Introduction

This reference manual targets application developers. It provides complete information on how to use memory and peripherals of the STM32U5 Series microcontrollers.

For ordering information, mechanical and electrical device characteristics, refer to the corresponding datasheets.

STM32U5 Series microcontrollers include ST state-of-the-art patented technology.

    5.7.2 GTZC1 TZIC interrupt enable register 2 (GTZC1_TZIC_IER2) ........ 226
    5.7.3 GTZC1 TZIC interrupt enable register 3 (GTZC1_TZIC_IER3) ........ 228
5.7.4 GTZC1 TZIC interrupt enable register 4 (GTZC1_TZIC_IER4) ........... 231
5.7.5 GTZC1 TZIC status register 1 (GTZC1_TZIC_SR1) ....................... 233
5.7.6 GTZC1 TZIC status register 2 (GTZC1_TZIC_SR2) ....................... 236
5.7.7 GTZC1 TZIC status register 3 (GTZC1_TZIC_SR3) ....................... 237
5.7.8 GTZC1 TZIC status register 4 (GTZC1_TZIC_SR4) ....................... 240
5.7.9 GTZC1 TZIC flag clear register 1 (GTZC1_TZIC_FCR1) ................. 243
5.7.10 GTZC1 TZIC flag clear register 2 (GTZC1_TZIC_FCR2) ............... 245
5.7.11 GTZC1 TZIC flag clear register 3 (GTZC1_TZIC_FCR3) ............... 246
5.7.12 GTZC1 TZIC flag clear register 4 (GTZC1_TZIC_FCR4) ............... 250
5.7.13 GTZC1 TZIC register map .................................................. 252

5.8 GTZC1 MPCBBz registers (z = 1, 2, 3, 5, 6) .................................. 254
5.8.1 GTZC1 SRAMz MPCBB control register
(GTZC1_MPCBBz_CR) (z = 1, 2, 3, 5, 6) ........................................ 254
5.8.2 GTZC1 SRAMz MPCBB configuration lock register 1
(GTZC1_MPCBBz_CFGLOCKR1) (z = 1, 2, 3, 5, 6) ........................ 255
5.8.3 GTZC1 SRAMz MPCBB configuration lock register 2
(GTZC1_MPCBBz_CFGLOCKR2) (z = 1, 2, 3, 5, 6) ........................ 255
5.8.4 GTZC1 SRAMz MPCBB security configuration for super-block x
register (GTZC1_MPCBBz_SECCFGRx) (z = 1, 2, 3, 5, 6) ............. 256
5.8.5 GTZC1 SRAMz MPCBB privileged configuration for super-block x
register (GTZC1_MPCBBz_PRIVCFGRx) (z = 1, 2, 3, 5, 6) .......... 256
5.8.6 GTZC1 MPCBBz register map (z = 1, 2, 3, 5, 6) ...................... 257

5.9 GTZC2 TZSC registers ................................................................. 258
5.9.1 GTZC2 TZSC control register (GTZC2_TZSC_CR) .......................... 258
5.9.2 GTZC2 TZSC secure configuration register 1
(GTZC2_TZSC_SECCFGR1) ....................................................... 258
5.9.3 GTZC2 TZSC privilege configuration register 1
(GTZC2_TZSC_PRIVCFGR1) ....................................................... 260
5.9.4 GTZC2 TZSC register map ........................................................ 261

5.10 GTZC2 TZIC registers ................................................................. 262
5.10.1 GTZC2 TZIC interrupt enable register 1 (GTZC2_TZIC_IER1) ......... 262
5.10.2 GTZC2 TZIC interrupt enable register 2 (GTZC2_TZIC_IER2) ......... 263
5.10.3 GTZC2 TZIC status register 1 (GTZC2_TZIC_SR1) ....................... 264
5.10.4 GTZC2 TZIC status register 2 (GTZC2_TZIC_SR2) ....................... 265
5.10.5 GTZC2 TZIC flag clear register 1 (GTZC2_TZIC_FCR1) ................. 267
5.10.6 GTZC2 TZIC flag clear register 2 (GTZC2_TZIC_FCR2) ............... 268
5.10.7 GTZC2 TZIC register map ...................................................... 269

5.11 GTZC2 MPCBB4 registers ............................................................. 270
5.11.1 GTZC2 SRAM4 MPCBB control register (GTZC2_MPCBB4_CR) ........ 270
6 RAM configuration controller (RAMCFG) ............................................. 274
   6.1 RAMCFG introduction ............................................................. 274
   6.2 RAMCFG main features ........................................................... 274
   6.3 RAMCFG functional description ............................................... 274
      6.3.1 Internal SRAMs features .................................................. 274
      6.3.2 Error code correction (SRAM2, SRAM3, BKPSRAM) .................. 275
      6.3.3 Write protection (SRAM2) ............................................... 278
      6.3.4 Read access latency ....................................................... 278
      6.3.5 Software erase ............................................................. 278
   6.4 RAMCFG low-power modes ..................................................... 279
   6.5 RAMCFG interrupts ............................................................. 279
   6.6 RAMCFG registers ............................................................... 280
      6.6.1 RAMCFG memory x control register (RAMCFG_MxCR) .............. 280
      6.6.2 RAMCFG memory x interrupt enable register (RAMCFG_MxIER) ... 281
      6.6.3 RAMCFG memory interrupt status register (RAMCFG_MxISR) .... 281
      6.6.4 RAMCFG memory x ECC single error address register (RAMCFG_MxEAR) ............................................................. 282
      6.6.5 RAMCFG memory x ECC double error address register (RAMCFG_MxDEAR) ............................................................. 283
      6.6.6 RAMCFG memory x interrupt clear register x (RAMCFG_MxICR) ... 283
      6.6.7 RAMCFG memory 2 write protection register 1 (RAMCFG_M2WPR1) ............................................................. 284
      6.6.8 RAMCFG memory 2 write protection register 2 (RAMCFG_M2WPR2) ............................................................. 284
      6.6.9 RAMCFG memory x ECC key register (RAMCFG_MxECCKEYR) .... 284

7.9.12 FLASH operation status register (FLASH_OPSR) ............................ 339
7.9.13 FLASH option register (FLASH_OPTR) .................................................... 340
7.9.14 FLASH nonsecure boot address 0 register (FLASH_NSBOOTADD0R) .......... 342
7.9.15 FLASH nonsecure boot address 1 register (FLASH_NSBOOTADD1R) .......... 343
7.9.16 FLASH secure boot address 0 register (FLASH_SECBOOTADD0R) ........... 344
7.9.17 FLASH secure watermark1 register 1 (FLASH_SECWM1R1) ............... 345
7.9.18 FLASH secure watermark1 register 2 (FLASH_SECWM1R2) ............... 346
7.9.19 FLASH WRP1 area A address register (FLASH_WRP1AR) .................. 347
7.9.20 FLASH WRP1 area B address register (FLASH_WRP1BR) .................. 348
7.9.21 FLASH secure watermark2 register 1 (FLASH_SECWM2R1) ............... 349
7.9.22 FLASH secure watermark2 register 2 (FLASH_SECWM2R2) ............... 350
7.9.23 FLASH WPR2 area A address register (FLASH_WRP2AR) .................. 351
7.9.24 FLASH WPR2 area B address register (FLASH_WRP2BR) .................. 352
7.9.25 FLASH OEM1 key register 1 (FLASH_OEM1KEYR1) ......................... 353
7.9.26 FLASH OEM1 key register 2 (FLASH_OEM1KEYR2) ......................... 353
7.9.27 FLASH OEM2 key register 1 (FLASH_OEM2KEYR1) ......................... 354
7.9.28 FLASH OEM2 key register 2 (FLASH_OEM2KEYR2) ......................... 354
7.9.29 FLASH secure block based bank 1 register x (FLASH_SECBB1Rrx) .......... 355
7.9.30 FLASH secure block based bank 2 register x (FLASH_SECBB2Rrx) .......... 355
7.9.31 FLASH secure HDP control register (FLASH_SECHDPCR) .................. 356
7.9.32 FLASH privilege configuration register (FLASH_PRIVCFGR) ................. 356
7.9.33 FLASH privilege block based bank 1 register x (FLASH_PRIVBB1Rrx) ........ 357
7.9.34 FLASH privilege block based bank 2 register x (FLASH_PRIVBB2Rrx) ........ 358
7.9.35 FLASH register map ................................................................. 358

8 Instruction cache (ICACHE) ......................................................... 362
8.1 ICACHE introduction ................................................................. 362
8.2 ICACHE main features ........................................ 362
8.3 ICACHE implementation ...................................... 363
8.4 ICACHE functional description ............................... 364
  8.4.1 ICACHE block diagram .................................. 364
  8.4.2 ICACHE reset and clocks ................................. 364
  8.4.3 ICACHE TAG memory .................................... 365
  8.4.4 Direct-mapped ICACHE (1-way cache) .................. 366
  8.4.5 ICACHE enable .......................................... 367
  8.4.6 Cacheable and non-cacheable traffic .................... 367
  8.4.7 Address remapping ...................................... 368
  8.4.8 Cacheable accesses ..................................... 370
  8.4.9 Dual-master cache ...................................... 371
  8.4.10 ICACHE security ....................................... 371
  8.4.11 ICACHE maintenance ................................... 371
  8.4.12 ICACHE performance monitoring ....................... 372
  8.4.13 ICACHE boot .......................................... 372
8.5 ICACHE low-power modes ................................. 372
8.6 ICACHE error management and interrupts ............... 373
8.7 ICACHE registers ........................................... 373
  8.7.1 ICACHE control register (ICACHE_CR) ................ 373
  8.7.2 ICACHE status register (ICACHE_SR) .................. 374
  8.7.3 ICACHE interrupt enable register (ICACHE_IER) ...... 375
  8.7.4 ICACHE flag clear register (ICACHE_FCR) ............ 375
  8.7.5 ICACHE hit monitor register (ICACHE_HMONR) ....... 376
  8.7.6 ICACHE miss monitor register (ICACHE_MMONR) .... 376
  8.7.7 ICACHE region x configuration register (ICACHE_CRRx) 376
  8.7.8 ICACHE register map ................................... 377

9 Data cache (DCACHE) .......................................... 379
  9.1 DCACHE introduction ....................................... 379
  9.2 DCACHE main features ..................................... 379
  9.3 DCACHE implementation .................................... 380
  9.4 DCACHE functional description ............................ 381
    9.4.1 DCACHE block diagram ................................ 381
    9.4.2 DCACHE reset and clocks .............................. 382
    9.4.3 DCACHE TAG memory ................................... 382
9.4.4 DCACHE enable ...................................................... 384
9.4.5 Cacheable and non-cacheable traffic .......................... 384
9.4.6 Cacheable accesses .............................................. 385
9.4.7 DCACHE security .................................................. 387
9.4.8 DCACHE maintenance ............................................ 387
9.4.9 DCACHE performance monitoring ......................... 389
9.4.10 DCACHE boot .................................................... 389
9.5 DCACHE low-power modes ...................................... 389
9.6 DCACHE error management and interrupts .................. 390
9.7 DCACHE registers .................................................. 391
  9.7.1 DCACHE control register (DCACHE.CR) ...................... 391
  9.7.2 DCACHE status register (DCACHE.SR) ...................... 392
  9.7.3 DCACHE interrupt enable register (DCACHE.IER) ........... 393
  9.7.4 DCACHE flag clear register (DCACHE.FCR) .................. 394
  9.7.5 DCACHE read-hit monitor register (DCACHE.RHMONR) ..... 394
  9.7.6 DCACHE read-miss monitor register (DCACHE.RMMONR) ..... 395
  9.7.7 DCACHE write-hit monitor register (DCACHE.WHMONR) ..... 395
  9.7.8 DCACHE write-miss monitor register (DCACHE.WMMONR) ... 395
  9.7.9 DCACHE command range start address register
    (DCACHE.CMDRSADDR) ........................................... 396
  9.7.10 DCACHE command range end address register
    (DCACHE.CMDREADDR) ........................................... 396
  9.7.11 DCACHE register map ........................................ 396

10 Power control (PWR) ................................................. 398
  10.1 PWR introduction ............................................... 398
  10.2 PWR main features ............................................. 398
  10.3 PWR pins and internal signals ............................... 398
  10.4 PWR power supplies and supply domains ................... 401
    10.4.1 External power supplies .................................. 401
    10.4.2 Internal regulators ....................................... 403
    10.4.3 Power-up and power-down power sequences ............... 403
    10.4.4 Independent analog peripherals supply ................. 403
    10.4.5 Independent I/O supply rail ............................. 404
    10.4.6 Independent USB transceivers supply .................... 404
    10.4.7 Battery backup domain ................................... 405
  10.5 PWR system supply voltage regulation ..................... 406
10.5.1 SMPS and LDO embedded regulators .............................................. 406
10.5.2 LDO and SMPS versus reset, voltage scaling, and low-power modes 406
10.5.3 LDO and SMPS step down converter fast startup ....................... 407
10.5.4 Dynamic voltage scaling management ........................................ 407

10.6 PWR power-supply supervision .................................................... 409
10.6.1 Brownout reset (BOR) ............................................................... 409
10.6.2 Programmable voltage detector (PVD) ...................................... 409
10.6.3 Peripheral voltage monitoring (PVM) ........................................ 410
10.6.4 Backup domain voltage and temperature monitoring ................. 411

10.7 PWR power management ............................................................... 412
10.7.1 Power modes ........................................................................... 412
10.7.2 Autonomous peripherals and low-power background autonomous mode (LPBAM) 419
10.7.3 Run mode ............................................................................... 421
10.7.4 Low-power modes ................................................................... 421
10.7.5 Sleep mode ............................................................................. 422

33.6.15 ADC offset y register (ADC_OFRy) .............................................. 1349
33.6.16 ADC gain compensation register (ADC_GCOMP) ............................. 1350
33.6.17 ADC injected data register (ADC_JDRy) ......................................... 1351
33.6.18 ADC analog watchdog 2 configuration register (ADC_AWD2CR) ........ 1351
33.6.19 ADC analog watchdog 3 configuration register (ADC_AWD3CR) ........ 1352
33.6.20 ADC watchdog threshold register 1 (ADC_LTR1) ............................. 1352
33.6.21 ADC watchdog threshold register 1 (ADC_HTR1) ............................. 1353
33.6.22 ADC watchdog lower threshold register 2 (ADC_LTR2) .................... 1353
33.6.23 ADC watchdog higher threshold register 2 (ADC_HTR2) .................. 1354
33.6.24 ADC watchdog lower threshold register 3 (ADC_LTR3) .................... 1354
33.6.25 ADC watchdog higher threshold register 3 (ADC_HTR3) .................. 1355
33.6.26 ADC differential mode selection register (ADC_DIFSEL) ................ 1355
33.6.27 ADC user control register (ADC_CALFACT) ................................... 1356
33.6.28 ADC calibration factor register (ADC_CALFACT2) ......................... 1356
33.7 ADC common registers ................................................................. 1357
33.7.1 ADC common status register (ADC12_CSR) .................................... 1357
33.7.2 ADC system control register (ADC12_CCR) .................................... 1359
33.7.3 ADC common regular data register for dual mode (ADC12_CDR) ....... 1362
33.7.4 ADC common regular data register for 32-bit dual mode (ADC12_CDR2) . 1362
33.8 ADC register map ................................................................. 1363

34 Analog-to-digital converter (ADC4) ............................................... 1367
34.1 Introduction ................................................................. 1367
34.2 ADC main features ............................................................... 1367
34.3 ADC implementation ................................................. 1368
34.4 ADC functional description ...................................... 1370
  34.4.1 ADC block diagram ............................................ 1370
  34.4.2 ADC pins and internal signals .............................. 1371
  34.4.3 ADC voltage regulator (ADVREGEN) ....................... 1372
  34.4.4 Calibration (ADCAL) .......................................... 1372
  34.4.5 ADC on-off control (ADEN, ADDIS, ADRDY) ............. 1374
  34.4.6 ADC clock (PRESC[3:0]) ................................... 1375
  34.4.7 ADC connectivity ............................................. 1377
  34.4.8 Configuring the ADC ......................................... 1378
  34.4.9 Channel selection (CHSEL, SCANDIR, CHSELRMOD) ...... 1378
  34.4.10 Programmable sampling time (SMPx[2:0]) .............. 1379
  34.4.11 Single conversion mode (CONT = 0) ...................... 1380
  34.4.12 Continuous conversion mode (CONT = 1) .................. 1380
  34.4.13 Starting conversions (ADSTART) ......................... 1381
  34.4.14 Timings ..................................................... 1382
  34.4.15 Stopping an ongoing conversion (ADSTP) .............. 1383
  34.4.16 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN) ............................................. 1383
  34.4.17 Discontinuous mode (DISCEN) ............................. 1384
  34.4.18 Programmable resolution (RES) - fast conversion mode 1384
  34.4.19 End of conversion, end of sampling phase (EOC, EOSMP flags) ............................... 1385
  34.4.20 End of conversion sequence (EOS flag) .................. 1386
  34.4.21 Example timing diagrams (single/continuous modes . 1386
    hardware/software triggers) ...................................... 1386
  34.4.22 Low-frequency trigger mode ............................... 1388
  34.4.23 Data management ............................................ 1388
  34.4.24 Low-power features ......................................... 1392
  34.4.25 Analog window watchdog .................................... 1396
  34.4.26 Oversampler ................................................ 1400
  34.4.27 Temperature sensor and internal reference voltage ...... 1403
  34.4.28 Battery voltage monitoring ............................... 1405
  34.4.29 Concurrent operation with another ADC .................. 1406
34.5 ADC low-power modes ............................................ 1407
34.6 ADC interrupts .................................................. 1407
34.7 ADC registers .................................................... 1409
  34.7.1 ADC interrupt and status register (ADC_ISR) .......... 1409

**35 Digital-to-analog converter (DAC)**  
35.1 Introduction  
35.2 DAC main features  
35.3 DAC implementation  
35.4 DAC functional description  
35.4.1 DAC block diagram  
35.4.2 DAC pins and internal signals  
35.4.3 DAC clocks  
35.4.4 DAC channel enable  
35.4.5 DAC data format  
35.4.6 DAC conversion  
35.4.7 DAC output voltage  
35.4.8 DAC trigger selection  
35.4.9 DMA requests  
35.4.10 Noise generation  
35.4.11 Triangle-wave generation  
35.4.12 DAC channel modes  
35.4.13 DAC channel buffer calibration
35.4.14 Dual DAC channel conversion modes (if dual channels are available) .................................................. 1448
35.4.15 DAC Autonomous mode .................................................. 1452
35.5 DAC in low-power modes .................................................. 1453
35.6 DAC interrupts .................................................. 1454
35.7 DAC registers .................................................. 1455
  35.7.1 DAC control register (DAC_CR) .................................................. 1455
  35.7.2 DAC software trigger register (DAC_SWTRGR) .................................................. 1458
  35.7.3 DAC channel1 12-bit right-aligned data holding register (DAC_DHR12R1) .................................................. 1459
  35.7.4 DAC channel1 12-bit left-aligned data holding register (DAC_DHR12L1) .................................................. 1460
  35.7.5 DAC channel1 8-bit right-aligned data holding register (DAC_DHR8R1) .................................................. 1460
  35.7.6 DAC channel2 12-bit right-aligned data holding register (DAC_DHR12R2) .................................................. 1461
  35.7.7 DAC channel2 12-bit left-aligned data holding register (DAC_DHR12L2) .................................................. 1461
  35.7.8 DAC channel2 8-bit right-aligned data holding register (DAC_DHR8R2) .................................................. 1462
  35.7.9 Dual DAC 12-bit right-aligned data holding register (DAC_DHR12RD) .................................................. 1462
  35.7.10 Dual DAC 12-bit left-aligned data holding register (DAC_DHR12LD) .................................................. 1463
  35.7.11 Dual DAC 8-bit right-aligned data holding register (DAC_DHR8RD) .................................................. 1463
  35.7.12 DAC channel1 data output register (DAC_DOR1) .................................................. 1464
  35.7.13 DAC channel2 data output register (DAC_DOR2) .................................................. 1464
  35.7.14 DAC status register (DAC_SR) .................................................. 1465
  35.7.15 DAC calibration control register (DAC_CCR) .................................................. 1466
  35.7.16 DAC mode control register (DAC_MCR) .................................................. 1467
  35.7.17 DAC channel1 sample and hold sample time register (DAC_SHSR1) .................................................. 1468
  35.7.18 DAC channel2 sample and hold sample time register (DAC_SHSR2) .................................................. 1469
  35.7.19 DAC sample and hold time register (DAC_SHHR) .................................................. 1469
  35.7.20 DAC sample and hold refresh time register (DAC_SHRR) .................................................. 1470
  35.7.21 DAC Autonomous mode control register (DAC_AUTOCR) .................................................. 1471
  35.7.22 DAC register map .................................................. 1471
36 Voltage reference buffer (VREFBUF) ........................................ 1474
  36.1 Introduction .......................................................... 1474
  36.2 VREFBUF implementation ............................................. 1474
  36.3 VREFBUF functional description .................................... 1474
  36.4 VREFBUF trimming ................................................... 1475
  36.5 VREFBUF registers ................................................... 1476
    36.5.1 VREFBUF control and status register (VREFBUF_CSR) ....... 1476
    36.5.2 VREFBUF calibration control register (VREFBUF_CCR) ....... 1477
    36.5.3 VREFBUF register map ....................................... 1477

37 Comparator (COMP) ..................................................... 1478
  37.1 Introduction .......................................................... 1478
  37.2 COMP main features ................................................ 1478
  37.3 COMP implementation ............................................... 1478
  37.4 COMP functional description ..................................... 1479
    37.4.1 COMP block diagram ...................................... 1479
    37.4.2 COMP pins and internal signals ............................ 1479
    37.4.3 Comparator LOCK mechanism ................................ 1481
    37.4.4 Window comparator ........................................ 1481
    37.4.5 Hysteresis .................................................. 1482
    37.4.6 Comparator output-blanking function ....................... 1482
    37.4.7 COMP power and speed modes ............................... 1483
    37.4.8 Scaler function ........................................... 1483
  37.5 COMP low-power modes ............................................. 1484
  37.6 COMP interrupts ................................................... 1484
  37.7 COMP registers .................................................... 1485
    37.7.1 COMP1 control and status register (COMP1_CSR) .......... 1485
    37.7.2 COMP2 control and status register (COMP2_CSR) .......... 1486
    37.7.3 COMP register map ....................................... 1488

38 Operational amplifier (OPAMP) ........................................ 1489
  38.1 OPAMP introduction ................................................ 1489
  38.2 OPAMP main features ............................................... 1489
  38.3 OPAMP functional description .................................... 1489
    38.3.1 OPAMP reset and clocks .................................... 1489
38.3.2 Initial configuration .............................................. 1490
38.3.3 Signal routing ................................................. 1490
38.3.4 OPAMP modes .................................................. 1491
38.3.5 Calibration ....................................................... 1494

38.4 OPAMP low-power modes ........................................ 1496

38.5 OPAMP registers .................................................. 1496
38.5.1 OPAMP1 control/status register (OPAMP1_CSR) .......... 1496
38.5.2 OPAMP1 offset trimming register in normal mode (OPAMP1_OTR) .... 1498
38.5.3 OPAMP1 offset trimming register in low-power mode (OPAMP1_LPOTR) .... 1498
38.5.4 OPAMP2 control/status register (OPAMP2_CRS) .......... 1499
38.5.5 OPAMP2 offset trimming register in normal mode (OPAMP2_OTR) .... 1500
38.5.6 OPAMP2 offset trimming register in low-power mode (OPAMP2_LPOTR) .... 1501
38.5.7 OPAMP register map .......................................... 1501

39 Multi-function digital filter (MDF) ........................................... 1503

39.1 Introduction ....................................................... 1503
39.2 MDF main features ............................................... 1504
39.3 MDF implementation .............................................. 1504
39.4 MDF functional description ...................................... 1506
39.4.1 MDF block diagram .......................................... 1506
39.4.2 MDF pins and internal signals ................................ 1506
39.4.3 Serial input interfaces (SITF) ................................. 1508
39.4.4 ADC slave interface (ADCITF) ................................ 1513
39.4.5 Clock generator (CKGEN) ...................................... 1514
39.4.6 Bitstream matrix (BSMX) ....................................... 1516
39.4.7 Short-circuit detectors (SCD) ................................. 1517
39.4.8 Digital filter processing (DFLT) ......................... 1519
39.4.9 Out-of-limit detector (OLD) .................................... 1529
39.4.10 Digital filter acquisition modes ......................... 1532
39.4.11 Start-up sequence examples .................................. 1541
39.4.12 Break interface ............................................... 1543
39.4.13 Data transfer to memory ..................................... 1544
39.4.14 Autonomous mode ............................................. 1549
39.4.15 Register protection ............................................ 1550

39.5 MDF low-power modes ............................................. 1551
39.6 MDF interrupts ........................................................... 1551
39.7 MDF application informations ...................................... 1553
   39.7.1 MDF configuration examples for audio capture .......... 1553
   39.7.2 Programming examples ...................................... 1554
   39.7.3 Connection examples .................................... 1556
   39.7.4 Global frequency response .......................... 1557
   39.7.5 Total MDF gain ........................................ 1558
39.8 MDF registers ....................................................... 1562
   39.8.1 MDF global control register (MDF_GCR) ............... 1563
   39.8.2 MDF clock generator control register (MDF_CKGC R) ........ 1563
   39.8.3 MDF serial interface control register x (MDF_SITFxCR) .......... 1566
   39.8.4 MDF bitstream matrix control register x (MDF_BSMXxCR) .......... 1567
   39.8.5 MDF digital filter control register x (MDF_DFLTxCR) .......... 1568
   39.8.6 MDF digital filter configuration register x (MDF_DFLTxCICR) .... 1570
   39.8.7 MDF reshape filter configuration register x (MDF_DFLTxRSFR) .... 1571
   39.8.8 MDF integrator configuration register x (MDF_DFLTxINTR) .... 1572
   39.8.9 MDF out-of-limit detector control register x (MDF_OL DxCR) .......... 1573
   39.8.10 MDF OL Dx low threshold register x (MDF_OL DxTHLR) .......... 1575
   39.8.11 MDF OL Dx high threshold register x (MDF_OL DxTHHR) .......... 1575
   39.8.12 MDF delay control register x (MDF_DLYxCR) ............ 1576
   39.8.13 MDF short circuit detector control register x (MDF_SCDxCR) .......... 1576
   39.8.14 MDF DFLT0 interrupt enable register 0 (MDF_DFLTxIER) .... 1577
   39.8.15 MDF DFLTx interrupt enable register x (MDF_DFLTxIER) .... 1579
   39.8.16 MDF DFLT0 interrupt status register 0 (MDF_DFLTxISR) .... 1580
   39.8.17 MDF DFLTx interrupt status register x (MDF_DFLTxISR) .... 1582
   39.8.18 MDF offset error compensation control register x (MDF_OECx CR) . 1583
   39.8.19 MDF snapshot data register x (MDF_SNPSxDR) ............ 1584
   39.8.20 MDF digital filter data register x (MDF_DFLTxDR) .......... 1584
   39.8.21 MDF register map ..................................... 1585

40 Audio digital filter (ADF) ................................................... 1587
   40.1 Introduction ................................................. 1587
   40.2 ADF main features .......................................... 1587
   40.3 ADF implementation ........................................ 1588
   40.4 ADF functional description ................................ 1589
      40.4.1 ADF block diagram .................................... 1589
40.4.2 ADF pins and internal signals ........................................ 1589
40.4.3 Serial input interface (SITF) ........................................ 1590
40.4.4 ADC slave interface (ADCITF) ...................................... 1594
40.4.5 Clock generator (CKGEN) .......................................... 1595
40.4.6 Bitstream matrix (BSMX) .......................................... 1597
40.4.7 Digital filter processing (DFLT) .................................... 1598
40.4.8 Digital filter acquisition modes .................................... 1608
40.4.9 Start-up sequence acquisition examples ......................... 1616
40.4.10 Sound activity detection (SAD) .................................... 1617
40.4.11 Data transfer to memory ........................................... 1625
40.4.12 Autonomous mode .................................................. 1628
40.4.13 Register protection .................................................. 1628
40.5 ADF low-power modes .................................................. 1629
40.6 ADF interrupts ......................................................... 1629
40.7 ADF application information .......................................... 1631
  40.7.1 ADF configuration examples for audio capture ............... 1631
  40.7.2 Programming examples ............................................ 1632
  40.7.3 Connection examples ............................................. 1634
  40.7.4 Global frequency response ...................................... 1635
  40.7.5 Total ADF gain .................................................... 1636
  40.7.6 How to compute SAD thresholds .................................. 1639
40.8 ADF registers ......................................................... 1644
  40.8.1 ADF global control register (ADF_GCR) ......................... 1644
  40.8.2 ADF clock generator control register (ADF_CKGR) ........... 1645
  40.8.3 ADF serial interface control register 0 (ADF_SITF0CR) .... 1647
  40.8.4 ADF bitstream matrix control register 0 (ADF_BSMX0CR) .. 1648
  40.8.5 ADF digital filter control register 0 (ADF_DFLT0CR) ........ 1649
  40.8.6 ADF digital filter configuration register 0 (ADF_DFLT0CFR) 1651

## 1.1 General information

The STM32U5 Series devices have an Arm®(a) Cortex®-M33 core, with Arm® TrustZone®.

## 1.2 List of abbreviations for registers

The following abbreviations(b) are used in register descriptions:

<table>
<thead>
<tr>
<th>Abbreviation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>read/write (rw)</td>
<td>Software can read and write to this bit.</td>
</tr>
<tr>
<td>read-only (r)</td>
<td>Software can only read this bit.</td>
</tr>
<tr>
<td>write-only (w)</td>
<td>Software can only write to this bit. Reading this bit returns the reset value.</td>
</tr>
<tr>
<td>read/clear write0 (rc_w0)</td>
<td>Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.</td>
</tr>
<tr>
<td>read/clear write1 (rc_w1)</td>
<td>Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.</td>
</tr>
<tr>
<td>read/clear write (rc_w)</td>
<td>Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.</td>
</tr>
<tr>
<td>read/clear by read (rc_r)</td>
<td>Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.</td>
</tr>
<tr>
<td>read/set by read (rs_r)</td>
<td>Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.</td>
</tr>
<tr>
<td>read/set (rs)</td>
<td>Software can read as well as set this bit. Writing 0 has no effect on the bit value.</td>
</tr>
<tr>
<td>read/write once (rwo)</td>
<td>Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.</td>
</tr>
<tr>
<td>toggle (t)</td>
<td>The software can toggle this bit by writing 1. Writing 0 has no effect.</td>
</tr>
<tr>
<td>read-only write trigger (rt_w1)</td>
<td>Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.</td>
</tr>
<tr>
<td>Reserved (Res.)</td>
<td>Reserved bit, must be kept at reset value.</td>
</tr>
</tbody>
</table>

---

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.
b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.
1.3 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **AHB**: advanced high-performance bus.
- **APB**: advanced peripheral bus.

1.4 Availability of peripherals

For availability of peripherals on specific devices, refer to *Table 6: Memory map and peripheral register boundary addresses*.

For detailed availability of peripherals and their number across all sales types (depending on product line and package), refer to the device datasheet.
2 Memory and bus architecture

2.1 System architecture

The STM32U5 Series architecture relies on an Arm Cortex-M33 core optimized for execution thanks to an instruction cache having a direct access to the embedded flash memory.

This architecture also features a 32-bit multi-layer AHB bus matrix that interconnects master and slave as shown in the tables below.

</table>
The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously. This architecture is shown in the figure below.

**Figure 1. System architecture**

### 2.1.1 Fast C-bus

This bus connects the C-bus of the Cortex-M33 core to the internal flash memory and to the bus matrix via the instruction cache. This bus is used for instruction fetch and data access to the internal memories mapped in the code region. This bus targets the internal flash memory and the internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM5, and SRAM6).

SRAM1, SRAM2, SRAM3, SRAM5, and SRAM6 are accessible on this bus with a continuous mapping.

### 2.1.2 Slow C-bus

This bus connects the C-bus of the Cortex-M33 core to the bus matrix via the instruction cache. This bus is used for instruction fetch and data access to the external memories mapped in the code region. This bus targets the external memories (FSMC, HSPI1, and OCTOSPIs).
2.1.3 S-bus

This bus connects the system bus of the Cortex-M33 core to the bus matrix. This bus is used by the core to access data located in a peripheral or SRAM area. This bus targets the internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM4, SRAM5, SRAM6, and BKPSRAM), the AHB1 peripherals including the APB1 and APB2 peripherals, the AHB2 peripherals and the SRD peripherals.

SRAM1, SRAM2, SRAM3, SRAM5, and SRAM6 are accessible on this bus with a continuous mapping.

*Note:* The bus matrix has a zero latency when accessing SRAM1, SRAM2, SRAM3, SRAM5, and SRAM6.

2.1.4 DCACHE S-bus

This bus connects the system bus of the Cortex-M33 core to the bus matrix via the data cache. This bus is used for instruction fetch and data access to the external memories mapped in the data region. This bus targets the external memories (FSMC, HSPI1, GFXMMU, and OCTOSPIs).

*Note:* Fetching instructions through this bus is less efficient than fetching instructions through the slow C-bus.

2.1.5 GPDMA-bus

These buses connect the two AHB master interfaces of the GPDMA to the bus matrix. These buses target the internal flash memory, the internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM4, SRAM5, SRAM6, and BKPSRAM), the AHB1 peripherals including the APB1 and APB2 peripherals, the AHB2 peripherals, the SRD peripherals and the external memories through FSMC, HSPI1, or OCTOSPIs.

2.1.6 OTG_HS-bus

This bus connects the OTG_HS master interface to the bus matrix. This bus is used only by the OTG_HS to load/store data from/to the memory. This bus targets the data memories: internal flash memory, internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM5, and SRAM6) and external memories through FSMC, HSPI1, or OCTOSPIs.

2.1.7 LTDC-bus

This bus connects the LTDC master interface to the bus matrix. This bus is used only to load data from the memory. This bus targets the GFXMMU in addition to the data memories: internal flash memory, internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM5, and SRAM6) and external memories through FSMC, HSPI1 or OCTOSPIs.

2.1.8 GPU2D-bus

These buses connect the GPU2D master interfaces to the bus matrix. These buses are used only by the GPU2D to load/store data from/to the memory. These buses target the GFXMMU in addition to the data memories: internal flash memory, internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM5, and SRAM6) and external memories through FSMC, HSPI1, or OCTOSPIs. A 16-Kbyte data cache (DCACHE2) is present on the GPU2D M0 bus in order to improve performances.
2.1.9 GFXMMU-bus

This bus connects the GFXMMU master interface to the bus matrix. This bus is used only by the GFXMMU to load/store data from/to the memory. This bus targets the data memories: internal flash memory, internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM5, and SRAM6) and external memories through FSMC, HSPI1, or OCTOSPIs. The GFXMMU has also a slave bus connection to be accessed by graphical peripheral master buses.

2.1.10 SDMMC1 and SDMMC2 controllers DMA buses

These buses connect the SDMMC1 and SDMMC2 DMA master interfaces to the bus matrix. These buses are used only by the SDMMC1 and SDMMC2 DMA to load/store data from/to the memory. These buses target the data memories: internal flash memory, internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM5, and SRAM6) and external memories through FSMC, HSPI1, or OCTOSPIs.

2.1.11 Bus matrix

The bus matrix manages the access arbitration between masters. The arbitration uses a round-robin algorithm. This bus matrix features a fast bus multiplexer used to connect each master to a given slave without latency (see Figure 1). For the same master, other slaves undergo a latency of at least one cycle at each new access.

2.1.12 AHB/APB bridges

The three AHB/APB bridges provide full synchronous connections between the AHB and the APB buses, allowing flexible selection of the peripheral frequency.

Refer to Section 2.3.2: Memory map and register boundary addresses for the address mapping of the peripherals connected to these bridges.

After each device reset, all peripheral clocks are disabled (except for the internal SRAMs and flash memory interfaces). Before using a peripheral, its clock must be enabled in the RCC_AHBxENR and RCC_APBxENR registers.

Note: When an 8- or 16-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 8- or 16-bit data to feed the 32-bit vector.

2.1.13 SmartRun domain (SRD)

The SRD architecture relies on a DMA allowing autonomous operation during low-power modes down to Stop 2.

This architecture also features a 32-bit AHB bus matrix that interconnects:

- two masters:
  - the main AHB bus matrix
  - LPDMA1 (low-power DMA featuring one master port)
- two slaves:
  - AHB3 peripherals including AHB to APB bridge connected to APB3
  - internal SRAM4

Note: The SRAM4 is the only SRAM that can be accessed by the LPDMA1.
This architecture is shown in the figure below.

**Figure 2. SmartRun domain architecture**

![SmartRun domain architecture diagram](image)

### 2.2 Arm TrustZone security architecture

The security architecture is based on Arm TrustZone with the Armv8-M mainline extension. The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.

When the TrustZone is enabled, the SAU (security-attribution unit) and IDAU (implementation-defined-attribution unit) defines the access permissions based on secure and nonsecure states.

- **SAU**: Up to eight SAU configurable regions are available for security attribution.
- **IDAU**: provides a first memory partition as nonsecure or nonsecure callable attributes. The IDAU memory map partition is not configurable and fixed by hardware implementation (refer to Figure 3 to Figure 6 in Section 2.3.2: Memory map and register boundary addresses). It is then combined with the results from the SAU security attribution and the higher security state is selected.

Based on IDAU security attribution, the flash memory, system SRAMs, and peripherals memory space are aliased twice for secure and nonsecure states. The external memories space is not aliased.

The table below shows an example of typical eight SAU regions mapping based on IDAU regions. The user can split and choose the secure, nonsecure or NSC regions for external memories as needed.

<table>
<thead>
<tr>
<th>Region description</th>
<th>Address range</th>
<th>IDAU security attribution</th>
<th>SAU security attribution typical configuration</th>
<th>Final security attribution</th>
</tr>
</thead>
<tbody>

<td>Nonsecure</td>
</tr>
<tr>
<td></td>
<td>0xC00_0000 0x0FF_FFFF</td>
<td>NSC</td>
<td>Secure or NSC</td>
<td>Secure or NSC</td>
</tr>
</tbody>
</table>

<sup>(1)</sup> NSC stands for Normal Secure Code.
2.2.1 Default Arm TrustZone security state

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR, the default system security state is detailed below:

- **CPU**: Cortex-M33 is in secure state after reset. The boot address must be at a secure address.
- **memory map**: SAU is fully secure after reset. Consequently, all memory map is fully secure. Up to height SAU configurable regions are available for security attribution.
- **flash memory**: The flash memory security area is defined by watermark user options.
- **Flash block-based security attributions are nonsecure after reset.**
- **SRAMs**: All SRAMs are secure after reset. MPCBBx (block-based memory protection controller) are secure.
- **external memories**: FSMC, HSPI1 and OCTOSPIs banks are secure after reset. MPCWMx (watermark-based memory protection controller) are secure.
- **peripherals (see Table 4 and Table 5 for a list of securable and TrustZone-aware peripherals)**
  - Securable peripherals are nonsecure after reset.
  - TrustZone-aware peripherals are nonsecure after reset. Their secure configuration registers are secure.
- **all GPIOs secure after reset**
- **interrupts**: 
  - NVIC: All interrupts are secure after reset. NVIC is banked for secure and nonsecure state.
  - TZIC: All illegal access interrupts are disabled after reset (see GTZC TrustZone system architecture).
2.2.2 **Arm TrustZone peripheral classification**

When the TrustZone security is active, a peripheral can be either securable or TrustZone-aware type as follows:

- **Securable**: peripheral protected by an AHB/APB firewall gate that is controlled from TZSC controller to define security properties.
- **TrustZone-aware**: peripheral connected directly to AHB or APB bus and implementing a specific TrustZone behavior such as a subset of registers being secure.

Refer to *GTZC TrustZone system architecture* for more details.

The tables below list the securable and TrustZone-aware peripherals within the system.

1. Always secure when TZEN = 1.
2.3 Memory organization

2.3.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word’s least significant byte and the highest numbered byte the most significant.
### 2.3.2 Memory map and register boundary addresses

**Note:** The table entries for the Secure boundary address, Nonsecure boundary address, Size (bytes), Peripheral, and Peripheral register map columns are in hexadecimal format. The last two columns represent the peripheral register map for different STM32U5 series processors (e.g., STM32U535/545, STM32U575/585, STM32U59x/5Ax, STM32U5Fx/5Gx).

1. Only one COMP in STM32U535/545.
2. No dual ADC mode on STM32U535/545/575/585.
3. MDF features only two filters in STM32U535/545.
2.3.3 Embedded SRAMs

These SRAMs can be accessed as bytes, half-words (16 bits), or full words (32 bits). These memories can be addressed both by CPU and DMAs.

The CPU can access the SRAM1, SRAM2, SRAM3, SRAM5, and SRAM6 through the system bus, or through the C-bus depending on the selected address. The CPU can access the SRAM4 and BKPSRAM through the system bus only.

When the TrustZone security is enabled, all SRAMs are secure after reset. The SRAM can be programmed as nonsecure with a block granularity. For more details, refer to Section 5: Global TrustZone controller (GTZC).

SRAM features are detailed in Section 6.3.1: Internal SRAMs features.

2.3.4 Flash memory overview

The flash memory is composed of two distinct physical areas:

- the main flash memory block, that contains the application program and user data
- the information block, that is composed of the following parts:
  - option bytes for hardware and memory protection user configuration
  - system memory that contains ST proprietary code
  - OTP (one-time programmable) area

The flash interface implements instruction access and data access based on the AHB protocol. It also implements the logic necessary to carry out the flash memory operations (program/erase) controlled through the FLASH registers plus security access control features. Refer to Section 7: Embedded flash memory (FLASH) for more details.
3 System security

The STM32U5 Series devices are designed with a comprehensive set of security features, some of which being based on the standard Arm TrustZone technology. These security features simplify the process of evaluating IoT devices against security standards. They also significantly reduce the cost and complexity of software development for OEM and third-party developers, by facilitating the reuse, improving the interoperability, and minimizing the API fragmentation.

This section explains the different security features available on STM32U5 Series devices.

3.1 Key security features

- Resource isolation using privilege mode and Armv8-M mainline security extension of the Cortex-M33, extended to securable I/Os, memories, and peripherals
- Secure firmware installation (SFI) with device unique cryptographic key pair
  - leveraging the on-chip immutable bootloader that supports the download of the image through USART, USB, I²C, SPI, FDCAN, and JTAG
- Secure boot thanks to the unique boot entry feature and hide-protect area (HDP) mechanism
- Secure storage, featuring:
  - Nonvolatile on-chip secure storage, protected with secure and HDP areas
  - Battery-powered volatile secure storage, automatically erased in case of tamper
  - Write-only key registers in the AES engines
  - Device 96-bit unique ID and JTAG 32-bit device-specific ID
  - On-chip enhance storage technology, using hardware secret nonvolatile derived hardware unique keys (DHUK), and application-defined volatile boot hardware key (BHK), both loadable by hardware to the DPA-resistant SAES engine
- General purpose cryptographic acceleration:
  - AES 256-bit engine, supporting ECB, CBC, CTR, GCM, and CCM chaining modes
  - Secure AES 256-bit security coprocessor, supporting ECB and CBC chaining modes with side-channel counter-measures and mitigations
  - HASH processor, supporting MD5/SHA-1 checksums and SHA-2 secure hash
  - Public key accelerator (PKA) for RSA/DH (up to 4096 bits) and ECC (up to 640 bits), implementing side-channel counter measures and mitigations when manipulating secrets
  - True random number generator (RNG), NIST SP800-90B pre-certified
- On-the-fly decryption of encrypted image stored on external flash memory connected through the OCTOSPI:
  - Almost-zero latency with standard NOR flash memories
  - Can be used to encrypt the image using device-unique secret keys
  - Automatic key erase in case of tamper
- Flexible life-cycle scheme with readout protection (RDP), including support for product decommissioning (auto-erase)
  - Debug protection, depending on the RDP level
3.2 Secure install

The secure firmware install (SFI) is an STMicroelectronics secure service authenticated and decrypted by the immutable RSS code stored in the device. The SFI allows secure and counted installation of OEM firmware in the untrusted production environment (such as the OEM contract manufacturer).

The confidentiality of the installed images written either in the internal flash memory or encrypted in an external flash memory, is also protected, using the AES.

The SFI native service leverages the following hardware security features:

- secure boot (see Section 3.3)
- resource isolation using TrustZone (see Section 3.5)
- temporal isolation using hide protection (see Section 3.6.1)
- secure execution (see Section 3.7)
- secure storage, with associated cryptographic engines (see Section 3.8 and Section 3.9)

Further information can be found in the application note: “STM32 MCUs secure firmware install (SFI) overview” (AN4992).

3.3 Secure boot

Secure boot is an immutable code that is always executed after a system reset. As a root of trust, this code checks the device static protections and activates available device runtime protections, reducing the risk that invalid or malicious code runs on the platform. As root of trust, the secure boot also checks the integrity and authenticity of the next level firmware before executing it.

The actual functions of the secure boot depend on the availability of TrustZone features, and on the firmware stored in the device. However, the secure boot typically initializes the secure storage, and installs on-the-fly decryption keys in the OTFDEC, to be able to use encrypted firmware stored in an external flash memory.

The device trusted firmware-M (TFM) application, supported by the STM32 ecosystem, provides a root of trust solution including secure boot functions. For more information, refer to the user manual Getting started with STM32CubeU5 TFM application (UM2851).

In the devices, the secure boot takes benefit of hardware security features such as:

- resource isolation using TrustZone (see Section 3.5)
- temporal isolation using hide protection (see Section 3.6.1)
- secure execution (see Section 3.7)
- secure install and update (see Section 3.2 and Section 3.4)
secure storage, with associated cryptographic engines if available (see Section 3.8 and Section 3.9)

This section describes the features specifically designed for secure boot.

3.3.1 Unique boot entry and BOOT_LOCK

When TrustZone is activated (TZEN = 1) and the BOOT_LOCK secure option bit is cleared, the application selects a boot entry point located either in the system flash memory (see the next section), or in the secure user flash memory, at the address defined by SECBOOTADD0 option bytes.

When TrustZone is activated (TZEN = 1) and the BOOT_LOCK secure option bit is set, the device unique boot entry is the unmodifiable secure address defined by SECBOOTADD0 option bytes. All these option bytes cannot be modified by the application anymore when BOOT_LOCK is set.

Note: As long as it is cleared, the BOOT_LOCK option bit can be set without any constraint. But once set, the BOOT_LOCK option bit cannot be cleared when RDP level > 0.

For more information on the boot mechanisms, refer to Section 4: Boot modes.

3.3.2 Immutable root of trust in system flash memory

The immutable root-of-trust code stored in the system flash memory is first used to initiate the SFI, allowing secure and counted installation of OEM firmware in the untrusted production environment (such as the OEM contract manufacturer).

The STMicroelectronics immutable code also includes secure runtime services that can be called at runtime when a secure application sets the SYSCFG_RSSCMDR register to a non-null value before triggering a system reset. This runtime feature is deactivated when the BOOT_LOCK secure option bit is set, and the secure address defined by SECBOOTADD0 is set on the secure user flash memory.

3.4 Secure update

The secure firmware update is a secure service that runs after a secure boot. Its actual functions depend on the availability of the TrustZone features, and on the firmware stored in the device.

The device trusted firmware-M (TFM) application, supported by the STM32 ecosystem, allows the update of the microcontroller built-in program with new firmware versions, adding new features and correcting potential issues. The update process is performed in a secure way to prevent unauthorized updates and access to confidential on-device data.

A firmware update can be done either on a single firmware image including both secure and nonsecure parts, or on the secure (respectively nonsecure) part of the firmware image, independently.

In the devices, the secure update application leverages the same hardware security as the firmware install described in Section 3.2. For more information, refer to the user manual: Getting started with STM32CubeU5 TFM application (UM2851).
3.5 Resource isolation using TrustZone

In the STM32U5 Series devices, the hardware and software resources can be partitioned so that they exist either in the secure world or in the nonsecure world, as shown in the figure below.

Figure 7. Secure/nonsecure partitioning using TrustZone technology

Note: The initial partitioning of the platform is under the responsibility of the secure firmware executed after the reset of the device.

Thanks to this resource isolation technology, the secure world can be used to protect critical code against intentional or unintentional tampering from the more exposed code running in the nonsecure world.

Note: The secure code is typically small and rarely modified, while nonsecure code is more exposed, and prone to firmware updates.

3.5.1 TrustZone security architecture

The Armv8-M TrustZone technology is a comprehensive hardware architecture that proposes to developers a comprehensive, holistic protection across the entire processor and system. The device TrustZone hardware features include:

- the Armv8-M mainline security extension of Cortex-M33, enabling a new processor secure state, with its associated secure interrupts
- the dynamic allocation of memory and peripherals to TrustZone using eight security attribution unit (SAU) regions of Cortex-M33
- a global TrustZone framework (GTZC), extending the TrustZone protection against transactions coming from other masters in the system than the Cortex-M33
- TrustZone-aware embedded flash memory and peripherals

Note: The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.
3.5.2 Armv8-M security extension of Cortex-M33

The Arm security extension of the Cortex-M33 is an evolution, not a revolution. It uses the programmer model from earlier Cortex-M subfamilies like Cortex-M4. Indeed, Armv8-M is architecturally similar to Armv7-M, using the same 32-bit architecture, the same memory mapped resources protected with an MPU. Armv8-M also uses the nested vectored interrupt controller (NVIC).

The Armv8-M TrustZone implementation in STM32U5 Series devices is composed of the following features:

- a new processor state, with almost no additional code/cycle overhead, as opposed to Armv8-A TrustZone that uses a dedicated exception routine for triggering a secure/nonsecure world change
- two memory map views of a shared 4-Gbyte address space
- a low interrupt latency for both secure and nonsecure domains, and a new interrupt configuration for security grouping and priority setting
- separated exception vector tables for the secure and nonsecure exceptions
- micro-coded context preservation
- banking of specific registers across secure/nonsecure states, including stack pointers with stack-limit checkers
- banking of the following Cortex-M33 programmable components (two separate units for secure and nonsecure):
  - SysTick timer
  - MPU configuration registers (eight MPU regions in secure, eight in nonsecure)
  - some of the system control block (SCB) registers
- new system exception (SecureFault) for handling of security violations
- configurable debug support, as defined in Section 3.11

For more information, refer to STM32 Cortex-M33 MCUs programming manual (PM0264).

3.5.3 Memory and peripheral allocation using IDAU/SAU

Security attributes

As illustrated on Figure 8, the Armv8-M nonsecure memory view is similar to Armv7-M (that can be found in Cortex-M4), with the difference that the secure memory is hidden. The secure memory view shows the flash memory, SRAM, and peripherals that are only accessible while the Cortex processor executes in Secure state.
The figure below shows the 32-bit address space viewed after the SAU configuration by the secure code.

**Figure 8. Sharing memory map between CPU in secure and nonsecure state**

The Cortex processor state (and associated rights) depends on the security attribute assigned to the memory region where it is executed:

- A processor in a nonsecure state only executes from nonsecure (NS) program memory, while a processor in a secure state only executes from secure (S) program memory.
- While running in the secure state, the processor can access data from both S and NS memories. Running in the nonsecure state, the CPU is limited to nonsecure memories.

In order to manage transitions to the secure world, developers must create nonsecure callable (NSC) regions that contain valid entry points to the secure libraries. The first instruction in these entry points must be the new secure gate (SG) instruction, used by the nonsecure code to call a secure function (see the figure below).

**Figure 9. Secure world transition and memory partitioning**
Programming security attributes

In Cortex-M33, the static implementation defined attribution unit (IDAU) works in conjunction with the programmable security attribution unit (SAU) to assign a specific security attribute (S, NS, or NSC) to a specific address, as shown in the table below.

<table>
<thead>
<tr>
<th>IDAU security attribution</th>
<th>SAU security attribution(1)</th>
<th>Final security attribution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nonsecure</td>
<td>Secure</td>
<td>Secure</td>
</tr>
<tr>
<td></td>
<td>Secure-NSC</td>
<td>Secure-NSC</td>
</tr>
<tr>
<td></td>
<td>Nonsecure</td>
<td>Nonsecure</td>
</tr>
<tr>
<td>Secure-NSC</td>
<td></td>
<td>Secure</td>
</tr>
<tr>
<td></td>
<td>Nonsecure</td>
<td>Secure-NSC</td>
</tr>
</tbody>
</table>

1. Defined regions are aligned to 32-byte boundaries.

The SAU can only be configured by the Cortex-M33 in the secure-privilege state. When the TrustZone is enabled, the SAU defaults all addresses as secure (S). A secure boot application can then program the SAU to create NSC or NS regions, as shown in the previous table.

**Note:** The SAU/IDAU settings are applicable only to the Cortex-M33. The other masters like DMA are not affected by these policies.

A memory space not covered by an SAU region is fixed as secure.

For more information on memory security attribution using IDAU/SAU, refer to the application note *TrustZone features on STM32L5 and STM32U5 Series (AN5347).*

### 3.5.4 Memory and peripheral allocation using GTZC

**Global TrustZone framework architecture**

On top of the Armv8-M TrustZone security extension in Cortex-M33, the devices embed complementary security features that reinforce, in a flexible way, the isolation between the secure and the nonsecure worlds. Unlike the SAU/IDAU, the GTZC can protect legacy memories and peripherals against insecure transactions coming from other masters than the Cortex-M33.
Securing peripherals with TZSC

When the TrustZone security is active, a peripheral is either securable through the TZSC in GTZC, or is natively TrustZone-aware, as shown in the previous figure:

- A securable peripheral or memory is protected by an AHB/APB firewall gate, that is controlled by the TrustZone security controller (TZSC).
- A TrustZone-aware peripheral or memory is connected directly to the AHB or APB interconnect, implementing a specific TrustZone behavior, such as a subset of secure registers, or a secure memory area.

When a securable peripheral is made secure-only with the GTZC, if this peripheral is master on the interconnect (such as SDMMC), it automatically issues secure transactions. The SDMMC is an example of securable master. TrustZone-aware AHB masters like Cortex-M33 or DMAs, drive a secure signal in the AHB interconnect, according to their security mode, independently to the GTZC.
**Note:** Like with TrustZone, a peripheral can be made privileged-only with TZSC (see Section 3.6.2). In this case, if this peripheral is master on the interconnect, it automatically issues privileged transactions.

**Securing memories with TZSC and MPCBB**

The TZSC block in GTZC provides the capability to manage the security and privilege for all securable external memories, programming the MPCWM resources.

The table below shows an implementation example. For all other implementations on the STM32U5 Series devices, refer to Section 5.3: GTZC implementation.

<table>
<thead>
<tr>
<th>Table 9. MPCWMx resources</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Memory</strong></td>
</tr>

</tr>
<tr>
<td>OCTOSPI2</td>
</tr>
<tr>
<td>HSPI1</td>
</tr>
</tbody>
</table>

1. Using the OTFDEC.
2. Assuming TrustZone is activated on the device, nonsecure unprivileged otherwise.

The MPCBB resources in GTZC provide the capability to configure the security and privilege of embedded SRAM blocks.

The table below shows an implementation example. For all other implementations on the STM32U5 Series devices, refer to Section 5.3: GTZC implementation.

<table>
<thead>
<tr>
<th>Table 10. MPCBBx resources</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Memory</strong></td>
</tr>
<tr>
<td>SRAM1</td>
</tr>
<tr>
<td>SRAM2</td>
</tr>
<tr>
<td>SRAM3</td>
</tr>
<tr>
<td>SRAM4</td>
</tr>
<tr>
<td>SRAM5</td>
</tr>
<tr>
<td>SRAM6</td>
</tr>
</tbody>
</table>

1. Blocks are grouped in super-blocks of 32 consecutive blocks, to manage the configuration locking.
2. Assuming TrustZone is activated on the device, nonsecure unprivileged otherwise.
Applying GTZC configurations

The TZSC and MPCBB blocks can be used in one of the following ways:

- statically programmed during the secure boot, locked and not changed afterwards
- dynamically reprogrammed using a specific application code or real-time kernel

When the dynamic option is selected and the configuration is not locked:

- MPCBB secure blocks or MPCWM nonsecure region size can be changed by a secure software. This software must be privileged for MPCWM, can be unprivileged if the particular block is not privileged-only.
- The secure (respectively privilege) state of each peripheral can be changed writing to GTZC_TZSC_SECCFRGx (respectively GTZC_TZSC_PRIVCFGRx) registers.

Securing peripherals with TZSC

The TZSC block in GTZC provides the capability to manage the security and the privilege for all securable peripherals. The list of these peripherals can be found in Section 5: Global TrustZone controller (GTZC).

Note: When the TrustZone is deactivated, the resource isolation hardware GTZC can still be used to isolate peripherals to privileged code only (see Section 3.6.2).

When the TrustZone is activated, peripherals are set as nonsecure and unprivileged after reset.

TrustZone-aware peripherals

The devices include the following TrustZone-aware peripherals:

- GPIOA to GPIOJ, configured in LPGPIO alternate function or not
- GTZCx_MPCBB, GTZCx_TZIC and GTZCx_TZSC (GTZC blocks)
- OTFDEC1/2, writable only in secure if TZEN = 1
- EXTI
- Flash memory
- RCC and PWR
- GPDMA and LPDMA
- SYSCFG registers
- RTC and TAMP
- MCU debug unit DBGMCU
- ICACHE and DCACHE1

The way illegal accesses to these peripherals are monitored through the TZIC registers is described in Section 5: Global TrustZone controller (GTZC).

For more details, refer to Section 3.5.5.

TrustZone illegal access controller (TZIC)

The TZIC block in GTZC gathers all illegal access events originated from sources either protected by GTZC or TrustZone-aware peripherals, generating one global secure interrupt towards the NVIC.

TZIC is available only when the system is TrustZone enabled (TZEN = 1). All accesses to TZIC registers must be secured and privileged.
For each illegal event source, a status flag and a clear bit exist. Each illegal event can be masked, not generating an interrupt toward the NVIC.

*Note:* *By default, all events are masked.*

### 3.5.5 Managing security in TrustZone-aware peripherals

This section gives more details on how the security is implemented in the TrustZone-aware peripherals listed in the previous section.

**Embedded flash memory**

When the TrustZone security is enabled through option bytes (TZEN = 1), the whole flash memory is secure after reset and the following protections, shown in the figure below, are available to the application:

- nonvolatile user secure areas, defined with nonvolatile secure user option bytes
  - watermark-based secure only area (x2)
  - secure hide protection (HDP) area, stickily hidden after boot (x2)
- volatile user secure pages, defined with volatile secure registers (lost after reset)
  - Any page set as nonsecure (example: outside the watermark-based secure only area), can be set as secure on-the-fly using the block-based configuration registers.

*Note:* *All areas are aligned on the flash memory page granularity.*

The flash memory area can be configured as secure while it is tagged as nonsecure in Cortex-M33 IDAU/SAU. In this case, nonsecure accesses by the CPU to the flash memory are denied.

Erase or program operations can be available to secure (resp. nonsecure) code only for secure (resp. nonsecure) pages or memory. A flash memory is considered secure if at least one page is secure.
As shown above, when TrustZone is activated (TZEN = 1), the application code can use the HDP area that is part of the flash memory watermark-based secure area. Indeed, when the application sets the HDPx_ACCDIS bit, data read, write, and instruction fetch on this HDP area is denied until the next system reset.

For example, the software code in the secure flash memory HDP area can be executed only once, with any further access to this area denied until the next system reset. Additionally, any flash memory page belonging to an active HDP area cannot be erased anymore.

When the TrustZone is deactivated (TZEN = 0), the volatile/non-volatile secure area features are deactivated and all secure registers are RAZ/WI.

See Section 7: Embedded flash memory (FLASH) for more details.

### On-the-fly encryption/decryption (OTFDEC)

When the TrustZone security is activated (TZEN = 1), the OTFDEC can only be initialized by secure applications. Each of the four encrypted regions, once the configuration is confirmed, can be write-locked until the next power-on-reset.

**Note:** Any application (secure or nonsecure) can verify the initialization context of each OTFDEC region (including the CRC of the keys), by reading the peripheral registers.

Key registers in each OTFDEC are write-only.

See Section 3.9.3 for more details on this cryptographic engine.

### Direct memory access controllers (LPDMA and GPDMA)

When a DMA channel x is defined as secure (SECx = 1 in LP/GPDMA_SECCFGR), the source and destination transfers can be independently set as secure or nonsecure by a secure application using SSEC and DSEC bits in LP/GPDMA_CxTR1.
The table below summarizes these security options available in each DMA channel.

**Table 11. DMA channel use (security)**

<table>
<thead>
<tr>
<th>Destination type</th>
<th>Secure DMA channel x (SECx = 1)</th>
<th>Nonsecure DMA channel y (SECy = 0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Secure source</td>
<td>Nonsecure source</td>
</tr>
<tr>
<td>Secure destination</td>
<td>OK</td>
<td>OK(2)</td>
</tr>
<tr>
<td>Nonsecure destination</td>
<td>OK(3)</td>
<td>OK(4)</td>
</tr>
</tbody>
</table>

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return zeros. Also an illegal access event to TZIC is automatically triggered by the memory/peripheral used as source or destination.

2. If the source is a memory, the transfer is only possible if SSEC = 0, otherwise the transfer is blocked.

3. If the destination is a memory, the transfer is only possible if DSEC = 0, otherwise the transfer is blocked.

4. If the transfer is memory-to-memory, the transfer is only possible if SSEC = 0 and DSEC = 0, otherwise the transfer is blocked.

When a channel is configured as secure:

- Registers allocated to this channel (excluding LP/GPDMA_SECCFGR, LP/GPDMA_PRIVCFGR, and LP/GPDMA_RCFGLOCKR) are read as zero. Write are ignored for nonsecure accesses. A secure illegal access event may also be triggered toward the TZIC peripheral.
  - Writes to LP/GPDMA_SECCFGR and LP/GPDMA_RCFGLOCKR must be secure. For each bit in LP/GPDMA_PRIVCFGR, write must be secure if the corresponding bit in LP/GPDMA_SECCFGR is set.

- In linked-list mode, the loading of the next linked-list data structure from memory is performed with secure transfers.

- When switching to a nonsecure state, the secure application must abort the channel or wait until the secure channel is completed before doing the switch.

*Note:* **DMA secure channels are not available when TrustZone is deactivated.**

When a channel is configured as nonsecure, in linked-list mode, the loading of the next linked-list data structure from memory is performed with nonsecure transfers.

See Section 18: **Low-power direct memory access controller (LPDMA)** and Section 17: **General purpose direct memory access controller (GPDMA)** for more details.

**Power control (PWR)**

When the TrustZone security is activated (TZEN = 1), the selected PWR registers can be secured through PWR_SECCFGR, protecting the following PWR features:

- low-power mode setup
- wake-up (WKUP) pins
- voltage detection and monitoring
- backup domain control

Other PWR configuration bits become secure:

- when the system clock selection is secure in the RCC: the voltage scaling (VOS) and the regulator booster (BOOSTEN) configurations become secure.
- when a GPIO is configured as secure: its corresponding bit for pull-up/pull-down configuration in Standby mode becomes secure.
• when the USB Type-C/USB power delivery interface (UCPD) is configured as secure in TZSC: PWR_UCPDR register becomes secure.

See Section 10: Power control (PWR) for details.

Secure clock and reset (RCC)

When the TrustZone security is activated (TZEN = 1) and security is enabled in the RCC, the bits controlling the peripheral clocks and resets become TrustZone-aware:

- If the peripheral is securable and programmed as secure in the TZSC, the peripheral clock and reset bits become secure.
- If the peripheral is TrustZone-aware, the peripheral clock and reset bits become secure as soon as at least one function is configured as secure inside the peripheral.

Note: Refer to Section 3.5.4 for the list of securable and TrustZone-aware peripherals.

The SHSI configuration and status bits are secured when the SAES is configured as secure. Additionally, the following configurations can be made secure-only using RCC_SECCFGR:

- external clock (such as HSE or LSE), internal oscillator (such as HSI, MSI, or LSI)
- main PLL and AHB prescaler
- system clock source selection
- reset flag clearing
- automatic internal oscillator waking up configuration

See Section 11: Reset and clock control (RCC) for details.

Real time clock (RTC)

Like all TrustZone-aware peripherals, a nonsecure read/write access to a secured RTC register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the RTC illegal access event is enabled in the TZIC.

After a backup domain power-on reset, all RTC registers can be read or written in both secure and nonsecure modes. The secure boot code can then change this security setup, making registers alarm A, alarm B, wake-up timer, and timestamp secure or not, using RTC_SECCFGR.

When the SEC bit is set in secure-only RTC_SECCFGR:

- Writing the RTC registers is possible only in secure mode.
- Reading RTC_SECCFGR, RTC_PRIVCFGR, RTC_MISR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER, and RTC_CALR is always possible in secure and nonsecure modes. All the other RTC registers can be read only in secure mode.

When the SEC is cleared in secure-only RTC_SECCFGR, it is still possible to restrict access in secure mode to some RTC registers by setting dedicated control bits: INITSEC, CALSEC, TSSEC, WUTSEC, ALRASEC, and ALRBSEC.

Note: The RTC security configuration is not affected by a system reset.

See Section 63: Real-time clock (RTC) for more details.
Tamper and backup registers (TAMP)

Like all TrustZone-aware peripherals, a nonsecure read/write access to a secured TAMP register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the TAMP illegal access event is enabled in the TZIC.

After a backup domain power-on reset, all TAMP registers can be read or written in both secure and nonsecure modes. The secure boot code can change this security setup, making some registers secure or not as needed, using the TAMP_SECCFGR register.

When TAMPSEC is set in TAMP_SECCFGR:

- Writing the TAMP registers is possible only in secure mode. Backup registers have their own write protection (see below).
- Reading the TAMP registers (except for TAMP_SECCFGR, TAMP_PRIVCFGR and TAMP_MISR) returns zero if the access is nonsecure. Backup registers have their own read protection (see below).

The application can also:

- make TAMP_COUNTR register read and write secure-only by setting the CNT1SEC bit in TAMP_SECCFGR secure register
- in backup registers increase security for two of the three protection zones configured using BKPRWSEC[7:0] and BKPWSEC[7:0] bitfields in TAMP_SECCFGR:
  - protection zone 1 is read nonsecure, write nonsecure
  - protection zone 2 is read nonsecure, write secure
  - protection zone 3 is read secure, write secure

Note: The TAMP security configuration is not affected by a system reset.

See Section 64: Tamper and backup registers (TAMP) for more details.

General-purpose I/Os (GPIO)

When the TrustZone security is activated (TZEN = 1), each I/O pin of the GPIO port can be individually configured as secure through the GPIOx_SECCFGR registers. Only a secure application can write to GPIOx_SECCFGR registers. After boot, each I/O pin of GPIO is set as secure.

When an I/O pin is configured as secure, its corresponding configuration bits for alternate function (AF), mode selection (MODE), and I/O data are RAZ/WI in case of nonsecure access.

When the digital alternate function is used (input/output mode), in order to protect the data transiting from/to the I/O managed by a secure peripheral, the devices add a secure alternate function gate on the path between the peripheral and its allocated I/Os:

- If the peripheral is secure, the I/O pin must also be secure to allow input/output of data.
- If the peripheral is not secure, the connection is allowed regardless of the I/O pin state.
The TrustZone-aware logic around GPIO ports, used as the alternate function, is summarized in the table below.

**Table 12. Secure alternate function between peripherals and allocated I/Os**

<table>

1. Used to find the I/O corresponding to the signal/function on the package (refer to the product datasheet).

Finally, regarding GPIO and security, the table below summarizes the list of peripheral functions that do not have any hardware protection linked to TrustZone. The listed signals (input and/or outputs) are not blocked when the I/O is set as secure, and the associated peripheral function is nonsecure.

