SCL synchronization to I2CxCLK clock. The I2C ties SCL to low level once the SCLH counter is reached reaches the value programmed in the SC LH[7:0] bits in the I2C_TIMINGR register.

Consequently the master clock period is:

\[
t_{SCL} = t_{SYNC1} + t_{SYNC2} + \left( [(SCLH+1) + (SCLL+1)] \times (PRESC+1) \times t_{I2CCLK}\right)
\]

The duration of \( t_{SYNC1} \) depends on these parameters:

- SCL falling slope
- When enabled, input delay induced by the analog filter.
- When enabled, input delay induced by the digital filter: DNF \( \times t_{I2CCLK} \)
- Delay due to SCL synchronization with i2c_ker_ck clock (two to three i2c_ker_ck periods)

The duration of \( t_{SYNC2} \) depends on these parameters:

- SCL rising slope
- When enabled, input delay induced by the analog filter.
- When enabled, input delay induced by the digital filter: DNF \( \times t_{I2CCLK} \)
- Delay due to SCL synchronization with i2c_ker_ck clock (two to three i2c_ker_ck periods)

**Note:** \( SCLL \) is also used to generate the \( t_{BUF} \) and \( t_{SU:STA} \) timings, and \( SCLH \) is also used to generate the \( t_{HD:STA} \) and \( t_{SU:STO} \) timings.

Refer to Section 65.4.10 for examples of I2C_TIMINGR settings vs. i2c_ker_ck frequency.

### Master communication initialization (address phase)

In order to initiate the communication, the user must program the following parameters for the addressed slave in the I2C_CR2 register:

- Addressing mode (7-bit or 10-bit): ADD10
- Slave address to be sent: SADD[9:0]
- Transfer direction: RD_WRN
- In case of 10-bit address read: HEAD10R bit. HEAD10R must be configure to indicate if the complete address sequence must be sent, or only the header in case of a direction change.
- The number of bytes to be transferred: NBYTES[7:0]. If the number of bytes is equal to or greater than 255 bytes, NBYTES[7:0] must initially be filled with 0xFF.

The user must then set the START bit in I2C_CR2 register. Changing all the above bits is not allowed when START bit is set.

Then the master automatically sends the START condition followed by the slave address as soon as it detects that the bus is free (BUSY = 0) and after a delay of \( t_{BUF} \).

In case of an arbitration loss, the master automatically switches back to slave mode and can acknowledge its own address if it is addressed as a slave.
Note: The START bit is reset by hardware when the slave address is sent on the bus, whatever the received acknowledge value. The START bit is also reset by hardware if an arbitration loss occurs.

In 10-bit addressing mode, when the slave address first 7 bits are NACKed by the slave, the master re-launches automatically the slave address transmission until ACK is received. In this case ADDRCF must be set if a NACK is received from the slave, in order to stop sending the slave address.

If the I2C is addressed as a slave (ADDR = 1) while the START bit is set, the I2C switches to slave mode and the START bit is cleared.

Note: The same procedure is applied for a repeated start condition. In this case BUSY = 1.

Initialization of a master receiver addressing a 10-bit address slave

- If the slave address is in 10-bit format, the user can choose to send the complete read sequence by clearing the HEAD10R bit in the I2C_CR2 register. In this case the master automatically sends the following complete sequence after the START bit is set:
  (Re)Start + Slave address 10-bit header Write + Slave address second byte + REStart + Slave address 10-bit header Read

Figure 785. 10-bit address read access with HEAD10R = 0
• If the master addresses a 10-bit address slave, transmits data to this slave and then reads data from the same slave, a master transmission flow must be done first. Then a repeated start is set with the 10 bit slave address configured with HEAD10R = 1. In this case the master sends this sequence: ReStart + Slave address 10-bit header Read.

Figure 786. 10-bit address read access with HEAD10R = 1

Master transmitter

In the case of a write transfer, the TXIS flag is set after each byte transmission, after the ninth SCL pulse when an ACK is received.

A TXIS event generates an interrupt if the TXIE bit is set in the I2C_CR1 register. The flag is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

The number of TXIS events during the transfer corresponds to the value programmed in NBYTES[7:0]. If the total number of data bytes to be sent is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when NBYTES data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

The TXIS flag is not set when a NACK is received.

• When RELOAD = 0 and NBYTES data have been transferred:
  – In automatic end mode (AUTOEND = 1), a STOP is automatically sent.
  – In software end mode (AUTOEND = 0), the TC flag is set and the SCL line is stretched low in order to perform software actions:
    A RESTART condition can be requested by setting the START bit in the I2C_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition is sent on the bus.
    A STOP condition can be requested by setting the STOP bit in the I2C_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.

• If a NACK is received: the TXIS flag is not set, and a STOP condition is automatically sent after the NACK reception. the NACKF flag is set in the I2C_ISR register, and an interrupt is generated if the NACKIE bit is set.

Master receiver

In the case of a read transfer, the RXNE flag is set after each byte reception, after the eighth SCL pulse. An RXNE event generates an interrupt if the RXIE bit is set in the I2C_CR1 register. The flag is cleared when I2C_RXDR is read.

If the total number of data bytes to be received is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when NBYTES[7:0] data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

• When RELOAD = 0 and NBYTES[7:0] data have been transferred:
  – In automatic end mode (AUTOEND = 1), a NACK and a STOP are automatically sent after the last received byte.
  – In software end mode (AUTOEND = 0), a NACK is automatically sent after the last received byte, the TC flag is set and the SCL line is stretched low in order to allow software actions:
    A RESTART condition can be requested by setting the START bit in the I2C_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition, followed by slave address, are sent on the bus.
    A STOP condition can be requested by setting the STOP bit in the I2C_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.

1. t\textsubscript{SCL} is greater than t\textsubscript{SCLL} + t\textsubscript{SCLH} due to SCL internal detection delay. Values provided for t\textsubscript{SCL} are examples only.
2. t\textsubscript{SYNC1} + t\textsubscript{SYNC2} minimum value is 4 x \textsubscript{I2CCLK} = 250 ns. Example with t\textsubscript{SYNC1} + t\textsubscript{SYNC2} = 1000 ns.
3. t\textsubscript{SYNC1} + t\textsubscript{SYNC2} minimum value is 4 x \textsubscript{I2CCLK} = 250 ns. Example with t\textsubscript{SYNC1} + t\textsubscript{SYNC2} = 750 ns.
4. t\textsubscript{SYNC1} + t\textsubscript{SYNC2} minimum value is 4 x \textsubscript{I2CCLK} = 250 ns. Example with t\textsubscript{SYNC1} + t\textsubscript{SYNC2} = 500 ns.
Introduction

The system management bus (SMBus) is a two-wire interface through which various devices can communicate with each other and with the rest of the system. It is based on I²C principles of operation. The SMBus provides a control bus for system and power management related tasks.

This peripheral is compatible with the SMBus specification (http://smbus.org).

The system management bus specification refers to three types of devices

- A slave is a device that receives or responds to a command.
- A master is a device that issues commands, generates the clocks and terminates the transfer.
- A host is a specialized master that provides the main interface to the system’s CPU. A host must be a master-slave and must support the SMBus host notify protocol. Only one host is allowed in a system.

This peripheral can be configured as master or slave device, and also as a host.

Bus protocols

There are eleven possible command protocols for any given device. A device may use any or all of the eleven protocols to communicate. The protocols are Quick Command, Send Byte, Receive Byte, Write Byte, Write Word, Read Byte, Read Word, Process Call, Block Read, Block Write and Block Write-Block Read Process Call. These protocols must be implemented by the user software.

For more details on these protocols, refer to SMBus specification (http://smbus.org).

Address resolution protocol (ARP)

SMBus slave address conflicts can be resolved by dynamically assigning a new unique address to each slave device. In order to provide a mechanism to isolate each device for the purpose of address assignment each device must implement a unique device identifier (UDID). This 128-bit number is implemented by software.

This peripheral supports the Address Resolution Protocol (ARP). The SMBus Device Default Address (0b1100 001) is enabled by setting SMBDEN bit in I2C_CR1 register. The ARP commands must be implemented by the user software.

Arbitration is also performed in slave mode for ARP support.

For more details of the SMBus address resolution protocol, refer to SMBus specification (http://smbus.org).

Received command and data acknowledge control

A SMBus receiver must be able to NACK each received command or data. In order to allow the ACK control in slave mode, the Slave Byte Control mode must be enabled by setting SBC bit in I2C_CR1 register. Refer to Slave byte control mode for more details.

Host notify protocol

This peripheral supports the host notify protocol by setting the SMBHEN bit in the I2C_CR1 register. In this case the host acknowledges the SMBus host address (0b0001 000). When this protocol is used, the device acts as a master and the host as a slave.
SMBus alert

The SMBus ALERT optional signal is supported. A slave-only device can signal the host through the SMBALERT# pin that it wants to talk. The host processes the interrupt and simultaneously accesses all SMBALERT# devices through the alert response address (0b0001 100). Only the device(s) which pulled SMBALERT# low acknowledges the alert response address.

When configured as a slave device (SMBHEN = 0), the SMBA pin is pulled low by setting the ALERTEN bit in the I2C_CR1 register. The Alert Response Address is enabled at the same time.

When configured as a host (SMBHEN = 1), the ALERT flag is set in the I2C_ISR register when a falling edge is detected on the SMBA pin and ALERTEN = 1. An interrupt is generated if the ERRIE bit is set in the I2C_CR1 register. When ALERTEN = 0, the ALERT line is considered high even if the external SMBA pin is low.

*If the SMBus ALERT pin is not needed, the SMBA pin can be used as a standard GPIO if ALERTEN = 0.*

Packet error checking

A packet error checking mechanism has been introduced in the SMBus specification to improve reliability and communication robustness. The packet error checking is implemented by appending a packet error code (PEC) at the end of each message transfer. The PEC is calculated by using the $C(x) = x^8 + x^2 + x + 1$ CRC-8 polynomial on all the message bytes (including addresses and read/write bits).

The peripheral embeds a hardware PEC calculator and allows a not acknowledge to be sent automatically when the received byte does not match with the hardware calculated PEC.

Timeouts

This peripheral embeds hardware timers in order to be compliant with the three timeouts defined in SMBus specification.

<table>

<td>25</td>
</tr>
<tr>
<td>$t_{\text{LOW:MEXT}}^{(2)}$</td>
<td>Cumulative clock low extend time (master device)</td>
<td>-</td>
<td>10</td>
</tr>
</tbody>
</table>

1. $t_{\text{LOW:SEXT}}$ is the cumulative time a given slave device is allowed to extend the clock cycles in one message from the initial START to the STOP. It is possible that, another slave device or the master also extends the clock causing the combined clock low extend time to be greater than $t_{\text{LOW:SEXT}}$. Therefore, this parameter is measured with the slave device as the sole target of a full-speed master.

2. $t_{\text{LOW:MEXT}}$ is the cumulative time a master device is allowed to extend its clock cycles within each byte of a message as defined from START-to-ACK, ACK-to-ACK, or ACK-to-STOP. It is possible that a slave device or another master also extends the clock, causing the combined clock low time to be greater than $t_{\text{LOW:MEXT}}$ on a given byte. Therefore, this parameter is measured with a full speed slave device as the sole target of the master.
Bus idle detection

A master can assume that the bus is free if it detects that the clock and data signals have been high for t_{IDLE} greater than t_{HIGH\_MAX} (refer to Table 653).

This timing parameter covers the condition where a master has been dynamically added to the bus and may not have detected a state transition on the SMBCLK or SMBDAT lines. In this case, the master must wait long enough to ensure that a transfer is not currently in progress. The peripheral supports a hardware bus idle detection.

65.4.12 SMBus initialization

This section is relevant only when SMBus feature is supported (see Section 65.3).

In addition to I2C initialization, some other specific initialization must be done to perform SMBus communication.

Received command and data acknowledge control (slave mode)

A SMBus receiver must be able to NACK each received command or data. In order to allow ACK control in slave mode, the Slave byte control mode must be enabled by setting the SBC bit in the I2C\_CR1 register. Refer to Slave byte control mode for more details.

Specific address (slave mode)

The specific SMBus addresses must be enabled if needed. Refer to Bus idle detection for more details.

- The SMBus device default address (0b1100 001) is enabled by setting the SMBDEN bit in the I2C\_CR1 register.
- The SMBus host address (0b0001 000) is enabled by setting the SMBHEN bit in the I2C\_CR1 register.
- The alert response address (0b0001100) is enabled by setting the ALERTEN bit in the I2C\_CR1 register.
Packet error checking

PEC calculation is enabled by setting the PECEN bit in the I2C_CR1 register. Then the PEC transfer is managed with the help of a hardware byte counter: NBYTES[7:0] in the I2C_CR2 register. The PECEN bit must be configured before enabling the I2C.

The PEC transfer is managed with the hardware byte counter, so the SBC bit must be set when interfacing the SMBus in slave mode. The PEC is transferred after NBYTES - 1 data have been transferred when the PECBYTE bit is set and the RELOAD bit is cleared. If RELOAD is set, PECBYTE has no effect.

Caution: Changing the PECEN configuration is not allowed when the I2C is enabled.

</tr>
</tbody>
</table>

Timeout detection

The timeout detection is enabled by setting the TIMOUTEN and TEXTEN bits in the I2C_TIMEOUTR register. The timers must be programmed in such a way that they detect a timeout before the maximum time given in the SMBus specification.

- t_TIMEOUT check
  To enable the t_TIMEOUT check, the 12-bit TIMEOUTA[11:0] bits must be programmed with the timer reload value, to check the t_TIMEOUT parameter. The TIDLE bit must be configured to ‘0’ to detect the SCL low level timeout.
  Then the timer is enabled by setting the TIMOUTEN in the I2C_TIMEOUTR register.
  If SCL is tied low for a time greater than (TIMEOUTA + 1) x 2048 x tI2CCLK, the TIMEOUT flag is set in the I2C_ISR register.
  Refer to Table 660.

Caution: Changing the TIMEOUTA[11:0] bits and TIDLE bit configuration is not allowed when the TIMEOUTEN bit is set.

- t_LOW:SEXT and t_LOW:MEXT check
  Depending on if the peripheral is configured as a master or as a slave, The 12-bit TIMEOUTB timer must be configured in order to check t_LOW:SEXT for a slave and t_LOW:MEXT for a master. As the standard specifies only a maximum, the user can choose the same value for the both.
  Then the timer is enabled by setting the TEXTEN bit in the I2C_TIMEOUTR register.
  If the SMBus peripheral performs a cumulative SCL stretch for a time greater than (TIMEOUTB + 1) x 2048 x tI2CCLK, and in the timeout interval described in Bus idle detection section, the TIMEOUT flag is set in the I2C_ISR register.
  Refer to Table 661

Caution: Changing the TIMEOUTB configuration is not allowed when the TEXTEN bit is set.
Bus idle detection

In order to enable the $t_{\text{IDLE}}$ check, the 12-bit TIMEOUTA[11:0] field must be programmed with the timer reload value in order to obtain the $t_{\text{IDLE}}$ parameter. The TIDLE bit must be configured to ‘1’ in order to detect both SCL and SDA high level timeout.

Then the timer is enabled by setting the TIMEOUTEN bit in the I2C_TIMEOUTR register.

If both the SCL and SDA lines remain high for a time greater than $(\text{TIMEOUTA} + 1) \times 4 \times t_{\text{I2CCLK}}$, the TIMEOUT flag is set in the I2C_ISR register.

Refer to Table 662.

Caution: Changing TIMEOUTA and TIDLE configuration is not allowed when TIMEOUTEN is set.

65.4.13 SMBus: I2C_TIMEOUTR register configuration examples

This section is relevant only when SMBus feature is supported. Refer to Section 65.3.

65.4.14 SMBus slave mode

This section is relevant only when the SMBus feature is supported (refer to Section 65.3). In addition to I2C slave transfer management (refer to Section 65.4.8), some additional software flows are provided to support the SMBus.

**SMBus slave transmitter**

When the IP is used in SMBus, SBC must be programmed to ‘1’ to enable the PEC transmission at the end of the programmed number of data bytes. When the PECBYTE bit is set, the number of bytes programmed in NBYTES[7:0] includes the PEC transmission. In that case the total number of TXIS interrupts is NBYTES - 1 and the content of the I2C_PECR register is automatically transmitted if the master requests an extra byte after the NBYTES - 1 data transfer.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

**Figure 794. Transfer sequence flow for SMBus slave transmitter N bytes + PEC**
When the I2C is used in SMBus mode, SBC must be programmed to ‘1’ to allow the PEC checking at the end of the programmed number of data bytes. In order to allow the ACK control of each byte, the reload mode must be selected (RELOAD = 1). Refer to **Slave byte control mode** for more details.

In order to check the PEC byte, the RELOAD bit must be cleared and the PECBYTE bit must be set. In this case, after NBYTES - 1 data have been received, the next received byte is compared with the internal I2C_PECR register content. A NACK is automatically generated if the comparison does not match, and an ACK is automatically generated if the comparison matches, whatever the ACK bit value. Once the PEC byte is received, it is copied into the I2C_RXDR register like any other data, and the RXNE flag is set.

In the case of a PEC mismatch, the PECERR flag is set and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

If no ACK software control is needed, the user can program PECBYTE = 1 and, in the same write operation, program NBYTES with the number of bytes to be received in a continuous flow. After NBYTES - 1 are received, the next received byte is checked as being the PEC.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.
Figure 796. Transfer sequence flow for SMBus slave receiver N bytes + PEC

1. **Slave initialization**
   - Check if I2C_ISR.ADDR = 1?
     - No
     - Yes: Read ADDCODE and DIR in I2C_ISR

2. Set I2C_CR2.NBYTES = 1, RELOAD = 1
   - PECBYTE = 1
   - Set I2C_ICR.ADDRCF

3. Check if I2C_ISR.RXNE = 1? and I2C_ISR.TCR = 1?
   - No
   - Yes:
     - Read I2C_RXDR.RXDATA
     - Program I2C_CR2.NACK = 0
     - I2C_CR2.NBYTES = 1
     - N = N - 1

4. Check if N = 1?
   - No
   - Yes:
     - Read I2C_RXDR.RXDATA
     - Program RELOAD = 0
     - NACK = 0 and NBYTES = 1

5. Check if I2C_ISR.RXNE = 1?
   - No
   - Yes: Read I2C_RXDR.RXDATA

6. End
This section is relevant only when the SMBus feature is supported (refer to Section 65.3).
In addition to I2C master transfer management (refer to Section 65.4.9), some additional software flows are provided to support the SMBus.

**SMBus master transmitter**

When the SMBus master wants to transmit the PEC, the PECBYTE bit must be set and the number of bytes must be programmed in the NBYTES[7:0] field, before setting the START bit. In this case the total number of TXIS interrupts is NBYTES - 1. So if the PECBYTE bit is set when NBYTES = 0x1, the content of the I2C_PECR register is automatically transmitted.

If the SMBus master wants to send a STOP condition after the PEC, automatic end mode must be selected (AUTOEND = 1). In this case, the STOP condition automatically follows the PEC transmission.

When the SMBus master wants to send a RESTART condition after the PEC, software mode must be selected (AUTOEND = 0). In this case, once NBYTES - 1 have been
transmitted, the I2C_PECR register content is transmitted and the TC flag is set after the PEC transmission, stretching the SCL line low. The RESTART condition must be programmed in the TC interrupt subroutine.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

**Figure 798. Bus transfer diagrams for SMBus master transmitter**

Example SMBus master transmitter 2 bytes + PEC, automatic end mode (STOP)

- **INIT:** program Slave address, program NBYTES = 3, AUTOEND=1, set PECBYTE, set START
- **EV1:** TXIS ISR: wr data1
- **EV2:** TXIS ISR: wr data2

Example SMBus master transmitter 2 bytes + PEC, software end mode (RESTART)

- **INIT:** program Slave address, program NBYTES = 3, AUTOEND=0, set PECBYTE, set START
- **EV1:** TXIS ISR: wr data1
- **EV2:** TXIS ISR: wr data2
- **EV3:** TC ISR: program Slave address, program NBYTES = N, set START
**SMBus master receiver**

When the SMBus master wants to receive the PEC followed by a STOP at the end of the transfer, automatic end mode can be selected (AUTOEND = 1). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES - 1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. A NACK response is given to the PEC byte, followed by a STOP condition.

When the SMBus master receiver wants to receive the PEC byte followed by a RESTART condition at the end of the transfer, software mode must be selected (AUTOEND = 0). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES - 1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. The TC flag is set after the PEC byte reception, stretching the SCL line low. The RESTART condition can be programmed in the TC interrupt subroutine.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.
65.4.15 Autonomous mode

The I2C peripheral can be functional in Stop mode thanks to its autonomous mode, supported in master and slave modes with NOSTRETCH = 0. The autonomous mode is not supported when NOSTRETCH = 1. It is possible to use this mode in Run, Sleep or Stop modes.

The APB clock is requested by the peripheral each time the I2C status needs to be updated. Once the APB clock is received by the peripheral, either an interrupt or a DMA request is generated, depending on the I2C configuration.

In case an interrupt is generated, the device wakes up from Stop mode.

If there is no interrupt, the device remains in Stop mode, but the kernel and AHB/APB clocks are available for the I2C and all the autonomous peripherals enabled in the RCC. If DMA
requests are enabled, the data are directly transferred to or from the SRAM thanks to the DMA, while the product remains in Stop mode.

**Slave mode**

In slave mode, the autonomous mode is enabled in Stop mode if WUPEN = 1 in the I2C_CR1. This mode is supported only when NOSTRETCH = 0.

The kernel clock is requested by the peripheral on Start detection during all the transfer until the Stop condition occurs, when the slave is addressed. If the slave is not addressed, the kernel clock request is released after the address phase.

To optimize the functionality in slave mode by using only DMA transfers, it is possible to set the ADDRACLR and STOPFACLR bits in the I2C_CR1 in order to avoid to serve the Address match (ADDR) and Stop detection (STOPF) events.