For example, when a secure application sets PA4 as secure to be used as LPTIM2_OUT, if the DAC is nonsecure, it can be programmed to output data to PA4, potentially causing malfunction to the secure application.

Similarly, when a secure application sets PA0 as secure to be used as UART4_TX, if TAMP is nonsecure, it can be programmed to capture the USART input traffic through the TAMP_IN function.

It is important that, for each case described in the table below, the secure application decides if a potential effect on data integrity or confidentiality is critical or not. For example, if the USART situation described above is not acceptable (data transiting on secure USART is confidential), then the secure application must configure the TAMP as secure even if it is not used by the secure application.
Note: How to make a peripheral secure is summarized in the right column of the table below.

</tbody>
</table>

1. To find the I/O corresponding to the signal/function on the package, refer to the product datasheet.

Refer to Section 13: General-purpose I/Os (GPIO) for more details.

Extended interrupts and event controller (EXTI)

When the TrustZone security is activated (TZEN = 1), the EXTI is able to protect event register bits from being modified by nonsecure accesses. The protection can individually be activated per input event via the register bits in EXTI_SECCFGR1. When an input event is configured as secure, only a secure application can change the configuration (including security if applicable), change the masking or clear the status of this input event.

The security configuration in EXTI_SECCFGR1 can be globally locked after reset in EXTI_LOCKR.

See Section 23: Extended interrupts and event controller (EXTI) for more details.

System configuration controller (SYSCFG)

Like all TrustZone-aware peripherals, when the TrustZone security is activated (TZEN = 1), a nonsecure read/write access to a secured SYSCFG register is RAZ/WI. Such access also generates an illegal access event that triggers a secure illegal access interrupt if the SYSCFG illegal access event is not masked in the TZIC.

See Section 15: System configuration controller (SYSCFG) for more details.

Microcontroller debug unit (DBGMCU)

The MCU debug component (DBGMCU) helps the debugger, providing support for:
- low-power mode behavior during debug
- peripheral freeze during debug, applicable to I2Cs, IWDG, WWWDG, timers, low-power timers, and LP/GPDMA channels
The DBGCMU is a TrustZone-aware peripheral, managing accesses to its control registers as described in the table below.

### Table 15. TrustZone-aware DBGMCU access management

1. As reported by the GTZC, the TrustZone-aware peripheral or the DMA channel.
2. Secure access from the debugger is converted to nonsecure access in the device.

Refer to Section 75.12: Microcontroller debug unit (DBGMCU) for more details.

### 3.5.6 Activating TrustZone security

The TrustZone is deactivated by default in all STM32U5 Series devices. It can be activated by setting the TZEN user option bit in FLASH_OPTR when in RDP level 0. Once TZEN has changed from 0 to 1, the default security state, after reset, is always the following:

- **CPU subsystem**
  - Cortex-M33 exits reset in secure state, hence the boot address must point toward a secure memory area.
  - All interrupt sources are secure (in NVIC).
  - The memory mapped viewed by the CPU through IDAU/SAU is fully secure.

- **Embedded flash memory**
  - Flash memory nonvolatile secure areas (with their HDP zone), are defined with nonvolatile registers FLASH_SECWMxR (x = 1, 2). Default secure option bytes setup is all user flash secure, without HDP area defined.
  - Volatile block-based security attributions of the flash memory are nonsecure. The secure boot code can change this setup, making the blocks secure.

- **Embedded SRAM memories**
  - All SRAMs are secure, as defined in GTZC/MPCBB (see Section 3.5.4). The secure boot code can change this security setup, making the blocks secure or not.

- **External memories**
  - All memory devices connected to the FSMC and OCTOSPIs are secure, as defined in GTZC/MPCWM (see Section 3.5.4). The secure-boot code can change this security setup, making the components secure or not.

- All GPIOs are secure.
- All LP/GPDMA channels are nonsecure.
- Backup registers are nonsecure.
• Peripherals and GTZC:
  – Securable peripherals are nonsecure and unprivileged.
  – TrustZone-aware peripherals are nonsecure, with their secure configuration
    registers being secure.
  – All illegal access interrupts in GTZC/TZIC are disabled.

Note: Refer to Section 3.5.4 for the list of securable and TrustZone-aware peripherals.

3.5.7 Deactivating TrustZone security

Once TrustZone is activated, it can only be deactivated during an RDP regression to level 0.

Note: Such RDP regression triggers the erase of embedded memories (SRAM2, flash memory),
and the reset of all peripherals, including OTFDEC and all cryptographic engines.

After the TrustZone deactivation, most of the features mentioned in Section 3.5 are no longer available:
• The nonvolatile secure area of the embedded flash memory is deactivated, including
  the HDP area.
• The NVIC only manages nonsecure interrupts.
• All secure registers in TrustZone-aware peripherals are RAZ/WI.

Note: When the TrustZone is deactivated, the resource isolation using privilege stays available
(see Section 3.6.2 for details).

For more information, refer to the application note Arm TrustZone features for STM32L5 and
STM32U5 Series (AN5347).

3.6 Other resource isolations

These are hardware mechanisms offering an additional level of isolation on top of the
TrustZone technology.

3.6.1 Temporal isolation using secure hide protection (HDP)

When the TrustZone security is enabled (TZEN = 1), the embedded flash memory allows an
HDP area per watermarked-secure area of each bank (8-Kbyte page granularity) to be
defined. The code executed in this HDP area, with its related data and keys, can be hidden
after boot until the next system reset.
The hide protection principle is pictured on the figure below.

**Figure 12. Flash memory secure HDP area**

When the HDPxEN and HDPx_ACCDIS bits (x = 1, 2) are set, data read, write, and instruction fetch on the area defined by SECWMx_PSTRT and HDPx_PEND option bytes, are denied until the next device reset.

*Note:* Bank erase aborts when it contains a write-protected area (WRP or HDP area).

The HDP area can be resized by a secure application if the area is not hidden, and if RDP level ≠ 2.

### 3.6.2 Resource isolation using Cortex privileged mode

In parallel to the TrustZone isolation described in Section 3.5, the hardware and software resources of STM32U5 Series devices can be partitioned so that they are restricted to software running in Cortex privileged mode.

Thanks to this hardware isolation technology, available even if TrustZone is deactivated (TZEN = 0), critical code or data can be protected against intentional or unintentional tampering from the more exposed unprivileged code.

#### Memory and peripheral privileged allocation using MPU

The Cortex-M33 MPU divides the unified memory into eight regions, each aligned to a multiple of 32 bytes. Each memory regions can be programmed to generate faults when accessed inappropriately by unprivileged software.

#### Memory and peripheral privileged allocation using GTZC

For the Cortex-M33 master, to complement the coarse isolation provided by the MPU, the GTZC reinforces, in a flexible way, the isolation between privileged and unprivileged tasks, for peripherals and selected memories.
For masters other than the Cortex-M33, the GTZC can assign them as unprivileged initiators, automatically protecting resources defined as privileged against this master.

- Securing peripherals with TZSC (privileged-only)
  In the devices, a peripheral is either securable privileged-only through GTZC, or is natively privileged-aware:
  - A securable privileged-only peripheral or memory is protected by an AHB/APB firewall gate that is controlled by the TZSC.
  - A privileged-aware peripheral or memory is connected directly to the AHB or APB interconnect, implementing a specific behavior such as a subset of registers or a memory area is privilege-only.

  When such peripheral is made privileged-only with GTZC, if it is master on the interconnect (SDMMC), it automatically issues privileged transactions. Privilege-aware masters like GPDMA or LPDMA, drive privileged signal in the AHB interconnect according to their internal privileged mode, independently to the GTZC.

  The list of securable peripherals can be found in *Section 5: Global TrustZone controller (GTZC)*.

- Securing memories with TZSC and MPCBB (privileged-only)
  The TZSC logic in GTZC provides the capability to manage the privilege level for all securable external memories, programming the MPCWM resources defined in *Section 3.5.4*.

  Similarly, the GTZC provides the capability to configure the privilege level of embedded SRAM blocks, programming the MPCBB resources defined in *Section 3.5.4*.

- Error management (privileged-only)
  - Any unprivileged transaction trying to access a privileged resource is considered as illegal. There is no illegal access event generated for illegal unprivileged read and write accesses.
  - The addressed resource follows a silent-fail behavior, returning all zero data for read and ignoring any write.
  - When an illegal unprivileged access occurs, no bus error is generated, except when this access is an instruction fetch, accessing a privileged memory or a peripheral register.
Managing security in privileged-aware peripherals

TrustZone-aware peripherals also implement privileged-only access mode. The privileged protection is valid even if TZEN = 0:

- **Embedded flash memory**
  By default all embedded flash registers can be read or programmed in both privileged and unprivileged modes.
  When secure privileged bit SPRIV is set in FLASH_PRIVCFGR, reading and writing the flash secure registers are possible only in privileged mode. Write access to this bit is ignored if TrustZone is deactivated (TZEN = 0).
  When nonsecure privileged bit NSPRIV is set in FLASH_PRIVCFGR, reading and writing the flash nonsecure registers are possible only in privileged mode.

Regarding privileged protection of the embedded flash memory, the devices offer the following features:

- The system flash memory can be accessed both in privileged and unprivileged modes.
- Each watermark-based secure area, including its secure HDP area, is accessible in secure-privileged and secure-unprivileged mode, if applicable.
- Each 8-Kbyte page of the embedded flash memory can be programmed on-the-fly as privileged only, using the block-based privileged configuration registers FLASH_PRIV1BBRx and FLASH_PRIV2BBRx. An unprivileged page is accessible by a privileged or unprivileged access.

**Note:** Switching a page from privileged to unprivileged does not erase the content of the page.

- On-the-fly encryption/decryption (OTFDEC)
  When privileged bit PRIV is set in OTFDEC_PRIVCFGR, the OTFDEC can only be initialized by a privileged application.

**Note:** OTFDEC_PRIVCFGR can be read by both privileged and unprivileged code.

- Direct memory access controllers (LPDMA and GPDMA)
  When a DMA channel x is defined as privileged (PRIVx = 1 in LP/GPDMA_PRIVCFGR), special rules apply when accessing privileged/unprivileged source or destination. Those rules are summarized on the table below.

<table>
<thead>
<tr>
<th>Table 16. DMA channel use (privilege)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Destination</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Privileged</td>
</tr>
<tr>
<td>Unprivileged</td>
</tr>
</tbody>
</table>

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return zeros.

See Section 18: Low-power direct memory access controller (LPDMA) and Section 17: General purpose direct memory access controller (GPDMA) for more details.
**Power control (PWR)**

By default, after a power-on or a system reset, all PWR registers but PWR_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

When secure privileged bit SPRIV is set in PWR_PRIVCFGR, reading and writing the PWR securable registers are possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0).

When nonsecure privileged bit NSPRIV is set in PWR_PRIVCFGR, reading and writing the PWR nonsecure registers are possible only in privileged mode.

See *Section 10: Power control (PWR)* for details.

**Secure clock and reset (RCC)**

By default, after a power-on or a system reset, all RCC registers but RCC_PRIVCFGR can be read or written in both privileged and unprivileged modes.

When the secure privileged bit SPRIV is set in RCC_PRIVCFGR, reading and writing the RCC securable bits are possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0).

When nonsecure privileged bit NSPRIV is set in RCC_PRIVCFGR, reading and writing the RCC nonsecure bits are possible only in privileged mode.

See *Section 11: Reset and clock control (RCC)* for details.

**Real time clock (RTC)**

By default after a backup domain reset, all RTC registers but RTC_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

When PRIV bit is set in privileged-only RTC_PRIVCFGR:
- Writing the RTC registers is possible only in privileged mode.
- Reading the RTC_SECCFG, RTC_PRIVCFGR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER and RTC_CALR is always possible in privileged and unprivileged modes.

All the other RTC registers can be read only in privileged mode.

When PRIV bit is cleared in privileged-only RTC_PRIVCFGR register, it is still possible to restrict access to privileged mode to some RTC registers by setting dedicated control bits: INITPRIV, CALPRIV, TSPRIV, WUTPRIV, ALAPRIV or ALRBPRIV.

See *Section 63: Real-time clock (RTC)* chapter for details.

**Tamper and backup registers (TAMP)**

By default after any backup domain reset, all TAMP registers but TAMP_PRIVCFGR can be read or written in both privileged and unprivileged modes.

When PRIV bit is set in privileged-only TAMP_PRIVCFGR:
- Writing the TAMP registers is possible only in privileged mode, except for the backup registers and the monotonic counters that have their own protection setting.
- Reading the TAMP_SECCFG or TAMP_PRIVCFGR is always possible in privilege and unprivileged modes. All the other TAMP registers can be read only in privilege mode, except for the backup registers and the monotonic counters that have their own protection setting.

The application can also:
- make TAMP_COUNT1R register read and write privileged-only by setting the CNTPRIV bit in TAMP_PRIVCFGR.
– increase security for two of the three protection zones in backup registers, using BKPRWPRIV and BKPWPRIV bits in TAMP_PRIVCFGR:
  – Make protection zone 1 read privileged, write privileged.
  – Make protection zone 2 read privileged or unprivileged, write privileged.
  – Protection zone 3 is always read and write privileged or unprivileged.

- **General-purpose I/Os (GPIO)**
  All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or nonsecure).

- **Extended interrupts and event controller (EXTI)**
  The EXTI peripheral is able to protect event register bits from being modified by unprivileged accesses. The protection is individually activated per input event via the register bits in the privileged-only EXTI_PRIVCFGR1 register. When an input event is configured as privileged, only a privileged application can change the configuration (including security if applicable), change the masking or clear the status of this input event.
  The security configuration in EXTI_PRIVCFGR1 can be globally locked after reset in EXTI_LOCKR.
  See [Section 23: Extended interrupts and event controller (EXTI)](#) for more details.

- **System configuration controller (SYSCFG)**
  All SYSCFG registers can be read and written in both privileged and unprivileged modes, except:
  - FPUSEC bit in SYSCFG_SECCFGR registers (privileged only)
  - SYSCFG registers for CPU configuration: SYSCFG_CSLCKR, SYSCFG_FPUIMR and SYSCFG_CNSLCKR
  See [Section 15: System configuration controller (SYSCFG)](#) for more details.

### 3.7 Secure execution

Through a mix of special software and hardware features, the devices ensure the correct operation of their functions against abnormal situations caused by programmer errors, software attacks through network access or local attempt for tampering code execution.

This section describes the hardware features specifically designed for secure execution.

#### 3.7.1 Memory protection unit (MPU)

The Cortex-M33 includes a memory protection unit (MPU) that can restrict the read and write accesses to memory regions (including regions mapped to peripherals), based on one or more of the following parameters:

- Cortex-M33 operating mode (privileged, unprivileged)
- data/instruction fetch

The memory map and the programming of the nonsecure and secure MPUs split memory into regions (up to eight per MPU). Secure MPU is only available when TrustZone is activated.
3.7.2 Embedded flash memory write protection

The embedded flash memory write protection (WRP) prevents illegal or unwanted write/erase to special sections of the embedded flash memory user area (system area is permanently write protected).

Write protected area is defined through the option bytes, writing the start and end addresses: two write-protected areas can be defined in each bank, with the granularity of an 8-Kbyte page.

WRP areas can be modified through option byte changes unless the corresponding FLASH_WRPxABR has its UNLOCK option bit cleared (meaning ROM emulation). UNLOCK can be set only when regressing from RDP level 1 to level 0.

*Note:* Bank erase aborts when it contains a write-protected area (WRP or HDP area).

3.7.3 Tamper detection and response

**Principle**

The devices include active protection of critical security assets against temperature, voltage and frequency attacks, with the following features:

- erasure of device secrets upon tamper detection
- improved guarantee of safe execution for the CPU and its associated security peripherals, including:
  - out-of-range voltage (example: \(V_{\text{BAT}}\), \(V_{\text{DDA}}\), temperature and clocking (LSE) detection
  - security watchdog IWDG clocked by the internal oscillator LSI
  - possible selection of internal oscillator HSI as system clock
- power supply protection
  - RTC/TAMP domain powered automatically with \(V_{\text{DD}}\) or \(V_{\text{BAT}}\)

See *Section 64: Tamper and backup registers (TAMP)* for more details.

**Tamper detection sources**

The devices support eight active input/output pins, allowing four independent active-tamper meshes, or up to seven meshes if the same output pin is shared by several input pins (for a total of eight active-tamper I/Os). The active-tamper balls are mapped in the center of packages that can be used in POS market (such as WLCSP90).

The active pins are clocked by the LSE, and are functional in all system operating modes (Run, Sleep, Stop, Standby or Shutdown), and in \(V_{\text{BAT}}\) mode.

Detection time is programmable, and a digital filtering is available (tamper triggered after two false comparison in four consecutive comparison samples).

*Note:* Timestamps are automatically generated when a tamper event occurs.
The internal tamper sources are listed in the table below.

### Table 17. Internal tampers in TAMP

</tbody>
</table>

\(^1\) LSE missing or over frequency detection (> 2MHz), glitch filter (> 2 MHz).

### Response to tamper

Each source of tamper in the device can be configured to trigger the following events:

- Generate an interrupt, capable of waking up the device from Stop and Standby modes (see TAMPxMSK bits in TAMP_CR2 register).
- Generate a hardware trigger for the low-power timers.
- Erase device secrets if the corresponding TAMPxNOER bit is cleared in TAMP_CR2 (for tamper pins) or TAMP_CR3 (for internal tamper). These erasable secrets are:
  - symmetric keys stored in backup registers (x32), in SAES, AES, HASH, and OTFDEC (encrypted flash memory regions are read as zero)
  - asymmetric keys stored in PKA SRAM, erased when \(V_{DD}\) is present
  - other secrets stored in SRAM2 and CPU instruction cache memory (SRAM2 erase when \(V_{DD}\) is present)
  - nonvolatile information used to derive the DHUK in SAES is zeroed until complete SRAM2 erase
  - 2-Kbyte backup SRAM (depending on configuration bit), erased when \(V_{DD}\) is present
  - ICACHE and DCACHE1 erased when \(V_{DD}\) is present

Read/write accesses by software to all these secrets can be blocked, by setting the BKBLOCK bit in TAMP_CR2. The device secrets access is possible only when BKBLOCK is cleared, and no tamper flag is set for any enabled tamper source.

If \(V_{DD}\) is not present, the secrets that are erased when \(V_{DD}\) is present, are only erased at the next \(V_{DD}\) power on.
**Note:** Device secret erase is also triggered by setting BKERASE in TAMP_CR2, or by performing an RDP regression as defined in Section 3.10.1.
Device secrets are not reset by system reset or when the device wakes up from Standby mode.

**Software filtering mechanism**

Each tamper source can be configured not to launch an immediate erase, by setting the corresponding TAMPxNOER bit in TAMP_CR2 (for external tamper pin) or TAMP_CR3 (for internal tamper).

In such situation, when the tamper flag is raised, the access to below secrets is blocked until all tamper flags are cleared:

- DHUK in SAES: fixed to a dummy value
- Backup registers, backup SRAM, SRAM2: read-as-zero, write-ignored
- AES, SAES, and HASH peripherals: automatically reset by RCC
- PKA peripheral: reset, with memory use blocked (meaning PKA not usable)

Once the application, notified by the tamper event, analyzes the situation, there are two possible cases:

- The application launches secrets erase with a software command (confirmed tamper).
- The application just clears the flags to release secrets blocking (false tamper).

**Note:** If the tamper software fails to react to such a tamper flag, an IWDG reset triggers automatically the erase of secrets.

**Tamper detection and low-power modes**

The effect of low-power modes on a tamper detection are summarized on the table below.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| Sleep | No effect on tamper detection features  
TAMP interrupts cause the device to exit Sleep mode. |
| Stop  | No effect on tamper detection features, except for level detection with filtering and active tamper modes that remain active only when the clock source is LSE or LSI  
Tamper events cause the device to exit Stop mode. |
| Standby | No effect on tamper detection features, except for level detection with filtering and active tamper modes, which remain active only when the clock source is LSE or LSI  
Tamper events cause the device to exit Standby mode. |
| Shutdown | No effect on tamper detection features, except for level detection with filtering and active tamper modes, which remain active only when the clock source is LSE  
Tamper events cause the device to exit Shutdown mode. |

**3.8 Secure storage**

A critical feature of any security system is how long-term keys are stored, protected, and provisioned. Such keys are typically used for loading a boot image, or handling of critical user data.
Figure 13 shows how the key management service application can use the AES engine, for example, to compute external image decryption keys. A nonvolatile key can be stored in the embedded secure HDP area (see Section 3.6.1), while volatile key storage consists in the battery-powered, tamper-protected SRAM or registers in TrustZone-aware TAMP.

Figure 13 also shows keys that are manipulated by software (like OTFDEC keys), or keys that are managed only by hardware (like DHUK). More information on those hardware keys can be found in Section 3.8.1.

Figure 13. Key management principle

Tamper protection is detailed in Section 3.7.3, while TAMP TrustZone features are briefly described in Section 3.5.5.

3.8.1 Hardware secret key management

As shown in the previous figure, the devices propose a better protection for application keys, using hardware secret keys. These AES keys can be made usable to the application, without exposing them in clear-text (unencrypted). Such keys also become immediately unusable in case of tamper.

There are three different sources of hardware secret keys:

- **DHUK**: derived keys based on 256-bit nonvolatile device unique secret in flash memory. The generation of this key takes into account the TrustZone state and key use state (KMOD).
  
  \textit{Note: DHUK is the same for all devices when \textit{RDP} = 0 (debug/development mode).}

- **BHK**: 256-bit application key stored in tamper-resistant volatile storage in TAMP. This key is written at boot time, then read/write locked to application until next reset.

- **XORK**: result of an XOR of BHK and DHUK.

Key转移

Legend

- Hardware transfer of key
- Software transfer of key
These keys can be used:

- as normal key, loading in write-only key registers (software key mode)
- as encryption/decryption key for another key, to be used in the DPA-resistant SAES (wrapped key mode)
- as encryption/decryption key for another key, to be used in a faster AES engine (shared key mode)

### 3.8.2 Unique ID

The devices store a 96-bit ID that is unique to each device (see [Section 76.1: Unique device ID register (96 bits)]).

Application services can use this unique identity key to identify the product in the cloud network, or make it difficult for counterfeit devices or clones to inject untrusted data into the network.

Alternatively, the 256-bit device unique key (DHUK) can be used (see [Section 3.8.1]).

### 3.9 Cryptographic engines

The devices implement state-of-the-art cryptographic algorithms featuring key sizes and computing protection as recommended by national security agencies such as NIST for the U.S.A, BSI for Germany or ANSSI for France. Those algorithms are used to support privacy, authentication, integrity, entropy and identity attestation.

The cryptographic engines embedded in STM32 reduce the weaknesses on the implementation of critical cryptographic functions, preventing, for example, the use of weak cryptographic algorithms and key sizes. They also enable lower processing times and lower power consumption when performing cryptographic operations, offloading those computations from Cortex-M33. This is especially true for asymmetric cryptography.

For product certification purpose, ST can provide certified device information on how these security functions are implemented and validated.

For more information on cryptographic engine processing times, refer to their respective sections in the reference manual.

#### 3.9.1 Cryptographic engines features

*Table 19 lists the accelerated cryptographic operations available in the devices. Two AES accelerators are available (both can be reserved to secure application only).*

*Note:* Additional operations can be added using the firmware.

The PKA can accelerate asymmetric cryptographic operations (like key pair generation, ECC scalar multiplication, point on curve check). See [Section 53: Public key accelerator (PKA)] for more details.
Note: Binary curves, Edwards curves, and Curve25519 are not supported by the PKA.

3.9.2 Secure AES co-processor (SAES)

The devices provide an additional on-chip hardware AES encryption and decryption engine, that implements counter-measures and mitigations against power and electromagnetic side-channel attacks.

With a dedicated 48 MHz SHSI clock, SAES is also slower than the AES, in order to provide best-in-class side-channel protections. The SAES engine supports 128-bit or 256-bit key in electronic code book (ECB) or cipher block chaining (CBC) mode.

As shown in Section 3.8, the SAES can be used for extra-secure on-chip storage for sensitive information. It can also be made secure-only.

For more information, refer to Section 50: Secure AES coprocessor (SAES).
3.9.3 On-the-fly decryption engine (OTFDEC)

The OTFDEC TrustZone-aware peripheral proposes on-the-fly decryption of encrypted images stored on external flash memory, connected through the OCTOSPI. This decryption process introduces almost no additional cycle overhead when the standard NOR flash memory is used. The OTFDEC can also be used to encrypt flash memory images on the device (for example to encrypt with a device unique secret key).

When a tamper event is confirmed in TAMP, all OTFDEC keys are erased and encrypted regions are read as zero until the OTFDEC is properly initialized again.

An OTFDEC typical use is detailed in Section 3.12.2. For more details on the peripheral programming, refer to Section 52: On-the-fly decryption engine (OTFDEC).

3.10 Product life-cycle

A typical IoT device life-cycle is summarized in the figure below. For each step, the devices propose secure life-cycle management mechanisms embedded in the hardware.

![Device life-cycle security diagram](MSv64454V1)
More details on the various phases and associated transitions, found either at the vendor or end-user premises, are summarized in the table below.

Table 20. Main product life-cycle transitions

<table>
<thead>
<tr>
<th>Transitions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device manufacturing</td>
<td>STMicroelectronics creates new STM32 devices, always checking for manufacturing defects. During this process STM32 is provisioned with ROM firmware, secure firmware install (SFI) unique key pair, and a public ID.</td>
</tr>
<tr>
<td>Vendor manufacturing</td>
<td>One (or more) vendor is responsible for the platform assembly, initialization, and provisioning before delivery to the end user. This end user can use the final product (“production” transition) or he/she can use the platform for software development (“user provisioning” transition).</td>
</tr>
<tr>
<td>Production</td>
<td>The end-user gets a product ready for use. All security functions of the platform are enabled, the debugging/testing features are restricted/disabled, and unique boot entry to immutable code is enforced.</td>
</tr>
<tr>
<td>User provisioning</td>
<td>Platform vendor prepares an individual platform for development, not to be connected to a production cloud network.</td>
</tr>
<tr>
<td>Field return or decommissioning</td>
<td>These are one-way transitions, with devices kept in user premises or returned to the manufacturer. In both cases, all data including user data is destroyed, therefore the devices lose the ability to operate securely (like connecting to a managed IoT network).</td>
</tr>
</tbody>
</table>

The features described hereafter contribute to secure the device life-cycle.
3.10.1 Life-cycle management with readout protection (RDP)

The readout protection mechanism (full hardware feature) controls the access to the devices debug, test and provisioned secrets, as summarized in the table below.

<table>

1. Debug is not available when executing RSS code.
2. Only applicable when TrustZone security is activated in the product.
3. External flash memory area decrypted on-the-fly with the OTFDEC.

Note: OEM1KEY option byte can be modified when OEM1LOCK = 0 (RDP = 0.5 or 1 only).
OEM2KEY option byte can be modified when OEM2LOCK = 0 (RDP = 1 only).
The supported transitions, summarized in the figure below, can be requested (when available) through the debug interface or via the system bootloader.

**Figure 15. RDP level transition scheme**

As shown in the previous figure, the user flash memory is automatically erased, either partially or in totality, during an RDP regression from RDP1. Those regressions can be conditioned to dedicated 64-bit password keys, if provisioned by the OEM (see next subsection). During the regression from RDP level 1 to RDP level 0.5, only nonsecure embedded flash memory is erased, keeping functional, for example, the secure boot and the secure firmware update. In all regressions from level 1, the OTP area in the flash memory is kept, all SRAMS and targeted device secrets are erased. Hence, no secrets must be stored in the OTP as they are revealed after a regression to RDP level 0. These secrets, also erased as response to tamper, are defined in Section 3.7.3.

**Note:** Enabling TrustZone using the option byte TZEN is only possible when RDP level is 0.

For more details on RDP, refer to Section 7: Embedded flash memory (FLASH).

**RDP unlocking sequences**

The use of the two OEM password keys described in the last figure is further described hereafter.

**Note:** The devices support both permanent RDP level 2 (legacy mode) or password-based RDP level 2 regression to level 1. This level 2 regression does not erase the application code, and it does not change the RDP level 1 protections in place.
Details on the password-based regression can be found in the table below.

### Table 22. OEM1/2 RDP unlocking methods

<table>
<thead>
<tr>
<th>OEM1 LOCK</th>

<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>2</td>
<td>Regression to level 1 never granted RDP remains a permanent state.</td>
<td></td>
</tr>
</tbody>
</table>

- OEM1 unlock sequence, starting at RDP level 1:
  - Shift the password key through JTAG/SWD (see the note below).
  - If this key matches the OEM1KEY provisioned in the device, the application can trigger a regression sequence to level 0. After the regression is completed, the whole embedded flash memory and device secrets are erased. The OTP area is not erased.
  - In case of mismatch value, the RDP regression is blocked and RDP level 1 protections are enforced until the next power-on reset.

- OEM2.1 unlock sequence, starting at RDP level 1:
  - Shift the password key through JTAG/SWD under reset (see the note below).
  - If this key matches the OEM2KEY provisioned in the device, the application can trigger a regression sequence to level 0.5. After the regression is completed, the nonsecure embedded flash memory and device secrets are erased. The OTP area is not erased.
  - In case of mismatch value, the RDP regression is blocked and RDP level 1 protections are enforced until the next power-on reset.

- OEM2.2 unlock sequence, starting at RDP level 2:
  - Shift the password key through JTAG/SWD under reset (see the note below).
  - If this key matches the OEM2KEY provisioned in the device, the device automatically triggers a regression sequence to level 1. After the regression is completed, a power-on reset has to be performed by the user.
  - In case of mismatch value, the RDP regression is blocked and RDP level 2 protections are enforced until the next power-on reset.

**Note:** Unlocking the device with a password is possible only once per power cycle.

*Shifting the password key through JTAG/SWD corresponds to writing two 32-bit key words, AUTH_KEY[31:0], then AUTH_KEY[63:32], in the DBGMCU_DBG_AUTH_HOST register.*
JTAG 32-bit device specific ID

Unless the JTAG port is deactivated (OEM2LOCK = 0 and RDP level = 2), a 32-bit device specific quantity can always be read though the JTAG port. This information is stored in DBGMCU(DBG_AUTH_DEVICE).

The OEM can use this 32-bit information to derive the expected OEM password keys to unlock this specific device.

3.10.2 Recommended option-byte settings

Most of the time, the user threat model focuses mainly on software attacks. In this case, it may be sufficient to keep the RDP level 1 as device protection.

For a more aggressive threat model, where the user fears physical attacks on the STM32 device, it is recommended to optimize the level of security by setting the RDP level 2.

The recommended settings are detailed below:
- If TrustZone is disabled (TZEN = 0)
  - RDP level 2
  - nonsecure boot address option bytes set in user flash memory
- If TrustZone is enabled (TZEN = 1)
  - RDP level 2
  - BOOT_LOCK = 1
  - secure boot address option bytes set in user secure flash memory

As described in the previous section, the customer can decide to allow any RDP level 2 part to regress to RDP level 1, provided the OEM Key2 has been successfully provisioned, and the OEM2LOCK option bit is set.

3.11 Access controlled debug

The device restricts access to embedded debug features, in order to guarantee the confidentiality of customer assets against unauthorized usage of debug and trace features.

3.11.1 Debug protection with readout protection (RDP)

As described in Section 3.10.1, the hardware RDP mechanism automatically controls the accesses to the device debug and test. The protection of these debug features is defined in the table below. Possible password-based regressions are described in Section 3.10.1.

Table 23. Debug protection with RDP

### 3.12 Software intellectual property protection and collaborative development

Thanks to the software intellectual property protection and collaborative model, the devices allow the design of solutions integrating innovative third-party libraries.

Collaborative development is summarized on the figure below. Starting from a personalized device sold by STMicroelectronics, a vendor A can integrate a portion of hardware and software on a platform A, that can then be used by a vendor B, who does the same before deploying a final product to the end users.

*Note:* Each platform vendor can provision individual platforms for development not to be connected to a production cloud network ("Development Platform X").

![Figure 16. Collaborative development principle](image)

The features described hereafter contribute to securing the software intellectual property within such a collaborative development.
3.12.1 Software intellectual property protection with RDP

As described in Section 3.10.1, the hardware RDP mechanism automatically controls the accesses to secrets provisioned in the device.

The protection of these secrets are defined in the table below.

<table>
<thead>
<tr>
<th>RDP protection level</th>
<th>Secrets protection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Level 0</td>

</tr>
</tbody>
</table>

1. Only applicable when TrustZone security is activated in the product.
2. External flash memory area decrypted on-the-fly with OTFDEC peripheral.

3.12.2 Software intellectual property protection with OTFDEC

As described in Section 3.9.3, the OTFDEC associated with the OCTOSPI is able to decrypt on the fly, the encrypted images stored in external SPI flash memories.

Thanks to this feature, the devices allow the installation of intellectual properties, in one of the following ways:

- over the air, with the image already encrypted with a key provisioned in the device
- through a provisioning host located in a trusted or a non-trusted environment/facility

Figure 17 illustrates this last case, with the provisioning, in a non-trusted environment, of software intellectual properties both in the embedded flash memory and in an external SPI flash memory (encrypted).

Note: Since the OTFDEC uses the AES in counter mode (CTR) to achieve the lowest possible latency, each time the content of one encrypted region is changed, the corresponding cryptographic context (key or initialization vector) must be changed. This constraint makes OTFDEC suitable to decrypt read-only data or code, stored in external NOR flash memory.
Figure 17. External flash memory protection using SFI

Provisioning

Assuming the device is virgin, the first step is to provision both flash memories, as detailed below:

1. The user creates a SFI image, composed of:
   - encrypted internal firmware and data (including external flash memory drivers)
   - encrypted external firmware and data AES key (up to 4)
   - encrypted external firmware and data image

2. The secure bootloader stored in the system memory, loads the second part of the secure bootloader in SRAM, through the supported communication ports (USART, SPI, I²C, FDCAN, USB, and JTAG). This second part runs in the secure SRAM and is responsible for executing the SFI process, applying the SFI protocol thanks to the commands received through the above mentioned supported communication ports.

Secure boot
3. The internal flash memory is programmed with decrypted option bytes, internal firmware and data, and external firmware and data AES keys. Alternatively, device unique external firmware AES keys can be used instead of such global keys.

4. The OTFDEC is properly initialized with encrypted region information, including the corresponding external firmware and data AES key.

5. Running the SFI process, chunks of encrypted external firmware and data image are decrypted in the device, then re-encrypted in the OTFDEC.

6. After a chunk OTFDEC re-encryption, the user external flash memory programmer is responsible for programming the last encrypted chunks to the external SPI flash memories through the OCTOSPI.

Alternatively, external firmware and data AES keys for OTFDEC can be generated on the device, if they are not generated by the signing tool.

Secure boot

After provisioning, each time the device initializes on a trusted firmware, the following actions are required:

1. Secure-boot firmware executes, programming the external firmware and data AES keys to the OTFDEC write-only key registers, along with the other needed information.

2. The application reads or executes the encrypted external firmware and data through the OCTOSPI in memory mapped mode, unless a tamper event is detected. In this case, all OTFDEC keys are erased and encrypted regions are read as zero until the OTFDEC is properly initialized again.

For more information on SFI solutions for the devices, refer to the application note: “STM32 MCUs secure firmware install (SFI) overview” (AN4992).

3.12.3 Other software intellectual property protections

The device additional protections to software intellectual property are:

- Invasive attacks such as physical tampering or perturbation are countered by detection then decommissioning of the device before the detected attack succeeds.
- Non-invasive attacks, such as side channel attacks, are countered by not leaking secret information via side channels such as timing, power, and EM emissions.
4 Boot modes

At startup, a BOOT0 pin, NBOOT0, and NSBOOTADDx[24:0]/SECBOOTADD0[24:0] option bytes are used to select the boot memory address that includes:

- Boot from any address in user flash memory
- Boot from system memory (bootloader)
- Boot from any address in the embedded SRAM
- Boot from root security service (RSS)

The BOOT0 value may come from the PH3-BOOT0 pin or from an option bit depending on the value of a user option bit to free the GPIO pad if needed.

The bootloader, located in the system memory, is used to reprogram the flash memory by using USART, I2C, SPI, FDCAN, or USB/OTG_FS/OTG_HS in device mode through the DFU (device firmware upgrade).

*Table 25* and *Table 26* detail the boot modes when TrustZone is disabled or enabled.

<table>
<thead>
<tr>
<th>NBOOT0 FLASH_OPTR[27]</th>
<th>BOOT0 pin PH3</th>
<th>NSWBOOT0 FLASH_OPTR[26]</th>
<th>Boot address option-byte selection</th>
<th>Boot area</th>
<th>ST programmed default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>0</td>
<td>1</td>
<td>NSBOOTADD0[24:0]</td>
<td>Boot address defined by user option bytes NSBOOTADD0[24:0]</td>
<td>Flash memory: 0x0800 0000</td>
</tr>
<tr>
<td>-</td>
<td>1</td>
<td>1</td>
<td>NSBOOTADD1[24:0]</td>
<td>Boot address defined by user option bytes NSBOOTADD1[24:0]</td>

<td>NSBOOTADD1[24:0]</td>
<td>Boot address defined by user option bytes NSBOOTADD1[24:0]</td>
<td>Bootloader: 0x0BF9 0000</td>
</tr>
</tbody>
</table>

When TrustZone is enabled by setting the TZEN option bit, the boot space must be in the secure area. The SECBOOTADD0[24:0] option bytes are used to select the boot secure memory address.

A unique boot entry option can be selected by setting the BOOT_LOCK option bit. All other boot options are ignored.
The boot address option bytes are used to program any boot memory address. However, the allowed address space depends on flash memory read protection RDP level.

If the programmed boot memory address is out of the allowed memory mapped area when RDP level is 0.5 or more, the default boot fetch address is forced either in the secure flash memory or the nonsecure flash memory depending on the TrustZone security option as described in the table below.

**Table 26. Boot modes when TrustZone is enabled (TZEN = 1)**

</tr>
</tbody>
</table>

The boot address option bytes are used to program any boot memory address. However, the allowed address space depends on flash memory read protection RDP level.

If the programmed boot memory address is out of the allowed memory mapped area when RDP level is 0.5 or more, the default boot fetch address is forced either in the secure flash memory or the nonsecure flash memory depending on the TrustZone security option as described in the table below.

**Table 27. Boot space versus RDP protection**

<table>

</tr>
<tr>
<td></td>
<td>Otherwise, the forced boot address is 0x0FF8 0000.</td>
<td>– 0x0800 0000-0x083F FFFF on STM32U59x/5Ax/5Fx/5Gx</td>
</tr>
</tbody>
</table>

Otherwise, the forced boot address is 0x0800 0000.

The BOOT0 value (either coming from the pin or the option bit) is latched upon reset release. It is up to the user to set nBOOT0 or BOOT0 values to select the required boot mode.
The BOOT0 pin or user option bit (depending on NSWBOOT0 in FLASH_OPTR) is also resampled when exiting Standby mode. Consequently, the BOOT0 pin or user option bit must be kept in the required boot mode configuration in Standby mode. After the startup delay, the selection of the boot area is done before releasing the processor reset.

PH3/BOOT0 GPIO is configured as follows:
- in input mode during the complete reset phase, if NSWBOOT0 is set in FLASH_OPTR, and then switches automatically in analog mode after reset is released (BOOT0 pin)
- in input mode from the reset phase to the completion of the option byte loading, if NSWBOOT0 is cleared in FLASH_OPTR (BOOT0 value coming from the option bit), and then switches automatically to the analog mode even if the reset phase is not complete

Embedded bootloader

The embedded bootloader is located in the system memory, programmed by ST during production. Refer to the application note *STM32 microcontroller system memory boot mode* (AN2606).

Embedded root security services (RSS)

The embedded RSS are located in the secure information block, programmed by ST during production. Refer to the application note *STM32 MCUs secure firmware install (SFI) overview* (AN4992).
5 Global TrustZone controller (GTZC)

5.1 GTZC introduction

This section describes the global TrustZone controller (GTZC) block that contains the following subblocks:

- **TZSC**: TrustZone security controller
  This subblock defines the secure/privileged state of slave peripherals. It also controls the sub-region area size and properties for the watermark memory peripheral controller (MPCWM). The TZSC informs some peripherals (such as RCC or GPIOs) about the secure status of each securable peripheral, by sharing with RCC and I/O logic.

- **MPCBB**: memory protection controller - block based
  This subblock configures the internal RAM in a TrustZone-system product having segmented SRAM (pages of 512 bytes) with programmable-security and privileged attributes.

- **TZIC**: TrustZone illegal access controller
  This subblock gathers all illegal access events in the system and generates a secure interrupt towards NVIC.

These subblocks are used to configure TrustZone system security in a product having bus agents with programmable-security and privileged attributes such as:

- on-chip RAM with programmable secure and/or privileged blocks (pages)
- AHB and APB peripherals with programmable security and/or privileged access
- off-chip memories with secure and/or privileged areas

5.2 GTZC main features

The GTZC main features are listed below:

- 3 independent 32-bit AHB interface for TZSC, TZIC and MPCBB
- TZIC accessible only with secure transactions
- Secure and nonsecure access supported for privileged and unprivileged part of TZSC and MPCBB
- Set of registers to define product security settings:
  - Secure/privileged blocks for internal SRAMs
  - Secure/privileged regions for external memories and internal backup SRAM
  - Secure/privileged access mode for securable peripherals
  - Secure/privileged access mode for securable masters

**GTZC TrustZone system architecture**

The Armv8-M supports security per TrustZone-M model with isolation between:

- a secure world, where usually security sensitive applications are run and critical resources are located
- a nonsecure or public world (such as usual nonsecure operating system and user space)
The TrustZone architecture is extended beyond AHB and Armv8-M with:

- AHB/APB bridge used as secure gate to block or propagate secure/nonsecure and privileged/unprivileged transaction towards APB agents
- PPC (peripheral protection controller) used as secure gate to block or propagate secure/nonsecure and privileged/unprivileged transaction towards AHB agents
- TrustZone block-based MPC firewalls used as secure gate to filter secure/nonsecure, privileged/unprivileged access towards internal SRAMs
- TrustZone watermark MPC firewalls used as secure gate to filter secure/nonsecure, privileged/unprivileged access towards external memories

AHB and APB Peripherals can be categorized as:

- **privileged**: peripherals protected by AHB/APB firewall stub that is controlled from TZSC to define privilege properties
- **secure**: peripherals always protected by an AHB/APB firewall stub. These peripherals are always secure (such as TZIC)
- **securable**: peripherals protected by an AHB/APB firewall stub that is controlled from TZSC to define security properties (optional)
- **nonsecure and unprivileged**: peripherals connected directly to AHB/APB interconnect without any secure gate
- **TrustZone-aware**: peripherals connected directly to AHB or APB bus and implementing a specific TrustZone behavior (such as a subset of registers being secure). TrustZone-aware AHB masters always drive HNONSEC signal according to their security mode (such as Armv8-M core or DMA)

AHB securable masters can be configured in the TZSC to be secure/nonsecure and/or privileged/unprivileged.

**Application information**

The TZSC, MPCBB and TZIC can be used in one of the following ways:

- programmed during secure boot only, locked and not changed afterwards
- dynamically re-programmed when using specific application code or secure kernel (microvisor). When not locked, MPC secure blocks or region size can be changed by secure software executing from the secure FLASH region or secure SRAM. Same remark applies to the GTZC_TZSC_SECCFGRx/PRIVCFG Rx registers that define secure/privileged state of each peripheral.
The Armv8-M security architecture with secure, securable and TrustZone-aware peripherals is shown in the figure below.

Figure 18. GTZC in Armv8-M subsystem block diagram

5.3 GTZC implementation

The STM32U5 Series devices embed two instances of GTZC.

5.4 GTZC functional description

5.4.1 GTZC block diagram

The figure below describes the combined feature of TZSC, MPCBB and TZIC. Each sub-block is controlled by its own AHB configuration port.

The TZSC defines which peripheral is secure and/or privileged. The privileged configuration bit of a peripheral can be modified by a secure privileged transaction when the peripheral is configured as secure. Otherwise, a privileged transaction (nonsecure) is sufficient.

On the opposite, the secure configuration bit of a peripheral can be modified only with a secure privileged transaction if the peripheral is configured as privileged. Otherwise, a secure transaction (unprivileged) is sufficient.

The secure configuration bit of a given ram block can be modified only with a secure privileged transaction if the same RAM block is configured as privileged. Otherwise, a secure transaction (unprivileged) is sufficient.

The TZIC gathers illegal events generated within the system when an illegal access is detected. TZIC can then generate a secure interrupt towards the CPU if needed.

Figure 19. GTZC block diagram
5.4.2 Illegal access definition

Three different types of illegal access exist:

- **Illegal nonsecure access**
  Any nonsecure transaction trying to write a secure resource is considered as illegal and thus the addressed resource generates an illegal access interrupt for illegal write access and a bus error for illegal fetch access. However, some exceptions exist on secure and privileged configuration registers: these later ones authorize nonsecure read access to secure registers (see GTZC_TZSC_SECCFGRx and GTZC_TZSC_PRIVCFGRx).

- **Illegal secure access**
  Any secure transaction trying to access nonsecure block in internal block-based SRAM or watermarked memory is considered as illegal. Correct TZIC settings allow the capture of the associated event and then generate the GTZC_IRQn interrupt to the NVIC. This applies for read, write and execute access. Concerning the MPCBB controller, there is an option to ignore secure data read/write access on nonsecure SRAM blocks, by setting the SRWILADIS bit in the GTZC_MPCBBz_CR register. Secure read and write data transactions are then allowed on nonsecure SRAM blocks, while secure execution access remains not allowed.
  Any secure execute transaction trying to access a nonsecure peripheral register is considered as illegal and generates a bus error.

- **Illegal unprivileged access**
  Any unprivileged transaction trying to access a privileged resource is considered as illegal. There is no illegal access event generated for illegal read and write access. The addressed resource follows a silent-fail behavior, returning all zero data for read and ignoring any write. No bus error is generated. A bus error is generated when any unprivileged execute transaction tries to access a privileged memory.

5.4.3 TrustZone security controller (TZSC)

The TZSC is composed of a configurable set of registers, providing the following features:

- **Control of secure and privileged state for all peripherals**, done through:
  - GTZC_TZSC_SECCFGRx registers to control AHB/APB firewall stubs for the securable peripherals
  - GTZC_TZSC_PRIVCFGRx registers to control AHB/APB firewall stubs for the privileged peripherals

- **For watermark memory protection controller (external memories and backup SRAM)**, two independent regions can be defined and the following fields are used to program:
  - the start of the first protected sub-region on external memory/backup SRAM: SUBA_START[10:0]
  - the length of the first protected sub-region on external memory/backup SRAM: SUBA_LENGTH[11:0]
  - the start of the second protected sub-region on external memory/backup SRAM: SUBB_START[10:0]
  - the length of the second protected sub-region on external memory/backup SRAM: SUBB_LENGTH[11:0]
A control register for each sub-region can be used to enable/disable the watermark memory protection controller as well as defining the right attributes of each sub-region.

**Figure 20. Watermark memory protection controller (region x/sub-regions A and B)**

In the figure above, region x represents the external memory or backup SRAM region (such as FSMC bank, OCTOSPI1, OCTOSPI2, HSPI1 or BKPSRAM). Secure and privileged attributes of sub-regions A and B are independently configurable. When no sub-regions are defined or enabled on the region x, then the default attribute of the region x is set as “secure-privileged”.

The tables below describe the secure/privileged properties of the common area of sub-region A and B when an overlapNonsecure exists.

5.4.4 Memory protection controller - block based (MPCBB)

The MPCBB is composed of a configurable set of registers allowing to define security and privileged policy for internal SRAM memories. The security and privileged policy can be individually configured per each 512-byte block of SRAM.

In order to setup the MPCBB, the following actions are needed (for example at boot time):

- Secure firmware must define which memory blocks are secure by setting the correct bits in GTZC_MPCBBz_SECCFGRx.
- Privileged firmware must define which memory blocks are privileged by setting the correct bits in GTZC_MPCBBz_PRIVCFGRx.

A MPCBB super-block is made of 32 consecutive blocks. For each super-block, secure application can lock all related security/privileged bits using the correct bits in GTZC_MPCBBz_CFGLOCKR1/2. This lock remains active until the next system reset.

Note: The block size is 512 bytes. The super-block size is 512 * 32 = 16 Kbytes.

5.4.5 TrustZone illegal access controller (TZIC)

The TZIC concentrates all illegal access source events. It is used only when the system is TrustZone enabled (TZEN = 1).

TZIC allows the trace (flag) of which event triggered the secure illegal access interrupt. Register masks (GTZC_TZIC_IERx) are available to filter unwanted events. On unmasked illegal event, TZIC generates the GTZC_IRQn interrupt to the NVIC.

For each illegal event source, a status flag and a clear bit exist (respectively within GTZC_TZIC_SRx and GTZC_TZIC_FCRx). The reset value of mask registers (GTZC_TZIC_IERx) is such that all events are masked.

5.4.6 Power-on/reset state

The power-on and reset state of the TZSC clear to 0 all bits of GTZC_TZSC_SECCFGRx and GTZC_TZSC_PRIVCFGRx, meaning that all securable peripherals are respectively set to nonsecure and unprivileged.

For internal SRAMx (x = 1 to 6), all GTZC_MPCBBz_SECCFGRx and GTZC_MPCBBz_PRIVCFGRx are set:

- to 0xFFFF FFFF, making these internal memories block secure and privileged by default when TrustZone security is enabled at system level (TZEN = 1).
to 0x0000 0000, making these internal memories block nonsecure and unprivileged by
default when TrustZone security is disabled at system level (TZEN = 0).

For external memories and backup SRAM:
• all GTZC_TZSC_MPCWMxzR registers are set to 0x0000 0000, making these
  memories secure and privileged by default when TrustZone security is enabled
  at system level (TZEN = 1).
• GTZC_TZSC_MPCWMxzR registers are not accessible, and these memories are
  nonsecure and non-privileged by default when TrustZone security is disabled at system
  level (TZEN = 0).

Secure boot code can then program the security settings, making components secure or not
as needed.

5.5 GTZC interrupts

TZIC is a secure peripheral, thus it systematically generates an illegal access event when
accessed by a nonsecure access. The MPCBB and TZSC are TrustZone-aware
peripherals, meaning that secure and nonsecure registers co-exist within the peripheral.

Global TrustZone controller (GTZC) RM0456

5.6.2 GTZC1 TZSC secure configuration register 1 (GTZC1_TZSC_SECCFGR1)

Address offset: 0x010
Reset value: 0x0000 0000

Write-secure access only.

This register can be written only by secure privileged transaction when corresponding GTZC1_TZSC_PRIVCFGR register signal is set to 1. If a given PRIV bit is not set, the equivalent SEC bit can be written by secure unprivileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

Bit 0 **MDF1SEC**: secure access mode for MDF1
- 0: nonsecure
- 1: secure

5.6.5 **GTZC1 TZSC privilege configuration register 1 (GTZC1_TZSC_PRIVCFGR1)**

Address offset: 0x020

Reset value: 0x0000 0000

Write-privileged access only.

This register can be read or written only by secure privileged transaction when corresponding GTZC1_TZSC_SECCFGR register signal is set to 1. If a given SEC bit is not set, the equivalent PRIV bit can be read/written by nonsecure privileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.6.6  GTZC1 TZSC privilege configuration register 2  
(GTZC1_TZSC_PRIVCFGR2)

Address offset: 0x024
Reset value: 0x0000 0000
Write-privileged access only.

This register can be read or written only by secure privileged transaction when 
corresponding GTZC1_TZSC_SECCFGR register signal is set to 1. If a given SEC bit is not 
set, the equivalent PRIV bit can be read/written by nonsecure privileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

</tbody>
</table>

Bits 31:10  Reserved, must be kept at reset value.

Bit 9  PRIV: Privileged sub-region z of base region x
This bit is taken into account only if SREN is set.
0: Privileged and unprivileged accesses are granted in sub-region z.
1: Only privileged accesses are granted in sub-region z of region x.

Bit 8  SEC: Secure sub-region z of base region x
This bit is taken into account only if SREN is set.
0: Only nonsecure data accesses are granted to sub-region z of region x.
1: Only secure data accesses are granted to sub-region z of region x.

Bits 7:2  Reserved, must be kept at reset value.

Bit 1  SRLOCK: Sub-region z lock
This bit, once set, can be cleared only by a system reset.
0: GTZC1_TZSC_MPCWMxCFGR, GTZC1_TZSC_MPCWMxAR and
GTZC1_TZSC_MPCWMxBR can be written.
1: Writes to GTZC1_TZSC_MPCWMxCFGR, GTZC1_TZSC_MPCWMxAR and
GTZC1_TZSC_MPCWMxBR are ignored.

Bit 0  SREN: Sub-region z enable
0: Sub-region z is disabled. Access control of base region x applies to any access between
this sub-region start- and end-addresses.
1: Sub-region z of region x is enabled. Access control defined in
GTZC1_TZSC_MPCWMx_CFGR applies to any access between this sub-region start- and
end-addresses, both defined in GTZC1_TZSC_MPCWMxAR and
GTZC1_TZSC_MPCWMxBR.

Note: External memories that are watermark controlled start fully nonsecure/unprivileged at
reset when TZEN = 0. When TZEN = 1, external memories start fully secure/fully
privileged (inverted reset-value).
5.6.9  GTZC1 TZSC memory x sub-region A watermark register
(GTZC1_TZSC_MPCWMxAR)

Address offset: 0x44 + 0x10 * (x - 1) (x = 1 to 6)
Reset value: 0x0000 0000
Secure privilege access only.
When SUBA_START + SUBA_LENGTH is higher than the maximum size allowed for the
memory, a saturation of SUBA_LENGTH is applied automatically.
When an overlap of sub-region A and B exists, secure/privileged attributes of both
sub-regions apply on the common section (see Section 5.4.3).

Note: Some registers are only available on some devices in the STM32U5 Series.
Refer to the device datasheet for availability of its associated memory region.

<table>
<thead>
<tr>
<th>Address</th>

</tr>
</tbody>
</table>

Bits 31:28  Reserved, must be kept at reset value.

Bits 27:16  SUBA_LENGTH[11:0]: Length of sub-region A in region x
This field defines the length of the sub-region A, to be multiplied by the granularity defined in
Table 31. When SUBA_START + SUBA_LENGTH is higher than the maximum size allowed for the
memory, a saturation of SUBA_LENGTH is applied automatically.
If SUBA_LENGTH = 0, the sub-region A is disabled. (SREN bit in GTZC1_TZSC_MPCWMxACFGR is cleared).

Bits 15:11   Reserved, must be kept at reset value.

Bits 10:0  SUBA_START[10:0]: Start of sub-region A in region x
This field defines the address offset of the sub-region A, to be multiplied by the granularity
defined in Table 31, versus the start of the region x.
External memories that are watermark controlled, start fully nonsecure at reset when
TZEN = 0. When TZEN = 1, external memories start fully secure (inverted reset-value).
5.6.10 GTZC1 TZSC memory x sub-region B watermark register (GTZC1_TZSC_MPCWMxBR)

Address offset: 0x4C + 0x10 * (x - 1) (x = 1, 2, 5, 6)
Reset value: 0x0000 0000
Secure privilege access only.
When SUBB_START + SUBB_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBB_LENGTH is applied automatically.
When an overlap of sub-region A and B exists, secure/privileged attributes of both sub-regions apply on the common section (see Section 5.4.3).

Note: Some registers are only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated memory region.

</tbody>
</table>

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **SUBB_LENGTH[11:0]**: Length of sub-region B in region x
This field defines the length of the sub-region B, to be multiplied by the granularity defined in Table 31.
When SUBB_START + SUBB_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBB_LENGTH is applied automatically.
If SUBB_LENGTH = 0, the sub-region B is disabled. (SREN bit in GTZC1_TZSC_MPCMWxCBCFG1 is cleared).

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **SUBB_START[10:0]**: Start of sub-region B in region x
This field defines the address offset of the sub-region B, to be multiplied by the granularity defined in Table 31, versus the start of the region x.
External memories that are watermark controlled, start fully nonsecure at reset when TZEN = 0. When TZEN = 1, external memories start fully secure (inverted reset-value).

Global TrustZone controller (GTZC)  RM0456

Refer to Table 29: GTZC1 subblocks address offset.

5.7 GTZC1 TZIC registers

All registers are accessed only by words (32-bit).

5.7.1 GTZC1 TZIC interrupt enable register 1 (GTZC1_TZIC_IER1)

Address offset: 0x000  
Reset value: 0x0000 0000  
Secure privileged access only.

This register is used to enable interrupt of illegal access.

<table>
<thead>
<tr>
<th>Bit 31:24</th>
<th>Reserved, must be kept at reset value.</th>

</thead>
</table>

Bit 23 **I2C6IE**: illegal access interrupt enable for I2C6
0: interrupt disabled  
1: interrupt enabled  
Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 22 **I2C5IE**: illegal access interrupt enable for I2C5
0: interrupt disabled  
1: interrupt enabled  
Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 21 **USART6IE**: illegal access interrupt enable for USART6
0: interrupt disabled  
1: interrupt enabled  
Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 20 Reserved, must be kept at reset value.
Bit 19 **UCPD1IE**: illegal access interrupt enable for UCPD1
   0: interrupt disabled
   1: interrupt enabled

   **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 18 **FDCAN1IE**: illegal access interrupt enable for FDCAN1
   0: interrupt disabled
   1: interrupt enabled

Bit 17 **LPTIM2IE**: illegal access interrupt enable for LPTIM2
   0: interrupt disabled
   1: interrupt enabled

Bit 16 **I2C4IE**: illegal access interrupt enable for I2C4
   0: interrupt disabled
   1: interrupt enabled

Bit 15 **CRSIE**: illegal access interrupt enable for CRS
   0: interrupt disabled
   1: interrupt enabled

Bit 14 **I2C2IE**: illegal access interrupt enable for I2C2
   0: interrupt disabled
   1: interrupt enabled

Bit 13 **I2C1IE**: illegal access interrupt enable for I2C1
   0: interrupt disabled
   1: interrupt enabled

Bit 12 **UART5IE**: illegal access interrupt enable for UART5
   0: interrupt disabled
   1: interrupt enabled

Bit 11 **UART4IE**: illegal access interrupt enable for UART4
   0: interrupt disabled
   1: interrupt enabled

Bit 10 **USART3IE**: illegal access interrupt enable for USART3
   0: interrupt disabled
   1: interrupt enabled

Bit 9 **USART2IE**: illegal access interrupt enable for USART2
   0: interrupt disabled
   1: interrupt enabled

   **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 8 **SPI2IE**: illegal access interrupt enable for SPI2
   0: interrupt disabled
   1: interrupt enabled

Bit 7 **IWDGIE**: illegal access interrupt enable for IWDG
   0: interrupt disabled
   1: interrupt enabled
5.7.2 **GTZC1 TZIC interrupt enable register 2 (GTZC1_TZIC_IER2)**

Address offset: 0x004

Reset value: 0x0000 0000

Secure privileged access only.

This register is used to enable interrupt of illegal access.

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **GFXTIMIE**: illegal access interrupt enable for GFXTIM

0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*
Bit 10  **DSIIE**: illegal access interrupt enable for DSI
0: interrupt disabled
1: interrupt enabled
*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 9  **LTDCUSBIE**: illegal access interrupt enable for LTDC or USB
0: interrupt disabled
1: interrupt enabled
*Note:* This bit controls the LTDC on STM32U59x/5Ax/5Fx/5Gx. It controls the USB on STM32U535/545. It is reserved on STM32U575/585.

Bit 8  **SAI2IE**: illegal access interrupt enable for SAI2
0: interrupt disabled
1: interrupt enabled
*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 7  **SAI1IE**: illegal access interrupt enable for SAI1
0: interrupt disabled
1: interrupt enabled

Bit 6  **TIM17IE**: illegal access interrupt enable for TIM7
0: interrupt disabled
1: interrupt enabled

Bit 5  **TIM16IE**: illegal access interrupt enable for TIM6
0: interrupt disabled
1: interrupt enabled

Bit 4  **TIM15IE**: illegal access interrupt enable for TIM5
0: interrupt disabled
1: interrupt enabled

Bit 3  **USART1IE**: illegal access interrupt enable for USART1
0: interrupt disabled
1: interrupt enabled

Bit 2  **TIM8IE**: illegal access interrupt enable for TIM8
0: interrupt disabled
1: interrupt enabled

Bit 1  **SPI1IE**: illegal access interrupt enable for SPI1
0: interrupt disabled
1: interrupt enabled

Bit 0  **TIM1IE**: illegal access interrupt enable for TIM1
0: interrupt disabled
1: interrupt enabled
5.7.3 GTZC1 TZIC interrupt enable register 3 (GTZC1_TZIC_IER3)

Address offset: 0x008
Reset value: 0x0000 0000

Secure privileged access only.

This register is used to enable interrupt of illegal access.

| Bit 31:29 Reserved, must be kept at reset value. |
| Bit 28 JPEGIE: illegal access interrupt enable for JPEG |
| 0: interrupt disabled |
| 1: interrupt enabled |
| Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value. |
| Bit 27 DCACHE2_REGIE: illegal access interrupt enable for DCACHE2 registers |
| 0: interrupt disabled |
| 1: interrupt enabled |
| Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value. |
| Bit 26 HSPI1_REGIE: illegal access interrupt enable for HSPI1 registers |
| 0: interrupt disabled |
| 1: interrupt enabled |
| Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value. |
| Bit 25 GFXMMU_REGIE: illegal access interrupt enable for GFXMMU registers |
| 0: interrupt disabled |
| 1: interrupt enabled |
| Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value. |
| Bit 24 GFXMMUIE: illegal access interrupt enable for GFXMMU |
| 0: interrupt disabled |
| 1: interrupt enabled |
| Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value. |
Bit 23 **GPU2DIE**: illegal access interrupt enable for GPU2D
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 22 **RAMCFGIE**: illegal access interrupt enable for RAMCFG
0: interrupt disabled
1: interrupt enabled

Bit 21 **OCTOSP12_REGIE**: illegal access interrupt enable for OCTOSPI2 registers
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 20 **OCTOSP11_REGIE**: illegal access interrupt enable for OCTOSPI1 registers
0: interrupt disabled
1: interrupt enabled

Bit 19 **FSMC_REGIE**: illegal access interrupt enable for FSMC registers
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 18 **SDMMC2IE**: illegal access interrupt enable for SDMMC1
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 17 **SDMMC1IE**: illegal access interrupt enable for SDMMC2
0: interrupt disabled
1: interrupt enabled

Bit 16 **OCTOSPIMIE**: illegal access interrupt enable for OCTOSPIM
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 15 **SAESIE**: illegal access interrupt enable for SAES
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*
Bit 14 **PKAIE**: illegal access interrupt enable for PKA
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 13 **RNGIE**: illegal access interrupt enable for RNG
0: interrupt disabled
1: interrupt enabled

Bit 12 **HASHIE**: illegal access interrupt enable for HASH
0: interrupt disabled
1: interrupt enabled

Bit 11 **AESIE**: illegal access interrupt enable for AES
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 10 **OTGIE**: illegal access interrupt enable for OTG_FS or OTG_HS
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 9 **DCMIIE**: illegal access interrupt enable for DCMI and PSSI
0: interrupt disabled
1: interrupt enabled

Bit 8 **ADC12IE**: illegal access interrupt enable for ADC1 or ADC2
0: interrupt disabled
1: interrupt enabled

Bit 7 **DCACHE1_REGIE**: illegal access interrupt enable for DCACHE1 registers
0: interrupt disabled
1: interrupt enabled

Bit 6 **ICACHE_REGIE**: illegal access interrupt enable for ICACHE registers
0: interrupt disabled
1: interrupt enabled

Bit 5 **DMA2DIE**: illegal access interrupt enable for register of DMA2D
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 4 **TSCIE**: illegal access interrupt enable for TSC
0: interrupt disabled
1: interrupt enabled
5.7.4 GTZC1 TZIC interrupt enable register 4 (GTZC1_TZIC_IER4)

Address offset: 0x00C
Reset value: 0x0000 0000
Secure privileged access only.

This register is used to enable interrupt of illegal access.

Global TrustZone controller (GTZC)

Bit 29 **MPCBB3_REGIE**: illegal access interrupt enable for MPCBB3 registers
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 28 **SRAM3IE**: illegal access interrupt enable for SRAM3
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 27 **MPCBB2_REGIE**: illegal access interrupt enable for MPCBB2 registers
0: interrupt disabled
1: interrupt enabled

Bit 26 **SRAM2IE**: illegal access interrupt enable for SRAM2
0: interrupt disabled
1: interrupt enabled

Bit 25 **MPCBB1_REGIE**: illegal access interrupt enable for MPCBB1 registers
0: interrupt disabled
1: interrupt enabled

Bit 24 **SRAM1IE**: illegal access interrupt enable for SRAM1
0: interrupt disabled
1: interrupt enabled

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **HSPI1_MEMIE**: illegal access interrupt enable for HSPI1 memory bank
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 19 **OCTOSPI2_MEMIE**: illegal access interrupt enable for OCTOSPI2 memory bank
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 18 **BKPSRAMIE**: illegal access interrupt enable for MPCWM3 (BKPSRAM) memory bank
0: interrupt disabled
1: interrupt enabled

Bit 17 **FSMC_MEMIE**: illegal access interrupt enable for MPCWM2 (FSMC NAND) and MPCWM3 (FSMC NOR)
0: interrupt disabled
1: interrupt enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*
5.7.5 GTZC1 TZIC status register 1 (GTZC1_TZIC_SR1)

Bits 31:12 Reserved, must be kept at reset value.

- **Bit 11 GFXTIMF**: illegal access flag for GFXTIM
  - 0: no illegal access event
  - 1: illegal access event
  
  **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

- **Bit 10 DSIF**: illegal access flag for DSI
  - 0: no illegal access event
  - 1: illegal access event
  
  **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

- **Bit 9 LTDCUSBF**: illegal access flag for LTDC or USB
  - 0: no illegal access event
  - 1: illegal access event
  
  **Note**: This bit flags the LTDC on STM32U59x/5Ax/5Fx/5Gx. It flags the USB on STM32U535/545. It is reserved on STM32U575/585.

- **Bit 8 SAI2F**: illegal access flag for SAI2
  - 0: no illegal access event
  - 1: illegal access event
  
  **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 JPEGF: illegal access flag for JPEG

0: no illegal access event
1: illegal access event

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 27 DCACHE2_REGF: illegal access flag for DCACHE2 registers

0: no illegal access event
1: illegal access event

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.
Bit 26 \textbf{HSPI1\_REGF}: illegal access flag for HSPI1 registers

- 0: no illegal access event
- 1: illegal access event

\textbf{Note}: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 25 \textbf{GFXMMU\_REGF}: illegal access flag for GFXMMU registers

- 0: no illegal access event
- 1: illegal access event

\textbf{Note}: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 24 \textbf{GFXMMUF}: illegal access flag for GFXMMU

- 0: no illegal access event
- 1: illegal access event

\textbf{Note}: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 23 \textbf{GPU2DF}: illegal access flag for GPU2D

- 0: no illegal access event
- 1: illegal access event

\textbf{Note}: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 22 \textbf{RAMCFGF}: illegal access flag for RAMCFG

- 0: no illegal access event
- 1: illegal access event

Bit 21 \textbf{OCTOSPI2\_REGF}: illegal access flag for OCTOSPI2 registers

- 0: no illegal access event
- 1: illegal access event

\textbf{Note}: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 20 \textbf{OCTOSPI1\_REGF}: illegal access flag for OCTOSPI1 registers

- 0: no illegal access event
- 1: illegal access event

Bit 19 \textbf{FSMC\_REGF}: illegal access flag for FSMC registers

- 0: no illegal access event
- 1: illegal access event

\textbf{Note}: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 18 \textbf{SDMMC2F}: illegal access flag for SDMMC1

- 0: no illegal access event
- 1: illegal access event

\textbf{Note}: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.
Bit 17 **SDMMC1F**: illegal access flag for SDMMC2
0: no illegal access event
1: illegal access event

Bit 16 **OCTOSPIMF**: illegal access flag for OCTOSPIM
0: no illegal access event
1: illegal access event

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 15 **SAESF**: illegal access flag for SAES
0: no illegal access event
1: illegal access event

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 14 **PKAF**: illegal access flag for PKA
0: no illegal access event
1: illegal access event

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 13 **RNGF**: illegal access flag for RNG
0: no illegal access event
1: illegal access event

Bit 12 **HASHF**: illegal access flag for HASH
0: no illegal access event
1: illegal access event

Bit 11 **AESF**: illegal access flag for AES
0: no illegal access event
1: illegal access event

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 10 **OTGF**: illegal access flag for OTG_FS or OTG_HS
0: no illegal access event
1: illegal access event

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 9 **DCMIF**: illegal access flag for DCMI and PSSI
0: no illegal access event
1: illegal access event

Bit 8 **ADC12F**: illegal access flag for ADC1 and ADC2
0: no illegal access event
1: illegal access event
Bit 7 **DCACHE1_REGF**: illegal access flag for DCACHE1 registers
   0: no illegal access event
   1: illegal access event

Bit 6 **ICACHE_REGF**: illegal access flag for ICACHE registers
   0: no illegal access event
   1: illegal access event

Bit 5 **DMA2DF**: illegal access flag for register of DMA2D
   0: no illegal access event
   1: illegal access event

   *Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 4 **TSCF**: illegal access flag for TSC
   0: no illegal access event
   1: illegal access event

Bit 3 **CRCF**: illegal access flag for CRC
   0: no illegal access event
   1: illegal access event

Bit 2 **FMACF**: illegal access flag for FMAC
   0: no illegal access event
   1: illegal access event

Bit 1 **CORDICF**: illegal access flag for CORDIC
   0: no illegal access event
   1: illegal access event

Bit 0 **MDF1F**: illegal access flag for MDF1
   0: no illegal access event
   1: illegal access event

### 5.7.8 GTZC1 TZIC status register 4 (GTZC1_TZIC_SR4)

Address offset: 0x01C

Reset value: 0x0000 0000

Secure privileged access only.
Bit 31  **MPCBB5_REGF**: illegal access flag for MPCBB5 registers
   0: no illegal access event
   1: illegal access event
   
   **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 30  **SRAM5F**: illegal access flag for SRAM5
   0: no illegal access event
   1: illegal access event
   
   **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 29  **MPCBB3_REGF**: illegal access flag for MPCBB3 registers
   0: no illegal access event
   1: illegal access event
   
   **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 28  **SRAM3F**: illegal access flag for SRAM3
   0: no illegal access event
   1: illegal access event
   
   **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 27  **MPCBB2_REGF**: illegal access flag for MPCBB2 registers
   0: no illegal access event
   1: illegal access event

Bit 26  **SRAM2F**: illegal access flag for SRAM2
   0: no illegal access event
   1: illegal access event

Bit 25  **MPCBB1_REGF**: illegal access flag for MPCBB1 registers
   0: no illegal access event
   1: illegal access event

Bit 24  **SRAM1F**: illegal access flag for SRAM1
   0: no illegal access event
   1: illegal access event

Bits 23:21 Reserved, must be kept at reset value.

Bit 20  **HSPI1_MEMF**: illegal access flag for HSPI1 memory bank
   0: no illegal access event
   1: illegal access event
   
   **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.
Bit 19 OCTOSPI2_MEMF: illegal access flag for OCTOSPI2 memory bank
0: no illegal access event
1: illegal access event

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 18 BKPSRAMF: illegal access flag for MPCWM3 (BKPSRAM) memory bank
0: no illegal access event
1: illegal access event

Bit 17 FSMC_MEMF: illegal access flag for MPCWM2 (FSMC NAND) and MPCWM3 (FSMC NOR)
0: no illegal access event
1: illegal access event

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 16 OCTOSPI1_MEMF: illegal access flag for MPCWM1 (OCTOSPI1) memory bank
0: no illegal access event
1: illegal access event

Bit 15 TZIC1F: illegal access flag for GTZC1 TZIC registers
0: no illegal access event
1: illegal access event

Bit 14 TZSC1F: illegal access flag for GTZC1 TZSC registers
0: no illegal access event
1: illegal access event

Bits 13:5 Reserved, must be kept at reset value.

Bit 4 OTFDEC2F: illegal access flag for OTFDEC2
0: no illegal access event
1: illegal access event

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 3 OTFDEC1F: illegal access flag for OTFDEC1
0: no illegal access event
1: illegal access event

Bit 2 FLASHF: illegal access flag for flash memory
0: no illegal access event
1: illegal access event

Bit 1 FLASH_REGF: illegal access flag for FLASH registers
0: no illegal access event
1: illegal access event

Bit 0 GPDMA1F: illegal access flag for GPDMA1
0: no illegal access event
1: illegal access event
5.7.9 GTZC1 TZIC flag clear register 1 (GTZC1_TZIC_FCR1)

Address offset: 0x020
Reset value: 0x0000 0000
Secure privileged access only.

### Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **CI2C6F**: clear the illegal access flag for I2C6
- 0: no action
- 1: status flag cleared

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 22 **CI2C5F**: clear the illegal access flag for I2C5
- 0: no action
- 1: status flag cleared

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 21 **CUSART6F**: clear the illegal access flag for USART6
- 0: no action
- 1: status flag cleared

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **CUCPD1F**: clear the illegal access flag for UCPD1
- 0: no action
- 1: status flag cleared

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 18 **CFDCAN1F**: clear the illegal access flag for FDCAN1
- 0: no action
- 1: status flag cleared

Bit 17 **CLPTIM2F**: clear the illegal access flag for LPTIM2
- 0: no action
- 1: status flag cleared
Bit 16 **CI2C4F**: clear the illegal access flag for I2C4
   0: no action
   1: status flag cleared

Bit 15 **CCRSF**: clear the illegal access flag for CRS
   0: no action
   1: status flag cleared

Bit 14 **CI2C2F**: clear the illegal access flag for I2C2
   0: no action
   1: status flag cleared

Bit 13 **CI2C1F**: clear the illegal access flag for I2C1
   0: no action
   1: status flag cleared

Bit 12 **CUART5F**: clear the illegal access flag for UART5
   0: no action
   1: status flag cleared

Bit 11 **CUART4F**: clear the illegal access flag for UART4
   0: no action
   1: status flag cleared

Bit 10 **CUSART3F**: clear the illegal access flag for USART3
   0: no action
   1: status flag cleared

Bit 9 **CUSART2F**: clear the illegal access flag for USART2
   0: no action
   1: status flag cleared

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 8 **CSPI2F**: clear the illegal access flag for SPI2
   0: no action
   1: status flag cleared

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **CGFXTIMF**: clear the illegal access flag for GFXTIM
0: no action
1: status flag cleared

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 10 **CDSIF**: clear the illegal access flag for DSI
0: no action
1: status flag cleared

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 9 **CLTDCUSBF**: clear the illegal access flag for LTDC or USB
0: no action
1: status flag cleared

*Note: This bit controls the LTDC on STM32U59x/5Ax/5Fx/5Gx. It controls the USB on STM32U535/545. It is reserved on STM32U575/585.*

Bits 31:29  Reserved, must be kept at reset value.

Bit 28  **CJPEGF**: clear the illegal access flag for JPEG

- 0: no action
- 1: status flag cleared

*Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 27  **CDCACHE2_REGF**: clear the illegal access flag for DCACHE2 registers

- 0: no action
- 1: status flag cleared

*Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 26  **CHSPI1_REGF**: clear the illegal access flag for HSPI1 registers

- 0: no action
- 1: status flag cleared

*Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 25  **CGFXMMU_REGF**: clear the illegal access flag for GFXMMU registers

- 0: no action
- 1: status flag cleared

*Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 24  **CGFXMMUF**: clear the illegal access flag for GFXMMU

- 0: no action
- 1: status flag cleared

*Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 23  **CGPU2DF**: clear the illegal access flag for GPU2D

- 0: no action
- 1: status flag cleared

*Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

Bit 22  **CRAMCFGF**: clear the illegal access flag for RAMCFG

- 0: no action
- 1: status flag cleared

Bit 21  **COCTOSPI2_REGF**: clear the illegal access flag for OCTOSPI2 registers

- 0: no action
- 1: status flag cleared

*Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

### Bit 31 CMPCBB5_REGF: clear the illegal access flag for MPCBB5 registers

- 0: no action
- 1: status flag cleared

**Note:** This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

### Bit 30 CSRAM5F: clear the illegal access flag for SRAM5

- 0: no action
- 1: status flag cleared

**Note:** This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

### Bit 29 CMPCBB3_REGF: clear the illegal access flag for MPCBB3 registers

- 0: no action
- 1: status flag cleared

**Note:** This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

### Bit 28 CSRAM3F: clear the illegal access flag for SRAM3

- 0: no action
- 1: status flag cleared

**Note:** This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.

### Bit 27 CMPCBB2_REGF: clear the illegal access flag for MPCBB2 registers

- 0: no action
- 1: status flag cleared

### Bit 26 CSRAM2F: clear the illegal access flag for SRAM2

- 0: no action
- 1: status flag cleared
Bit 25 **CMPCBB1_REGF**: clear the illegal access flag for MPCBB1 registers
0: no action
1: status flag cleared

Bit 24 **CSRAM1F**: clear the illegal access flag for SRAM1
0: no action
1: status flag cleared

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **CHSPI1_MEMF**: clear the illegal access flag for HSPI1 memory bank
0: no action
1: status flag cleared

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 19 **COCTOSPI2_MEMF**: clear the illegal access flag for OCTOSPI2 memory bank
0: no action
1: status flag cleared

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 18 **CBKPSRAMF**: clear the illegal access flag for MPCWM3 (BKPSRAM) memory bank
0: no action
1: status flag cleared

Bit 17 **CFSMC_MEMF**: clear the illegal access flag for MPCWM2 (FSMC NAND) and MPCWM3 (FSMC NOR)
0: no action
1: status flag cleared

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*

Bit 16 **COCTOSPI1_MEMF**: clear the illegal access flag for MPCWM1 (OCTOSPI1) memory bank
0: no action
1: status flag cleared

Bit 15 **CTZIC1F**: clear the illegal access flag for GTZC1 TZIC registers
0: no action
1: status flag cleared

Bit 14 **CTZSC1F**: clear the illegal access flag for GTZC1 TZSC registers
0: no action
1: status flag cleared

Bits 13:5 Reserved, must be kept at reset value.

Bit 4 **COTFDEC2F**: clear the illegal access flag for OTFDEC2
0: no action
1: status flag cleared

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and kept at reset value.*
Bit 3 **COTFDEC1F**: clear the illegal access flag for OTFDEC1  
0: no action  
1: status flag cleared

Bit 2 **CFLASHF**: clear the illegal access flag for flash memory  
0: no action  
1: status flag cleared

Bit 1 **CFLASH_REGF**: clear the illegal access flag for FLASH registers  
0: no action  
1: status flag cleared

Bit 0 **CGPDMA1F**: clear the illegal access flag for GPDMA1  
0: no action  
1: status flag cleared

Refer to Table 29: GTZC1 subblocks address offset.
5.8 GTZC1 MPCBBz registers (z = 1, 2, 3, 5, 6)

All registers are accessed only by words (32-bit).

5.8.1 GTZC1 SRAMz MPCBB control register (GTZC1_MPCBBz_CR) (z = 1, 2, 3, 5, 6)

Address offset: 0x0000
Reset value: 0x0000 0000
Secure privileged access only.

Note: Some registers are only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated memory region.

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 SPLCKy: Security/privilege configuration lock for super-block (y = 51 to 32)
This bit is set by software and can be cleared only by system reset.
0: GTZC1_MPCBBz_SECCFGRy and GTZC1_MPCBBz_PRIVCFGRy can be written.
1: Writes to GTZC1_MPCBBz_SECCFGRy and GTZC1_MPCBBz_PRIVCFGRy are ignored
5.8.4  **GTZC1 SRAMz MPCBB security configuration for super-block x register (GTZC1_MPCBBz_SECCFGRx) (z = 1, 2, 3, 5, 6)**

Address offset: 0x100 + 0x04 * x, (x = 0 to 51)

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 1. The reset value is 0x0000 0000 when TZEN = 0.

Write access to this register is secure only. Any read is allowed.

**Note:** Some registers are only available on some devices in the STM32U5 series. Refer to the device datasheet for availability of its associated memory region.

**LCK:** lock the configuration of GTZC2_TZSC_SECCFGRx and GTZC2_TZSC_PRIVCFGRx registers until next reset  
This bit is cleared by default and once set, it can not be reset until system reset.  
0: configuration of all GTZC2_TZSC_SECCFGRx and all GTZC2_TZSC_PRIVCFGRx registers not locked  
1: configuration of all GTZC2_TZSC_SECCFGRx and all GTZC2_TZSC_PRIVCFGRx registers locked

#### 5.9.2 GTZC2 TZSC secure configuration register 1 (GTZC2_TZSC_SECCFGR1)

**Address offset:** 0x010  
**Reset value:** 0x0000 0000  
Write-secure access only.

This register can be written only by secure privileged transaction when corresponding GTZC2_TZSC_PRIVCFGR register signal is set to 1. If a given PRIV bit is not set, the equivalent SEC bit can be written by secure unprivileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.9.3 GTZC2 TZSC privilege configuration register 1 (GTZC2_TZSC_PRIVCFGR1)

Address offset: 0x020
Reset value: 0x0000 0000
Write-privileged access only.

This register can be read or written only by secure privilege transaction when corresponding GTZC2_TZSC_SECFCGR register signal is set to 1. If a given SEC bit is not set, the equivalent PRIV bit can be read/written by nonsecure privileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privilege or not.

Refer to **Table 30: GTZC2 subblocks address offset**.
5.10 GTZC2 TZIC registers

All registers are accessed only by words (32-bit).

5.10.1 GTZC2 TZIC interrupt enable register 1 (GTZC2_TZICIER1)

Address offset: 0x000
Reset value: 0x0000 0000
Secure privilege access only.

This register is used to enable interrupt of illegal access.

5.11.3 **GTZC2 SRAM4 MPCBB security configuration for super-block 0 register (GTZC2_MPCBB4_SECCFGR0)**

Address offset: 0x100

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 1. The reset value is 0x0000 0000 when TZEN = 0.

Write access to this register is secure only. Any read is allowed.
5.11.4 GTZC2 SRAM4 MPCBB privileged configuration for super-block 0 register (GTZC2_MPCBB4_PRIVCFGR0)

Address offset: 0x200

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 1. The reset value is 0x0000 0000 when TZEN = 0.

Write access to this register is privileged only. Any read is allowed.

Bits 31:0 PRIVy: Privileged configuration for block y, belonging to super-block 0 (y = 31 to 0).
0: Privileged and unprivileged access to block y, belonging to super-block 0
1: privileged access only to block y, belonging to super-block 0
Nonsecure write to this bit is ignored if SECy bit is set in GTZC2_MPCBB4_SECCFG0.
Write are ignored if SPLCK0 bit is set in GTZC2_MPCBB4_CFGLOCKR1.

5.11.5 GTZC2 MPCBB4 register map

Table 44. GTZC2 MPCBB4 register map and reset values

6  RAM configuration controller (RAMCFG)

6.1  RAMCFG introduction

The RAMCFG configures the features of the internal SRAMs (SRAM1/2/3/4/5/6 and BKPSRAM).

6.2  RAMCFG main features

The internal SRAM supports some of the features listed hereafter, configured in RAMCFG:
- Error code correction (ECC):
  - Single error detection and correction with interrupt generation
  - Double error detection with interrupt or NMI generation
  - Status with failing address
- Write protection (1-Kbyte granularity)
- Programmable wait states for voltage scaling range 4
- SRAM software erase

6.3  RAMCFG functional description

6.3.1  Internal SRAMs features

Up to seven SRAMs are embedded in the devices, each with specific features:
- SRAM1/2/3/5/6 are the main SRAMs. The SRAM4 is in the SRAM used for peripheral low-power background autonomous mode (LPBAM) in Stop 2 mode.

<table>

<td>2 Kbytes</td>
</tr>
</tbody>
</table>

The backup SRAM (BKPSRAM) can be retained in all low-power modes and when VDD is off in VBAT mode (see Section 10: Power control (PWR) for more details).
- All internal SRAMs are erased by hardware in case of readout protection (RDP) level regression to level 0.5 or level 0. Refer to Section 7: Embedded flash memory (FLASH) for more details.

- The SRAM2 is erased when a system reset occurs if the SRAM2_RST option bit is selected in the flash memory user option bytes. SRAM1/3/4/5/6 are erased when a system reset occurs if the SRAM_RST option bit is selected in the flash memory user option bytes. Refer to Section 7: Embedded flash memory (FLASH) for more details.

- The SRAM2 and optionally the BKPSRAM are protected by the tamper detection circuit, and are erased by hardware in case of tamper detection. BKPSRAM is also erased by hardware in case of a backup domain reset. Refer to Section 64: Tamper and backup registers (TAMP) for more details.

- The RAMCFG embeds the registers related to the internal SRAMs ECC, write protection, wait-state configuration, and software erase.

The table below summarizes the features supported by each internal SRAM.

1. Optional: BKPSRAM can be configured to be erased or not on tamper detection.

### 6.3.2 Error code correction (SRAM2, SRAM3, BKPSRAM)

The ECC is supported by SRAM2/3 and BKPSRAM when enabled with the SRAM2_ECC, SRAM3_ECC, and BKPRAM_ECC user option bits. Refer to Section 7: Embedded flash memory (FLASH) for more details.

Seven ECC bits are added per 32 bits of SRAM, allowing two bits error detection, and one bit error correction on memory read access.

As the ECC is calculated and checked for a 32-bit word, the byte and half-word write accesses are managed by the SRAM interface by first reading the whole word, then write the word again with the new byte/half-word value. ECC double errors are also detected during these byte or half-word AHB write accesses (read/modify/write done by interface). The byte or half-word write access latency is WSC[2:0] + 2 AHB clock cycles (see Section 6.3.4).
Caution: In case of a byte or half-word write on SRAM with ECC, the read/modify/write operation is done in a buffer. The buffer content is written into the SRAM two AHB clock cycles after the SRAM AHB is released (when SRAM is no more accessed).

**Single and double ECC errors**

When a single error is detected, it is automatically corrected, and SEDC/CSEDLC bits are set in RAMCFG_MxISR and RAMCFG_MxICR respectively. An interrupt is generated if enabled by SEIE in RAMCFG_MxIER. The failing address is stored in RAMCFG_MxSEAR if the ALE bit is set in RAMCFG_MxCR.

Caution: Single errors cannot be detected when the SEDC bit is set.

When a double error is detected, DED and CDED bits are set in RAMCFG_MxISR and RAMCFG_MxICR respectively. An interrupt or NMI is generated if enabled by DEIE or ECCNMI bit in RAMCFG_MxIER. The failing address is stored in RAMCFG_MxDEAR if ALE is set in RAMCFG_MxCR.

Caution: Double errors cannot be detected when the DED bit is set.

**SRAM3 ECC specific management**

When the ECC is enabled for SRAM3, only the first 256 Kbytes of SRAM3 are with ECC. The next 192 Kbytes for STM32U575/585 or 512 Kbytes for STM32U59x/5Ax/5Fx/5Gx are without ECC, and the last block is used to store the ECC, so cannot be used for application.
The figure below shows the SRAM areas, when SRAM2 and SRAM3 ECC are enabled.

1. SRAM3 is not available on STM32U535/545 devices.

When ECC is enabled by user option bits, the ECCE bit is automatically set after system reset in the related RAMCFG_MxCR.

The ECC can be deactivated by executing the following software sequence:

1. Write 0xAE in RAMCFG_MxECCKEYR.
2. Write 0x75 in RAMCFG_MxECCKEYR.
3. Write 0 in the ECCE bit of RAMCFG_MxCR.

In case ECC is deactivated (ECCE = 0), the SRAM3 ECC storage area (from offset 0xB0000 to offset 0xBFFFF) can be read and written as other SRAM3 areas. In order to test the ECC mechanism, only the first 256 Kbytes of SRAM3 can be modified, 1 or 2 bits by word (for single or double error test respectively).
The procedure to check ECC is the following:
1. On an erased memory, write data with ECC on.
2. Disable ECC.
3. Write same data with 1- or 2-bit modification (for single or double error test respectively).
4. Enable ECC.
5. Wait until ECCE bit of RAMCFG_M3CR is read at 1.
6. Read data. Enabled interrupt is generated because of single or double error.

Steps 4 and 5 instructions must not be located in SRAM3 with ECC area. Any access to SRAM3 with ECC area by the other masters is forbidden during the steps 4 and 5 executions, until they are completed.

**Warning:** The ECC fault injection test triggers a system break event in TIM1/8/15/16/17, if the SPL bit is set in SYSCFG_CFGR2. This implies that the test must be performed while the PWM outputs of the timers are in idle state.

### 6.3.3 Write protection (SRAM2)

The SRAM2 is made of 64 1-Kbyte pages. Each 1-Kbyte page can be write-protected by setting its corresponding PxWP (x = 0 to 63) bit in RAMCFG_M2WPR1 and RAMCFG_M2WPR2.

### 6.3.4 Read access latency

To correctly read data from SRAMs, the number of wait states must be correctly programmed in WSC[2:0] field of RAMCFG_MxCR, depending on AHB clock frequency (HCLK) and voltage scaling range, as shown in the table below.

#### Table 47. Number of wait states versus HCLK frequency and voltage range scaling

<table>
<thead>
<tr>
<th>Wait states (WS) (latency)</th>
<th>HCLK (MHz)</th>
<th>( \text{V}_{\text{CORE}} \text{ range 1} )</th>
<th>( \text{V}_{\text{CORE}} \text{ range 2} )</th>
<th>( \text{V}_{\text{CORE}} \text{ range 3} )</th>
<th>( \text{V}_{\text{CORE}} \text{ range 4 and Stop 0/1/2 modes}^{(1)} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 WS (1 AHB cycle)</td>
<td></td>
<td>( \leq 160 )</td>
<td>( \leq 110 )</td>
<td>( \leq 55 )</td>
<td>( \leq 16 )</td>
</tr>
<tr>
<td>1 WS (2 AHB cycle)</td>
<td></td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>( \leq 25 )</td>
</tr>
</tbody>
</table>

1. The system clock can be requested in Stop 0/1/2 modes to perform DMA transfers to SRAM.

### 6.3.5 Software erase

SRAM erase can be requested by executing this software sequence:
1. Write 0xCA in RAMCFG_MxERKEYR.
2. Write 0x53 in RAMCFG_MxERKEYR.
3. Write 1 in RAMCFG_MxCR.
SRAMBUSY flag is set in the related SRAM interrupt status register as long as the erase is on going.

The total duration of each SRAM erase is N AHB clock cycles, where N is the size of the SRAM in 32-bit words.

If the SRAM is read or written while an erase is on going, wait states are inserted on the AHB bus until the end of the erase operation.

### 6.4 RAMCFG low-power modes

Table 48. Effect of low-power modes on RAMCFG

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. RAMCFG interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The content of RAMCFG registers is kept. The ECC is functional and ECC error interrupt or NMI causes the device to exit from Stop 0 and Stop 1 modes.</td>
</tr>
<tr>
<td>Standby</td>
<td>The RAMCFG peripheral is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

### 6.5 RAMCFG interrupts

The table below gives the list of RAMCFG interrupt requests.

Table 49. RAMCFG interrupt requests

<table>
<thead>
<tr>

</table>

1. Stop 0 and Stop 1 modes only.
6.6 RAMCFG registers

In the registers described below, x refers to:
- SRAM1/2/3/4 when x = 1/2/3/4 respectively
- BKPSRAM when x = 5
- SRAM5 when x = 6
- SRAM6 when x = 7

6.6.1 RAMCFG memory x control register (RAMCFG_MxCR)

Address offset: 0x040 * (x - 1), (x = 1 to 7)
Reset value: 0x0000 000X

ECCE reset value depends on ECC enable user option bit.

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 WSC[2:0]: Wait state configuration
This field is used to program the number of wait states inserted on the AHB when reading the SRAM, depending on its access time.
000: 0 wait state
001: 1 wait state
...
111: 7 wait states (not needed)

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 SRAMER: SRAM erase
This bit can be set by software only after writing the unlock sequence in the ERASEKEY field of the RAMCFG_MxERKEYR register. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.
0: No erase operation on going
1: Erase operation on going

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 ALE: Address latch enable
0: Failing address not stored in the SRAMx ECC single/double error address registers
1: Failing address stored in the SRAMx ECC single/double error address registers

Note: This bit is reserved and must be kept at reset value in SRAM1/4/5/6 control registers.

Bits 3:1 Reserved, must be kept at reset value.
6.6.2 RAMCFG memory x interrupt enable register (RAMCFG_MxIER)

Address offset: $0x004 + 0x40 \times (x - 1)$, ($x = 2, 3, 5$)
Reset value: $0x0000 \ 0000$

<table>
<thead>
<tr>

<td>Single error interrupt enabled</td>
</tr>
</tbody>
</table>

6.6.3 RAMCFG memory interrupt status register (RAMCFG_MxISR)

Address offset: $0x008 + 0x40 \times (x - 1)$, ($x = 1$ to 7)
Reset value: $0x0000 \ 0000$

| Bit 31:16 | Reserved, must be kept at reset value. |
| SRAM BUSY |                                           |
| DED       |                                           |
| SEDC      |                                           |

**Bit 0** **ECCE**: ECC enable.
This bit reset value is defined by the user option bit configuration. When set, it can be cleared by software only after writing the unlock sequence in the RAMCFG_MxECCKEYR register.

- 0: ECC disabled
- 1: ECC enabled

*Note: This bit is reserved and must be kept at reset value in SRAM1/4/5/6 control registers.*
Bits 31:9  Reserved, must be kept at reset value.

Bit 8  **SRAMBUSY**  : SRAM busy with erase operation
0: No erase operation on going
1: Erase operation on going

*Note:* Depending on the SRAM, the erase operation can be performed due to software request, system reset if the option bit is enabled, tamper detection or readout protection regression (see Table 46).

Bits 7:2  Reserved, must be kept at reset value.

Bit 1  **DED**  : ECC double error detected
0: No double error
1: Double error detected

*Note:* This bit is reserved and must be kept at reset value in SRAM1/4/5/6 interrupt status registers.

Bit 0  **SEDC**  : ECC single error detected and corrected
0: No single error
1: Single error detected and corrected

*Note:* This bit is reserved and must be kept at reset value in SRAM1/4/5/6 interrupt status registers.

### 6.6.4  RAMCFG memory x ECC single error address register (RAMCFG_MxSEAR)

Address offset: 0x00C + 0x40 * (x - 1), (x = 2, 3, 5)
Reset value: 0x0000 0000

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  **ERASEKEY[7:0]**: Erase write protection key

The following steps are required to unlock the write protection of SRAMER in RAMCFG_MxCR.
1) Write 0xCA into ERASEKEY[7:0].
2) Write 0x53 into ERASEKEY[7:0].

Note: Writing a wrong key reactivates the write protection.

6.6.11  **RAMCFG register map**

Refer to Section 2.3 for the register boundary addresses.
7 Embedded flash memory (FLASH)

7.1 FLASH introduction

The flash memory interface manages accesses to the flash memory, maximizing throughput to the CPU, instruction cache and DMAs. It implements the flash memory erase and program operations as well as the read and write protection mechanisms. It also implements the security and privilege access control features. It is optimized in terms of power consumption with dedicated modes when the MCU is in low-power modes.

7.2 FLASH main features

- Up to 4 Mbytes of flash memory supporting read-while-write capability (RWW).
- Memory organization
  - Dual bank architecture (bank 1 and bank 2)
  - Main memory: up to 2 Mbytes per bank
  - Information block: 64.5 Kbytes in bank 1
- 128-bit wide data read with prefetch
- Standard and burst programming modes
- Read, program and erase operations in all voltage ranges
- 10 kcycles endurance on all flash memory, 100 kcycles on up to 256 Kbytes per bank
- Page erase, bank erase and mass erase (both banks)
- Bank swapping: the user flash memory address mapping of each bank can be swapped.
- Product security activated by TrustZone option bit (TZEN)
- Device life cycle managed by readout protection option byte (RDP)
- Four write protection areas (two per bank)
- TrustZone support:
  - Two secure areas (1 per bank)
  - Two secure HDP (hide protection) areas part of the secure areas (one per bank)
- Configurable protection against unprivileged accesses with flash page granularity
- Error code correction: 9-bit ECC per 128-bit quad-word allowing two bits error detection and one bit error correction
- Option-byte loader
- Advanced low-power modes (low-power read mode, bank power-down mode)
7.3  **FLASH functional description**

7.3.1  **Flash memory organization**

The flash memory has the following main features:

- Capacity up to 4 Mbytes
- Dual-bank mode:
  - up to 2 Mbytes per bank for main memory
  - 8 Kbytes page size
  - 137 bits wide data read and write (128 effective bits plus 9 ECC bits)
  - Page, bank and mass erase
  - Support read-while-write feature
  - Support bank shutdown feature for power consumption saving

The flash memory is organized as follows:

- Main memory block organized as two banks of up to 2 Mbytes each containing up to 256 pages of 8 Kbytes
- An information block containing:
  - 32 Kbytes for system memory. This area is immutable and reserved for use by STMicroelectronics. It contains the bootloader that is used to reprogram the flash memory through one of the user communication interfaces such as USB (DFU). The system memory is programmed by STMicroelectronics when the device is manufactured. For further details, refer to the application note *STM32 microcontroller system memory boot mode* (AN2606).
  - 32 Kbytes immutable secure area containing the root security services (RSS and RSS library) developed by STMicroelectronics
  - 512 bytes OTP (one-time programmable) bytes for user data (32 quad-words). The OTP data cannot be erased and can be written only once.
  - option bytes for user configuration. Unlike user flash memory and system memory, it is not mapped to any memory address and can be accessed only through the flash register interface.
The memory organization is based on a main area and an information block as shown in the tables below.

### Table 51. Flash module 512-Kbyte dual-bank organization for STM32U535/545(1)

<table>
<thead>

7.3.2 Error code correction (ECC)

Data in flash memory are 137-bit words: Nine bits are added per quad-word (128 bits). The ECC mechanism supports:

- one error detection and correction
- two errors detection

When one error is detected and corrected, the ECCC flag (ECC correction) is set in FLASH_ECCR. If the ECCCIE bit is set, an interrupt is generated.

When two errors are detected, the ECCD flag (ECC detection) is set in FLASH_ECCR. In this case, an NMI is generated.

When an ECC error is detected, the address of the failing quad-word and its associated bank are saved in ADDR_ECC[19:0] and BK_ECC in FLASH_ECCR. ADDR_ECC[3:0] are always cleared.

When ECC or ECCD is set, ADDR_ECC and BK_ECC are not updated if a new ECC error occurs. FLASH_ECCR is updated only when ECC flags are cleared.

Caution: When the ECCC flag is set, a further two-errors detection is not able to generate the NMI or break signal to timers. It is therefore recommended to clear the ECC flag as soon as a correction is operated, to preserve the ECC error detection capability. In case of a double
ECC error detection (ECCD flag set and NMI triggered), the software must clean the cache in the NMI handler. Refer to STM32U5 Series safety manual (UM2875) for the full description of the implications on safety standards compliance.

**Note:** For an erased flash line, one error is detected and corrected but two errors detection is not supported. When an ECC error is reported, a new read at the failing address may not generate an ECC error if the data is still present in the current buffer, even if ECCC and ECCD are cleared.

The following addresses in the system flash memory are used to store words including ECC errors to allow run-time tests by software on ECC correction detection capability:

- 0x0BFA1F00 (embeds a word with 1-bit error)
- 0x0BFA1F80 (embeds a word with 2-bit error)

In case the second address is read, for instance by the debugger memory viewer, an NMI is generated.

### 7.3.3 Read access latency

To correctly read data from flash memory, the number of wait states (latency) must be correctly programmed in FLASH_ACR according to the frequency of the CPU clock (HCLK), and the internal voltage range of the device $V_{\text{CORE}}$. Refer to Section 10.5.4: Dynamic voltage scaling management.

The table below shows the correspondence between wait states and CPU clock frequency.

<table>
<thead>
<tr>
<th>Wait states (WS) (latency)</th>
<th>HCLK (MHz)</th>
<th>$V_{\text{CORE}}$ range 1</th>
<th>$V_{\text{CORE}}$ range 2</th>
<th>$V_{\text{CORE}}$ range 3</th>
<th>$V_{\text{CORE}}$ range 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 WS (1 CPU cycle)</td>
<td>0 - 64</td>
<td>≤ 32</td>
<td>≤ 30</td>
<td>≤ 24</td>
<td>≤ 12</td>
</tr>
<tr>
<td>1 WS (2 CPU cycles)</td>
<td>0 - 64</td>
<td>≤ 64</td>
<td>≤ 60</td>
<td>≤ 48</td>
<td>≤ 25</td>
</tr>
<tr>
<td>2 WS (3 CPU cycles)</td>
<td>0 - 64</td>
<td>≤ 96</td>
<td>≤ 90</td>
<td>≤ 55</td>
<td>-</td>
</tr>
<tr>
<td>3 WS (4 CPU cycles)</td>
<td>0 - 64</td>
<td>≤ 128</td>
<td>≤ 110</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>4 WS (5 CPU cycles)</td>
<td>0 - 64</td>
<td>≤ 160</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>
The flash memory supports a low-power read mode when setting LPM in FLASH_ACR. The table below shows the correspondence between wait states and CPU clock frequency when LPM bit is set.

Table 55. Number of wait states according to CPU clock (HCLK) frequency (LPM = 1)

<table>
<thead>
<tr>
<th>Wait states (WS) (latency)</th>
<th>HCLK (MHz)</th>
<th>( V_{\text{CORE}} ) range 1/2/3</th>
<th>( V_{\text{CORE}} ) range 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 WS (1 CPU cycle)</td>
<td>( \leq ) 8</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1 WS (2 CPU cycles)</td>
<td>( \leq ) 16</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2 WS (3 CPU cycles)</td>
<td>( \leq ) 25</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3 WS (4 CPU cycles)</td>
<td>Maximum HCLK frequency is given by Table 54</td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td>-</td>
<td></td>
<td></td>
</tr>
<tr>
<td>15 WS (16 CPU cycles)</td>
<td>-</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

After reset, the CPU clock frequency is 4 MHz, 0 wait state (WS) is configured in FLASH_ACR and the normal read mode is selected (LPM = 0).

Instruction prefetch

The Cortex-M33 fetches instructions and literal pools (constants/data) over the C-Bus and through the instruction cache if it is enabled. The prefetch block aims at increasing the efficiency of C-Bus accesses in case the instruction cache is enabled by reducing the cache refill latency. Prefetch is efficient in case of sequential code; prefetch in the flash memory allows the next sequential instruction line to be read from the flash memory while the current instruction line is being filled in instruction cache and executed by the CPU.

Prefetch is enabled by setting PRFTEN in FLASH_ACR. PRFTEN must be set only if at least one wait state is needed to access the flash memory.

Note: Prefetch tends to increase the code execution performance at the cost extra flash memory accesses. It must be used carefully in low-power applications.

When changing the CPU frequency, the software sequences detailed below must be applied in order to tune the number of wait states needed to access the flash memory.

Increase the CPU frequency

1. Program the new number of wait states to LATENCY bits in FLASH_ACR.
2. Check that the new number of wait states is taken into account to access the flash memory by reading back FLASH_ACR.
3. Modify the CPU clock source by writing W bits in RCC_CFGR1.
4. Modify the CPU clock prescaler, if needed, by writing HPRE bits in RCC_CFGR2.
5. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in RCC_CFGR1 and RCC_CFGR2.
Decrease the CPU frequency
1. Modify the CPU clock source by writing SW bits in RCC_CFG1.
2. Modify the CPU clock prescaler, if needed, by writing HPRE bits in RCC_CFG2.
3. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in RCC_CFG1 and RCC_CFG2.
4. Program the new number of wait states to LATENCY bits in FLASH_ACR.
5. Check that the new number of wait states is used to access the flash memory by reading back FLASH_ACR.

The software sequences detailed below must be applied in order to modify the read mode.

From normal read mode to low-power read mode
1. Set LPM in FLASH_ACR.
2. Check that the low-power read mode is activated by reading FLASH_ACR.

From low-power read mode to normal read mode
1. Reset LPM bit in FLASH_ACR.
2. Check that the normal read mode is activated by reading FLASH_ACR.

7.3.4 Bank power-down mode
After reset, both banks are in normal mode. In order to reduce power consumption, each bank can be independently put in power-down mode by setting PDREQx in FLASH_ACR.

Request entry in power-down mode for bank x
- Check that bank x is not in power-down mode, and that no request to put it in power-down mode is pending (PDx in FLASH_NSSR and PDREQx in FLASH_ACR must be reset).
- Unlock PDKEYxR with correct keys (see FLASH_PDKEY1R or FLASH_PDKEY2R).
- Set PDREQx in FLASH_ACR.
- Check that PDx is set in LFASH_NSSR PDREQx in FLASH_ACR is automatically reset, and the PDKEYxR is locked.

Note: If bank x is currently being accessed, the power-down request is delayed until the access is completed.
Requesting power-down entry for a bank already in power-down mode has no effect. PDREQx in FLASH_ACR is automatically reset, and the PDKEYxR is locked.

Return to normal mode
Any access to a bank in power-down mode automatically wakes up the bank. A penalty of 5 µs minimum is taken to wake up the bank.

Waking up bank 1 (respectively bank 2) is done in one of the following cases:
- upon a valid read access to bank 1 (resp. bank 2)
- upon a valid write access to bank 1 (resp. bank 2)
- upon a valid bank erase on bank 1 (resp. bank 2)
Waking up both bank 1 and bank 2 is done in one of the following cases:
- upon a valid mass erase
- upon an option byte modification
- upon an option byte loading
- upon system reset

*Note:* The software can reduce the flash bank wake-up time by enabling HSI16 before waking up the bank.

### 7.3.5 Flash memory program and erase operations

The embedded flash memory can be programmed using in-circuit programming (ICP) or in-application programming (IPA).

The ICP method is used to update the entire contents of the flash memory, using the JTAG, SWD protocol, or the bootloader to load the user application into the microcontroller. The ICP offers quick and efficient design iterations, and eliminates unnecessary package handling or socketing of devices.

The IAP can use any communication interface supported by the microcontroller (such as I/Os, USB, CAN, UART, I2C, or SPI) to download programming data into the memory.

The IAP allows the user to reprogram the flash memory while the application is running. Part of the application must have been previously programmed in the flash memory using ICP.

An ongoing flash memory operation does not block the CPU as long as the CPU does not access the same flash memory bank. Code or data fetches are possible on one bank while a write/erase operation is performed to the other bank (refer to *Section 7.3.10*).

On the contrary, during a program/erase operation to the flash memory, any attempt to read the same flash memory bank stalls the bus. The read operation proceeds correctly once the program/erase operation has been completed.

The MCU supports TrustZone that defines secure and nonsecure areas in the flash memory. All program and erase operations can be performed in secure mode through the secure registers or in nonsecure mode through the nonsecure registers.

For more information, refer to *Section 7.5*.

**Unlock the secure/nonsecure FLASH control registers**

After reset, write is not allowed in FLASH_SECCR and FLASH_NSCR in order to protect the flash memory against possible unwanted operations (due, for example, to electric disturbances).

The following sequence is used to unlock these registers:

1. Write KEY1 = 0x45670123 in FLASH_SECKEYR or FLASH_NSKEYR.
2. Write KEY2 = 0xCDEF89AB in FLASH_SECKEYR or FLASH_NSKEYR.

Any wrong sequence locks up FLASH_SECCR or FLASH_NSCR until the next system reset. In the case of a wrong key sequence, a bus error is detected and a HardFault interrupt is generated.

FLASH_NSCR (resp. FLASH_SECCR) can be locked again by software by setting LOCK in FLASH_NSCR (resp. FLASH_SECCR).
**Note:** FLASH_NSCR and FLASH_SECCR cannot be written when the BSY bits are set. Any attempt to write them with BSY bits set, causes the AHB bus to stall until the BSY bits are cleared.

**Wait for data-to-write flags (WDW)**

The WDW flags in FLASH_NSSR and FLASH_SECSR are both set when a secure or non-secure write access has been done in the write buffer. They are cleared when BSY flags are set (meaning that the write buffer is freed and the programming operation actually starts in the flash memory) or in case of error.

The software must ensure that the four words in the same quad-word are all written.

**Flash secure and nonsecure busy flags**

BSY flags in FLASH_NSSR and FLASH_SECSR are both set when a secure or nonsecure flash operation is started:

- Erase operation: setting STRT in FLASH_NSCR or FLASH_SECCR.
- Write operation: setting PG in FLASH_NSCR or FLASH_SECCR, and writing a quad-word in the flash memory.
- Option-byte programming: setting OPTSTRT in FLASH_NSCR.

**7.3.6 Flash main memory erase sequences**

The flash memory erase operation can be performed at page level, bank level or on the whole flash memory (mass erase). Mass erase does not affect the information block (system flash, OTP and option bytes). The erase operation is either secure or nonsecure.

**Page erase**

To erase a page, follow the procedure below:

1. Check that no flash memory operation is ongoing by checking BSY in FLASH_NSSR or FLASH_SECSR.
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set PER bit and select the page to erase (PNB) with the associated bank (BKER) in FLASH_NSCR or FLASH_SECCR.
4. Set STRT in FLASH_NSCR or FLASH_SECCR.
5. Wait for BSY to be cleared in FLASH_NSSR or FLASH_SECSR.

**Bank 1 or bank 2 mass erase**

To perform a bank mass erase, follow the procedure below:

1. Check that no flash memory operation is ongoing by checking BSY in FLASH_NSSR or FLASH_SECSR.
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the MER1 or MER2 bit (depending on the bank) in FLASH_NSCR or FLASH_SECCR. Both banks can be selected in the same operation, in that case it corresponds to a mass erase.
4. Set STRT in FLASH_NSCR or FLASH_SECCR.
5. Wait for BSY bit to be cleared in FLASH_NSSR or FLASH_SECSR.
6. The MER1 or MER2 bits can be cleared if no more bank erase is requested.

**Mass erase**

To perform a mass erase, follow the procedure below:

1. Check that no flash memory operation is ongoing by checking BSY in FLASH_NSSR or FLASH_SECSR.
2. Check and clear all nonsecure error programming flags due to a previous programming. If not, the PGSERR bit is set.
3. Set MER1 bit and MER2 bits in FLASH_NSCR or FLASH_SECCR.
4. Set STRT in FLASH_NSCR or FLASH_SECCR.
5. Wait for BSY bit to be cleared in FLASH_NSSR or FLASH_SECSR.
6. The MER1 and MER2 bit can be cleared if no more mass erase is requested.

**Note:**
The internal oscillator HSI16 (16 MHz) is enabled automatically when the STRT bit is set, and disabled automatically when the STRT bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR.

To erase a page, a bank or to perform a mass erase, the software must have sufficient privilege (see Table 73 and Table 74).

### 7.3.7 Flash main memory programming sequences

The flash memory is programmed 137 bits at a time (128-bit data + 9 bits ECC).

Programming in a previously programmed address is not allowed except if the data to write is full zero, and any attempt sets PROGERR flag in FLASH_NSSR or FLASH_SECSR.

It is only possible to program quad-word (4 x 32-bit data).

- Any attempt to write byte or half-word sets SIZERR flag in FLASH_NSSR or FLASH_SECSR.
- Any attempt to write a quad-word that is not aligned with a quad-word address sets PGAERR flag in FLASH_NSSR or FLASH_SECSR.

**Flash programming**

The flash memory programming sequence is as follows:

1. Check that no flash main memory operation is ongoing by checking BSY in FLASH_NSSR or FLASH_SECSR.
2. Check that the write buffer is empty by checking WDW in FLASH_NSSR or FLASH_SECSR.
3. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
4. Set PG bit in FLASH_NSCR or FLASH_SECCR.
5. Perform the data write operation at the desired flash memory address, or in the OTP area. Only a quad-word can be programmed and OTP can be only programmed in non-secure access:
   - Write a first word in an address aligned on a quad-word address. WDW bits in FLASH_NSSR and FLASH_SECSR are set to indicate that more data can be written in the write buffer.
   - Write the second, third and fourth word in the same quad-word.
6. The BSY bit gets set. WDW is reset automatically.

7. Wait until BSY is cleared in FLASH_NSSR or FLASH_SECSR. The software must make sure that BSY is set or WDW is cleared before waiting for BSY to get cleared.

8. If the EOP flag is set in FLASH_NSSR or FLASH_SECSR (meaning that the programming operation has succeeded and the EOPIE bit is set), it must be cleared by software.

9. Clear PG in FLASH_NSCR or FLASH_SECCR if there is no more programming request.

**Note:** When the flash memory interface received a good sequence (a quad-word), programming is automatically launched and BSY bits are set. The internal oscillator HSI16 (16 MHz) is enabled automatically when PG bit is set, and disabled automatically when PG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR.

No option bytes modification nor erase request is allowed when WDW bit is set.

Programming is possible only if the privileged and security attributes are respected (refer to Section 7.7).

If the user needs to program only one word, the quad-word must be completed with the erase value 0xFFFF FFFF to launch automatically the programming.

ECC is calculated from the quad-word to program.

**Flash burst programming (8 quad-words)**

The flash memory burst programming sequence is as follows:

1. Check that no flash main memory operation is ongoing by checking BSY bit in FLASH_NSSR or FLASH_SECSR.

2. Check that the write buffer is empty by checking WDW in FLASH_NSSR or FLASH_SECSR.

3. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.

4. Set BWR and PG bits in FLASH_NSCR or FLASH_SECCR.

5. Perform the data write operation at the desired flash memory address, or in the OTP area. Only 8 quad-words can be programmed:
   - Write a first 32-bit word in an address aligned on a 8 * quad-word address (multiple of 0x80). WDW bits in FLASH_NSSR and FLASH_SECSR are set to indicate that more data can be written in the write buffer.
   - Write the 31 other 32-bit words consecutively.

6. The BSY bit gets set. WDW is reset automatically.

7. Wait until BSY is cleared in FLASH_NSSR or FLASH_SECSR. The software must make sure that BSY is set or WDW is cleared before waiting for BSY to get cleared.

8. If EOP flag is set in FLASH_NSSR or FLASH_SECSR (meaning that the programming operation has succeeded and EOPIE is set), it has to be cleared by software.

9. Clear BWR and PG bits in FLASH_NSCR or FLASH_SECCR if there is no more programming request.

**Note:** When the flash memory interface received a good sequence, programming is automatically launched and the BSY bits are set. The internal oscillator HSI16 (16 MHz) is enabled.
automatically when PG bit is set, and disabled automatically when PG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

No option bytes modification nor erase request is allowed when WDW bit is set.

Programming is possible only if the privileged and security attributes are respected (see Section 7.7).

7.3.8 Flash memory endurance

Each flash memory page can be written and erased 10 000 or 100 000 times. A maximum of 32 pages (256 Kbytes) per bank feature this increased endurance of 100 kcycles. This enhanced endurance can be used for data storage that usually needs more intensive cycling capability than code storage.

Any flash page can be chosen to be cycled up to 100 kcycles. As soon as a page is above 10 kcycles, it is considered as high cycling page (even if not yet at 100 kcycles). The application must take care not to exceed 32 pages cycled more than 10 000 times.

For STM32U535/545, as it fits a maximum of 32 pages (256 Kbytes) per bank, the entire flash memory is 100-kcycle capable.

7.3.9 Flash memory errors flags

Flash programming errors

Several kind of errors can be detected during secure and nonsecure operations. In case of error, the flash memory operation (programming or erasing) is aborted.

The secure errors flags are only set during a secure operation and nonsecure flags are only set during a nonsecure operation.

- **PROGERR**: secure/nonsecure programming error
  It is set when the word to program is pointing to an address:
  - not previously erased
  - already fully programmed to 0
  - already partially programmed (contains 0 and 1) and the new value to program is not full zero
  - for OTP programming, when the address is already partially programmed (contains 0 and 1)

- **SIZERR**: secure/nonsecure size programming error
  Only 32-bit data can be written. SIZERR flag is set if a byte or a half-word is written.

- **PGAERR**: secure/nonsecure alignment programming error
  It is set when the first word to be programmed is not aligned with a quad-word address, or the second, third or forth word does not belong to the same quad-word address.
  For burst programming, it is set when the first word to be programmed is not aligned on a 8 *quad-word address or if the following word writes are not done at consecutive 32-bit addresses.

- **PGSERR**: programming sequence error
  PGSERR is set if one of the following conditions occurs during a erase or program operation:
  - A data is written when PG is cleared.
A program operation is requested during erase: PG is set while MER1, MER2, or PER is set.

– In the erase sequence, PG is set while STRT is already set.
– In the erase sequence, if STRT is set while MER1, MER2, and PER are cleared.
– If page and mass erase are requested at the same time, STRT and PER are set while MER1 or MER2 is set.
– If an operation is started while the write buffer is waiting for the next data, STRT or OPTSTRT is set while WDW is already set.
– If STRT and OPTSTRT are set at the same time.

A nonsecure PGSERR is set if the nonsecure STRT bit is set by a secure access.

– A secure PGSERR is set if PROGERR, SIZERR, PGAERR, WRPER, R or PGSERR is already set due to a previous programming error.
– A nonsecure PGSERR is set if PROGERR, SIZERR, PGAERR, WRPER, PGAERR, or OPTWERR is already set due to a previous programming error.

\* WRPEERR: write protection error

– Refer to Table 68 to Table 71 for all the conditions of WRPEERR flag setting.

\* OPTWERR: option bytes write error

OPTWERR is set if when user option bytes are modified with an invalid configuration. It is set when attempting:

– to program an invalid secure watermark-based area. Refer to Table 59
– to set or clear the TZEN option bit when RDP is not at correct level (refer to Rules for modifying specific option bytes)
– to clear the BOOT_LOCK option bit when RDP is not at correct level (refer to Rules for modifying specific option bytes)
– to modify SWAP_BANK option bit while BOOT_LOCK and TZEN are set
– to modify SECBOOTADD0 option bit while BOOT_LOCK is set
– to modify DUALBANK option bit while BOOT_LOCK and TZEN are set
– to modify SECWM1Rx (resp. SECWM2Rx) while HDP1_ACCDIS (resp. HDP2_ACCDIS) is set
– to modify the option bytes, except the SWAP_BANK option bit, when RDP is set to level 2
– to regress from RDP level 0.5 to RDP level 0
– to modify OEM1KEYRxR while RDP level is 0.5 or 1 and OEM1LOCK bit is set
– to modify OEM2KEYRx while RDP level is 1 and OEM2LOCK bit is set
– to regress from RDP level 1 to RDP level 0 while OEM1LOCK bit is set and a wrong OEM1KEY is shifted through JTAG or SWD
– to regress from RDP level 1 to RDP level 0.5 while OEM2LOCK bit is set and a wrong OEM2KEY is shifted through JTAG or SWD
– to modify WRPxyR while its UNLOCK bit is cleared
– to set the UNLOCK bit in the WRPxyR when RDP is not at correct level (refer to Rules for modifying specific option bytes)
If an error occurs during a secure or nonsecure program or erase operation, one of the following programming error flags is set:

- **nonsecure programming error flags:** PROGERR, SIZERR, PGAERR, PGSERR, OPTWRERR, or WRPERR is set in FLASH_NSSR.
  
  If ERRIE is set in FLASH_NSCCR, an interrupt is generated and the operation error flag OPERR is set in the FLASH_NSSR register.

- **Secure programming error flags:** PROGERR, SIZERR, PGAERR, PGSERR, or WRERR is set in FLASH_SECSR.
  
  If ERRIE is set in FLASH_SECCR, an interrupt is generated and the operation error flag OPERR is set in FLASH_SECSR.

*Note:* If several successive errors are detected (for example, in case of DMA transfer to the flash memory), the error flags cannot be cleared until the end of the successive write requests. Any programming error flushes the write buffer.

### 7.3.10 Read-while-write (RWW)

The flash memory is divided into two banks allowing read-while-write operations. This feature allows a read operation to be performed from one bank while erase or program operation is performed to the other bank.

*Note:* Write-while-write operations are not allowed. As an example, it is not possible to perform an erase operation on one bank while programming the other one.

**Read from bank 1 while page erasing in bank 2 (or vice versa)**

While executing a program code from bank 1, it is possible to perform a page erase operation on bank 2 (and vice versa).

**Read from bank 1 while mass erasing bank 2 (or vice versa)**

While executing a program code from bank 1, it is possible to perform a mass erase operation on bank 2 (and vice versa).

**Read from bank 1 while programming bank 2 (or vice versa)**

While executing a program code from bank 1, it is possible to perform a program operation on the bank 2 (and vice versa).

*Note:* Due to the Cortex-M33 unified C-Bus, the user software must ensure to not stall C-Bus with multiple consecutive writes. It is recommended to wait for the BSY flag to be cleared before programming the next quad-word.

### 7.3.11 Power-down during FLASH programming or erase operation

The contents of the flash memory currently being accessed are not guaranteed if a power-down occurs during a flash memory program or erase operation.

### 7.3.12 Reset during FLASH programming or erase operation

The contents of the flash memory currently being accessed are not guaranteed if a reset occurs during a flash memory program or erase operation. The status of the flash memory can be recovered from FLASH_OPSR when a system reset occurs during a flash memory program or erase operation.
The software must check the status of the flash memory and take corrective actions. This must be done after each system reset before any other programming or erase operation is performed.

The table below describes the corrective action to be taken according to the status provided by CODE_OP field in FLASH_OPSR.

### Table 56. Flash operation interrupted by a system reset

<table>
<thead>

<td></td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**Note:** For single and burst write, it is mandatory to perform a page erase because the current flash memory locations may no longer be writable. Consequently, the remaining page content must be saved before page erase and restored afterwards.

For OTP write, it is not possible to perform a page erase. The OTP quad-word is lost.

For burst write, ADDR_OP gives the first address of burst. User must restart the same burst operation.

For page erase, ADDR_OP gives the first address of erased page.

### 7.4 FLASH option bytes

#### 7.4.1 Option bytes description

The option bytes are configured by the end user depending on the application requirements. As a configuration example, the watchdog may be selected in hardware or software mode (refer to Section 7.4.2). The user option bytes are accessible through the flash memory registers.

*Table 57* describes the organization of all user option bytes available in flash memory registers.

7.4.2 Option-byte programming

After reset, the following option registers (FLASH_OPTR, FLASH_NSBOOTADD0R, FLASH_NSBOOTADD1R, FLASH_SECBOOTADD0R, FLASH_SECW1R, FLASH_SECW1R2, FLASH_WRP1AR, FLASH_WRP1BR, FLASH_SECW2R1, FLASH_SECW2R2, FLASH_WRP2AR, FLASH_WRP2BR), as well as the OPT_STRT and OBL_LAUNCH bits in FLASH_NSCR are write protected. To run any option-byte operation, OPTLOCK must be cleared in FLASH_NSCR.

The following sequence is used to unlock this register:

1. Unlock FLASH_NSCR register with the LOCK clearing sequence (refer to Unlock the secure/nonsecure FLASH control registers).
2. Write OPTKEY1 = 0x08192A3B in FLASH_OPTKEYR.
3. Write OPTKEY2 = 0x4C5D6E7F in FLASH_OPTKEYR.

The user options can be protected against unwanted erase/program operations by setting OPTLOCK bit by software.

Note: If LOCK in FLASH_NSCR is set by software, OPTLOCK is automatically set too.

Option-byte modification sequence

To modify the user option value, follow the procedure below:

1. Check that no flash memory operation is on going by checking BSY in FLASH_NSSR.
2. Clear OPTLOCK with the clearing sequence described above.
3. Write the desired options value in options registers.
4. Set OPTSTRT in FLASH_NSCR.
5. Wait for BSY bit to be cleared.
6. Set OBL_LAUNCH option bit to start option-byte loading.

Note: If OPTWERR or PGSERR error bit is set, the old option-byte values are kept.

Option-byte loading (OBL)

After BSY is cleared, all new options are updated in the flash memory but they are not applied to the system. They affect the system when they are loaded. The OBL is performed in two cases:

- when OBL_LAUNCH is set in FLASH_NSCR
- after a power reset (BOR reset or exit from Standby or Shutdown mode)

On system-reset rising, internal option registers are copied into option registers. These registers are also used to modify the option bytes. If these registers are not modified by the user, they reflect the option states of the system.

Rules for modifying specific option bytes

Some of the option-byte bitfields must respect specific rules before being updated with new values. These option bytes, as well as the associated constraints, are described below:

- TZEN option bit
  - TZEN can only be set on RDP level 0.
  - TZEN deactivation is only possible when RDP is changing from level 1 to level 0.
• BOOT_LOCK option bit
  – BOOT_LOCK has only effect when TZEN is set.
  – BOOT_LOCK can be set without any constraint.
  – BOOT_LOCK deactivation is only possible when RDP is level 0.
• SWAP_BANK option bit
  – It cannot be modified when BOOT_LOCK and TZEN option bits are set.
• SECBOOTADD0 option bytes
  – It cannot be modified when BOOT_LOCK option bit is set.
• DUAL_BANK option bit
  – It cannot be modified when BOOT_LOCK and TZEN option bits are set.
• SECWMxRy option bits
  – Secure option bits (SECWMx_PSTRT[6:0] and SECWMx_PEND[6:0]), and HDP option bits (HDPx_PEND[6:0] and HDPxEN) area in bank x cannot be modified when HDPx_ACCDIS bit is set.
• RDP option bits
  – Refer to Device life cycle managed by readout protection (RDP) transitions.
• WRPxyR option bits
  – These bits cannot be modified when their UNLOCK bit is cleared.
• UNLOCK option bits
  – These bits can be set only when regressing from RDP level 1 to level 0.

If the user options modification tries to set or modify one of the listed option bytes without following their associated rules, the option-byte modification is discarded and OPTWERR error flag is set.

## 7.5 FLASH TrustZone security and privilege protections

### 7.5.1 TrustZone security protection

The global TrustZone system security is activated by setting TZEN in FLASH_OPTR.

When TrustZone is active (TZEN = 1), the following additional security features are available:

- secure watermark-based user option bytes defining secure and HDP areas
- secure or nonsecure block-based area that can be configured on-the-fly after reset (volatile secure area)
- an additional RDP protection: RDP level 0.5
- erase or program operation that can be performed in secure or nonsecure mode with associated configuration bit.

When the TrustZone is disabled (TZEN = 0), the above features are deactivated and all secure registers are RAZ/WI.

**Activate TrustZone security**

When the TrustZone is activated (TZEN is modified from 0 to 1), the secure watermark-based user options bytes are set to default secure state: all flash memory is secure, and no HDP area, as shown in *Table 58*. 
Illegal access generation

A nonsecure access to a secure flash memory area is RAZ/WI, and generates an illegal access event. An illegal access interrupt is generated if the FLASHIE illegal access interrupt is enabled in TZIC_IER2.

A nonsecure access to a secure FLASH register generates an illegal access event. An illegal access interrupt is generated if the FLASH_REGIE illegal access interrupt is enabled in TZIC_IER2.

Deactivate TrustZone security

Deactivation of TZEN (from 1 to 0) is only possible when the RDP changes from level 1 to level 0.

When the TrustZone is deactivated (TZEN is modified from 1 to 0) after the OBL, the following security features are deactivated:

- watermark-based secure area (refer to Section 7.5.2)
- block-based secure area (refer to Section 7.5.4)
- RDP level 0.5 (refer to Section 7.6.2)
- secure interrupts (refer to Section 7.8)

All secure registers are RAZ/WI.

7.5.2 Watermark-based secure flash memory area protection

When TrustZone security is active (TZEN = 1), a part of the flash memory can be protected against nonsecure read and write accesses. Up to two different non-volatile secure areas can be defined by option bytes, and can be read or written by a secure access only: one area per bank can be selected with a page granularity.

The secure areas are defined by a start-page offset and end-page offset using SECWMx_PSTRT and SECWMx_PEND (x = 1,2 for area 1 and area 2) option bytes. These offsets are defined in FLASH_SECWM1R1 and FLASH_SECWM2R1.

SECWMx_PSTRT and SECWMx_PEND option bytes can only be modified by secure firmware when HDPx_ACCDIS bit is reset. If this bit is set, SECWMx_PSTRT and SECWMx_PEND cannot be modified until next system reset.

Table 58. Default secure option bytes after TZEN activation

<table>
<thead>
<tr>
<th>Secure watermark option-byte values after OBL when TZEN is activated</th>
<th>Security attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECWMx_PSTRT = 0 and SECWMx_PEND = 0x7F</td>
<td>All flash memory secure</td>
</tr>
<tr>
<td>HDPxEN = 0 and HDPx_PEND = 0</td>
<td>No secure HDP area</td>
</tr>
</tbody>
</table>

Table 59. Secure watermark-based area

<table>
<thead>
<tr>
<th>Secure watermark option-byte values (x = 1,2)</th>
<th>Secure watermark protection area</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECWMx_PSTRT &gt; SECWMx_PEND</td>
<td>No secure area</td>
</tr>
</tbody>
</table>
Caution: Switching a flash memory area from secure to no-secure does not erase its content. The user secure software must perform the needed operation to erase the secure area before switching an area to nonsecure attribute whenever is needed. It is also recommended to flush the instruction cache.

7.5.3 Secure hide protection (HDP)

The secure HDP area is part of the flash memory watermark-based secure area. Access to the hide-protection area can be denied by setting HDPx_ACCDIS in FLASH_SECHDPCR.

When HDPx_ACCDIS is set, instruction fetch, data read, write, and erase operations on this HDP area are denied. For example, software code in the secure-flash hide-protected area can be executed only once, and deny any further access to this area until next system reset. HDPx_ACCDIS can be only cleared by a system reset.

Note: The software must take any appropriate action to protect the HDP code before resetting the HDPxEN bit such as erasing the HDP area and flushing the instruction cache.

One non-volatile secure HDP area per bank can be defined with a page granularity.

The secure HDP area is enabled by HDPxEN (x = 1,2 for area 1 and area 2). When HDPxEN is reset, there is no HDP area. The HDPxEN bit can be set or reset on the fly by the secure firmware if HDPx_ACCDIS bit is reset. If HDPx_ACCDIS is set, HDPxEN and secure watermark configuration cannot be modified until next system reset.

The secure HDP area size is defined by the end-page offset using HDPx_PEND option bytes while the start-page offset is already defined by SECWMx_PSTRT option bytes. These offsets are defined in the secure watermark registers address registers: FLASH_SECWM1R1, FLASH_SECWM1R2, FLASH_SECWM2R1, and FLASH_SECWM2R2.

For example, to protect by HDP from the address 0x0C00 4000 (included) to the address 0x0C00 5FFF (included):

- If the banks are not swapped, the option bytes registers must be programmed with:
  - SECWM1_PSTRT = 0x2
  - HDP1_PEND = 0x3
- If the two banks are swapped, the protection must apply to bank 2 and the option bytes registers must be programmed with:
  - SECWM2_PSTRT = 0x2
  - HDP2_PEND = 0x3

Note: For more details on the bank swapping mechanism, refer to Section 7.5.8.
If an invalid secure HDP area is defined as described in the table below, the OPTWERR flag error is set and option bytes modification is discarded.

### Table 60. Secure hide protection

<table>
<thead>
<tr>
<th>HDPx watermark option-byte values (x = 1,2)</th>
<th>HDP area</th>

</tr>
</tbody>
</table>

### 7.5.4 Block-based secure flash memory area protection

Any page can be programmed on-the-fly as secure or nonsecure using the block-based configuration registers. FLASH_SECBB1Rx (resp. FLASH_SECBB2Rx) are used to configure the security attribute for pages in bank 1 (resp. bank 2).

When the page security attribute, bit i in SECyBBRx, is set, the security attribute is the same as the secure watermark-based area. The secure page is only accessible by a secure access.

If SECyBBi bit is set or reset for a page already included in a secure watermark-based area, the page keeps the watermark-based protection security attributes.

To modify a block-based page security attribution, the following actions are recommended:
- Check that no flash memory operation is ongoing on the related page.
- Add an ISB instruction after modifying the page security attribute bit i in SECyBBRx.
Caution: Switching a page or memory block from secure to nonsecure does not erase the content of the associated block. User secure software must perform the following needed operations before switching a block to nonsecure attribute:

- Erase page content,
- Invalidate the instruction cache.

Note: For SECyBBRx bit i access control, refer to Table 75.

7.5.5 Flash security attribute state

The flash memory is secure when at least one secure area is defined either by watermark-based option bytes or block-based security registers.

It is possible to override the flash security state using the INV bit in the FLASH_SECCR register.

The FLASHEN and FLASHSMEN bits security attributes in RCC follow the flash memory security attribute. It is possible to override the flash memory security attribute in RCC using the INV bit in the FLASH_SECCR register. A secure firmware setting this INV bit allows a nonsecure firmware to disable the flash memory clock when the flash memory is in power down or when the MCU enters low-power modes.

<table>
<thead>
<tr>
<th>Secure area</th>

<td>1</td>
<td>Secure</td>
</tr>
<tr>
<td>Yes</td>
<td>0</td>
<td>Secure</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>Nonsecure</td>
</tr>
</tbody>
</table>

7.5.6 Block-based privileged flash memory area protection

Any page can be programmed on the fly as privileged or unprivileged using the block-based configuration registers. FLASH_PRIVBB1Rx (resp. FLASH_PRIVBB2Rx) registers are used to configure the privilege attribute for pages in bank 1 (resp. bank 2).

When the page privilege attribute, bit i in PRIVyBBRx, is set, the page is only accessible by a privileged access. An unprivileged page is accessible by a privileged or unprivileged access.

To modify a block-based privilege attribution, the following actions are recommended:

- Check that no flash operation is ongoing on the related page.
- Add an ISB instruction after modifying the page security attribute bit i in PRIVyBBRx.

Caution: Switching a page or memory block from privileged to unprivileged does not erase the content of the associated block.

Note: For PRIVyBBRx bit i access control, refer to Table 76 and Table 77.
7.5.7 Flash memory registers privileged and unprivileged modes

The flash memory registers can be read and written by privileged and unprivileged accesses depending on SPRIV and NSPRIV bits in FLASH_PRIVCFGR, with the following rules:

- When the SPRIV (resp. NSPRIV) is reset, all secure (resp. nonsecure) flash memory registers can be read and written by both privileged or unprivileged access.
- When the SPRIV (resp. NSPRIV) is set, all secure (resp. nonsecure) flash memory registers can be read and written by privileged access only. Unprivileged access to a privileged registers is RAZ/WI.

Table 72 summarizes the flash memory registers access control.

7.5.8 Flash memory bank attributes in case of bank swap

The SWAP_BANK option bit modifies the address of each bank in the memory map. When SWAP_BANK is reset, the flash memory bank 1 is at the lower address range. When SWAP_BANK is set, the flash memory bank 1 is at the higher address range.

Flash memory bank attributes follow their bank so there is no need to modify the following registers when swapping banks:

- FLASH secure watermark y register x FLASH_SECWMyRx
- FLASH write protection x area y FLASH_WRPxyR (refer to Section 7.6.1)
- FLASH secure block based bank y register x FLASH_SECyBBRx
- FLASH privilege block based bank y register x FLASH_PRIVyBBRx
- PDREQx bits in FLASH_ACR
- PDx bits in FLASH_NSSR

Note: BK_ECC bit in FLASH_ECCR always refers to bank 1 (resp. bank 2) when it is low (resp. high), whatever SWAP_BANK value.