*Note:* *If the I2C clock is the system clock, or if WUPEN = 0, the internal oscillator is not switched on after a START is received in slave mode.*

**Master mode**

In master mode, a transfer can be automatically launched when an asynchronous trigger is detected in Run, Sleep or Stop mode. The trigger, selected by TRIGSEL in the I2C_AUTOCR register, generates a kernel clock request to allow the transfer, and launches a START condition and the I2C transfer as defined in the I2C_CR2 register. The kernel clock is requested until the Stop condition occurs.

To avoid to wake up the CPU too often, it is possible to replace some interrupts by DMA requests, to make some control registers write actions. In master mode, Transfer Complete (TC) and Transfer Complete Reload (TCR) events can generate a DMA request when the corresponding TCDMAEN or TCRDMAEN are set in the I2C_AUTOCR register. Consequently, the I2C_CR2 can be written thanks to a DMA transfer, in order to program a new transfer (in TC event) or to reload the number of bytes (in TCR event).

In case a trigger is enabled, but the application needs to take back control in order to start a different transfer, the following steps are required before writing in the I2C_CR2 register to launch the new transfer:

1. Wait for BUSY = 0 in the I2C_ISR
2. Disable the TRIGEN bit in I2C_AUTOCR register
3. Wait for a delay greater than the tBUF timing (bus free time between a STOP and a START condition)
4. Wait for BUSY = 0 in the I2C_ISR

*Caution:* When the product is in Stop mode, the I2C receives its kernel clock only when it is implicated in the transfer. Consequently, some features (e.g. timeouts, bus idle detection) are not reliable in Stop mode.

*Caution:* The digital filter is not compatible with the functionality in Stop mode. If the DNF bit is not equal to 0, setting the WUPEN bit has no effect.

*Caution:* Clock stretching must be enabled (NOSTRETCH = 0) to ensure proper operation of the wake-up from Stop mode feature.

*Caution:* If wake-up from Stop mode is disabled (WUPEN = 0), the I2C peripheral must be disabled before entering Stop mode (PE = 0).
65.4.16 Error conditions

The following errors are the conditions that can cause a communication fail.

**Bus error (BERR)**

A bus error is detected when a START or a STOP condition is detected and is not located after a multiple of nine SCL clock pulses. A START or a STOP condition is detected when an SDA edge occurs while SCL is high.

The bus error flag is set only if the I2C is involved in the transfer as master or addressed slave (i.e not during the address phase in slave mode).

In case of a misplaced START or RESTART detection in slave mode, the I2C enters address recognition state like for a correct START condition.

When a bus error is detected, the BERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

**Arbitration lost (ARLO)**

An arbitration loss is detected when a high level is sent on the SDA line, but a low level is sampled on the SCL rising edge.

- In master mode, arbitration loss is detected during the address phase, data phase and data acknowledge phase. In this case, the SDA and SCL lines are released, the START control bit is cleared by hardware and the master switches automatically to slave mode.
- In slave mode, arbitration loss is detected during data phase and data acknowledge phase. In this case, the transfer is stopped, and the SCL and SDA lines are released.

When an arbitration loss is detected, the ARLO flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

**Overrun/underrun error (OVR)**

An overrun or underrun error is detected in slave mode when NOSTRETCH = 1 and:

- In reception when a new byte is received and the RXDR register has not been read yet. The new received byte is lost, and a NACK is automatically sent as a response to the new byte.
- In transmission:
  - When STOPF = 1 and the first data byte must be sent. The content of the I2C_TXDR register is sent if TXE = 0, 0xFF if not.
  - When a new byte must be sent and the I2C_TXDR register has not been written yet, 0xFF is sent.

When an overrun or underrun error is detected, the OVR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

**Packet error checking error (PECERR)**

This section is relevant only when the SMBus feature is supported (refer to Section 65.3).

A PEC error is detected when the received PEC byte does not match with the I2C_PECR register content. A NACK is automatically sent after the wrong PEC reception.
When a PEC error is detected, the PECERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

**Timeout error (TIMEOUT)**

This section is relevant only when the SMBus feature is supported (refer to Section 65.3). A timeout error occurs for any of these conditions:

- **TIDLE = 0 and SCL remained low for the time defined in the TIMEOUTA[11:0] bits:** this is used to detect an SMBus timeout.
- **TIDLE = 1 and both SDA and SCL remained high for the time defined in the TIMEOUTA[11:0] bits:** this is used to detect a bus idle condition.
- **Master cumulative clock low extend time reached the time defined in the TIMEOUTB[11:0] bits (SMBus tLOW:MEXT parameter).**
- **Slave cumulative clock low extend time reached the time defined in TIMEOUTB[11:0] bits (SMBus tLOW:SEXT parameter).**

When a timeout violation is detected in master mode, a STOP condition is automatically sent.

When a timeout violation is detected in slave mode, SDA and SCL lines are automatically released.

When a timeout error is detected, the TIMEOUT flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

**Alert (ALERT)**

This section is relevant only when the SMBus feature is supported (refer to Section 65.3). The ALERT flag is set when the I2C interface is configured as a Host (SMBHEN = 1), the alert pin detection is enabled (ALERTEN = 1) and a falling edge is detected on the SMBA pin. An interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

### 65.4.17 DMA requests

**Transmission using DMA**

DMA (direct memory access) can be enabled for transmission by setting the TXDMAEN bit in the I2C_CR1 register. Data is loaded from an SRAM area configured using the DMA peripheral (see ) to the I2C_TXDR register whenever the TXIS bit is set.

Only the data are transferred with DMA.

- **In master mode:** the initialization, the slave address, direction, number of bytes and START bit are programmed by software (the transmitted slave address cannot be transferred with DMA). When all data are transferred using DMA, the DMA must be
initialized before setting the START bit. The end of transfer is managed with the NBYTES counter. Refer to Master transmitter.

- In slave mode:
  - With NOSTRETCH = 0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in ADDR interrupt subroutine, before clearing ADDR.
  - With NOSTRETCH = 1, the DMA must be initialized before the address match event.
- For instances supporting SMBus: the PEC transfer is managed with NBYTES counter. Refer to SMBus slave transmitter and SMBus master transmitter.

**Note:** If DMA is used for transmission, the TXIE bit does not need to be enabled.

**Reception using DMA**

DMA (direct memory access) can be enabled for reception by setting the RXDMAEN bit in the I2C_CR1 register. Data is loaded from the I2C_RXDR register to an SRAM area configured using the DMA peripheral (refer to ) whenever the RXNE bit is set. Only the data (including PEC) are transferred with DMA.

- In master mode, the initialization, the slave address, direction, number of bytes and START bit are programmed by software. When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter.
- In slave mode with NOSTRETCH = 0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in the ADDR interrupt subroutine, before clearing the ADDR flag.
- If SMBus is supported (see Section 65.3): the PEC transfer is managed with the NBYTES counter. Refer to SMBus Slave receiver and SMBus master receiver.

**Note:** If DMA is used for reception, the RXIE bit does not need to be enabled.

**Master event control using DMA**

In master mode, the transfer can be automatically managed while the product is in Run, Sleep or Stop mode thanks to TC and TCR DMA requests.

- If TCDMAEN is set in the I2C_AUTOCR register, the I2C_EVC (I2C Control Event) DMA request is generated when TC is set in the I2C_ISR register. The DMA must be programmed to write the next command in the I2C_CR2 register. If both STOP and START bit are set in the new I2C_CR2 command, a STOP condition followed by a START condition is sent, followed by the address, direction and number of bytes defined in I2C_CR2. If only START bit is set in the new I2C_CR2 command, a ReSTART condition is sent, followed by the address, direction and number of bytes defined in I2C_CR2.
- If TCRDMAEN is set in the I2C_AUTOCR register, the I2C_EVC (I2C Control Event) DMA request is generated when TCR is set in the I2C_ISR register. The DMA must be programmed to write the remaining number of bytes to be transferred in the I2C_CR2 register.

**65.4.18 Debug mode**

When the microcontroller enters debug mode (core halted), the SMBus timeout either continues to work normally or stops, depending on the DBG_I2Cx_ configuration bits in the DBG module.
65.5 I2C low-power modes

Table 663. Effect of low-power modes on the I2C

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. I2C interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop(^{(1)})</td>
<td>The I2C registers content is kept. If the autonomous mode is enabled and I2C is clocked by an internal oscillator available in Stop mode: transfers in master and in slave modes are functional. DMA requests are functional, and the interrupts cause the device to exit the Stop mode. If WUPEN = 0: the I2C must be disabled before entering Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The I2C peripheral is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

1. Refer to I2C implementation table for information about the Stop modes supported by each instance. If wake-up from a specific Stop mode is not supported, the instance must be disabled before entering this Stop mode.
## 65.6 I2C interrupts

The following table gives the list of I2C interrupt requests.

1. Refer to the I2C implementation table for information about wake-up from Stop mode support per instance.
65.7 I2C registers

Refer to Section 1.2 on page 126 for a list of abbreviations used in register descriptions.

The peripheral registers are accessed by words (32-bit).

65.7.1 I2C control register 1 (I2C_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

<table>
<thead>
<tr>
<th>Bit 31</th>

</tr>
<tr>
<td>1:</td>
<td>PEC calculation enabled</td>
<td></td>
</tr>
</tbody>
</table>

Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’.
Refer to Section 65.3.
Bit 22 **ALERTEN**: SMBus alert enable
0: The SMBus alert pin (SMBA) is not supported in host mode (SMBHEN = 1). In device mode (SMBHEN = 0), the SMBA pin is released and the Alert Response Address header is disabled (0001100x followed by NACK).
1: The SMBus alert pin is supported in host mode (SMBHEN = 1). In device mode (SMBHEN = 0), the SMBA pin is driven low and the Alert Response Address header is enabled (0001100x followed by ACK).

*Note*: When ALERTEN = 0, the SMBA pin can be used as a standard GPIO.

*If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 65.3.*

Bit 21 **SMBDEN**: SMBus device default address enable
0: Device default address disabled. Address 0b1100001x is NACKed.
1: Device default address enabled. Address 0b1100001x is ACKed.

*Note*: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 65.3.

Bit 20 **SMBHEN**: SMBus host address enable
0: Host address disabled. Address 0b0001000x is NACKed.
1: Host address enabled. Address 0b0001000x is ACKed.

*Note*: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 65.3.

Bit 19 **GCEN**: General call enable
0: General call disabled. Address 0b00000000 is NACKed.
1: General call enabled. Address 0b00000000 is ACKed.

Bit 18 **WUPEN**: Wake-up from Stop mode enable
0: Wake-up from Stop mode disable.
1: Wake-up from Stop mode enable.

*Note*: If the wake-up from Stop mode feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 65.3.

*Note*: WUPEN can be set only when DNF = '0000'

Bit 17 **NOSTRETCH**: Clock stretching disable
This bit is used to disable clock stretching in slave mode. It must be kept cleared in master mode.
0: Clock stretching enabled
1: Clock stretching disabled

*Note*: This bit can only be programmed when the I2C is disabled (PE = 0).

Bit 16 **SBC**: Slave byte control
This bit is used to enable hardware byte control in slave mode.
0: Slave byte control disabled
1: Slave byte control enabled

Bit 15 **RXDMAEN**: DMA reception requests enable
0: DMA mode disabled for reception
1: DMA mode enabled for reception

Bit 14 **TXDMAEN**: DMA transmission requests enable
0: DMA mode disabled for transmission
1: DMA mode enabled for transmission

Bit 13 Reserved, must be kept at reset value.
Bit 12 **ANFOFF**: Analog noise filter OFF

0: Analog noise filter enabled
1: Analog noise filter disabled

*Note*: This bit can only be programmed when the I2C is disabled (PE = 0).

Bits 11:8 **DNF[3:0]**: Digital noise filter

These bits are used to configure the digital noise filter on SDA and SCL input. The digital filter, filters spikes with a length of up to $\text{DNF}[3:0] \times \frac{t}{I2CCLK}$

- 0000: Digital filter disabled
- 0001: Digital filter enabled and filtering capability up to 1 $t_{I2CCLK}$
- 0010: Digital filter enabled and filtering capability up to 2 $t_{I2CCLK}$
- 0011: Digital filter enabled and filtering capability up to 3 $t_{I2CCLK}$
- 0100: Digital filter enabled and filtering capability up to 4 $t_{I2CCLK}$
- 0101: Digital filter enabled and filtering capability up to 5 $t_{I2CCLK}$
- 0110: Digital filter enabled and filtering capability up to 6 $t_{I2CCLK}$
- 0111: Digital filter enabled and filtering capability up to 7 $t_{I2CCLK}$
- 1000: Digital filter enabled and filtering capability up to 8 $t_{I2CCLK}$
- 1001: Digital filter enabled and filtering capability up to 9 $t_{I2CCLK}$
- 1010: Digital filter enabled and filtering capability up to 10 $t_{I2CCLK}$
- 1011: Digital filter enabled and filtering capability up to 11 $t_{I2CCLK}$
- 1100: Digital filter enabled and filtering capability up to 12 $t_{I2CCLK}$
- 1101: Digital filter enabled and filtering capability up to 13 $t_{I2CCLK}$
- 1110: Digital filter enabled and filtering capability up to 14 $t_{I2CCLK}$
- 1111: digital filter enabled and filtering capability up to 15 $t_{I2CCLK}$

*Note*: If the analog filter is also enabled, the digital filter is added to the analog filter. This filter can only be programmed when the I2C is disabled (PE = 0).

Bit 7 **ERRIE**: Error interrupts enable

0: Error detection interrupts disabled
1: Error detection interrupts enabled

*Note*: Any of these errors generate an interrupt:
- Arbitration Loss (ARLO)
- Bus Error detection (BERR)
- Overrun/Underrun (OVR)
- Timeout detection (TIMEOUT)
- PEC error detection (PECERR)
- Alert pin event detection (ALERT)

Bit 6 **TCIE**: Transfer complete interrupt enable

0: Transfer complete interrupt disabled
1: Transfer complete interrupt enabled

*Note*: Any of these events generate an interrupt:
- Transfer complete (TC)
- Transfer complete reload (TCR)

Bit 5 **STOPIE**: Stop detection Interrupt enable

0: Stop detection (STOPF) interrupt disabled
1: Stop detection (STOPF) interrupt enabled

Bit 4 **NACKIE**: Not acknowledge received Interrupt enable

0: Not acknowledge (NACKF) received interrupts disabled
1: Not acknowledge (NACKF) received interrupts enabled

Bit 3 **ADDRIE**: Address match Interrupt enable (slave only)

0: Address match (ADDR) interrupts disabled
1: Address match (ADDR) interrupts enabled

Bit 2 **RXIE**: RX Interrupt enable

0: Receive (RXNE) interrupts disabled
1: Receive (RXNE) interrupts enabled

Bit 1 **TXIE**: TX Interrupt enable

0: Transmit (TXIS) interrupts disabled
1: Transmit (TXIS) interrupts enabled
Bit 0 **PE**: Peripheral enable
0: Peripheral disable
1: Peripheral enable

*Note: When PE = 0, the I2C SCL and SDA lines are released. Internal state machines and status bits are put back to their reset value. When cleared, PE must be kept low for at least three APB clock cycles.*

### 65.7.2 I2C control register 2 (I2C_CR2)

Address offset: 0x04

Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

<table>
<thead>
<tr>
<th>Bit 31:27</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 26</td>
<td><strong>PECBYTE</strong>: Packet error checking byte</td>
</tr>
<tr>
<td></td>
<td>This bit is set by software, and cleared by hardware when the PEC is transferred, or when a STOP condition or an Address matched is received, also when PE = 0.</td>
</tr>
<tr>
<td></td>
<td>0: No PEC transfer.</td>
</tr>
<tr>
<td></td>
<td>1: PEC transmission/reception is requested</td>
</tr>
<tr>
<td></td>
<td><em>Note: Writing '0' to this bit has no effect.</em></td>
</tr>
<tr>
<td></td>
<td><em>This bit has no effect when RELOAD is set.</em></td>
</tr>
<tr>
<td></td>
<td><em>This bit has no effect is slave mode when SBC = 0.</em></td>
</tr>
<tr>
<td></td>
<td><em>If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 65.3.</em></td>
</tr>
<tr>
<td>Bit 25</td>
<td><strong>AUTOEND</strong>: Automatic end mode (master mode)</td>
</tr>
<tr>
<td></td>
<td>This bit is set and cleared by software.</td>
</tr>
<tr>
<td></td>
<td>0: software end mode: TC flag is set when NBYTES data are transferred, stretching SCL low.</td>
</tr>
<tr>
<td></td>
<td>1: Automatic end mode: a STOP condition is automatically sent when NBYTES data are transferred.</td>
</tr>
<tr>
<td></td>
<td><em>Note: This bit has no effect in slave mode or when the RELOAD bit is set.</em></td>
</tr>
<tr>
<td>Bit 24</td>
<td><strong>RELOAD</strong>: NBYTES reload mode</td>
</tr>
<tr>
<td></td>
<td>This bit is set and cleared by software.</td>
</tr>
<tr>
<td></td>
<td>0: The transfer is completed after the NBYTES data transfer (STOP or RESTART follows).</td>
</tr>
<tr>
<td></td>
<td>1: The transfer is not completed after the NBYTES data transfer (NBYTES is reloaded). TCR flag is set when NBYTES data are transferred, stretching SCL low.</td>
</tr>
</tbody>
</table>
Bits 23:16 **NBYTES[7:0]**: Number of bytes

The number of bytes to be transmitted/received is programmed there. This field is don’t care in slave mode with SBC = 0.

*Note:* Changing these bits when the START bit is set is not allowed.

Bit 15 **NACK**: NACK generation (slave mode)

The bit is set by software, cleared by hardware when the NACK is sent, or when a STOP condition or an Address matched is received, or when PE = 0.

0: an ACK is sent after current received byte.
1: a NACK is sent after current received byte.

*Note:* Writing '0' to this bit has no effect.

This bit is used in slave mode only: in master receiver mode, NACK is automatically generated after last byte preceding STOP or RESTART condition, whatever the NACK bit value.

When an overrun occurs in slave receiver NOSTRETCH mode, a NACK is automatically generated whatever the NACK bit value.

When hardware PEC checking is enabled (PECBYTE = 1), the PEC acknowledge value does not depend on the NACK value.

Bit 14 **STOP**: Stop generation (master mode)

The bit is set by software, cleared by hardware when a STOP condition is detected, or when PE = 0.

In master mode:

0: No Stop generation.
1: Stop generation after current byte transfer.

*Note:* Writing '0' to this bit has no effect.

Bit 13 **START**: Start generation

This bit is set by software, and cleared by hardware after the Start followed by the address sequence is sent, by an arbitration loss, by an address matched in slave mode, by a timeout error detection, or when PE = 0.

0: No Start generation.
1: Restart/Start generation:

- If the I2C is already in master mode with AUTOEND = 0, setting this bit generates a Repeated start condition when RELOAD = 0, after the end of the NBYTES transfer.
- Otherwise setting this bit generates a START condition once the bus is free.

*Note:* Writing '0' to this bit has no effect.

The START bit can be set even if the bus is BUSY or I2C is in slave mode.

This bit has no effect when RELOAD is set.

Bit 12 **HEAD10R**: 10-bit address header only read direction (master receiver mode)

0: The master sends the complete 10 bit slave address read sequence: Start + 2 bytes 10bit address in write direction + Restart + 1st 7 bits of the 10 bit address in read direction.
1: The master only sends the 1st 7 bits of the 10 bit address, followed by Read direction.

*Note:* Changing this bit when the START bit is set is not allowed.

Bit 11 **ADD10**: 10-bit addressing mode (master mode)

0: The master operates in 7-bit addressing mode,
1: The master operates in 10-bit addressing mode

*Note:* Changing this bit when the START bit is set is not allowed.
Bit 10  **RD_WRN**: Transfer direction (master mode)
0: Master requests a write transfer.
1: Master requests a read transfer.

*Note: Changing this bit when the START bit is set is not allowed.*

Bits 9:0  **SADD[9:0]**: Slave address (master mode)

**In 7-bit addressing mode (ADD10 = 0):**
SADD[7:1] must be written with the 7-bit slave address to be sent. The bits SADD[9], SADD[8] and SADD[0] are don’t care.

**In 10-bit addressing mode (ADD10 = 1):**
SADD[9:0] must be written with the 10-bit slave address to be sent.

*Note: Changing these bits when the START bit is set is not allowed.*

### 65.7.3  I2C own address 1 register (I2C_OAR1)

Address offset: 0x08
Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

Bits 31:16  Reserved, must be kept at reset value.

Bit 15  **OA1EN**: Own address 1 enable
0: Own address 1 disabled. The received slave address OA1 is NACKed.
1: Own address 1 enabled. The received slave address OA1 is ACKed.

Bits 14:11  Reserved, must be kept at reset value.

Bit 10  **OA1MODE**: Own address 1 10-bit mode
0: Own address 1 is a 7-bit address.
1: Own address 1 is a 10-bit address.

*Note: This bit can be written only when OA1EN = 0.*

Bits 9:0  **OA1[9:0]**: Interface own slave address

7-bit addressing mode: OA1[7:1] contains the 7-bit own slave address. The bits OA1[9], OA1[8] and OA1[0] are don’t care.

10-bit addressing mode: OA1[9:0] contains the 10-bit own slave address.

*Note: These bits can be written only when OA1EN = 0.*
65.7.4  **I2C own address 2 register (I2C_OAR2)**

Address offset: 0x0C

Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access, until the previous one is completed. The latency of the second write access can be up to 2x i2c_pclk + 6 x i2c_ker_ck.