BK_OP bit in FLASH_OPSR always refers to bank 1 (resp. bank 2) when it is low (resp. high), whatever SWAP_BANK value.
The figures below show how security attributes and protections behave in case of bank swap.

**Figure 23. Flash memory security attributes and protections in case of no bank swap (SWAP_BANK = 0)**

1. Valid for STM32U59x/5Ax/5Fx/5Gx. Bank 2 base address is 0x0810 0000/0xC10 0000 for STM32U575/585, and 0x0804 0000/0xC04 0000 for STM32U535/545.
2. Refer to Table 51 to Table 53 for last page number on each device.

**Figure 24. Flash memory security attributes and protections in case of bank swap (SWAP_BANK = 1)**

1. Valid for STM32U59x/5Ax/5Fx/5Gx. Bank 1 base address is 0x0810 0000/0xC10 0000 for STM32U575/585, and 0x0804 0000/0xC04 0000 for STM32U535/545.
2. Refer to Table 51 to Table 53 for last page number on each device.

### 7.6 FLASH memory protection

The flash memory interface implements the following protection mechanisms:

- write protection (WRP)
- readout protection (RDP)
• additional secure protections when TrustZone is active (refer to Section 7.5)
  – up to two secure watermark-based non-volatile areas
  – up to two secure hide protection areas
  – secure block-based volatile areas with page granularity
• privileged block-based volatile areas with page granularity (refer to Section 7.5.6)

7.6.1 Write protection (WRP)

The user area in flash memory can be protected against unwanted write operations. Two write-protected (WRP) areas can be defined in each bank, with page granularity.

Each area is defined by a start page offset and an end page offset related to the physical flash bank base address. These offsets are defined in the WRP address registers: FLASH_WRP1AR, FLASH_WRP1BR, FLASH_WRP2AR, and FLASH_WRP2BR.

The bank “x” WRP “y” area (x = 1,2 and y = A,B) is defined as follows:
• from the address: bank “x” base address + [WRPxy_PSTRT x 0x2000] (included)
• to the address: bank “x” base address + [(WRPxy_PEND+1) x 0x2000] (excluded)

For example, to protect by WRP from the address 0x0806 2000 (included) to the address 0x0807 3FFF (included):
• If the banks are not swapped, FLASH_WRP1AR register must be programmed with:
  – WRP1A_PSTRT = 0x31
  – WRP1A_PEND = 0x39
WRP1B_PSTRT and WRP1B_PEND in FLASH_WRP1BR can be used instead (area “B” in bank 1).
• If the two banks are swapped, the protection must apply to bank 2, and FLASH_WRP2AR register must be programmed with:
  – WRP2A_PSTRT = 0x31
  – WRP2A_PEND = 0x39
WRP2B_PSTRT and WRP2B_PEND in FLASH_WRP2BR can be used instead (area “B in bank 2).

Note: For more details on the bank swapping mechanism, refer to Section 7.5.8.

When WRP is active, protected flash memory pages cannot be erased or programmed. Consequently, a software mass erase cannot be performed if one area is write-protected.

If an erase/program operation to a write-protected part of the flash memory is attempted, the secure or nonsecure write protection error flag (WRPERR) is set in the FLASH_NSSR or FLASH_SECSR register. This flag is also set for any write access to the following:
• system flash memory
• OTP area

Note: When the memory readout protection level 1 is selected (RDP level = 1), it is not possible to program or erase the flash memory (secure or nonsecure) if the CPU debug features are connected (JTAG or single wire) or boot code is being executed from RAM or system flash memory, even if WRP is not activated.

When the memory readout protection level 0.5 is selected (RDP level = 0.5), it is not possible to program or erase the flash secure memory if the CPU debug features are connected (JTAG or single wire), even if WRP is not activated.
**Note:** To validate the WRP options, the option bytes must be reloaded through the OBL_LAUNCH bit in the flash control register.

### Write protection lock

Each WRP area can be independently locked by writing 0 to UNLOCK in FLASH_WRP1AR, FLASH_WRP1BR, FLASH_WRP2AR, or FLASH_WRP2BR. Once a WRP area is locked, it is not possible to modify its settings. In order to unlock a WRP area, a regression to RDP level 0 must be launched.

In order to make the WRP area immutable and act as a ROM, the following actions are needed:

- If RDP level is 0, 0.5 or 1, provision a OEM1KEY in order to prevent a regression to RDP level 0 for users not knowing the key.
- If RDP level is 2, either provision a OEM1KEY (refer to first bullet) or do not provision a OEM2KEY (preventing regression from level 2 to level 1).

For more information on RDP regressions, refer to *Device life cycle managed by readout protection (RDP) transitions*.

### 7.6.2 Readout protection (RDP)

The readout protection protects the flash main memory, the option bytes, the backup registers, the backup RAM and the SRAMs. In order to reach the best protection level, it is recommended to activate TrustZone and to set the RDP Level 2 with password authentication regression enabled (refer to *Readout protection levels when TrustZone is enabled*).

#### Readout protection levels when TrustZone is disabled

There are three levels of readout protection from no protection (level 0) to maximum protection or no debug (level 2).
The flash memory is protected according to the RDP option byte value shown in the table below.

<table>
<thead>
<tr>
<th>RDP byte value</th>
<th>Readout protection level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xAA</td>
<td>Level 0</td>
</tr>
<tr>
<td>Any value except 0xAA or 0xCC</td>
<td>Level 1</td>
</tr>
<tr>
<td>0xCC</td>
<td>Level 2</td>
</tr>
</tbody>
</table>

- **Level 0: no protection**
  Read, program and erase operations into the flash main memory area are possible. The option bytes, the SRAMs and the backup registers are also accessible by all operations.

- **Level 1: readout protection**
  When the readout protection level 1 is set:
  - **User mode**: code executing in user mode (boot flash) can access the flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).
  - **Debug, boot RAM, and bootloader modes**: in debug mode or when the MCU boots from RAM or system memory, the flash main memory, backup registers, the backup RAM, and the SRAM2 are totally inaccessible: any read or write access to the flash main memory generates a bus error and a HardFault interrupt. The on-the-fly decryption region (OTFDEC on OCTOSPI) is read as zero.

- **Level 2: no debug**
  When the readout protection level 2 is set:
  - The protection level 1 is guaranteed.
  - All debug features are disabled:
    - if OEM2 key has not been provided, JTAG and SWD are definitively disabled.
    - if OEM2 key has been provided under a lower RDP protection, JTAG and SWD remain enabled under reset only to interface with DBGMCU_SR, DBGMCU_DBG_AUTH_HOST and DBGMCU_DBG_AUTHDEVICE registers to obtain device identification and provide OEM2 key to request RDP regression.
  - The boot from SRAM (boot RAM mode) and the boot from system memory (bootloader mode) are no longer available.
  - Only boot from main flash memory is possible; all operations are allowed on the flash main memory. Read, erase and program accesses to the flash memory and SRAMs from user code are allowed.
  - Option bytes cannot be programmed nor erased except the SWAP_BANK option bit. Thus, the level 2 cannot be removed: it is an irreversible operation unless an OEM2 key has been provisioned (refer to OEM2 RDP lock mechanism).

**Note:** The debug feature is also disabled under reset.

STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set. Regress parts to RDP level 1 before returning them for analysis (refer to OEM2 RDP lock mechanism).
Readout protection levels when TrustZone is enabled

There are four levels of readout protection from no protection (level 0) to maximum protection or no debug (level 2). The flash memory is protected according to the RDP option byte value shown in the table below.

Table 66. Flash memory readout protection status (TZEN = 1)

<table>
<thead>
<tr>
<th>RDP byte value</th>
<th>Readout protection level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xAA</td>
<td>Level 0</td>
</tr>
<tr>
<td>0x55</td>
<td>Level 0.5</td>
</tr>
</tbody>
</table>

1. When the protection level 2 is active, the debug port, the boot from RAM and the boot from system memory are disabled.
2. The system memory is only read-accessible, whatever the protection level (0, 1 or 2) and execution mode.
3. Option bytes are only accessible through the FLASH registers interface and OPTSTRT bit.
4. The flash main memory is erased when the RDP option byte changes from level 1 to level 0.
5. SWAP_BANK option bit can be modified.
6. OTP can only be written once.
7. The backup registers are erased when RDP changes from level 1 to level 0.
8. All SRAMs are erased when RDP changes from level 1 to level 0.
9. The OTFDEC keys are erased when the RDP option byte changes from level 1 to level 0.
Level 0: no protection
Read, program and erase operations into the flash main memory area are possible. The option bytes, the SRAMs and the backup registers are also accessible by all operations.
- **RSS mode**: when booting from RSS, the debug access is disabled while executing RSS code.

Level 0.5: nonsecure debug only
All read and write operations (if no write protection is set) from/to the nonsecure flash memory are possible. The debug access to secure area is prohibited. Debug access to nonsecure area remains possible.
- **User mode**: code executing in user mode (boot flash) can access the flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).
- **Nonsecure debug mode**: nonsecure debug is possible when the CPU is in nonsecure state. The secure flash memory, the secure backup registers and SRAMs area are inaccessible; the nonsecure flash memory, the nonsecure backup registers and the nonsecure SRAMs area remain accessible for debug purpose.
- **RSS mode**: when booting from RSS, the debug access is disabled while executing RSS code.
- **Boot RAM mode**: boot from SRAM is not possible.

Level 1: readout protection
When the readout protection level 1 is set:
- **User mode**: code executing in user mode (boot flash) can access the flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).
- **Nonsecure debug mode**: nonsecure debug is possible when the CPU is in nonsecure state. However, an intrusion is detected in case of debug access: the flash main memory, the backup registers, the backup RAM and the SRAM2 are totally inaccessible; any read or write access to the flash main memory generates a bus error and a hard fault interrupt. The on-the-fly decryption region (OTFDEC on OCTOSPI) is read as zero.
- **RSS mode**: when booting from RSS, the debug access is disabled while executing RSS code.
- **Boot RAM mode**: boot from SRAM is not possible.

<table>
<thead>

</tr>
<tr>
<td>0xCC</td>
<td>Level 2</td>
</tr>
</tbody>
</table>

Table 66. Flash memory readout protection status (TZEN = 1) (continued)
Level 2: no debug

When the readout protection level 2 is set:
- The protection level 1 is guaranteed.
- All debug features are disabled
  . if OEM2 key has not been provided, JTAG and SWD are definitively disabled.
  . if OEM2 key has been provided under a lower RDP protection, JTAG and SWD remain enabled under reset only to interface with DBGMCU_SR, DBGMCU_DBG_AUTH_HOST and DBGMCU_DBG_AUTH_DEVICE registers to obtain device identification and provide OEM2 key to request RDP regression.
- The boot from SRAM (boot RAM mode) and the boot from system memory (boot loader mode) are no longer available.
- Boot from RSS is possible.
- When booting from main flash or RSS, all operations are allowed on the flash main memory. Read, erase and program accesses to flash memory and SRAMs from user code are allowed.
- Option bytes cannot be programmed nor erased except the SWAP_BANK option bit. Thus, the level 2 cannot be removed: it is an irreversible operation unless an OEM2 key has been provisioned (refer to OEM2 RDP lock mechanism).

Note: The debug feature is also disabled under reset.

STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set. Regress parts to RDP level 1 before returning them for analysis (refer to OEM2 RDP lock mechanism).

</table>
Device life cycle managed by readout protection (RDP) transitions

It is easy to move from level 0 or level 0.5 to level 1 by changing the value of the RDP byte to any value (except 0xCC). By programming the 0xCC value in the RDP byte, it is possible to go to level 2 either directly from level 0 or from level 0.5 or from level 1. Once in level 2, it is no longer possible to modify the readout protection level unless an OEM2 key is provisioned (refer to OEM2 RDP lock mechanism).

When the RDP is reprogrammed to the value 0xAA to move from level 1 to level 0, a mass erase of the flash main memory and all SRAMs is performed. The backup registers, the OTFDEC keys, ICACHE, DCACHE, and PKA SRAM are also erased. The OTP area is not erased.

At RDP level 0.5, it is not possible to request RDP level 0. Instead, a RDP increase to level 1 followed by a RDP regression to level 0 is required.

When the RDP is programmed to the value 0x55 to move from level 1 to level 0.5, a partial mass erase of the flash main memory is performed. Only nonsecure watermark-based
areas are erased (even if it is defined as secure by block-based). The backup registers, the OTFDEC keys, ICACHE, DCACHE, PKA SRAM, and all SRAMs are mass erased. The OTP area is not erased. The RDP level 0.5 and partial nonsecure erase are only available when TrustZone is active.

Note: Full mass erase is performed only when level 1 is active and level 0 requested. When the protection level is increased (0 to 0.5, 0 to 1, 0.5 to 1, 1 to 2, 0 to 2 or 0.5 to 2), there is no mass erase.

To validate the readout protection level change, the option bytes must be reloaded through the OBL_LAUNCH bit in FLASH nonsecure control register (FLASH_NSCR).

Before launching a RDP regression, the software must invalidate the ICACHE and wait for the BUSYF bit to get cleared.

**Figure 25. RDP level transition scheme when TrustZone is disabled (TZEN = 0)**
OEM1/OEM2 lock activation

Two 64-bit keys (OEM1KEY and OEM2KEY) can be defined in order to lock the RDP regression. Each 64-bit key is coded on two registers: FLASH_OEM1KEYR1 (resp. FLASH_OEM2KEYR1), and FLASH_OEM1KEYR2 (resp. FLASH_OEM2KEYR2). OEM1KEY and OEM2KEY cannot be read through these registers. They are read as zero.

OEM1KEY can be modified:
- in readout protection level 0
- in readout protection level 0.5 or 1 if OEM1LOCK = 0 in FLASH_NSSR

OEM2KEY can be modified:
- in readout protection level 0 or 0.5
- in readout protection level 1 if OEM2LOCK = 0 in FLASH_NSSR

When attempting to modify FLASH_OEM1KEYR1, FLASH_OEM1KEYR2 (or FLASH_OEM2KEYR1, FLASH_OEM2KEYR2) without following these rules, the user option modification is not done, and the OPTWERR bit is set.

In order to activate OEM1 lock mechanism, the following steps are needed:
- Check that the OEM1LOCK bit is not set or that the readout protection is at level 0.
- Write a 64-bit key in FLASH_OEM1KEYR1 and FLASH_OEM1KEYR2.
- Launch option modification by setting the OPTSTRT bit in FLASH_NSCR.
- Wait for the BSY bit to be cleared and check that OPTWERR is not set.
Set the OBL_LAUNCH option bit to start option bytes loading or perform a power-on reset.

Check that OEM1LOCK is set.

In order to activate OEM2 lock mechanism, the following steps are needed:

- Check that the OEM2LOCK bit is not set or that the readout protection is at level 0 or 0.5.
- Write a 64-bit key in FLASH_OEM2KEYR1 and FLASH_OEM2KEYR2.
- Launch option modification by setting the OPTSTRT bit in FLASH_NSCR.
- Wait for the BSY bit to be cleared and check that OPTWERR is not set.
- Set the OBL_LAUNCH option bit to start option bytes loading or perform a power-on reset.
- Check that OEM2LOCK is set.

**Note:** The OEM1KEY and OEM2KEY must not contain only 1 or only 0.

### OEM1 RDP lock mechanism

The OEM1 RDP lock mechanism is active when the OEM1LOCK bit is set. It blocks the RDP level 1 to RDP level 0 regression.

In order to regress from RDP level 1 to RDP level 0, the following unlock sequence must be applied:

- Shift OEM1KEY[31:0] then OEM1KEY[63:32] through JTAG or SWD in the DBGMCUDBG.AUTH_HOST register.
- If this key matches the OEM1KEY value, the RDP regression can be launched by setting the OPTSTRT bit.
- If the key does not match the OEM1KEY value, the RDP regression and any access to the flash memory are blocked until a next power-on reset.

Attempting to regress from RDP level 1 to RDP level 0 without following this sequence sets the OPTWERR option bit and the option bytes remain unchanged.

When the lock mechanism is not activated (OEM1LOCK = 0), the regression from RDP level 1 to RDP level 0 is always granted.

### OEM2 RDP lock mechanism

The OEM2 RDP lock mechanism is active when the OEM2LOCK bit is set. It allows the following actions:

- Block RDP level 1 to RDP level 0.5 regression.
- Authorize RDP level 2 to RDP level 1 regression.

In order to regress from RDP level 1 to RDP level 0.5, the following unlock sequence must be applied:

- Shift OEM2KEY[31:0] then OEM2KEY[63:32] through JTAG or SWD under reset in the DBGMCUDBG.AUTH_HOST register.
- If this key matches the OEM2KEY value, the RDP regression can be launched by setting the OPTSTRT bit.
- If the key does not match the OEM2KEY value, the RDP regression and any access to the flash memory are blocked until a next power-on reset.
In order to regress from RDP level 2 to RDP level 1, the following unlock sequence must be applied:

- Shift OEM2KEY[31:0] then OEM2KEY[63:32] through JTAG or SWD under reset in the DBGMCU_DBG_AUTH_HOST register.
- If this key matches the OEM2KEY value:
  - the RDP regression is launched by hardware (it is not possible to execute instructions when the key is matching).
  - apply a power-on reset (cycle V_DD power supply OFF and ON).
- if the key does not match the OEM2KEY value, the RDP regression and any access to the flash memory are blocked until a next power-on reset.

Attempting to regress from RDP level 2 to RDP level 1 without following these sequences, leaves option bytes unchanged.

Attempting to regress from RDP level 1 to RDP level 0.5 without following these sequences, sets the OPTWERR option bit and the option bytes remain unchanged.

When the lock mechanism is not activated (OEM2LOCK = 0), the following happens:

- The regression from RDP level 1 to RDP level 0.5 is always granted.
- The regression from RDP level 2 to RDP level 1 is never granted. When attempting to modify the options bytes, the protection error flag OPTWERR is set in the FLASH_NSSR register and an interrupt can be generated.

### 7.7 Flash memory and FLASH registers access control

The tables below summarize all the flash memory and registers accesses status versus RDP level, WRP and HDP protections.

<table>
<thead>
<tr>
<th>Access type</th>
<th>RDP level 0, level 0.5, level 1 no intrusion(1) or level 2</th>
<th>RDP level 1 with intrusion(2)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Nonsecure page</td>
<td>Secure page</td>
</tr>
<tr>
<td></td>
<td>RDP area (HDPxEN = 1 and ACCDIS = 1)</td>
<td>Others(3)</td>
</tr>
<tr>
<td>Fetch</td>
<td>Bus error</td>
<td>RAZ</td>
</tr>
<tr>
<td>Read</td>
<td>RAZ, FLASH illegal access event</td>
<td></td>
</tr>
<tr>
<td>Write</td>
<td>WI, secure WRPERR flag set, FLASH illegal access event</td>
<td>WI, secure WRPERR flag set</td>
</tr>
<tr>
<td>Page erase</td>
<td>WI, secure WRPERR flag set, FLASH illegal access event</td>
<td></td>
</tr>
<tr>
<td>Fetch</td>
<td>OK</td>
<td>Bus error</td>
</tr>
<tr>
<td>Read</td>
<td></td>
<td>RAZ, FLASH illegal access event</td>
</tr>
<tr>
<td>Write</td>
<td>No WRP: Ok</td>
<td>WI, nonsecure WRPERR flag set</td>
</tr>
<tr>
<td>Page erase</td>
<td>WRP pages: WI and nonsecure WRPERR flag set</td>
<td>WI, nonsecure WRPERR flag set</td>
</tr>
</tbody>
</table>
1. RDP level 1 no intrusion = when booting from user flash memory and no debug access.
2. RDP level 1 with intrusion = when debug access detected.
3. Others refers to the other flash memory secure configurations than the one described for HDP protections.
   Example: Flash memory secure and HDP area enabled but ACCDIS = 0.

Table 69. Flash memory access versus RDP level when TrustZone is disabled (TZEN = 0)

<table>
<thead>
<tr>
<th>Access type</th>
<th>RDP level 0, level 1 no intrusion(1), or level 2</th>
<th>RDP level 1 with intrusion(2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fetch</td>
<td>OK</td>
<td>Bus error</td>
</tr>
<tr>
<td>Read</td>
<td></td>
<td></td>
</tr>
<tr>

<td>Nonsecure ERRIE</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>ECC correction</td>
<td>ECC</td>
<td>ECC</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

1. Secure EOP (resp. nonsecure EOP) is set only if secure EOPIE (resp. nonsecure EOPIE) is set.
2. Secure OPERR (resp. nonsecure OPERR) is set only if secure ERRIE (resp. nonsecure ERRIE) is set.

### 7.9 FLASH registers

#### 7.9.1 FLASH access control register (FLASH_ACR)

Address offset: 0x00

Reset value: 0x0000 0000

Access: no wait state when no flash memory read is ongoing; word, half-word, and byte access

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when NSPRIV = 1 in FLASH_PRIVCFGR register.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
Bit 14  **SLEEP_PD**: Flash memory power-down mode during Sleep mode
This bit determines whether the flash memory is in power-down mode or Idle mode when the device is in Sleep mode.
0: Flash memory in Idle mode during Sleep mode
1: Flash memory in power-down mode during Sleep mode

**Caution**: The flash memory must not be put in power-down while a program or an erase operation is ongoing.

Bit 13  **PDREQ2**: Bank 2 power-down mode request
This bit is write-protected with FLASH_PDKEY2R. This bit requests bank 2 to enter power-down mode. When bank 2 enters power-down mode, this bit is cleared by hardware and the PDKEY2R is locked.
0: No request for bank 2 to enter power-down mode
1: Bank 2 requested to enter power-down mode

Bit 12  **PDREQ1**: Bank 1 power-down mode request
This bit is write-protected with FLASH_PDKEY1R. This bit requests bank 1 to enter power-down mode. When bank 1 enters power-down mode, this bit is cleared by hardware and the PDKEY1R is locked.
0: No request for bank 1 to enter power-down mode
1: Bank 1 requested to enter power-down mode

Bit 11  **LPM**: Low-power read mode
This bit puts the flash memory in low-power read mode.
0: Flash memory not in low-power read mode
1: Flash memory in low-power read mode

Bits 10:9  Reserved, must be kept at reset value.

Bit 8  **PRFTEN**: Prefetch enable
This bit enables the prefetch buffer in the embedded flash memory.
0: Prefetch disabled
1: Prefetch enabled

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:0  **LATENCY[3:0]**: Latency
These bits represent the ratio between the HCLK (AHB clock) period and the flash memory access time.
0000: Zero wait state
0001: One wait state
0010: Two wait states
...
1111: Fifteen wait states
7.9.2 FLASH nonsecure key register (FLASH_NSKEYR)

Address offset: 0x08
Reset value: 0x0000 0000
Access: one wait state; word access

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when NSPRIV = 1 in FLASH_PRIVCFGR register.

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</th>
</tr>
</thead>
<tbody>
<tr>
<td>w w w w w w w w w w w w w w w w w w w w w w w w</td>
</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

Bits 31:0 NSKEY[31:0]: Flash memory nonsecure key

The following values must be written consecutively to unlock the FLASH_NSCR register, allowing the flash memory nonsecure programming/erasing operations:

KEY1: 0x4567 0123
KEY2: 0xCDEF 89AB

7.9.3 FLASH secure key register (FLASH_SECKEYR)

Address offset: 0x0C
Reset value: 0x0000 0000
Access: one wait state; word access

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI.

This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR register.

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</th>

<td>w w w w w w w w w w w w w w w w w w w w w w w w</td>
</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

Bits 31:0 SECKEY[31:0]: Flash memory secure key

The following values must be written consecutively to unlock the FLASH_SECCR register, allowing the flash memory secure programming/erasing operations:

KEY1: 0x4567 0123
KEY2: 0xCDEF 89AB
7.9.4 FLAST option key register (FLASH_OPTKEYR)

Address offset: 0x10
Reset value: 0x0000 0000
Access: one wait state; word access

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when NSPRIV = 1 in FLASH_PRIVCFGR register.

<table>

Bits 31:0 OPTKEY[31:0]: Option-byte key
The following values must be written consecutively to unlock the FLASH_OPTR register allowing option byte programming/erasing operations:
KEY1: 0x0819 2A3B
KEY2: 0x4C5D 6E7F

7.9.5 FLAST bank 1 power-down key register (FLASH_PDEKEY1R)

Address offset: 0x18
Reset value: 0x0000 0000
Access: no wait state; word access

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when NSPRIV = 1 in FLASH_PRIVCFGR register.

Bits 31:0 PDEKEY[31:0]: Bank 1 power-down key
The following values must be written consecutively to unlock PDREQ1 bit in FLASH_ACR:
PDEKEY1_1: 0x0415 2637
PDEKEY1_2: 0xFAFB FCFD
7.9.6   **FLASH bank 2 power-down key register (FLASH_PDKEY2R)**

Address offset: 0x1C
Reset value: 0x0000 0000
Access: no wait state; word access

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when NSPRIV = 1 in FLASH_PRIVCFGR register.

<table>

Bits 31:0 **PDKEY2[31:0]**: Bank 2 power-down key

The following values must be written consecutively to unlock PDREQ2 bit in FLASH_ACR:
PDKEY2_1: 0x4051 6273
PDKEY2_2: 0xAFBF CFDF

7.9.7   **FLASH nonsecure status register (FLASH_NSSR)**

Address offset: 0x20
Reset value: 0x000X 0000
Access: no wait state; word, half-word and byte access

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when NSPRIV = 1 in FLASH_PRIVCFGR register.

</tbody>
</table>

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **PD2**: Bank 2 in power-down mode

This bit indicates that the flash memory bank 2 is in power-down state. It is reset when bank 2 is in normal mode or being awaken.

Bit 20 **PD1**: Bank 1 in power-down mode

This bit indicates that the flash memory bank 1 is in power-down state. It is reset when bank 1 is in normal mode or being awaken.
Bit 19 **OEM2LOCK**: OEM2 lock
This bit indicates that the OEM2 RDP key read during the OBL is not virgin. When set, the OEM2 RDP lock mechanism is active.

Bit 18 **OEM1LOCK**: OEM1 lock
This bit indicates that the OEM1 RDP key read during the OBL is not virgin. When set, the OEM1 RDP lock mechanism is active.

Bit 17 **WDW**: Nonsecure wait data to write
This bit indicates that the flash memory write buffer has been written by a secure or non-secure operation. It is set when the first data is stored in the buffer and cleared when the write is performed in the flash memory.

Bit 16 **BSY**: Nonsecure busy
This indicates that a flash memory secure or nonsecure operation is in progress. This bit is set at the beginning of a flash operation and reset when the operation finishes or when an error occurs.

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OPTWERR**: Option write error
This bit is set by hardware when the options bytes are written with an invalid configuration. It is cleared by writing 1. Refer to Section 7.3.9 for full conditions of error flag setting.

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **PGSERR**: Nonsecure programming sequence error
This bit is set by hardware when programming sequence is not correct. It is cleared by writing 1. Refer to Section 7.3.9 for full conditions of error flag setting.

Bit 6 **SIZERR**: Nonsecure size error
This bit is set by hardware when the size of the access is a byte or half-word during a nonsecure program sequence. Only quad-word programming is allowed by means of successive word accesses. This bit is cleared by writing 1.

Bit 5 **PGAERR**: Nonsecure programming alignment error
This bit is set by hardware when the first word to be programmed is not aligned with a quad-word address, or the second, third or forth word does not belong to the same quad-word address. This bit is cleared by writing 1.

Bit 4 **WRPERR**: Nonsecure write protection error
This bit is set by hardware when a nonsecure address to be erased/programmed belongs to a write-protected part (by WRP, HDP or RDP level 1) of the flash memory. This bit is cleared by writing 1. Refer to Section 7.3.9 for full conditions of error flag setting.

Bit 3 **PROGERR**: Nonsecure programming error
This bit is set by hardware when a nonsecure quad-word address to be programmed contains a value different from all 1 before programming, except if the data to write is all 0. This bit is cleared by writing 1.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **OPERR**: Nonsecure operation error
This bit is set by hardware when a flash memory nonsecure operation (program/erase) completes unsuccessfully. This bit is set only if nonsecure error interrupts are enabled (NSERRIE = 1). This bit is cleared by writing 1.
7.9.8 FLASH secure status register (FLASH_SECSR)

Address offset: 0x24
Reset value: 0x0000 0000
Access: no wait state; word, half-word and byte access

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR register.

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **WDW:** Secure wait data to write
This bit indicates that the flash memory write buffer has been written by a secure or non-secure operation. It is set when the first data is stored in the buffer and cleared when the write is performed in the flash memory.

Bit 16 **BSY:** Secure busy
This bit indicates that a flash memory secure or nonsecure operation is in progress. This is set on the beginning of a flash operation and reset when the operation finishes or when an error occurs.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **PGSERR:** Secure programming sequence error
This bit is set by hardware when programming sequence is not correct. It is cleared by writing 1. Refer to Section 7.3.9 for full conditions of error flag setting.

Bit 6 **SIZERR:** Secure size error
This bit is set by hardware when the size of the access is a byte or half-word during a secure program sequence. Only quad-word programming is allowed by means of successive word accesses. This bit is cleared by writing 1.

Bit 5 **PGAERR:** Secure programming alignment error
This bit is set by hardware when the first word to be programmed is not aligned with a quad-word address, or the second, third or forth word does not belong to the same quad-word address. This bit is cleared by writing 1.

Bit 0 **EOP:** Nonsecure end of operation
This bit is set by hardware when one or more flash memory nonsecure operation (program/erase) has been completed successfully. This bit is set only if the nonsecure end of operation interrupts are enabled (EOPIE = 1 in FLASH_NSCR). This bit is cleared by writing 1.
Bit 4 **WRPERR**: Secure write protection error

This bit is set by hardware when a secure address to be erased/programmed belongs to a write-protected part (by WRP, HDP or RDP level 1) of the flash memory. This bit is cleared by writing 1. Refer to Section 7.3.9 for full conditions of error flag setting.

Bit 3 **PROGERR**: Secure programming error

This bit is set by hardware when a secure quad-word address to be programmed contains a value different from all 1 before programming, except if the data to write is all 0. This bit is cleared by writing 1.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **OPERR**: Secure operation error

This bit is set by hardware when a flash memory secure operation (program/erase) completes unsuccessfully. This bit is set only if secure error interrupts are enabled (SECERRIE = 1). This bit is cleared by writing 1.

Bit 0 **EOP**: Secure end of operation

This bit is set by hardware when one or more flash memory secure operation (program/erase) has been completed successfully. This bit is set only if the secure end of operation interrupts are enabled (EOPIE = 1 in FLASH_SECCR). This bit is cleared by writing 1.

### 7.9.9 FLASH nonsecure control register (FLASH_NSCR)

Address offset: 0x28

Reset value: 0xC000 0000

Access: no wait state when no flash memory operation is ongoing; word, half-word, and byte access

This register can only be written when BSY or OBL_LAUNCH is reset. Otherwise, the write access is stalled until BSY bits are reset.

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when NSPRIV = 1 in FLASH_PRIVCFGR register.

Bit 31 **LOCK**: Nonsecure lock

This bit is set only. When set, the FLASH_NSCR register is locked. It is cleared by hardware after detecting the unlock sequence in FLASH_NSKEYR register.

In case of an unsuccessful unlock operation, this bit remains set until the next system reset.
Bit 30  **OPTLOCK**: Option lock
This bit is set only. When set, all bits concerning user options in FLASH_NSCR register are locked. This bit is cleared by hardware after detecting the unlock sequence. LOCK bit in FLASH_NSCR must be cleared before doing the unlock sequence for OPTLOCK bit. In case of an unsuccessful unlock operation, this bit remains set until the next reset.

Bits 29:28  Reserved, must be kept at reset value.

Bit 27  **OBL_LAUNCH**: Force the option-byte loading
When set to 1, this bit forces the option byte reloading. This bit is cleared only when the option-byte loading is complete. It cannot be written if OPTLOCK is set.
0: Option-byte loading complete
1: Option-byte loading requested

Bit 26  Reserved, must be kept at reset value.

Bit 25  **ERRIE**: Nonsecure error interrupt enable
This bit enables the interrupt generation when OPERR = 1 in FLASH_NSSR.
0: Nonsecure OPERR error interrupt disabled
1: Nonsecure OPERR error interrupt enabled

Bit 24  **EPIE**: Nonsecure end of operation interrupt enable
This bit enables the interrupt generation when EOP = 1 in FLASH_NSSR.
0: Nonsecure EOP Interrupt disabled
1: Nonsecure EOP Interrupt enabled

Bits 23:18  Reserved, must be kept at reset value.

Bit 17  **OPTSTRT**: Options modification start
This bit triggers an options operation when set. It can not be written if OPTLOCK bit is set. This bit is set only by software, and is cleared when the BSY bit is cleared in FLASH_NSSR.

Bit 16  **STRT**: Nonsecure start
This bit triggers a nonsecure erase operation when set. If MER1, MER2, and PER bits are reset and the STRT bit is set, PGSERR is set in FLASH_NSSR (this condition is forbidden). This bit is set only by software and is cleared when BSY is cleared in FLASH_NSSR.

Bit 15  **MER2**: Nonsecure bank 2 mass erase
This bit triggers the bank 2 nonsecure mass erase (all bank 2 user pages) when set.

Bit 14  **BWR**: Nonsecure burst write programming mode
When set, this bit selects the burst write programming mode.

Bits 13:12  Reserved, must be kept at reset value.

Bit 11  **BKER**: Nonsecure bank selection for page erase
0: Bank 1 selected for nonsecure page erase
1: Bank 2 selected for nonsecure page erase
Bits 10:3 **PNB[7:0]**: Nonsecure page number selection
These bits select the page to erase.
00000000: page 0
00000001: page 1
...
00111111: page 31 (upper page for STM32U535/545)

01111111: page 127 (upper page for STM32U575/585)
...
11111111: page 255 (upper page for STM32U59x/5Ax/5Fx/5Gx)

Bit 2 **MER1**: Nonsecure bank 1 mass erase
This bit triggers the bank 1 nonsecure mass erase (all bank 1 user pages) when set.

Bit 1 **PER**: Nonsecure page erase
0: Nonsecure page erase disabled
1: Nonsecure page erase enabled

Bit 0 **PG**: Nonsecure programming
0: Nonsecure FLASH programming disabled
1: Nonsecure FLASH programming enabled

7.9.10 **FLASH secure control register (FLASH_SECCR)**
Address offset: 0x2C
Reset value: 0x8000 0000
Access: no wait state when no flash memory operation is ongoing; word, half-word, and byte access

This register can only be written when BSY or OBL_LAUNCH is reset. Otherwise, the write access stalls until the BSY bits are reset.

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR register.

Bit 31 **LOCK**: Secure lock
This bit is set only. When set, this register is locked. It is cleared by hardware after detecting the unlock sequence in FLASH_SECKEYR register.
In case of an unsuccessful unlock operation, this bit remains set until the next system reset.

Bit 30 Reserved, must be kept at reset value.

Bit 29 **INV**: Flash memory security state invert
This bit inverts the flash memory security state.

Bits 28:26 Reserved, must be kept at reset value.
Bit 25 **ERRIE**: Secure error interrupt enable
This bit enables the interrupt generation when OPERR = 1 in FLASH_SECSR.
0: Secure OPERR error interrupt disabled
1: Secure OPERR error interrupt enabled

Bit 24 **EOPIE**: Secure End of operation interrupt enable
This bit enables the interrupt generation when EOP = 1 in FLASH_SECSR.
0: Secure EOP Interrupt disabled
1: Secure EOP Interrupt enabled

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **STRT**: Secure start
This bit triggers a secure erase operation when set. If MER1, MER2, and PER bits are reset and the STRT bit is set, PGSERR is set in FLASH_SECSR (this condition is forbidden).
This bit is set only by software and is cleared when BSY is cleared in FLASH_SECSR.

Bit 15 **MER2**: Secure bank 2 mass erase
This bit triggers the bank 2 secure mass erase (all bank 2 user pages) when set.

Bit 14 **BWR**: Secure burst write programming mode
When set, this bit selects the burst write programming mode.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **BKER**: Secure bank selection for page erase
0: Bank 1 selected for secure page erase
1: Bank 2 selected for secure page erase

Bits 10:3 **PNB[7:0]**: Secure page number selection
These bits select the page to erase.

...
11111111: page 255 (upper page for STM32U59x/5Ax/5Fx/5Gx)

Bit 2 **MER1**: Secure bank 1 mass erase
This bit triggers the bank 1 secure mass erase (all bank 1 user pages) when set.

Bit 1 **PER**: Secure page erase
0: Secure page erase disabled
1: Secure page erase enabled

Bit 0 **PG**: Secure programming
0: Secure FLASH programming disabled
1: Secure FLASH programming enabled
7.9.11  FLASH ECC register (FLASH_ECCR)

Address offset: 0x30
Reset value: 0x0000 0000
Access: no wait state; word, half-word, and byte access

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when NSPRIV = 1 in FLASH_PRIVCFGR register.

Bit 31  **ECCD**: ECC detection
This bit is set by hardware when two ECC errors have been detected (only if ECCC and ECCD were previously cleared). When this bit is set, a NMI is generated. This bit is cleared by writing 1.

Bit 30  **ECCC**: ECC correction
This bit is set by hardware when one ECC error has been detected and corrected (only if ECCC and ECCD were previously cleared). An interrupt is generated if ECCIE is set. This bit is cleared by writing 1.

Bits 29:25  Reserved, must be kept at reset value.

Bit 24  **ECCIE**: ECC correction interrupt enable
This bit enables the interrupt generation when the ECCC bit in the FLASH_ECCR register is set.
0: ECCC interrupt disabled
1: ECCC interrupt enabled.

Bit 23  Reserved, must be kept at reset value.

Bit 22  **SYSF_ECC**: System flash memory ECC fail
This bit indicates that the ECC error correction or double ECC error detection is located in the system flash memory.

Bit 21  **BK_ECC**: ECC fail bank
This bit indicates which bank is concerned by the ECC error correction or by the double ECC error detection.
0: Bank 1
1: Bank 2

Bits 20:0  **ADDR_ECC[20:0]**: ECC fail address
This field indicates which address is concerned by the ECC error correction or by the double ECC error detection. The address is given by bank from address 0x0 0000 to address:
0x7 FFF0: upper address for STM32U535/545
0xF FFF0: upper address for STM32U575/585
0x1F FFF0: upper address for STM32U59x/5Ax/5Fx/5Gx
# 7.9.12 FLASH operation status register (FLASH_OPSR)

Address offset: 0x34

Reset value: 0xX0XX XXXX

(0xX0XX XXXX after system reset, and 0x0000 0000 after power-on reset)

Access: no wait state; word, half-word, and byte access

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when NSPRIV = 1 in FLASH_PRIVCFG register.

**Bits 31:29 CODE_OP[2:0]: Flash memory operation code**

This field indicates which flash memory operation has been interrupted by a system reset:

- 000: No flash operation interrupted by previous reset
- 001: Single write operation interrupted
- 010: Burst write operation interrupted
- 011: Page erase operation interrupted
- 100: Bank erase operation interrupted
- 101: Mass erase operation interrupted
- 110: Option change operation interrupted
- 111: Reserved

**Bits 28:23 Reserved, must be kept at reset value.**

**Bit 22 SYSF_OP: Operation in system flash memory interrupted**

This bit indicates that the reset occurred during an operation in the system flash memory.

**Bit 21 BK_OP: Interrupted operation bank**

This bit indicates which flash memory bank was accessed when reset occurred

- 0: Bank 1
- 1: Bank 2

**Bits 20:0 ADDR_OP[20:0]: Interrupted operation address**

This field indicates which address in the flash memory was accessed when reset occurred. The address is given by bank from address 0x0 0000 to address:

- 0x7 FFF0: upper address for STM32U535/545
- 0xF FFF0: upper address for STM32U575/585
- 0x1F FFF0 upper address for STM32U59x/5Ax/5Fx/5Gx
### 7.9.13 FLASH option register (FLASH_OPTR)

Address offset: 0x40

Reset value: 0xXXXX XXXX (bits 0 to 31 loaded with values from the flash memory at OBL)

ST production value: 0x1FEF F8AA

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access.

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when NSPRIV = 1 in FLASH_PRIVCFGR register.

#### Bit 31 TSEN: Global TrustZone security enable
- 0: Global TrustZone security disabled
- 1: Global TrustZone security enabled

#### Bit 30 IO_VDDIO2_HSLV: High-speed IO at low VDDIO2 voltage configuration bit
- This bit can be set only with VDDIO2 below 2.5 V.
- 0: High-speed IO at low VDDIO2 voltage feature disabled (VDDIO2 can exceed 2.5 V)
- 1: High-speed IO at low VDDIO2 voltage feature enabled (VDDIO2 remains below 2.5 V)

#### Bit 29 IO_VDD_HSLV: High-speed IO at low VDD voltage configuration bit
- This bit can be set only with VDD below 2.5V
- 0: High-speed IO at low VDD voltage feature disabled (VDD can exceed 2.5 V)
- 1: High-speed IO at low VDD voltage feature enabled (VDD remains below 2.5 V)

#### Bit 28 PA15_PUPEN: PA15 pull-up enable
- 0: USB power delivery dead-battery enabled/TDI pull-up deactivated
- 1: USB power delivery dead-battery disabled/TDI pull-up activated

#### Bit 27 NBOOT0: NBOOT0 option bit
- 0: NBOOT0 = 0
- 1: NBOOT0 = 1

#### Bit 26 NSWBOOT0: Software BOOT0
- 0: BOOT0 taken from the option bit NBOOT0
- 1: BOOT0 taken from PH3/BOOT0 pin

#### Bit 25 SRAM2_RST: SRAM2 erase when system reset
- 0: SRAM2 erased when a system reset occurs
- 1: SRAM2 not erased when a system reset occurs

#### Bit 24 SRAM2_ECC: SRAM2 ECC detection and correction enable
- 0: SRAM2 ECC check enabled
- 1: SRAM2 ECC check disabled

| Bit 11 | **Reserved**, must be kept at reset value. |
Bits 10:8  **BOR_LEV[2:0]**: BOR reset level

These bits contain the $V_{DD}$ supply level threshold that activates/releases the reset.

- 000: BOR level 0 (reset level threshold around 1.7 V)
- 001: BOR level 1 (reset level threshold around 2.0 V)
- 010: BOR level 2 (reset level threshold around 2.2 V)
- 011: BOR level 3 (reset level threshold around 2.5 V)
- 100: BOR level 4 (reset level threshold around 2.8 V)

Bits 7:0  **RDP[7:0]**: Readout protection level

- 0xAA: Level 0 (readout protection not active)
- 0x55: Level 0.5 (readout protection not active, only nonsecure debug access is possible).
- Only available when TrustZone is active (TZEN = 1)
- 0xCC: Level 2 (chip readout protection active)
- Others: Level 1 (memories readout protection active)

*Note: Refer to Section 7.6.2 for more details.*

### 7.9.14  FLASH nonsecure boot address 0 register

**(FLASH_NSBOOTADD0R)**

**Address offset:** 0x44

**Reset value:** 0xXXXX XXXX

*(Option bytes loaded with values from the flash memory at reset release)*

**ST production value:** 0x0800 007F

**Access:** no wait state when no option bytes modification is ongoing; word, half-word, and byte access.

This register can not be written if OPTLOCK bit is set. This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when NSPRIV = 1 in FLASH_PRIVCFGR register.

**Bits 31:7**  **NSBOOTADD0[24:0]**: Nonsecure boot base address 0

The nonsecure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes. These bits correspond to address [31:7]. NSBOOTADD0 option bytes are selected following the BOOT0 pin or NSWBOOT0 state.

**Examples:**

- **NSBOOTADD0[24:0] = 0x01000000**: Boot from nonsecure flash memory (0x0800 0000)
- **NSBOOTADD0[24:0] = 0x017F2000**: Boot from system memory bootloader (0x0BF9 0000)
- **NSBOOTADD0[24:0] = 0x04000000**: Boot from nonsecure SRAM1 on S-Bus (0x2000 0000)

**Bits 6:0**  Reserved, must be kept at reset value.
7.9.15  **FLASH nonsecure boot address 1 register**

*(FLASH_NSBOOTADD1R)*

Address offset: 0x48  
Reset value: 0xXXXX XXXX  
(option bytes loaded with values from the flash memory at reset release)

ST production value: 0x0BF9 007F

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access.

This register can not be written if OPTLOCK bit is set. This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when NSPRIV = 1 in FLASH_PRIVCFGR register.

**NSBOOTADD1[24:9]**

Bits 31:7  **NSBOOTADD1[24:0]**: Nonsecure boot address 1

The nonsecure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes. These bits correspond to address [31:7]. NSBOOTADD1 option bytes are selected following the BOOT0 pin or NSWBOOT0 state.

Examples:

NSBOOTADD1[24:0] = 0x0100000: Boot from nonsecure flash memory (0x0800 0000)

NSBOOTADD1[24:0] = 0x017F200: Boot from system memory bootloader (0x0BF9 0000)

NSBOOTADD1[24:0] = 0x0400000: Boot from nonsecure SRAM1 on S-Bus (0x2000 0000)

Bits 6:0  Reserved, must be kept at reset value.
7.9.16  FLASH secure boot address 0 register (FLASH_SECBOOTADD0R)

Address offset: 0x4C
Reset value: 0xXXXX XXXX
ST production value: 0x0C00 007C
(option bytes loaded with values from the flash memory at reset release)
Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access.

This register can not be written if OPTLOCK bit is set. This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR.

SECBOOTADD[8:0]  

Bits 31:7  SECBOOTADD[24:0]: Secure boot base address 0
The secure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes. This bits correspond to address [31:7].
SECBOOTADD0 option bytes are selected following the BOOT0 pin or NSWBOOT0 state.
Examples:
SECBOOTADD[24:0] = 0x018 0000: Boot from secure flash memory (0x0C00 0000)
SECBOOTADD[24:0] = 0x01F F000: Boot from RSS (0xFF8 0000)
SECBOOTADD[24:0] = 0x060 0000: Boot from secure SRAM1 on S-Bus (0x3000 0000)

Bits 6:1  Reserved, must be kept at reset value.

Bit 0  BOOT_LOCK: Boot lock
When set, the boot is always forced to base address value programmed in SECBOOTADD[24:0] option bytes whatever the boot selection option. This bit can only be cleared when RDP is at Level 0.
7.9.17  FLASH secure watermark1 register 1 (FLASH_SECWM1R1)

Address offset: 0x50
Reset value: 0xXXXX XXXX  (bits loaded with values from the flash memory at OBL. Reserved bits are read as 1.)
ST production value: 0xFFFF FF80 (for STM32U535/545/575/585)
0xFFFF FF00 (for STM32U59x/5Ax/5Fx/5Gx)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access.
This register can not be written if OPTLOCK bit is set. This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in FLASH_PRIVCFGR.

| Bits 15:0 | Reserved, must be kept at reset value. |
7.9.23  **FLASH WPR2 area A address register (FLASH_WRP2AR)**

Address offset: 0x68

Reset value: 0xXXXX XXXX (bits loaded with values from the flash memory at OBL)

ST production value:
- 0xFFE0 FFFF (for STM32U535/545)
- 0xFF80 FFFF (for STM32U575/585)
- 0xFF00 FFFF (for STM32U59x/5Ax/5Fx/5Gx)

Access: no wait state when no option bytes modification is ongoing; word, half-word, and byte access

This register can not be written if OPTLOCK bit is set. This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when NSPRIV = 1 in FLASH_PRIVCFGR register.

The table continues with detailed information about each register and its reset values. The offsets are provided in hexadecimal format. The registers include various bits and fields such as WRP1A_PEND[7:0], WRP1B_PEND[7:0], SECWM2_PEND[7:0], SECWM2_PSTRT[7:0], HDP2_PEND[7:0], SEC1BB[31:0], SEC2BB[31:0], SECBB1[31:0], and SECBB2[31:0].
Refer to Section 2.3 for the register boundary addresses.
8 Instruction cache (ICACHE)

8.1 ICACHE introduction

The instruction cache (ICACHE) is introduced on C-AHB code bus of Cortex-M33 processor to improve performance when fetching instruction and data from internal and external memories.

Some specific features like dual master ports, hit-under-miss and critical-word-first refill policy, allow close to zero-wait-state performance in most use cases.

8.2 ICACHE main features

The main features of ICACHE are described below:

- **Bus interface**
  - one 32-bit AHB slave port, the execution port (input from Cortex-M33 C-AHB code interface)
  - two AHB master ports: master1 and master2 ports (outputs to Fast and Slow buses of main AHB bus matrix, respectively)
  - one 32-bit AHB slave port for control (input from AHB peripherals interconnect, for ICACHE registers access)

- **Cache access**
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Dual master access: feature used to decouple the traffic according to targeted memory. For example, the ICACHE assigns fast traffic (addressing flash and SRAM memories) to the AHB master1 port, and slow traffic (addressing external memories) to AHB master2 port, thus preventing processor stalls on lines refills from external memories. This allows ISR (interrupt service routine) fetching on internal flash memory to take place in parallel with a cache line refill from external memories.
  - Minimal impact on interrupt latency, thanks to dual master
  - Optimal cache line refill thanks to WRAPw bursts of the size of the cache line (32-bit word size, w, aligned on cache line size)
  - n-way set-associative default configuration with possibility to configure as 1-way, means direct mapped cache, for applications needing very-low-power consumption profile

- **Memory address remap**
  - Possibility to remap input address falling into up to four memory regions (used to remap aliased code in external memories to the Code region, for execution from C-AHB code interface)

- **Replacement and refill**
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Critical-word-first refill policy, minimizing processor stalls
Possibility to configure burst type of AHB memory transaction for remapped regions: INCRw or WRAPw (size w aligned on cache line size)

Performance counters
The ICACHE implements two performance counters:
- Hit monitor counter (32-bit)
- Miss monitor counter (16-bit)

Error management
- Possibility to detect an unexpected cacheable write access, to flag an error and optionally to raise an interrupt

TrustZone security support

Maintenance operation
- Cache invalidate: full cache invalidation, fast command, non interruptible

### 8.3 ICACHE implementation

8.4 ICACHE functional description

The purpose of the instruction cache is to cache instruction fetches or instruction memories loads, coming from the processor. As such, the ICACHE only manages read transactions and does not manage write transactions.

For error management purpose, in case a write cacheable transaction is presented (this only happens in case of bad software programming), the ICACHE sets an error flag and, if enabled, raises an interrupt to the processor.

8.4.1 ICACHE block diagram

Figure 27. ICACHE block diagram

8.4.2 ICACHE reset and clocks

The ICACHE is clocked on Cortex-M33 C-AHB bus clock.

When the ICACHE reset signal is released, a cache invalidate procedure is automatically launched, making the ICACHE busy (ICACHE_SR = 0x0000 0001).
When this procedure is finished:
- the ICACHE is invalidated: “cold cache”, with all cache line valid bits = 0 (ICACHE must be filled up)
- ICACHE_SR = 0x0000 0002 (reflecting the cache is no more busy)
- the ICACHE is disabled: the EN bit in ICACHE_CR holds its reset state (=0).

Note: When disabled, the ICACHE is bypassed, except the remapping mechanism that is still functional: slave input requests (remapped or not) are just forwarded to the master port(s).

8.4.3 ICACHE TAG memory

The ICACHE TAG memory contains:
- address tags, that indicate which data are contained in the cache data memories
- validity bits

There is one valid bit per cache line (per way).

The valid bit is set when a cache line is refilled (after a miss).

Valid bits are reset in any of the below cases:
- after the ICACHE reset is released
- when the cache is disabled, by setting EN = 0 in ICACHE_CR (by software)
- when executing an ICACHE invalidate command, by setting CACHEINV = 1 in ICACHE_CR (by software)

When a cacheable transaction is received at the execution input port, its AHB address (HADDR_in) is split into the following fields (see Table 82 for B and W definitions):
- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to the TAG memory address to check if the requested data is already available (meaning valid) inside the ICACHE.

The table below gives a summary of ICACHE main parameters for TAG memory dimensioning. Figure 28 shows the functional view of TAG and data memories, for an n-way set associative ICACHE.

<table>
<thead>
<tr>
<th>Parameter</th>

<td>20-bit</td>
</tr>
</tbody>
</table>
8.4.4 Direct-mapped ICACHE (1-way cache)

The default configuration (at reset) is an n-way set associative cache (WAYSEL = 1 in ICACHE_CR), but the user can configure the ICACHE as direct mapped by writing WAYSEL = 0 (only possible when the cache is disabled, EN = 0 in ICACHE_CR).

The table below gives a summary of ICACHE main parameters for TAG memory when the direct-mapped cache operating mode is selected.

### Table 83. TAG memory dimensioning parameters for direct-mapped cache mode

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache size</td>
<td>S Kbytes = s bytes (s = 1024 x S)</td>
<td>8 Kbytes = 8192 bytes</td>
</tr>
<tr>
<td>Cache number of ways</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Cache line size</td>
<td>L-byte = l-bit (l = 8 x L)</td>
<td>16-byte = 128-bit</td>
</tr>
<tr>
<td>Number of cache lines</td>

<td>9-bit</td>
</tr>
<tr>
<td>TAG address size</td>
<td>T = (32 - W - B) bit</td>
<td>19-bit</td>
</tr>
</tbody>
</table>
All cache operations (such as read, refill, remapping, invalidation) remain the same in direct-mapped configuration. The only difference is the absence of a replacement algorithm in case of line eviction (as explained in Section 8.4.8): only one way (the unique one) is possible for any data refill.

8.4.5 ICACHE enable

To activate the ICACHE, the EN bit must be set to 1 in ICACHE_CR.

When the ICACHE is disabled, it is bypassed and all transactions are copied from the slave port to the master ports in the same clock cycle.

It is recommended to initialize or modify the main memory content (region to be later cached) with the ICACHE disabled, and to enable the ICACHE only when this region remains unchanged (an enabled ICACHE detects cacheable write transactions as errors).

In order to insure performance determinism, it is recommended to wait for the end of a potential cache invalidate procedure before enabling the ICACHE. This invalidate procedure occurs when the hardware reset signal is released, when CACHEINV is set, or when EN is cleared in ICACHE_CR. During the procedure, BUSYF is set in ICACHE_SR, and once finished, BUSYF is cleared and BSYENDF is set in the same register (raising the ICACHE interrupt if enabled on such a busy end condition).

The software must test BUSYF and/or BSYENDF values before enabling the ICACHE. Else, if the ICACHE is enabled before the end of an invalidate procedure, any cache access (while BUSYF = 1) is treated as non cacheable, and its performance depends on the main memory access time.

The address remapping is performed, whether the ICACHE is enabled or not, if the input transaction address falls into memory regions defined and enabled in ICACHE_CRRx (see Figure 29).

The ICACHE is by default disabled at boot.

8.4.6 Cacheable and non-cacheable traffic

The ICACHE is developed for Cortex-M33 core. It is placed on C-AHB bus, and thus caches the code memory region, ranging from address 0x0000 0000 to 0x1FFF FFFF of the memory map.

In order to make some other memory regions cacheable, the ICACHE supports a memory-region-remapping feature. It is used to define up to four external memory regions, which addresses have an alias in the code region. Addressing these external memory regions through their code alias address allows the memory request to be routed to the C-AHB bus, and to be managed by the ICACHE.

Any external memory space physically mapped at an address in range [0x6000 0000:0xAFFF FFFF] can be aliased with an address in range [0x0000 0000:0x07FF FFFF] or [0x1000 0000:0x1FFF FFFF].

For a given memory request in the code region, the ICACHE implements the address remapping functionality first. If aliased, it is the remapped address which is then cached, and, if needed, provided to the master port to address the main AHB bus matrix.

The destination physical address does not need further manipulation on the AHB bus.

The remapping functionality is available also for non-cacheable traffic, and when the cache is disabled.
Further details on address remapping are provided in Section 8.4.7.

An incoming memory request to the ICACHE is defined as cacheable according to its AHB transaction memory lookup attribute, as shown in Table 84. This AHB attribute depends on the MPU (memory protection unit) programming for the addressed region.

### Table 84. ICACHE cacheability for AHB transaction

<table>
<thead>
<tr>
<th>AHB lookup attribute</th>
<th>Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Cacheable</td>
</tr>
<tr>
<td>0</td>
<td>Non cacheable</td>
</tr>
</tbody>
</table>

In case of a non-cacheable access, the ICACHE is bypassed, meaning that the AHB transaction is propagated unchanged to the master output port, except the transaction address which may be modified due to the address remapping feature (see Section 8.4.7).

The bypass, and eventual remap logic, does not increase the latency of the access to the targeted memory.

In case of a cacheable access, the ICACHE behaves as explained in Section 8.4.8.

Cacheable memory regions are defined and programmed by the user in the MPU, that is responsible for the generation of the AHB attribute signals for any transaction addressing a given region.

The table below summarizes programmable configurations of various memories.

</table>

#### 8.4.7 Address remapping

The ICACHE allows an alias address to be defined in the code region for up to four external memory regions.

The address remapping is applied on the code alias address, transforming it into the destination external physical address.

The remapping operation is fully software configurable by programming ICACHE_CRRx (x = 0 to 3, number of remapped regions). This programming can be done only when the ICACHE is disabled.

Each region x can be individually enabled with REN in ICACHE_CRRx. Once enabled, the remap operation occurs even if the ICACHE is disabled, or if the transaction is not cacheable.
Remap regions can have different size: each region size can be programmed in RSIZE of its ICACHE_CRRx. The size of each region is a power of two multiple of range granularity (2 Mbytes), with a minimum region size of 2 Mbytes, and a maximum region size of 128 Mbytes.

The address remapping mechanism is based on the matching of an incoming AHB address (HADDR_in) with a given code subregion base-address, and the modification of this address into its (remapped) external physical address, as follows:

- HADDR_in belongs to region x if HADDR_in[31:RI] = 000:BASEADDR[28:RI], where:
  - 000:BASEADDR is the code subregion base-address programmed in BASEADDR of ICACHE_CRRx.
  - RI defines the number of significant bits to consider. RI = log2(region size) with a minimum value of 21 (for a 2-Mbyte region) and a maximum value of 27 (for a 128-Mbyte region).
- If the region x is enabled, the master port output AHB address (HADDR_out) is composed by concatenating the two below parts:
  - REMAPADDR[31:RI] field of ICACHE_CRRx as MSBs
  - HADDR_in[RI-1:0] as LSBs.

The figure below describes the matching and the output address generation.

**Figure 29. ICACHE remapping address mechanism**

![ICACHE remapping address mechanism](image)

The table below summarizes all possible configurations of BASEADDR and REMAPADDR sizes (number of significant MSBs) in ICACHE_CRRx, depending on RSIZE.

**Table 86. ICACHE remap region size, base address and remap address**

<table>
<thead>
<tr>
<th>Region size (Mbytes)</th>
<th>Base address size (MSBs)</th>
<th>Remap address (MSBs)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>8</td>
<td>11</td>
</tr>
<tr>
<td>4</td>
<td>7</td>
<td>10</td>
</tr>
<tr>
<td>8</td>
<td>6</td>
<td>9</td>
</tr>
<tr>
<td>16</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>32</td>
<td>4</td>
<td>7</td>
</tr>
<tr>
<td>64</td>
<td>3</td>
<td>6</td>
</tr>
<tr>
<td>128</td>
<td>2</td>
<td>5</td>
</tr>
</tbody>
</table>
Care must be taken while programming BASEADDR and REMAPADDR in ICACHE_CRRx: if the programmed value is bigger than expected (number of MSBs, see Table 86), the unnecessary extra LSBs are ignored.

Typical remapping example: a 128-Mbyte FMC region (NOR/SRAM) physically located in the external address range [0x6800 0000:0x6FFF FFFF], remapped in the code section range [0x1000 0000:0x17FF FFFF]:
- REMAPADDR[31:21] = 0x340
- BASEADDR[28:21] = 0x80
- HADDR_in[31:27] is compared to 000:BASEADDR[28:27], and HADDR_in/BASEADDR[26:21] are ignored for the comparison.

If the comparison matches:
- HADDR_out[31:27] gets REMAPADDR[31:27] (in place of HADDR_in[31:27])
- HADDR_out[26:0] gets HADDR_in[26:0]

The software can program the kind of AHB burst that is generated by the ICACHE master ports on the bus matrix (for cache line refill), by setting HBURST in ICACHE_CRRx with:
- WRAP for remapped external memories accessed through interfaces that can support WRAP burst mode, providing the benefit of the critical-word-first feature performance:
  - WRAP burst size = cache line size
  - WRAP burst start address = word address of the first data requested by the core
- INCR: INCR burst mode for external memories accessed through the interfaces that do not support WRAP burst mode (losing the benefit of critical-word-first feature):
  - INCR burst size = cache line size
  - INCR burst start address = address aligned on the boundary of the cache line containing the requested word.

Note: Coherency is needed when programming the SAU (secure attribution unit) and the MPU (memory protection unit) attributes for both the external regions and their aliased code subregions.

8.4.8 Cacheable accesses

When the ICACHE receives a cacheable transaction from the Cortex-M33, the ICACHE checks if the address requested is present in its TAG memory, and if the corresponding cache line is valid.

There are then three alternatives:
- The address is present inside the TAG memory, the cache line is valid: cache hit, the data is read from the cache and provided to the processor in the same cycle.
- The address is not present in the TAG memory: cache miss, the data is read from the main memory and provided to the processor, and a cache line refill is performed. The critical-word-first policy insures minimum wait cycles for the processor, since read data can be provided while the cache still performs a cache line refill (associated latency is the latency of fetching one word from the main memory).
  The burst generated on the ICACHE master bus is WRAPw (w being the cache line width, in words) in case no address remap occurs. If an address remap occurs, the kind of burst depends on HBURST programmed in corresponding ICACHE_CRRx.
  The AHB transaction attributes are also propagated to the main AHB bus matrix on the master port selected for the line refill.
• The address is not present in TAG memory, but belongs to the refill burst from the main memory that is currently ongoing: cache hit (hit-under-miss feature).

This happens during cache-line refill. The ICACHE can provide the requested data as soon as the data is available at its master interface, thus avoiding a miss (fetching data from the main memory).

In case of cache refill (due to cache miss), the ICACHE selects which cache line is written with the refill data:

• In direct map (1-way) mode, only one line can be used to store the refill data: the line pointed by the index of the input address.

• In n-way set associative mode, one line among n can be used (the line pointed by the address index, in each of the n ways). The way selection is based on a pLRU-t replacement algorithm, that points, for each index, on the way candidate for the next refill.

If ever the cache line where the refill data must be written is already valid, the targeted cache line must be invalidated first. This is true whatever the direct map or n-way set associative cache mode.

8.4.9 Dual-master cache

The ICACHE can implement a dual-port AHB master on the main AHB bus matrix: master1 and master2 ports. This is used to split the traffic going to different destination memories.

The non-remapped traffic goes systematically to master1 port. The re-mapped traffic to external memories must be routed on master2 port by programming MSTSEL in ICACHE_CRRx (on a region basis).

The code can typically be fetched as follows:

• internal flash memory and internal SRAM on master1 port (Fast bus)
• external flash memory/RAM on master2 port (Slow bus)

For systems not implementing external memories, the traffic to the internal flash memory can be decoupled from the traffic to the internal SRAM (when remapped by the ICACHE). This feature is used to prevent further processor stalls on misses.

Alongside with hit-under-miss, this dual-master feature allows the processor to have an alternative path in case of fetching from different memories.

8.4.10 ICACHE security

The ICACHE implements an Armv8-M TrustZone.

ICACHE configuration registers are protected at system level.

8.4.11 ICACHE maintenance

The software can invalidate the whole content of the ICACHE by programming CACHEINV in ICACHE_CR register.

When CACHEINV = 1, the ICACHE control logic sets BUSYF flag in ICACHE_SR and launches the invalidate cache operation, resetting each TAG valid bit to 0 (one valid bit per cache line). CACHEINV is automatically cleared.

Once the invalidate operation is finished, the ICACHE automatically clears BUSYF, and sets BSYENDF in ICACHE_SR register.
If enabled on this flag condition (BSYENDIE = 1 in ICACHE_IER), the ICACHE interrupt is raised. Then, the (empty) cache is available again.

### 8.4.12 ICACHE performance monitoring

The ICACHE provides the following monitors for performance analysis:

- The 32-bit hit monitor counts the cacheable AHB-transactions on the slave cache port that hits the ICACHE content. It also takes into account all accesses whose address is present in the TAG memory or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from cache master port) (see Section 8.4.8).
- The 16-bit miss monitor counts the cacheable AHB-transactions on the slave cache port that misses the ICACHE content. It also takes into account all accesses whose address is not present neither in the TAG memory nor in the refill buffer.

Upon reaching their maximum values, these monitors do not wrap over. Hit and miss monitors can be enabled and reset by software allowing the analysis of specific pieces of code.

The software can perform the following tasks:

- Enable/stop the hit monitor through HITMEN in ICACHE_CR.
- Reset the hit monitor by setting HITMRST in ICACHE_CR.
- Enable/stop the miss monitor through MISSMEN in ICACHE_CR.
- Reset the miss monitor by setting MISSMRST in ICACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

### 8.4.13 ICACHE boot

The ICACHE is disabled (EN = 0 in ICACHE_CR) at boot. The code remapping at boot is not needed for Cortex-M33 since it implements the VTOR (vector tables) that allows a boot start address definition different than 0x0. Once the boot is finished, the ICACHE can be enabled (software setting EN = 1 in CACHE_CR).

### 8.5 ICACHE low-power modes

At device level, using the ICACHE reduces the power consumption by fetching instructions from the internal ICACHE most of the time, rather than from the bigger and then more-power-consuming main memories. This reduction is even higher if the cached main memories are external.

Applications with a lower-performance profile (in terms of hit ratio) and stringent low-power consumption constraints may benefit from the lower power consumption of an ICACHE configured as direct mapped. This single-way cache configuration is obtained by programming WAYSEL = 0 in ICACHE_CR (see Figure 28). The power consumption is then reduced by accessing, for each request, only the necessary cut of TAG and data memories. Meanwhile, the cache effect still improves fetch performance. Even if for most code execution, it is a little less efficient than with an n-way set associative cache mode.
8.6 ICACHE error management and interrupts

In case an unsupported cacheable write request is detected (functional error), the ICACHE generates an error by setting the ERRF flag in ICACHE_SR. An interrupt is then generated if the corresponding interrupt enable bit is set (ERRIE = 1 in ICACHE_IER).

The other possible interrupt generation is at the end of a cache invalidation operation. When the cache-busy state is finished, the ICACHE sets BSYENDF flag in ICACHE_SR. An interrupt is then generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in ICACHE_IER).

All ICACHE interrupt sources raise the same and unique interrupt signal, icache_it, and then use the same interrupt vector.

<table>
<thead>
<tr>
<th>Interrupt vector</th>

</tbody>
</table>

The ICACHE also propagates all AHB bus errors (such as security issues, address decoding issues) from master1 or master2 port back to the execution port.

| r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16 Reserved, must be kept at reset value.  
Bits 15:0 **MISSMON[15:0]**: cache miss monitor counter

8.7.7 **ICACHE region x configuration register (ICACHE_CRRx)**

Address offset: 0x020 + 0x4 * x, (x = 0 to 3)  
Reset value: 0x0000 0200

Define an alias address in Code region for other regions, making them cacheable.  
BASEADDR and REMAPADDR fields are write locked (read only) when EN = 1 in ICACHE_CR.
Bit 31 **HBURST**: output burst type for region x
0: WRAP
1: INCR

Bits 30:29 Reserved, must be kept at reset value.

Bit 28 **MSTSEL**: AHB cache master selection for region x
0: no action (master1 selected by default)
1: master2 selected

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **REMAPADDR[31:21]**: remapped address for region x
This field replaces the alias address defined by BASEADDR field.
The only useful bits are [31:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see Section 8.4.7). If the programmed value has more LSBs, the useless bits are ignored.

Bit 15 **REN**: enable for region x
0: disabled
1: enabled

Bits 14:12 Reserved, must be kept at reset value.

Bits 11:9 **RSIZE[2:0]**: size for region x
000: reserved
001: 2 Mbytes
010: 4 Mbytes
011: 8 Mbytes
100: 16 Mbytes
101: 32 Mbytes
110: 64 Mbytes
111: 128 Mbytes

Bit 8 Reserved, must be kept at reset value.

Bits 7:0 **BASEADDR[28:21]**: base address for region x
This alias address is replaced by REMAPADDR field.
The only useful bits are [28:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see Section 8.4.7). If the programmed value has more LSBs, the useless bits are ignored.

### ICACHE register map

#### Table 88. ICACHE register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x000  | ICACHE_CR    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value  | 0  | 0  | 0  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x004  | ICACHE_SR    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value  | 0  | 0  | 0  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

**Note:** The table above is a simplified representation of the register map for the ICACHE. The actual implementation may vary depending on the specific ICACHE configuration and may include additional fields for advanced features such as cache modes, error conditions, and more.

9 Data cache (DCACHE)

9.1 DCACHE introduction

The data cache (DCACHE) is introduced on S-AHB system bus of Cortex-M33 processor, or on an AHB bus driven by a master peripheral, to improve the performance of data traffic to/from external memories.

Some specific features like hit-under-miss and critical-word-first refill policy allow optimum performance on external memories data accesses.

9.2 DCACHE main features

The main features of DCACHE are described below:

- Bus interface
  - one 32-bit AHB slave port, the system port (input from Cortex-M33 S-AHB system interface, or input from AHB bus driven by the port M0 of GPU2D)
  - one 32-bit AHB master port (output to main AHB bus matrix)
  - one 32-bit AHB slave port for control (input from AHB peripherals interconnect, for access to DCACHE registers)

- Cache access
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Optimized cache line refill thanks to WRAP bursts of the size of the cache line (such as WRAP4 for 128-bit cache line)
  - 2-ways set-associative
  - Supports both write-back and write-through policies (selectable with AHB bufferable attribute)
  - Read and write-back always allocate
  - Write-through always non-allocate (write-around)
  - Supports byte, half-word and word writes

- Replacement and refill
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Critical-word-first refill policy for read transactions, minimizing processor stalls
  - Possibility to configure burst type of all AHB memory transactions: INCRw or WRAPw (size w aligned on cache line size)

- Performance counters
  The DCACHE implements four performance counters:
  - Two hit-monitor counters (32-bit): number of read hits, number of write hits
  - Two miss-monitor counters (16-bit): number of read misses, number of write misses
- Error management
  - Possibility to detect error for master port request initiated by DCACHE itself (a cache line written back into main memory, because of an eviction or a clean operation), to flag this error, and optionally to raise an interrupt
- TrustZone security support
- Maintenance operations
  - Cache invalidate: full cache invalidation, fast command, non interruptible
  - Cache invalidate range: invalidates cache lines (reset valid bit = 0) whose address belongs to defined range, background task, interruptible
  - Cache clean range: cleans cache lines (if dirty bit = 1, write back line, then clear dirty bit) whose address belongs to defined range, background task, interruptible
  - Cache clean and invalidate range: cleans and invalidates cache lines (if dirty bit = 1, write back line, then clear valid bit) whose address belongs to defined range, background task, interruptible

### 9.3 DCACHE implementation

The DCACHE1 is placed on Cortex-M33 S-AHB bus and caches only the external RAM memory region (OCTOSPI, HSPI, and FMC), in address range [0x6000 0000:0xAFFF FFFF] of the memory map.

Indeed, by placing a bus matrix demultiplexing node in front of the DCACHE1, S-AHB bus memory requests addressing SRAM region or peripherals region (respectively in ranges [0x2000 0000:0x3FFF FFFF] and [0x4000 0000:0x5FFF FFFF]) are routed directly to the main AHB bus matrix, and the DCACHE1 is bypassed.

In STM32U59x/5Ax/5Fx/5Gx, the DCACHE2 is placed on the AHB bus driven by the port M0 of GPU2D, and caches all the memory regions accessed by it.

All GPU2D transactions are cacheable, except transactions to internal SRAMs that can be made cacheable or non-cacheable, depending on the related configuration programmed in the system configuration controller.

As the GPU2D traffic is non-secure, the DCACHE2 does not support TrustZone.

9.4 DCACHE functional description

The purpose of the data cache is to cache external memory data loads and stores, coming from the processor or from another bus master peripheral. These accesses include the instruction fetches that may occur at an external memory address. The DCACHE manages both read and write transactions.

9.4.1 DCACHE block diagram

![DCACHE block diagram](image)
9.4.2 DCACHE reset and clocks

The DCACHE is clocked on the Cortex-M33 S-AHB bus clock.

When the DCACHE reset signal is released, a cache invalidate procedure is automatically launched, making the DCACHE busy (DCACHE_SR = 0x0000 0001).

When this procedure is finished:
- The DCACHE is invalidated: “cold cache”, with all cache line valid, dirty and privilege bits = 0 (DCACHE must be filled up)
- DCACHE_SR = 0x0000 0002 (reflecting the cache is no more busy)
- The DCACHE is disabled: the EN bit in DCACHE_CR holds its reset state (= 0).

Note: When disabled, the DCACHE is bypassed: slave input requests are just forwarded to the master port.

9.4.3 DCACHE TAG memory

The DCACHE TAG memory contains:
- address tags, that indicate which data are contained in the cache data memories
- validity bits
- dirty bits
- privilege bits

There is one valid bit, one dirty bit, and one privilege bit per cache line (per way).

The valid bit enables/disables access to the data cache line: if the line is not valid, the data access (read or write) is performed in the main memory.

The valid bit is set when the cache line is written (refilled by either a read miss or a write-back miss).

Valid bits are reset in any of the below cases:
- after the DCACHE reset is released
- when the cache is disabled, by setting EN = 0 in DCACHE_CR (by software)
- when executing one of the DCACHE invalidate commands, setting by software CACHEINV = 0, or CACHECMD = 0b010 or 0b011 in DCACHE_CR (see Section 9.4.8).

The dirty bit indicates that the cache line has up-to-date values with respect to the main memory content (the cache has last right value, the main memory is not up to date).

The dirty bit is set when the cache line is written by a slave port write transaction (only in case of an access with write-back attribute).

Dirty bits are reset in any of the below cases:
- after the DCACHE reset is released
- when a line refill is performed on a read miss (on a write-back miss, the refilled cache line is modified by the written data, and dirty bit = 1)
- when the cache invalidation is performed
- when executing one of the DCACHE clean operations (cache line written back to the main memory), setting by software CACHECMD = 0b001 or 0b011 in DCACHE_CR (see Section 9.4.8).
The privilege bit indicates if the data is managed by a privileged entity. It is assigned according to the value of AHB privileged attribute at input slave port, for the first access to this line (it is written only during the line refill, on read miss or write-back miss).

The privilege bit holds same polarity as the privileged attribute: 1 for privileged access, 0 for unprivileged access.

Privilege bits are reset when the cache is invalidated, and after the DCACHE reset is released.

When a cacheable transaction is received at input slave port, its AHB address (HADDR_in) is split into the following fields (see the table below for B and W values):

- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to TAG memory address to check if the requested data is already available (meaning valid) inside the DCACHE.

The table below gives DCACHE main parameters for TAG memory dimensioning.

### Table 91. TAG memory dimensioning parameters

</tbody>
</table>
9.4.4 **DCACHE enable**

In order to activate the DCACHE functioning, the EN bit must be set in DCACHE_CR control register.

When DCACHE is disabled, it is bypassed and all transactions are copied from slave port to master port in the same clock cycle, and no comparison is performed with TAG address. DCACHE is by default disabled at boot.

9.4.5 **Cacheable and non-cacheable traffic**

DCACHE is developed for Cortex-M33 core or another bus master peripheral and caches the memory regions addressed by the AHB bus connected to it.

In addition, the AHB bus traffic to the memory regions can be cacheable or non-cacheable. An incoming memory request to DCACHE is defined as cacheable according to its AHB transaction memory lookup attribute.

In case of write transaction, the DCACHE write policy is defined as write-through or write-back according to its AHB transaction memory bufferable attribute (see the table below).

These AHB attributes depend on the memory protection unit (MPU) programming for the addressed region.
In case of non cacheable access, the DCACHE is bypassed, meaning that the AHB transaction is propagated unchanged to the master output port.

The bypass does not increase the latency of the access to the targeted memory.

In case of cacheable access, the DCACHE behaves as explained in Section 9.4.6.

Cacheable memory regions are defined and programmed by the user in the MPU, responsible for the generation of the AHB attribute signals for any transaction addressing a given region.

### 9.4.6 Cacheable accesses

When the DCACHE receives a cacheable transaction from Cortex-M33 or from another bus master peripheral, on its slave port, the DCACHE checks if the address requested is present in its TAG memory and if the corresponding cache line is valid.

For **read** transaction, there are three alternatives:

- The address is present inside the TAG memory, cache line is valid: **cache read hit**, the data is read from cache and provided to the processor in the same cycle.
- The address is not present in the TAG memory: **cache read miss**, the data is read from the main memory and provided to the processor, and a cache line refill is performed.
  
  The critical-word-first refill policy insures minimum wait cycles for the processor, since read data can be provided while cache is still performing cache line refill (associated latency is the latency of fetching one word from main memory).

  The kind of burst generated on the DCACHE master bus depends on HBURST bit in DCACHE_CR: either INCRw or WRAPw (w being the cache line width, in words).

  The AHB transaction attributes are also propagated from the slave input (missing) request to the master output refill request.

- The address is not present in the TAG memory but belongs to the refill burst from main memory that is currently ongoing: **cache read hit** as well (hit-under-miss feature).

  Whatever the line refill is due to a read or write (missing) transaction, the DCACHE can provide the requested read data as soon as the data is available at its master interface, thus avoiding a miss (with data fetch from main memory).
For **write-back** transaction (write transaction, with write-back bufferable attribute), there are three alternatives as well:

- The address is present inside the TAG memory, cache line is valid: **cache write-back hit**, the data is written in cache.
- The address is not present in the TAG memory (or cache line is not valid): **cache write-back miss**.

  First, a line allocation is performed by reading the entire cache line data from main memory. The kind of burst generated on the DCACHE master bus for this line refill depends on HBURST bit in DCACHE_CR: either INCRw or WRAPw (w being the cache line width, in words), and the AHB transaction attributes are propagated from the slave port initial request.

  Once the refilled line is written in the DCACHE, the initial data provided on slave port is written in this DCACHE line (it overwrites the data part of the cache line that was refilled just before).

- The address is not present in the TAG memory but belongs to the refill burst from main memory that is currently ongoing: **cache write-back hit** as well (hit-under-miss feature).

  Whatever the line refill is due to a read or write (missing) transaction, the DCACHE can write incoming data directly inside the refilled line, thus avoiding a miss (with refill from main memory).

For **write-through** transaction (write transaction, with write-through bufferable attribute), only two alternatives exist:

- The address is present inside the TAG memory, cache line is valid: **cache write-through hit**, the data is written both in cache and in main memory (through master port).
- The address is not present in the TAG memory (or cache line is not valid): **cache write-through miss**, the data incoming at slave port is written only in main memory (unlike the write-back miss, there is no line allocation and data written in cache).

In case of cache refill (due to cache miss), the DCACHE selects which cache line is written with the refill data: as a 2-way set associative cache, one line among two can be used (line pointed by the address index, in each of the two ways). The way selection is based on a pLRU-t replacement algorithm, that points, for each index, on the way candidate for the next refill.

If the cache line where the refill data must be written is already valid, the targeted cache line must be evicted first:

- If the dirty tag of this line equals 0 (clean data), the line is simply invalidated.
- If it equals 1 (dirty data), the line must be written back in the main memory.

  The DCACHE generates a burst write transaction on its master port, with burst type set to INCRw (w being the cache line width, in words), and with AHB memory transaction attribute signals set as below:

  - data (not instruction)
  - privileged = TAG privilege bit
  - write-back (even if it does not care)
  - normal memory
  - cacheable
  - allocate (even if it does not care)
These AHB attributes cannot be propagated from the slave port (as it is the case for all other transactions emitted by the DCACHE) because the evicting transaction has no relation with the initial missing transaction. Setting of the AHB attributes is fixed, except for the privileged bit that is copied from the TAG privilege bit of the evicted line.

9.4.7 DCACHE security

The DCACHE implements an Armv8-M TrustZone.

DCACHE configuration registers are protected at system level.

9.4.8 DCACHE maintenance

The DCACHE features several maintenance operations that the software can programmed in DCACHE_CR control register:

- **Full invalidate**: invalidates the whole cache, non interruptible task.
  
The software can invalidate the whole DCACHE content by programming CACHEINV in DCACHE_CR.
  
  When CACHEINV = 1, the DCACHE control logic sets BUSYF flag in DCACHE_SR status register, and performs the operation of cache invalidation, resetting each TAG valid bit to 0 (one valid bit per cache line). Each dirty and privilege bits are also reset during cache invalidation to prevent unknown values at next cache line validation. CACHEINV is automatically cleared.
  
  Once the full invalidate operation is finished, the DCACHE automatically clears BUSYF flag, and sets BSYENDF in DCACHE_SR.
  
  If enabled on this flag condition (BSYENDIE = 1 in DCACHE_IER), the DCACHE interrupt is raised. Then, the (empty) cache is available again.
  
  This full invalidate operation is not interruptible, meaning that the cache does not treat any cacheable request while BUSYF = 1. However, non-cacheable traffic is treated (since the request address is not compared to TAG ones), the DCACHE being bypassed in the same clock cycle (same behavior as when the DCACHE is disabled).

- **Invalidate range**: invalidates a certain range of addresses in the cache, background task (interruptible).
  
The software can invalidate a given data region in the DCACHE by programming STARTCMD = 1 and CACHECMD = 0b010 in DCACHE_CR, after the address range was programmed into DCACHE_CMDSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).
  
The DCACHE control logic then parses the whole TAG memory. If the read line address (TAG address + line index) falls in the programmed address range (DCACHE_CMDSADDRR ≤ Line Addr ≤ DCACHE_CMDREADDRR), the
corresponding cache line is invalidated (line TAG bits cleared, valid bit = dirty bit = privilege bit = 0).

When STARTCMD is set, the DCACHE control logic sets BUSYCMDF in DCACHE_SR and launches the invalidate range operation. STARTCMD is also automatically cleared. Once the operation is finished (all TAG memory parsed), the DCACHE automatically clears BUSYCMDF and sets CMDENDF in DCACHE_SR.

If enabled on this flag condition (CMDENDIE = 1 in DCACHE_IER), the DCACHE interrupt is raised.

During this invalidate range operation, the DCACHE is interruptible, meaning it can accept new incoming requests that take higher priority than the invalidation process. The TAG memory is accessed for invalidate range operation only if not already accessed by an external cache request. This implies that invalidate range execution is usually not performed in one go, but can be interrupted.

- **Clean range**: cleans a certain range of addresses in the cache, background task (interruptible).

Cleaning a cache line means making sure that the main memory content is up-to-date with the data which may have been modified in the cache. The clean operation consists in performing the write-back in the main memory of the cache lines that are tagged as “dirty” (the ones with TAG dirty bit set).

The software can clean a given data region in DCACHE by programming STARTCMD = 1, and CACHECMD = 0b001 in DCACHE_CR, after the address range was programmed into DCACHE_CMDRSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).

The DCACHE control logic then parses the whole TAG memory. If the read line address (TAG address + line index) falls in the programmed address range (DCACHE_CMDRSADDRR ≤ Line Addr ≤ DCACHE_CMDREADDRR), and the corresponding line is dirty, this line is cleaned, meaning the whole cache line is written-back in the memory through the DCACHE master port, and its TAG dirty bit is cleared.

When STARTCMD is set, the DCACHE control logic sets BUSYCMDF in DCACHE_SR and launches the clean range operation. STARTCMD is also automatically cleared. Once the operation is finished (all TAG memory parsed), the DCACHE automatically clears BUSYCMDF and sets CMDENDF in DCACHE_SR.

If enabled on this flag condition (CMDENDIE = 1 in DCACHE_IER), the DCACHE interrupt is raised.

During this clean range operation, the DCACHE is interruptible, meaning it can accept new incoming requests that take higher priority than the cleaning process. The TAG memory is accessed for clean range operation only if not already accessed by an external cache request. This implies that clean range execution is usually not performed in one go, but can be interrupted.

It is under the software responsibility that no bus initiator attempts to change the content of the region being cleaned until clean range is completed. For that, the software can take advantage of BUSYCMDF flag in DCACHE_SR, and can poll this flag to prevent any spurious access to the area being cleaned.
Alternatively it can also rely on the command end flag (CMDENDF) or on the DCACHE interrupt to detect the end of the clean range execution.

- **Clean and invalidate range**: cleans and invalidates a certain range of addresses in the cache, background task (interruptible).

  This operation cleans the “dirty” cache lines that belong to the operation address range (the same as clean range operation), and also invalidates all the (valid) cache lines that belong to this address range (whether they are dirty or not).

  The software can launch this clean and invalidate range operation, by programming STARTCMD = 1, and CACHECMD = 0b011 in DCACHE_CR, after the address range was programmed into DCACHE_CMDRSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).

  This sets and clears the same flags, and potentially the same interrupt as invalidate range or clean range operations.

### 9.4.9 DCACHE performance monitoring

The DCACHE provides the following monitors for performance analysis:

- The two 32-bit read-hit and write-hit monitors count the AHB transactions at the DCACHE input (slave port) that do not generate a transaction on the DCACHE output (master port).

  These monitors also take into account all accesses whose address is present in the TAG memory, or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from cache master port) (see Section 9.4.6).

- The two 16-bit read-miss and write-miss monitors count the AHB transactions at the DCACHE input (slave port) that generate a transaction on the DCACHE output (master port).

  These monitors also take into account all accesses whose address is not present neither in the TAG memory, nor in the refill buffer.

Upon reaching their maximum values, the monitors do not wrap over.

The software can perform the following tasks:

- Enable/stop the read (write) hit monitor, through R(W)HITMEN in DCACHE_CR.
- Reset the read (write) hit monitor, by setting R(W)HITMRST in DCACHE_CR.
- Enable/stop the read (write) miss monitor, through R(W)MISSMEN in DCACHE_CR.
- Reset the read (write) miss monitor, by setting R(W)MISSMRST in DCACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

### 9.4.10 DCACHE boot

The DCACHE is disabled (EN = 0 in DCACHE_CR) at boot.

Once the boot is finished, the DCACHE can be enabled (software setting EN = 1 in DCACHE_CR).

### 9.5 DCACHE low-power modes

At product level, using the DCACHE reduces the power consumption by loading/storing data from/to the internal DCACHE most of the time, rather than from the bigger and then
more power consuming main memories. This reduction is even much higher, since the cached main memories are external.

9.6 DCACHE error management and interrupts

A transaction initiated on the DCACHE master port may return an error (a write attempt into a read-only memory, for instance). If the master port request was propagated from a slave port request, the error is propagated back to the slave port. If ever the master port request is initiated by the DCACHE itself (a cache line is written back into the main memory because of an eviction or a clean operation), the DCACHE receives this functional error and flags it internally by setting the ERRF flag in DCACHE_SR.

In such a case, an interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in DCACHE_IER).

Another case of potential interrupt generation is at the end of a full invalidate operation: when the cache busy state is finished, the DCACHE sets BSYENDF flag in DCACHE_SR.

An interrupt is then generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in DCACHE_IER).

Last case is at the end of invalidate and/or clean range operations: when the command busy state is finished, the DCACHE sets CMDENDF flag in DCACHE_SR.

An interrupt is also generated if the corresponding interrupt enable bit is set (CMDENDIE = 1 in DCACHE_IER).

All DCACHE interrupt sources raise the same and unique interrupt signal, dcache_it, and then use the same interrupt vector.

<table>
<thead>
<tr>
<th>Interrupt vector</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
</tr>
</thead>
<tbody>
<tr>
<td>DCACHE</td>
<td>Functional error</td>
<td>ERRF in DCACHE_SR</td>

<td>End of cache operations (address range based)</td>
<td>CMDENDF in DCACHE_SR</td>
<td>CMDENDIE in DCACHE_IER</td>
<td>Set CCMDENDF to 1 in DCACHE_FCR</td>
</tr>
</tbody>
</table>

The DCACHE also propagates all AHB bus errors (such as security issues, address decoding issues) from master port back to the S-AHB slave port.
### 9.7 DCACHE registers

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 STARTCMD: starts maintenance command (maintenance operation defined in CACHECMD).
   Can be set by software, only when EN = 1, BUSYCMDF = 0, BUSYF = 0 and
   CACHECMD = 0b001, 0b010 or 0b011.
   Cleared by hardware when the BUSYCMDF flag is set (during cache maintenance
   operation). Writing 0 has no effect.
   0: command operation (cache maintenance) finished
   1: start maintenance command (cache maintenance)

Bits 10:8 CACHECMD[2:0]: cache command maintenance operation (cleans and/or invalidates
   an address range)
   Can be set and cleared by software, only when no maintenance command is ongoing
   (BUSYCMDF = 0).
   000: no operation
   001: clean range
   010: invalidate range
   011: clean and invalidate range
   others: reserved

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 CACHEINV: full cache invalidation
   Can be set by software, only when EN = 1.
   Cleared by hardware when the BUSYF flag is set (during full cache invalidation operation).
   Writing 0 has no effect.
   0: no effect
   1: invalidate entire cache (all cache lines valid bit = 0)

Bit 0 EN: enable
   0: cache disabled
   1: cache enabled
Bit 3 **BUSYCMDF**: command busy flag
- 0: cache not busy on a CACHECMD command
- 1: cache busy on a CACHECMD command (clean and/or invalidate an address range)

Bit 2 **ERRF**: cache error flag
- Cleared by writing DCACHE_FCR.CERRF = 1.
  - 0: no error
  - 1: an error occurred during the operation (eviction or clean operation write-back error).

Bit 1 **BSYENDF**: full invalidate busy end flag
- Cleared by writing DCACHE_FCR.CBSYENDF = 1.
  - 0: cache busy or in idle
  - 1: full invalidate CACHEINV operation finished

Bit 0 **BUSYF**: full invalidate busy flag
- 0: cache not busy on a CACHEINV operation
- 1: cache executing a full invalidate CACHEINV operation

10 Power control (PWR)

10.1 PWR introduction
The power controller manages all device power supplies and power modes transitions.

10.2 PWR main features
The power controller (PWR) main features are:
- Power supplies and supply domains
  - Core domain ($V_{\text{CORE}}$)
  - $V_{\text{DD}}$ domain
  - Backup domain

1. Interconnection available in all STM32U5 Series devices except STM32U575/585.
10.4 PWR power supplies and supply domains

Figure 32. Power supply overview

10.4.1 External power supplies

The devices require a 1.71 V to 3.6 V VDD operating voltage supply. Several independent supplies can be provided for specific peripherals. These supplies must not be provided without a valid operating supply on VDD pin:

- \( V_{DD} = 1.71 \text{ V to 3.6 V} \) (functionality guaranteed down to \( V_{BOR} \) minimum value)

\( V_{DD} \) is the external power supply for the I/Os, the internal regulator, and the system analog such as reset, power management, and internal clocks. It is provided externally through VDD pins.
• $V_{\text{DDA}} = 1.58 \text{ V (COMPs)} / 1.6 \text{ V (DACs, OPAMPs)} / 1.62 \text{ V (ADCs)} / 1.8 \text{ V (VREFBUF)}$ to 3.6 V

$V_{\text{DDA}}$ is the external analog power supply for A/D converters, D/A converters, voltage reference buffer, operational amplifiers and comparators. The $V_{\text{DDA}}$ voltage level is independent from the $V_{\text{DD}}$ voltage and must be connected to VDD or VSS (preferably to VDD) when these peripherals are not used.

• $V_{\text{DDSMP}} = 1.71 \text{ V to 3.6 V}$

$V_{\text{DDSMP}}$ is the external power supply for the SMPS step-down converter. It is provided externally through VDDSMPS supply pin, and must be connected to the same supply as VDD pin when the SMPS is used in the application. When the SMPS is not used, it is recommended to connect both $V_{\text{DDSMP}}$ and $V_{\text{LXSMPS}}$ to GND.

• $V_{\text{LXSMPS}}$ is the switched SMPS step-down converter output.

Note: The SMPS power supply pins are available only on a specific package with SMPS step-down converter option.

• $V_{\text{DDUSB}} = 3.0 \text{ V to 3.6 V}$

$V_{\text{DDUSB}}$ is the external independent power supply for USB/OTG_FS/OTG_HS transceivers. The $V_{\text{DDUSB}}$ voltage level is independent from the $V_{\text{DD}}$ voltage and must preferably be connected to $V_{\text{DD}}$ when the USB is not used.

• $V_{\text{DD11USB}} = 1.0 \text{ V to 1.26 V (only available on STM32U59x/5Ax/5Fx/5Gx devices)}$

$V_{\text{DD11USB}}$ is the external power supply for the OTG_HS transceiver. This supply is only available on specific packages and must be connected to VDD11.

• $V_{\text{DDIO}} = 1.08 \text{ V to 3.6 V}$

$V_{\text{DDIO}}$ is the external power supply for 14 I/Os (port G[15:2]). The $V_{\text{DDIO}}$ voltage level is independent from the $V_{\text{DD}}$ voltage and must preferably be connected to $V_{\text{DD}}$ when PG[15:2] are not used.

• $V_{\text{BAT}} = 1.65 \text{ V to 3.6 V (functionality guaranteed down to } V_{\text{BOR_{VBAT}}} \text{ minimum value, refer to the product datasheet)}$

$V_{\text{BAT}}$ is the power supply when $V_{\text{DD}}$ is not present (through power switch) for RTC, TAMP, external and internal clocks 32 kHz oscillator, backup registers and optionally backup SRAM.

• $V_{\text{DDD}} = 1.71 \text{ V to 3.6 V (only available on STM32U59x/5Ax/5Fx/5Gx devices)}$

$V_{\text{DDD}}$ is the external power supply for the DSI controller. It is provided externally through VDDDSI supply pin, and must be connected to the same supply as VDD pin.

• $V_{\text{DD11DSI}} = 1.0 \text{ V to 1.26 V (only available on STM32U59x/5Ax/5Fx/5Gx devices)}$

$V_{\text{DD11DSI}}$ is the external power supply for the DSI transceiver and must be connected to VDD11 pin.

• $V_{\text{REF+}}, V_{\text{REF+}}$

$V_{\text{REF+}}$ is the input reference voltage for ADCs and DACs. It is also the output of the internal voltage reference buffer when enabled.

$V_{\text{REF+}}$ can be grounded when ADCs and DACs are not active.

The internal voltage reference buffer supports four output voltages, that are configured with VRS bit in the VREFBUF_CSR register:

- $V_{\text{REF+}}$ around 1.5 V. This requires $V_{\text{DDA}} \geq 1.8 \text{ V}$.
- $V_{\text{REF+}}$ around 1.8 V. This requires $V_{\text{DDA}} \geq 2.1 \text{ V}$.
- $V_{\text{REF+}}$ around 2.048 V. This requires $V_{\text{DDA}} \geq 2.4 \text{ V}$.
- $V_{\text{REF+}}$ around 2.5 V. This requires $V_{\text{DDA}} \geq 2.8 \text{ V}$.
VREF- and VREF+ pins are not available on all packages. When not available, they are bonded to VSSA and VDDA, respectively. When the VREF+ is double-bonded with VDDA in a package, the internal voltage reference buffer is not available and must be kept disabled. VREF- must always be equal to VSSA.

10.4.2 Internal regulators

The devices embed two regulators: one LDO and one SMPS in parallel to provide the V_{CORE} supply for digital peripherals, SRAMs (except BKPSRAM) and embedded flash memory. The SMPS generates this voltage on VDD11 (two or three pins) with a total external capacitor of 4.7 \mu F typical and requires an external coil of 2.2 \mu H typical.

The LDO generates this voltage on VCAP (one or two pins depending on packages) with a total of external capacitor of 4.7 \mu F typical.

Both regulators can provide four different voltages (voltage scaling) and can operate in Stop mode.

It is possible to switch from SMPS to LDO and from LDO to SMPS on-the-fly.

10.4.3 Power-up and power-down power sequences

During power-up and power-down phases, the following power sequence requirements must be respected:

- When VDD is below 1 V, other power supplies (VDDA, VDDIO2, VDDUSB) must remain below VDD + 300 mV.
- When VDD is above 1 V, all power supplies are independent.

During the power-down phase, VDD can temporarily become lower than other supplies only if the energy provided to the MCU remains below 1 mJ. This allows external decoupling capacitors to be discharged with different time constants during the power-down transient phase.

10.4.4 Independent analog peripherals supply

To improve ADC and DAC conversion accuracy and to extend the supply flexibility, the analog peripherals have an independent power supply that can be separately filtered and shielded from noise on the PCB:

- The analog peripherals voltage supply input is available on a separate VDDA pin.
- An isolated supply ground connection is provided on VSSA pin.

The VDDA supply voltage can be different from VDD. The presence of VDDA must be checked before enabling any of the analog peripherals supplied by VDDA (A/D converter, D/A converter, comparators, operational amplifiers, voltage reference buffer).

After reset, the ADC and analog switch control supplied by VDDA are logically and electrically isolated and therefore are not available. The isolation must be removed before using the analog peripherals, by setting the ASV bit in the PWR_SVMCR register, once the VDDA supply is present.

The VDDA supply can be monitored by the analog voltage monitors (AVM), and compared with two thresholds (1.6 V for AVM1 or 1.8 V for AVM2), refer to Section 10.6.3 for more details.
When a single supply is used, $V_{DDA}$ can be externally connected to $V_{DD}$ through the external filtering circuit in order to ensure a noise-free $V_{DDA}$ reference voltage.

**ADC and DAC reference voltage**

To ensure a better accuracy on low-voltage inputs and outputs, the user can connect to $V_{REF+}$, a separate reference voltage lower than $V_{DDA}$. $V_{REF+}$ is the highest voltage, represented by the full scale value, for an analog input (ADC) or output (DAC) signal.

$V_{REF+}$ can be provided either by an external reference or by an internal buffered voltage reference ($V_{REFBUF}$). The internal voltage reference can output a configurable voltage: 1.5 V, 1.8 V, 2.048 V or 2.4 V. The internal voltage reference can also provide the voltage to external components through $V_{REF+}$ pin. Refer to the device datasheet and to Section 36: Voltage reference buffer ($V_{REFBUF}$) for further information.

### 10.4.5 Independent I/O supply rail

Some I/Os from port G (PG[15:2]) are supplied from a separate supply rail. The power supply for this rail can range from 1.08 V to 3.6 V and is provided externally through the $V_{DDIO2}$ pin. The $V_{DDIO2}$ voltage level is completely independent from $V_{DD}$ or $V_{DDA}$. The $V_{DDIO2}$ pin is available only for some packages. Refer to the pinout diagrams or tables in the related device datasheet(s) for I/O list(s).

After reset, the I/Os supplied by $V_{DDIO2}$ are logically and electrically isolated and therefore are not available. The isolation must be removed before using any I/O from PG[15:2], by setting the IO2SV bit in the PWR_SVMCR register, once the $V_{DDIO2}$ supply is present.

The $V_{DDIO2}$ supply is monitored by the IO2 voltage monitoring (IO2VM) and compared with the internal reference voltage ($3/4 V_{REFINT}$, around 0.9 V). Refer to Section 10.6.3 for more details.

### 10.4.6 Independent USB transceivers supply

The USB transceivers are supplied from a separate VDDUSB power supply pin. The $V_{DDUSB}$ range is from 3.0 V to 3.6 V and is completely independent from $V_{DD}$ or $V_{DDA}$.

After reset, the USB features supplied by $V_{DDUSB}$ are logically and electrically isolated, and therefore are not available. The isolation must be removed before using USB/OTG_FS/OTG_HS, by setting USV in PWR_SVMCR, once the $V_{DDUSB}$ supply is present.

The $V_{DDUSB}$ supply is monitored by the USB voltage monitoring (UVM), and compared with the internal reference voltage ($V_{REFINT}$, around 1.2 V). Refer to Section 10.6.3 for more details.

**Internal OTG_HS transceiver supply (STM32U59x/5Ax/5Fx/5Gx only)**

The OTG_HS high-speed transceiver is functional in voltage scaling range 1 and range 2. The USB EPOD (embedded power distribution) booster must be enabled and ready before using the OTG_HS: USBPWREN and USBBOOSTEN bits must be set to one in PWR_VOSR (refer to Section 10.6.3 and Section 10.7.12 for more details).
10.4.7 Battery backup domain

To retain the content of backup registers, backup SRAM, and to supply RTC and TAMP functions when $V_{DD}$ is turned off, the VBAT pin can be connected to an optional backup voltage supplied by a battery or by another source.

The Backup domain supply is $V_{SW}$, which is the output of a power switch between $V_{DD}$ and $V_{BAT}$. The switch between $V_{DD}$ and $V_{BAT}$ supplies is automatically controlled by the brownout reset circuitry.

When $V_{DD}$ is below the lowest brownout reset threshold ($V_{BOR0}$), the VBAT pin powers the RTC and TAMP peripherals, the LSI and LSE oscillators. The backup SRAM is optionally powered by VBAT pin when BREN is set in PWR_BDCR1.

The following pin functions are also powered by the VBAT pin:

- PC13, PC14, and PC15 that can be configured by the RTC, the TAMP, or the LSE (see Section 63.3: RTC functional description)
- PE3, PE4, PE5, PE6, PC13, PA0, PA1, and PC5 when they are configured by the TAMP as tamper pins
- PB2 when configured by the RTC as RTC_OUT2 output

When $V_{DD}$ is higher than $V_{BOR0}$, the VDD pin powers all previous functions.

Note: Due to the fact that the analog power switch can transfer only a limited amount of current (3 mA), the use of GPIO PC13 to PC15 in output mode is restricted: the speed must be limited to 2 MHz with a maximum load of 30 pF and these I/Os must not be used as a current source (for example to drive a LED).

Warning: During $t_{RSTTEMPO}$ (temporization at $V_{DD}$ startup) or after a PDR has been detected, the power switch between $V_{BAT}$ and $V_{DD}$ remains connected to $V_{BAT}$. During the startup phase, if $V_{DD}$ is established in less than $t_{RSTTEMPO}$ (refer to the datasheet for the value of $t_{RSTTEMPO}$) and $V_{DD} > V_{BAT} + 0.6$ V, a current may be injected into $V_{BAT}$ through an internal diode connected between $V_{DD}$ and the power switch ($V_{BAT}$).

If the power supply/battery connected to the VBAT pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the VBAT pin.

If no external battery is used in the application, it is recommended to connect $V_{BAT}$ externally to $V_{DD}$ with a 100 nF external ceramic decoupling capacitor.
Backup domain access

After a system reset, the backup domain (RCC backup domain control register RCC_BDCR, RTC registers, TAMP registers, backup registers and backup SRAM) is protected against possible unwanted write accesses.

To enable access to the backup domain, proceed as follows:
1. Enable the power interface clock by setting the PWREN bits in RCC_AHB3ENR.
2. Set the DBP bit in PWR_DBPR to enable access to the backup domain.

V\textsubscript{BAT} battery charging

When V\textsubscript{DD} is present, it is possible to charge the external battery on V\textsubscript{BAT} through an internal resistance.

The V\textsubscript{BAT} charging is done either through a 5 kΩ resistor or through a 1.5 kΩ resistor depending on VBRS value in PWR_BDCR2.

The battery charging is enabled by setting VBE in PWR_BDCR2. It is automatically disabled in V\textsubscript{BAT} mode.

10.5 PWR system supply voltage regulation

10.5.1 SMPS and LDO embedded regulators

The devices embed two internal regulators, that can be selected when the application runs, depending on the application requirements:
- a SMPS step-down converter
- a linear voltage regulator (LDO)

The SMPS allows the power consumption to be reduced but some applications can be perturbed by the noise generated by the SMPS, requiring the application to switch to LDO.

The LDO and the SMPS regulators have two modes: main regulator mode (used when performance is needed), and low-power regulator mode. LDO or SMPS can be used in all voltage scaling ranges, and in all Stop modes.

10.5.2 LDO and SMPS versus reset, voltage scaling, and low-power modes

After reset, the regulator is the LDO, in range 4. Switching to SMPS provides lower consumption in particular at high V\textsubscript{DD} voltage. It is possible to switch from LDO to SMPS, or from SMPS to LDO in any range, by configuring the REGSEL bit.

When exiting Stop or Standby mode, the regulator is the same than when entering low-power modes. The voltage range is the range 4.

Warning: On STM32U59x/5Ax/5Fx/5Gx devices only, when using the device in VOS range 1 at extended temperature ranges (from 85 to 125 °C), the system frequency must be reduced below 110 MHz before switching from LDO to SMPS, or vice versa. It is required to proceed as follow:
1. Reduce the system frequency below 110 MHz.
2. Configure REGSEL bit to select the required regulator.
3. Wait for 8 µs.
4. Increase the system frequency to the required frequency.

10.5.3 LDO and SMPS step down converter fast startup

After BOR reset, the LDO and SMPS regulators start in slow-startup mode. This startup feature is selected to limit the inrush current after power-on reset. This increases the wake-up time when exiting Stop or Standby mode.

However, it is possible to configure a faster startup on-the-fly, and it is applied for next startup either after a system reset or after a wake-up from low-power mode except Shutdown and V_{BAT} modes. The fast startup is selected by setting FSTEN in PWR.CR3.

10.5.4 Dynamic voltage scaling management

The dynamic voltage scaling is a power management technique that consists in increasing or decreasing the voltage used for the digital peripherals (V_{CORE}), according to the application performance and power consumption needs.

Dynamic voltage scaling to increase V_{CORE} is known as overvolting. It allows the device to improve its performance.

Dynamic voltage scaling to decrease V_{CORE} is known as undervolting. It is performed to save power, particularly in laptop and other mobile devices where the energy comes from a battery and is thus limited.

The regulator operates in the following ranges:

- **Range 1: high performance**
  - It provides a typical output voltage at 1.2 V. It is used when the system clock frequency is up to 160 MHz.

- **Range 2: medium-high performance**
  - It provides a typical output voltage at 1.1 V. It is used when the system clock frequency is up to 110 MHz.

- **Range 3: medium-low power range**
  - It provides a typical output voltage at 1.0 V. The system clock frequency can be up to 55 MHz.

- **Range 4: low-power range**
  - It provides a typical output voltage at 0.9 V. The system clock frequency can be up to 25 MHz.

Voltage scaling is selected through VOS[1:0] in PWR.VOSR. The EPOD (embedded power distribution) booster must be enabled and ready before increasing the system clock frequency above 55 MHz in range 1 and range 2.

The sequence to switch the voltage scaling from range L (lower power) to range P (higher performance) with L > P, is the following:

1. If target SYSCLK > 55 MHz:
   a) Configure PLL1MBOOST[3:0] in RCC.PLL1CFGR to generate a booster clock frequency between 4 and 16 MHz.
   b) Switch on the PLL1 oscillator clock source.
c) Select the PLL1 clock source (PLL1SRC[1:0] in RCC_PLL1CFGR).

2. Program VOS[1:0] to range P in PWR_VOSR.

3. Wait until the VOSRDY flag is set in PWR_VOSR.

4. If target SYSCLK > 55 MHz:
   a) Set BOOSTEN in PWR_VOSR. This step can be done together with VOS programming.
   b) Wait until the BOOSTRDY flag is set in PWR_VOSR.

5. Adjust number of wait states according new frequency target in range P (LATENCY bits in FLASH_ACR, and WSC bits in RAMCFG_MxCR).

6. Configure and enable the PLL if needed.

7. Configure and switch to new system frequency.

The sequence to switch the voltage scaling from range P (higher performance) to range L (lower power) with L > P, is the following:

1. Reduce the system frequency to a value lower than range L maximum frequency.

2. Adjust number of wait states according new frequency target (LATENCY bits in FLASH_ACR and WSC bits in the RAMCFG_MxCR).

3. If new SYSCLK < 55 MHz, clear BOOSTEN in PWR_VOSR if it was set.

4. Program VOS bits to range L in PWR_VOSR. This step can be done together with BOOSTEN clearing.

**System frequency steps on STM32U59x/5Ax/5Fx/5Gx devices**

On STM32U59x/5Ax/5Fx/5Gx devices only, the maximum system frequency increase or decrease in the VOS range 1 is 80 MHz.

The sequence to increase the frequency in the VOS range 1 above 80 MHz is the following:

1. Divide the system clock by two, using the AHB prescaler (HPRE = 0b1000 in RCC_CFGR2).

2. Configure and enable the PLL1 if needed.

3. Select PLL1 as system clock source (SW = 0b11 in RCC_CFGR1).

4. Wait for 5 µs.

5. Set the AHB prescaler to 1 (HPRE = 0b0000 in RCC_CFGR2).

When running at higher frequencies than 80 MHz in the VOS range 1, the sequence to decrease the frequency is the following:

1. Divide the system clock by two using the AHB prescaler (HPRE = 0b1000 in RCC_CFGR2).

2. Wait for 5 µs.

3. Define the lower speed clock as system clock source.

4. Set the AHB prescaler back to 1 (HPRE = 0b0000 in RCC_CFGR2).

In other VOS ranges, there is no limitation during system frequency increase or decrease.
10.6  PWR power-supply supervision

10.6.1 Brownout reset (BOR)

The device has an integrated brownout reset (BOR) circuitry. The BOR is active in all power modes except Shutdown mode, and cannot be disabled.

Five BOR thresholds can be selected through option bytes. BOR0 provides the always enabled power-on/power-down functionality, independent from any other higher BOR level selection.

During power-on, the BOR keeps the device under reset until the supply voltage $V_{DD}$ reaches the specified $V_{BORx}$ threshold. When $V_{DD}$ drops below the selected threshold, a device reset is generated. When $V_{DD}$ is above the $V_{BORx}$ upper limit, the device reset is released and the system can start.

For more details on the brownout reset thresholds, refer to the electrical characteristics section in the datasheet.

During Standby mode, and if BOR level 0 is selected, it is possible to set the BOR in ultra-low-power mode to further reduce the current consumption by setting ULPMEN in PWR_CR1.

Figure 33. Brownout reset waveform

1. The reset temporization $t_{RSTTEMPO}$ is present only for the BOR lowest threshold ($V_{BOR0}$).

10.6.2 Programmable voltage detector (PVD)

The PVD can be used to monitor the $V_{DD}$ power supply by comparing it to a threshold selected by PVDLS[2:0] in PWR_SVMCR.

The PVD is enabled by setting PVDE bit.

A PVDO flag is available in PWR_SVMCR to indicate if $V_{DD}$ is higher or lower than the PVD threshold. This event is internally connected to the EXTI, and can generate an interrupt if enabled through the EXTI registers (refer to Table 110).

The rising/falling edge sensitivity of the EXTI Line must be configured according to PVD output behavior. For example, if the EXTI line is configured to rising edge sensitivity, the interrupt is generated when $V_{DD}$ drops below the PVD threshold. As an example, the service routine can perform emergency shutdown tasks.
The PVD can remain active in Stop 0, Stop 1, and Stop 2 modes, and the PVM interrupt can wake up from Stop mode. The PVD is not functional in Stop 3 mode.

**Figure 34. PVD thresholds**

10.6.3 **Peripheral voltage monitoring (PVM)**

Only \( V_{DD} \) is monitored by default, as it is the only supply required for all system-related functions. The other supplies (\( V_{DDA}, V_{DDIO2}, \) and \( V_{DDUSB} \)) can be independent from \( V_{DD} \) and can be monitored with four peripheral voltage monitoring (PVM):

- The UVM monitors the USB supply \( V_{DDUSB} \). \( V_{DDUSB} \) indicates if the \( V_{DDUSB} \) independent power supply is higher or lower than the \( V_{UVM} \) threshold.
- The IO2VM monitors the PG[15:2] supply \( V_{DDIO2} \). \( V_{DDIO2} \) indicates if the \( V_{DDIO2} \) independent power supply is higher or lower than the \( V_{IO2VM} \) threshold.
- The AVM1 monitors the analog supply \( V_{DDA} \). \( V_{DDA} \) indicates if the \( V_{DDA} \) independent power supply is higher or lower than the \( V_{AVM1} \) threshold.
- The AVM2 monitors the analog supply \( V_{DDA} \). \( V_{DDA} \) indicates if the \( V_{DDA} \) independent power supply is higher or lower than the \( V_{AVM2} \) threshold.

Each PVM output is connected to an EXTI line and can generate an interrupt if enabled through the EXTI registers. The PVMx output interrupt is generated when the independent power supply drops below the PVM threshold and/or when it rises above the PVM threshold, depending on EXTI line rising/falling edge configuration (refer to Table 110).

Each PVM can remain active in Stop 0, Stop 1, and Stop 2 modes, and the PVM interrupt can wake up from the Stop mode. The PVM is not functional in Stop 3 mode.

</table>
The independent supplies (VDDA, VDDIO2, and VDDUSB) are not considered as present by default, and a logical and electrical isolation is applied to ignore any information coming from the peripherals supplied by these dedicated supplies:

- If these supplies are shorted externally to VDD, the application assumes they are available without enabling any peripheral voltage monitoring.
- If these supplies are independent from VDD, the peripheral voltage monitoring (PVM) can be enabled to confirm whether the supply is present or not.

The following sequence must be done before using the USB/OTG_FS/OTG_HS:

1. If VDDUSB is independent from VDD:
   a) Enable the UVM by setting UVMEN in PWR_SVMCR.
   b) Wait for the UVM wake-up time.
   c) Wait until VDDUSBRDY is set in PWR_SVMSR.
   d) Disable the UVM for consumption saving (optional).

2. Set USV in PWR_SVMCR to remove the VDDUSB power isolation.

3. On STM32U59x/5Ax/5Fx/5Gx devices only:
   a) Make sure the voltage scaling is in range 1 or in range 2 (using VOS[1:0] in PWR_VOSR).
   b) Make sure the EPOD booster clock is enabled (using PLL1MBOOST[3:0] in RCC_PLL1CFGR).
   c) Enable the USB internal power by setting USBPWREN and USBBOOSTEN in PWR_VOSR.
   d) Wait for USBBOOSTRDY to be set in PWR_VOSR.

The following sequence must be done before using any I/O from PG[15:2]:

1. If VDDIO2 is independent from VDD:
   a) Enable the IO2VM by setting IO2VM in PWR_SVMCR.
   b) Wait for the IO2CVM wake-up time.
   c) Wait until VDDIO2RDY is set in PWR_SVMSR.
   d) Disable the IO2VM for consumption saving (optional).

2. Set IO2SV in PWR_SVMCR to remove the VDDIO2 power isolation.

The following sequence must be done before using any of these analog peripherals: analog to digital converters, digital to analog converters, comparators, operational amplifiers, voltage reference buffer:

1. If VDDA is independent from VDD:
   a) Enable the AVM1 or AVM2 by setting AVM1EN or AVM2EN in PWR_SVMCR.
   b) Wait for the AVM wake-up time.
   c) Wait until VDDA1RDY or VDDA2RDY is set in PWR_SVMCR.
   d) Disable the AVM for consumption saving (optional).

2. Set the ASV in PWR_SVMCR to remove the VDDA power isolation.

### 10.6.4 Backup domain voltage and temperature monitoring

When the backup domain voltage and temperature monitoring is enabled (MONEN = 1 in PWR_DBPR), the backup domain voltage and the temperature are monitored.
If the backup domain voltage monitoring internal tamper is enabled in the TAMP peripheral (ITAMP1E = 1 in TAMP_CR1), a tamper event is generated when the backup domain voltage is above the functional range. In case the backup domain voltage is below the functional range, a brownout reset is generated, erasing all device including backup domain.

**Note:** The backup domain voltage is $V_{DD}$ when present, $V_{BAT}$ otherwise.

If the temperature monitoring internal tamper is enabled in the TAMP peripheral (ITAMP2E = 1 in TAMP_CR1), a tamper event is generated when the temperature is above or below the functional range.

### 10.7 PWR power management

#### 10.7.1 Power modes

By default, the microcontroller is in Run mode after a system or a power reset. Reducing the power consumption in Run mode is done by configuring the voltage scaling according to application performance needs. Refer to [Section 10.5.4](#) for more details. Unused RAMs can be powered-off with SRAMxPD bits in PWR_CR1. The power consumption is also reduced by reducing SYSCCLK, HCLK, and PCLK clocks speed, or gating unused peripherals clocks. Refer to [Section 11: Reset and clock control (RCC)](#) for more details.

Several low-power modes are available to save power when the CPU does not need to be kept running, for example when waiting for an external event. It is up to the user to select the mode that gives the best compromise between low-power consumption, short startup time and available wake-up sources.

The device features these low-power modes:

- **Sleep mode:**
  
  CPU clock off, all peripherals including Cortex-M33 core such as NVIC and SysTick can run and wake up the CPU when an interrupt or an event occurs. Refer to [Section 10.7.5](#).

- **Stop 0, Stop 1, Stop 2, Stop 3 modes:**
  
  Stop mode achieves the lowest power consumption while retaining the content of SRAM and registers. All clocks in the core domain are stopped. The PLL, the MSI (MSIS and MSIK) RC, the HSI16 RC and the HSE crystal oscillators are disabled. The LSE or LSI is still running.

  The RTC can remain active (Stop mode with RTC, Stop mode without RTC).

  Some peripherals are autonomous and can operate in Stop mode by requesting their kernel clock and their bus (APB or AHB) when needed, in order to transfer data with DMA (GPDMA1 or LPDMA1 depending on peripherals and power mode).

  In Stop 2 and Stop 3 modes, most of the core domain is put in a lower leakage mode. Stop 0 and Stop 1 offers the largest number of active peripherals and wake-up sources, a smaller wake-up time but a higher consumption than Stop 2.

  In Stop 0 mode, the regulator remains in main regulator mode, allowing a very fast wake-up time but with much higher consumption.

  Stop 3 is the lowest power mode with full retention, but the functional peripherals and sources of wake-up are reduced to the same ones than in Standby mode.

  The system clock when exiting from Stop mode can be either MSIS up to 24 MHz or...
HSI16, depending on software configuration.
Refer to Section 10.7.6, Section 10.7.7, Section 10.7.8 and Section 10.7.9.

- **Standby mode:**
  The Standby mode is used to achieve the lowest power consumption with BOR. The internal regulator is switched off so that the core domain is powered off. The PLL, the MSI (MSIS and MSIK) RC, the HSI16 RC and the HSE crystal oscillators are also switched off.
  The RTC can remain active (Standby mode with RTC, Standby mode without RTC).
  The brownout reset (BOR) always remains active in Standby mode.
  The state of each I/O during Standby mode can be selected by software: I/O with internal pull-up, internal pull-down or floating.
  After entering Standby mode, SRAMs and register contents are lost except for registers and backup SRAM in the backup domain and Standby circuitry. Optionally, the full SRAM2 or 8 Kbytes or 56 Kbytes can be retained in Standby mode, supplied by the low-power regulator (standby with SRAM2 retention mode).
  The BOR can be configured in ultra-low-power mode to further reduce power consumption during standby mode and when the lowest threshold is selected ($V_{BOR0}$).
  The device exits Standby mode when an external reset (NRST pin), an IWDG reset, WKUP pin event (configurable rising or falling edge), a RTC event occurs (alarm, periodic wake-up, timestamp), or a tamper detection. The tamper detection can be raised either due to external pins or due to an internal failure detection.
  The system clock after wake-up is MSIS up to 4 MHz.
  Refer to Section 10.7.10.

- **Shutdown mode:**
  The Shutdown mode allows the lowest power consumption. The internal regulator is switched off so that the core domain is powered off. The PLL, the HSI16, the MSI (MSIS and MSIK), the LSI and the HSE oscillators are also switched off.
  The RTC can remain active (Shutdown mode with RTC, Shutdown mode without RTC).
  The BOR is not available in Shutdown mode. No power voltage monitoring is possible in this mode, therefore the switch to backup domain is not supported.
  SRAMs and register contents are lost except for registers in the backup domain.
  The device exits Shutdown mode when an external reset (NRST pin), a WKUP pin event (configurable rising or falling edge), or a RTC event occurs (alarm, periodic wake-up, timestamp), or a tamper detection.
  The system clock after wake-up is MSIS at 4 MHz. Refer to Section 10.7.11.
The table below shows the power modes overview.

**Table 99. Low-power mode summary**

<table>
<thead>
<tr>
<th>Mode name</th>

<td>O</td>
<td>O</td>
<td>(20) 24 pins</td>
<td>(20) 24 pins</td>
<td>(21) 24 pins</td>
</tr>
</tbody>
</table>

1. Y = yes (enable). O = optional (disable by default, can be enabled by software). - = not available.

Gray cells highlight the wake-up capability in each mode.

2. The flash memory can be configured in power-down mode. By default, it is not in power-down mode.
3. The SRAMs can be powered on or off independently.
4. The SRAM clock can be gated on or off independently.
5. ECC error interrupt or NMI wakes up from this Stop mode.
6. 8 Kbytes, 56 Kbytes or full SRAM2 content can be preserved.
7. This feature is only available on some STM32U5 Series devices. Refer to the device datasheet for availability of its associated peripheral.
8. Sub-blocks or full SRAM1, SRAM3, SRAM5, SRAM6, full SRAM2 and SRAM4 can be powered-off to save power consumption. SRAM1, SRAM2, SRAM3, SRAM4, SRAM5, and SRAM6 can be accessed by GPDMA in Stop 0 and Stop 1 modes. SRAM4 can be accessed by LPDMA in Stop 0, Stop 1, and Stop 2 modes.
9. GPDMA transfers are functional and autonomous in Stop mode, and generates a wake-up interrupt on transfer events.
10. LPDMA transfers are functional and autonomous in Stop mode, and generates a wake-up interrupt on transfer events.
11. Some peripherals with autonomous mode and wake-up from Stop capability can request HSI16, MSIS or MSIK to be enabled. In this case, the oscillator is woken up by the peripheral, and is automatically put off when no peripheral needs it.
12. OTG_FS and USB are functional in voltage scaling range 1, 2, and 3. OTG_HS is functional in voltage scaling range 1 and 2.
13. USART and LPUART reception and transmission is functional and autonomous in Stop mode, in asynchronous, and in SPI master modes, and generates a wake-up interrupt on transfer events.
14. I2C reception and transmission is functional and autonomous in Stop mode, and generates a wake-up interrupt on transfer events.
15. SPI reception and transmission is functional and autonomous in Stop mode, and generates a wake-up interrupt on transfer events.
16. ADC conversion is functional and autonomous in Stop mode, and generates a wake-up interrupt on conversion events.
17. LPTIM is functional and autonomous in Stop mode, and generates a wake-up interrupt on events.
18. MDF and ADF is functional and autonomous in Stop mode, and generates a wake-up interrupt on events.
19. DSI is functional in voltage scaling range 1 and 2.
20. I/Os can be configured with internal pull-up, pull-down or floating in Standby mode.
21. I/Os can be configured with internal pull-up, pull-down or floating in Shutdown mode but the configuration is lost when exiting Shutdown mode.
In addition, the power consumption in Run mode can be reduced by one of the following means:

- Slowing down the system clocks and configuring voltage scaling to lower-power ranges.
- Gating the clocks to the APB and AHB peripherals when they are unused.
- Powering off unused RAMs

When a SRAM has been powered off, it can be powered on again by following the procedure:
1. Reset SRAMxPD in PWR_CR1.
2. Wait for 1.6 µs.
3. Set SRAMxEN in RCC_AHBxENR.

**Debug mode**

By default, the debug connection is lost if the application puts the MCU in Stop 0, Stop 1, Stop 2, Stop 3, Standby, or Shutdown mode while the debug features are used. This is due to the fact that the Cortex-M33 core is no longer clocked.

However, by setting some configuration bits in the DBGMCU control registers, the software can be debugged even when using the low-power modes extensively. For more details, refer to Section 75.2.5: Debug and low-power modes.

### 10.7.2 Autonomous peripherals and low-power background autonomous mode (LPBAM)

Several peripherals support the autonomous mode which allows it to be functional and perform DMA transfers in Stop 0, Stop 1, and Stop 2 modes. In addition, the low-power background autonomous mode (LPBAM) is supported in Stop 2 mode, allowing to build more complex use cases with autonomous peripherals, without any CPU wake-up thanks to DMA transfers.

**Stop 0 and Stop 1 modes**

In Stop 0 and Stop 1 modes, the autonomous peripherals are ADC4, DAC1, LPTIMx (x = 1 to 4), USARTx (x = 1 to 6), LPUART1, SPIx (x = 1 to 3), I2Cx (x = 1 to 6), MDF1, ADF1, GPDMA1 and LPDMA1:

- ADC4, DAC1, LPTIM1, LPTIM3, LPUART1, SPI3, I2C3 and ADF1 are autonomous only with LPDMA1 and SRAM4.
- LPTIM2, USARTx (x = 1 to 6), SPI1, SPI2, I2C1, I2C2, I2C4 and MDF1 are autonomous only with GPDMA1 and SRAM1 to SRAM5.

**Stop 2 mode**

In Stop 2 mode, the autonomous peripherals are ADC4, DAC1, LPTIM1, LPTIM3, LPUART1, SPI3, I2C3, ADF1, and LPDMA1. In this mode, the SRAM4 can be accessed by the LPDMA1.

**Autonomous peripherals and LPBAM features**

These autonomous peripherals support the following features:

- Functionality in Stop mode thanks to its own independent clock (named kernel clock) request capability: the peripheral kernel clock is automatically switched on when
requested by a peripheral, and automatically switched off when no peripheral requests it.

- DMA transfers supported in Stop mode thanks to the system clock request capability: the system clock (MSIS or HSI16) automatically switched on when requested by a peripheral, and automatically switched off when no peripheral requests it. When the system clock is requested by an autonomous peripheral, the system clock is woken up and distributed to all peripherals enabled in the RCC. This allows the DMA to access the enabled SRAM, and any enabled peripheral register (for instance GPIO or LPGPIO registers).

- Automatic start of the peripheral thanks to the hardware synchronous or asynchronous triggers (such as I/Os edge detection and low-power timer event)

- wake-up from Stop mode with peripheral interrupt

The GPDMA1 and LPDMA1 are fully functional and the linked-list is updated in Stop mode, allowing the different DMA transfers to be linked without any CPU wake-up. This can be used to chain different peripherals transfers, or to write peripherals registers in order to change their configuration while remaining in Stop mode. LPBAM application drivers and tools are available in STM32CubeMX, to help building those peripherals scenarios in Stop 2 mode, thanks to LPDMA1 linked-list transfers.

The DMA transfers from memory to memory can be started by hardware synchronous or asynchronous triggers, and the DMA transfers between peripherals and memories can also be gated by those triggers.

Here below some use-cases that can be done while remaining in Stop mode:

- ADC or DAC conversion triggered by a low-power timer (or any other trigger)
  – Wake-up from Stop mode on analog watchdog if the ADC conversion result is out of the programmed thresholds
  – Wake-up from Stop mode on DMA buffer event

- Audio digital filter data transfer into SRAM
  – Wake-up from Stop on sound activity detection

- I2C slave reception or transmission, SPI reception, UART/LPUART reception
  – Wake-up at the end of peripheral transfer or on DMA buffer event

- I2C master transfer, SPI transmission, UART/LPUART transmission, triggered by a low-power timer (or any other trigger)
  – Example: sensor periodic read
  – Wake-up at the end of peripheral transfer or on DMA buffer event

- Bridges between peripherals
  – Example: ADC converted data transferred by communication peripherals

- Data transfer from/to GPIO/LPGPIO to/from SRAM for:
  – Controlling external components
  – Implementing data transmission and reception protocols

- Data transfer from a SRAM to another one
10.7.3 Run mode

Slowing down system clocks

In Run mode, the speed of the system clocks (SYSCLK, HCLK, PCLK) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down the peripherals before entering the Sleep mode.

For more details, refer to Section 11: Reset and clock control (RCC).

Peripheral clock gating

In Run mode, the HCLK and PCLK for individual peripherals and memories can be stopped at any time to reduce the power consumption.

To further reduce the power consumption in Sleep mode, the peripheral clocks can be disabled prior to executing the WFI or WFE instructions.

The peripheral clock gating is controlled by the RCC_AHBxENR and RCC_APBxENR registers.

Disabling the peripherals clocks in Sleep mode can be performed automatically by resetting the corresponding bit in the RCC_AHBxSMENR and RCC_APBxSMENR registers. This bit must be set for the peripherals requesting clocks in Stop mode for autonomous DMA transfers or to generate a wake-up interrupt.

Disabling the peripherals autonomous clock in Stop 2 mode can be performed automatically by resetting the corresponding bit in RCC_AHB3AMENR and RCC_APB3AMENR.

10.7.4 Low-power modes

Entering into a low-power mode

The MCU enters in low-power modes by executing the WFI (wait for interrupt), or WFE (wait for event) instructions, or when the SLEEPONEXIT bit in the Cortex-M33 system control register is set on Return from ISR.

Entering into a low-power mode through WFI or WFE is executed only if no interrupt is pending or no event is pending.

Caution: The peripherals with autonomous mode feature are able to generate an AHB or APB clock request, depending on their internal events. If a clock request is present when WFI or WFE is executed, the low-power mode entry is delayed until the clock request is released.

Exiting a low-power mode

The way the MCU exits Sleep or Stop mode depends on the way the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter the low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the device.
• If the WFE instruction is used to enter the low-power mode, the MCU exits the low-power mode as soon as an event occurs. The wake-up event can be generated either by:
  – an NVIC IRQ/peripheral interrupt:
    - When SEVONPEND = 0 in the Cortex-M33 system control register
      By enabling an interrupt in the peripheral control register and in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) must be cleared. Only NVIC interrupts with high enough priority wake up and interrupt the MCU.
    - When SEVONPEND = 1 in the Cortex-M33 system control register
      By enabling an interrupt in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) must be cleared. All NVIC interrupts wake up the MCU, even the disabled ones. Only enabled NVIC interrupts with high enough priority wake up and interrupt the MCU.
  – an event:
    Configuring a EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set. It may be necessary to clear the interrupt flag in the peripheral.

The MCU exits Stop 3, Standby, or Shutdown mode through an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC/TAMP event (see Figure 766: RTC block diagram).

After waking up from Standby or Shutdown mode, the program execution restarts in the same way as after a reset (boot pin sampling, option bytes loading, reset vector is fetched).

**Caution:** When the device is in Stop mode, a peripheral interrupt powers on an internal oscillator. The corresponding NVIC interrupt channel must be enabled to allow the interrupt to exit the device from Stop mode. It is not allowed to disable a peripheral interrupt by disabling only the NVIC channel while keeping the peripheral interrupt enable, as the device may remain in Stop mode with clock on.

The peripherals with autonomous mode feature are able to generate an AHB or APB clock request when the device is in Stop mode, depending on their internal events. The software must ensure that either DMA transfer or interrupt is served, by configuring properly and in a consistent way the RCC, the autonomous peripherals, the DMA channels and NVIC. Note that when an autonomous peripheral requests the bus clock in Stop mode, the AHB and APB clocks are distributed to all enabled peripherals (limited to SmartRun domain peripherals in Stop 2 mode). Consequently, enabled peripherals, even without autonomous mode capability, are temporarily clocked and can also generate an interrupt during this time. These peripherals interrupts wake up the device from Stop mode.

### 10.7.5 Sleep mode

**I/O states in Sleep mode**

In Sleep mode, all I/O pins keep the same state as in Run mode.
Entering Sleep mode

The MCU enters the Sleep mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is clear (see Table 101 for details on how to enter Sleep mode).

Exiting Sleep mode

The MCU exits the Sleep mode as described in *Exiting a low-power mode* (see Table 101 for details on how to exit Sleep mode).

10.7.6 Stop 0 mode

The Stop 0 mode is based on the Cortex-M33 Deepsleep mod combined with the peripheral clock gating. The voltage regulator is configured in main regulator mode. In Stop 0 mode, all clocks in the core domain are stopped. The PLL, MSIS, MSIK, HSI16 and HSE oscillators are disabled.

Some peripherals with the autonomous mode capability can switch on HSI16 or MSIS or MSIK for transferring data (see Section 10.7.2 for details).

All SRAMs and register contents are preserved, but the SRAMs can be totally or partially switched off to further reduced consumption.

The BOR is always available in Stop 0 mode.

I/O states in Stop 0 mode

In Stop 0 mode, all I/O pins keep the same state as in the Run mode.
Entering Stop 0 mode

The MCU enters the Stop 0 mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see *Table 102* for details on how to enter Stop 0 mode).

If the flash memory programming is ongoing, the Stop 0 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 0 mode entry is delayed until the APB access is finished.

In Stop 0 mode, the following features can be selected by programming the individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started, it cannot be stopped except by a reset (see *Section 61.4: IWDG functional description*).
- The real-time clock (RTC) and Tamper (TAMP) kernel clock enabled by RTCE in RCC_BDCR.
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by LSION and LSIPREDIV bits in RCC_BDCR.
- The external 32.768 kHz oscillator (LSE) is configured by LSEON bit in RCC_BDCR.

Several peripherals can be autonomous in Stop 0 mode and can add consumption if they are enabled (see *Section 10.7.2* for more details).

OPAMPs, COMPs, the PVM, and the PVD can be used in Stop 0 mode. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx (x = 1, 4), the DAC1 (two channels), the temperature sensor and the VREFBUF can consume power during Stop 0 mode, unless they are disabled before entering this mode.

Exiting Stop 0 mode

The MCU exits Stop 0 mode as described in *Exiting a low-power mode* (see *Table 102* for details on how to exit Stop 0 mode).

When exiting Stop 0 mode by issuing an interrupt or a wake-up event, HSI16 is selected as system clock if STOPWUCK is set in RCC_CFGR1. The MSIS oscillator is selected as system clock if STOPWUCK is cleared. The MSIS selection allows a wake-up at higher frequency (up to 24 MHz).

Several peripherals are autonomous in Stop mode, and can generate interrupts with wake-up from Stop capability. All peripheral clocks must be enabled to allow a wake-up from Stop interrupt (see *Peripheral clock gating*).

When exiting the Stop 0 mode, the MCU is in Run mode, range 4.

10.7.7 Stop 1 mode

The Stop 1 mode is the same as Stop 0 mode except that the regulator is in low-power mode (see the table below for details on how to enter and exit Stop 1 mode).

</tbody>
</table>

*Note:* All peripheral clocks must be enabled to allow this peripheral to generate a wake-up from Stop interrupt ([PERIPH]EN, [PERIPH]SMEN and [PERIPH]AMEN bits must be set in the RCC, and a functional independent clock must be selected).

| wake-up latency | Longest wake-up time between: MSIS or HSI16 wake-up time and regulator wake-up time from low-power mode + FLASH wake-up time from Stop 1 mode. |

10.7.8 Stop 2 mode

The Stop 2 mode is similar to Stop 1 except that most of the core domain is put in a lower leakage mode. Only the part of the core domain embedding AHB3 and APB3 peripherals remains fully powered, allowing those peripherals to be functional.

The AHB3 and APB3 peripherals with the autonomous mode capability can switch on HSI16, or MSIS, or MSIK for transferring data (see Section 10.7.2 for more details).
All SRAMs and register contents are preserved, but the SRAMs can be totally or partially switched off to further reduced consumption.

The BOR is always available in Stop 2 mode.

I/O states in Stop 2 mode

In Stop 2 mode, all I/O pins keep the same state as in Run mode.

Entering Stop 2 mode

The MCU enters Stop 2 mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see Table 104 for details on how to enter the Stop 2 mode).

If the flash memory programming is ongoing, the Stop 2 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 2 mode entry is delayed until the APB access is finished.