**Bits 31:28** **PRESC[3:0]:** Timing prescaler  
This field is used to prescale i2c_ker_ck in order to generate the clock period \( t_{\text{PRESC}} \) used for data setup and hold counters (refer to **I2C timings**) and for SCL high and low level counters (refer to **I2C master initialization**).  
\[ t_{\text{PRESC}} = (\text{PRESC} + 1) \times t_{\text{I2CCLK}} \]

**Bits 27:24** Reserved, must be kept at reset value.

**Bits 23:20** **SCLDEL[3:0]:** Data setup time  
This field is used to generate a delay \( t_{\text{SCLDEL}} \) between SDA edge and SCL rising edge. In master mode and in slave mode with NOSTRETCH = 0, the SCL line is stretched low during \( t_{\text{SCLDEL}} \):  
\[ t_{\text{SCLDEL}} = (\text{SCLDEL} + 1) \times t_{\text{PRESC}} \]

**Note:** \( t_{\text{SCLDEL}} \) is used to generate \( t_{\text{SU:DAT}} \) timing.

**Bits 19:16** **SDADEL[3:0]:** Data hold time  
This field is used to generate the delay \( t_{\text{SDADEL}} \) between SCL falling edge and SDA edge. In master mode and in slave mode with NOSTRETCH = 0, the SCL line is stretched low during \( t_{\text{SDADEL}} \):  
\[ t_{\text{SDADEL}} = \text{SDADEL} \times t_{\text{PRESC}} \]

**Note:** \( \text{SDADEL} \) is used to generate \( t_{\text{HD:DAT}} \) timing.

**Bits 15:8** **SCLH[7:0]:** SCL high period (master mode)  
This field is used to generate the SCL high period in master mode.  
\[ t_{\text{SCLH}} = (\text{SCLH} + 1) \times t_{\text{PRESC}} \]

**Note:** \( \text{SCLH} \) is also used to generate \( t_{\text{SU:STO}} \) and \( t_{\text{HD:STA}} \) timing.

**Bits 7:0** **SCLL[7:0]:** SCL low period (master mode)  
This field is used to generate the SCL low period in master mode.  
\[ t_{\text{SCLL}} = (\text{SCLL} + 1) \times t_{\text{PRESC}} \]

**Note:** \( \text{SCLL} \) is also used to generate \( t_{\text{BUF}} \) and \( t_{\text{SU:STA}} \) timings.

**Note:** This register must be configured when the I2C is disabled (PE = 0).

**Note:** The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C Configuration window.
65.7.6 I2C timeout register (I2C_TIMEOUTR)

Address offset: 0x14
Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to $2 \times \text{i2c_pclk} + 6 \times \text{i2c_ker_ck}$.

Note: If the SMBus feature is not supported, this register is reserved and forced by hardware to “0x00000000”. Refer to Section 65.3.

Bit 31 TEXTEN: Extended clock timeout enable
0: Extended clock timeout detection is disabled
1: Extended clock timeout detection is enabled. When a cumulative SCL stretch for more than $t_{\text{LOW:EXT}}$ is done by the I2C interface, a timeout error is detected (TIMEOUT = 1).

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 TIMEOUTB[11:0]: Bus timeout B
This field is used to configure the cumulative clock extension timeout:
In master mode, the master cumulative clock low extend time ($t_{\text{LOW:MEXT}}$) is detected
In slave mode, the slave cumulative clock low extend time ($t_{\text{LOW:SEXT}}$) is detected
$t_{\text{LOW:EXT}} = (\text{TIMEOUTB} + \text{TIDLE} = 01) \times 2048 \times \text{i2CCLK}$

Note: These bits can be written only when TEXTEN = 0.

Bit 15 TIMOUTEN: Clock timeout enable
0: SCL timeout detection is disabled
1: SCL timeout detection is enabled: when SCL is low for more than $t_{\text{TIMEOUT}}$ (TIDLE = 0) or high for more than $t_{\text{IDLE}}$ (TIDLE = 1), a timeout error is detected (TIMEOUT = 1).

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 TIDLE: Idle clock timeout detection
0: TIMEOUTA is used to detect SCL low timeout
1: TIMEOUTA is used to detect both SCL and SDA high timeout (bus idle condition)

Note: This bit can be written only when TIMOUTEN = 0.

Bits 11:0 TIMEOUTA[11:0]: Bus Timeout A
This field is used to configure:
The SCL low timeout condition $t_{\text{TIMEOUT}}$ when TIDLE = 0
$t_{\text{TIMEOUT}} = (\text{TIMEOUTA} + 1) \times 2048 \times \text{i2CCLK}$
The bus idle condition (both SCL and SDA high) when TIDLE = 1
$t_{\text{IDLE}} = (\text{TIMEOUTA} + 1) \times 4 \times \text{i2CCLK}$

Note: These bits can be written only when TIMOUTEN = 0.
I2C interrupt and status register (I2C_ISR)

Address offset: 0x18
Reset value: 0x0000 0001
Access: No wait states

| Bits 31:24 | Reserved, must be kept at reset value. |
| Bits 23:17 | ADDCODE[6:0]: Address match code (slave mode) |
|           | These bits are updated with the received address when an address match event occurs (ADDR = 1). |
|           | In the case of a 10-bit address, ADDCODE provides the 10-bit header followed by the two MSBs of the address. |
| Bit 16    | DIR: Transfer direction (slave mode) |
|           | This flag is updated when an address match event occurs (ADDR = 1). |
|           | 0: Write transfer, slave enters receiver mode. |
|           | 1: Read transfer, slave enters transmitter mode. |
| Bit 15    | BUSY: Bus busy |
|           | This flag indicates that a communication is in progress on the bus. It is set by hardware when a START condition is detected. It is cleared by hardware when a STOP condition is detected, or when PE = 0. |
| Bit 14    | Reserved, must be kept at reset value. |
| Bit 13    | ALERT: SMBus alert |
|           | This flag is set by hardware when SMBHEN = 1 (SMBus host configuration), ALERTEN = 1 and an SMBALERT event (falling edge) is detected on SMBA pin. It is cleared by software by setting the ALERTCF bit. |
|           | Note: This bit is cleared by hardware when PE = 0. If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 65.3. |
| Bit 12    | TIMEOUT: Timeout or t_LOW detection flag |
|           | This flag is set by hardware when a timeout or extended clock timeout occurred. It is cleared by software by setting the TIMEOUTCF bit. |
|           | Note: This bit is cleared by hardware when PE = 0. If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 65.3. |
Bit 11 **PECERR**: PEC Error in reception

This flag is set by hardware when the received PEC does not match with the PEC register content. A NACK is automatically sent after the wrong PEC reception. It is cleared by software by setting the PECCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

*If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’. Refer to Section 65.3.*

Bit 10 **OVR**: Overrun/Underrun (slave mode)

This flag is set by hardware in slave mode with NOSTRETCH = 1, when an overrun/underrun error occurs. It is cleared by software by setting the OVRCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 9 **ARLO**: Arbitration lost

This flag is set by hardware in case of arbitration loss. It is cleared by software by setting the ARLOCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 8 **BERR**: Bus error

This flag is set by hardware when a misplaced Start or STOP condition is detected whereas the peripheral is involved in the transfer. The flag is not set during the address phase in slave mode. It is cleared by software by setting the BERRCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 7 **TCR**: Transfer Complete Reload

This flag is set by hardware when RELOAD = 1 and NBYTES data have been transferred. It is cleared by software when NBYTES is written to a non-zero value.

*Note: This bit is cleared by hardware when PE = 0.*

*This flag is only for master mode, or for slave mode when the SBC bit is set.*

Bit 6 **TC**: Transfer Complete (master mode)

This flag is set by hardware when RELOAD = 0, AUTOEND = 0 and NBYTES data have been transferred. It is cleared by software when START bit or STOP bit is set.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 5 **STOPF**: Stop detection flag

This flag is set by hardware when a STOP condition is detected on the bus and the peripheral is involved in this transfer:

- either as a master, provided that the STOP condition is generated by the peripheral.
- or as a slave, provided that the peripheral has been addressed previously during this transfer.

It is cleared by software by setting the STOPCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 4 **NACKF**: Not Acknowledge received flag

This flag is set by hardware when a NACK is received after a byte transmission. It is cleared by software by setting the NACKCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 3 **ADDR**: Address matched (slave mode)

This bit is set by hardware as soon as the received slave address matched with one of the enabled slave addresses. It is cleared by software by setting the ADDRCF bit.

*Note: This bit is cleared by hardware when PE = 0.*
### 65.7.8 I2C interrupt clear register (I2C_ICR)

Address offset: 0x1C  
Reset value: 0x0000 0000  
Access: No wait states

<table>
<thead>
<tr>

</thead>
</table>

Bits 31:14 Reserved, must be kept at reset value.

- **Bit 13** ALERTCF: Alert flag clear  
  Writing 1 to this bit clears the ALERT flag in the I2C_ISR register.  
  Note: *If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’.*  
  Refer to Section 65.3.

- **Bit 12** TIMOUTCF: Timeout detection flag clear  
  Writing 1 to this bit clears the TIMEOUT flag in the I2C_ISR register.  
  Note: *If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’.*  
  Refer to Section 65.3.

- **Bit 11** PECCF: PEC Error flag clear  
  Writing 1 to this bit clears the PECERR flag in the I2C_ISR register.  
  Note: *If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’.*  
  Refer to Section 65.3.
Bit 10 **OVRCF**: Overrun/Underrun flag clear
   Writing 1 to this bit clears the OVR flag in the I2C_ISR register.

Bit 9 **ARLOCF**: Arbitration lost flag clear
   Writing 1 to this bit clears the ARLO flag in the I2C_ISR register.

Bit 8 **BERRCF**: Bus error flag clear
   Writing 1 to this bit clears the BERRF flag in the I2C_ISR register.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **STOPCF**: STOP detection flag clear
   Writing 1 to this bit clears the STOPF flag in the I2C_ISR register.

Bit 4 **NACKCF**: Not Acknowledge flag clear
   Writing 1 to this bit clears the NACKF flag in I2C_ISR register.

Bit 3 **ADDRCF**: Address matched flag clear
   Writing 1 to this bit clears the ADDR flag in the I2C_ISR register. Writing 1 to this bit also clears the START bit in the I2C_CR2 register.

Bits 2:0 Reserved, must be kept at reset value.

**65.7.9 I2C PEC register (I2C_PECR)**

Address offset: 0x20
Reset value: 0x0000 0000
Access: No wait states

66 Universal synchronous/asynchronous receiver transmitter (USART/UART)

This section describes the universal synchronous asynchronous receiver transmitter (USART/UART).

66.1 Introduction

The USART offers a flexible means to perform Full-duplex data exchange with external equipments requiring an industry standard NRZ asynchronous serial data format. A very wide range of baud rates can be achieved through a fractional baud rate generator.

The USART supports both synchronous one-way and Half-duplex Single-wire communications, as well as LIN (local interconnection network), Smartcard protocol, IrDA (infrared data association) SIR ENDEC specifications, and Modem operations (CTS/RTS). Multiprocessor communications are also supported.

High-speed data communications are possible by using the DMA (direct memory access) for multibuffer configuration.

66.2 USART main features

- Full-duplex asynchronous communication
- NRZ standard format (mark/space)
- Configurable oversampling method by 16 or 8 to achieve the best compromise between speed and clock tolerance
- Baud rate generator systems
- Two internal FIFOs for transmit and receive data
  Each FIFO can be enabled/disabled by software and come with a status flag.
- A common programmable transmit and receive baud rate
- Dual clock domain with dedicated kernel clock for peripherals independent from PCLK
- Auto baud rate detection
- Programmable data word length (7, 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Synchronous Master/Slave mode and clock output/input for synchronous communications
- SPI slave transmission underrun error flag
- Single-wire Half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA.
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
• Communication control/error detection flags
• Parity control:
  – Transmits parity bit
  – Checks parity of received data byte
• Interrupt sources with flags
• Multiprocessor communications: wake-up from Mute mode by idle line detection or address mark detection
• Wake-up from Stop mode
• Autonomous functionality in Stop mode

66.3 **USART extended features**

• LIN master synchronous break send capability and LIN slave break detection capability
  – 13-bit break generation and 10/11 bit break detection when USART is hardware configured for LIN
• IrDA SIR encoder decoder supporting 3/16 bit duration for Normal mode
• Smartcard mode
  – Supports the T=0 and T=1 asynchronous protocols for smartcards as defined in the ISO/IEC 7816-3 standard
  – 0.5 and 1.5 stop bits for Smartcard operation
• Support for Modbus communication
  – Timeout feature
  – CR/LF character recognition

66.4 **USART implementation**

The table below describe USART implementation. It also includes LPUART for comparison.

66.5  USART functional description

66.5.1  USART block diagram

![USART block diagram](image)

66.5.2  USART pins and internal signals

Description USART input/output pins

- **USART bidirectional communications**
  
  USART bidirectional communications require a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):
  - **RX** (Receive Data Input)
    
    RX is the serial data input. Oversampling techniques are used for data recovery. They discriminate between valid incoming data and noise.
  - **TX** (Transmit Data Output)
    
    When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and no data needs to be transmitted, the TX pin is High. In Single-wire and Smartcard modes, this I/O is used to transmit and receive data.
• RS232 Hardware flow control mode
  The following pins are required in RS232 Hardware flow control mode:
  – **CTS** (Clear To Send)
    When driven high, this signal blocks the data transmission at the end of the current transfer.
  – **RTS** (Request To Send)
    When it is low, this signal indicates that the USART is ready to receive data.

• RS485 Hardware control mode
  The **DE** (Driver Enable) pin is required in RS485 Hardware control mode. This signal activates the Transmission mode of the external transceiver.

• Synchronous Master/Slave mode and Smartcard mode
  The following pins are required in synchronous Master/Slave mode and Smartcard mode:
  – **CK**
    This pin acts as Clock output in Synchronous master and Smartcard modes. It acts as Clock input in Synchronous slave mode.
    In Synchronous master mode, this pin outputs the transmitter data clock for synchronous transmission corresponding to SPI master mode (no clock pulses on start bit and stop bit, and a software option to send a clock pulse on the last data bit). In parallel, data can be received synchronously on RX pin. This mechanism can be used to control peripherals featuring shift registers (for example LCD drivers). The clock phase and polarity are software programmable.
    In Smartcard mode, CK output provides the clock to the smartcard.
  – **NSS**
    This pin acts as Slave Select input in Synchronous slave mode.

Refer to Table 668 and Table 669 for the list of USART input/output pins and internal signals.

66.5.3 USART clocks

The simplified block diagram given in Figure 800 shows two fully-independent clock domains:

- The **usart_pclk** clock domain
  
  The **usart_pclk** clock signal feeds the peripheral bus interface. It must be active when accesses to the USART registers are required.

- The **usart_ker_ck** kernel clock domain.
  
  The **usart_ker_ck** is the USART clock source. It is independent from **usart_pclk** and delivered by the RCC. The USART registers can consequently be written/read even when the **usart_ker_ck** clock is stopped.

  When the dual clock domain feature is not supported, the **usart_ker_ck** clock is the same as the **usart_pclk** clock.

There is no constraint between **usart_pclk** and **usart_ker_ck**; **usart_ker_ck** can be faster or slower than **usart_pclk**. The only limitation is the software ability to manage the communication fast enough.

When the USART operates in SPI slave mode, it handles data flow using the serial interface clock derived from the external CK signal provided by the external master SPI device. The **usart_ker_ck** clock must be at least 3 times faster than the clock on the CK input.

66.5.4 USART character description

The word length can be set to 7, 8 or 9 bits, by programming the M bits (M0: bit 12 and M1: bit 28) in the USART_CR1 register (see Figure 801):

- 7-bit character length: M[1:0] = 10
- 8-bit character length: M[1:0] = 00
- 9-bit character length: M[1:0] = 01

**Note:** In 7-bit data length mode, the Smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames detection) are not supported.

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

An **Idle character** is interpreted as an entire frame of “1”s (the number of “1”s includes the number of stop bits).

A **Break character** is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator. The transmission and reception clock are generated when the enable bit is set for the transmitter and receiver, respectively.

A detailed description of each block is given below.

66.5.5 USART FIFOs and thresholds

The USART can operate in FIFO mode.

The USART comes with a Transmit FIFO (TXFIFO) and a Receive FIFO (RXFIFO). The FIFO mode is enabled by setting FIFOEN in USART_CR1 register (bit 29). This mode is supported only in UART, SPI and Smartcard modes.

Since the maximum data word length is 9 bits, the TXFIFO is 9-bit wide. However the RXFIFO default width is 12 bits. This is due to the fact that the receiver does not only store the data in the FIFO, but also the error flags associated to each character (Parity error, Noise error and Framing error flags).

Note: The received data is stored in the RXFIFO together with the corresponding flags. However, only the data are read when reading the RDR. 
The status flags are available in the USART_ISR register.

It is possible to configure the TXFIFO and RXFIFO levels at which the Tx and RX interrupts are triggered. These thresholds are programmed through RXFTCFG and TXFTCFG bitfields in USART_CR3 control register.

In this case:

- The Rx interrupt is generated when the number of received data in the RXFIFO reaches the threshold programmed in the RXFTCFG bits fields.
  
  In this case, the RXFT flag is set in the USART_ISR register. This means that RXFTCFG data have been received: 1 data in USART_RDR and (RXFTCFG - 1) data in the RXFIFO. As an example, when the RXFTCFG is programmed to 101, the RXFT flag is set when a number of data corresponding to the FIFO size has been received (FIFO size -1 data in the RXFIFO and 1 data in the USART_RDR). As a result, the next received data does not set the overrun flag.

- The Tx interrupt is generated when the number of empty locations in the TXFIFO reaches the threshold programmed in the TXFTCFG bits fields.

66.5.6 USART transmitter

The transmitter can send data words of either 7 or 8 or 9 bits, depending on the M bit status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin while the corresponding clock pulses are output on the CK pin.

Character transmission

During an USART transmission, data shifts out the least significant bit first (default configuration) on the TX pin. In this mode, the USART_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register.

When FIFO mode is enabled, the data written to the transmit data register (USART_TDR) are queued in the TXFIFO.

Every character is preceded by a start bit which corresponds to a low logic level for one bit period. The character is terminated by a configurable number of stop bits.

The number of stop bits can be configured to 0.5, 1, 1.5 or 2.
**Note:** The TE bit must be set before writing the data to be transmitted to the USART_TDR. The TE bit must not be reset during data transmission. Resetting the TE bit during the transmission corrupts the data on the TX pin as the baud rate counters get frozen. The current data being transmitted are then lost.

An idle frame is sent when the TE bit is enabled.

### Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in USART_CR2, bits 13, 12.

- **1 stop bit**: This is the default value of number of stop bits.
- **2 stop bits**: This is supported by normal USART, Single-wire and Modem modes.
- **1.5 stop bits**: To be used in Smartcard mode.

An idle frame transmission includes the stop bits.

A break transmission is 10 low bits (when M[1:0] = 00) or 11 low bits (when M[1:0] = 01) or 9 low bits (when M[1:0] = 10) followed by 2 stop bits (see Figure 802). It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

**Character transmission procedure**

To transmit a character, follow the sequence below:

1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the USART_BRR register.
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to 1.
5. Select DMA enable (DMAT) in USART_CR3 if multibuffer communication must take place. Configure the DMA register as explained in Section 66.5.20: Continuous communication using USART and DMA.
6. Set the TE bit in USART_CR1 to send an idle frame as first transmission.
7. Write the data to send in the USART_TDR register. Repeat this for each data to be transmitted in case of single buffer.
   – When FIFO mode is disabled, writing a data to the USART_TDR clears the TXE flag.
   – When FIFO mode is enabled, writing a data to the USART_TDR adds one data to the TXFIFO. Write operations to the USART_TDR are performed when TXFNF flag is set. This flag remains set until the TXFIFO is full.

8. When the last data is written to the USART_TDR register, wait until TC=1.
   – When FIFO mode is disabled, this indicates that the transmission of the last frame is complete.
   – When FIFO mode is enabled, this indicates that both TXFIFO and shift register are empty.
   This check is required to avoid corrupting the last transmission when the USART is disabled or enters Halt mode.

Single byte communication

• When FIFO mode is disabled
   Writing to the transmit data register always clears the TXE bit. The TXE flag is set by hardware. It indicates that:
   – the data have been moved from the USART_TDR register to the shift register and the data transmission has started;
   – the USART_TDR register is empty;
   – the next data can be written to the USART_TDR register without overwriting the previous data.
   This flag generates an interrupt if the TXEIE bit is set.
   When a transmission is ongoing, a write instruction to the USART_TDR register stores the data in the TDR buffer. It is then copied in the shift register at the end of the current transmission.
   When no transmission is ongoing, a write instruction to the USART_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

• When FIFO mode is enabled, the TXFNF (TXFIFO not full) flag is set by hardware to indicate that:
   – the TXFIFO is not full;
   – the USART_TDR register is empty;
   – the next data can be written to the USART_TDR register without overwriting the previous data. When a transmission is ongoing, a write operation to the USART_TDR register stores the data in the TXFIFO. Data are copied from the TXFIFO to the shift register at the end of the current transmission.
   When the TXFIFO is not full, the TXFNF flag stays at 1 even after a write operation to USART_TDR register. It is cleared when the TXFIFO is full. This flag generates an interrupt if the TXFNFE bit is set.
   Alternatively, interrupts can be generated and data can be written to the FIFO when the TXFIFO threshold is reached. In this case, the CPU can write a block of data defined by the programmed trigger level.
   If a frame is transmitted (after the stop bit) and the TXE flag (TXFE in case of FIFO mode) is set, the TC flag goes high. An interrupt is generated if the TCIE bit is set in the USART_CR1 register.
After writing the last data to the USART_TDR register, it is mandatory to wait until TC is set before disabling the USART or causing the microcontroller to enter the low-power mode (see Figure 803: TC/TXE behavior when transmitting).

**Figure 803. TC/TXE behavior when transmitting**

![Diagram showing TC/TXE behavior](image)

**Note:** When FIFO management is enabled, the TXFNF flag is used for data transmission.

### Break characters

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bit (see Figure 801).

If a 1 is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The USART inserts a logic 1 signal (stop) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

When the SBKRQ bit is set, the break character is sent at the end of the current transmission.

When FIFO mode is enabled, sending the break character has priority on sending data even if the TXFIFO is full.

### Idle characters

Setting the TE bit drives the USART to send an idle frame before the first data frame.

### 66.5.7 USART receiver

The USART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the USART_CR1 register.

#### Start bit detection

The start bit detection sequence is the same when oversampling by 16 or by 8.
In the USART, the start bit is detected when a specific sequence of samples is recognized. This sequence is: 1 1 1 0 X 0 X 0 X 0 X 0 X 0.

**Figure 804. Start bit detection when oversampling by 16 or 8**

<table>
<thead>
<tr>
<th>RX state</th>
<th>Idle</th>
<th>Start bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>RX line</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Ideal sample clock</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Real sample clock</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** If the sequence is not complete, the start bit detection aborts and the receiver returns to the idle state (no flag is set), where it waits for a falling edge.

The start bit is confirmed (RXNE flag set and interrupt generated if RXNEIE=1, or RXFNE flag set and interrupt generated if RXFNEIE=1 if FIFO mode enabled) if the 3 sampled bits are at 0 (first sampling on the 3rd, 5th and 7th bits finds the 3 bits at 0 and second sampling on the 8th, 9th and 10th bits also finds the 3 bits at 0).

The start bit is validated but the NE noise flag is set if,

a) for both samplings, 2 out of the 3 sampled bits are at 0 (sampling on the 3rd, 5th and 7th bits and sampling on the 8th, 9th and 10th bits)

or

b) for one of the samplings (sampling on the 3rd, 5th and 7th bits or sampling on the 8th, 9th and 10th bits), 2 out of the 3 bits are found at 0.

If neither of the above conditions are met, the start detection aborts and the receiver returns to the idle state (no flag is set).
Character reception

During an USART reception, data are shifted out least significant bit first (default configuration) through the RX pin.

Character reception procedure

To receive a character, follow the sequence below:

1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register USART_BRR
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to 1.
5. Select DMA enable (DMAR) in USART_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in Section 66.5.20: Continuous communication using USART and DMA.
6. Set the RE bit USART_CR1. This enables the receiver which begins searching for a start bit.

When a character is received:

- When FIFO mode is disabled, the RXNE bit is set to indicate that the content of the shift register is transferred to the RDR. In other words, data have been received and can be read (as well as their associated error flags).
- When FIFO mode is enabled, the RXFNE bit is set to indicate that the RXFIFO is not empty. Reading the USART_RDR returns the oldest data entered in the RXFIFO. When a data is received, it is stored in the RXFIFO together with the corresponding error bits.
- An interrupt is generated if the RXNEIE (RXFNEIE when FIFO mode is enabled) bit is set.
- The error flags can be set if a frame error, noise, parity or an overrun error was detected during reception.
- In Multibuffer communication mode:
  - When FIFO mode is disabled, the RXNE flag is set after every byte reception. It is cleared when the DMA reads the Receive data Register.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every DMA request, a data is retrieved from the RXFIFO. A DMA request is triggered when the RXFIFO is not empty i.e. when there are data to be read from the RXFIFO.
- In Single-buffer mode:
  - When FIFO mode is disabled, clearing the RXNE flag is done by performing a software read from the USART_RDR register. The RXNE flag can also be cleared by programming RXFRQ bit to 1 in the USART_RQR register. The RXNE flag must be cleared before the end of the reception of the next character to avoid an overrun error.
  - When FIFO mode is enabled, the RXFNE is set when the RXFIFO is not empty. After every read operation from USART_RDR, a data is retrieved from the RXFIFO. When the RXFIFO is empty, the RXFNE flag is cleared. The RXFNE flag can also be cleared by programming RXFRQ bit to 1 in USART_RQR. When the RXFIFO is full, the first entry in the RXFIFO must be read before the end of the reception of the next character, to avoid an overrun error. The RXFNE flag generates an interrupt if the RXFNEIE bit is set. Alternatively, interrupts can be
generated and data can be read from RXFIFO when the RXFIFO threshold is reached. In this case, the CPU can read a block of data defined by the programmed threshold.

**Break character**

When a break character is received, the USART handles it as a framing error.

**Idle character**

When an idle frame is detected, it is handled in the same way as a data character reception except that an interrupt is generated if the IDLEIE bit is set.

**Overrun error**

- **FIFO mode disabled**
  
  An overrun error occurs if a character is received and RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared. The RXNE flag is set after every byte reception. An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:
  
  - the ORE bit is set;
  - the RDR content is not lost. The previous data is available by reading the USART_RDR register.
  - the shift register is overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXNEIE or the EIE bit is set.

- **FIFO mode enabled**
  
  An overrun error occurs when the shift register is ready to be transferred and the receive FIFO is full. Data can not be transferred from the shift register to the USART_RDR register until there is one free location in the RXFIFO. The RXFNE flag is set when the RXFIFO is not empty. An overrun error occurs if the RXFIFO is full and the shift register is ready to be transferred. When an overrun error occurs:
  
  - The ORE bit is set.
  - The first entry in the RXFIFO is not lost. It is available by reading the USART_RDR register.
  - The shift register is overwritten. After that point, any data received during overrun is lost.
  - An interrupt is generated if either the RXFNEIE or EIE bit is set.

The ORE bit is reset by setting the ORECF bit in the USART_ICR register.

**Note:** The ORE bit, when set, indicates that at least 1 data has been lost.

When the FIFO mode is disabled, there are two possibilities

- if RXNE=1, then the last valid data is stored in the receive register (RDR) and can be read,
- if RXNE=0, the last valid data has already been read and there is nothing left to be read in the RDR register. This case can occur when the last valid data is read in the RDR register at the same time as the new (and lost) data is received.
Selecting the clock source and the appropriate oversampling method

The choice of the clock source is done through the Clock Control system (see Section : Reset and Clock Control (RCC)). The clock source must be selected through the UE bit before enabling the USART.

The clock source must be selected according to two criteria:

- Possible use of the USART in low-power mode
- Communication speed.

The clock source frequency is `usart_ker_ck`.

When the dual clock domain and the wake-up from low-power mode features are supported, the `usart_ker_ck` clock source can be configurable in the RCC (see Section : Reset and Clock Control (RCC)). Otherwise the `usart_ker_ck` clock is the same as `usart_pclk`.

The `usart_ker_ck` clock can be divided by a programmable factor, defined in the `USART_PRESC` register.

Some `usart_ker_ck` sources enable the USART to receive data while the MCU is in low-power mode. Depending on the received data and wake-up mode selected, the USART wakes up the MCU, when needed, in order to transfer the received data, by performing a software read to the USART_RDR register or by DMA.

For the other clock sources, the system must be active to enable USART communications.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver implements different user-configurable oversampling techniques (except in Synchronous mode) for data recovery by discriminating between valid incoming data and noise. This enables obtaining the best a trade-off between the maximum communication speed and noise/clock inaccuracy immunity.

The oversampling method can be selected by programming the OVER8 bit in the `USART_Cr1` register either to 16 or 8 times the baud rate clock (see Figure 806 and Figure 807).

Depending on the application:

- select oversampling by 8 (OVER8=1) to achieve higher speed (up to `usart_ker_ck_pres/8`). In this case the maximum receiver tolerance to clock deviation is reduced (refer to Section 66.5.9: Tolerance of the USART receiver to clock deviation on page 2766)
- select oversampling by 16 (OVER8=0) to increase the tolerance of the receiver to clock deviations. In this case, the maximum speed is limited to maximum
usart_ker_ck_pres/16 (where usart_ker_ck_pres is the USART input clock divided by a prescaler).

Programming the ONEBIT bit in the USART_CR3 register selects the method used to evaluate the logic level. Two options are available:

- The majority vote of the three samples in the center of the received bit. In this case, when the 3 samples used for the majority vote are not equal, the NE bit is set.
- A single sample in the center of the received bit

Depending on the application:
- select the three sample majority vote method (ONEBIT=0) when operating in a noisy environment and reject the data when a noise is detected (refer to Table 671) because this indicates that a glitch occurred during the sampling.
- select the single sample method (ONEBIT=1) when the line is noise-free to increase the receiver tolerance to clock deviations (see Section 66.5.9: Tolerance of the USART receiver to clock deviation on page 2766). In this case the NE bit is never set.

When noise is detected in a frame:
- The NE bit is set at the rising edge of the RXNE bit (RXFNE in case of FIFO mode enabled).
- The invalid data is transferred from the Shift register to the USART_RDR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case of FIFO mode enabled) which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The NE bit is reset by setting NFCF bit in ICR register.

*Note:* Noise error is not supported in SPI mode.

Oversampling by 8 is not available in the Smartcard, IrDA and LIN modes. In those modes, the OVER8 bit is forced to 0 by hardware.

**Figure 806. Data sampling when oversampling by 16**
A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:
- the FE bit is set by hardware;
- the invalid data is transferred from the Shift register to the USART_RDR register (RXFIFO in case FIFO mode is enabled).
- no interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case FIFO mode is enabled) which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The FE bit is reset by writing 1 to the FECF in the USART_ICR register.

**Note:** Framing error is not supported in SPI mode.
Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of USART_CR: it can be either 1 or 2 in Normal mode and 0.5 or 1.5 in Smartcard mode.

- **0.5 stop bit (reception in Smartcard mode)**: no sampling is done for 0.5 stop bit. As a consequence, no framing error and no break frame can be detected when 0.5 stop bit is selected.
- **1 stop bit**: sampling for 1 stop bit is done on the 8th, 9th and 10th samples.
- **1.5 stop bits (Smartcard mode)**
  When transmitting in Smartcard mode, the device must check that the data are correctly sent. The receiver block must consequently be enabled (RE = 1 in USART_CR1) and the stop bit is checked to test if the Smartcard has detected a parity error.

  In the event of a parity error, the Smartcard forces the data signal low during the sampling (NACK signal), which is flagged as a framing error. The FE flag is then set through RXNE flag (RXFNE if the FIFO mode is enabled) at the end of the 1.5 stop bit. Sampling for 1.5 stop bits is done on the 16th, 17th and 18th samples (1 baud clock period after the beginning of the stop bit). The 1.5 stop bit can be broken into 2 parts: one 0.5 baud clock period during which nothing happens, followed by 1 normal stop bit period during which sampling occurs halfway through (refer to **Section 66.5.17: USART receiver timeout on page 2779** for more details).

- **2 stop bits**
  Sampling for 2 stop bits is done on the 8th, 9th and 10th samples of the first stop bit. The framing error flag is set if a framing error is detected during the first stop bit. The second stop bit is not checked for framing error. The RXNE flag (RXFNE if the FIFO mode is enabled) is set at the end of the first stop bit.

**66.5.8 USART baud rate generation**

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the value programmed in the USART_BRR register.

**Equation 1: baud rate for standard USART (SPI mode included) (OVER8 = 0 or 1)**

In case of oversampling by 16, the baud rate is given by the following formula:

\[
\text{Tx/Rx baud} = \frac{\text{ USART}_{\text{ker}}\_\text{ck}_{\text{pres}}}{\text{USARTDIV}}
\]

In case of oversampling by 8, the baud rate is given by the following formula:

\[
\text{Tx/Rx baud} = 2 \times \frac{\text{ USART}_{\text{ker}}\_\text{ck}_{\text{pres}}}{\text{USARTDIV}}
\]

**Equation 2: baud rate in Smartcard, LIN and IrDA modes (OVER8 = 0)**

The baud rate is given by the following formula:

\[
\text{Tx/Rx baud} = \frac{\text{ USART}_{\text{ker}}\_\text{ck}_{\text{pres}}}{\text{USARTDIV}}
\]
USARTDIV is an unsigned fixed point number that is coded on the USART_BRR register.

- When OVER8 = 0, BRR = USARTDIV.
- When OVER8 = 1

Note: The baud counters are updated to the new value in the baud registers after a write operation to USART_BRR. Hence the baud rate register value must not be changed during communication.

In case of oversampling by 16 and 8, USARTDIV must be greater than or equal to 16.

**How to derive USARTDIV from USART_BRR register values**

**Example 1**

To obtain 9600 bauds with usart_ker_ck_pres = 8 MHz:

- In case of oversampling by 16:
  
  USARTDIV = 8 000 000/9600
  BRR = USARTDIV = 0d833 = 0x0341

- In case of oversampling by 8:
  
  USARTDIV = 2 * 8 000 000/9600
  USARTDIV = 1666.66 (0d1667 = 0x683)
  BRR[3:0] = 0x3 >> 1 = 0x1
  BRR = 0x681

**Example 2**

To obtain 921.6 kbauds with usart_ker_ck_pres = 48 MHz:

- In case of oversampling by 16:
  
  USARTDIV = 48 000 000/921 600
  BRR = USARTDIV = 0x52 = 0x34

- In case of oversampling by 8:
  
  USARTDIV = 2 * 48 000 000/921 600
  USARTDIV = 104 (0d104 = 0x68)
  BRR[3:0] = USARTDIV[3:0] >> 1 = 0x8 >> 1 = 0x4
  BRR = 0x64
66.5.9 **Tolerance of the USART receiver to clock deviation**

The USART asynchronous receiver operates correctly only if the total clock system deviation is less than the tolerance of the USART receiver.

The causes which contribute to the total deviation are:

- **DTRA**: deviation due to the transmitter error (which also includes the deviation of the transmitter’s local oscillator)
- **DQUANT**: error due to the baud rate quantization of the receiver
- **DREC**: deviation of the receiver local oscillator
- **DTCL**: deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

\[
\text{DTRA} + \text{DQUANT} + \text{DREC} + \text{DTCL} + \text{DWU} < \text{USART receiver tolerance}
\]

where

- DWU is the error due to sampling point deviation when the wake-up from low-power mode is used.
- when \( M[1:0] = 01 \):
  \[
  \text{DWU} = \frac{t_{\text{WUUSART}}}{11 \times \text{Tbit}}
  \]
- when \( M[1:0] = 00 \):
  \[
  \text{DWU} = \frac{t_{\text{WUUSART}}}{10 \times \text{Tbit}}
  \]
- when \( M[1:0] = 10 \):
  \[
  \text{DWU} = \frac{t_{\text{WUUSART}}}{9 \times \text{Tbit}}
  \]

\( t_{\text{WUUSART}} \) is the time between the detection of the start bit falling edge and the instant when the clock (requested by the peripheral) is ready and reaching the peripheral, and the regulator is ready.

The USART receiver can receive data correctly at up to the maximum tolerated deviation specified in **Table 672, Table 673**, depending on the following settings:

- 9-, 10- or 11-bit character length defined by the M bits in the USART_CR1 register
- Oversampling by 8 or 16 defined by the OVER8 bit in the USART_CR1 register
- Bits BRR[3:0] of USART_BRR register are equal to or different from 0000.
- Use of 1 bit or 3 bits to sample the data, depending on the value of the ONEBIT bit in the USART_CR3 register.
Table 672. Tolerance of the USART receiver when BRR [3:0] = 0000

<table>
<thead>

Note: The data specified in Table 672 and Table 673 may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M bits = 00 (11-bit times when M= 01 or 9-bit times when M = 10).

66.5.10 USART auto baud rate detection

The USART can detect and automatically set the USAR T_BRR register value based on the reception of one character. Automatic baud rate detection is useful under two circumstances:
- The communication speed of the system is not known in advance.
- The system is using a relatively low accuracy clock source and this mechanism enables the correct baud rate to be obtained without measuring the clock deviation.

The clock source frequency must be compatible with the expected communication speed.
- When oversampling by 16, the baud rate ranges from \( \text{usart_ker_ck_pres/65535} \) and \( \text{usart_ker_ck_pres/16} \).
- When oversampling by 8, the baud rate ranges from \( \text{usart_ker_ck_pres/65535} \) and \( \text{usart_ker_ck_pres/8} \).

Before activating the auto baud rate detection, the auto baud rate detection mode must be selected through the ABRMOD[1:0] field in the USART_CR2 register. There are four modes based on different character patterns. In these auto baud rate modes, the baud rate is measured several times during the synchronization data reception and each measurement is compared to the previous one.
These modes are the following:

- **Mode 0**: Any character starting with a bit at 1.
  
  In this case the USART measures the duration of the start bit (falling edge to rising edge).

- **Mode 1**: Any character starting with a 10xx bit pattern.
  
  In this case, the USART measures the duration of the Start and of the 1st data bit. The measurement is done falling edge to falling edge, to ensure a better accuracy in the case of slow signal slopes.

- **Mode 2**: A 0x7F character frame (it may be a 0x7F character in LSB first mode or a 0xFE in MSB first mode).
  
  In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 6 (based on the measurement done from falling edge to falling edge: BR6).
  
  Bit 0 to bit 6 are sampled at BRs while further bits of the character are sampled at BR6.

- **Mode 3**: A 0x55 character frame.
  
  In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 0 (based on the measurement done from falling edge to falling edge: BR0), and finally at the end of bit 6 (BR6). Bit 0 is sampled at BRs, bit 1 to bit 6 are sampled at BR0, and further bits of the character are sampled at BR6. In parallel, another check is performed for each intermediate RX line transition. An error is generated if the transitions on RX are not sufficiently synchronized with the receiver (the receiver being based on the baud rate calculated on bit 0).

Prior to activating the auto baud rate detection, the USART_BRR register must be initialized by writing a non-zero baud rate value.

The automatic baud rate detection is activated by setting the ABREN bit in the USART_CR2 register. The USART then waits for the first character on the RX line. The auto baud rate operation completion is indicated by the setting of the ABRF flag in the USART_ISR register. If the line is noisy, the correct baud rate detection cannot be guaranteed. In this case the BRR value may be corrupted and the ABRE error flag is set. This also happens if the communication speed is not compatible with the automatic baud rate detection range (bit duration not between 16 and 65536 clock periods (oversampling by 16) and not between 8 and 65536 clock periods (oversampling by 8)).

The auto baud rate detection can be re-launched later by resetting the ABRF flag (by writing a 0).

When FIFO management is disabled and an auto baud rate error occurs, the ABRE flag is set through RXNE and FE bits.

When FIFO management is enabled and an auto baud rate error occurs, the ABRE flag is set through RXFNE and FE bits.

If the FIFO mode is enabled, the auto baud rate detection must be made using the data on the first RXFIFO location. So, prior to launching the auto baud rate detection, make sure that the RXFIFO is empty by checking the RXFNE flag in USART_ISR register.

**Note:** The BRR value might be corrupted if the USART is disabled (UE=0) during an auto baud rate operation.
66.5.11 USART multiprocessor communication

It is possible to perform USART multiprocessor communications (with several USARTs connected in a network). For instance one of the USARTs can be the master with its TX output connected to the RX inputs of the other USARTs, while the others are slaves with their respective TX outputs logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations, it is often desirable that only the intended message recipient actively receives the full message contents, thus reducing redundant USART service overhead for all non addressed receivers.

The non-addressed devices can be placed in Mute mode by means of the muting function. To use the Mute mode feature, the MME bit must be set in the USART_CR1 register.

Note: When FIFO management is enabled and MME is already set, MME bit must not be cleared and then set again quickly (within two usart_ker_ck cycles), otherwise Mute mode might remain active.

When the Mute mode is enabled:
- none of the reception status bits can be set;
- all the receive interrupts are inhibited;
- the RWU bit in USART_ISR register is set to 1. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the USART_RQR register, under certain conditions.

The USART can enter or exit from Mute mode using one of two methods, depending on the WAKE bit in the USART_CR1 register:
- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

Idle line detection (WAKE=0)

The USART enters Mute mode when the MMRQ bit is written to 1 and the RWU is automatically set.

The USART wakes up when an Idle frame is detected. The RWU bit is then cleared by hardware but the IDLE bit is not set in the USART_ISR register. An example of Mute mode behavior using Idle line detection is given in Figure 808.
**4-bit/7-bit address mark detection (WAKE=1)**

In this mode, bytes are recognized as addresses if their MSB is a 1, otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the USART_CR2 register.

**Note:** In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The USART enters Mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the USART enters Mute mode. When FIFO management is enabled, the software must ensure that there is at least one empty location in the RXFIFO before entering Mute mode.

The USART also enters Mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case.

The USART exits from Mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE/RXFNE bit is set for the address character since the RWU bit has been cleared.

**Note:** When FIFO management is enabled, when MMRQ is set while the receiver is sampling last bit of a data, this data may be received before effectively entering in Mute mode

An example of Mute mode behavior using address mark detection is given in Figure 809.
66.5.12 USART Modbus communication

The USART offers basic support for the implementation of Modbus/RTU and Modbus/ASCII protocols. Modbus/RTU is a Half-duplex, block-transfer protocol. The control part of the protocol (address recognition, block integrity control and command interpretation) must be implemented in software.

The USART offers basic support for the end of the block detection, without software overhead or other resources.

**Modbus/RTU**

In this mode, the end of one block is recognized by a “silence” (idle line) for more than 2 character times. This function is implemented through the programmable timeout function.

The timeout function and interrupt must be activated, through the RTOEN bit in the USART_CR2 register and the RTOIE in the USART_CR1 register. The value corresponding to a timeout of 2 character times (for example 22 x bit time) must be programmed in the RTO register. When the receive line is idle for this duration, after the last stop bit is received, an interrupt is generated, informing the software that the current block reception is completed.

**Modbus/ASCII**

In this mode, the end of a block is recognized by a specific (CR/LF) character sequence. The USART manages this mechanism using the character match function.

By programming the LF ASCII code in the ADD[7:0] field and by activating the character match interrupt (CMIE = 1), the software is informed when a LF has been received and can check the CR/LF in the DMA buffer.
66.5.13 USART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the USART_CR1 register. Depending on the frame length defined by the M bits, the possible USART frame formats are as listed in Table 674.