In Stop 2 mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started it cannot be stopped except by a reset (see *Section 61.4: IWDG functional description*).
- The real-time clock (RTC) and Tamper (TAMP) kernel clock enabled by the RTCEN bit in RCC_BDCR.
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPREDIV bits in RCC_BDCR.
- The external 32.768 kHz oscillator (LSE) is configured by LSEON in RCC_BDCR.

Several peripherals can be autonomous in Stop 2 mode and can add consumption if they are enabled (see *Section 10.7.2* for more details).

OPAMPs, COMPs, the PVM, and the PVD can be used in Stop 2 mode. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx (x = 1, 2, 4), the DAC1 (two channels), the temperature sensor and the VREFBUF can consume power during Stop 2 mode, unless they are disabled before entering this mode.

Caution: All the peripherals that cannot be enabled in Stop 2 mode must be either disabled by clearing the enable bit in the peripheral itself, or put under reset state by configuring RCC registers.

Exiting Stop 2 mode

The MCU exits Stop 2 mode as defined in *Exiting a low-power mode* (see Table 104 for details on how to exit Stop 2 mode).

When exiting Stop 2 mode by issuing an interrupt or a wake-up event, HSI16 is selected as system clock if the bit STOPWUCK is set in RCC_CFGR1. MSIS is selected as system clock if STOPWUCK is cleared. The MSI selection allows a wake-up at higher frequency (up to 24 MHz).
Several peripherals are autonomous in Stop mode, and can generate interrupts with wake-up from Stop capability. All peripheral clocks must be enabled to allow a wake-up from Stop interrupt (see Peripheral clock gating).

When exiting the Stop 2 mode, the MCU is in Run mode, range 4.

**Note:** All peripheral clocks must be enabled to allow this peripheral to generate a wake-up from Stop interrupt ([PERIPH]EN, [PERIPH]SMEN and [PERIPH]AMEN bits must be set in the RCC, and a functional independent clock must be selected).

| Wake-up latency | Longest wake-up time between: MSIS or HSI16 wake-up time and regulator wake-up time from low-power mode + FLASH wake-up time from Stop 2 mode. |

### 10.7.9 Stop 3 mode

The Stop 3 mode is based on the Cortex-M33 Deepsleep mode combined with peripheral clock gating. In Stop 3 mode, all clocks in the core domain are stopped. The PLL, MSIS, MSIK, HSI16, and HSE oscillators are disabled.

All SRAMs and register contents are preserved, but the SRAMs can be totally or partially switched off to further reduce consumption.
The BOR is always available in Stop 3 mode.
All other peripherals must be either disabled by clearing the enable bit in the peripheral itself, or put under reset state by configuring RCC registers.

I/O states in Stop 3 mode
In the Stop 3 mode, the I/Os are by default in floating state. If the APC bit in the PWR_APCR register is set, the I/Os can be configured either with a pull-up (see PWR_PUCRx registers), or with a pull-down (see PWR_PDCRx registers), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register is set. The pull-down configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same I/O.

Some I/Os (listed in Section 13: General-purpose I/Os (GPIO)) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Stop 3 mode setting their respective bit to 1 in the PWR_PUCRx or PWR_PDCRx registers, or to be configured to floating state if the bit is kept at 0.

The RTC outputs on PC13 and PB2 are functional in Stop 3 mode. PC14 and PC15 used for LSE are also functional. The 24 wake-up pins multiplexed on eight events (WKUPx, x = 1 to 8) and the eight RTC tampers pins are available.

Entering Stop 3 mode
The MCU enters the Stop 3 mode as described in Entering into a low-power mode, when the SLEEPDEEP bit in the Cortex-M33 System Control register is set (see Table 105 for details on how to enter the Stop 3 mode).

If the flash memory programming is ongoing, the Stop 3 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 3 mode entry is delayed until the APB access is finished.

In Stop 3 mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started it cannot be stopped except by a reset (see Section 30.3: IWDG functional description).
- The real-time clock (RTC) and Tamper (TAMP) kernel clock enabled by the RTCEN bit in RCC_BDCR.
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPREDIV bits in RCC_BDCR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BDCR.

Exiting Stop 3 mode
The MCU exits the Stop 3 mode as described in Exiting a low-power mode (see Table 105 for details on how to exit Stop 3 mode).

When exiting Stop 3 mode by issuing an interrupt or a wake-up event, HSI16 is selected as system clock if the STOPWUCK bit is set in RCC_CFGR1. MSIS is selected as system clock if STOPWUCK is cleared. The MSIS selection allows a wake-up at higher frequency (up to 24 MHz).
When exiting the Stop 3 mode, the MCU is in Run mode, range 4.

### 10.7.10 Standby mode

The lowest power mode in which the BOR is active is the Standby mode. It is based on the Cortex-M33 Deepsleep mode, with the voltage regulators disabled (except when SRAM2 content is preserved). The PLL, HSI16, MSIS, MSIK and HSE oscillators are also switched off.

The SRAMs and register contents are lost except for registers in the backup domain and Standby circuitry (see Figure 32). SRAM2 content can be partially or fully preserved depending on RRSB1 and RRSB2 bits configuration in PWR_CR1. In this case, the low-power regulator is ON and provides the supply to SRAM2 only.

The BOR is always available in Standby mode. ULPMEN in PWR_CR1 must be configured to 1 to reach the lowest power consumption by forcing the BOR in ultra-low-power mode (only available when BOR level 0 is selected).

### I/O states in Standby mode

In the Standby mode, the I/Os are by default in floating state. If APC bit is set in PWR_APCR, the I/Os can be configured either with a pull-up (see PWR_PUCRx), or with a pull-down (see PWR_PDCRx), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register is set. The pull-down configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same I/O.

Some I/Os (listed in Section 13: General-purpose I/Os (GPIO)) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during...
Standby mode setting their respective bit to 1 in the PWR_PUCRx or PWR_PDCRx registers, or to be configured to floating state if the bit is kept at 0.

The RTC outputs on PC13 and PB2 are functional in Standby mode. PC14 and PC15 used for LSE are also functional. The 24 wake-up pins multiplexed on eight events (WKUPx, x = 1 to 8) and the eight RTC tampers pins are available.

**Entering Standby mode**

The MCU enters the Standby mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see Table 106 for details on how to enter Standby mode).

In Standby mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a reset (see Section 61.4: IWDG functional description).
- The real-time clock (RTC) and Tamper (TAMP) kernel clock enabled by the RTCEN bit in RCC_BDCR.
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPRE bits in RCC_BDCR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BDCR.

**Exiting Standby mode**

The MCU exits the Standby mode as described in *Exiting a low-power mode*. The SBF status flag in PWR status register (PWR_SR) indicates that the MCU was in Standby mode. All registers are reset after wake-up from Standby except for PWR control register 3 (PWR_CR3) (see Table 106 for more details on how to exit Standby mode).

When exiting Standby mode, I/Os that were configured with pull-up or pull-down during Standby through PWR_PUCRx or PWR_PDCRx, keep this configuration upon exiting Standby mode until the APC bit in PWR_CR3 is cleared. Once APC is cleared, the I/Os are either configured to their reset values or to the pull-up/pull-down state according to the GPIOx_PUPDR registers. The content of the PWR_PUCRx or PWR_PDCRx registers is not lost and can be re-used for a subsequent entering into Standby mode.

Some I/Os (listed in Section 13: General-purpose I/Os (GPIO)) are used for JTAG/SW debug and have internal pull-up or pull-down activated after reset so is configured at this reset value, as well when exiting Standby mode.

For I/Os, with a pull-up or pull-down pre-defined after reset (some JTAG/SW I/Os) or with the GPIOx_PUPDR programming done after exiting from Standby, in case those programming is different from the PWR_PUCRx or PWR_PDCRx programmed value during Standby, both a pull-down and pull-up are applied until APC is cleared, releasing the PWR_PUCRx or PWR_PDCRx programmed value.
### 10.7.11 Shutdown mode

The lowest power consumption is reached in Shutdown mode. It is based on the Deepsleep mode with the voltage regulator disabled. The core domain is consequently powered off. The PLL, HSI16, MSIS, MSIK and HSE oscillators are also switched off.

The SRAMs and register contents are lost except for registers in the backup domain. The BOR is not available in Shutdown mode. No power voltage monitoring is possible in this mode, therefore the switch to backup domain is not supported.

### I/O states in Shutdown mode

In the Shutdown mode, I/Os are by default in floating state. If the APC bit in the PWR_APCR register is set, the I/Os can be configured either with a pull-up (see PWR_PUCRx registers (x = A to J)), or with a pull-down (see PWR_PDCRx registers (x = A to J)), or can be kept in analog state if none of PWR_PUCRx or PWR_PDCRx register is set. The pull-down configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same I/O. However this configuration is lost when exiting the Shutdown mode due to the power-on reset.

Some I/Os (listed in Section 13: General-purpose I/Os (GPIO)) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Shutdown mode setting to 1 their respective bit in the PWR_PUCRx or PWR_PDCRx registers, or to be configured to floating state if the bit is kept at 0.

The RTC outputs on PC13 and PB2 are functional in Shutdown mode. PC14 and PC15 used for LSE are also functional. The 24 wake-up pins multiplexed on eight events (WKUPx, x = 1 to 8) and the eight RTC tampers pins are available.

---

**Table 106. Standby mode**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

1. The Standby mode is also entered if LPMS = 11X in PWR_CR1 with BREN = 1 in PWR_BDCR1.
Entering Shutdown mode

The MCU enters the Shutdown mode as described in Entering into a low-power mode, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see Table 107 for details on how to enter Shutdown mode).

In Shutdown mode, the following features can be selected by programming individual control bits:

- The real-time clock (RTC) and Tamper (TAMP) kernel clock enabled by the RTCEN bit in the backup domain control register (RCC_BDCR). Caution: in case of VDD power-down, the RTC content is lost.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in the backup domain control register (RCC_BDCR).

**Caution:** The Shutdown mode cannot be entered if the BREN bit is set in the PWR backup domain control register 1 (PWR_BDCR1). If BREN = 1, the Standby mode is entered instead of Shutdown mode.

Exiting Shutdown mode

The MCU exits the Shutdown mode as described in Exiting a low-power mode. A power-on reset occurs when exiting from Shutdown mode. All registers (except for the ones in the backup domain) are reset after a wake-up from Shutdown (see Table 107 for more details on how to exit Shutdown mode).

When exiting Shutdown mode, I/Os that were configured with pull-up or pull-down during Shutdown through registers PWR_PUCRx or PWR_PDCRx lose their configuration and are configured in floating state or to their pull-up pull-down reset value (for some I/Os listed in Section 13: General-purpose I/Os (GPIO)).

Table 107. Shutdown mode
10.7.12 USB power management in low-power modes
(STM32U59x/5Ax/5Fx/5Gx only)

In Stop 0 and Stop 1 modes, it is possible to keep the OTG_HS configuration by leaving the
USBPWREN bit set. This allows the OTG_HS to wake up the MCU from Stop mode.
However, in order to decrease the power consumption, it is recommended to shut off the
OTG_HS before entering Stop 0 or Stop 1 mode.

In Stop 2 and Stop 3 modes, it is not possible to keep the OTG_HS configuration. The
OTG_HS must be shut off before entering Stop 2 or Stop 3 mode.

The following steps are needed to shut off the OTG_HS before entering Stop mode:
1. Clear USBPWREN and USBBOOSTEN bits in PWR_VOSR.
2. Request entry in Stop mode.

Upon wake-up from Stop mode, and before configuring the OTG_HS:
1. Make sure the voltage scaling is in range 1 or in range 2 (using VOS[1:0]
in PWR_VOSR).
2. Make sure the EPOD booster clock is enabled (using PLL1MBOOST[3:0]
in RCC_PLL1CFGR).
3. Enable the USB internal power by setting USBPWREN and USBBOOSTEN bits
   in PWR_VOSR.
4. Wait for USBBOOSTRDY in PWR_VOSR to be set.

Using PA11 and PA12 GPIOs

When PA11 and PA12 are used as OTG_HS_DM and OTG_HS_DP additional functions,
GPIOs must be configured in analog mode (default setting).

When PA11 and PA12 are used as standard GPIOs, USBPWREN and VDD11USBDIS bits
in PWR_VOSR must be set prior to configure the GPIOs in a mode other than analog.

In Stop 2, Stop 3, and Standby modes, it is possible to use PA11 and PA12 as standard
GPIOs or alternate functions. However, when entering the Stop 2, Stop 3 and Standby low
power modes, the OTG_HS PHY power is switched off by hardware and PA11 (driven by
OTG_HS_DM) and PA12 (driven by OTG_HS_DP) are strongly pulled-down. Setting the
FORCE_USBPWR bit in PWR_CR1 maintain the OTG_HS PHY supply and allows to use
PA11 and PA12 as GPIOs.

Note: Setting the FORCE_USBPWR bit induces an extra consumption (typically 50 µA when
VDD11USBDIS is set) in Stop 2, Stop 3, and Standby modes. If this is not acceptable, then
FORCE_USBPWR bit must remain cleared and in this case, PA11 and PA12 must be kept
at low level during Stop 2, Stop 3, and Standby modes.

10.7.13 Power modes output pins

In order to help the debug, three signals are available as device pins alternate functions:

- **CSLEEP**
  When set, CSLEEP indicates that the CPU is in Sleep mode: WFI or WFE has been
  executed. When cleared, CSLEEP indicates that the CPU is in Run mode.

- **CDSTOP**
  When set, CDSTOP indicates that the CPU domain (CD) is in CStop mode, meaning
  that the following conditions are filled:
When cleared, CDSTOP indicates that the CPU domain is not in CStop mode: AHB/APB clocks run in the CPU domain.

• **SRDSTOP**
  When set, SRDSTOP indicates that the SmartRun domain (SRD) is in DStop mode, meaning that the following conditions are filled:
  - WFI or WFE has been executed with CPU SLEEPDEEP = 1.
  - No AHB/APB clock is running in the SRD domain.
  When cleared, SRDSTOP indicates that the SmartRun domain is not in DStop mode: AHB/APB clocks run in the SRD domain.

*Note:* The AHB/APB clocks run after WFI or WFE has been executed if an autonomous peripheral requests its bus clock in Stop mode. The peripherals bus clock request can delay or prevent the device to enter low-power modes (refer to Section 10.7.2 and Section 10.7.4).

The table below explains the MCU power mode depending on these signals states.

<table>
<thead>
<tr>
<th>CSLEEP</th>
<th>CDSTOP</th>
<th>SRDSTOP</th>
<th>MCU power modes&lt;sup&gt;(1)&lt;/sup&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>Run mode</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>Sleep mode or Stop 0 or Stop 1 mode, with AHB/APB clocks running in CPU domain (CD) and SmartRun domain (SRD)</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
<td>Stop 0, Stop 1 or Stop 2 mode, with AHB/APB clocks running in SmartRun domain (SRD)</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>Stop 0, Stop 1, or Stop 2 mode</td>
</tr>
</tbody>
</table>

1. CSLEEP, CDSTOP, and SRDSTOP are generated in core domain, consequently they are not driven in Stop 3, Standby, and Shutdown modes.

### 10.8 PWR security and privileged protection

#### 10.8.1 PWR security protection

When the TrustZone security is activated by TZEN in FLASH_OPTR, some PWR register fields can be secured against nonsecure access.

The PWR TrustZone security allows the following features to be secured through PWR_SECCFGR:

- low-power mode
- wake-up (WKUP) pins
- voltage detection and monitoring
- \( V_{BAT} \) mode
- I/O pull-up/pull-down configuration
Other PWR configuration bits are secure when:

- The system clock selection is secure in RCC: the voltage scaling (VOS) configuration and the regulator booster (BOOSTEN) are secure.
- A GPIO is configured as secure: its corresponding bit for pull-up/pull-down configuration in Standby mode is secure.
- The UCPD1 is secure in the GTZC: the PWR_UCPDR register is secure.

*Table 109* gives a summary of the PWR secured bits following the security configuration bit in PWR_SECCFGR. As soon as at least one function is configured to be secure, the PWR clock control is also secure in the RCC.

A nonsecure access to a secure-protected register bit is denied:

- The secured bits are not written (WI) with a nonsecure write access.
- The secured bits are read as 0 (RAZ) with a nonsecure read access.

A nonsecure write access to PWR_SECCFGR is WI and generates an illegal access event and an interrupt if enabled in the GTZC. It can be read with a nonsecure read access.

When the TrustZone security is disabled (TZEN = 0), PWR_SECCFGR is RAZ/WI, and all other registers are nonsecure.

436/3637  RM0456 Rev 5
WR privileged protection

By default, after a reset, all PWR registers can be read or written with both privileged and unprivileged accesses, except PWR_PRIVCFGR that can be written with privileged access only. PWR_PRIVCFGR can be read by secure and nonsecure, privileged and unprivileged accesses.

SPRIV in PWR_PRIVCFGR can be written with secure privileged access only. This bit configures the privileged access of all PWR secure functions (defined by PWR_SECCFGR, GTZC, RCC or GPIO as shown in Table 109).

When SPRIV is set in PWR_PRIVCFGR:
- The PWR secure bits can be written only with privileged access, including PWR_SECCFGR.
- The PWR secure bits can be read only with privileged access except PWR_SECCFGR and PWR_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged PWR bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

NSPRIV in PWR_PRIVCFGR can be written with privileged access only, secure or nonsecure. This bit configures the privileged access of all PWR securable functions that are configured as nonsecure (defined by PWR_SECCFGR, GTZC, RCC or GPIO as shown in Table 109).

When NSPRIV is set in PWR_PRIVCFGR:
- The PWR securable bits that are configured as nonsecure, can be written only with privileged access.
- The PWR securable bits that are configured as nonsecure, can be read only with privileged access except PWR_PRIVCFGR that can be read by privileged or unprivileged accesses.
- The VOSRDY and BOOSTRDY bits in PWR_VOSR, PWR_SR, PWR_SVMSR, PWR_BDSR and PWR_WUSR, can be read with privileged or unprivileged accesses.
- An unprivileged access to a privileged PWR bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

Table 109. PWR Security configuration summary (continued)

</table>

1. The PWR_S3WU interrupt is generated only when the device is in Stop 3 mode (not applicable in Run, Sleep, Stop 0, Stop 1, and Stop 2 modes).
2. Only an interrupt can wake up from Stop 3 mode (not possible with an event).
10.10 PWR registers

10.10.1 PWR control register 1 (PWR_CR1)

Address offset: 0x00
Reset value: 0x0000 0000
(reset value not affected by exit Standby mode)

This register is protected against nonsecure access when LPMSEC = 1 in PWR_SECCFGR. This register is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when LPMSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **FORCE_USB_PWR**: OTG_HS PHY power maintained during Stop 2, Stop 3, and Standby low-power modes.

0: OTG_HS PHY power is not maintained during low-power modes.
1: OTG_HS PHY power is maintained during low-power modes.

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.*

Bit 14 Reserved, must be kept at reset value.

Bit 13 **SRAM6_PD**: SRAM6 power down
This bit is used to reduce the consumption by powering off the SRAM6.

0: SRAM6 powered on
1: SRAM6 powered off

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.*

Bit 12 **SRAM5_PD**: SRAM5 power down
This bit is used to reduce the consumption by powering off the SRAM5.

0: SRAM5 powered on
1: SRAM5 powered off

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.*

Bit 11 **SRAM4_PD**: SRAM4 power down
This bit is used to reduce the consumption by powering off the SRAM4.

0: SRAM4 powered on
1: SRAM4 powered off
Bit 10 **SRAM3PD**: SRAM3 power down
This bit is used to reduce the consumption by powering off the SRAM3.
0: SRAM3 powered on
1: SRAM3 powered off

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.*

Bit 9 **SRAM2PD**: SRAM2 power down
This bit is used to reduce the consumption by powering off the SRAM2.
0: SRAM2 powered on
1: SRAM2 powered off

Bit 8 **SRAM1PD**: SRAM1 power down
This bit is used to reduce the consumption by powering off the SRAM1.
0: SRAM1 powered on
1: SRAM1 powered off

Bit 7 **ULPMEN**: BOR0 ultra-low power mode
This bit is used to reduce the consumption by configuring the BOR in discontinuous mode.
This bit has effect only when the BOR level 0 is selected and when the device is in Standby mode.
0: BOR level 0 operating in continuous (normal) mode in Standby mode
1: BOR level 0 operating in discontinuous (ultra-low power) mode in Standby mode

*Caution:* This bit must be set to reach the lowest power consumption in Standby mode.

Bit 6 **RRSB2**: SRAM2 page 2 retention in Stop 3 and Standby modes
This bit is used to keep the SRAM2 page 2 content in Stop 3 and Standby modes.
The SRAM2 page 2 corresponds to the last 56 Kbytes of the SRAM2 (from SRAM2 base address + 0x2000 to SRAM2 base address + 0xFFFF).
0: SRAM2 page 2 content not retained in Stop 3 and Standby modes
1: SRAM2 page 2 content retained in Stop 3 and Standby modes

*Note:* This bit has no effect in Shutdown mode.
The backup SRAM is also retained when this bit is set.

Bit 5 **RRSB1**: SRAM2 page 1 retention in Stop 3 and Standby modes
This bit is used to keep the SRAM2 page 1 content in Stop 3 and Standby modes. The SRAM2 page 1 corresponds to the first 8 Kbytes of the SRAM2 (from SRAM2 base address to SRAM2 base address + 0x1FFF).
0: SRAM2 page 1 content not retained in Stop 3 and Standby modes
1: SRAM2 page 1 content retained in Stop 3 and Standby modes

*Note:* This bit has no effect in Shutdown mode.
The backup SRAM is also retained when this bit is set.

Bits 4:3 Reserved, must be kept at reset value.

Bits 2:0 **LPMS[2:0]**: Low-power mode selection
These bits select the low-power mode entered when the CPU enters Deepsleep mode.
000: Stop 0 mode
001: Stop 1 mode
010: Stop 2 mode
011: Stop 3 mode
10x: Standby mode (Standby mode also entered if LPMS = 11X in PWR_CR1 with BREN = 1 in PWR_BDCR1)
11x: Shutdown mode if BREN = 0 in PWR_BDCR1
10.10.2  PWR control register 2 (PWR_CR2)

Address offset: 0x04
Reset value: 0x0000 0000

This register is protected against nonsecure access when LPMSEC = 1 in PWR_SECFCGR. This register is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when LPMSEC = 0 and NSPRIV = 1.

**Note:** LTDC SRAM content is always lost in Stop 2 and Stop 3 modes. It can be retained only in Stop 0 and Stop 1 modes. This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.
Bit 23 **SRAM3PDS8**: SRAM3 page 8 (64 Kbytes) power-down in all Stop modes
0: SRAM3 page 8 content retained in Stop modes
1: SRAM3 page 8 content lost in Stop modes

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.*

Bit 22 **SRAM3PDS7**: SRAM3 page 7 (64 Kbytes) power-down in all Stop modes
0: SRAM3 page 7 content retained in Stop modes
1: SRAM3 page 7 content lost in Stop modes

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.*

Bit 21 **SRAM3PDS6**: SRAM3 page 6 (64 Kbytes) power-down in all Stop modes
0: SRAM3 page 6 content retained in Stop modes
1: SRAM3 page 6 content lost in Stop modes

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.*

Bit 20 **SRAM3PDS5**: SRAM3 page 5 (64 Kbytes) power-down in all Stop modes
0: SRAM3 page 5 content retained in Stop modes
1: SRAM3 page 5 content lost in Stop modes

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.*

Bit 19 **SRAM3PDS4**: SRAM3 page 4 (64 Kbytes) power-down in all Stop modes
0: SRAM3 page 4 content retained in Stop modes
1: SRAM3 page 4 content lost in Stop modes

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.*

Bit 18 **SRAM3PDS3**: SRAM3 page 3 (64 Kbytes) power-down in all Stop modes
0: SRAM3 page 3 content retained in Stop modes
1: SRAM3 page 3 content lost in Stop modes

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.*

Bit 17 **SRAM3PDS2**: SRAM3 page 2 (64 Kbytes) power-down in all Stop modes
0: SRAM3 page 2 content retained in Stop modes
1: SRAM3 page 2 content lost in Stop modes

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.*

Bit 16 **SRAM3PDS1**: SRAM3 page 1 (64 Kbytes) power-down in all Stop modes
0: SRAM3 page 1 content retained in Stop modes
1: SRAM3 page 1 content lost in Stop modes

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.*
Bit 15  Reserved, must be kept at reset value.

Bit 14  **FLASHFWU**: Flash memory fast wake-up from Stop 0 and Stop 1 modes
        This bit is used to obtain the best trade-off between low-power consumption and wake-up time when exiting the Stop 0 or Stop 1 modes.
        When this bit is set, the flash memory remains in normal mode in Stop 0 and Stop 1 modes, which offers a faster startup time with higher consumption.
        0: Flash memory enters low-power mode in Stop 0/1 modes (lower-power consumption).
        1: Flash memory remains in normal mode in Stop 0/1 modes (faster wake-up time).

Bit 13  **SRAM4FWU**: SRAM4 fast wake-up from Stop 0/1/2 modes
        This bit is used to obtain the best trade-off between low-power consumption and wake-up time. SRAM4 wake-up time increases the wake-up time when exiting Stop 0/1/2 modes, and also increases the LPDMA access time to SRAM4 during Stop modes.
        0: SRAM4 enters low-power mode in Stop 0/1/2 modes (source biasing for lower-power consumption).
        1: SRAM4 remains in normal mode in Stop 0/1/2 modes (higher consumption but no SRAM4 wake-up time).

Bit 12  **PKARAMPDS**: PKA SRAM power-down in all Stop modes (Stop 0/1/2/3)
        0: PKA SRAM content retained in Stop modes
        1: PKA SRAM content lost in Stop modes
        
        **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral.
        If not present, consider this bit reserved and keep it at reset value.

Bit 11  **PRAMPDS**: FMAC, FDCAN, and USB/OTG_FS/OTG_HS SRAM power-down in all Stop modes (Stop 0/1/2/3)
        0: FMAC, FDCAN, and USB/OTG_FS/OTG_HS SRAM content retained in Stop modes
        1: FMAC, FDCAN, and USB/OTG_FS/OTG_HS SRAM content lost in Stop modes

Bit 10  **DMA2DRAMPDS**: DMA2D SRAM power-down in all Stop modes
        0: DMA2D SRAM content retained in Stop modes
        1: DMA2D SRAM content lost in Stop modes
        
        **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.

Bit 9   **DC1RAMPDS**: DCAHCE1 SRAM power-down in all Stop modes
        0: DCAHCE1 SRAM content retained in Stop modes
        1: DCAHCE1 SRAM content lost in Stop modes

Bit 8   **ICRAMPDS**: ICACHE SRAM power-down in all Stop modes
        0: ICACHE SRAM content retained in Stop modes
        1: ICACHE SRAM content lost in Stop modes

Bit 7   **DC2RAMPDS**: DCAHCE2 SRAM power-down in all Stop modes
        0: DCAHCE2 SRAM content retained in Stop modes
        1: DCAHCE2 SRAM content lost in Stop modes
        
        **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.

Bit 6   **SRAM4PDS**: SRAM4 power-down in all Stop modes
        0: SRAM4 content retained in Stop modes
        1: SRAM4 content lost in Stop modes
Bit 5 **SRAM2PDS2**: SRAM2 page 2 (56 Kbytes) power-down in Stop 0/1/2 modes
- 0: SRAM2 page 2 content retained in Stop modes
- 1: SRAM2 page 2 content lost in Stop modes

*Note: The SRAM2 page 2 retention in Stop 3 is controlled by RRSB2 bit in PWR_CR1.*

Bit 4 **SRAM2PDS1**: SRAM2 page 1 (8 Kbytes) power-down in Stop 0/1/2 modes
- 0: SRAM2 page 1 content retained in Stop modes
- 1: SRAM2 page 1 content lost in Stop modes

*Note: The SRAM2 page 1 retention in Stop 3 is controlled by RRSB1 bit in PWR_CR1.*

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SRAM1PDS3**: SRAM1 page 3 (64 Kbytes) power-down in all Stop modes
- 0: SRAM1 page 3 content retained in Stop modes
- 1: SRAM1 page 3 content lost in Stop modes

Bit 1 **SRAM1PDS2**: SRAM1 page 2 (64 Kbytes) power-down in all Stop modes
- 0: SRAM1 page 2 content retained in Stop modes
- 1: SRAM1 page 2 content lost in Stop modes

Bit 0 **SRAM1PDS1**: SRAM1 page 1 (64 Kbytes) power-down in all Stop modes
- 0: SRAM1 page 1 content retained in Stop modes
- 1: SRAM1 page 1 content lost in Stop modes

### 10.10.3 PWR control register 3 (PWR_CR3)

Address offset: 0x08

Power-on reset value: 0x0000 0000

Exit from Standby modes: not affected

System reset: not affected, except REGSEL that is cleared to 0

This register is protected against nonsecure access when VDMSEC = 1 in PWR_SECCFGR. This register is protected against unprivileged access when VDMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VDMSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access.

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FSTEN**: Fast soft start
- 0: LDO/SMPS fast startup disabled (limited inrush current)
- 1: LDO/SMPS fast startup enabled
Bit 1  **REGSEL**: Regulator selection

0: LDO selected  
1: SMPS selected  

*Note*: **REGSEL** is reserved and must be kept at reset value in packages without SMPS.  

Bit 0  Reserved, must be kept at reset value.  

### 10.10.4 PWR voltage scaling register (PWR_VOSR)

Address offset: 0x0C  
Reset value: 0x0000 8000  

Some register fields are protected against nonsecure access depending on RCC_SECCFGR. These fields can be protected against unprivileged access depending on PWR_PRIVCFGR.

Bits 31:22  Reserved, must be kept at reset value.  

**Bit 21 VDD11USBDIS**: OTG_HS VDD11USB disable  
This bit is protected against nonsecure access when SYCLKSEC = 1 in RCC_SECCFGR.  It is protected against unprivileged access when SYCLKSEC = 1 in RCC_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SYCLKSEC = 0 and NSPRIV = 1.  
0: VDD11USB enabled  
1: VDD11USB disabled  

*Note*: **This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.**  

**Bit 20 USBBOOSTEN**: OTG_HS EPOD booster enable  
This bit is protected against nonsecure access when SYCLKSEC = 1 in RCC_SECCFGR.  It is protected against unprivileged access when SYCLKSEC = 1 in RCC_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SYCLKSEC = 0 and NSPRIV = 1.  
This bit must be set in range 1 and range 2 before enabling the OTG_HS.  
This bit is reset when going in all Stop modes.  
0: OTG_HS booster disabled  
1: OTG_HS booster enabled  

*Note*: **This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.**
Bit 19 **USBPWREN**: OTG_HS power enable

This bit is protected against nonsecure access when SYSCLKSEC = 1 in RCC_SECCFGR. It is protected against unprivileged access when SYSCLKSEC = 1 in RCC_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SYSCLKSEC = 0 and NSPRIV = 1.

0: OTG_HS power disabled
1: OTG_HS power enabled

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.

Bit 18 **BOOSTEN**: EPOD booster enable

This bit is protected against nonsecure access when SYSCLKSEC = 1 in RCC_SECCFGR. It is protected against unprivileged access when SYSCLKSEC = 1 in RCC_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SYSCLKSEC = 0 and NSPRIV = 1.

This bit must be set in range 1 and range 2 before increasing the system clock frequency above 55 MHz. This bit is reset when going in all Stop modes.

0: Booster disabled
1: Booster enabled

Bits 17:16 **VOS[1:0]**: Voltage scaling range selection

This field is protected against nonsecure access when SYSCLKSEC = 1 in RCC_SECCFGR. It is protected against unprivileged access when SYSCLKSEC = 1 in RCC_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SYSCLKSEC = 0 and NSPRIV = 1.

00: Range 4 (lowest power)
01: Range 3
10: Range 2
11: Range 1 (highest frequency)

Bit 15 **VOSRDY**: Ready bit for V_CORE voltage scaling output selection

0: Not ready, voltage level < VOS selected level
1: Ready, voltage level \(\geq\) VOS selected level

Bit 14 **BOOSTRDY**: EPOD booster ready

This bit is set to one by hardware when the power booster startup time is reached. The system clock frequency can be switched higher than 55 MHz only after this bit is set.

0: Power booster not ready
1: Power booster ready

Bit 13 **USBBOOSTRDY**: OTG_HS EPOD booster ready

This bit is set to one by hardware when the power booster startup time is set. The OTG_HS clock can be provided only after this bit is set.

0: OTG_HS power booster not ready
1: OTG_HS power booster ready

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.

Bits 12:0 Reserved, must be kept at reset value.
10.10.5 PWR supply voltage monitoring control register (PWR_SVMCR)

Address offset: 0x10
Reset value: 0x0000 0000

This register is protected against nonsecure access when VDMSEC = 1 in PWR_SECCFGR. This register is protected against unprivileged access when VDMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VDMSEC = 0 and NSPRIV = 1.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **ASV**: VDDA independent analog supply valid
- This bit is used to validate the VDDA supply for electrical and logical isolation purpose.
- Setting this bit is mandatory to use the analog peripherals. If VDDA is not always present in the application, the VDDA voltage monitor can be used to determine whether this supply is ready or not.
- 0: VDDA not present: logical and electrical isolation is applied to ignore this supply.
- 1: VDDA valid

Bit 29 **IO2SV**: VDDIO2 independent I/Os supply valid
- This bit is used to validate the VDDIO2 supply for electrical and logical isolation purpose.
- Setting this bit is mandatory to use PG[15:2]. If VDDIO2 is not always present in the application, the VDDIO2 voltage monitor can be used to determine whether this supply is ready or not.
- 0: VDDIO2 not present: logical and electrical isolation is applied to ignore this supply.
- 1: VDDIO2 valid

Bit 28 **USV**: VDDUSB independent USB supply valid
- This bit is used to validate the VDDUSB supply for electrical and logical isolation purpose.
- Setting this bit is mandatory to use the USB/OTG_FS/OTG_HS. If VDDUSB is not always present in the application, the VDDUSB voltage monitor can be used to determine whether this supply is ready or not.
- 0: VDDUSB not present: logical and electrical isolation is applied to ignore this supply.
- 1: VDDUSB valid

Bit 27 **AVM2EN**: VDDA independent analog supply voltage monitor 2 enable (1.8 V threshold)
- 0: VDDA voltage monitor 2 disabled
- 1: VDDA voltage monitor 2 enabled

Bit 26 **AVM1EN**: VDDA independent analog supply voltage monitor 1 enable (1.6 V threshold)
- 0: VDDA voltage monitor 1 disabled
- 1: VDDA voltage monitor 1 enabled

Bit 25 **IO2VMEN**: VDDIO2 independent I/Os voltage monitor enable
- 0: VDDIO2 voltage monitor disabled
- 1: VDDIO2 voltage monitor enabled
Bit 24  **UVMEN**: $V_{DDUSB}$ independent USB voltage monitor enable
0: $V_{DDUSB}$ voltage monitor disabled
1: $V_{DDUSB}$ voltage monitor enabled

Bits 23:8  Reserved, must be kept at reset value.

Bits 7:5  **PVDLS[2:0]**: Programmable voltage detector (PVD) level selection
These bits select the voltage threshold detected by the PVD:
- 000: $V_{PVD0}$ around 2.0 V
- 001: $V_{PVD1}$ around 2.2 V
- 010: $V_{PVD2}$ around 2.4 V
- 011: $V_{PVD3}$ around 2.5 V
- 100: $V_{PVD4}$ around 2.6 V
- 101: $V_{PVD5}$ around 2.8 V
- 110: $V_{PVD6}$ around 2.9 V
- 111: External input analog voltage $PVD\_IN$ (compared internally to $V_{REFINT}$)

Bit 4  **PVDE**: Programmable voltage detector enable
0: PVD disabled
1: PVD enabled

Bits 3:0  Reserved, must be kept at reset value.

### 10.10.6  **PWR wake-up control register 1 (PWR_WUCR1)**

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x14

Reset value: 0x0000 0000

(reset value not affected by exiting Standby mode)

Each WUPENx ($x = 1$ to 8) is protected against nonsecure access when WUPxSEC = 1 in PWR_SECCFGR. Each WUPENx is protected against unprivileged access when WUPxSEC = 1 in PWR_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when WUPxSEC = 0 and NSPRIV = 1.

<table>

Bits 31:5  Reserved, must be kept at reset value.

Bit 4 **MONE**: Backup domain voltage and temperature monitoring enable

0: Backup domain voltage and temperature monitoring disabled
1: Backup domain voltage and temperature monitoring enabled

Bits 3:1  Reserved, must be kept at reset value.

Bit 0 **BREN**: Backup RAM retention in Standby and V_{BAT} modes

When this bit is set, the backup RAM content is kept in Standby\(^{(1)}\) and V_{BAT} modes.

If BREN is reset, the backup RAM can still be used in Run, Sleep, and Stop modes. However, its content is lost in Standby, Shutdown, and V_{BAT} modes. This bit can be written only when the regulator is LDO, which must be configured before switching to SMPS.

0: Backup RAM content lost in Standby\(^{(1)}\) and V_{BAT} modes
1: Backup RAM content preserved in Standby and V_{BAT} modes

**Note:** Backup RAM cannot be preserved in Shutdown mode.

1. The backup SRAM content is lost in Standby mode without SRAM2 retention. If either RRSB1 or RRSB2 bit is set in Standby mode, the backup SRAM is also retained.
10.10.10  PWR backup domain control register 2 (PWR_BDCR2)

Address offset: 0x24

Power-on reset value: 0x0000 0000

(reset value not affected by exiting from Standby mode)

System reset: not affected

This register is protected against nonsecure access when VBSEC = 1 in PWR_SECCFGR.
This register is protected against unprivileged access when VBSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VBSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Bits 31:1  Reserved, must be kept at reset value.
Bit 0 **DBP**: Disable backup domain write protection
In reset state, all registers and SRAM in backup domain are protected against parasitic write access. This bit must be set to enable the write access to these registers.
0: Write access to backup domain disabled
1: Write access to backup domain enabled

### 10.10.12 PWR UCPD register (PWR_UCPDR)

Address offset: 0x2C
Reset value: 0x0000 0000
(reset value not affected by exiting from Standby modes)

This register is protected against nonsecure access when UCPD1SEC = 1 in TZSC_SEC_CFG. This register is protected against unprivileged access when UCPD1SEC = 1 and SPRIV = 1 in PWR_PRIVCFG, or when UCPD1SEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

<table>

</tr>
</tbody>
</table>

**Bits 31:2** Reserved, must be kept at reset value.

**Bit 1 **UCPD_STBY**: UCPD Stop 3 and Standby modes
When set, this bit is used to memorize the UCPD configuration in Stop 3 and Standby modes. This bit must be written to one just before entering Stop 3 or Standby mode when using UCPD. It must be written to zero after exiting Stop 3 or Standby mode, and before writing any UCPD registers.

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.

**Bit 0 **UCPD_DBDIS**: UCPD dead battery disable
After exiting reset, the USB Type-C “dead battery” behavior is enabled, which may have a pull-down effect on CC1 and CC2 pins. It is recommended to disable it in all cases, either to stop this pull-down, or to handover control to the UCPD (that must be initialized before doing the disable).
0: UCPD dead battery pull-down behavior enabled on UCPDx_CC1 and UCPDx_CC2 pins
1: UCPD dead battery pull-down behavior disabled on UCPDx_CC1 and UCPDx_CC2 pins

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and keep it at reset value.
10.10.13 PWR security configuration register (PWR_SECCCFGR)