### Table 674. USART frame formats

</tr>
</tbody>
</table>

1. Legends: SB: start bit, STB: stop bit, PB: parity bit. In the data register, the PB is always taking the MSB position (8th or 7th, depending on the M bit value).

#### Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101, and 4 bits are set, then the parity bit is equal to 0 if even parity is selected (PS bit in USART_CR1 = 0).

#### Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101 and 4 bits set, then the parity bit is equal to 1 if odd parity is selected (PS bit in USART_CR1 = 1).

#### Parity checking in reception

If the parity check fails, the PE flag is set in the USART_ISR register and an interrupt is generated if PEIE is set in the USART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the USART_ICR register.

#### Parity generation in transmission

If the PCE bit is set in USART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).
**66.5.14 USART LIN (local interconnection network) mode**

This section is relevant only when LIN mode is supported. Refer to Section 66.4: USART implementation on page 2747.

The LIN mode is selected by setting the LINEN bit in the USART_CR2 register. In LIN mode, the following bits must be kept cleared:

- CLKEN in the USART_CR2 register,
- STOP[1:0], SCEN, HDSEL and IREN in the USART_CR3 register.

**LIN transmission**

The procedure described in Section 66.5.5 has to be applied for LIN Master transmission. It must be the same as for normal USART transmission with the following differences:

- Clear the M bit to configure 8-bit word length.
- Set the LINEN bit to enter LIN mode. In this case, setting the SBKRQ bit sends 13 zero bits as a break character. Then 2 bits of value ‘1’ are sent to enable the next start detection.

**LIN reception**

When LIN mode is enabled, the break detection circuit is activated. The detection is totally independent from the normal USART receiver. A break can be detected whenever it occurs, during Idle state or during a frame.

When the receiver is enabled (RE=1 in USART_CR1), the circuit looks at the RX input for a start signal. The method for detecting start bits is the same when searching break characters or data. After a start bit has been detected, the circuit samples the next bits exactly like for the data (on the 8th, 9th and 10th samples). If 10 (when the LBDL = 0 in USART_CR2) or 11 (when LBDL=1 in USART_CR2) consecutive bits are detected as 0, and are followed by a delimiter character, the LBDF flag is set in USART_ISR. If the LBDIE bit=1, an interrupt is generated. Before validating the break, the delimiter is checked for as it signifies that the RX line has returned to a high level.

If a ‘1’ is sampled before the 10 or 11 have occurred, the break detection circuit cancels the current detection and searches for a start bit again.

If the LIN mode is disabled (LINEN=0), the receiver continues working as normal USART, without taking into account the break detection.

If the LIN mode is enabled (LINEN=1), as soon as a framing error occurs (i.e. stop bit detected at 0, which is the case for any break frame), the receiver stops until the break detection circuit receives either a ‘1’, if the break word was not complete, or a delimiter character if a break has been detected.

The behavior of the break detector state machine and the break flag is shown on the Figure 810: Break detection in LIN mode (11-bit break length - LBDL bit is set) on page 2774.

Examples of break frames are given on Figure 811: Break detection in LIN mode vs. Framing error detection on page 2775.

66.5.15 **USART synchronous mode**

**Master mode**

The Synchronous master mode is selected by programming the CLKEN bit in the USART_CR2 register to 1. In Synchronous mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in Master mode. The CK pin is the output of the USART transmitter clock. No clock pulses are sent to the CK pin during start bit and stop bit. Depending on the state of the LBCL bit in the USART_CR2 register, clock pulses are, or are not, generated during the last valid data bit (address mark). The CPOL bit in the USART_CR2 register is used to select the clock polarity, and the CPHA bit in the USART_CR2 register is used to select the phase of the external clock (see Figure 812, Figure 813 and Figure 814).

During the Idle state, preamble and send break, the external CK clock is not activated.

In Synchronous master mode, the USART transmitter operates exactly like in Asynchronous mode. However, since CK is synchronized with TX (according to CPOL and CPHA), the data on TX is synchronous.

In Synchronous master mode, the USART receiver operates in a different way compared to Asynchronous mode. If RE is set to 1, the data are sampled on CK (rising or falling edge, depending on CPOL and CPHA), without any oversampling. A given setup and a hold time must be respected (which depends on the baud rate: 1/16 bit time).
Note: In Master mode, the CK pin operates in conjunction with the TX pin. Thus, the clock is provided only if the transmitter is enabled (TE=1) and data are being transmitted (USART_TDR data register written). This means that it is not possible to receive synchronous data without transmitting data.

Figure 812. USART example of synchronous master transmission

Figure 813. USART data clock timing diagram in Synchronous master mode (M bits =00)

*LBCL bit controls last data pulse
Slave mode

The Synchronous slave mode is selected by programming the SLVEN bit in the USART_CR2 register to 1. In Synchronous slave mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in Slave mode. The CK pin is the input of the USART in Slave mode.

Note: When the peripheral is used in SPI slave mode, the frequency of peripheral clock source (usart_ker_ck_pres) must be greater than 3 times the CK input frequency.

The CPOL bit and the CPHA bit in the USART_CR2 register are used to select the clock polarity and the phase of the external clock, respectively (see Figure 815).

An underrun error flag is available in Slave transmission mode. This flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value to USART_TDR.

The slave supports the hardware and software NSS management.
Slave Select (NSS) pin management

The hardware or software slave select management can be set through the DIS_NSS bit in the USART_CR2 register:

- Software NSS management (DIS_NSS = 1)
  SPI slave is always selected and NSS input pin is ignored.
  The external NSS pin remains free for other application uses.

- Hardware NSS management (DIS_NSS = 0)
  The SPI slave selection depends on NSS input pin. The slave is selected when NSS is low and deselected when NSS is high.

Note: The LBCL (used only on SPI master mode), CPOL and CPHA bits have to be selected when the USART is disabled (UE=0) to ensure that the clock pulses function correctly.

In SPI slave mode, the USART must be enabled before starting the master communications (or between frames while the clock is stable). Otherwise, if the USART slave is enabled while the master is in the middle of a frame, it becomes desynchronized with the master. The data register of the slave needs to be ready before the first edge of the communication clock or before the end of the ongoing communication, otherwise the SPI slave transmits zeros.

**SPI Slave underrun error**

When an underrun error occurs, the UDR flag is set in the USART_ISR register, and the SPI slave goes on sending the last data until the underrun error flag is cleared by software.

The underrun flag is set at the beginning of the frame. An underrun error interrupt is triggered if EIE bit is set in the USART_CR3 register.

The underrun error flag is cleared by setting bit UDRCF in the USART_ICR register.
In case of underrun error, it is still possible to write to the TDR register. Clearing the underrun error enables sending new data.

If an underrun error occurred and there is no new data written in TDR, then the TC flag is set at the end of the frame.

Note: An underrun error may occur if the moment the data is written to the USART_TDR is too close to the first CK transmission edge. To avoid this underrun error, the USART_TDR must be written 3 \text{usr}_\text{t}_{\text{kr}} \cdot \text{ck} cycles before the first CK edge.

66.5.16 USART single-wire Half-duplex communication

Single-wire Half-duplex mode is selected by setting the HDSEL bit in the USART_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CKEN bits in the USART_CR2 register,
- SCEN and IREN bits in the USART_CR3 register.

The USART can be configured to follow a Single-wire Half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in USART_CR3.

As soon as HDSEL is written to 1:

- The TX and RX lines are internally connected.
- The RX pin is no longer used.
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal USART mode. Any conflict on the line must be managed by software (for instance by using a centralized arbiter). In particular, the transmission is never blocked by hardware and continues as soon as data are written in the data register while the TE bit is set.

66.5.17 USART receiver timeout

The receiver timeout feature is enabled by setting the RTOEN bit in the USART_CR2 control register.

The timeout duration is programmed using the RTO bitfields in the USART_RTOR register.

The receiver timeout counter starts counting:

- from the end of the stop bit if \text{STOP} = 00 or \text{STOP} = 11
- from the end of the second stop bit if \text{STOP} = 10.
- from the beginning of the stop bit if \text{STOP} = 01.

When the timeout duration has elapsed, the RTOF flag in the USART_ISR register is set. A timeout is generated if RTOIE bit in USART_CR1 register is set.
**66.5.18 USART Smartcard mode**

This section is relevant only when Smartcard mode is supported. Refer to Section 66.4: USART Implementation on page 2747.

Smartcard mode is selected by setting the SCEN bit in the USART_CR3 register. In Smartcard mode, the following bits must be kept cleared:
- LINEN bit in the USART_CR2 register,
- HDSEL and IREN bits in the USART_CR3 register.

The CLKEN bit can also be set to provide a clock to the Smartcard.

The Smartcard interface is designed to support asynchronous Smartcard protocol as defined in the ISO 7816-3 standard. Both T=0 (character mode) and T=1 (block mode) are supported.

The USART must be configured as:
- 8 bits plus parity: M=1 and PCE=1 in the USART_CR1 register
- 1.5 stop bits when transmitting and receiving data: STOP=11 in the USART_CR2 register. It is also possible to choose 0.5 stop bit for reception.

In T=0 (character) mode, the parity error is indicated at the end of each character during the guard time period.

*Figure 816* shows examples of what can be seen on the data line with and without parity error.

![Figure 816. ISO 7816-3 asynchronous protocol](image)

When connected to a Smartcard, the TX output of the USART drives a bidirectional line that is also driven by the Smartcard. The TX pin must be configured as open drain.

Smartcard mode implements a single wire half duplex communication protocol.
- Transmission of data from the transmit shift register is guaranteed to be delayed by a minimum of 1/2 baud clock. In normal operation a full transmit shift register starts shifting on the next baud clock edge. In Smartcard mode this transmission is further delayed by a guaranteed 1/2 baud clock.
- In transmission, if the Smartcard detects a parity error, it signals this condition to the USART by driving the line low (NACK). This NACK signal (pulling transmit line low for 1 baud clock) causes a framing error on the transmitter side (configured with 1.5 stop bits). The USART can handle automatic re-sending of data according to the protocol.
The number of retries is programmed in the SCARCNT bitfield. If the USART continues receiving the NACK after the programmed number of retries, it stops transmitting and signals the error as a framing error. The TXE bit (TXFNF bit in case FIFO mode is enabled) may be set using the TXFRQ bit in the USART_RQR register.

- **Smartcard auto-retry in transmission:** A delay of 2.5 baud periods is inserted between the NACK detection by the USART and the start bit of the repeated character. The TC bit is set immediately at the end of reception of the last repeated character (no guardtime). If the software wants to repeat it again, it must insure the minimum 2 baud periods required by the standard.

- If a parity error is detected during reception of a frame programmed with a 1.5 stop bit period, the transmit line is pulled low for a baud clock period after the completion of the receive frame. This is to indicate to the Smartcard that the data transmitted to the USART has not been correctly received. A parity error is NACKed by the receiver if the NACK control bit is set, otherwise a NACK is not transmitted (to be used in T=1 mode). If the received character is erroneous, the RXNE (RXFNE in case FIFO mode is enabled)/receive DMA request is not activated. According to the protocol specification, the Smartcard must resend the same character. If the received character is still erroneous after the maximum number of retries specified in the SCARCNT bitfield, the USART stops transmitting the NACK and signals the error as a parity error.

- **Smartcard auto-retry in reception:** the BUSY flag remains set if the USART NACKs the card but the card doesn’t repeat the character.

- In transmission, the USART inserts the Guard Time (as programmed in the Guard Time register) between two successive characters. As the Guard Time is measured after the stop bit of the previous character, the GT[7:0] register must be programmed to the desired CGT (Character Guard Time, as defined by the 7816-3 specification) minus 12 (the duration of one character).

- The assertion of the TC flag can be delayed by programming the Guard Time register. In normal operation, TC is asserted when the transmit shift register is empty and no further transmit requests are outstanding. In Smartcard mode an empty transmit shift register triggers the Guard Time counter to count up to the programmed value in the Guard Time register. TC is forced low during this time. When the Guard Time counter reaches the programmed value TC is asserted high. The TCBGT flag can be used to detect the end of data transfer without waiting for guard time completion. This flag is set just after the end of frame transmission and if no NACK has been received from the card.

- The de-assertion of TC flag is unaffected by Smartcard mode.

- If a framing error is detected on the transmitter end (due to a NACK from the receiver), the NACK is not detected as a start bit by the receive block of the transmitter. According to the ISO protocol, the duration of the received NACK can be 1 or 2 baud clock periods.

- On the receiver side, if a parity error is detected and a NACK is transmitted the receiver does not detect the NACK as a start bit.

**Note:** Break characters are not significant in Smartcard mode. A 0x00 data with a framing error is treated as data and not as a break.

No Idle frame is transmitted when toggling the TE bit. The Idle frame (as defined for the other configurations) is not defined by the ISO protocol.

Figure 817 shows how the NACK signal is sampled by the USART. In this example the USART is transmitting data and is configured with 1.5 stop bits. The receiver part of the USART is enabled in order to check the integrity of the data and the NACK signal.
The USART can provide a clock to the Smartcard through the CK output. In Smartcard mode, CK is not associated to the communication but is simply derived from the internal peripheral input clock through a 5-bit prescaler. The division ratio is configured in the USART_GTPR register. CK frequency can be programmed from usart_ker_ck_pres/2 to usart_ker_ck_pres/62, where usart_ker_ck_pres is the peripheral input clock divided by a programmed prescaler.

**Block mode (T=1)**

In T=1 (block) mode, the parity error transmission can be deactivated by clearing the NACK bit in the UART_CR3 register.

When requesting a read from the Smartcard, in block mode, the software must program the RTOR register to the BWT (block wait time) - 11 value. If no answer is received from the card before the expiration of this period, a timeout interrupt is generated. If the first character is received before the expiration of the period, it is signaled by the RXNE/RXFNE interrupt.

**Note:** The RXNE/RXFNE interrupt must be enabled even when using the USART in DMA mode to read from the Smartcard in block mode. In parallel, the DMA must be enabled only after the first received byte.

After the reception of the first character (RXNE/RXFNE interrupt), the RTO register must be programmed to the CWT (character wait time -11 value), in order to enable the automatic check of the maximum wait time between two consecutive characters. This time is expressed in baud time units. If the Smartcard does not send a new character in less than the CWT period after the end of the previous character, the USART signals it to the software through the RTOF flag and interrupt (when RTOIE bit is set).

**Note:** As in the Smartcard protocol definition, the BWT/CWT values must be defined from the beginning (start bit) of the last character. The RTO register must be programmed to BWT - 11 or CWT - 11, respectively, taking into account the length of the last character itself.

A block length counter is used to count all the characters received by the USART. This counter is reset when the USART is transmitting. The length of the block is communicated by the Smartcard in the third byte of the block (prologue field). This value must be programmed to the BLEN field in the USART_RTOR register. When using DMA mode, before the start of the block, this register field must be programmed to the minimum value.
(0x0). With this value, an interrupt is generated after the 4th received character. The software must read the LEN field (third byte), its value must be read from the receive buffer.

In interrupt driven receive mode, the length of the block may be checked by software or by programming the BLEN value. However, before the start of the block, the maximum value of BLEN (0xFF) may be programmed. The real value is programmed after the reception of the third character.

If the block is using the LRC longitudinal redundancy check (1 epilogue byte), the BLEN=LEN. If the block is using the CRC mechanism (2 epilog bytes), BLEN=LEN+1 must be programmed. The total block length (including prologue, epilogue and information fields) equals BLEN+4. The end of the block is signaled to the software through the EOBF flag and interrupt (when EOBIE bit is set).

In case of an error in the block length, the end of the block is signaled by the RTO interrupt (Character Wait Time overflow).

**Note:** The error checking code (LRC/CRC) must be computed/verified by software.

### Direct and inverse convention

The Smartcard protocol defines two conventions: direct and inverse.

The direct convention is defined as: LSB first, logical bit value of 1 corresponds to a H state of the line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST=0, DATAINV=0 (default values).

The inverse convention is defined as: MSB first, logical bit value 1 corresponds to an L state on the signal line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST=1, DATAINV=1.

**Note:** When logical data values are inverted (0=H, 1=L), the parity bit is also inverted in the same way.

In order to recognize the card convention, the card sends the initial character, TS, as the first character of the ATR (Answer To Reset) frame. The two possible patterns for the TS are: LHHL LLL LLH and LHHL HHH LLH.

- (H) LHHL LLL LLH sets up the inverse convention: state L encodes value 1 and moment 2 conveys the most significant bit (MSB first). When decoded by inverse convention, the conveyed byte is equal to '3F'.
- (H) LHHL HHH LLH sets up the direct convention: state H encodes value 1 and moment 2 conveys the least significant bit (LSB first). When decoded by direct convention, the conveyed byte is equal to '3B'.

Character parity is correct when there is an even number of bits set to 1 in the nine moments 2 to 10.

As the USART does not know which convention is used by the card, it needs to be able to recognize either pattern and act accordingly. The pattern recognition is not done in hardware, but through a software sequence. Moreover, supposing that the USART is configured in direct convention (default) and the card answers with the inverse convention, TS = LHHL LLL LLH => the USART received character is equal to 03 and the parity is odd.
Therefore, two methods are available for TS pattern recognition:

**Method 1**

The USART is programmed in standard Smartcard mode/direct convention. In this case, the TS pattern reception generates a parity error interrupt and error signal to the card.

- The parity error interrupt informs the software that the card did not answer correctly in direct convention. Software then reprograms the USART for inverse convention
- In response to the error signal, the card retries the same TS character, and it is correctly received this time, by the reprogrammed USART

Alternatively, in answer to the parity error interrupt, the software may decide to reprogram the USART and to also generate a new reset command to the card, then wait again for the TS.

**Method 2**

The USART is programmed in 9-bit/no-parity mode, no bit inversion. In this mode it receives any of the two TS patterns as:

(H) LHHL LLL LLH = 0x103 -> inverse convention to be chosen
(H) LHHL HHH LLH = 0x13B -> direct convention to be chosen

The software checks the received character against these two patterns and, if any of them match, then programs the USART accordingly for the next character reception.

If none of the two is recognized, a card reset may be generated in order to restart the negotiation.

**66.5.19 USART IrDA SIR ENDEC block**

This section is relevant only when IrDA mode is supported. Refer to Section 66.4: USART implementation on page 2747.

IrDA mode is selected by setting the IREN bit in the USART_CR3 register. In IrDA mode, the following bits must be kept cleared:

- LINEN, STOP and CLKEN bits in the USART_CR2 register,
- SCEN and HDSEL bits in the USART_CR3 register.

The IrDA SIR physical layer specifies use of a Return to Zero, Inverted (RZI) modulation scheme that represents logic 0 as an infrared light pulse (see Figure 818).

The SIR Transmit encoder modulates the Non Return to Zero (NRZ) transmit bit stream output from USART. The output pulse stream is transmitted to an external output driver and infrared LED. USART supports only bit rates up to 115.2 kbauds for the SIR ENDEC. In Normal mode the transmitted pulse width is specified as 3/16 of a bit period.

The SIR receive decoder demodulates the return-to-zero bit stream from the infrared detector and outputs the received NRZ serial bit stream to the USART. The decoder input is normally high (marking state) in the Idle state. The transmit encoder output has the opposite polarity to the decoder input. A start bit is detected when the decoder input is low.

- IrDA is a half duplex communication protocol. If the Transmitter is busy (when the USART is sending data to the IrDA encoder), any data on the IrDA receive line is ignored by the IrDA decoder and if the Receiver is busy (when the USART is receiving decoded data from the USART), data on the TX from the USART to IrDA is not
encoded. While receiving data, transmission must be avoided as the data to be transmitted may be corrupted.

- A 0 is transmitted as a high pulse and a 1 is transmitted as a 0. The width of the pulse is specified as 3/16th of the selected bit period in Normal mode (see Figure 819).
- The SIR decoder converts the IrDA compliant receive signal into a bit stream for USART.
- The SIR receive logic interprets a high state as a logic one and low pulses as logic zeros.
- The transmit encoder output has the opposite polarity to the decoder input. The SIR output is in low state when Idle.
- The IrDA specification requires the acceptance of pulses greater than 1.41 µs. The acceptable pulse width is programmable. Glitch detection logic on the receiver end filters out pulses of width less than 2 PSC periods (PSC is the prescaler value programmed in the USART_GTPR). Pulses of width less than 1 PSC period are always rejected, but those of width greater than one and less than two periods may be accepted or rejected, those greater than 2 periods are accepted as a pulse. The IrDA encoder/decoder doesn’t work when PSC=0.
- The receiver can communicate with a low-power transmitter.
- In IrDA mode, the stop bits in the USART_CR2 register must be configured to ‘1 stop bit’.

**IrDA low-power mode**

- **Transmitter**
  In low-power mode, the pulse width is not maintained at 3/16 of the bit period. Instead, the width of the pulse is 3 times the low-power baud rate which can be a minimum of 1.42 MHz. Generally, this value is 1.8432 MHz (1.42 MHz < PSC< 2.12 MHz). A low-power mode programmable divisor divides the system clock to achieve this value.
- **Receiver**
  Receiving in low-power mode is similar to receiving in Normal mode. For glitch detection the USART must discard pulses of duration shorter than 1/PSC. A valid low is accepted only if its duration is greater than 2 periods of the IrDA low-power baud clock (PSC value in the USART_GTPR).

**Note:**  A pulse of width less than two and greater than one PSC period(s) may or may not be rejected.  
The receiver set up time must be managed by software. The IrDA physical layer specification specifies a minimum of 10 ms delay between transmission and reception (IrDA is a half duplex protocol).
Figure 818. IrDA SIR ENDEC block diagram

Figure 819. IrDA data modulation (3/16) - Normal mode
66.5.20 Continuous communication using USART and DMA

The USART is capable of performing continuous communications using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

Note: Refer to Section 66.4: USART implementation on page 2747 to determine if the DMA mode is supported. If DMA is not supported, use the USART as explained in Section 66.5.7. To perform continuous communications when the FIFO is disabled, clear the TXE/RXNE flags in the USART_ISR register.

Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the USART_CR3 register. Data are loaded from an SRAM area configured using the DMA peripheral (refer to section Direct memory access controller (DMA)) to the USART_TDR register whenever the TXE flag (TXFNF flag if FIFO mode is enabled) is set. To map a DMA channel for USART transmission, use the following procedure (x denotes the channel number):

1. Write the USART_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE (or TXFNF if FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the USART_TDR register from this memory area after each TXE (or TXFNF if FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA register
5. Configure DMA interrupt generation after half/full transfer as required by the application.
6. Clear the TC flag in the USART_ISR register by setting the TCCF bit in the USART_ICR register.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In Transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the TC flag can be monitored to make sure that the USART communication is complete. This is required to avoid corrupting the last transmission before disabling the USART or before the system enters a low-power mode when the peripheral clock is disabled. Software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.

Note: The DMAT bit must not be cleared before the DMA end of transfer.
Figure 820. Transmission using DMA

Note: When FIFO management is enabled, the DMA request is triggered by Transmit FIFO not full (i.e. TXFNF = 1).

Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in USART_CR3 register. Data are loaded from the USART_RDR register to an SRAM area configured using the DMA peripheral (refer to section Direct memory access controller (DMA)) whenever a data byte is received. To map a DMA channel for USART reception, use the following procedure:

1. Write the USART_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE (RXFNE in case FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from USART_RDR to this memory area after each RXNE (RXFNE in case FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register
5. Configure interrupt generation after half/ full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

Note: The DMAR bit must not be cleared before the DMA end of transfer.
Error flagging and interrupt generation in multibuffer communication

If any error occurs during a transaction in Multibuffer communication mode, the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set.

For framing error, overrun error and noise flag which are asserted with RXNE (RXFNE in case FIFO mode is enabled) in single byte reception, there is a separate error flag interrupt enable bit (EIE bit in the USART_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

66.5.21 RS232 Hardware flow control and RS485 Driver Enable

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The Figure 822 shows how to connect 2 devices in this mode:

Figure 822. Hardware flow control between 2 USARTs
RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits to 1 in the USART_CR3 register.

**RS232 RTS flow control**

If the RTS flow control is enabled (RTSE=1), then RTS is deasserted (tied low) as long as the USART receiver is ready to receive a new data. When the receive register is full, RTS is asserted, indicating that the transmission is expected to stop at the end of the current frame. *Figure 823* shows an example of communication with RTS flow control enabled.

![Figure 823. RS232 RTS flow control](image)

*Note:* When FIFO mode is enabled, RTS is asserted only when RXFIFO is full.

**RS232 CTS flow control**

If the CTS flow control is enabled (CTSE = 1), then the transmitter checks the CTS input before transmitting the next frame. If CTS is deasserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE/TXFE=0), else the transmission does not occur. When CTS is asserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE = 1, the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the USART_CR3 register is set. *Figure 824* shows an example of communication with CTS flow control enabled.
Note: For correct behavior, CTS must be deasserted at least 3 USART clock source periods before the end of the current character. In addition it must be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.

RS485 driver enable

The driver enable feature is enabled by setting bit DEM in the USART_CR3 control register. This enables the user to activate the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the start bit. It is programmed using the DEAT [4:0] bitfields in the USART_CR1 control register. The de-assertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bitfields in the USART_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the USART_CR3 control register.

In USART, the DEAT and DEDT are expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).

66.5.22 USART Autonomous mode

The USART peripheral can be functional in Stop mode thanks to the Autonomous mode. This mode can also be used in Run and Sleep mode. The UESM bit must be set prior to entering low-power mode.

The APB clock is requested by the peripheral each time the USART status needs to be updated. Once the USART receives the APB clock, it generates either an interrupt or a DMA request, depending on the peripheral configuration.

If an interrupt is generated, the device wakes up from Stop mode. If no interrupt is generated, the device remains in Stop mode but the kernel and APB clocks are still available for the USART and all the autonomous peripherals enabled in the reset and clock controller (RCC). If DMA requests are enabled, the data are directly transferred to/from the SRAM thanks to the DMA while the product remains in Stop mode.
Transmission mode

In transmission, the APB clock is requested only when the TE bit is set and in the following cases:

- If the FIFO mode is enabled, the APB clock is requested when
  - the TxFIFO is empty (TXFE = 1) and the corresponding interrupt is enabled (TXFEIE = 1)
  - the TxFIFO threshold is reached (TXFT = 1) and the corresponding interrupt is enabled (TXFTIE = 1)
  - the TxFIFO is not full (TXFNF = 1) and the corresponding interrupt or DMA is enabled (TXFNFIE = 1 or DMAT = 1)
- If the FIFO mode is disabled, the APB clock is requested as soon as data are transferred to the shift register. The DMA or associated interrupt must be enabled.

The TE bit is set by hardware if an asynchronous trigger is detected.

A transmission is automatically launched when an asynchronous trigger is detected in Run, Sleep or Stop mode. The trigger is selected through the TRIGSEL bit in the USART_AUTOCR register. It sets the TE bit in the USART_CR1 register and generates an APB clock request to enable the transfer. The APB clock is requested until the transmission completes and the TE bit is cleared by hardware when the programmed number of data to be transmitted (TDN bits field in the USART_AUTOCR register) is reached. In this case, the TC flag is set when the number of data to be transmitted is reached and the last byte is transmitted.

Reception mode

- If the FIFO mode is enabled, the APB clock is requested when
  - the RxFIFO is full (RXFF = 1) and the corresponding interrupt is enabled (RXFFIE = 1)
  - the RxFIFO threshold is reached (RXFT = 1) and the corresponding interrupt is enabled (RXFTIE = 1)
  - the RxFIFO is not empty (RXFNE = 1) and the corresponding interrupt or DMA is enabled (RXFNEIE = 1 or DMAR = 1)
- If the FIFO mode is disabled, the APB clock is requested when the USART finishes sampling data and it is ready to be written in the USART_RDR. The DMA or the associated interrupt must be enabled.

Note: The APB clock is requested in Reception mode when an overrun error occurs (ORE = 1). The EIE bit must be set to enable the generation of an interrupt and waking up the MCU, and the OVRDIS bit must remain cleared. The APB clock request is kept until the interrupt flag is cleared.

The APB clock is also requested in Reception mode when a Parity/Noise/Framing error occurs and the DMA is used for reception. The APB clock request is kept until the interrupt flag is cleared.

Only UART and SPI master modes support the Autonomous mode.
Determining the maximum USART baud rate that enables to correctly wake up the microcontroller from low-power mode

The maximum baud rate that enables to correctly wake up the microcontroller from low-power mode depends on the wake-up time parameter (refer to the device datasheet) and on the USART receiver tolerance (see Section 66.5.9: Tolerance of the USART receiver to clock deviation).

Let us take the example of OVER8 = 0, M bits = 01, ONEBIT = 0 and BRR [3:0] = 0000.

In these conditions, according to Table 672: Tolerance of the USART receiver when BRR [3:0] = 0000, the USART receiver tolerance equals 3.41%.

\[
D_{WU,max} = \frac{t_{WU,USART}}{11 \times T_{bit,min}}
\]

\[
T_{bit,min} = \frac{t_{WU,USART}}{11 \times D_{WU,max}}
\]

where \(t_{WU,USART}\) is the wake-up time from low-power mode.

If we consider the ideal case where DTRA, DQUANT, DREC and DTCL parameters are at 0%, the maximum value of DWU is 3.41%. In fact, we need to consider at least the usart_ker_ck inaccuracy (DREC).

For example, if HSI is used as usart_ker_ck, and the HSI inaccuracy is of 1%, then we obtain:

\[
t_{WU,USART} = 3 \mu s \text{ (values provided only as examples; for correct values, refer to the device datasheet).}
\]

\[
D_{WU,max} = \text{USART receiver tolerance} - \text{DREC} = 3.41\% - 1\% = 2.41\%
\]

\[
T_{bit,min} = \frac{3 \mu s}{11 \times 2.41\%} = 11.32 \mu s.
\]

As a result, the maximum baud rate enables to wake up correctly from low-power mode is: \(1/11.32 \mu s = 88.36\text{ kbauds}\).

<tr>
<td>Stop(^{(1)})</td>
<td>The content of the USART registers is kept. If the USART is clocked by an oscillator available in Stop mode, transfers in Asynchronous and SPI master modes are functional. DMA requests are functional, and the interrupts cause the device to exit Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The USART peripheral is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

1. Refer to Section 66.4: USART implementation to know if the wake-up from Stop mode is supported for a given peripheral instance. If an instance is not functional in a given Stop mode, it must be disabled before entering this Stop mode.

### 66.7 USART interrupts

Refer to Table 676 for a detailed description of all USART interrupt requests.

</table>

1. The USART can wake up the device from Stop mode only if the peripheral instance supports the wake-up from Stop mode feature. Refer to Section 66.4: USART implementation for the list of supported Stop modes.
2. RXFF flag is asserted if the USART receives n+1 data (n being the RXFIFO size): n data in the RXFIFO and 1 data in USART_RDR. In Stop mode, USART_RDR is not clocked. As a result, this register is not written and once n data are received and written in the RXFIFO, the RXFF interrupt is asserted (RXFF flag is not set).
3. Parity/Noise/Framing error interrupts enable waking up from Stop modes when the DMA is used.
4. When OVRDIS = 0.
5. The DMA must be used when the FIFO mode is enabled.
66.8 USART registers

Refer to Section 1.2 on page 126 for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32 bits).

66.8.1 USART control register 1 (USART_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

**FIFO mode enabled**

</table>
Bit 27 **EOBIE**: End of Block interrupt enable
   This bit is set and cleared by software.
   0: Interrupt inhibited
   1: USART interrupt generated when the EOBF flag is set in the USART_ISR register
   **Note:** If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bit 26 **RTOIE**: Receiver timeout interrupt enable
   This bit is set and cleared by software.
   0: Interrupt inhibited
   1: USART interrupt generated when the RTOF bit is set in the USART_ISR register.
   **Note:** If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Section 66.4: USART implementation on page 2747.

Bits 25:21 **DEAT[4:0]**: Driver Enable assertion time
   This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).
   This bitfield can only be written when the USART is disabled (UE=0).
   **Note:** If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bits 20:16 **DEDT[4:0]**: Driver Enable deassertion time
   This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).
   If the USART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.
   This bitfield can only be written when the USART is disabled (UE=0).
   **Note:** If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bit 15 **OVER8**: Oversampling mode
   0: Oversampling by 16
   1: Oversampling by 8
   This bit can only be written when the USART is disabled (UE=0).
   **Note:** In LIN, IrDA and Smartcard modes, this bit must be kept cleared.

Bit 14 **CMIE**: Character match interrupt enable
   This bit is set and cleared by software.
   0: Interrupt inhibited
   1: USART interrupt generated when the CMF bit is set in the USART_ISR register.

Bit 13 **MME**: Mute mode enable
   This bit enables the USART Mute mode function. When set, the USART can switch between active and Mute mode, as defined by the WAKE bit. It is set and cleared by software.
   0: Receiver in Active mode permanently
   1: Receiver can switch between Mute mode and Active mode.

Bit 12 **M0**: Word length
   This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).
   This bit can only be written when the USART is disabled (UE=0).
Bit 11  **WAKE**: Receiver wake-up method
This bit determines the USART wake-up method from Mute mode. It is set or cleared by software.
0: Idle line
1: Address mark
This bitfield can only be written when the USART is disabled (UE=0).

Bit 10  **PCE**: Parity control enable
This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and the parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).
0: Parity control disabled
1: Parity control enabled
This bitfield can only be written when the USART is disabled (UE=0).

Bit 9  **PS**: Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.
0: Even parity
1: Odd parity
This bitfield can only be written when the USART is disabled (UE=0).

Bit 8  **PEIE**: PE interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever PE=1 in the USART_ISR register

Bit 7  **TXFNFIE**: TXFIFO not full interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TXFNF =1 in the USART_ISR register

Bit 6  **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TC=1 in the USART_ISR register

Bit 5  **RXFNEIE**: RXFIFO not empty interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever ORE=1 or RXFNE=1 in the USART_ISR register

Bit 4  **IDLEIE**: IDLE interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever IDLE=1 in the USART_ISR register
Bit 3 **TE**: Transmitter enable

This bit enables the transmitter. When the Autonomous mode is not used, TE bit is set and cleared by software. When the Autonomous mode is used, TE bit becomes a status bit, which is set and cleared by hardware.

0: Transmitter is disabled
1: Transmitter is enabled

*Note:* During transmission, a low pulse on the TE bit (0 followed by 1) sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to 1. To ensure the required duration, the software can poll the TEACK bit in the USART_ISR register.

In Smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.

Bit 2 **RE**: Receiver enable

This bit enables the receiver. It is set and cleared by software.

0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1 **UESM**: USART enable in low-power mode

When this bit is cleared, the USART cannot request its kernel clock and is not functional in low-power mode.

When this bit is set, the USART can wake up the MCU from low-power mode.

This bit is set and cleared by software.

0: USART not functional in low-power mode.
1: USART functional in low-power mode.

*Note:* The UESM bit must be set at the initialization phase.

If the USART does not support the wake-up from low-power mode, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bit 0 **UE**: USART enable

When this bit is cleared, the USART prescalers and outputs are stopped immediately, and all current operations are discarded. The USART configuration is kept, but all the USART_ISR status flags are reset. This bit is set and cleared by software.

0: USART prescaler and outputs disabled, low-power mode
1: USART enabled

*Note:* To enter low-power mode without generating errors on the line, the TE bit must be previously reset and the software must wait for the TC bit in the USART_ISR to be set before resetting the UE bit.

The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.

In Smartcard mode, (SCEN = 1), the CK is always available when CLKEN = 1, regardless of the UE bit value.
66.8.2 USART control register 1 [alternate] (USART_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (previous section) and FIFO mode
disabled (this section).

FIFO mode disabled

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **FIFOEN**: FIFO mode enable

This bit is set and cleared by software.

0: FIFO mode is disabled.
1: FIFO mode is enabled.

This bitfield can only be written when the USART is disabled (UE=0).

*Note: FIFO mode can be used on standard UART communication, in SPI Master/Slave mode
d and in Smartcard modes only. It must not be enabled in IrDA and LIN modes.*

Bit 28 **M1**: Word length

This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or
cleared by software.

M[1:0] = 00: 1 start bit, 8 Data bits, n Stop bit
M[1:0] = 01: 1 start bit, 9 Data bits, n Stop bit
M[1:0] = 10: 1 start bit, 7 Data bits, n Stop bit

This bit can only be written when the USART is disabled (UE=0).

*Note: In 7-bits data length mode, the Smartcard mode, LIN master mode and auto baud rate
(0x7F and 0x55 frames detection) are not supported.*

Bit 27 **EOBIE**: End of Block interrupt enable

This bit is set and cleared by software.

0: Interrupt inhibited
1: USART interrupt generated when the EOBF flag is set in the USART_ISR register

*Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at
reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 26 **RTOIE**: Receiver timeout interrupt enable

This bit is set and cleared by software.

0: Interrupt inhibited
1: USART interrupt generated when the RTOF bit is set in the USART_ISR register.

*Note: If the USART does not support the Receiver timeout feature, this bit is reserved and
must be kept at reset value. Section 66.4: USART implementation on page 2747.*
Bits 25:21  **DEAT[4:0]**: Driver Enable assertion time
This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).
This bitfield can only be written when the USART is disabled (UE=0).
*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bits 20:16  **DEDT[4:0]**: Driver Enable deassertion time
This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).
If the USART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.
This bitfield can only be written when the USART is disabled (UE=0).
*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 15  **OVER8**: Oversampling mode
0: Oversampling by 16
1: Oversampling by 8
This bit can only be written when the USART is disabled (UE=0).
*Note: In LIN, IrDA and Smartcard modes, this bit must be kept cleared.*

Bit 14  **CMIE**: Character match interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the CMF bit is set in the USART_ISR register.

Bit 13  **MME**: Mute mode enable
This bit enables the USART Mute mode function. When set, the USART can switch between active and Mute mode, as defined by the WAKE bit. It is set and cleared by software.
0: Receiver in Active mode permanently
1: Receiver can switch between Mute mode and Active mode.

Bit 12  **M0**: Word length
This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).
This bit can only be written when the USART is disabled (UE=0).

Bit 11  **WAKE**: Receiver wake-up method
This bit determines the USART wake-up method from Mute mode. It is set or cleared by software.
0: Idle line
1: Address mark
This bitfield can only be written when the USART is disabled (UE=0).

Bit 10  **PCE**: Parity control enable
This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and the parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).
0: Parity control disabled
1: Parity control enabled
This bitfield can only be written when the USART is disabled (UE=0).
Bit 9 **PS**: Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.
- 0: Even parity
- 1: Odd parity
This bitfield can only be written when the USART is disabled (UE=0).

Bit 8 **PEIE**: PE interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever PE=1 in the USART_ISR register

Bit 7 **TXEIE**: Transmit data register empty
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever TXE =1 in the USART_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever TC=1 in the USART_ISR register

Bit 5 **RXNEIE**: Receive data register not empty
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever ORE=1 or RXNE=1 in the USART_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever IDLE=1 in the USART_ISR register

Bit 3 **TE**: Transmitter enable
This bit enables the transmitter. When the Autonomous mode is not used, TE bit is set and cleared by software. When the Autonomous mode is used, TE bit becomes a status bit, which is set and cleared by hardware.
- 0: Transmitter is disabled
- 1: Transmitter is enabled

**Note:** During transmission, a low pulse on the TE bit (0 followed by 1) sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to 1. To ensure the required duration, the software can poll the TEACK bit in the USART_ISR register.

In Smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.
Bit 2 RE: Receiver enable
This bit enables the receiver. It is set and cleared by software.
0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1 UESM: USART enable in low-power mode
When this bit is cleared, the USART cannot request its kernel clock and is not functional in low-power mode.
When this bit is set, the USART can wake up the MCU from low-power mode.
This bit is set and cleared by software.
0: USART not functional in low-power mode.
1: USART functional in low-power mode.

Note: The UESM bit must be set at the initialization phase.
If the USART does not support the wake-up from low-power mode, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bit 0 UE: USART enable
When this bit is cleared, the USART prescalers and outputs are stopped immediately, and all current operations are discarded. The USART configuration is kept, but all the USART_ISR status flags are reset. This bit is set and cleared by software.
0: USART prescaler and outputs disabled, low-power mode
1: USART enabled

Note: To enter low-power mode without generating errors on the line, the TE bit must be previously reset and the software must wait for the TC bit in the USART_ISR to be set before resetting the UE bit.
The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.
In Smartcard mode, (SCEN = 1), the CK is always available when CLKEN = 1, regardless of the UE bit value.