Address offset: 0x30
Reset value: 0x0000 0000

This register can be written only when the access is secure. It can be read by secure or nonsecure access. This register is write-protected against unprivileged write access when SPRIV = 1 in PWR_PRIVCFGR.

```

Bits 31:16 Reserved, must be kept at reset value.

- **Bit 15** APCSEC: Pull-up/pull-down secure protection
  0: PWR_APCR can be read and written with secure or nonsecure access.
  1: PWR_APCR can be read and written only with secure access.

- **Bit 14** VBSEC: Backup domain secure protection
  0: PWR_BDCR1, PWR_BDCR2, and PWR_DBPR can be read and written with secure or nonsecure access.
  1: PWR_BDCR1, PWR_BDCR2, and PWR_DBPR can be read and written only with secure access.

- **Bit 13** VDMSEC: Voltage detection and monitoring secure protection
  0: PWR_SVMCR and PWR_CR3 can be read and written with secure or nonsecure access.
  1: PWR_SVMCR and PWR_CR3 can be read and written only with secure access.

- **Bit 12** LPMSEC: Low-power modes secure protection
  0: PWR_CR1, PWR_CR2 and CSSF in the PWR_SR can be read and written with secure or nonsecure access.
  1: PWR_CR1, PWR_CR2, and CSSF in the PWR_SR can be read and written only with secure access.

Bits 11:8 Reserved, must be kept at reset value.

- **Bit 7** WUP8SEC: WUP8 secure protection
  0: Bits related to WKUP8 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3, and PWR_WUSCR can be read and written with secure or nonsecure access.
  1: Bits related to WKUP8 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3, and PWR_WUSCR can be read and written only with secure access.

- **Bit 6** WUP7SEC: WUP7 secure protection
  0: Bits related to WKUP7 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3, and PWR_WUSCR can be read and written with secure or nonsecure access.
  1: Bits related to WKUP7 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3, and PWR_WUSCR can be read and written only with secure access.
10.10.14  PWR privilege control register (PWR_PRIVCFGR)

Address offset: 0x34
Reset value: 0x0000 0000

This register can be written only when the access is privileged. It can be read by privileged or unprivileged access.

<table>

Bits 31:2  Reserved, must be kept at reset value.
Bit 1 **NSPRIV**: PWR nonsecure functions privilege configuration
This bit is set and reset by software. It can be written only by privileged access, secure or nonsecure.
0: Read and write to PWR nonsecure functions can be done by privileged or unprivileged access.
1: Read and write to PWR nonsecure functions can be done by privileged access only.

Bit 0 **SPRIV**: PWR secure functions privilege configuration
This bit is set and reset by software. It can be written only by a secure privileged access.
0: Read and write to PWR secure functions can be done by privileged or unprivileged access.
1: Read and write to PWR secure functions can be done by privileged access only.

### 10.10.15 PWR status register (PWR_SR)

**Address offset**: 0x38

**Reset value**: 0x0000 0000

Some register fields are protected against nonsecure access depending on PWR_SECCFGR. Some register fields are protected against unprivileged access depending on PWR_PRIVCFGR.

**Bits 31:3** Reserved, must be kept at reset value.

**Bit 2 SBF**: Standby flag
This bit is set by hardware when the device enters Standby mode, and is cleared by writing one to CSSF bit, or by a power-on reset. It is not cleared by the system reset.
0: The device did not enter Standby mode.
1: The device entered Standby mode.

**Bit 1 STOPF**: Stop flag
This bit is set by hardware when the device enters a Stop mode, and is cleared by software by writing one to CSSF bit.
0: The device did not enter any Stop mode.
1: The device entered a Stop mode.

**Bit 0 CSSF**: Clear Stop and Standby flags
This bit is protected against nonsecure access when LPMSEC = 1 in PWR_SECCFGR. This bit is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when LPMSEC = 0 and NSPRIV = 1.
Writing 1 to this bit clears the STOPF and SBF flags.
10.10.16  PWR supply voltage monitoring status register (PWR_SVMSR)

Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **VDDA2RDY**: VDDA ready versus 1.8 V voltage monitor
0: VDDA is below the threshold of the VDDA voltage monitor 2 (around 1.8 V).
1: VDDA is equal or above the threshold of the VDDA voltage monitor 2 (around 1.8 V).

Bit 26  **VDDA1RDY**: VDDA ready versus 1.6V voltage monitor
0: VDDA is below the threshold of the VDDA voltage monitor 1 (around 1.6 V).
1: VDDA is equal or above the threshold of the VDDA voltage monitor 1 (around 1.6 V).

Bit 25  **VDDIO2RDY**: VDDIO2 ready
0: VDDIO2 is below the threshold of the VDDIO2 voltage monitor.
1: VDDIO2 is equal or above the threshold of the VDDIO2 voltage monitor.

Bit 24  **VDDUSBRDY**: VDDUSB ready
0: VDDUSB is below the threshold of the VDDUSB voltage monitor.
1: VDDUSB is equal or above the threshold of the VDDUSB voltage monitor.

Bits 23:18  Reserved, must be kept at reset value.

Bits 17:16  **ACTVOS[1:0]**: VOS currently applied to VCORE(last VOS value)
00: Range 4 (lowest power)
01: Range 3
10: Range 2
11: Range 1 (highest frequency)

Bit 15  **ACTVOSRDY**: Voltage level ready for currently used VOS
0: VCORE is above or below the current voltage scaling provided by ACTVOS[1:0].
1: VCORE is equal to the current voltage scaling provided by ACTVOS[1:0]

Bits 14:5  Reserved, must be kept at reset value.

Bit 4  **PVDO**: Programmable voltage detector output
0: VDD is equal or above the PVD threshold selected by PVDLS[2:0].
1: VDD is below the PVD threshold selected by PVDLS[2:0].

Bits 3:2  Reserved, must be kept at reset value.

Bit 1  **REGS**: Regulator selection
0: LDO selected
1: SMPS selected

Bit 0  Reserved, must be kept at reset value.
10.10.17 PWR backup domain status register (PWR_BDSR)

Address offset: 0x40
Backup domain reset value: 0x0000 0000
Power-on reset: not affected
(reset value not affected by exiting Standby modes)
System reset: not affected
Access: 14 AHB clock cycles added compared to a standard AHB access

Bits 31:8 Reserved, must be kept at reset value.
Bit 7  **WUF8**: wake-up flag 8
This bit is set when a wake-up event is detected on WKUP8 pin. This bit is cleared by writing one in CWUF8 bit of PWR_WUSCR when WUSEL8 ≠ 11, or by hardware when WUPEN8 = 0.
If WUSEL8 = 11, this bit is cleared by hardware when all internal wake-up source are cleared.

Bit 6  **WUF7**: wake-up flag 7
This bit is set when a wake-up event is detected on WKUP7 pin. This bit is cleared by writing one in CWUF7 bit of PWR_WUSCR when WUSEL7 ≠ 11, or by hardware when WUPEN7 = 0.
If WUSEL7 = 11, this bit is cleared by hardware when all internal wake-up source are cleared.

Bit 5  **WUF6**: wake-up flag 6
This bit is set when a wake-up event is detected on WKUP6 pin. This bit is cleared by writing one in CWUF6 bit of PWR_WUSCR when WUSEL6 ≠ 11, or by hardware when WUPEN6 = 0.
If WUSEL6 = 11, this bit is cleared by hardware when all internal wake-up source are cleared.

Bit 4  **WUF5**: wake-up flag 5
This bit is set when a wake-up event is detected on WKUP5 pin. This bit is cleared by writing 1 in the CWUF5 bit of PWR_WUSCR, or by hardware when WUPEN5 = 0.

Bit 3  **WUF4**: wake-up flag 4
This bit is set when a wake-up event is detected on WKUP4 pin. This bit is cleared by writing one in CWUF4 bit of PWR_WUSCR, or by hardware when WUPEN4 = 0.

Bit 2  **WUF3**: wake-up flag 3
This bit is set when a wake-up event is detected on WKUP3 pin. This bit is cleared by writing one in CWUF3 bit of PWR_WUSCR, or by hardware when WUPEN3 = 0.

Bit 1  **WUF2**: wake-up flag 2
This bit is set when a wake-up event is detected on WKUP2 pin. This bit is cleared by writing one in CWUF2 bit of PWR_WUSCR, or by hardware when WUPEN2 = 0.

Bit 0  **WUF1**: wake-up flag 1
This bit is set when a wake-up event is detected on WKUP1 pin. This bit is cleared by writing one in CWUF1 bit of PWR_WUSCR, or by hardware when WUPEN1 = 0.

### 10.10.19 PWR wake-up status clear register (PWR_WUSCR)

Address offset: 0x48
Reset value: 0x0000 0000

Each CWUFx (x = 1 to 8) is protected against nonsecure access when WUPxSEC = 1 in PWR_SECCFGR. Each CWUFx is protected against unprivileged access when
WUPxSEC = 1 in PWR_SECCFRG and SPRIV = 1 in PWR_PRIVCFGR, or when WUPxSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
  8   7   6   5   4   3   2   1
w  w  w  w  w  w  w  w

Bits 31:8  Reserved, must be kept at reset value.

Bit 7  CWUF8: wake-up flag 8
Writing one to this bit clears the WUF8 flag in PWR_WUSR.

Bit 6  CWUF7: wake-up flag 7
Writing one to this bit clears the WUF7 flag in PWR_WUSR.

Bit 5  CWUF6: wake-up flag 6
Writing one to this bit clears the WUF6 flag in PWR_WUSR.

Bit 4  CWUF5: wake-up flag 5
Writing one to this bit clears the WUF5 flag in PWR_WUSR.

Bit 3  CWUF4: wake-up flag 4
Writing one to this bit clears the WUF4 flag in PWR_WUSR.

Bit 2  CWUF3: wake-up flag 3
Writing one to this bit clears the WUF3 flag in PWR_WUSR.

Bit 1  CWUF2: wake-up flag 2
Writing one to this bit clears the WUF2 flag in PWR_WUSR.

Bit 0  CWUF1: wake-up flag 1
Writing one to this bit clears the WUF1 flag in PWR_WUSR.
10.10.20  PWR apply pull configuration register (PWR_APCR)

Address offset: 0x4C

Reset value: 0x0000 0000

(reset value not affected by exiting Standby mode)

This register is protected against nonsecure access when APCSEC = 1 in PWR_SECCFGR. This register is protected against unprivileged access when APCSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when APCSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Bits 31:16  Reserved, must be kept at reset value.

Bit 15  PU15: Port A pull-up bit 15

When set, this bit activates the pull-up on PA15 when APC is set in PWR_APCR. The pull-up is not activated if the corresponding PD15 bit is also set.

Bit 14  Reserved, must be kept at reset value.
Bits 13:0 **PUy**: Port A pull-up bit y (y = 13 to 0)
When set, each bit activates the pull-up on PAy when APC is set in PWR_APCR. The pull-up is not activated if the corresponding PDy bit is also set.

### 10.10.22 PWR port A pull-down control register (PWR_PDCRA)

Address offset: 0x54
Reset value: 0x0000 0000
(reset value not affected by exiting Standby mode)
Each PDy is protected against nonsecure access when SECy = 1 in GPIOA_SECCFGR.
Each PDy is protected against unprivileged access when SECy = 1 in GPIOA_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 PDy: Port J pull-down bit y (y = 11 to 0)
When set, each bit activates the pull-down on PJy when APC is set in PWR_APCR

10.10.41 PWR control register 4 (PWR_CR4)

Address offset: 0xA8
Reset value: 0x0000 0000

This register is protected against nonsecure access when LPMSEC = 1 in PWR_SECCFGR. This register is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when LPMSEC = 0 and NSPRIV = 1.

Note: Some bits are only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and kept at reset value.

Bits 31:29 Reserved, must be kept at reset value.
10.10.42 PWR control register 5 (PWR_CR5)

Address offset: 0xAC
Reset value: 0x0000 0000

This register is protected against nonsecure access when LPMSEC = 1 in PWR_SECCFGR. This register is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when LPMSEC = 0 and NSPRIV = 1.

Note: Some bits are only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit reserved and kept at reset value.

Bits 28:16 **SRAM5PDSx**: SRAM5 64-Kbyte page x (x = 13 to 1) power-down in all Stop modes
- 0: SRAM5 page x content retained in Stop modes
- 1: SRAM5 page x content lost in Stop modes

Bit 15 Reserved, must be kept at reset value.

Bits 14:10 **SRAM3PDSx**: SRAM3 64-Kbyte page x (x = 13 to 9) power-down in all Stop modes
- 0: SRAM3 page x content retained in Stop modes
- 1: SRAM3 page x content lost in Stop modes

Bit 9 Reserved, must be kept at reset value.

Bits 8:0 **SRAM1PDSx**: SRAM1 64-Kbyte page x (x = 12 to 4) power-down in all Stop modes
- 0: SRAM1 page x content retained in Stop modes
- 1: SRAM1 page x content lost in Stop modes

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **SRAM6PDSx**: SRAM6 64-Kbyte page x (x = 8 to 1) power-down in all Stop modes
- 0: SRAM6 page x content retained in Stop modes
- 1: SRAM6 page x content lost in Stop modes
## 10.10.43 PWR register map

11  Reset and clock control (RCC)

11.1  RCC introduction

The reset and clock control (RCC) manages the different kind of reset, and generates all
clocks for the bus and peripherals.

11.2  RCC pins and internal signals

The table below lists the RCC inputs and output signals connected to package pins or balls.

11.3  RCC reset functional description

There are three types of reset:
- a system reset
- a power reset
- a backup domain reset

11.3.1  Power reset

A power reset is generated when one of the following events occurs:
- a brownout reset (BOR)
- when exiting Standby mode
- when exiting Shutdown mode

A BOR sets all registers to their reset values except the ones in the backup domain.

When exiting Standby mode, all registers in the core domain are set to their reset value. Registers outside the core domain (RTC, TAMPER, WUP, IWDG, and Standby/Shutdown mode control) are not impacted.

When exiting Shutdown mode, a brownout reset is generated, resetting all registers except those in the backup domain.
11.3.2 System reset

A system reset sets all registers to their reset values except the reset flags in RCC_CSR, and the registers in the backup domain.

A system reset is generated when one of the following events occurs:

- a low level on the NRST pin (external reset)
- a window watchdog event (WWDG reset)
- an independent watchdog event (IWDG reset)
- a software reset (SW reset) (see Software reset)
- a low-power mode security reset (see Low-power mode security reset)
- an option-byte loader reset (see Option byte loader reset)
- a brownout reset

The reset source can be identified by checking the reset flags in RCC_CSR.

These sources act on the NRST pin and this pin is always kept low during the delay phase. The reset service routine vector is selected via the boot option bytes.

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20 µs for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.

In case on an internal reset, the internal pull-up RPU is deactivated in order to save the power consumption through the pull-up resistor.

Software reset

The SYSRESETREQ bit in Cortex-M33 application interrupt and reset control register must be set to force a software reset on the device.
Low-power mode security reset

To avoid that critical applications mistakenly enter a low-power mode, the following low-power mode security resets are available. If enabled in option bytes, the resets are generated in any of the following conditions:

- Entering Standby mode: this type of reset is enabled by resetting NRST_STDBY bit in user option bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering Standby mode.
- Entering Stop mode: this type of reset is enabled by resetting NRST_STOP bit in user option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering Stop mode.
- Entering Shutdown mode: this type of reset is enabled by resetting NRST_SHDW bit in user option bytes. In this case, whenever a Shutdown mode entry sequence is successfully executed, the device is reset instead of entering Shutdown mode.

For further information on the user option bytes, refer to Section 7.4.1: Option bytes description.

Option byte loader reset

The option byte loader reset is generated when the OBL_LAUNCH bit is set in the FLASH_NSCR register. This bit is used to launch the option byte loading by software.

11.3.3 Backup domain reset

The backup domain has two specific resets.

A backup domain reset is generated when one of the following events occurs:

- a software reset, triggered by setting BDRST bit RCC_BDCR
- a V_DD or V_BAT power on, if both supplies have previously been powered off

A backup domain reset affects the LSE oscillator, the RTC, the TAMP, the backup registers, RCC_BDCR, and PWR_BDCR1. The reset of PWR_BDCR1 affects the backup SRAM.

11.4 RCC clock functional description

Four different clock sources can be used to drive the system clock (SYSCLK):

- HSI16: high-speed internal 16 MHz RC oscillator clock
- MSIS: multi-speed internal RC oscillator clock
- HSE: high-speed external crystal or clock, from 4 to 50 MHz
- PLL1 clock

The MSIS is used as system clock source after startup from reset, configured at 4 MHz.

The devices have the following additional clock sources:

- MSIK: multi-speed internal RC oscillator clock used for peripherals kernel clocks
- LSI: 32 kHz/250 Hz low-speed internal RC that drives the independent watchdog and optionally the RTC used for auto-wake-up from Stop and Standby modes
- LSE: 32.768 kHz low-speed external crystal or clock that optionally drives the real-time clock (rtc_ck)
• HSI48: internal 48 MHz RC that potentially drives the OTG_FS, the USB, the SDMMC, and the RNG
• SHSI: secure high-speed internal 48 MHz RC that drives the SAES
• PLL2 and PLL3 clocks

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Several prescalers can be used to configure the AHB frequency, the APB1 and APB2 domains. The maximum frequency of the AHB and APB domains is 160 MHz.

All the peripheral clocks are derived from their bus clock (HCLK, PCLK1, PCLK2, or PCLK3) except the following ones that receive an independent kernel clock. This kernel clock can be selected by software between several sources thanks to RCC_CCIPRx registers (x = 1,2,3): OTG_FS, USB, or OTG_HS, SDMMCx (x = 1,2), RNG, ADCx (x = 1, 2, 4), DAC1, U(S)ARTx (x = 1 to 6), LPUART1, I2Cx (x = 1 to 6), SPIx (x = 1 to 3), OCTOSPIx (x = 1,2), SAlx (x = 1,2), MDF1, ADF1, FDCAN1, LPTIMx (x = 1 to 4), SAES, DSI, LTDC, HSPI1.

In addition, the RTC kernel clock is selected by software in RCC_BDCR. The IWDG clock is always the LSI 32 kHz clock.

The RCC feeds the Cortex system timer (SysTick) external clock with the AHB clock (HCLK) divided by eight, or LSE or LSI. The SysTick can work either with this clock or directly with the Cortex clock (HCLK), configurable in the SysTick control and status register.

FCLK acts as Cortex-M33 free-running clock.
Figure 36. Clock tree for STM32U5 Series

Highlighted connections or peripheral may not be present in all devices of the STM32U5 Series. Refer to the device datasheet for more information.
11.4.1 HSE clock

The high-speed external clock signal (HSE) can be generated from two possible clock sources:

- HSE external crystal/ceramic resonator
- HSE user external clock

The resonator and the load capacitors must be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

**Figure 37. HSE/ LSE clock sources**

<table>
<thead>
<tr>

<td>External clock</td>
<td><img src="image" alt="External clock" /></td>
</tr>
<tr>
<td>Crystal/ceramic resonators</td>
<td><img src="image" alt="Crystal/ceramic resonators" /></td>
</tr>
</tbody>
</table>

**External crystal/ceramic resonator (HSE crystal)**

The 4 to 50 MHz external oscillator has the advantage of producing a very accurate rate on the main clock.

The associated hardware configuration is shown in *Figure 37*. Refer to the electrical characteristics section of the datasheet for more details.

HSERDY in RCC_CR indicates if the HSE oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in RCC_CIER.

The HSE crystal can be switched on and off using HSEON in RCC_CR.
External source (HSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 50 MHz. This mode is selected by setting HSEBYP and HSEON in RCC_CR. The external clock signal (square, sinus, or triangle) with ~40-60% duty cycle depending on the frequency (refer to the datasheet) must drive the OSC_IN pin while the OSC_OUT pin can be used as GPIO (see Figure 37).

11.4.2 HSI16 clock

The HSI16 clock signal is generated from an internal 16 MHz RC oscillator.

The HSI16 RC oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator. However, even with calibration, the frequency is less accurate than an external crystal oscillator or ceramic resonator.

The HSI16 clock can be selected as system clock after wake-up from Stop modes. Refer to Section 11.8.6. It can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to Section 11.4.11.

Calibration

The RC oscillator frequencies may vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1% accuracy at $T_A = 25^\circ C$.

After reset, the factory calibration value is loaded in HSICAL[7:0] of RCC_ICSCR3.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator speed. The HSI16 frequency can be trimmed in the application using HSITRIM[6:0] in RCC_ICSCR3.

For more details on how to measure the HSI16 frequency variation, refer to Section 11.4.23.

HSIRDY in RCC_CR indicates if the HSI16 RC is stable or not. At startup, the HSI16 RC output clock is not released until this bit is set by hardware.

The HSI16 RC can be switched on and off using HSION in RCC_CR.

The HSI16 signal can also be used as a backup source (auxiliary clock) if the HSE crystal oscillator fails. Refer to Section 11.4.11.

11.4.3 MSI (MSIS and MSIK) clocks

The MSI is made of four internal RC oscillators: MSIRC0 at 48 MHz, MSIRC1 at 4 MHz, MSIRC2 at 3.072 MHz, and MSIRC3 at 400 kHz. Each oscillator feeds a prescaler providing a division by 1, 2, 3, or 4. Two output clocks are generated from these divided oscillators: MSIS that can be selected as system clock, and MSIK that can be selected by some peripherals as kernel clock.
MSIS and MSIK frequency ranges can be adjusted by software, by using respectively MSISRANGE[3:0] and MSIKRANGE[3:0] in RCC_ICSCR1, with MSIRGSEL = 1. Sixteen frequency ranges are available, generated from the four internal RCs, as shown in the table below.

### Table 113. MSIS and MSIK ranges per internal MSIRCs

The MSIS clock is used as system clock after restart from reset, wake-up from Standby, and Shutdown low-power modes. After restart from reset or when exiting Shutdown mode, MSIS and MSIK frequencies are set to their default value 4 MHz. The frequency range at wake-up

![Figure 38. MSI block diagram](MSv64328V1)
from Standby mode can be adjusted by software, using respectively MSISSRANGE[3:0] and MSIKSRANGE[3:0] with MSIRGSEL = 0 (refer to RCC_CSR).

The MSIS clock can be selected as system clock after a wake-up from Stop mode (Stop 0, Stop 1, Stop 2, or Stop 3) depending on STOPWUCK in RCC_CR. It can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. See Section 11.4.11.

The MSI advantage is to provide a low-cost (no external components) low-power clock source. In addition, when used in PLL-mode with the LSE, the MSI provides a very accurate clock source that can be used by the OTG_FS, or the USB, and feeds the PLL.

MSISRDY and MSIKRDY in RCC_CR indicate whether the MSIS and MSIK RC are stable or not. At startup, MSIS and MSIK RC output clocks are not released until their respective bit is set by hardware. The MSIS and MSIK RC can be switched on and off by using MSISON and MSIKON in RCC_CR.

**Hardware auto calibration with LSE (PLL-mode)**

When a 32.768 kHz external oscillator is present in the application, it is possible to configure either the MSIS or the MSIK in a PLL-mode. This mode is enabled:
- for MSIS by setting MSIPLLEN with MSIPLLSEL = 1 in RCC_CR
- for MSIK by setting MSIPLLEN with MSIPLLSEL = 0

In case MSIS and MSIK ranges are generated from the same MSIRC source, the PLL-mode is applied on both MSIS and MSIK. When configured in PLL-mode, the MSIS or MSIK automatically calibrates itself thanks to the LSE. This mode is available for all MSI frequency ranges. At 48 MHz, the MSIK in PLL-mode can be used for the OTG_FS, or the USB, avoiding the need of an external high-speed crystal.

If LSE clocks pulses are stopped, the MSI PLL-mode is automatically unlocked, and the MSI accuracy is consequently degraded. On all STM32U5 devices except STM32U575/585 rev. X, the MSI PLL-mode unlock event is connected to an EXTI line: this is used to generate an event or interrupt supporting wake-up from Stop 0, Stop 1, or Stop 2 mode (see Table 118: Interrupt sources and control and Table 187: EXTI line connections).

**MSI PLL-mode stabilization time**

When MSIPLLEN = 1, the final accuracy after enabling the MSI (by writing MSISON = 1 or MSIKON = 1 or following a peripheral clock request in Stop mode) is reached after a stabilization time \( t_{STAB}(MSI) \) when MSIPPLLFAST = 0. This stabilization time is needed even if the LSE is kept enable. Refer to datasheet for \( t_{STAB}(MSI) \) value.

If MSIPLLEN = 1 with MSIPPLLFAST = 1, the MSI oscillator is kept powered on when a request to switch it off is received (either by writing MSISON = 0 and MSIKON = 0, or because no peripheral requests this clock in Stop mode). In this case the MSI PLL-mode accuracy is kept when the MSI is switched on again, providing that the \( t_{STAB}(MSI) \) stabilization time is reached before switching off the MSI. This mode can be used for autonomous peripherals requiring accuracy in Stop mode, with an extra consumption as the oscillator remains powered on, but gated off when disabled.

**Software calibration**

The MSIRCx (x = 0 to 3) oscillators frequency may vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1 % accuracy at an ambient temperature, \( T_A = 25 \) °C. After reset, the factory calibration value is loaded in MSICALx[4:0] (x = 0 to 3) in RCC_ICSCR1. If the application is subject to voltage
or temperature variations, this may affect the RC oscillator speed. The MSIRCx frequency can be trimmed in the application by using MSITRIMx[4:0] (x = 0 to 3) in RCC_ICSCR.

**Note:** The final accuracy after applying the calibration value is reached after a stabilization time. This stabilization time is needed after reset of exiting Standby or Shutdown mode. It is also needed when switching from PLL-mode to normal mode.

The hardware auto calibration with LSE must not be used in conjunction with software calibration.

For more details on how to measure the MSI frequency variation, refer to Section 11.4.23.

### 11.4.4 HSI48 clock

The HSI48 clock signal is generated from an internal 48 MHz RC oscillator and can be used directly for USB/OTG_FS, and for the RNG, as well as the SDMMC.

The internal 48 MHz RC oscillator is mainly dedicated to provide a high-precision clock to the OTG_FS and the USB by means of a special clock recovery system (CRS) circuitry. The CRS can use the USB SOF signal (only on STM32U535/545/575/585), the LSE, or an external signal to automatically and quickly adjust the oscillator frequency on-the-fly. It is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, the HSI48 RC oscillator runs on its default frequency that is subject to manufacturing process variations.

For more details on how to configure and use the CRS peripheral, refer to Section 12: Clock recovery system (CRS).

The HSI48RDY flag in the RCC_CR register indicates whether the HSI48 RC oscillator is stable or not. At startup, the HSI48 RC oscillator output clock is not released until this bit is set by hardware.

The HSI48 can be switched on and off using the HSI48ON bit in the RCC_CR register.

### 11.4.5 SHSI clock

The SHSI is an internal securable RC oscillator dedicated to clock the SAES. SHSIRDY flag in RCC_CR indicates if the SHSI RC is stable or not. At startup, the SHSI RC output clock is not released until this bit is set by hardware.

The SHSI RC can be switched on and off using SHSION in RCC_CR.

### 11.4.6 PLL

The RCC features three PLLs:

- a main PLL, PLL1, that is generally used to provide clocks to the CPU and to some peripherals
- two dedicated PLL2 and PLL3 that are used to generate the kernel clock for peripherals

The PLLs integrated into the RCC are completely independent. They offer the following features:

- Input frequency range: 4 to 16 MHz
- Capability to work either in integer or fractional mode
- 13-bit sigma-delta (ΣΔ) modulator, allowing to fine-tune the VCO frequency by steps of 11 to 0.3 ppm
- The $\Sigma\Delta$ modulator can be updated on-the-fly, without generating frequency overshoots on PLLs outputs.
- Each PLL offers three outputs with post-dividers.

The PLLs are controlled via RCC_PLLxDIVR, RCC_PLLxFRACR, RCC_PLLxCFGR, and RCC_CR ($x = 1, 2, 3$).

The frequency of the reference clock provided to the PLLs (refx_ck) must range from 4 to 16 MHz. The user application must program properly the PLLxM ($x = 1, 2, 3$) dividers in RCC_PLL1CFGR), RCC_PLL2CFGR, and RCC_PLL3CFGR, in order to match this condition. In addition, PLLxRGE must be set according to the reference input frequency to guarantee an optimal performance of the PLL.

To reduce the power consumption, it is recommended to configure the VCOx output to the lowest frequency.

Figure 39. PLL block diagram

PLLxN loop divider must be programmed to achieve the expected frequency at VCO output. In addition, the VCO output range must be respected.

The PLLx operates in integer mode when PLLxFRACEN is 0, and the PLL is enabled with PLLxON. The fractional mode can be enabled at any time by setting PLL1FRACN to the required value, and subsequently setting PLLxFRACEN from 0 to 1. The $\Sigma\Delta$ modulator is designed to minimize the jitter impact while allowing very small step frequency adjustments. To update the fractional value, first set PLLxFRACEN to 0 before updating the PLLxFRACN value, and subsequently set PLLxFRACEN from 0 to 1. PLLxFRACN must only be updated by software when PLLxFRACEN is 0.

The PLLs can be enabled by setting PLLxON = 1 in RCC_CR. The PLLxRDY bit indicates that the PLL is ready (meaning locked).

Note: Before enabling the PLLs, make sure that the reference frequency (refx_ck) provided to the PLL is stable. The following PLLx parameters cannot be changed once the PLLx is enabled: PLLxSRC, PLLxN, PLLxRGE, PLLxP, PLLxQ, and PLLxR.

The hardware prevents writing PLL1ON to 0 if the PLL1 is currently used to deliver the system clock.
The following PLL parameters cannot be changed once the PLL is enabled: PLLxN, PLLxRGE, PLLxP, PLLxQ, and PLLxR.

To ensure an optimal behavior of the PLL when one of the post-dividers (PLLxP, PLLxQ, or PLLxR) is not used, the application must clear the enable bit (PLLxPEN, PLLxQEN, PLLxREN), and configure the corresponding post-dividers to their minimum value (PLLxR = 0, PLLxP = 0, or PLLxQ = 0).

If the above rules are not respected, the PLL output frequency is not guaranteed.

**Output frequency computation**

When the PLL operates in integer mode (SH_REG = 0), the VCO frequency (FVCO) is given by the following formula (x = 1, 2, 3):

\[
F_{VCOx} = F_{refx\_ck} \times PLLxN
\]

When the PLL operates in fractional mode (SH_REG ≠ 0), the PLLxN divider must be initialized before enabling the PLLs. However, the PLLxFRACN value can be changed on-the-fly without disturbing the PLL output.

This feature can be used either to generate a specific frequency from any crystal value with a good accuracy, or to fine-tune the frequency on-the-fly.

For each PLL, the VCO frequency is given by the following formula:

\[
F_{VCOx} = F_{refx\_ck} \times \left(\frac{PLLxN + PLLxFRACN}{2^{13}}\right)
\]

For both integer and fractional mode, the PLL1 output frequency is given by the following formula:

\[
F_{pllx\_y\_ck} = \frac{F_{VCOx}}{(PLLxy + 1)} \text{ with } y = P, Q \text{ or } R
\]

The PLLs are disabled by hardware:
- when the system enters Stop or Standby mode
- when an HSE failure occurs, when HSE or PLL (clocked by HSE) are used as system clock

The fractional information used by the PLL is reset when disabling the PLL.

**PLL initialization phase**

The following PLL initialization sequence in integer and fractional mode is recommended. The PLLx are supposed to be disabled at the start of the initialization sequence:
1. Initialize the PLLs registers according to the required frequency.
   - For integer mode, set PLLxFRACEN to 0 in RCC_PLL1CFGR, RCC_PLL2CFGR, and RCC_PLL3CFGR.
   - For fractional mode, set PLLxFRACN to the required initial value (FracInitValue), and then set PLLxFRACEN = 1.
2. Once PLLxON = 1, the application must wait until PLLxRDY = 1. As long as PLLxRDY = 0, PLLxFRACEN must not be altered.
3. Once PLLxRDY = 1, the PLLx is ready to be used.
4. If the application intends to tune the PLLx frequency on-the-fly, then:
   a) PLLxFRACEN must be set to 0 to update the PLLxFRACN value while keeping the PLL running.
   b) A new value can be uploaded into PLLxFRACN (FracValue(n)).
   c) PLLxFRACEN must be set to 1 to activate the new programmed value in PLLxFRACN that is taken into account by the PLL.
11.4.7 LSE clock

The LSE crystal is a 32.768 kHz low-speed external crystal or ceramic resonator. It has the advantage of providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

The LSE crystal is switched on and off using LSEON in RCC_BDCR. If the LSE is used by other peripherals of functions than RTC, TAMP, and LSECSS, the LSESYSEN bit must be also be set in RCC_BDCR (refer to LSE when used by peripherals other than RTC/TAMP, and RCC functions).

The crystal oscillator driving strength is configured using the LSEDRV[1:0] bits, according to crystal specification, to obtain the best compromise between robustness and short startup.
time on one side and low-power-consumption on the other side. The LSE drive must be programmed before enabling the LSE.

LSERDY in RCC_BDCR indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in RCC_CIER.

**External source (LSE bypass)**

In this mode, an external clock source must be provided. This mode is selected by setting LSEBYP and LSEON in RCC_BDCR. The external clock signal (square, sinus, or triangle) with ~50% duty cycle, must drive the OSC32_IN pin while the OSC32_OUT pin can be used as GPIO (see Figure 37).

**LSE when used by peripherals other than RTC/TAMP, and RCC functions**

By default, when enabled, the LSE is sent only to RTC and TAMP (assuming that RTCSEL = 01).

If the LSE is needed for other peripherals (such as peripheral clock or trigger source), or if the LSE is used by an RCC function (such as LSCO, MCO, MSI PLL mode), the sequence below must be done:

1. Set LSEON in RCC_BDCR, and wait for LSERD = 1 in RCC_BDCR.
2. Set LSESYSEN = 1 in RCC_BDCR.
3. Wait for LSESYSRDY = 1 in RCC_BDCR.

The LSE consumption is increased when LSESYSEN = 1.

**11.4.8 LSI clock**

The LSI RC acts as a low-power clock source that can be kept running in Stop and Standby modes for the independent watchdog (IWDG) and RTC. The clock frequency is either 32 kHz or 250 Hz depending on LSIPREDIV in RCC_BDCR. Setting LSIPREDIV allows a lower consumption (refer to the electrical characteristics section of the datasheet for more details).

When the IWDG is enabled or when the RTC or TAMP is clocked by the LSI, LSIPREDIV cannot be changed anymore.

The LSI RC can be switched on and off using LSION in RCC_BDCR.

LSIRDY in RCC_BDCR indicates if the LSI oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in RCC_CIER.

**11.4.9 System clock (SYSCLK) selection**

Four different clock sources can be used to drive the system clock (SYSCLK):

- MSIS oscillator
- HSI16 oscillator
- HSE oscillator
- PLL
The system clock maximum frequency is 160 MHz. After a system reset, the MSIS oscillator, at 4 MHz, is selected as system clock. When a clock source is used directly or through the PLL as a system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source becomes ready. Status bits in RCC_CR indicate which clocks are ready and which clock is currently used as a system clock.

The table below gives the different bus frequencies depending on the product voltage range.

#### 11.4.11 Clock security system (CSS)

The CSS can be activated by software. In this case, the clock detector is enabled after the HSE oscillator wake-up time, and disabled when this oscillator is stopped.

If a failure is detected on the HSE clock, the HSE oscillator is automatically disabled. A clock failure event is sent to some timers break input and an interrupt is generated to inform the software about the failure (clock security system interrupt CSSI). This allows the MCU to perform rescue operations. The CSSI is linked to the Cortex-M33 NMI (nonmaskable interrupt) exception vector.

**Note:** Once the CSS is enabled and if the HSE clock fails, the CSSI occurs and an NMI is automatically generated. The NMI is executed indefinitely unless CSSI bit is cleared. As a consequence, in the NMI ISR, the user must clear the CSSI by setting CSSC in RCC_CICR.
If the HSE oscillator is used directly or indirectly as the system clock (indirectly means: it is used as PLL input clock and the PLL clock is used as system clock), a detected failure causes a switch of the system clock to the MSIS or the HSI16 oscillator depending on STOPWUCK configuration in RCC_CR, and the disabling of the HSE oscillator. If the HSE clock (divided or not) is the clock entry of the PLL used as system clock when the failure occurs, the PLL is disabled too.

11.4.12 Clock security system on LSE

A clock security system on LSE can be activated by software writing LSECSSON in RCC_BDCR. This bit can be disabled only by a hardware reset or RTC software reset, or after a failure detection on LSE. LSECSSON must be written after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware), and after the RTC clock has been selected by RTCSEL.

The CSS on LSE works in all modes, including VBAT mode. It works also under system reset (excluding power-on reset).

The CSS on LSE detects when the LSE disappears or in case of over frequency. In addition, the glitches on LSE can be filtered by setting LSEGFON. LSEGFON must be written when the LSE is disabled (LSEON = 0 and LSERDY = 0).

If a failure is detected on the external 32 kHz oscillator, the LSE clock is no longer supplied to the RTC, but no hardware action is made to the registers. If the MSI was in PLL-mode, this mode is disabled.

The CSS on LSE detection event is connected to the internal tamper 3 of the TAMP:

- On STM32U575/585 rev. X devices, the internal tamper 3 must be enabled (ITAMP3E = 1 in TAMP_CR1) and the associated interrupt enabled (ITAMP3IE in TAMP_IER) in order to wake up from the low-power modes. This erases also the TAMP backup registers and backup SRAM unless ITAMP3NOER = 1 in TAMP_CR3 (see Section 64: Tamper and backup registers (TAMP) for more details).

- On all other STM32U575/585 revisions, and the other STM32U5 devices, the CSS on LSE detection event is also connected to an EXTI line, allowing to generate an event or interrupt supporting wake-up from Stop 0, Stop 1, or Stop 2 mode, without requiring to enable tamper detection (see Table 118: Interrupt sources and control and Table 187: EXTI line connections).

In case of CSS on LSE detection event (LSECSSD = 1 in RCC_BDCR), the software must then disable the LSECSSON bit, stop the defective 32 kHz oscillator (disabling LSEON), and change the RTC clock source (no clock or LSI or HSE, with RTCSEL), or take any required action to secure the application.

Refer to datasheet for CSS on LSE electrical characteristics.

11.4.13 ADC and DAC clocks

The ADC and DAC kernel clock source is selected thanks to ADCDACSEL[2:0] in RCC_CCIPR3. The ADC clock ratio must be around 50 %. For this reason, the AHB clock, when selected as ADC clock, must not be divided with HPRE prescaler. If pll2_r_ck is selected as ADC clock, the PLL2R division factor must be even (division by 2 or 4 for example).

If the application requires that the ADC or DAC is precisely triggered by a TIMx timer without any uncertainty, the HCLK must be selected as ADC and DAC kernel clock source.
The other clock sources are asynchronous to TIMx timers therefore an uncertainty of the trigger instant is added by the resynchronization between the two clock domains. LPTIMx timers are also asynchronous.

The DAC requires an additional low-power clock (LSI or LSE) to operate in sample and hold mode, available in Stop mode. This clock is selected with DAC1SEL in the RCC_CCIPR3.

11.4.14 RTC and TAMP clock

The RTCCCLK clock source is used by RTC and TAMP, and can be either the HSE / 32, LSE, or LSI clock. It is selected by programming RTCSEL[1:0] in RCC_BDCR. This selection cannot be modified without resetting the backup domain. The system must always be configured so as to get a PCLK frequency greater than or equal to the RTCCCLK frequency for a proper operation of the RTC. The TAMP does not require any kernel clock if only backup registers are used, with tamperers in edge detection mode. All other tamper detection modes require a kernel clock (refer to Section 64: Tamper and backup registers (TAMP) for more details).

LSE and LSI clocks are in the backup domain, whereas the HSE clock is not. Consequently:

- If LSE or LSI is selected as RTC and TAMP clock, these peripherals continue to work even if the VDD supply is switched off, provided the VBAT supply is maintained.
- If the HSE clock divided by a prescaler is used as the RTC or TAMP clock, the RTC state is not guaranteed if the VDD supply is powered off, or if the internal voltage regulator is powered off (removing power from the core domain). Depending on the TAMP configuration, this one can remain functional if used in a mode that does not need any kernel clock.

When the RTC and TAMP clock is LSE or LSI, the RTC remains clocked and functional under system reset.

If the LSE is needed only for the RTC or TAMP, LSESYSEN must be kept at reset value to get the lowest consumption.

11.4.15 Timer clock

The timer clock frequencies are automatically defined by hardware.

There are two cases:

- If the APB prescaler equals 1, the timer clock frequencies are set to the APB domain frequency.
- Otherwise, they are set to twice (×2) the APB domain frequency.

11.4.16 Watchdog clock

If the independent watchdog (IWDG) is started by either hardware option or software access, the LSI oscillator is forced on and cannot be disabled. After the LSI oscillator temporization, the LSI 32 kHz clock is provided to the IWDG.

11.4.17 OCTOSPI clock

The OCTOSPIx kernel clock, selected by OCTOSPIxSEL[1:0], can be up to 200 MHz when pll1_q_ck or pll2_q_ck are used.
11.4.18 HSPI1 clock

The HSPI1 kernel clock, selected by HSPI1SEL[1:0], can be up to 200 MHz when pll1_q_ck, pll2_q_ck or pll3_r_ck are used.

11.4.19 OTG_HS clock

The OTG_HS kernel clock is generated by the OTG_HS PHY. This PHY can accept only frequencies of following list (16, 19.2, 20, 24, 26 or 32 MHz), with an accuracy of ± 400 ppm. Those frequencies can be achieved using either HSE, HSE/2, PLL1_P or PLL1_P/2, and selected by the OTGHSSEL[1:0] multiplexer.

11.4.20 DSI clock

The DSI interface clock can be derived from the internal DSI PHY PLL or by the pll3_p_ck clocks, selected by DSISEL multiplexer.

11.4.21 LTDC clock

The LTDC interface clock can be derived from the pll2_r_ck or pll3_r_ck clocks, selected by LTDCSEL multiplexer.

11.4.22 Clock-out capability

- **MCO**
  
The microcontroller clock output (MCO) capability allows the clock to be output onto the external MCO pin. One of the following clock signals can be selected as MCO clock.
  
  - LSI
  - LSE
  - SYSCLK
  - HSI16
  - HSI48
  - HSE
  - PLLCLK
  - MSIS
  - MSIK

  The selection is controlled by MCOSEL[3:0] in RCC_CR. The selected clock can be divided with MCOPRE[2:0] in RCC_CR.

- **LSCO**
  
  Another output (LSCO) allows one of the low-speed clocks below to be output onto the external LSCO pin:
  
  - LSI
  - LSE

  This output remains available in all Stop modes, Standby, and Shutdown modes. This output is not available in VBAT mode. The selection is controlled by LSCOSEL bit and enabled with LSCOEN in RCC_BDCR.

  The MCO clock output requires the corresponding alternate function selected on MCO pin.
11.4.23 **Internal/external clock measurement with TIM15/TIM16/TIM17**

The frequency of all on-board clock sources can be indirectly measured by means of the TIM15, TIM16, or TIM17 channel 1 input capture, and LPTIM1 or LPTIM2 channel 2 input capture.

**HSI16 and MSI calibration using LSE**

The primary purpose of connecting the LSE to the channel 1 input capture of TIM15, TIM16, and TIM17, and to the channel 2 input capture of LPTIM2, is to be able to precisely measure the HSI16 and MSI system clocks (for this, either HSI16 or MSIS must be used as system clock source). The number of HSI16 (MSIS respectively) clock counts between consecutive edges of the LSE signal provides a measure of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm), the internal clock frequency can be determined with the same resolution, and the source can be trimmed to compensate the manufacturing, process, temperature and/or voltage related frequency deviations.

The four oscillators of MSI and HSI16 oscillator have dedicated user-accessible calibration bits for this purpose.

The basic concept consists in providing a relative measurement (such as HSI16/LSE ratio). The precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is.

*Note:* *When the LSE is available, the MSI can be automatically trimmed by LSE using PLL-mode.*

**HSI16 and MSI calibration using HSE**

If the HSE is available, it can be used as system clock, and the timer input capture must be connected either to MSI (divided by 1024 or by 4) or to HSI/256. TIM16 and TIM17 channel 1 input capture, as well and the LPTIM2 input capture 2, are connected to the divided oscillator only when TIMICSEL[2:0] ≠ 0 in RCC_CCIPR1.

Considering that the timer counter is 16-bit, and that the ratio between HSE and the input capture signal must be the highest possible, a division by 1024 must be selected when MSIRC0, MSIRC1, or MSIRC2 is measured, and a division by 4 when MSIRC4 is measured.

**LSI calibration**

The calibration of the LSI follows the same principle, but changing the reference clock. The LSI clock must be connected to the channel 1 input capture of the TIM16 or TIM17, or to the channel 2 input capture of the LPTIM1. Then defining the HSE as system clock source, the number of its clock counts between consecutive edges of the LSI signal, provides a measure of the internal low-speed clock period.

The basic concept consists in providing a relative measurement (such as HSE/LSI ratio). The precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is.

11.4.24 **Peripherals clock gating and autonomous mode**

**Peripherals clock gating in Run mode**

Each peripheral clock can be enabled by the corresponding EN bit in RCC_AHBxENR and RCC_APBxENR registers.
When the peripheral clock is not active, read or write accesses to the peripheral registers are not supported.

The enable bit has a synchronization mechanism to create a glitch-free clock for the peripheral. After the enable bit is set, the clock is active after 2 cycles of the peripheral bus clock.

**Caution:** Just after enabling the clock for a peripheral, the software must wait for these two clock cycles before accessing the peripheral registers.

### Peripherals clock gating in Sleep and Stop modes

When a peripheral is enabled, its clock can be automatically gated off when the device is in Sleep mode, by clearing the peripheral SMEN bit in RCC_AHBxSMENR and RCC_APBxSMENR. Both EN and SMEN of the peripheral must be set to keep the clock on in Sleep mode.

The SMEN bit of the peripheral is also used to allow peripheral clocking in Stop 0 and Stop 1 modes, upon peripheral request.

When the clock is requested by a peripheral, this clock is distributed to all enabled peripherals. Therefore, the SMEN bit must be cleared before entering Stop mode, if the peripheral is not used in Stop mode.

**Caution:** The SMEN bit of the peripheral must be set to allow the generation of an interrupt capable to wake up the device from Stop mode. This is not necessary when the peripheral wake-up interrupt is generated through the EXTI.

### Peripherals clock gating and autonomous mode in Stop 0/1/2 modes

Some peripherals support autonomous mode (refer to Table 116). These peripherals are able to generate a kernel clock request and an AHB/APB bus clock request when they need, in order to operate and update their status register even in Stop mode. Depending on the peripheral configuration, either a DMA request or an interrupt can be associated to the peripheral event.

Upon an AHB or APB bus clock request from an autonomous peripheral, either MSI or HSI16 oscillator is woken up, depending on the oscillator selected by STOPWUCK in RCC_CFGR1.

If the autonomous peripheral is configured with DMA requests enabled, a data transfer is performed thanks to the AHB/APB clock. The bus clocks as well as the oscillator (HSI16 or MSI) are automatically switched off as soon as the transfer is finished, if no other peripheral requests it. The device automatically goes back in Stop mode.

If the autonomous peripheral is configured with interrupt enabled, the interrupt wakes up the device into Run mode.

The autonomous peripherals mapped on AHB3 or APB3 belong to the SmartRun domain and are autonomous in Stop 0, Stop 1, and Stop 2 with the LPDMA1 and SRAM4.

The autonomous peripherals mapped on AHB1, AHB2, APB1, and APB2, belong to the CPU domain, and are autonomous in Stop 0 and Stop 1 mode, only with GPDMA1 and SRAM1/2/3/4/5/6.
The table below shows the list of peripherals with autonomous mode capability.

</table>

1. Enabled if both xxEN and xxSMEN bits of the peripheral are set (xx = instance name)
2. SRAM4 belongs to SmartRun domain (SRD) but can be addressed by GPDMA 1 in Stop 0 and Stop 1 modes.
3. Enabled if all xxEN, xxSMEN, and xxAMEN bits of the peripheral are set (xx = instance name)

For peripherals in the CPU domain, the autonomous mode is enabled in Stop 0 and Stop 1 modes if both xxEN and xxSMEN bits of the peripheral are set.

For peripherals in SmartRun domain, the autonomous mode is enabled in Stop 0, Stop 1, and Stop 2 modes if both xxEN and xxSMEN bits of the peripheral are set, plus xxAMEN bit of the peripheral in RCC_SRDAMR.

If an autonomous peripheral requests its kernel clock in Stop 0, Stop 1, or Stop 2 mode, the internal oscillator (HSI16 or MSI) is woken up if it was off, and the kernel clock is propagated only to the peripheral requesting it. When the peripheral releases its kernel clock request, the HSI16 or MSI is switched off if no other peripheral requests it.

If an autonomous peripheral belonging to CPU domain requests its bus clock (AHB1, AHB2, APB1, or APB2 clock) in Stop 0 or Stop 1 mode, the internal oscillator (HSI16 or MSI depending on STOPWUCK value in RCC_CFGR1) is woken up if it was off, and the system clock is propagated to all peripherals configured with both xxEN = xxSMEN = 1.

If an autonomous peripheral belonging to SmartRun domain requests its bus clock (AHB3 or APB3 clock) in Stop 0, Stop 1, or Stop 2 mode, the internal oscillator (HSI16 or MSI depending on STOPWUCK value in RCC_CFGR1) is woken up if it was off, and HCLK3/PCLK3 clocks are propagated to all peripherals of the SmartRun domain configured with xxEN = xxSMEN = xxAMEN = 1.
Caution: The AMEN bit of the peripheral must be set to allow the generation of an interrupt capable to wake up the device from Stop mode. This is not necessary when the peripheral wake-up interrupt is generated through the EXTI.

Note: MSIK or HSI16 can be forced to remain on in Stop 0, Stop 1, or Stop 2 mode, by configuring MSIKERON or HSIPON in RCC_CR. In this case, the oscillator is propagated only to the kernel clock of the enabled autonomous peripherals with this oscillator selected as kernel clock. This allows the peripheral baudrate or conversion rate increase, as there is no need to wait for the oscillator wake-up time when the peripheral requests its kernel clock.

The LSE or LSI selected as peripheral kernel clock remains always on in Stop modes.

AHB3 and APB3 clocks can be forced to remain on by setting SRDRUN in PWR_CR2. This allows the LPDMA1 latency to be improved as there is no need to wait for the oscillator wake-up time when the peripheral requests its bus clock.

11.5 RCC security and privilege functional description

11.5.1 RCC TrustZone security protection modes

When the TrustZone security is activated by TZEN option bit in FLASH_OPTR, the RCC is able to secure RCC configuration and status bits from being modified by nonsecure accesses.

This is configured through RCC_SECCFGR to prevent nonsecure access to read or modify the following features:

- HSE, HSE-CSS, HSI, MSI, LSI, LSE, LSE-CSS, LSCO, HSI48 configuration and status bits
- PLL1, PLL2, PLL3, AHB, and APB prescaler configuration and status bits
- system clock (SYSCLK) and ICLK source clock selection and status bits
- MCO clock output configuration, and STOPWUCK and STOPKERWUCK bit
- Remove reset flag RMVF configuration

If SPRIV = 1 in RCC_PRIVCFGR, the RCC_SECCFGR register can be written only by secure and privileged access. If SPRIV = 0 in RCC_PRIVCFGR, RCC_SECCFGR can be written only by secure access, privileged or unprivileged.

RCC_SECCFGR can be read by secure, nonsecure, privileged and unprivileged access.

When a peripheral is configured as secure, its related clock, reset, clock source selection and clock enable during low-power modes control bits, are also secure in RCC_AHBxENR, RCC_APBxENR, RCC_AHBxSMEN, RCC_APBxSMEN, RCC_SRDAMEN, RCC_CCIPR1, RCC_CCIPR2, RCC_CCIPR3, and RCC_BDCR registers.

The SHSI configuration and status bits are secured when the SAES is configured as secure.

BDRST in RCC_BDCR is secure when at least one function is secure in RTC or TAMP.

A peripheral is secure when:

- For securable peripherals by TZSC (TrustZone security controller), the SEC security bit corresponding to this peripheral is set in GTZC TZSC secure configuration registers.
- For TrustZone-aware peripherals, a security feature of this peripheral is enabled through its dedicated bits.
Table 117 summarizes the RCC secured bits following the security configuration bit in RCC_SECCFGR register.

When one security configuration bit is set, some configuration and status bits are secured. The RCC registers may contain secure and nonsecure bits:

- **Secured bits**: read and write operations are only allowed by a secure access. Nonsecure read returns 0 and write accesses are ignored. No illegal access event is generated.
- **Nonsecure bits**: no restriction. Read and write operations are allowed by both secure and nonsecure accesses.
- **A nonsecure write access to RCC_SECCFGR** is ignored and generates an illegal access event. An illegal access interrupt is generated if the RCC illegal access interrupt is enabled in the GTZC TZIC registers. RCC_SECCFGR can be read by secure or nonsecure access.

When the TrustZone security is disabled (TZEN = 0 in FLASH_OPTR), all registers are nonsecure. RCC_SECCFGR write accesses are ignored.

11.5.2 RCC privilege protection modes

By default, after reset, all RCC registers can be read or written with both privileged and unprivileged access, except RCC_PRIVCFGR that can be written with privileged access only. RCC_PRIVCFGR can be read by secure and nonsecure, privileged and unprivileged access.

SPRIV in RCC_PRIVCFGR can be written with secure privileged access only. This bit configures the privileged access of all RCC secure functions (as defined by RCC_SECCFGR), or by the GTZC for securable peripherals, or by the peripheral itself in case of TrustZone-aware peripherals).

When SPRIV = 1 in RCC_PRIVCFGR:
- Writing the RCC secure bits is possible only with privileged access, including RCC_SECCFGR.
- The RCC secure bits can be read only with privileged access, except RCC_SECCFGR and RCC_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged RCC bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

NSPRIV in RCC_PRIVCFGR can be written with privileged access only, secure or nonsecure functions (as defined by RCC_SECCFGR, or by the GTZC for securable peripherals, or by the peripheral itself in case of TrustZone-aware peripherals).

When NSPRIV = 1 in RCC_PRIVCFGR:
- Writing the RCC nonsecure bits is possible only with privileged access.
- The RCC nonsecure bits can be read only with privileged access except RCC_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged RCC bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

1. TRIM field of the HSI48 is located in CRS peripheral. Be sure to secure it using CRSSEC bit in GTZC1 TZSC secure configuration register 1.
11.6 RCC low-power modes

- AHB and APB peripheral clocks, including DMA clock, can be disabled by software.
- Sleep mode stops the CPU clock. The memory interface clocks (flash memory, caches, and all SRAM interfaces) can be stopped by software during Sleep mode. The AHB to APB bridge clocks are disabled by hardware during Sleep mode when all the clocks of the peripherals connected to them are disabled.
- Stop modes (Stop 0, Stop 1, Stop 2, Stop 3) stop all the clocks in the core domain and disable the PLLs, HSI16, HSI48, SHSI, MSI, and HSE oscillators. However, HSI16 or MSI can be switched ON if the peripheral requests it for autonomous mode purpose, or to generate a wake-up interrupt (see Section 11.4.24 for more details). LSI and LSE remain active in Stop modes.
- Standby and Shutdown modes stop all the clocks in the core domain and disable the PLLs, HSI16, HSI48, SHSI, MSI, and HSE oscillators.

The CPU deep-sleep mode can be overridden for debugging by setting the DBG_STOP or DBG_STANDBY bit in the DBGMCU_CR register.

When exiting Stop modes (Stop 0, Stop 1, Stop 2, or Stop 3), the system clock is either MSIS or HSI16, depending on STOPWUCK in RCC_CFGR1. The frequency (range and user trim) of MSIS and MSIK oscillators is the one configured before entering Stop mode, except if above 24 MHz. In this case, the MSIS or MSIK range is the 24 MHz range. The user trim of HSI16 is kept. If MSI is in PLL-mode before entering Stop mode with MSIPLLFAST = 0, the PLL-mode stabilization time must be waited for after wake-up even if the LSE was kept on during Stop mode. The PLL-mode accuracy is kept after wake-up from Stop 0, Stop 1, or Stop 2 mode without stabilization time if MSIPLLFAST = 1. MSIPLLFAST bit has no effect when exiting Stop 3 mode.

The other internal oscillator can be automatically woken up in addition to the one used by the system clock, in order to avoid waiting for the other oscillator wake-up time when the device is back in Run mode. This is done thanks to STOPKERWUCK in RCC_CFGR1.

When leaving the Standby and Shutdown modes, the system clock is MSIS. The MSIS and MSIK frequency at wake-up from Standby mode is configured with MSISSRANGE and MSIKSRANGE in RCC_CSR, from 1 to 4 MHz. The MSI frequency at wake-up from Shutdown mode is 4 MHz. The user trim is lost.

If a flash memory programming operation is ongoing, a Stop, Standby, or Shutdown mode entry is delayed until the flash memory interface access is finished. If an access to the APB domain is ongoing, a Stop, Standby, or Shutdown mode entry is delayed until the APB access is finished. If an autonomous peripheral generates a system clock request, a Stop, Standby, or Shutdown mode entry is delayed until the system clock request is released.
## 11.7 RCC interrupts

</tbody>
</table>

1. The RCC secure interrupt vector is used only when TrustZone is enabled.
2. The SAESSEC bit is in the GTZC peripheral.
3. The LSE CSS failure event (LSECSSD) is connected to TAMP internal tamper 3. In order to get the interrupt associated to this event, the internal tamper 3 must be enabled, and the internal tamper 3 interrupt must be enabled. The ITAMP3F, ITAMP3E, ITAMP3IE, and CITAMP3F bits are in the TAMP peripheral. Consequently, the LSE CSS tamper interrupt erases or blocks the device secrets as described in Table 637: TAMP interconnection.
4. It is not possible to mask this interrupt when the security system feature is enabled (HSECSSON = 1).
6. This interrupt can wake up from Stop 0, Stop 1, and Stop 2 modes only.
7. This interrupt indicates that the MSI has left the PLL_mode, due to LSE missing pulses. As a consequence, the MSI frequency accuracy is degraded.
11.8 RCC registers

11.8.1 RCC clock control register (RCC_CR)

Address offset: 0x000
Reset value: 0x0000 0035
Access: no wait state; word, half-word, and byte access

HSEBYP and HSEEXT are cleared upon power-on reset. They are not affected upon other types of reset.

</table>

This bit is set by hardware to indicate that the PLL is locked.
0: PLL unlocked
1: PLL locked
Bit 24  **PLL1ON**: PLL1 enable
This bit is set and cleared by software to enable the main PLL. It is cleared by hardware when entering Stop, Standby, or Shutdown mode. This bit cannot be reset if the PLL1 clock is used as the system clock.
0: PLL1 OFF
1: PLL1 ON

Bits 23:21  Reserved, must be kept at reset value.

Bit 20  **HSEEXT**: HSE external clock bypass mode
This bit is set and reset by software to select the external clock mode in bypass mode. External clock mode must be configured with HSEON bit to be used by the device. This bit can be written only if the HSE oscillator is disabled. This bit is active only if the HSE bypass mode is enabled.
0: external HSE clock analog mode
1: external HSE clock digital mode (through I/O Schmitt trigger)

Bit 19  **CSSON**: Clock security system enable
This bit is set by software to enable the clock security system. When CSSON is set, the clock detector is enabled by hardware when the HSE oscillator is ready, and disabled by hardware if a HSE clock failure is detected. This bit is set only and is cleared by reset.
0: clock security system OFF (clock detector OFF)
1: clock security system ON (clock detector ON if the HSE oscillator is stable, OFF if not).

Bit 18  **HSEBYP**: HSE crystal oscillator bypass
This bit is set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit set, to be used by the device. This bit can be written only if the HSE oscillator is disabled.
0: HSE crystal oscillator not bypassed
1: HSE crystal oscillator bypassed with external clock

Bit 17  **HSERDY**: HSE clock ready flag
This bit is set by hardware to indicate that the HSE oscillator is stable.
0: HSE oscillator not ready
1: HSE oscillator ready

*Note: Once the HSEON bit is cleared, HSERDY goes low after six HSE clock cycles.*

Bit 16  **HSEON**: HSE clock enable
This bit is set and cleared by software. It is cleared by hardware to stop the HSE oscillator when entering Stop, Standby, or Shutdown mode. This bit cannot be reset if the HSE oscillator is used directly or indirectly as the system clock.
0: HSE oscillator off
1: HSE oscillator on

Bit 15  **SHSIRDY**: SHSI clock ready flag
This bit is set by hardware to indicate that the SHSI oscillator is stable. It is set only when SHSI is enabled by software (by setting SHSION).
0: SHSI oscillator not ready
1: SHSI oscillator ready

*Note: Once the SHSION bit is cleared, SHSIRDY goes low after six SHSI clock cycles.*

Bit 14  **SHSION**: SHSI clock enable
This bit is set and cleared by software. It is cleared by hardware to stop the SHSI when entering in Stop, Standby, or Shutdown modes.
0: SHSI oscillator off
1: SHSI oscillator on
Bit 13 **HSI48RDY**: HSI48 clock ready flag

   This bit is set by hardware to indicate that HSI48 oscillator is stable. It is set only when HSI48 is enabled by software (by setting HSI48ON).
   0: HSI48 oscillator not ready
   1: HSI48 oscillator ready

Bit 12 **HSI48ON**: HSI48 clock enable

   This bit is set and cleared by software. It is cleared by hardware to stop the HSI48 when entering in Stop, Standby, or Shutdown modes.
   0: HSI48 oscillator off
   1: HSI48 oscillator on

Bit 11 Reserved, must be kept at reset value.

Bit 10 **HSIRDY**: HSI16 clock ready flag

   This bit is set by hardware to indicate that HSI16 oscillator is stable. It is set only when HSI16 is enabled by software (by setting HSION).
   0: HSI16 oscillator not ready
   1: HSI16 oscillator ready

   **Note**: Once the HSION bit is cleared, HSIRDY goes low after six HSI16 clock cycles.

Bit 9 **HSIKERON**: HSI16 enable for some peripheral kernels

   This bit is set and cleared by software to force HSI16 ON even in Stop modes. Keeping HSI16 on in Stop mode allows the communication speed not to be reduced by the HSI16 startup time. This bit has no effect on HSION value. Refer to Section 11.4.24 for more details.
   This bit must be configured at 0 before entering Stop 3 mode.
   0: No effect on HSI16 oscillator
   1: HSI16 oscillator forced on even in Stop mode

Bit 8 **HSION**: HSI16 clock enable

   This bit is set and cleared by software. It is cleared by hardware to stop the HSI16 oscillator when entering Stop, Standby, or Shutdown mode. This bit is set by hardware to force the HSI16 oscillator on when STOPWUCK = 1 when leaving Stop modes, or in case of failure of the HSE crystal oscillator. This bit is set by hardware if the HSI16 is used directly or indirectly as system clock.
   0: HSI16 oscillator off
   1: HSI16 oscillator on

Bit 7 **MSIPLLFAST**: MSI PLL mode fast startup

   This bit is set and reset by software to enable/disable the fast PLL mode start-up of the MSI clock source. This bit is used only if PLL mode is selected (MSIPLLEN = 1).
   **Caution**: The fast start-up feature is not active the first time the PLL mode is selected. The fast start-up is active when the MSI in PLL mode returns from switch off.
   0: MSI PLL normal start-up
   1: MSI PLL fast start-up

Bit 6 **MSIPLLSSEL**: MSI clock with PLL mode selection

   This bit is set and cleared by software to select which MSI output clock uses the PLL mode. It can be written only when the MSI PLL mode is disabled (MSIPLLEN = 0).
   0: PLL mode applied to MSIK (MSI kernel) clock output
   1: PLL mode applied to MSIS (MSI system) clock output

   **Note**: If the MSI kernel clock output uses the same oscillator source than the MSI system clock output, then the PLL mode is applied to both clock outputs.
Bit 5 **MSIKRDY**: MSIK clock ready flag  
This bit is set by hardware to indicate that the MSIK is stable. It is set only when MSI kernel oscillator is enabled by software by setting MSIKON.  
0: MSIK (MSI kernel) oscillator not ready  
1: MSIK (MSI kernel) oscillator ready  
*Note*: Once MSIKON bit is cleared, MSIKRDY goes low after six MSIK oscillator clock cycles.  

Bit 4 **MSIKON**: MSIK clock enable  
This bit is set and cleared by software. It is cleared by hardware to stop the MSIK when entering Stop, Standby, or Shutdown mode. This bit is set by hardware to force the MSIK oscillator ON when exiting Standby or Shutdown mode. It is set by hardware to force the MSIK oscillator on when STOPWUCK = 0 or STOPKERWUCK = 0 when exiting Stop modes, or in case of a failure of the HSE oscillator.  
0: MSIK (MSI kernel) oscillator disabled  
1: MSIK (MSI kernel) oscillator enabled  

Bit 3 **MSIPLLEN**: MSI clock PLL-mode enable  
This bit is set and cleared by software to enable/disable the PLL part of the MSI clock source. MSIPLLEN must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware). A hardware protection prevents from enabling MSIPLLEN if LSE is not ready. This bit is cleared by hardware when LSE is disabled (LSEON = 0) or when the CSS on LSE detects a LSE failure (see RCC_CSR).  
0: MSI PLL-mode OFF  
1: MSI PLL-mode ON  

Bit 2 **MSISRDY**: MSIS clock ready flag  
This bit is set by hardware to indicate that the MSIS oscillator is stable. It is set only when MSIS is enabled by software (by setting MSISON).  
0: MSIS (MSI system) oscillator not ready  
1: MSIS (MSI system) oscillator ready  
*Note*: Once the MSISON bit is cleared, MSISRDY goes low after six MSIS clock cycles.  

Bit 1 **MSIKERON**: MSI enable for some peripheral kernels  
This bit is set and cleared by software to force MSI ON even in Stop modes. Keeping the MSI on in Stop mode allows the communication speed not to be reduced by the MSI startup time.  
This bit has no effect on MSISON and MSIKON values (see Section 11.4.24 for more details). This bit must be configured at 0 before entering Stop 3 mode.  
0: No effect on MSI oscillator  
1: MSI oscillator forced ON even in Stop mode  

Bit 0 **MSISON**: MSIS clock enable  
This bit is set and cleared by software. It is cleared by hardware to stop the MSIS oscillator when entering Stop, Standby or Shutdown mode. This bit is set by hardware to force the MSIS oscillator on when exiting Standby or Shutdown mode. It is set by hardware to force the MSIS oscillator ON when STOPWUCK = 0 when exiting Stop modes, or in case of a failure of the HSE oscillator.  
Set by hardware when used directly or indirectly as system clock.  
0: MSIS (MSI system) oscillator off  
1: MSIS (MSI system) oscillator on
11.8.2 RCC internal clock sources calibration register 1 (RCC_ICSCR1)

Address offset: 0x008
Reset value: 0x440X XXXX
X is factory-programmed.

Access: no wait state; word, half-word, and byte access

Bits 31:28 **MSISRANGE[3:0]**: MSIS clock ranges

These bits are configured by software to choose the frequency range of MSIS oscillator when MSIRGSEL is set. 16 frequency ranges are available:

- **0000**: range 0 around 48 MHz
- **0001**: range 1 around 24 MHz
- **0010**: range 2 around 16 MHz
- **0011**: range 3 around 12 MHz
- **0100**: range 4 around 4 MHz (reset value)
- **0101**: range 5 around 2 MHz
- **0110**: range 6 around 1.33 MHz
- **0111**: range 7 around 1 MHz
- **1000**: range 8 around 3.072 MHz
- **1001**: range 9 around 1.536 MHz
- **1010**: range 10 around 1.024 MHz
- **1011**: range 11 around 768 kHz
- **1100**: range 12 around 400 kHz
- **1101**: range 13 around 200 kHz
- **1110**: range 14 around 133 kHz
- **1111**: range 15 around 100 kHz

*Note*: **MSISRANGE can be modified when MSIS is off (MSISON = 0) or when MSIS is ready (MSISRDY = 1). MSISRANGE must NOT be modified when MSIS is on and NOT ready (MSISON = 1 and MSISRDY = 0)**

**MSISRANGE is kept when the device wakes up from Stop mode, except when the MSIS range is above 24 MHz. In this case MSISRANGE is changed by hardware into range 2 (24 MHz).**
Bits 27:24 **MSIKRANGE[3:0]**: MSIK clock ranges

These bits are configured by software to choose the frequency range of MSIK oscillator when MSIRGSEL is set. 16 frequency ranges are available:

- 0000: range 0 around 48 MHz
- 0001: range 1 around 24 MHz
- 0010: range 2 around 16 MHz
- 0011: range 3 around 12 MHz
- 0100: range 4 around 4 MHz (reset value)
- 0101: range 5 around 2 MHz
- 0110: range 6 around 1.33 MHz
- 0111: range 7 around 1 MHz
- 1000: range 8 around 3.072 MHz
- 1001: range 9 around 1.536 MHz
- 1010: range 10 around 1.024 MHz
- 1011: range 11 around 768 kHz
- 1100: range 12 around 400 kHz
- 1101: range 13 around 200 kHz
- 1110: range 14 around 133 kHz
- 1111: range 15 around 100 kHz

*Note: MSIKRANGE can be modified when MSIK is off (MSISON = 0) or when MSIK is ready (MSIKRDY = 1). MSIKRANGE must NOT be modified when MSIK is on and NOT ready (MSIKON = 1 and MSIKRDY = 0)*

MSIKRANGE is kept when the device wakes up from Stop mode, except when the MSIK range is above 24 MHz. In this case MSIKRANGE is changed by hardware into range 2 (24 MHz).

Bit 23 **MSIRGSEL**: MSI clock range selection

This bit is set by software to select the MSIS and MSIK clocks range with MSISRANGE[3:0] and MSIKRANGE[3:0]. Write 0 has no effect.

After exiting Standby or Shutdown mode, or after a reset, this bit is at 0 and the MSIS and MSIK ranges are provided by MSISRANGE[3:0] and MSIKSRANGE[3:0] in RCC_CSR.

- 0: MSIS/MSIK ranges provided by MSISRANGE[3:0] and MSIKSRANGE[3:0] in RCC_CSR
- 1: MSIS/MSIK ranges provided by MSISRANGE[3:0] and MSIKRANGE[3:0] in RCC_ICSCR1

Bit 22 **MSIBIAS**: MSI bias mode selection

This bit is set by software to select the MSI bias mode. By default, the MSI bias is in continuous mode in order to maintain the output clocks accuracy. Setting this bit reduces the MSI consumption when the regulator is in range 4, or when the device is in Stop 1 or Stop 2 mode, but it decreases the MSI accuracy.

- 0: MSI bias continuous mode (clock accuracy fast settling time)
- 1: MSI bias sampling mode when the regulator is in range 4, or when the device is in Stop 1 or Stop 2 (ultra-low-power mode)

Bits 21:20 Reserved, must be kept at reset value.

Bits 19:15 **MSICAL0[4:0]**: MSIRC0 clock calibration for MSI ranges 0 to 3

These bits are initialized at startup with the factory-programmed MSIRC0 calibration trim value for ranges 0 to 3. When MSITRIM0 is written, MSICAL0 is updated with the sum of MSITRIM0[4:0] and the factory-programmed calibration trim value MSIRC0[4:0].

*Caution:* There is no hardware protection to limit a potential overflow due to the addition of MSITRIM bitfield and factory program bitfield for this calibration value. Control must be managed by software at user level.
### 11.8.3 RCC internal clock sources calibration register 2 (RCC_ICSCR2)

Address offset: 0x00C  
Reset value: 0x0008 4210  
Access: no wait state; word, half-word, and byte access

| Bit 31  | Bit 30  | Bit 29  | Bit 28  | Bit 27  | Bit 26  | Bit 25  | Bit 24  | Bit 23  | Bit 22  | Bit 21  | Bit 20  | Bit 19  | Bit 18  | Bit 17  | Bit 16  | Bit 15  | Bit 14  | Bit 13  | Bit 12  | Bit 11  | Bit 10  | Bit 9   | Bit 8   | Bit 7   | Bit 6   | Bit 5   | Bit 4   | Bit 3   | Bit 2   | Bit 1   | Bit 0   |
|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|
| MSITRIM0[4:1] |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |
| rw      | rw      | rw      | rw      | rw      | rw      | rw      |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:15 **MSITRIM0[4:0]**: MSI clock trimming for ranges 0 to 3  
These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MISO[4:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.

Bits 14:10 **MSITRIM1[4:0]**: MSI clock trimming for ranges 4 to 7  
These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MISO[4:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.
Bits 9:5 **MSITRIM2[4:0]**: MSI clock trimming for ranges 8 to 11
These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MSIRC2[4:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.

Bits 4:0 **MSITRIM3[4:0]**: MSI clock trimming for ranges 12 to 15
These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MSIRC3[4:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.

**Note:** The hardware auto calibration with LSE must not be used in conjunction with software calibration.

### 11.8.4 RCC internal clock sources calibration register 3 (RCC ICSCR3)

Address offset: 0x010

Reset value: 0x0010 0XXX

X is factory-programmed.

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **HSITRIM[4:0]**: HSI clock trimming
These bits provide an additional user-programmable trimming value. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the HSI.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSICAL[11:0]**: HSI clock calibration
These bits are initialized at startup with the factory-programmed HSI calibration trim value.
11.8.5 RCC clock recovery RC register (RCC_CRRCR)

Address offset: 0x014
Reset value: 0x0000 0XXX
X is factory-programmed.

Access: no wait state; word, half-word, and byte access

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **HSI4CAL[8:0]**: HSI48 clock calibration
These bits are initialized at startup with the factory-programmed HSI48 calibration trim value.

11.8.6 RCC clock configuration register 1 (RCC_CFGR1)

Address offset: 0x01C
Reset value: 0x0000 0000

Access: 0 ≤ wait state ≤ 2; word, half-word, and byte access
1 or 2 wait states are inserted only if the access occurs during clock source switch.

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **MCOEPRE[2:0]**: microcontroller clock output prescaler
This bitfield is set and cleared by software. It is highly recommended to change this prescaler before MCO output is enabled.

000: MCO divided by 1
001: MCO divided by 2
010: MCO divided by 4
011: MCO divided by 8
100: MCO divided by 16
Others: not allowed
Bits 27:24 **MCOSEL[3:0]**: microcontroller clock output
This bitfield is set and cleared by software.
0000: MCO output disabled, no clock on MCO
0001: SYCLK system clock selected
0010: MSIS clock selected
0011: HSI16 clock selected
0100: HSE clock selected
0101: Main PLL clock pll1_r_ck selected
0110: LSI clock selected
0111: LSE clock selected
1000: Internal HSI48 clock selected
1001: MSIK clock selected
Others: reserved

*Note:* This clock output may have some truncated cycles at startup or during MCO clock source switching.

Bits 23:6 Reserved, must be kept at reset value.

Bit 5 **STOPKERWUCK**: wake-up from Stop kernel clock automatic enable selection
This bit is set and cleared by software to enable automatically another oscillator when exiting Stop mode. This oscillator can be used as independent kernel clock by peripherals.
0: MSIK oscillator automatically enabled when exiting Stop mode or when a CSS on HSE event occurs.
1: HSI16 oscillator automatically enabled when exiting Stop mode or when a CSS on HSE event occurs.

Bit 4 **STOPWUCK**: wake-up from Stop and CSS backup clock selection
This bit is set and cleared by software to select the system clock used when exiting Stop mode. The selected clock is also used as emergency clock for the clock security system on HSE.

*Note:* If this bit is used for CSS backup clock selection, the STOPKERWUCK bit value must be programmed with the same value than STOPWUCK to avoid the other oscillator power-on after CSS event.

*Caution:* STOPWUCK must not be modified when the CSS is enabled by HSECSSON in RCC_CR, and the system clock is HSE (SWS = 10) or a switch on HSE is requested (SW = 10).
0: MSIS oscillator selected as wake-up from stop clock and CSS backup clock
1: HSI16 oscillator selected as wake-up from stop clock and CSS backup clock

Bits 3:2 **SWS[1:0]**: system clock switch status
This bitfield is set and cleared by hardware to indicate which clock source is used as system clock.
00: MSIS oscillator used as system clock
01: HSI16 oscillator used as system clock
10: HSE used as system clock
11: PLL pll1_r_ck used as system clock
Bits 1:0  **SW[1:0]: system clock switch**

This bitfield is set and cleared by software to select system clock source (SYSCLK). It is configured by hardware to force MSIS oscillator selection when exiting Standby or Shutdown mode. This bitfield is configured by hardware to force MSIS or HSI16 oscillator selection when exiting Stop mode or in case of HSE oscillator failure, depending on STOPWUCK.

00: MSIS selected as system clock
01: HSI16 selected as system clock
10: HSE selected as system clock
11: PLL pll1_r_ck selected as system clock

**11.8.7 RCC clock configuration register 2 (RCC_CFGR2)**

Address offset: 0x020

Reset value: 0x0000 0000 (for STM32U535/545/575/585)

Reset value: 0x0000 6000 (for STM32U59x/5Ax/5Fx/5Gx)

Access: word, half-word, and byte access

From 0 to 15 wait states are inserted if the access occurs when the APB or AHB prescalers values update is on going.

| Bit 31:21 | Reserved, must be kept at reset value. |
| Bit 20 | **APB2DIS**: APB2 clock disable |
| This bit can be set in order to further reduce power consumption, when none of the APB2 peripherals are used and when their clocks are disabled in RCC_APB2ENR. When this bit is set, all APB2 peripherals clocks are off. |
| 0: APB2 clock enabled, distributed to peripherals according to their dedicated clock enable control bits |
| 1: APB2 clock disabled |

| Bit 19 | **APB1DIS**: APB1 clock disable |
| This bit can be set in order to further reduce power consumption, when none of the APB1 peripherals (except IWDG) are used and when their clocks are disabled in RCC_APB1ENR. When this bit is set, all the APB1 peripherals clocks are off, except for IWDG. |
| 0: APB1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits |
| 1: APB1 clock disabled |
Bit 18 **AHB2DIS2**: AHB2_2 clock disable
This bit can be set in order to further reduce power consumption, when none of the AHB2 peripherals from RCC_AHB2ENR2 are used and when their clocks are disabled in RCC_AHB2ENR2. When this bit is set, all the AHB2 peripherals clocks from RCC_AHB2ENR2 are off.

0: AHB2_2 clock enabled, distributed to peripherals according to their dedicated clock enable control bits
1: AHB2_2 clock disabled

Bit 17 **AHB2DIS1**: AHB2_1 clock disable
This bit can be set in order to further reduce power consumption, when none of the AHB2 peripherals from RCC_AHB2ENR1 (except SRAM2 and SRAM3) are used and when their clocks are disabled in RCC_AHB2ENR1. When this bit is set, all the AHB2 peripherals clocks from RCC_AHB2ENR1 are off, except for SRAM2 and SRAM3.

0: AHB2_1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits
1: AHB2_1 clock disabled

Bit 16 **AHB1DIS**: AHB1 clock disable
This bit can be set in order to further reduce power consumption, when none of the AHB1 peripherals (except those listed hereafter) are used and when their clocks are disabled in RCC_AHB1ENR. When this bit is set, all the AHB1 peripherals clocks are off, except for FLASH, BKPSRAM, ICACHE, DCACHE1 and SRAM1.

0: AHB1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits
1: AHB1 clock disabled

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **DPRE[2:0]**: DSI PHY prescaler
This bitfield is set and cleared by software to control the division factor of DSI PHY bus clock (DCLK).

0xx: DCLK not divided
100: DCLK divided by 2
101: DCLK divided by 4
110: DCLK divided by 8
111: DCLK divided by 16

*Note: This bitfield is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bitfield as reserved and keep it at reset value.*

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **PPRE2[2:0]**: APB2 prescaler
This bitfield is set and cleared by software to control the division factor of APB2 clock (PCLK2).

0xx: PCLK2 not divided
100: PCLK2 divided by 2
101: PCLK2 divided by 4
110: PCLK2 divided by 8
111: PCLK2 divided by 16

Bit 7 Reserved, must be kept at reset value.
Bits 6:4 **PPRE1[2:0]**: APB1 prescaler

This bitfiled is set and cleared by software to control the division factor of APB1 clock (PCLK1).

- 0xx: PCLK1 not divided
- 100: PCLK1 divided by 2
- 101: PCLK1 divided by 4
- 110: PCLK1 divided by 8
- 111: PCLK1 divided by 16

Bits 3:0 **HPRE[3:0]**: AHB prescaler

This bitfiled is set and cleared by software to control the division factor of the AHB clock (HCLK).

**Caution:** Depending on the device voltage range, the software must set these bits correctly to ensure that the system frequency does not exceed the maximum allowed frequency (for more details, refer to Table 114). After a write operation to these bits and before decreasing the voltage range, this register must be read to be sure that the new value is taken into account.

- 0xxx: SYSCLK not divided
- 1000: SYSCLK divided by 2
- 1001: SYSCLK divided by 4
- 1010: SYSCLK divided by 8
- 1011: SYSCLK divided by 16
- 1100: SYSCLK divided by 64
- 1101: SYSCLK divided by 128
- 1110: SYSCLK divided by 256
- 1111: SYSCLK divided by 512

### 11.8.8 RCC clock configuration register 3 (RCC_CFGR3)

Address offset: 0x024

Reset value: 0x0000 0000

Access: word, half-word, and byte access

From 0 to 15 wait states are inserted if the access occurs when the APB or AHB prescalers values update is on going.

Bits 31:18 Reserved, must be kept at reset value.
Bit 17 APB3DIS: APB3 clock disable
This bit can be set in order to further reduce power consumption, when none of the APB3 peripherals from RCC_APB3ENR are used and when their clocks are disabled in RCC_APB3ENR. When this bit is set, all the APB3 peripherals clocks are off.
0: APB3 clock enabled, distributed to peripherals according to their dedicated clock enable control bits
1: APB3 clock disabled

Bit 16 AHB3DIS: AHB3 clock disable
This bit can be set in order to further reduce power consumption, when none of the AHB3 peripherals (except SRAM4) are used and when their clocks are disabled in RCC_AHB3ENR. When this bit is set, all the AHB3 peripherals clocks are off, except for SRAM4.
0: AHB3 clock enabled, distributed to peripherals according to their dedicated clock enable control bits
1: AHB3 clock disabled

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 PPRE3[2:0]: APB3 prescaler
This bitfield is set and cleared by software to control the division factor of the APB3 clock (PCLK3).
0xx: HCLK not divided
100: HCLK divided by 2
101: HCLK divided by 4
110: HCLK divided by 8
111: HCLK divided by 16

Bits 3:0 Reserved, must be kept at reset value.

11.8.9 RCC PLL1 configuration register (RCC_PLL1CFGR)

PLL1MOOST[3:0] PLL1M[3:0] PLL1F RACEN PLL1RGE[1:0] PLL1SRC[1:0]

| Bit 31:19 Reserved, must be kept at reset value. |

Bit 18 PLL1REN: PLL1 DIVR divider output enable
This bit is set and reset by software to enable the pll1_r_ck output of the PLL1. To save power, PLL1RENPLL2REN and PLL1R bits must be set to 0 when pll1_r_ck is not used. This bit can be cleared only when the PLL1 is not used as SYSCLK.
0: pll1_r_ck output disabled
1: pll1_r_ck output enabled
Bit 17 **PLL1QEN**: PLL1 DIVQ divider output enable
This bit is set and reset by software to enable the pll1_q_ck output of the PLL1. To save power, PLL1QEN and PLL1Q bits must be set to 0 when pll1_q_ck is not used.
0: pll1_q_ck output disabled
1: pll1_q_ck output enabled

Bit 16 **PLL1PEN**: PLL1 DIVP divider output enable
This bit is set and reset by software to enable the pll1_p_ck output of the PLL1. To save power, PLL1PEN and PLL1P bits must be set to 0 when pll1_p_ck is not used.
0: pll1_p_ck output disabled
1: pll1_p_ck output enabled

Bits 15:12 **PLL1MBOOST[3:0]**: Prescaler for EPOD booster input clock
This bitfield is set and cleared by software to configure the prescaler of the PLL1, used for the EPOD booster. The EPOD booster input frequency is PLL1 input clock frequency/PLL1MBOOST.
This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0) and EPODboost mode is disabled (see Section 10: Power control (PWR)).
0000: division by 1 (bypass)
0001: division by 2
0010: division by 4
0011: division by 6
0100: division by 8
0101: division by 10
0110: division by 12
0111: division by 14
1000: division by 16
others: reserved

Bits 11:8 **PLL1M[3:0]**: Prescaler for PLL1
This bitfield is set and cleared by software to configure the prescaler of the PLL1. The VCO1 input frequency is PLL1 input clock frequency/PLL1M.
This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0000: division by 1 (bypass)
0001: division by 2
0010: division by 3
...
1111: division by 16

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PLL1FRACEN**: PLL1 fractional latch enable
This bit is set and reset by software to latch the content of PLL1FRACN in the ΣΔ modulator. In order to latch the PLL1FRACN value into the ΣΔ modulator, PLL1FRACEN must be set to 0, then set to 1: the transition 0 to 1 transfers the content of PLL1FRACN into the modulator (see PLL initialization phase for details).

Bits 3:2 **PLL1RGE[1:0]**: PLL1 input frequency range
This bit is set and reset by software to select the proper reference frequency range used for PLL1. It must be written before enabling the PLL1.
00-01-10: PLL1 input (ref1_ck) clock range frequency between 4 and 8 MHz
11: PLL1 input (ref1_ck) clock range frequency between 8 and 16 MHz
11.8.10 RCC PLL2 configuration register (RCC_PLL2CFGR)

Address offset: 0x02C
Reset value: 0x0000 0000
Access: no wait state; word, half-word, and byte access

</tbody>
</table>

Bits 15:12 Reserved, must be kept at reset value.
Bits 11:8 **PLL2M[3:0]**: Prescaler for PLL2
This bitfield is set and cleared by software to configure the prescaler of the PLL2. The VCO2 input frequency is PLL2 input clock frequency/PLL2M.
This bit can be written only when the PLL2 is disabled (PLL2ON = 0 and PLL2RDY = 0).
0000: division by 1 (bypass)
0001: division by 2
0010: division by 3

1111: division by 16

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PLL2FRACEN**: PLL2 fractional latch enable
This bit is set and reset by software to latch the content of PLL2FRACN in the ΣΔ modulator.
In order to latch the PLL2FRACN value into the ΣΔ modulator, PLL2FRACEN must be set to 0, then set to 1: the transition 0 to 1 transfers the content of PLL2FRACN into the modulator (see **PLL initialization phase** for details).

Bits 3:2 **PLL2RGE[1:0]**: PLL2 input frequency range
This bitfield is set and reset by software to select the proper reference frequency range used for PLL2. It must be written before enabling the PLL2.
00-01-10: PLL2 input (ref2_ck) clock range frequency between 4 and 8 MHz
11: PLL2 input (ref2_ck) clock range frequency between 8 and 16 MHz

Bits 1:0 **PLL2SRC[1:0]**: PLL2 entry clock source
This bitfield is set and cleared by software to select PLL2 clock source. It can be written only when the PLL2 is disabled. To save power, when no PLL2 is used, this bitfield value must be zero.
00: No clock sent to PLL2
01: MSIS clock selected as PLL2 clock entry
10: HSI16 clock selected as PLL2 clock entry
11: HSE clock selected as PLL2 clock entry

### 11.8.11 RCC PLL3 configuration register (RCC_PLL3CFGR)

Bits 31:19 Reserved, must be kept at reset value.
Bit 18 **PLL3REN**: PLL3 DIVR divider output enable
This bit is set and reset by software to enable the pll3_r_ck output of the PLL3. To save power, PLL3REN and PLL3R bits must be set to 0 when pll3_r_ck is not used.
0: pll3_r_ck output disabled
1: pll3_r_ck output enabled

Bit 17 **PLL3QEN**: PLL3 DIVQ divider output enable
This bit is set and reset by software to enable the pll3_q_ck output of the PLL3. To save power, PLL3QEN and PLL3Q bits must be set to 0 when pll3_q_ck is not used.
0: pll3_q_ck output disabled
1: pll3_q_ck output enabled

Bit 16 **PLL3PEN**: PLL3 DIVP divider output enable
This bit is set and reset by software to enable the pll3_p_ck output of the PLL3. To save power, PLL3PEN and PLL3P bits must be set to 0 when pll3_p_ck is not used.
0: pll3_p_ck output disabled
1: pll3_p_ck output enabled

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **PLL3M[3:0]**: Prescaler for PLL3
This bitfield is set and cleared by software to configure the prescaler of the PLL3. The VCO3 input frequency is PLL3 input clock frequency/PLL3M. This bitfield can be written only when the PLL3 is disabled (PLL3ON = 0 and PLL3RDY = 0).
0000: division by 1 (bypass)
0001: division by 2
0010: division by 3
...
1111: division by 16

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PLL3FRACEN**: PLL3 fractional latch enable
This bit is set and reset by software to latch the content of PLL3FRACN in the ΣΔ modulator. In order to latch the PLL3FRACN value into the ΣΔ modulator, PLL3FRACEN must be set to 0, then set to 1: the transition 0 to 1 transfers the content of PLL3FRACN into the modulator (see PLL initialization phase for details).

Bits 3:2 **PLL3RGE[1:0]**: PLL3 input frequency range
This bit is set and reset by software to select the proper reference frequency range used for PLL3. It must be written before enabling the PLL3.
00: PLL3 input (ref3_ck) clock range frequency between 4 and 8 MHz
01: PLL3 input (ref3_ck) clock range frequency between 8 and 16 MHz
11: PLL3 input (ref3_ck) clock range frequency between 8 and 16 MHz

Bits 1:0 **PLL3SRC[1:0]**: PLL3 entry clock source
This bitfield is set and cleared by software to select PLL3 clock source. It can be written only when the PLL3 is disabled. To save power, when no PLL3 is used, this bitfield value must be zero.
00: No clock sent to PLL3
01: MSIS clock selected as PLL3 clock entry
10: HSI16 clock selected as PLL3 clock entry
11: HSE clock selected as PLL3 clock entry
11.8.12 RCC PLL1 dividers register (RCC_PLL1DIVR)

PLL1P[6:0] PLL1N[8:0]

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 PLL1R[6:0]: PLL1 DIVR division factor
This bitfield is set and reset by software to control frequency of the pll1_r_ck clock. It can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0). Only division by one and even division factors are allowed.
0000000: pll1_r_ck = vco1_ck
0000001: pll1_r_ck = vco1_ck / 2 (default after reset)
0000010: reserved
0000011: pll1_r_ck = vco1_ck / 4
...
1111111: pll1_r_ck = vco1_ck / 128

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 PLL1Q[6:0]: PLL1 DIVQ division factor
This bitfield is set and reset by software to control the frequency of the pll1_q_ck clock. It can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0000000: pll1_q_ck = vco1_ck
0000001: pll1_q_ck = vco1_ck / 2 (default after reset)
0000010: pll1_q_ck = vco1_ck / 3
0000011: pll1_q_ck = vco1_ck / 4
...
1111111: pll1_q_ck = vco1_ck / 128

Bits 15:9 PLL1P[6:0]: PLL1 DIVP division factor
This bitfield is set and reset by software to control the frequency of the pll1_p_ck clock. It can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0000000: pll1_p_ck = vco1_ck
0000001: pll1_p_ck = vco1_ck / 2 (default after reset)
0000010: pll1_p_ck = vco1_ck / 3
0000011: pll1_p_ck = vco1_ck / 4
...
1111111: pll1_p_ck = vco1_ck / 128
Bits 8:0 **PLL1N[8:0]**: Multiplication factor for PLL1 VCO

This bitfield is set and reset by software to control the multiplication factor of the VCO. It can be written only when the PLL is disabled (PLL1ON = 0 and PLL1RDY = 0).

- 0x003: PLL1N = 4
- 0x004: PLL1N = 5
- 0x005: PLL1N = 6

... 0x080: PLL1N = 129 (default after reset)

... 0x1FF: PLL1N = 512

Others: reserved

VCO output frequency = \( F_{\text{ref1}_\text{ck}} \times \text{PLL1N} \), when fractional value 0 has been loaded in PLL1FRACN, with:

- PLL1N between 4 and 512
- input frequency \( F_{\text{ref1}_\text{ck}} \) between 4 and 16 MHz

**PLL1FRACN[12:0]**  
**Access:** read/write

Bits 31:16 Reserved, must be kept at reset value.

**Bits 15:3** **PLL1FRACN[12:0]**: Fractional part of the multiplication factor for PLL1 VCO

This bitfield is set and reset by software to control the fractional part of the VCO multiplication factor. It can be written at any time, allowing dynamic fine-tuning of the PLL1 VCO.

VCO output frequency = \( F_{\text{ref1}_\text{ck}} \times (\text{PLL1N + (PLL1FRACN / 2^{13})}) \), with:

- PLL1N must be between 4 and 512.
- PLL1FRACN can be between 0 and \( 2^{13} - 1 \).
- The input frequency \( F_{\text{ref1}_\text{ck}} \) must be between 4 and 16 MHz.

To change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

- Set PLL1FRACEN = 0.
- Write the new fractional value into PLL1FRACN.
- Set PLL1FRACEN = 1.

**Bits 2:0** Reserved, must be kept at reset value.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **PLL3FRACN[12:0]**: Fractional part of the multiplication factor for PLL3 VCO

This bitfield is set and reset by software to control the fractional part of the VCO multiplication factor. It can be written at any time, allowing dynamic fine-tuning of the PLL3 VCO.

VCO output frequency = $F_{ref3\_ck} \times (PLL3N + (PLL3FRACN / 2^{13}))$, with:

- PLL3N must be between 4 and 512.
- PLL3FRACN can be between 0 and $2^{13} - 1$.
- The input frequency $F_{ref3\_ck}$ must be between 4 and 16 MHz.

In order to change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

- Set the bit PLL3FRACEN to 0.
- Write the new fractional value into PLL3FRACN.
- Set the bit PLL3FRACEN to 1.

Bits 2:0 Reserved, must be kept at reset value.

Bits 31:13  Reserved, must be kept at reset value.

Bit 12  **SHSIRDYF**: SHSI ready interrupt flag
This bit is set by hardware when the SHSI clock becomes stable and SHSIRDYIE is set. It is cleared by software by setting the SHSIRDYC bit.
0: No clock ready interrupt caused by the SHSI oscillator
1: Clock ready interrupt caused by the SHSI oscillator
Bit 11 **MSIKRDYF**: MSIK ready interrupt flag
This bit is set by hardware when the MSIK clock becomes stable and MSIKRDYIE is set. It is cleared by software by setting the MSIKRDYC bit.
0: No clock ready interrupt caused by the MSIK oscillator
1: Clock ready interrupt caused by the MSIK oscillator

Bit 10 **CSSF**: Clock security system interrupt flag
This bit is set by hardware when a failure is detected in the HSE oscillator. It is cleared by software by setting the CSSC bit.
0: No clock security interrupt caused by HSE clock failure
1: Clock security interrupt caused by HSE clock failure

Bit 9 Reserved, must be kept at reset value.

Bit 8 **PLL3RDYF**: PLL3 ready interrupt flag
This bit is set by hardware when the PLL3 locks and PLL3RDYIE is set. It is cleared by software by setting the PLL3RDYC bit.
0: No clock ready interrupt caused by PLL3 lock
1: Clock ready interrupt caused by PLL3 lock

Bit 7 **PLL2RDYF**: PLL2 ready interrupt flag
This bit is set by hardware when the PLL2 locks and PLL2RDYIE is set. It is cleared by software by setting the PLL2RDYC bit.
0: No clock ready interrupt caused by PLL2 lock
1: Clock ready interrupt caused by PLL2 lock

Bit 6 **PLL1RDYF**: PLL1 ready interrupt flag
This bit is set by hardware when the PLL1 locks and PLL1RDYIE is set. It is cleared by software by setting the PLL1RDYC bit.
0: No clock ready interrupt caused by PLL1 lock
1: Clock ready interrupt caused by PLL1 lock

Bit 5 **HSI48RDYF**: HSI48 ready interrupt flag
This bit is set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set. It is cleared by software by setting the HSI48RDYC bit.
0: No clock ready interrupt caused by the HSI48 oscillator
1: Clock ready interrupt caused by the HSI48 oscillator

Bit 4 **HSERDYF**: HSE ready interrupt flag
This bit is set by hardware when the HSE clock becomes stable and HSERDYIE is set. It is cleared by software by setting the HSERDYC bit.
0: No clock ready interrupt caused by the HSE oscillator
1: Clock ready interrupt caused by the HSE oscillator

Bit 3 **HSIRDYF**: HSI16 ready interrupt flag
This bit is set by hardware when the HSI16 clock becomes stable and HSIRDYIE = 1 in response to setting the HSION (see RCC_CR). When HSION = 0 but the HSI16 oscillator is enabled by the peripheral through a clock request, this bit is not set and no interrupt is generated. This bit is cleared by software by setting the HSIRDYC bit.
0: No clock ready interrupt caused by the HSI16 oscillator
1: Clock ready interrupt caused by the HSI16 oscillator

Bit 2 **MSISRDYF**: MSIS ready interrupt flag
This bit is set by hardware when the MSIS clock becomes stable and MSISRDYIE is set. It is cleared by software by setting the MSISRDYC bit.
0: No clock ready interrupt caused by the MSIS oscillator
1: Clock ready interrupt caused by the MSIS oscillator
Bit 1 **LSERDYF**: LSE ready interrupt flag
This bit is set by hardware when the LSE clock becomes stable and LSERDYIE is set. It is cleared by software by setting the LSERDYC bit.
0: No clock ready interrupt caused by the LSE oscillator
1: Clock ready interrupt caused by the LSE oscillator

Bit 0 **LSIRDYF**: LSI ready interrupt flag
This bit is set by hardware when the LSI clock becomes stable and LSIRDYIE is set. It is cleared by software by setting the LSIRDYC bit.
0: No clock ready interrupt caused by the LSI oscillator
1: Clock ready interrupt caused by the LSI oscillator

Bits 31:13 Reserved, must be kept at reset value.

- **Bit 12** **SHSIRDYC**: SHSI oscillator ready interrupt clear
  Writing this bit to 1 clears the SHSIRDYF flag. Writing 0 has no effect.

- **Bit 11** **MSIKRDYC**: MSIK oscillator ready interrupt clear
  Writing this bit to 1 clears the MSIKRDYF flag. Writing 0 has no effect.

- **Bit 10** **CSSC**: Clock security system interrupt clear
  Writing this bit to 1 clears the CSSF flag. Writing 0 has no effect.

- **Bit 9** Reserved, must be kept at reset value.

- **Bit 8** **PLL3RDYC**: PLL3 ready interrupt clear
  Writing this bit to 1 clears the PLL3RDYF flag. Writing 0 has no effect.

- **Bit 7** **PLL2RDYC**: PLL2 ready interrupt clear
  Writing this bit to 1 clears the PLL2RDYF flag. Writing 0 has no effect.

- **Bit 6** **PLL1RDYC**: PLL1 ready interrupt clear
  Writing this bit to 1 clears the PLL1RDYF flag. Writing 0 has no effect.

- **Bit 5** **HSI48RDYC**: HSI48 ready interrupt clear
  Writing this bit to 1 clears the HSI48RDYF flag. Writing 0 has no effect.

- **Bit 4** **HSERDYC**: HSE ready interrupt clear
  Writing this bit to 1 clears the HSERDYF flag. Writing 0 has no effect.

- **Bit 3** **HSIRDYC**: HSI16 ready interrupt clear
  Writing this bit to 1 clears the HSIRDYF flag. Writing 0 has no effect.

Bit 17 **RAMCFGRST**: RAMCFG reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the RAMCFG.

Bit 16 **TSCRST**: TSC reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the TSC.

Bit 15 **JPEGRST**: JPEG reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the JPEG.

   *Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **CRCRST**: CRC reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the CRC.

Bits 11:4 Reserved, must be kept at reset value.

Bit 3 **MDF1RST**: MDF1 reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the MDF1.

Bit 2 **FMACRST**: FMAC reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the FMAC.

Bit 1 **CORDICRST**: CORDIC reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the CORDIC.

Bit 0 **GPDMA1RST**: GPDMA1 reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the GPDMA1.

</table>
Bit 21 **OCTOSPIMRST**: OCTOSPIM reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the OCTOSPIM.
   \*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 20 **SAESRST**: SAES hardware accelerator reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the SAES.
   \*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 19 **PKARST**: PKA reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the PKA.
   \*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 18 **RNGRST**: RNG reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the RNG.

Bit 17 **HASHRST**: HASH reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the HASH.

Bit 16 **AESRST**: AES hardware accelerator reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the AES.
   \*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **OTGRST**: OTG_FS or OTG_HS reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the OTG_FS or OTG_HS.
   \*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 13 Reserved, must be kept at reset value.
Bit 12 **DCMI_PSSIRST**: DCMI and PSSI reset
This bit is set and cleared by software.
0: No effect
1: Reset the DCMI and PSSI.

Bit 11 Reserved, must be kept at reset value.

Bit 10 **ADC12RST**: ADC1 and ADC2 reset
This bit is set and cleared by software.
0: No effect
1: Reset the ADC1 and ADC2.

*Note: This bit impacts ADC1 in STM32U535/545/575/585, and ADC1/ADC2 in STM32U59x/5Ax/5Fx/5Gx.*

Bit 9 **GPIOJRST**: I/O port J reset
This bit is set and cleared by software.
0: No effect
1: Reset the I/O port J.

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 8 **GPIOIRST**: I/O port I reset
This bit is set and cleared by software.
0: No effect
1: Reset the I/O port I.

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 7 **GPIOHRST**: I/O port H reset
This bit is set and cleared by software.
0: No effect
1: Reset the I/O port H.

Bit 6 **GPIOGRST**: I/O port G reset
This bit is set and cleared by software.
0: No effect
1: Reset the I/O port G.

Bit 5 **GPIOFRST**: I/O port F reset
This bit is set and cleared by software.
0: No effect
1: Reset I/O port F

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 4 **GPIOERST**: I/O port E reset
This bit is set and cleared by software.
0: No effect
1: Reset the I/O port E.

Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **DSIRST**: DSI reset
This bit is set and cleared by software.
0: No effect
1: Reset the DSI.

**Note:** This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 26  **LTDCRST**: LTDC reset
This bit is set and cleared by software.
0: No effect
1: Reset the LTDC.

**Note:** This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 25  **GFXTIMRST**: GFXTIM reset
This bit is set and cleared by software.
0: No effect
1: Reset the GFXTIM.

**Note:** This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.
Bit 24 **USBRST**: USB reset
This bit is set and cleared by software.
0: No effect
1: Reset the USB.

*Note:* This bit is only available on STM32U535/545 devices, it is reserved on other devices in the STM32U5 Series. If not present, consider this bit as reserved and keep it at reset value.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **SAI2RST**: SAI2 reset
This bit is set and cleared by software.
0: No effect
1: Reset the SAI2.

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 21 **SAI1RST**: SAI1 reset
This bit is set and cleared by software.
0: No effect
1: Reset the SAI1.

Bits 20:19 Reserved, must be kept at reset value.

Bit 18 **TIM17RST**: TIM17 reset
This bit is set and cleared by software.
0: No effect
1: Reset the TIM17.

Bit 17 **TIM16RST**: TIM16 reset
This bit is set and cleared by software.
0: No effect
1: Reset the TIM16.

Bit 16 **TIM15RST**: TIM15 reset
This bit is set and cleared by software.
0: No effect
1: Reset the TIM15.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **USART1RST**: USART1 reset
This bit is set and cleared by software.
0: No effect
1: Reset the USART1.

Bit 13 **TIM8RST**: TIM8 reset
This bit is set and cleared by software.
0: No effect
1: Reset the TIM8.

Bit 12 **SPI1RST**: SPI1 reset
This bit is set and cleared by software.
0: No effect
1: Reset the SPI1.
Bit 11  **TIM1RST**: TIM1 reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset the TIM1.

Bits 10:0  Reserved, must be kept at reset value.

## 11.8.28  RCC APB3 peripheral reset register (RCC_APB3RSTR)

Address offset: 0x080  
Reset value: 0x0000 0000  
Access: no wait state; word, half-word, and byte access

Bits 31:21  Reserved, must be kept at reset value.

Bit 20  **VREFRST**: VREFBUF reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset the VREFBUF.

Bits 19:16  Reserved, must be kept at reset value.

Bit 15  **COMPRST**: COMP reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset the COMP.

Bit 14  **OPAMPRST**: OPAMP reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset the OPAMP.

Bit 13  **LPTIM4RST**: LPTIM4 reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset the LPTIM4.

Bit 12  **LPTIM3RST**: LPTIM3 reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset the LPTIM3.

Bit 11  **LPTIM1RST**: LPTIM1 reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset the LPTIM1.
Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **I2C3RST**: I2C3 reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the I2C3.

Bit 6 **LPUART1RST**: LPUART1 reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the LPUART1.

Bit 5 **SPI3RST**: SPI3 reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the SPI3.

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **SYSCFRGRT**: SYSCFG reset
   This bit is set and cleared by software.
   0: No effect
   1: Reset the SYSCFG.

Bit 0 Reserved, must be kept at reset value.

### 11.8.29 RCC AHB1 peripheral clock enable register (RCC_AHB1ENR)

Address offset: 0x088

Reset value: 0xD000 0100 (for STM32U535/545/575/585)

Reset value: 0xD020 0100 (for STM32U59x/5Ax/5Fx/5Gx)

Access: no wait state; word, half-word, and byte access

*Note:* When the peripheral clock is not active, read or write access to peripheral registers is not supported.