66.8.3 USART control register 2 (USART_CR2)

```
Bits 31:24  **ADD[7:0]: Address of the USART node**

These bits give the address of the USART node in Mute mode or a character code to be recognized in low-power or Run mode:

- In Mute mode: they are used in multiprocessor communication to wake up from Mute mode with 4-bit/7-bit address mark detection. The MSB of the character sent by the transmitter must be equal to 1. In 4-bit address mark detection, only ADD[3:0] bits are used.
- In low-power mode: they are used for wake up from low-power mode on character match. When a character, received during low-power mode, corresponds to the character programmed through ADD[7:0] bitfield, the CMF flag is set and wakes up the device from low-power mode if the corresponding interrupt is enabled by setting CMIE bit.
- In Run mode with Mute mode inactive (for example, end-of-block detection in ModBus protocol): the whole received character (8 bits) is compared to ADD[7:0] value and CMF flag is set on match. An interrupt is generated if the CMIE bit is set.

These bits can only be written when the reception is disabled (RE = 0) or when the USART is disabled (UE = 0).

Bit 23  **RTOEN**: Receiver timeout enable

This bit is set and cleared by software.

0: Receiver timeout feature disabled.
1: Receiver timeout feature enabled.

When this feature is enabled, the RTOF flag in the USART_ISR register is set if the RX line is idle (no reception) for the duration programmed in the RTOR (receiver timeout register).

**Note:** *If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bits 22:21  **ABRMOD[1:0]: Auto baud rate mode**

These bits are set and cleared by software.

00: Measurement of the start bit is used to detect the baud rate.
01: Falling edge to falling edge measurement (the received frame must start with a single bit = 1 -> Frame = Start10xxxxxx)
10: 0x7F frame detection.
11: 0x55 frame detection

This bitfield can only be written when ABREN = 0 or the USART is disabled (UE=0).

**Note:** *If DATAINV=1 and/or MSBFIRST=1 the patterns must be the same on the line, for example 0xAA for MSBFIRST)*

*If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 20  **ABREN**: Auto baud rate enable

This bit is set and cleared by software.

0: Auto baud rate detection is disabled.
1: Auto baud rate detection is enabled.

**Note:** *If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 19  **MSBFIRST**: Most significant bit first

This bit is set and cleared by software.

0: data is transmitted/received with data bit 0 first, following the start bit.
1: data is transmitted/received with the MSB (bit 7/8) first, following the start bit.

This bitfield can only be written when the USART is disabled (UE=0).
Bit 18 **DATAINV:** Binary data inversion
This bit is set and cleared by software.
0: Logical data from the data register are send/received in positive/direct logic. (1=H, 0=L)
1: Logical data from the data register are send/received in negative/inverse logic. (1=L, 0=H). The parity bit is also inverted.
This bitfield can only be written when the USART is disabled (UE=0).

Bit 17 **TXINV:** TX pin active level inversion
This bit is set and cleared by software.
0: TX pin signal works using the standard logic levels (VDD =1/idle, Gnd=0/mark)
1: TX pin signal values are inverted. ((VDD =0/mark, Gnd=1/idle).
This enables the use of an external inverter on the TX line.
This bitfield can only be written when the USART is disabled (UE=0).

Bit 16 **RXINV:** RX pin active level inversion
This bit is set and cleared by software.
0: RX pin signal works using the standard logic levels (VDD =1/idle, Gnd=0/mark)
1: RX pin signal values are inverted. ((VDD =0/mark, Gnd=1/idle).
This enables the use of an external inverter on the RX line.
This bitfield can only be written when the USART is disabled (UE=0).

Bit 15 **SWAP:** Swap TX/RX pins
This bit is set and cleared by software.
0: TX/RX pins are used as defined in standard pinout
1: The TX and RX pins functions are swapped. This enables to work in the case of a cross-wired connection to another UART.
This bitfield can only be written when the USART is disabled (UE=0).

Bit 14 **LINEN:** LIN mode enable
This bit is set and cleared by software.
0: LIN mode disabled
1: LIN mode enabled
The LIN mode enables the capability to send LIN synchronous breaks (13 low bits) using the SBKRQ bit in the USART_CR1 register, and to detect LIN Sync breaks.
This bitfield can only be written when the USART is disabled (UE=0).
*Note:* If the USART does not support LIN mode, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bits 13:12 **STOP[1:0]:** stop bits
These bits are used for programming the stop bits.
00: 1 stop bit
01: 0.5 stop bit.
10: 2 stop bits
11: 1.5 stop bits
This bitfield can only be written when the USART is disabled (UE=0).
Bit 11 **CLKEN**: Clock enable
This bit enables the user to enable the CK pin.
0: CK pin disabled
1: CK pin enabled
This bit can only be written when the USART is disabled (UE=0).

*Note*: *If neither Synchronous mode nor Smartcard mode is supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

In Smartcard mode, in order to provide correctly the CK clock to the smartcard, the steps below must be respected:
UE = 0
SCEN = 1
GTPR configuration
CLKEN = 1
UE = 1

Bit 10 **CPOL**: Clock polarity
This bit enables the user to select the polarity of the clock output on the CK pin in Synchronous mode. It works in conjunction with the CPHA bit to produce the desired clock/data relationship
0: Steady low value on CK pin outside transmission window
1: Steady high value on CK pin outside transmission window
This bit can only be written when the USART is disabled (UE=0).

*Note*: *If Synchronous mode is not supported, this bit is reserved and must be kept at reset value.*
Refer to Section 66.4: USART implementation on page 2747.

Bit 9 **CPHA**: Clock phase
This bit is used to select the phase of the clock output on the CK pin in Synchronous mode. It works in conjunction with the CPOL bit to produce the desired clock/data relationship (see Figure 806 and Figure 807)
0: The first clock transition is the first data capture edge
1: The second clock transition is the first data capture edge
This bit can only be written when the USART is disabled (UE=0).

*Note*: *If Synchronous mode is not supported, this bit is reserved and must be kept at reset value.*
Refer to Section 66.4: USART implementation on page 2747.

Bit 8 **LBCL**: Last bit clock pulse
This bit is used to select whether the clock pulse associated with the last data bit transmitted (MSB) has to be output on the CK pin in Synchronous mode.
0: The clock pulse of the last data bit is not output to the CK pin
1: The clock pulse of the last data bit is output to the CK pin

*Caution*: The last bit is the 7th or 8th or 9th data bit transmitted depending on the 7 or 8 or 9 bit format selected by the M bit in the USART_CR1 register.
This bit can only be written when the USART is disabled (UE=0).

*Note*: *If Synchronous mode is not supported, this bit is reserved and must be kept at reset value.*
Refer to Section 66.4: USART implementation on page 2747.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LBDIE**: LIN break detection interrupt enable
Break interrupt mask (break detection using break delimiter).
0: Interrupt is inhibited
1: An interrupt is generated whenever LBDF=1 in the USART_ISR register

*Note*: *If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*
Bit 5  **LBDL**: LIN break detection length
   This bit is for selection between 11 bit or 10 bit break detection.
   0: 10-bit break detection
   1: 11-bit break detection
   This bit can only be written when the USART is disabled (UE=0).
   **Note**: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bit 4  **ADDM7**: 7-bit Address Detection/4-bit Address Detection
   This bit is for selection between 4-bit address detection or 7-bit address detection.
   0: 4-bit address detection
   1: 7-bit address detection (in 8-bit data mode)
   This bit can only be written when the USART is disabled (UE=0)
   **Note**: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.

Bit 3  **DIS_NSS**:
   When the DIS_NSS bit is set, the NSS pin input is ignored.
   0: SPI slave selection depends on NSS input pin.
   1: SPI slave is always selected and NSS input pin is ignored.
   **Note**: When SPI slave mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bits 2:1 Reserved, must be kept at reset value.

Bit 0  **SLVEN**: Synchronous Slave mode enable
   When the SLVEN bit is set, the Synchronous slave mode is enabled.
   0: Slave mode disabled.
   1: Slave mode enabled.
   **Note**: When SPI slave mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

**Note**: The CPOL, CPHA and LBCL bits must not be written while the transmitter is enabled.

Bits 31:29 **TXFTCFG[2:0]**: TXFIFO threshold configuration
- 000: TXFIFO reaches 1/8 of its depth
- 001: TXFIFO reaches 1/4 of its depth
- 010: TXFIFO reaches 1/2 of its depth
- 011: TXFIFO reaches 3/4 of its depth
- 100: TXFIFO reaches 7/8 of its depth
- 101: TXFIFO becomes empty
- Remaining combinations: Reserved

Bit 28 **RXFTIE**: RXFIFO threshold interrupt enable
- This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated when Receive FIFO reaches the threshold programmed in RXFTCFG.

Bits 27:25 **RXFTCFG[2:0]**: Receive FIFO threshold configuration
- 000: Receive FIFO reaches 1/8 of its depth
- 001: Receive FIFO reaches 1/4 of its depth
- 010: Receive FIFO reaches 1/2 of its depth
- 011: Receive FIFO reaches 3/4 of its depth
- 100: Receive FIFO reaches 7/8 of its depth
- 101: Receive FIFO becomes full
- Remaining combinations: Reserved

Bit 24 **TCBGTE**: Transmission Complete before guard time, interrupt enable
- This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever TCBGT=1 in the USART_ISR register

*Note: If the USART does not support the Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 23 **TXFTIE**: TXFIFO threshold interrupt enable
- This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated when TXFIFO reaches the threshold programmed in TXFTCFG.

Bits 22:20 Reserved, must be kept at reset value.

Bits 19:17 **SCARCNT[2:0]**: Smartcard auto-retry count
- This bitfield specifies the number of retries for transmission and reception in Smartcard mode.
- In Transmission mode, it specifies the number of automatic retransmission retries, before generating a transmission error (FE bit set).
- In Reception mode, it specifies the number of erroneous reception trials, before generating a reception error (RXNE/RXFNE and PE bits set).
- This bitfield must be programmed only when the USART is disabled (UE=0).
- When the USART is enabled (UE=1), this bitfield may only be written to 0x0, in order to stop retransmission.
- 0x0: retransmission disabled - No automatic retransmission in Transmission mode.
- 0x1 to 0x7: number of automatic retransmission attempts (before signaling error)

*Note: If Smartcard mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 16 Reserved, must be kept at reset value.
Bit 15 **DEP**: Driver enable polarity selection
0: DE signal is active high.
1: DE signal is active low.
This bit can only be written when the USART is disabled (UE=0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 14 **DEM**: Driver enable mode
This bit enables the user to activate the external transceiver control, through the DE signal.
0: DE function is disabled.
1: DE function is enabled. The DE signal is output on the RTS pin.
This bit can only be written when the USART is disabled (UE=0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Section 66.4: USART implementation on page 2747.*

Bit 13 **DDRE**: DMA Disable on Reception Error
0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data is transferred. (used for Smartcard mode)
1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE (RXFNE is case FIFO mode is enabled) before clearing the error flag.
This bit can only be written when the USART is disabled (UE=0).

*Note: The reception errors are: parity error, framing error or noise error.*

Bit 12 **OVRDIS**: Overrun Disable
This bit is used to disable the receive overrun detection.
0: Overrun Error Flag, ORE, is set when received data is not read before receiving new data.
1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the USART_RDR register. When FIFO mode is enabled, the RXFIFO is bypassed and data are written directly in USART_RDR register. Even when FIFO management is enabled, the RXNE flag is to be used.
This bit can only be written when the USART is disabled (UE=0).

*Note: This control bit enables checking the communication flow w/o reading the data*

Bit 11 **ONEBIT**: One sample bit method enable
This bit enables the user to select the sample method. When the one sample bit method is selected the noise detection flag (NE) is disabled.
0: Three sample bit method
1: One sample bit method
This bit can only be written when the USART is disabled (UE=0).

Bit 10 **CTSIE**: CTS interrupt enable
0: Interrupt is inhibited
1: An interrupt is generated whenever CTSIF=1 in the USART_ISR register

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*
Bit 9  **CTSE**: CTS enable
- 0: CTS hardware flow control disabled
- 1: CTS mode enabled, data is only transmitted when the CTS input is deasserted (tied to 0).
  If the CTS input is asserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while CTS is asserted, the transmission is postponed until CTS is deasserted.
  This bit can only be written when the USART is disabled (UE=0)
  *Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 8  **RTSE**: RTS enable
- 0: RTS hardware flow control disabled
- 1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The RTS output is deasserted (pulled to 0) when data can be received.
  This bit can only be written when the USART is disabled (UE=0).
  *Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 7  **DMAT**: DMA enable transmitter
- This bit is set/reset by software
- 1: DMA mode is enabled for transmission
- 0: DMA mode is disabled for transmission

Bit 6  **DMAR**: DMA enable receiver
- This bit is set/reset by software
- 1: DMA mode is enabled for reception
- 0: DMA mode is disabled for reception

Bit 5  **SCEN**: Smartcard mode enable
- This bit is used for enabling Smartcard mode.
- 0: Smartcard mode disabled
- 1: Smartcard mode enabled
  This bitfield can only be written when the USART is disabled (UE=0).
  *Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 4  **NACK**: Smartcard NACK enable
- 0: NACK transmission in case of parity error is disabled
- 1: NACK transmission during parity error is enabled
  This bitfield can only be written when the USART is disabled (UE=0).
  *Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 3  **HDSEL**: Half-duplex selection
- Selection of Single-wire Half-duplex mode
- 0: Half-duplex mode is not selected
- 1: Half-duplex mode is selected
  This bit can only be written when the USART is disabled (UE=0).
Bit 2 **IRLP**: IrDA low-power
This bit is used for selecting between normal and low-power IrDA modes
0: Normal mode
1: Low-power mode
This bit can only be written when the USART is disabled (UE=0).
*Note: If IrDA mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 1 **IREN**: IrDA mode enable
This bit is set and cleared by software.
0: IrDA disabled
1: IrDA enabled
This bit can only be written when the USART is disabled (UE=0).
*Note: If IrDA mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 0 **EIE**: Error interrupt enable
Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error, noise flag or SPI slave underrun error (FE=1 or ORE=1 or NE=1 or UDR = 1 in the USART_ISR register).
0: Interrupt inhibited
1: interrupt generated when FE=1 or ORE=1 or NE=1 or UDR = 1 (in SPI slave mode) in the USART_ISR register.

### 66.8.5 USART baud rate register (USART_BRR)
This register can only be written when the USART is disabled (UE=0). It may be automatically updated by hardware in auto baud rate detection mode.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **GTP[7:0]: Guard time value**

- This bitfield is used to program the Guard time value in terms of number of baud clock periods.
- This is used in Smartcard mode. The Transmission Complete flag is set after this guard time value.
- This bitfield can only be written when the USART is disabled (UE=0).

**Note:** If Smartcard mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bits 7:0 **PSC[7:0]: Prescaler value**

**Condition: IrDA low-power and normal IrDA mode**

PSC[7:0] = IrDA Normal and Low-power baud rate

- This bitfield is used for programming the prescaler for dividing the USART source clock to achieve the low-power frequency.
- The source clock is divided by the value given in the register (8 significant bits):
  - 00000000: Reserved - do not program this value
  - 00000001: divides the source clock by 1
  - 00000010: divides the source clock by 2
  - ...

**Condition: Smartcard mode**

PSC[4:0]: Prescaler value

- This bitfield is used for programming the prescaler for dividing the USART source clock to provide the Smartcard clock.
- The value given in the register (5 significant bits) is multiplied by 2 to give the division factor of the source clock frequency:
  - 00000: Reserved - do not program this value
  - 00001: divides the source clock by 2
  - 00010: divides the source clock by 4
  - 00011: divides the source clock by 6
  - ...

- This bitfield can only be written when the USART is disabled (UE=0).

**Note:** Bits [7:5] must be kept cleared if Smartcard mode is used.

This bitfield is reserved and forced by hardware to 0 when the Smartcard and IrDA modes are not supported. Refer to Section 66.4: USART implementation on page 2747.
66.8.7  USART receiver timeout register (USART_RTOR)

Address offset: 0x14
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>BLEN[7:0]</th>
<th>RTO[23:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:24  **BLEN[7:0]:** Block Length

This bitfield gives the Block length in Smartcard T=1 Reception. Its value equals the number of information characters + the length of the Epilogue Field (1-LEC/2-CRC) - 1.

Examples:
- BLEN = 0 -> 0 information characters + LEC
- BLEN = 1 -> 0 information characters + CRC
- BLEN = 255 -> 254 information characters + CRC (total 256 characters)

In Smartcard mode, the Block length counter is reset when TXE=0 (TXFE = 0 in case FIFO mode is enabled).

This bitfield can be used also in other modes. In this case, the Block length counter is reset when RE=0 (receiver disabled) and/or when the EOBCF bit is written to 1.

*Note:* This value can be programmed after the start of the block reception (using the data from the LEN character in the Prologue Field). It must be programmed only once per received block.

Bits 23:0  **RTO[23:0]:** Receiver timeout value

This bitfield gives the Receiver timeout value in terms of number of bit duration.

In Standard mode, the RTOF flag is set if, after the last received character, no new start bit is detected for more than the RTO value.

In Smartcard mode, this value is used to implement the CWT and BWT. See Smartcard chapter for more details. In the standard, the CWT/BWT measurement is done starting from the start bit of the last received character.

*Note:* This value must only be programmed once per received character.

*Note:* RTOR can be written on-the-fly. If the new value is lower than or equal to the counter, the RTOF flag is set.

This register is reserved and forced by hardware to “0x00000000” when the Receiver timeout feature is not supported. Refer to Section 66.4: USART implementation on page 2747.
### 66.8.8 USART request register (USART_RQR)

**Address offset:** 0x18  
**Reset value:** 0x0000 0000

#### Bits 31:5
- **Reserved, must be kept at reset value.**

#### Bit 4 TXFRQ: Transmit data flush request
- When FIFO mode is disabled, writing 1 to this bit sets the TXE flag. This enables to discard the transmit data. This bit must be used only in Smartcard mode, when data have not been sent due to errors (NACK) and the FE flag is active in the USART_ISR register. If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value.
- When FIFO is enabled, TXFRQ bit is set to flush the whole FIFO. This sets the TXFE flag (Transmit FIFO empty, bit 23 in the USART_ISR register). Flushing the Transmit FIFO is supported in both UART and Smartcard modes.

*Note:* In FIFO mode, the TXFNF flag is reset during the flush request until TxFIFO is empty in order to ensure that no data are written in the data register.

#### Bit 3 RXFRQ: Receive data flush request
- Writing 1 to this bit empties the entire receive FIFO i.e. clears the bit RXFNE.
- This enables to discard the received data without reading them, and avoid an overrun condition.

#### Bit 2 MMRQ: Mute mode request
- Writing 1 to this bit puts the USART in Mute mode and resets the RWU flag.

#### Bit 1 SBKRQ: Send break request
- Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available.

*Note:* When the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software must wait for the TXE flag assertion before setting the SBKRQ bit.

#### Bit 0 ABRRQ: Auto baud rate request
- Writing 1 to this bit resets the ABRF and ABRE flags in the USART_ISR and requests an automatic baud rate measurement on the next received data frame.

*Note:* If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.
66.8.9  USART interrupt and status register (USART_ISR)

Address offset: 0x1C  
Reset value: 0x0XX0 00C0  
XX = 28 if FIFO/Smartcard mode enabled  
XX = 08 if FIFO enabled and Smartcard mode disabled  
The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

**FIFO mode enabled**

Bits 31:28  Reserved, must be kept at reset value.

**Bit 27  TXFT:** TXFIFO threshold flag

This bit is set by hardware when the TXFIFO reaches the threshold programmed in TXFTCFG of USART_CR3 register i.e. the TXFIFO contains TXFTCFG empty locations. An interrupt is generated if the TXFTIE bit =1 (bit 31) in the USART_CR3 register.

0: TXFIFO does not reach the programmed threshold.  
1: TXFIFO reached the programmed threshold.

**Bit 26  RXFT:** RXFIFO threshold flag

This bit is set by hardware when the threshold programmed in RXFTCFG in USART_CR3 register is reached. This means that there are (RXFTCFG - 1) data in the Receive FIFO and one data in the USART_RDR register. An interrupt is generated if the RXFTIE bit =1 (bit 27) in the USART_CR3 register.

0: Receive FIFO does not reach the programmed threshold.  
1: Receive FIFO reached the programmed threshold.

**Note:** When the RXFTCFG threshold is configured to 101, RXFT flag is set if 16 data are available i.e. 15 data in the RXFIFO and 1 data in the USART_RDR. Consequently, the 17th received data does not cause an overrun error. The overrun error occurs after receiving the 18th data.
Bit 25 **TCBG**: Transmission complete before guard time flag

This bit is set when the last data written in the USART_TDR has been transmitted correctly out of the shift register.

It is set by hardware in Smartcard mode, if the transmission of a frame containing data is complete and if the smartcard did not send back any NACK. An interrupt is generated if TCBGTIE=1 in the USART_CR3 register.

This bit is cleared by software, by writing 1 to the TCBGTCF in the USART_ICR register or by a write to the USART_TDR register.

0: Transmission is not complete or transmission is complete unsuccessfully (i.e. a NACK is received from the card)
1: Transmission is complete successfully (before Guard time completion and there is no NACK from the smart card).

*Note: If the USART does not support the Smartcard mode, this bit is reserved and kept at reset value. If the USART supports the Smartcard mode and the Smartcard mode is enabled, the TCBGT reset value is 1. Refer to Section 66.4: USART implementation on page 2747.*

Bit 24 **RXFF**: RXFIFO Full

This bit is set by hardware when the number of received data corresponds to RXFIFO size + 1 (RXFIFO full + 1 data in the USART_RDR register.

An interrupt is generated if the RXFFIE bit =1 in the USART_CR1 register.

0: RXFIFO not full.
1: RXFIFO Full.

Bit 23 **TXFE**: TXFIFO Empty

This bit is set by hardware when TXFIFO is Empty. When the TXFIFO contains at least one data, this flag is cleared. The TXFE flag can also be set by writing 1 to the bit TXFRQ (bit 4) in the USART_RQR register.

An interrupt is generated if the TXFEIE bit =1 (bit 30) in the USART_CR1 register.

0: TXFIFO not empty.
1: TXFIFO empty.

Bit 22 **REACK**: Receive enable acknowledge flag

This bit is set/reset by hardware, when the Receive Enable value is taken into account by the USART.

It can be used to verify that the USART is ready for reception before entering low-power mode.

*Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 21 **TEACK**: Transmit enable acknowledge flag

This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the USART.

It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the USART_CR1 register, in order to respect the TE=0 minimum period.
Bit 20  Reserved, must be kept at reset value.

Bit 19  **RWU: Receiver wake-up from Mute mode**
- This bit indicates if the USART is in Mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART_CR1 register.
- When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART_RQR register.
  - 0: Receiver in Active mode
  - 1: Receiver in Mute mode

*Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 18  **SBKF: Send break flag**
- This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the USART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.
  - 0: No break character transmitted
  - 1: Break character transmitted

Bit 17  **CMF: Character match flag**
- This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART_ICR register.
- An interrupt is generated if CMIE=1 in the USART_CR1 register.
  - 0: No Character match detected
  - 1: Character match detected

Bit 16  **BUSY: Busy flag**
- This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).
  - 0: USART is idle (no reception)
  - 1: Reception on going

Bit 15  **ABRF: Auto baud rate flag**
- This bit is set by hardware when the automatic baud rate has been set (RXFNE is also set, generating an interrupt if RXFNEIE = 1) or when the auto baud rate operation was completed without success (ABRE=1) (ABRE, RXFNE and FE are also set in this case)
- It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRRQ in the USART_RQR register.
*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 14  **ABRE: Auto baud rate error**
- This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed)
- It is cleared by software, by writing 1 to the ABRRQ bit in the USART_RQR register.
*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*
Bit 13  **UDR**: SPI slave underrun error flag

In Slave transmission mode, this flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value into USART_TDR. This flag is reset by setting UDRCF bit in the USART_ICR register.

0: No underrun error
1: underrun error

*Note: If the USART does not support the SPI slave mode, this bit is reserved and kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 12  **EOBF**: End of block flag

This bit is set by hardware when a complete block has been received (for example T=1 Smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4.

An interrupt is generated if EOBIE = 1 in the USART_CR1 register.

It is cleared by software, writing 1 to EOBCF in the USART_ICR register.

0: End of Block not reached
1: End of Block (number of characters) reached

*Note: If Smartcard mode is not supported, this bit is reserved and kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 11  **RTOF**: Receiver timeout

This bit is set by hardware when the timeout value, programmed in the RTOR register has lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in the USART_ICR register.

An interrupt is generated if RTOIE=1 in the USART_CR2 register.

In Smartcard mode, the timeout corresponds to the CWT or BWT timings.

0: Timeout value not reached
1: Timeout value reached without any data reception

*Note: If a time equal to the value programmed in RTOR register separates 2 characters, RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, depending on the oversampling method), RTOF flag is set. The counter counts even if RE = 0 but RTOF is set only when RE = 1. If the timeout has already elapsed when RE is set, then RTOF is set. If the USART does not support the Receiver timeout feature, this bit is reserved and kept at reset value.*

Bit 10  **CTS**: CTS flag

This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.

0: CTS line set
1: CTS line reset

*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 9  **CTSIF**: CTS interrupt flag

This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the USART_ICR register.

An interrupt is generated if CTSIE=1 in the USART_CR3 register.

0: No change occurred on the CTS status line
1: A change occurred on the CTS status line

*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*
Bit 8 **LBDF**: LIN break detection flag

This bit is set by hardware when the LIN break is detected. It is cleared by software, by writing 1 to the LBDCF in the USART_ICR.

An interrupt is generated if LBDIE = 1 in the USART_CR2 register.

0: LIN Break not detected
1: LIN break detected

*Note: If the USART does not support LIN mode, this bit is reserved and kept at reset value. Refer to Section 66.4: USART implementation on page 2747.*

Bit 7 **TXFNF**: TXFIFO not full

TXFNF is set by hardware when TXFIFO is not full meaning that data can be written in the USART_TDR. Every write operation to the USART_TDR places the data in the TXFIFO. This flag remains set until the TXFIFO is full. When the TXFIFO is full, this flag is cleared indicating that data can not be written into the USART_TDR.

An interrupt is generated if the TXFNFIE bit =1 in the USART_CR1 register.

0: Transmit FIFO is full
1: Transmit FIFO is not full

*Note: The TXFNF is kept reset during the flush request until TXFIFO is empty. After sending the flush request (by setting TXFRQ bit), the flag TXFNF must be checked prior to writing in TXFIFO (TXFNF and TXFE is set at the same time).*

This bit is used during single buffer transmission.

Bit 6 **TC**: Transmission complete

This bit indicates that the last data written in the USART_TDR has been transmitted out of the shift register. The TC flag behaves as follows:

- When TDN = 0, the TC flag is set when the transmission of a frame containing data is complete and when TXE/TXFE is set.
- When TDN is equal to the number of data in the TXFIFO, the TC flag is set when TXFIFO is empty and TDN is reached.
- When TDN is greater than the number of data in the TXFIFO, TC remains cleared until the TXFIFO is filled again to reach the programmed number of data to be transferred.
- When TDN is less than the number of data in the TXFIFO, TC is set when TDN is reached even if the TXFIFO is not empty.

An interrupt is generated if TCIE=1 in the USART_CR1 register.

TC bit is cleared by software by writing 1 to the TCCF in the USART_ICR register or by writing to the USART_TDR register.

Bit 5 **RXFNE**: RXFIFO not empty

RXFNE bit is set by hardware when the RXFIFO is not empty, meaning that data can be read from the USART_RDR register. Every read operation from the USART_RDR frees a location in the RXFIFO.

RXFNE is cleared when the RXFIFO is empty. The RXFNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR register.

An interrupt is generated if RXFNEIE=1 in the USART_CR1 register.

0: Data is not received
1: Received data is ready to be read.
Bit 4 **IDLE**: Idle line detected  
This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE=1 in the USART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the USART_ICR register.  
0: No Idle line is detected  
1: Idle line is detected  
**Note:** The IDLE bit is not set again until the RXFNE bit has been set (i.e. a new idle line occurs).  
If Mute mode is enabled (MME=1), IDLE is set if the USART is not mute (RWU=0), whatever the Mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.  

Bit 3 **ORE**: Overrun error  
This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the USART_RDR register while RXFF = 1. It is cleared by a software, writing 1 to the ORECF, in the USART_ICR register.  
An interrupt is generated if RXFNEIE=1 in the USART_CR1 register, or EIE = 1 in the USART_CR3 register.  
0: No overrun error  
1: Overrun error is detected  
**Note:** When this bit is set, the USART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.  
This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the USART_CR3 register.
Bit 2  **NE**: Noise detection flag
This bit is set by hardware when noise is detected on a received frame. It is cleared by software, writing 1 to the NFCF bit in the USART_ICR register.
0: No noise is detected
1: Noise is detected

*Note:* This bit does not generate an interrupt as it appears at the same time as the RXFNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set. When the line is noise-free, the NE flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (Refer to Section 66.5.9: Tolerance of the USART receiver to clock deviation on page 2766).
This error is associated with the character in the USART_RDR.

Bit 1  **FE**: Framing error
This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the USART_ICR register.
When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).
An interrupt is generated if EIE = 1 in the USART_CR3 register.
0: No Framing error is detected
1: Framing error or break character is detected

*Note:* This error is associated with the character in the USART_RDR.

Bit 0  **PE**: Parity error
This bit is set by hardware when a parity error occurs in Reception mode. It is cleared by software, writing 1 to the PECF in the USART_ICR register.
An interrupt is generated if PEIE = 1 in the USART_CR1 register.
0: No parity error
1: Parity error

*Note:* This error is associated with the character in the USART_RDR.

### 66.8.10 USART interrupt and status register [alternate] (USART_ISR)

Address offset: 0x1C
Reset value: 0x0000 00C0
The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

#### FIFO mode disabled

Bits 31:26  Reserved, must be kept at reset value.

Bit 25  **TCBGT**: Transmission complete before guard time flag

This bit is set when the last data written in the USART_TDR has been transmitted correctly out of the shift register.

It is set by hardware in Smartcard mode, if the transmission of a frame containing data is complete and if the smartcard did not send back any NACK. An interrupt is generated if TCBGTIE=1 in the USART_CR3 register.

This bit is cleared by software, by writing 1 to the TCBGTCF in the USART_ICR register or by a write to the USART_TDR register.

0: Transmission is not complete or transmission is complete unsuccessfully (i.e. a NACK is received from the card)
1: Transmission is complete successfully (before Guard time completion and there is no NACK from the smart card).

**Note:** If the USART does not support the Smartcard mode, this bit is reserved and kept at reset value. If the USART supports the Smartcard mode and the Smartcard mode is enabled, the TCBGT reset value is 1. Refer to Section 66.4: USART implementation on page 2747.

Bits 24:23  Reserved, must be kept at reset value.

Bit 22  **REACK**: Receive enable acknowledge flag

This bit is set/reset by hardware, when the Receive Enable value is taken into account by the USART.

It can be used to verify that the USART is ready for reception before entering low-power mode.

**Note:** If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bit 21  **TEACK**: Transmit enable acknowledge flag

This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the USART.

It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the USART_CR1 register, in order to respect the TE=0 minimum period.

Bit 20  Reserved, must be kept at reset value.

Bit 19  **RWU**: Receiver wake-up from Mute mode

This bit indicates if the USART is in Mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART_CR1 register.

When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART_RQR register.

0: Receiver in Active mode
1: Receiver in Mute mode

**Note:** If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bit 18  **SBKF**: Send break flag

This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the USART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.

0: No break character transmitted
1: Break character transmitted
Bit 17 **CMF**: Character match flag
This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART_ICR register. An interrupt is generated if CMIE=1 in the USART_CR1 register.
0: No Character match detected
1: Character match detected

Bit 16 **BUSY**: Busy flag
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).
0: USART is idle (no reception)
1: Reception on going

Bit 15 **ABRF**: Auto baud rate flag
This bit is set by hardware when the automatic baud rate has been set (RXNE is also set, generating an interrupt if RXNEIE = 1) or when the auto baud rate operation was completed without success (ABRE=1) (ABRE, RXNE and FE are also set in this case) It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRRQ in the USART_RQR register.
*Note*: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.

Bit 14 **ABRE**: Auto baud rate error
This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed)
It is cleared by software, by writing 1 to the ABRRQ bit in the USART_RQR register.
*Note*: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.

Bit 13 **UDR**: SPI slave underrun error flag
In Slave transmission mode, this flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value into USART_TDR. This flag is reset by setting UDRCF bit in the USART_ICR register.
0: No underrun error
1: underrun error
*Note*: If the USART does not support the SPI slave mode, this bit is reserved and kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bit 12 **EOBF**: End of block flag
This bit is set by hardware when a complete block has been received (for example T=1 Smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4. An interrupt is generated if EOBIE = 1 in the USART_CR1 register.
It is cleared by software, writing 1 to EOBCF in the USART_ICR register.
0: End of Block not reached
1: End of Block (number of characters) reached
*Note*: If Smartcard mode is not supported, this bit is reserved and kept at reset value. Refer to Section 66.4: USART implementation on page 2747.
Bit 11 **RTOF**: Receiver timeout

This bit is set by hardware when the timeout value, programmed in the RTOR register has lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in the USART_ICR register.

An interrupt is generated if RTOIE=1 in the USART_CR2 register.

In Smartcard mode, the timeout corresponds to the CWT or BWT timings.

0: Timeout value not reached
1: Timeout value reached without any data reception

**Note:** If a time equal to the value programmed in RTOR register separates 2 characters, RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, depending on the oversampling method), RTOF flag is set.

The counter counts even if RE = 0 but RTOF is set only when RE = 1. If the timeout has already elapsed when RE is set, then RTOF is set.

If the USART does not support the Receiver timeout feature, this bit is reserved and kept at reset value.

Bit 10 **CTS**: CTS flag

This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.

0: CTS line set
1: CTS line reset

**Note:** If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 9 **CTSIF**: CTS interrupt flag

This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the USART_ICR register.

An interrupt is generated if CTSIE=1 in the USART_CR3 register.

0: No change occurred on the CTS status line
1: A change occurred on the CTS status line

**Note:** If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 8 **LBDF**: LIN break detection flag

This bit is set by hardware when the LIN break is detected. It is cleared by software, by writing 1 to the LBDCF in the USART_ICR.

An interrupt is generated if LBDIE = 1 in the USART_CR2 register.

0: LIN Break not detected
1: LIN break detected

**Note:** If the USART does not support LIN mode, this bit is reserved and kept at reset value.

Refer to Section 66.4: USART implementation on page 2747.

Bit 7 **TXE**: Transmit data register empty

TXE is set by hardware when the content of the USART_TDR register has been transferred into the shift register. It is cleared by writing to the USART_TDR register. The TXE flag can also be set by writing 1 to the TXFRQ in the USART_RQR register, in order to discard the data (only in Smartcard T=0 mode, in case of transmission failure).

An interrupt is generated if the TXEIE bit =1 in the USART_CR1 register.

0: Data register full
1: Data register full
Bit 6  **TC**: Transmission complete  
This bit indicates that the last data written in the USART_TDR has been transmitted out of  
the shift register. The TC flag is set when the transmission of a frame containing data is  
complete and when TXE is set.  
An interrupt is generated if TCIE=1 in the USART_CR1 register.  
TC bit is cleared by software by writing 1 to the TCCF in the USART_ICR register or by  
writing to the USART_TDR register.

Bit 5  **RXNE**: Read data register not empty  
RXNE bit is set by hardware when the content of the USART_RDR shift register has been  
transferred to the USART_RDR register. It is cleared by reading from the USART_RDR  
register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR  
register.  
An interrupt is generated if RXNEIE=1 in the USART_CR1 register.  
0: Data is not received  
1: Received data is ready to be read.

Bit 4  **IDLE**: Idle line detected  
This bit is set by hardware when an Idle Line is detected. An interrupt is generated if  
IDLEIE=1 in the USART_CR1 register. It is cleared by software, writing 1 to the IDLECF in  
the USART_ICR register.  
0: No Idle line is detected  
1: Idle line is detected  

*Note:* The IDLE bit is not set again until the RXNE bit has been set (i.e. a new idle line  
occurs).  
If Mute mode is enabled (MME=1), IDLE is set if the USART is not mute (RWU=0),  
whatever the Mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.

Bit 3  **ORE**: Overrun error  
This bit is set by hardware when the data currently being received in the shift register is  
ready to be transferred into the USART_RDR register while RXNE=1. It is cleared by a  
software, writing 1 to the ORECF, in the USART_ICR register.  
An interrupt is generated if RXNEIE=1 in the USART_CR1 register, or EIE = 1 in the  
USART_CR3 register.  
1: Overrun error is detected  

*Note:* When this bit is set, the USART_RDR register content is not lost but the shift register is  
overwritten. An interrupt is generated if the ORE flag is set during multi buffer  
communication if the EIE bit is set.  
This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in  
the USART_CR3 register.
Bit 2 **NE**: Noise detection flag

This bit is set by hardware when noise is detected on a received frame. It is cleared by software, writing 1 to the NFCF bit in the USART_ICR register.

0: No noise is detected
1: Noise is detected

**Note:** This bit does not generate an interrupt as it appears at the same time as the RXNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

When the line is noise-free, the NE flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (Refer to Section 66.5.9: Tolerance of the USART receiver to clock deviation on page 2766).

This error is associated with the character in the USART_RDR.

Bit 1 **FE**: Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the USART_ICR register.

When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).

An interrupt is generated if EIE = 1 in the USART_CR3 register.

0: No Framing error is detected
1: Framing error or break character is detected

**Note:** This error is associated with the character in the USART_RDR.

Bit 0 **PE**: Parity error

This bit is set by hardware when a parity error occurs in Reception mode. It is cleared by software, writing 1 to the PECF in the USART_ICR register.

An interrupt is generated if PEIE = 1 in the USART_CR1 register.

0: No parity error
1: Parity error

**Note:** This error is associated with the character in the USART_RDR.

### 66.8.11 USART interrupt flag clear register (USART_ICR)

**Address offset:** 0x20

**Reset value:** 0x0000 0000

**Bits 31:18** Reserved, must be kept at reset value.

**Bit 17 CMCF**: Character match clear flag

Writing 1 to this bit clears the CMF flag in the USART_ISR register.

**Bits 16:14** Reserved, must be kept at reset value.
Bit 13  **UDRCF**: SPI slave underrun clear flag
    Writing 1 to this bit clears the UDRF flag in the USART_ISR register.
    Note: If the USART does not support SPI slave mode, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bit 12  **EOBCF**: End of block clear flag
    Writing 1 to this bit clears the EOBF flag in the USART_ISR register.
    Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bit 11  **RTOCF**: Receiver timeout clear flag
    Writing 1 to this bit clears the RTOF flag in the USART_ISR register.
    Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bit 10  Reserved, must be kept at reset value.

Bit 9  **CTSCF**: CTS clear flag
    Writing 1 to this bit clears the CTSIF flag in the USART_ISR register.
    Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bit 8  **LBDCF**: LIN break detection clear flag
    Writing 1 to this bit clears the LBDF flag in the USART_ISR register.
    Note: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 66.4: USART implementation on page 2747.

Bit 7  **TCBGTCF**: Transmission complete before Guard time clear flag
    Writing 1 to this bit clears the TCBGT flag in the USART_ISR register.

Bit 6  **TCCF**: Transmission complete clear flag
    Writing 1 to this bit clears the TC flag in the USART_ISR register.

Bit 5  **TXFECF**: TXFIFO empty clear flag
    Writing 1 to this bit clears the TXFE flag in the USART_ISR register.

Bit 4  **IDLECF**: Idle line detected clear flag
    Writing 1 to this bit clears the IDLE flag in the USART_ISR register.

Bit 3  **ORECF**: Overrun error clear flag
    Writing 1 to this bit clears the ORE flag in the USART_ISR register.

Bit 2  **NECF**: Noise detected clear flag
    Writing 1 to this bit clears the NE flag in the USART_ISR register.

Bit 1  **FECF**: Framing error clear flag
    Writing 1 to this bit clears the FE flag in the USART_ISR register.

Bit 0  **PECF**: Parity error clear flag
    Writing 1 to this bit clears the PE flag in the USART_ISR register.
66.8.12  **USART receive data register (USART_RDR)**  

Address offset: 0x24  
Reset value: 0x0000 0000

Bits 31:9  Reserved, must be kept at reset value.

Bits 8:0  **RDR[8:0]**: Receive data value  
Contains the received data character.  
The RDR register provides the parallel interface between the input shift register and the internal bus (see Figure 800).  
When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.

66.8.13  **USART transmit data register (USART_TDR)**

Bits 31:9  Reserved, must be kept at reset value.

Bits 8:0  **TDR[8:0]**: Transmit data value  
Contains the data character to be transmitted.  
The USART_TDR register provides the parallel interface between the internal bus and the output shift register (see Figure 800).  
When transmitting with the parity enabled (PCE bit set to 1 in the USART_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

*Note*: This register must be written only when TXE/TXENF=1.
## 66.8.14 USART prescaler register (USART_PRESC)

This register can only be written when the USART is disabled (UE=0).

Address offset: 0x2C

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:4</th>
<th>Bit 3:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved (must be kept at reset value)</td>
<td>RES 3:0 (PRESCALER[3:0]) - Clock prescaler</td>
</tr>
</tbody>
</table>

The USART input clock can be divided by a prescaler factor:
- 0000: input clock not divided
- 0001: input clock divided by 2
- 0010: input clock divided by 4
- 0011: input clock divided by 6
- 0100: input clock divided by 8
- 0101: input clock divided by 10
- 0110: input clock divided by 12
- 0111: input clock divided by 16
- 1000: input clock divided by 32
- 1001: input clock divided by 64
- 1010: input clock divided by 128
- 1011: input clock divided by 256
- Remaining combinations: Reserved

**Note:** When PRESCALER is programmed with a value different of the allowed ones, programmed prescaler value is equal to 1011 i.e. input clock divided by 256.

## 66.8.15 USART Autonomous mode control register (USART_AUTOCR)

Address offset: 0x30

Reset value: 0x8000 0000

<table>
<thead>
<tr>
<th>Bit 31:4</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved</td>
<td>TRIGSEL[3:0]</td>
</tr>
<tr>
<td></td>
<td>15:0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit 7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>TDN[15:0]</td>
</tr>
</tbody>
</table>
Bits 31:23  Reserved, must be kept at reset value.

Bits 22:19  **TRIGSEL[3:0]**: Trigger selection bits
Refer to Description of USART interconnections.
This bitfield can be written only when the UE bit is cleared in USART_CR1 register.
0000: usart_trg0 selected
0001: usart_trg1 selected
...
1111: usart_trg15 selected

*Note: This bitfield can be written only when the UE bit of USART_CR1 register is cleared.*

Bit 18  **IDLEDIS**: Idle frame transmission disable bit after enabling the transmitter
0: Idle frame sent after enabling the transmitter (TE = 1 in USART_CR1)
1: Idle frame not sent after enabling the transmitter

*Note: This bitfield can be written only when the UE bit of USART_CR1 register is cleared.*

Bit 17  **TRIGEN**: Trigger enable bit
0: Trigger disabled
1: Trigger enabled

*Note: This bitfield can be written only when the UE bit of USART_CR1 register is cleared.*

When a trigger is detected, TE is set to 1 in USART_CR1 and the data transfer is launched.

Bit 16  **TRIGPOL**: Trigger polarity bit
This bitfield can be written only when the UE bit is cleared in USART_CR1 register.
0: Trigger active on rising edge
1: Trigger active on falling edge

Bits 15:0  **TDN[15:0]**: TDN transmission data number
This bitfield enables the programming of the number of data to be transmitted. It can be written only when UE is cleared in USART_CR1.

### 66.8.16 USART register map

| Offset | Register name          | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Refer to Section 2.3 on page 139 for the register boundary addresses.
67 Low-power universal asynchronous receiver transmitter (LPUART)

This section describes the low-power universal asynchronous receiver transmitted (LPUART).

67.1 Introduction

The LPUART is an UART which enables bidirectional UART communications with a limited power consumption. Only 32.768 kHz LSE clock is required to enable UART communications up to 9600 bauds. Higher baud rates can be reached when the LPUART is clocked by clock sources different from the LSE clock.

Even when the microcontroller is in low-power mode, the LPUART can wait for an incoming UART frame while having an extremely low energy consumption. The LPUART includes all necessary hardware support to make asynchronous serial communications possible with minimum power consumption.

It supports Half-duplex Single-wire communications and modem operations (CTS/RTS). It also supports multiprocessor communications.

DMA (direct memory access) can be used for data transmission/reception.

67.2 LPUART main features

- Full-duplex asynchronous communications
- NRZ standard format (mark/space)
- Programmable baud rate
- From 300 bauds to 9600 bauds using a 32.768 kHz clock source.
- Higher baud rates can be achieved by using a higher frequency clock source
- Two internal FIFOs to transmit and receive data
  Each FIFO can be enabled/disabled by software and come with status flags for FIFOs states.
- Dual clock domain with dedicated kernel clock for peripherals independent from PCLK.
- Programmable data word length (7 or 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Single-wire Half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA.
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
• Transfer detection flags:
  – Receive buffer full
  – Transmit buffer empty
  – Busy and end of transmission flags
• Parity control:
  – Transmits parity bit
  – Checks parity of received data byte
• Four error detection flags:
  – Overrun error
  – Noise detection
  – Frame error
  – Parity error
• Interrupt sources with flags
• Multiprocessor communications: wake-up from Mute mode by idle line detection or address mark detection
• Wake-up from Stop mode
• Autonomous functionality in Stop mode

67.3 LPUART implementation

The table below describe LPUART implementation. It also includes USARTs and UARTs for comparison.

67.4 LPUART functional description

67.4.1 LPUART block diagram

Figure 825. LPUART block diagram
67.4.2 LPUART pins and internal signals

Description LPUART input/output pins

- LPUART bidirectional communications
  LPUART bidirectional communications requires a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):
  - **RX** (Receive Data Input):
    RX is the serial data input.
  - **TX** (Transmit Data Output)
    When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In Single-wire mode, this I/O is used to transmit and receive the data.

- RS232 hardware flow control mode
  The following pins are required in RS232 Hardware flow control mode:
  - **CTS** (Clear To Send)
    When driven high, this signal blocks the data transmission at the end of the current transfer.
  - **RTS** (Request to send)
    When it is low, this signal indicates that the USART is ready to receive data.

- RS485 hardware flow control mode
  The **DE** (Driver Enable) pin is required in RS485 Hardware control mode. This signal activates the transmission mode of the external transceiver.

Refer to **Table 680** and **Table 681** for the list of LPUART input/output pins and internal signals.

<table>