```
  31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16

```

Bit 31 **SRAM1EN**: SRAM1 clock enable
   This bit is set and reset by software.
   0: SRAM1 clock disabled
   1: SRAM1 clock enabled
Reset and clock control (RCC)

Bit 30 **DCACHE1EN**: DCACHE1 clock enable
This bit is set and reset by software.
0: DCACHE1 clock disabled
1: DCACHE1 clock enabled

*Note: DCACHE1 clock must be enabled when external memories are accessed through OCTOSPI1, OCTOSPI2, HSPI1 or FSMC, even if the DCACHE1 is bypassed.*

Bit 29 Reserved, must be kept at reset value.

Bit 28 **BKPSRAMEN**: BKPSRAM clock enable
This bit is set and reset by software.
0: BKPSRAM clock disabled
1: BKPSRAM clock enabled

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **GTZC1EN**: GTZC1 clock enable
This bit is set and reset by software.
0: GTZC1 clock disabled
1: GTZC1 clock enabled

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **DCACHE2EN**: DCACHE2 clock enable
This bit is set and reset by software.
0: DCACHE2 clock disabled
1: DCACHE2 clock enabled

*Note: DCACHE2 clock must be enabled to access memories, even if the DCACHE2 is bypassed.*

This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 20 **GPU2DEN**: GPU2D clock enable
This bit is set and cleared by software.
0: GPU2D clock disabled
1: GPU2D clock enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 19 **GFXMMUEN**: GFXMMU clock enable
This bit is set and cleared by software.
0: GFXMMU clock disabled
1: GFXMMU clock enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 18 **DMA2DEN**: DMA2D clock enable
This bit is set and cleared by software.
0: DMA2D clock disabled
1: DMA2D clock enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 31 **SRAM3EN**: SRAM3 clock enable
- This bit is set and reset by software.
- 0: SRAM3 clock disabled
- 1: SRAM3 clock enabled

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 30 **SRAM2EN**: SRAM2 clock enable
- This bit is set and reset by software.
- 0: SRAM2 clock disabled
- 1: SRAM2 clock enabled

Bit 29 Reserved, must be kept at reset value.

Bit 28 **SDMMC2EN**: SDMMC2 clock enable
- This bit is set and cleared by software.
- 0: SDMMC2 clock disabled
- 1: SDMMC2 clock enabled

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 27 **SDMMC1EN**: SDMMC1 clock enable
- This bit is set and cleared by software.
- 0: SDMMC1 clock disabled
- 1: SDMMC1 clock enabled

Bits 26:25 Reserved, must be kept at reset value.
Bit 24 **OTFDEC2EN**: OTFDEC2 clock enable
This bit is set and cleared by software.
0: OTFDEC2 clock disabled
1: OTFDEC2 clock enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 23 **OTFDEC1EN**: OTFDEC1 clock enable
This bit is set and cleared by software.
0: OTFDEC1 clock disabled
1: OTFDEC1 clock enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 22 Reserved, must be kept at reset value.

Bit 21 **OCTOPI""""MEN**: OCTOPI""""M clock enable
This bit is set and cleared by software.
0: OCTOPI""""M clock disabled
1: OCTOPI""""M clock enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 20 **SAESEN**: SAES clock enable
This bit is set and cleared by software.
0: SAES clock disabled
1: SAES clock enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 19 **PKAEN**: PKA clock enable
This bit is set and cleared by software.
0: PKA clock disabled
1: PKA clock enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 18 **RNGEN**: RNG clock enable
This bit is set and cleared by software.
0: RNG clock disabled
1: RNG clock enabled

Bit 17 **HASHEN**: HASH clock enable
This bit is set and cleared by software
0: HASH clock disabled
1: HASH clock enabled
Bit 16 **AES**: AES clock enable

This bit is set and cleared by software.

0: AES clock disabled
1: AES clock enabled

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 15 **OTG**: OTG clock enable

This bit is set and cleared by software.

0: OTG clock disabled
1: OTG clock enabled

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 14 **OTGEN**: OTG clock enable

This bit is set and cleared by software.

0: OTG clock disabled
1: OTG clock enabled

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **DCMI_PSSIEN**: DCMI and PSSI clock enable

This bit is set and cleared by software.

0: DCMI and PSSI clock disabled
1: DCMI and PSSI clock enabled

Bit 11 Reserved, must be kept at reset value.

Bit 10 **ADC12EN**: ADC1 and ADC2 clock enable

This bit is set and cleared by software.

0: ADC1 and ADC2 clock disabled
1: ADC1 and ADC2 clock enabled

*Note:* This bit impacts ADC1 in STM32U535/545/575/585, and ADC1/ADC2 in STM32U59x/5Ax/5Fx/5Gx.

Bit 9 **GPIOJ**: I/O port J clock enable

This bit is set and cleared by software.

0: I/O port J clock disabled
1: I/O port J clock enabled

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 8 **GPIOI**: I/O port I clock enable

This bit is set and cleared by software.

0: I/O port I clock disabled
1: I/O port I clock enabled

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.
Bit 7  **GPIOHEN**: I/O port H clock enable
This bit is set and cleared by software.
0: I/O port H clock disabled
1: I/O port H clock enabled

Bit 6  **GPIOGEN**: I/O port G clock enable
This bit is set and cleared by software.
0: I/O port G clock disabled
1: I/O port G clock enabled

Bit 5  **GPIOFEN**: I/O port F clock enable
This bit is set and cleared by software.
0: I/O port F clock disabled
1: I/O port F clock enabled

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 4  **GPIOEEN**: I/O port E clock enable
This bit is set and cleared by software.
0: I/O port E clock disabled
1: I/O port E clock enabled

Bit 3  **GPIODEN**: I/O port D clock enable
This bit is set and cleared by software.
0: I/O port D clock disabled
1: I/O port D clock enabled

Bit 2  **GPIOCEN**: I/O port C clock enable
This bit is set and cleared by software.
0: I/O port C clock disabled
1: I/O port C clock enabled

Bit 1  **GPIOBEN**: I/O port B clock enable
This bit is set and cleared by software.
0: I/O port B clock disabled
1: I/O port B clock enabled

Bit 0  **GPIOAEN**: I/O port A clock enable
This bit is set and cleared by software.
0: I/O port A clock disabled
1: I/O port A clock enabled
11.8.31 RCC AHB2 peripheral clock enable register 2 (RCC_AHB2ENR2)

Address offset: 0x090
Reset value: 0x0000 0000 (for STM32U535/545/575/585)
Reset value: 0x8000 0000 (for STM32U59x/5Ax)
Reset value: 0xC000 0000 (for STM32U5Fx/5Gx)

Access: no wait state; word, half-word, and byte access

Note: When the peripheral clock is not active, read or write access to peripheral registers is not supported.

Bit 31 **SRAM5EN**: SRAM5 clock enable
This bit is set and reset by software.
0: SRAM5 clock disabled
1: SRAM5 clock enabled

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 30 **SRAM6EN**: SRAM6 clock enable
This bit is set and reset by software.
0: SRAM6 clock disabled
1: SRAM6 clock enabled

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bits 29:13 Reserved, must be kept at reset value.

Bit 12 **HSPI1EN**: HSPI1 clock enable
This bit is set and cleared by software.
0: HSPI1 clock disabled
1: HSPI1 clock enabled

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bits 11:9 Reserved, must be kept at reset value.
Bit 8 **OCTOSPI2EN**: OCTOSPI2 clock enable
This bit is set and cleared by software.
0: OCTOSPI2 clock disabled
1: OCTOSPI2 clock enabled

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **OCTOSPI1EN**: OCTOSPI1 clock enable
This bit is set and cleared by software.
0: OCTOSPI1 clock disabled
1: OCTOSPI1 clock enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **FSMCEN**: FSMC clock enable
This bit is set and cleared by software.
0: FSMC clock disabled
1: FSMC clock enabled

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

### 11.8.32 RCC AHB3 peripheral clock enable register (RCC_AHB3ENR)

Address offset: 0x094

Reset value: 0x8000 0000

Access: no wait state; word, half-word, and byte access

*Note:* When the peripheral clock is not active, read or write access to peripheral registers is not supported.

### 11.8.34 RCC APB1 peripheral clock enable register 2 (RCC_APB1ENR2)

Address offset: 0x0A0
Reset value: 0x0000 0000
Access: no wait state; word, half-word, and byte access

*Note: When the peripheral clock is not active, read or write access to peripheral registers is not supported.*
Bits 31:24  Reserved, must be kept at reset value.

Bit 23 **UCPD1EN**: UCPD1 clock enable
This bit is set and cleared by software.
0: UCPD1 clock disabled
1: UCPD1 clock enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bits 22:10  Reserved, must be kept at reset value.

Bit 9 **FDcan1EN**: FDCAN1 clock enable
This bit is set and cleared by software.
0: FDCAN1 clock disabled
1: FDCAN1 clock enabled

Bit 8 Reserved, must be kept at reset value.

Bit 7 **I2C6EN**: I2C6 clock enable
This bit is set and cleared by software.
0: I2C6 clock disabled
1: I2C6 clock enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 6 **I2C5EN**: I2C5 clock enable
This bit is set and cleared by software.
0: I2C5 clock disabled
1: I2C5 clock enabled

*Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 5 **LPTIM2EN**: LPTIM2 clock enable
This bit is set and cleared by software.
0: LPTIM2 clock disabled
1: LPTIM2 clock enabled

Bits 4:2  Reserved, must be kept at reset value.

Bit 1 **I2C4EN**: I2C4 clock enable
This bit is set and cleared by software.
0: I2C4 clock disabled
1: I2C4 clock enabled

Bit 0 Reserved, must be kept at reset value.
11.8.35  **RCC APB2 peripheral clock enable register (RCC_APB2ENR)**

Address offset: 0x0A4
Reset value: 0x0000 0000
Access: word, half-word, and byte access

*Note:* When the peripheral clock is not active, read or write access to peripheral registers is not supported.

### 11.8.37 RCC AHB1 peripheral clock enable in Sleep and Stop modes register (RCC_AHB1SMENR)

Address offset: 0x0B0

Reset value: 0xFFFF FFFF

Access: no wait state, word, half-word, and byte access

This register only configures the clock gating, not the clock source itself. When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests the AHB or APB clock (refer to Section 11.4.24).

<table>

0: BKPSRAM clocks disabled by the clock gating during Sleep and Stop modes
1: BKPSRAM clocks enabled by the clock gating during Sleep and Stop modes

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **GTZC1SMEN**: GTZC1 clock enable during Sleep and Stop modes
0: GTZC1 clocks disabled by the clock gating during Sleep and Stop modes
1: GTZC1 clocks enabled by the clock gating during Sleep and Stop modes

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **DCACHE2SMEN**: DCACHE2 clock enable during Sleep and Stop modes
0: DCACHE2 clocks disabled by the clock gating during Sleep and Stop modes
1: DCACHE2 clocks enabled by the clock gating during Sleep and Stop modes

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 20 **GPU2DSMEN**: GPU2D clock enable during Sleep and Stop modes
0: GPU2D clocks disabled by the clock gating during Sleep and Stop modes
1: GPU2D clocks enabled by the clock gating during Sleep and Stop modes

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 19 **GFXMUSMEN**: GFXMMU clock enable during Sleep and Stop modes
0: GFXMMU clocks disabled by the clock gating during Sleep and Stop modes
1: GFXMMU clocks enabled by the clock gating during Sleep and Stop modes

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 18 **DMA2DSMEN**: DMA2D clock enable during Sleep and Stop modes
0: DMA2D clocks disabled by the clock gating during Sleep and Stop modes
1: DMA2D clocks enabled by the clock gating during Sleep and Stop modes

Note: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.
Bit 17 **RAMCFGSMEN**: RAMCFG clock enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: RAMCFG clocks disabled by the clock gating during Sleep and Stop modes
   1: RAMCFG clocks enabled by the clock gating during Sleep and Stop modes

Bit 16 **TSCSMEN**: TSC clocks enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: TSC clocks disabled by the clock gating during Sleep and Stop modes
   1: TSC clocks enabled by the clock gating during Sleep and Stop modes

Bit 15 **JPEGSMEN**: JPEG clocks enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: JPEG clocks disabled by the clock gating during Sleep and Stop modes
   1: JPEG clocks enabled by the clock gating during Sleep and Stop modes

   **Note**: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **CRCSMEN**: CRC clocks enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: CRC clocks disabled by the clock gating during Sleep and Stop modes
   1: CRC clocks enabled by the clock gating during Sleep and Stop modes

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLASHSMEN**: FLASH clocks enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: FLASH clocks disabled by the clock gating during Sleep and Stop modes
   1: FLASH clocks enabled by the clock gating during Sleep and Stop modes

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **MDF1SMEN**: MDF1 clocks enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: MDF1 clocks disabled by the clock gating during Sleep and Stop modes
   1: MDF1 clocks enabled by the clock gating during Sleep and Stop modes

   **Note**: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 2 **FMACSMEN**: FMAC clocks enable during Sleep and Stop modes.
   This bit is set and cleared by software.
   0: FMAC clocks disabled by the clock gating during Sleep and Stop modes
   1: FMAC clocks enabled by the clock gating during Sleep and Stop modes

Bit 1 **CORDICSMEN**: CORDIC clocks enable during Sleep and Stop modes
   This bit is set and cleared by software during Sleep mode.
   0: CORDIC clocks disabled by the clock gating during Sleep and Stop modes
   1: CORDIC clocks enabled by the clock gating during Sleep and Stop modes

Bit 0 **GPDMA1SMEN**: GPDMA1 clocks enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: GPDMA1 clocks disabled by the clock gating during Sleep and Stop modes
   1: GPDMA1 clocks enabled by the clock gating during Sleep and Stop modes

   **Note**: This bit must be set to allow the peripheral to wake up from Stop modes.
11.8.38  RCC AHB2 peripheral clock enable in Sleep and Stop modes register 1 (RCC_AHB2SMENR1)

Address offset: 0x0B4

Reset value: 0xFFFF FFFF

Access: no wait state; word, half-word, and byte access

This register only configures the clock gating, not the clock source itself. When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests the AHB or APB clock (refer to Section 11.4.24).

Bit 24 **OTFDEC2SMEN**: OTFDEC2 clock enable during Sleep and Stop modes
This bit is set and cleared by software.
0: OTFDEC2 clocks disabled by the clock gating during Sleep and Stop modes
1: OTFDEC2 clocks enabled by the clock gating during Sleep and Stop modes

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 23 **OTFDEC1SMEN**: OTFDEC1 clock enable during Sleep and Stop modes
This bit is set and cleared by software.
0: OTFDEC1 clocks disabled by the clock gating during Sleep and Stop modes
1: OTFDEC1 clocks enabled by the clock gating during Sleep and Stop modes

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 22 Reserved, must be kept at reset value.

Bit 21 **OCTOSPIMSMEN**: OCTOSPIM clock enable during Sleep and Stop modes
This bit is set and cleared by software.
0: OCTOSPIM clocks disabled by the clock gating during Sleep and Stop modes
1: OCTOSPIM clocks enabled by the clock gating during Sleep and Stop modes

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 20 **SAESSMEN**: SAES accelerator clock enable during Sleep and Stop modes
This bit is set and cleared by software.
0: SAES clocks disabled by the clock gating during Sleep and Stop modes
1: SAES clocks enabled by the clock gating during Sleep and Stop modes

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 19 **PKASMEN**: PKA clock enable during Sleep and Stop modes
This bit is set and cleared by software.
0: PKA clocks disabled by the clock gating during Sleep and Stop modes
1: PKA clocks enabled by the clock gating during Sleep and Stop modes

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 18 **RNGSMEN**: RNG clock enable during Sleep and Stop modes
This bit is set and cleared by software.
0: RNG clocks disabled by the clock gating during Sleep and Stop modes
1: RNG clocks enabled by the clock gating during Sleep and Stop modes

Bit 17 **HASHSMEN**: HASH clock enable during Sleep and Stop modes
This bit is set and cleared by software.
0: HASH clocks disabled by the clock gating during Sleep and Stop modes
1: HASH clocks enabled by the clock gating during Sleep and Stop modes
**Bit 16 AESSMEN**: AES clock enable during Sleep and Stop modes
   This bit is set and cleared by software
   0: AES clocks disabled by the clock gating during Sleep and Stop modes
   1: AES clocks enabled by the clock gating during Sleep and Stop modes
   *Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

**Bit 15 OTGSPHYMEN**: OTG_HS PHY clock enable during Sleep and Stop modes
   This bit is set and cleared by software
   0: OTG_HS PHY clocks disabled by the clock gating during Sleep and Stop modes
   1: OTG_HS PHY clocks enabled by the clock gating during Sleep and Stop modes
   *Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

**Bit 14 OTGSMEN**: OTG_FS and OTG_HS clocks enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: OTG_FS and OTG_HS clocks disabled by the clock gating during Sleep and Stop modes
   1: OTG_FS and OTG_HS clocks enabled by the clock gating during Sleep and Stop modes
   *Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

**Bit 13 Reserved, must be kept at reset value.**

**Bit 12 DCMI_PSSISMEN**: DCMI and PSSI clock enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: DCMI and PSSI clocks disabled by the clock gating during Sleep and Stop modes
   1: DCMI and PSSI clocks enabled by the clock gating during Sleep and Stop modes

**Bit 11 Reserved, must be kept at reset value.**

**Bit 10 ADC12SMEN**: ADC1 and ADC2 clock enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: ADC1 and ADC2 clocks disabled by the clock gating during Sleep and Stop modes
   1: ADC1 and ADC2 clocks enabled by the clock gating during Sleep and Stop modes
   *Note*: This bit impacts ADC1 in STM32U535/545/575/585 and ADC1/ADC2 in STM32U59x/5Ax/5Fx/5Gx.

**Bit 9 GPIOJSMEN**: I/O port J clock enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: I/O port J clocks disabled by the clock gating during Sleep and Stop modes
   1: I/O port J clocks enabled by the clock gating during Sleep and Stop modes
   *Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

**Bit 8 GPIOISMEN**: I/O port I clocks enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: I/O port I clocks disabled by the clock gating during Sleep and Stop modes
   1: I/O port I clocks enabled by the clock gating during Sleep and Stop modes
   *Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.
Bit 7  **GPIOHSMEN**: I/O port H clocks enable during Sleep and Stop modes
This bit is set and cleared by software.
0: I/O port H clocks disabled by the clock gating during Sleep and Stop modes
1: I/O port H clocks enabled by the clock gating during Sleep and Stop modes

Bit 6  **GPIOGSMEN**: I/O port G clocks enable during Sleep and Stop modes
This bit is set and cleared by software.
0: I/O port G clocks disabled by the clock gating during Sleep and Stop modes
1: I/O port G clocks enabled by the clock gating during Sleep and Stop modes

Bit 5  **GPIOFSMEN**: I/O port F clocks enable during Sleep and Stop modes
This bit is set and cleared by software.
0: I/O port F clocks disabled by the clock gating during Sleep and Stop modes
1: I/O port F clocks enabled by the clock gating during Sleep and Stop modes

*Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 4  **GPIOESMEN**: I/O port E clocks enable during Sleep and Stop modes
This bit is set and cleared by software.
0: I/O port E clocks disabled by the clock gating during Sleep and Stop modes
1: I/O port E clocks enabled by the clock gating during Sleep and Stop modes

Bit 3  **GPIODSMEN**: I/O port D clocks enable during Sleep and Stop modes
This bit is set and cleared by software.
0: I/O port D clocks disabled by the clock gating during Sleep and Stop modes
1: I/O port D clocks enabled by the clock gating during Sleep and Stop modes

Bit 2  **GPIOCSMEN**: I/O port C clocks enable during Sleep and Stop modes
This bit is set and cleared by software.
0: I/O port C clocks disabled by the clock gating during Sleep and Stop modes
1: I/O port C clocks enabled by the clock gating during Sleep and Stop modes

Bit 1  **GPIOBSMEN**: I/O port B clocks enable during Sleep and Stop modes
This bit is set and cleared by software.
0: I/O port B clocks disabled by the clock gating during Sleep and Stop modes
1: I/O port B clocks enabled by the clock gating during Sleep and Stop modes

Bit 0  **GPIOASMEN**: I/O port A clocks enable during Sleep and Stop modes
This bit is set and cleared by software.
0: I/O port A clocks disabled by the clock gating during Sleep and Stop modes
1: I/O port A clocks enabled by the clock gating during Sleep and Stop modes
11.8.39 RCC AHB2 peripheral clock enable in Sleep and Stop modes register 2 (RCC_AHB2SMENR2)

Address offset: 0x0B8
Reset value: 0xFFFF FFFF
Access: no wait state; word, half-word and byte access

This register only configures the clock gating, not the clock source itself.

When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests AHB or APB clock (refer to Section 11.4.24).

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **USART6SMEN**: USART6 clock enable during Sleep and Stop modes

This bit is set and cleared by software.

0: USART6 clocks disabled by the clock gating during Sleep and Stop modes
1: USART6 clocks enabled by the clock gating during Sleep and Stop modes

*Note*: This bit must be set to allow the peripheral to wake up from Stop modes.

This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 24 **CRSSMEN**: CRS clock enable during Sleep and Stop modes

This bit is set and cleared by software.

0: CRS clocks disabled by the clock gating during Sleep and Stop modes
1: CRS clocks enabled by the clock gating during Sleep and Stop modes

Bit 23 Reserved, must be kept at reset value.

Bit 22 **I2C2S SMEN**: I2C2 clock enable during Sleep and Stop modes

This bit is set and cleared by software.

0: I2C2 clocks disabled by the clock gating during Sleep and Stop modes
1: I2C2 clocks enabled by the clock gating during Sleep and Stop modes

*Note*: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 21 **I2C1SMEN**: I2C1 clock enable during Sleep and Stop modes

This bit is set and cleared by software.

0: I2C1 clocks disabled by the clock gating during Sleep and Stop modes
1: I2C1 clocks enabled by the clock gating during Sleep and Stop modes

*Note*: This bit must be set to allow the peripheral to wake up from Stop modes.
Bit 20  **UART5SMEN**: UART5 clock enable during Sleep and Stop modes
       This bit is set and cleared by software.
       0: UART5 clocks disabled by the clock gating during Sleep and Stop modes
       1: UART5 clocks enabled by the clock gating during Sleep and Stop modes
       *Note*: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 19  **UART4SMEN**: UART4 clock enable during Sleep and Stop modes
       This bit is set and cleared by software.
       0: UART4 clocks disabled by the clock gating during Sleep and Stop modes
       1: UART4 clocks enabled by the clock gating during Sleep and Stop modes
       *Note*: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 18  **USART3SMEN**: USART3 clock enable during Sleep and Stop modes
       This bit is set and cleared by software.
       0: USART3 clocks disabled by the clock gating during Sleep and Stop modes
       1: USART3 clocks enabled by the clock gating during Sleep and Stop modes
       *Note*: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 17  **USART2SMEN**: USART2 clock enable during Sleep and Stop modes
       This bit is set and cleared by software.
       0: USART2 clocks disabled by the clock gating during Sleep and Stop modes
       1: USART2 clocks enabled by the clock gating during Sleep and Stop modes
       *Note*: This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bits 16:15 Reserved, must be kept at reset value.

Bit 14  **SPI2SMEN**: SPI2 clock enable during Sleep and Stop modes
       This bit is set and cleared by software.
       0: SPI2 clocks disabled by the clock gating during Sleep and Stop modes
       1: SPI2 clocks enabled by the clock gating during Sleep and Stop modes
       *Note*: This bit must be set to allow the peripheral to wake up from Stop modes.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11  **WWDGSMEN**: Window watchdog clock enable during Sleep and Stop modes
       This bit is set and cleared by software. It is forced to one by hardware when the hardware WWDG option is activated.
       0: Window watchdog clocks disabled by the clock gating during Sleep and Stop modes
       1: Window watchdog clocks enabled by the clock gating during Sleep and Stop modes

Bits 10:6 Reserved, must be kept at reset value.

Bit 5  **TIM7SMEN**: TIM7 clock enable during Sleep and Stop modes
       This bit is set and cleared by software.
       0: TIM7 clocks disabled by the clock gating during Sleep and Stop modes
       1: TIM7 clocks enabled by the clock gating during Sleep and Stop modes

Bit 4  **TIM6SMEN**: TIM6 clock enable during Sleep and Stop modes
       This bit is set and cleared by software.
       0: TIM6 clocks disabled by the clock gating during Sleep and Stop modes
       1: TIM6 clocks enabled by the clock gating during Sleep and Stop modes
Bit 3  **TIM5SMEN**: TIM5 clock enable during Sleep and Stop modes
This bit is set and cleared by software.
0: TIM5 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM5 clocks enabled by the clock gating during Sleep and Stop modes

Bit 2  **TIM4SMEN**: TIM4 clock enable during Sleep and Stop modes
This bit is set and cleared by software.
0: TIM4 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM4 clocks enabled by the clock gating during Sleep and Stop modes

Bit 1  **TIM3SMEN**: TIM3 clock enable during Sleep and Stop modes
This bit is set and cleared by software.
0: TIM3 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM3 clocks enabled by the clock gating during Sleep and Stop modes

Bit 0  **TIM2SMEN**: TIM2 clock enable during Sleep and Stop modes
This bit is set and cleared by software.
0: TIM2 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM2 clocks enabled by the clock gating during Sleep and Stop modes

### 11.8.42  RCC APB1 peripheral clocks enable in Sleep and Stop modes register 2 (RCC_APB1SMENR2)

Address offset: 0x0C8
Reset value: 0xFFFF FFFF
Access: no wait state; word, half-word, and byte access

This register only configures the clock gating, not the clock source itself. When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests the AHB or APB clock (refer to Section 11.4.24).

Bits 31:24  Reserved, must be kept at reset value.

Bit 23  **UCPD1SMEN**: UCPD1 clock enable during Sleep and Stop modes
This bit is set and cleared by software.
0: UCPD1 clocks disabled by the clock gating during Sleep and Stop modes
1: UCPD1 clocks enabled by the clock gating during Sleep and Stop modes

**Note:** This bit is only available on some devices in the STM32U6 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bits 22:10  Reserved, must be kept at reset value.
Bit 9  **FDCAN1SMEN**: FDCAN1 clock enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: FDCAN1 clocks disabled by the clock gating during Sleep and Stop modes
   1: FDCAN1 clocks enabled by the clock gating during Sleep and Stop modes

Bit 8  Reserved, must be kept at reset value.

Bit 7  **I2C6SMEN**: I2C6 clock enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: I2C6 clocks disabled by the clock gating during Sleep and Stop modes
   1: I2C6 clocks enabled by the clock gating during Sleep and Stop modes
   *Note*:  This bit must be set to allow the peripheral to wake up from Stop modes.
   *This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 6  **I2C5SMEN**: I2C5 clock enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: I2C5 clocks disabled by the clock gating during Sleep and Stop modes
   1: I2C5 clocks enabled by the clock gating during Sleep and Stop modes
   *Note*:  This bit must be set to allow the peripheral to wake up from Stop modes.
   *This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.*

Bit 5  **LPTIM2SMEN**: LPTIM2 clock enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: LPTIM2 clocks disabled by the clock gating during Sleep and Stop modes
   1: LPTIM2 clocks enabled by the clock gating during Sleep and Stop modes
   *Note*:  This bit must be set to allow the peripheral to wake up from Stop modes.

Bits 4:2  Reserved, must be kept at reset value.

Bit 1  **I2C4SMEN**: I2C4 clock enable during Sleep and Stop modes
   This bit is set and cleared by software.
   0: I2C4 clocks disabled by the clock gating during Sleep and Stop modes
   1: I2C4 clocks enabled by the clock gating during Sleep and Stop modes
   *Note*:  This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 0  Reserved, must be kept at reset value.
11.8.43  RCC APB2 peripheral clocks enable in Sleep and Stop modes register (RCC_APB2SMENR)

Address offset: 0x0CC
Reset value: 0xFFFF FFFF
Access: word, half-word, and byte access

This register only configures the clock gating, not the clock source itself. When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests the AHB or APB clock (refer to Section 11.4.24).

Bits 31:28: Reserved, must be kept at reset value.

Bit 27  **DSISMEN**: DSI clock enable during Sleep and Stop modes

This bit is set and cleared by software.

0: DSI clocks disabled by the clock gating during Sleep and Stop modes
1: DSI clocks enabled by the clock gating during Sleep and Stop modes

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 26  **LTDCSMEN**: LTDC clock enable during Sleep and Stop modes

This bit is set and cleared by software.

0: LTDC clocks disabled by the clock gating during Sleep and Stop modes
1: LTDC clocks enabled by the clock gating during Sleep and Stop modes

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 25  **GFXTIMSMEN**: GFXTIM clock enable during Sleep and Stop modes

This bit is set and cleared by software.

0: GFXTIM clocks disabled by the clock gating during Sleep and Stop modes
1: GFXTIM clocks enabled by the clock gating during Sleep and Stop modes

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 24  **USBSMEN**: USB clock enable during Sleep and Stop modes

This bit is set and cleared by software.

0: USB clocks disabled by the clock gating during Sleep and Stop modes
1: USB clocks enabled by the clock gating during Sleep and Stop modes

*Note:* This bit is only available on STM32U535/545 devices, it is reserved on other devices in the STM32U5 Series. If not present, consider this bit as reserved and keep it at reset value.
Bit 23  Reserved, must be kept at reset value.

Bit 22  **SAI2SMEN**: SAI2 clock enable during Sleep and Stop modes
        This bit is set and cleared by software.
        0: SAI2 clocks disabled by the clock gating during Sleep and Stop modes
        1: SAI2 clocks enabled by the clock gating during Sleep and Stop modes
        Note:  This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 21  **SA11SMEN**: SAI1 clock enable during Sleep and Stop modes
        This bit is set and cleared by software.
        0: SAI1 clocks disabled by the clock gating during Sleep and Stop modes
        1: SAI1 clocks enabled by the clock gating during Sleep and Stop modes

Bits 20:19  Reserved, must be kept at reset value.

Bit 18  **TIM17SMEN**: TIM17 clock enable during Sleep and Stop modes
        This bit is set and cleared by software.
        0: TIM17 clocks disabled by the clock gating during Sleep and Stop modes
        1: TIM17 clocks enabled by the clock gating during Sleep and Stop modes

Bit 17  **TIM16SMEN**: TIM16 clock enable during Sleep and Stop modes
        This bit is set and cleared by software.
        0: TIM16 clocks disabled by the clock gating during Sleep and Stop modes
        1: TIM16 clocks enabled by the clock gating during Sleep and Stop modes

Bit 16  **TIM15SMEN**: TIM15 clock enable during Sleep and Stop modes
        This bit is set and cleared by software.
        0: TIM15 clocks disabled by the clock gating during Sleep and Stop modes
        1: TIM15 clocks enabled by the clock gating during Sleep and Stop modes

Bit 15  Reserved, must be kept at reset value.

Bit 14  **USART1SMEN**: USART1 clock enable during Sleep and Stop modes
        This bit is set and cleared by software.
        0: USART1 clocks disabled by the clock gating during Sleep and Stop modes
        1: USART1 clocks enabled by the clock gating during Sleep and Stop modes
        Note:  This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 13  **TIM8SMEN**: TIM8 clock enable during Sleep and Stop modes
        This bit is set and cleared by software.
        0: TIM8 clocks disabled by the clock gating during Sleep and Stop modes
        1: TIM8 clocks enabled by the clock gating during Sleep and Stop modes

Bit 12  **SPI1SMEN**: SPI1 clock enable during Sleep and Stop modes
        This bit is set and cleared by software.
        0: SPI1 clocks disabled by the clock gating during Sleep and Stop modes
        1: SPI1 clocks enabled by the clock gating during Sleep and Stop modes
        Note:  This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 11  **TIM1SMEN**: TIM1 clock enable during Sleep and Stop modes
        This bit is set and cleared by software.
        0: TIM1 clocks disabled by the clock gating during Sleep and Stop modes
        1: TIM1 clocks enabled by the clock gating during Sleep and Stop modes

Bits 10:0  Reserved, must be kept at reset value.
11.8.44  **RCC APB3 peripheral clock enable in Sleep and Stop modes register (RCC_APB3SMENR)**

Address offset: 0x0D0

Reset value: 0xFFFF FFFF

Access: no wait state; word, half-word, and byte access

This register only configures the clock gating, not the clock source itself. When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests the AHB or APB clock (refer to Section 11.4.24).

**Bit 31**  **SRAM4 AMEN**: SRAM4 autonomous mode enable in Stop 0/1/2 mode  
This bit is set and cleared by software.  
0: SRAM4 autonomous mode disabled during Stop 0/1/2 mode  
1: SRAM4 autonomous mode enabled during Stop 0/1/2 mode

**Bit 29**  **ADF1 AMEN**: ADF1 autonomous mode enable in Stop 0/1/2 mode  
This bit is set and cleared by software.  
0: ADF1 autonomous mode disabled during Stop 0/1/2 mode  
1: ADF1 autonomous mode enabled during Stop 0/1/2 mode  
*Note: This bit must be set to allow the peripheral to wake up from Stop modes.*

**Bit 28**  **LPDMA1 AMEN**: LPDMA1 autonomous mode enable in Stop 0/1/2 mode  
This bit is set and cleared by software.  
0: LPDMA1 autonomous mode disabled during Stop 0/1/2 mode  
1: LPDMA1 autonomous mode enabled during Stop 0/1/2 mode  
*Note: This bit must be set to allow the peripheral to wake up from Stop modes.*

**Bit 27**  **DAC1 AMEN**: DAC1 autonomous mode enable in Stop 0/1/2 mode  
This bit is set and cleared by software.  
0: DAC1 autonomous mode disabled during Stop 0/1/2 mode  
1: DAC1 autonomous mode enabled during Stop 0/1/2 mode  
*Note: This bit must be set to allow the peripheral to wake up from Stop modes.*

**Bit 26**  **LPGPIO1 AMEN**: LPGPIO1 autonomous mode enable in Stop 0/1/2 mode  
This bit is set and cleared by software.  
0: LPGPIO1 autonomous mode disabled during Stop 0/1/2 mode  
1: LPGPIO1 autonomous mode enabled during Stop 0/1/2 mode

**Bit 25**  **ADC4 AMEN**: ADC4 autonomous mode enable in Stop 0/1/2 mode  
This bit is set and cleared by software.  
0: ADC4 autonomous mode disabled during Stop 0/1/2 mode  
1: ADC4 autonomous mode enabled during Stop 0/1/2 mode  
*Note: This bit must be set to allow the peripheral to wake up from Stop modes.*

**Bits 24:22**  Reserved, must be kept at reset value.
Bit 21 **RTCAPBAMEN**: RTC and TAMP autonomous mode enable in Stop 0/1/2 mode
   This bit is set and cleared by software.
   0: RTC and TAMP autonomous mode disabled during Stop 0/1/2 mode
   1: RTC and TAMP autonomous mode enabled during Stop 0/1/2 mode
   **Note**: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 20 **VREFAMEN**: VREFBUF autonomous mode enable in Stop 0/1/2 mode
   This bit is set and cleared by software.
   0: VREFBUF autonomous mode disabled during Stop 0/1/2 mode
   1: VREFBUF autonomous mode enabled during Stop 0/1/2 mode

Bits 19:16 Reserved, must be kept at reset value.

Bit 15 **COMPAMEN**: COMP autonomous mode enable in Stop 0/1/2 mode
   This bit is set and cleared by software.
   0: COMP autonomous mode disabled during Stop 0/1/2 mode
   1: COMP autonomous mode enabled during Stop 0/1/2 mode

Bit 14 **OPAMPAMEN**: OPAMP autonomous mode enable in Stop 0/1/2 mode
   This bit is set and cleared by software.
   0: OPAMP autonomous mode disabled during Stop 0/1/2 mode
   1: OPAMP autonomous mode enabled during Stop 0/1/2 mode

Bit 13 **LPTIM4AMEN**: LPTIM4 autonomous mode enable in Stop 0/1/2 mode
   This bit is set and cleared by software.
   0: LPTIM4 autonomous mode disabled during Stop 0/1/2 mode
   1: LPTIM4 autonomous mode enabled during Stop 0/1/2 mode
   **Note**: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 12 **LPTIM3AMEN**: LPTIM3 autonomous mode enable in Stop 0/1/2 mode
   This bit is set and cleared by software.
   0: LPTIM3 autonomous mode disabled during Stop 0/1/2 mode
   1: LPTIM3 autonomous mode enabled during Stop 0/1/2 mode
   **Note**: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 11 **LPTIM1AMEN**: LPTIM1 autonomous mode enable in Stop 0/1/2 mode
   This bit is set and cleared by software.
   0: LPTIM1 autonomous mode disabled during Stop 0/1/2 mode
   1: LPTIM1 autonomous mode enabled during Stop 0/1/2 mode
   **Note**: This bit must be set to allow the peripheral to wake up from Stop modes.

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **I2C3AMEN**: I2C3 autonomous mode enable in Stop 0/1/2 mode
   This bit is set and cleared by software.
   0: I2C3 autonomous mode disabled during Stop 0/1/2 mode
   1: I2C3 autonomous mode enabled during Stop 0/1/2 mode
   **Note**: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 6 **LPUART1AMEN**: LPUART1 autonomous mode enable in Stop 0/1/2 mode
   This bit is set and cleared by software.
   0: LPUART1 autonomous mode disabled during Stop 0/1/2 mode
   1: LPUART1 autonomous mode enabled during Stop 0/1/2 mode
   **Note**: This bit must be set to allow the peripheral to wake up from Stop modes.
Bit 5  **SPI3AMEN**: SPI3 autonomous mode enable in Stop 0,1, 2 mode  
This bit is set and cleared by software.  
0: SPI3 autonomous mode disabled during Stop 0/1/2 mode  
1: SPI3 autonomous mode enabled during Stop 0/1/2 mode  
*Note: This bit must be set to allow the peripheral to wake up from Stop modes.*  

Bits 4:0  Reserved, must be kept at reset value.

### 11.8.46  RCC peripherals independent clock configuration register 1 (RCC_CCIPR1)

**Address offset**: 0x0E0  
**Reset value**: 0x0000 0000  
**Access**: no wait states; word, half-word, and byte access

<table>
<thead>
<tr>
<th>Bit 31:29</th>
<th>TIMICSEL[2:0]: Clock sources for TIM16,TIM17, and LPTIM2 internal input capture</th>

</tr>
</tbody>
</table>

**Bits 31:29  TIMICSEL[2:0]**: Clock sources for TIM16, TIM17, and LPTIM2 internal input capture  
When TIMICSEL2 is set, the TIM16, TIM17, and LPTIM2 internal input capture can be connected either to HSI/256, MSI/4, or MSI/1024. Depending on TIMICSEL[1:0] value, MSI is either MSIK or MSIS.  
When TIMICSEL2 is cleared, the HSI, MSIK, and MSIS clock sources cannot be selected as TIM16, TIM17, or LPTIM2 internal input capture.  
0xx: HSI, MSIK and MSIS dividers disabled  
100: HSI/256, MSIS/1024 and MSIS/4 generated and can be selected by TIM16, TIM17, and LPTIM2 as internal input capture  
101: HSI/256, MSIS/1024 and MSIK/4 generated and can be selected by TIM16, TIM17, and LPTIM2 as internal input capture  
110: HSI/256, MSIK/1024 and MSIS/4 generated and can be selected by TIM16, TIM17, and LPTIM2 as internal input capture  
111: HSI/256, MSIK/1024 and MSIK/4 generated and can be selected by TIM16, TIM17, and LPTIM2 as internal input capture  
*Note: The clock division must be disabled (TIMICSEL configured to 0xx) before selecting or changing a clock sources division.*

Bit 28  Reserved, must be kept at reset value.

**Bits 27:26  ICLKSEL[1:0]**: Intermediate clock source selection  
These bits are used to select the clock source for the OTG_FS, the USB, and the SDMMC.  
00: HSI48 clock selected  
01: PLL2 "O" (pll2_q_ck selected  
10: PLL1 "O" (pll1_q_ck selected  
11: MSIK clock selected
Bits 25:24 **FDCAN1SEL[1:0]**: FDCAN1 kernel clock source selection
These bits are used to select the FDCAN1 kernel clock source.
00: HSE clock selected
01: PLL1 “Q” (pll1_q_ck) selected
10: PLL2 “P” (pll2_p_ck) selected
11: reserved

Bits 23:22 **SYSTICKSEL[1:0]**: SysTick clock source selection
These bits are used to select the SysTick clock source.
00: HCLK/8 selected
01: LSI selected
10: LSE selected
11: reserved

*Note:* When LSE or LSI is selected, the AHB frequency must be at least four times higher than the LSI or LSE frequency. In addition, a jitter up to one HCLK cycle is introduced, due to the LSE or LSI sampling with HCLK in the SysTick circuitry.

Bits 21:20 **SPI1SEL[1:0]**: SPI1 kernel clock source selection
These bits are used to select the SPI1 kernel clock source.
00: PCLK2 selected
01: SYSCLK selected
10: HSI16 selected
11: MSIK selected

*Note:* The SPI1 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or MSIK.

Bits 19:18 **LPTIM2SEL[1:0]**: Low-power timer 2 kernel clock source selection
These bits are used to select the LPTIM2 kernel clock source.
00: PCLK1 selected
01: LSI selected
10: HSI16 selected
11: LSE selected

*Note:* The LPTIM2 is functional in Stop 0 and Stop 1 mode only when the kernel clock is LSI, LSE or HSI16 if HSIKERON = 1.

Bits 17:16 **SPI2SEL[1:0]**: SPI2 kernel clock source selection
These bits are used to select the SPI2 kernel clock source.
00: PCLK1 selected
01: SYSCLK selected
10: HSI16 selected
11: MSIK selected

*Note:* The SPI2 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or MSIK.

Bits 15:14 **I2C4SEL[1:0]**: I2C4 kernel clock source selection
These bits are used to select the I2C4 kernel clock source.
00: PCLK1 selected
01: SYSCLK selected
10: HSI16 selected
11: MSIK selected

*Note:* The I2C4 is functional in Stop 0 and Stop 1 modes only when the kernel clock is HSI16 or MSIK.
Bits 13:12 **I2C2SEL[1:0]**: I2C2 kernel clock source selection

These bits are used to select the I2C2 kernel clock source.

- 00: PCLK1 selected
- 01: SYSLCK selected
- 10: HSI16 selected
- 11: MSIK selected

*Note:* The I2C2 is functional in Stop 0 and Stop 1 modes only when the kernel clock is HSI16 or MSIK.

Bits 11:10 **I2C1SEL[1:0]**: I2C1 kernel clock source selection

These bits are used to select the I2C1 kernel clock source.

- 00: PCLK1 selected
- 01: SYSLCK selected
- 10: HSI16 selected
- 11: MSIK selected

*Note:* The I2C1 is functional in Stop 0 and Stop 1 modes only when the kernel clock is HSI16 or MSIK.

Bits 9:8 **UART5SEL[1:0]**: UART5 kernel clock source selection

These bits are used to select the UART5 kernel clock source.

- 00: PCLK1 selected
- 01: SYSLCK selected
- 10: HSI16 selected
- 11: LSE selected

*Note:* The UART5 is functional in Stop 0 and Stop 1 modes only when the kernel clock is HSI16 or LSE.

Bits 7:6 **UART4SEL[1:0]**: UART4 kernel clock source selection

These bits are used to select the UART4 kernel clock source.

- 00: PCLK1 selected
- 01: SYSLCK selected
- 10: HSI16 selected
- 11: LSE selected

*Note:* The UART4 is functional in Stop 0 and Stop 1 modes only when the kernel clock is HSI16 or LSE.

Bits 5:4 **USART3SEL[1:0]**: USART3 kernel clock source selection

These bits are used to select the USART3 kernel clock source.

- 00: PCLK1 selected
- 01: SYSLCK selected
- 10: HSI16 selected
- 11: LSE selected

*Note:* The USART3 is functional in Stop 0 and Stop 1 modes only when the kernel clock is HSI16 or LSE.
Bits 3:2 **USART2SEL[1:0]:** USART2 kernel clock source selection
These bits are used to select the USART2 kernel clock source.
00: PCLK1 selected
01: SYSLCK selected
10: HSI16 selected
11: LSE selected

*Note:* The USART2 is functional in Stop 0 and Stop 1 modes only when the kernel clock is HSI16 or LSE.
This bitfield is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bitfield as reserved and keep it at reset value.

Bits 1:0 **USART1SEL[1:0]:** USART1 kernel clock source selection
These bits are used to select the USART1 kernel clock source.
00: PCLK2 selected
01: SYSLCK selected
10: HSI16 selected
11: LSE selected

*Note:* The USART1 is functional in Stop 0 and Stop 1 modes only when the kernel clock is HSI16 or LSE.

Bits 31:30 **OTGHSEL[1:0]:** OTG_HS PHY kernel clock source selection
These bits are used to select the OTG_HS PHY kernel clock source.
00: HSE selected
01: PLL1 “P” (pll1_q_ck) selected,
10: HSE/2 selected
11: PLL1 “P” divided by 2 (pll1_p_ck/2) selected

*Note:* This bitfield is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bitfield as reserved and keep it at reset value.

Bits 29:28 Reserved, must be kept at reset value.
Bits 27:26 **I2C6SEL[1:0]**: I2C6 kernel clock source selection

These bits are used to select the I2C6 kernel clock source.

- 00: PCLK1 selected
- 01: SYSCLK selected
- 10: HSI16 selected
- 11: MSIK selected

*Note:* The I2C6 is functional in Stop 0 and Stop 1 modes only when the kernel clock is HSI16 or MSIK.

This bitfield is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bitfield as reserved and keep it at reset value.

Bits 25:24 **I2C5SEL[1:0]**: I2C5 kernel clock source selection

These bits are used to select the I2C5 kernel clock source.

- 00: PCLK1 selected
- 01: SYSCLK selected
- 10: HSI16 selected
- 11: MSIK selected

*Note:* The I2C5 is functional in Stop 0 and Stop 1 modes only when the kernel clock is HSI16 or MSIK.

This bitfield is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bitfield as reserved and keep it at reset value.

Bits 23:22 **HSPI1SEL[1:0]**: HSPI1 kernel clock source selection

These bits are used to select the HSPI1 kernel clock source.

- 00: SYSCLK selected
- 01: PLL1 “Q” (pll1_q_ck) selected, can be up to 200 MHz
- 10: PLL2 “Q” (pll2_q_ck) selected, can be up to 200 MHz
- 11: PLL3 “R” (pll3_r_ck) selected, can be up to 200 MHz

*Note:* This bitfield is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bitfield as reserved and keep it at reset value.

Bits 21:20 **OCTOSPISEL[1:0]**: OCTOSPI1 and OCTOSPI2 kernel clock source selection

These bits are used to select the OCTOSPI1 and OCTOSPI2 kernel clock source.

- 00: SYSCLK selected
- 01: MSIK selected
- 10: PLL1 “Q” (pll1_q_ck) selected, can be up to 200 MHz
- 11: PLL2 “Q” (pll2_q_ck) selected, can be up to 200 MHz

Bit 19 Reserved, must be kept at reset value.

Bit 18 **LTDCSEL**: LTDC kernel clock source selection

This bit is used to select the LTDC kernel clock source.

- 0: PLL3 “R” (pll3_r_ck) selected
- 1: PLL2 “R” (pll2_r_ck) selected

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.
Bits 17:16 **USART6SEL[1:0]**: USART6 kernel clock source selection

These bits are used to select the USART6 kernel clock source.

00: PCLK1 selected
01: SYSCLK selected
10: HSI16 selected
11: LSE selected

*Note:* The USART6 is functional in Stop 0 and Stop 1 modes only when the kernel clock is HSI16 or LSE.

This bitfield is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bitfield as reserved and keep it at reset value.

Bit 15 **DSISEL**: DSI kernel clock source selection

This bit is used to select the DSI kernel clock source.

0: PLL3 "P" (pll3_p_ck) selected
1: DSI PHY PLL output selected

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 14 **SDMMCSEL**: SDMMC1 and SDMMC2 kernel clock source selection

This bit is used to select the SDMMC kernel clock source. It is recommended to change it only after reset and before enabling the SDMMC.

0: ICLK clock selected
1: PLL1 "P" (pll1_p_ck) selected, in case higher than 48 MHz is needed (for SDR50 mode)

Bits 13:12 **RNGSEL[1:0]**: RNG kernel clock source selection

These bits are used to select the RNG kernel clock source.

00: HSI48 selected
01: HSI48 / 2 selected, can be used in range 4
10: HSI16 selected
11: reserved

Bit 11 **SAESSEL**: SAES kernel clock source selection

This bit is used to select the SAES kernel clock source.

0: SHSI selected
1: SHSI / 2 selected, can be used in range 4

*Note:* This bit is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bits 10:8 **SAI2SEL[2:0]**: SAI2 kernel clock source selection

These bits are used to select the SAI2 kernel clock source.

000: PLL2 "P" (pll2_p_ck) selected
001: PLL3 "P" (pll3_p_ck) selected
010: PLL1 "P" (pll1_p_ck) selected
011: input pin AUDIOCLK selected
100: HSI16 clock selected
others: reserved

*Note:* If the selected clock is the external clock and this clock is stopped, a switch to another clock is impossible.

This bitfield is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bitfield as reserved and keep it at reset value.
### Reset and clock control (RCC)

101: MSIK clock selected
others: reserved

*Note: The ADC1, ADC2, ADC4, and DAC1 are functional in Stop 0, Stop 1, and Stop 2 modes only when the kernel clock is HSI16 or MSIK (only ADC4 and DAC1 are functional in Stop 2 mode).*

Bits 11:10 **LPTIM1SEL[1:0]**: LPTIM1 kernel clock source selection
These bits are used to select the LPTIM1 kernel clock source.
00: MSIK clock selected
01: LSI selected
10: HSI16 selected
11: LSE selected

*Note: The LPTIM1 is functional in Stop 0, Stop 1, and Stop 2 modes only when the kernel clock is LSI, LSE, HSI16 with HSIFIERON = 1, or MSIK with MSIKERON = 1.*

Bits 9:8 **LPTIM34SEL[1:0]**: LPTIM3 and LPTIM4 kernel clock source selection
These bits are used to select the LPTIM3 and LPTIM4 kernel clock source.
00: MSIK clock selected
01: LSI selected
10: HSI selected
11: LSE selected

*Note: The LPTIM3 and LPTIM4 are functional in Stop 0, Stop 1, and Stop 2 modes only when the kernel clock is LSI, LSE, HSI16 with HSIFIERON = 1, or MSIK with MSIKERON = 1.*

Bits 7:6 **I2C3SEL[1:0]**: I2C3 kernel clock source selection
These bits are used to select the I2C3 kernel clock source.
00: PCLK3 selected
01: SYSLCK selected
10: HSI16 selected
11: MSIK selected

*Note: The I2C3 is functional in Stop 0, Stop 1, and Stop 2 modes only when the kernel clock is HSI16 or MSIK.*

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **SPI3SEL[1:0]**: SPI3 kernel clock source selection
These bits are used to select the SPI3 kernel clock source.
00: PCLK3 selected
01: SYSLCK selected
10: HSI16 selected
11: MSIK selected

*Note: The SPI3 is functional in Stop 0, Stop 1, and Stop 2 modes only when the kernel clock is HSI16 or MSIK.*
**11.8.49 RCC backup domain control register (RCC_BDCR)**

Address offset: 0x00F0

Backup domain reset value: 0x0000 0000 (for STM32U575/585)

Backup domain reset value: 0x0000 X000 (for the other STM32U5 Series devices)

Reset by backup domain reset, except LSCOSEL, LSCOEN, and BDRST that are reset only by backup domain power-on reset.

Access: 0 ≤ wait state ≤ 3; word, half-word, and byte access

Wait states are inserted in case of successive accesses to this register.

*Note: These register bits are outside of the core domain. After reset, these bits are then write-protected, and DBP must be set in PWR_BDCR1 before these can be modified (see Section 10: Power control (PWR) for further information). These bits (except LSCOSEL, LSCOEN, and BDRST) are only reset after a backup domain reset (see Section 11.3.3). Any internal or external reset does not have any effect on these bits.*

*Bits 2:0 LPUART1SEL[2:0]: LPUART1 kernel clock source selection*

These bits are used to select the LPUART1 kernel clock source.

- 000: PCLK3 selected
- 001: SYSCLK selected
- 010: HSI16 selected
- 011: LSE selected
- 100: MSIK selected
- others: reserved

*Note: The LPUART1 is functional in Stop 0, Stop 1, and Stop 2 modes only when the kernel clock is HSI16, LSE, or MSIK.*
Bit 27  **LSIRDY**: LSI oscillator ready
   This bit is set and cleared by hardware to indicate when the LSI oscillator is stable. After LSION is cleared, LSIRDY goes low after three internal low-speed oscillator clock cycles. This bit is set when the LSI is used by IWDG or RTC, even if LSION = 0.
   0: LSI oscillator not ready
   1: LSI oscillator ready

Bit 26  **LSION**: LSI oscillator enable
   This bit is set and cleared by software. The LSI oscillator is disabled 60 µs maximum after the LSION bit is cleared.
   0: LSI oscillator OFF
   1: LSI oscillator ON

Bit 25  **LSCOSEL**: Low-speed clock output selection
   This bit is set and cleared by software.
   0: LSI clock selected
   1: LSE clock selected

Bit 24  **LSCOEN**: Low-speed clock output (LSCO) enable
   This bit is set and cleared by software.
   0: LSCO disabled
   1: LSCO enabled

Bits 23:17 Reserved, must be kept at reset value.

Bit 16  **BDRST**: Backup domain software reset
   This bit is set and cleared by software.
   0: Reset not activated
   1: Reset the entire backup domain.

Bit 15  **RTCEN**: RTC and TAMP clock enable
   This bit is set and cleared by software.
   0: RTC and TAMP clock disabled
   1: RTC and TAMP clock enabled

Bits 14:13 Reserved, must be kept at reset value.

Bit 12  **LSEGFON**: LSE clock glitch filter enable
   This bit is set and cleared by hardware to enable the LSE glitch filter. It can be written only when the LSE is disabled (LSEON = 0 and LSERDY = 0).
   0: LSE glitch filter disabled
   1: LSE glitch filter enabled

Bit 11  **LSESYSRDY**: LSE system clock (LSESYS) ready
   This bit is set and cleared by hardware to indicate when the LSE system clock is stable. When LSESYSEN is set, this LSESYSRDY flag is set after two LSE clock cycles. The LSE clock must be already enabled and stable (LSEON and LSERDY are set). When the LSEON bit is cleared, LSERDY goes low after six external low-speed oscillator clock cycles.
   0: LSESYS clock not ready
   1: LSESYS clock ready

Bit 10  Reserved, must be kept at reset value.
Bits 9:8 **RTCSEL[1:0]**: RTC and TAMP clock source selection
This bit is set by software to select the clock source for the RTC and TAMP. Once the RTC and TAMP clock source has been selected, it cannot be changed anymore unless the backup domain is reset, or unless a failure is detected on LSE (LSECSSD is set). BDRST bit can be used to reset them.
00: No clock selected
01: LSE oscillator clock selected
10: LSI oscillator clock selected
11: HSE oscillator clock divided by 32 selected

Bit 7 **LSESYSEN**: LSE system clock (LSESYS) enable
This bit is set by software to enable always the LSE system clock generated by RCC, which can be used by any peripheral when its source clock is the LSE, or at system level if one of LSCOSEL, MCO, or MSI PLL mode is needed.
0: LSE can be used only for RTC, TAMP, and CSS on LSE.
1: LSE can be used by any other peripheral or function.

Bit 6 **LSECSSD**: CSS on LSE failure detection
This bit is set by hardware to indicate when a failure is detected by the CCS on the external 32 kHz oscillator (LSE).
0: No failure detected on LSE
1: Failure detected on LSE

Bit 5 **LSECSSON**: CSS on LSE enable
This bit is set by software to enable the CSS on LSE. It must be enabled after the LSE oscillator is enabled (LSEON bit enabled) and ready (LSERDY flag set by hardware), and after the RTCSEL bit is selected.
Once enabled, this bit cannot be disabled, except after a LSE failure detection (LSECSSD = 1). In that case, the software must disable this LSECSSON bit.
0: CSS on LSE OFF
1: CSS on LSE ON

Bits 4:3 **LSEDRV[1:0]**: LSE oscillator drive capability
This bitfield is set by software to modulate the drive capability of the LSE oscillator. It can be written only when the external 32 kHz oscillator is disabled (LSEON = 0 and LSERDY = 0).
00: 'Xtal mode' lower driving capability
01: 'Xtal mode' medium-low driving capability
10: 'Xtal mode' medium-high driving capability
11: 'Xtal mode' higher driving capability
*Note: The oscillator is in 'Xtal mode' when it is not in bypass mode.*

Bit 2 **LSEBYP**: LSE oscillator bypass
This bit is set and cleared by software to bypass oscillator in debug mode. It can be written only when the external 32 kHz oscillator is disabled (LSEON = 0 and LSERDY = 0).
0: LSE oscillator not bypassed
1: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready
This bit is set and cleared by hardware to indicate when the external 32 kHz oscillator is stable. After LSEON is cleared, this LSERDY bit goes low after six external low-speed oscillator clock cycles.
0: LSE oscillator not ready
1: LSE oscillator ready
Bit 0 **LSEON**: LSE oscillator enable
   - This bit is set and cleared by software.
   - 0: LSE oscillator off
   - 1: LSE oscillator on

### 11.8.50 RCC control/status register (RCC_CSR)

**Address offset**: 0x0F4

**Reset value**: 0x0C00 4400

Reset by system reset, except reset flags by power reset only.

Access: 0 ≤ wait state ≤ 3; word, half-word, and byte access

Wait states are inserted in case of successive accesses to this register.

</tbody>
</table>
Bit 26 **PINRSTF**: NRST pin reset flag
This bit is set by hardware when a reset from the NRST pin occurs. It is cleared by writing to the RMVF bit.
- 0: No reset from NRST pin occurred
- 1: Reset from NRST pin occurred

Bit 25 **OBLRSTF**: Option-byte loader reset flag
This bit is set by hardware when a reset from the option-byte loading occurs. It is cleared by writing to the RMVF bit.
- 0: No reset from option-byte loading occurred
- 1: Reset from option-byte loading occurred

Bit 24 Reserved, must be kept at reset value.

Bit 23 **RMVF**: Remove reset flag
This bit is set by software to clear the reset flags.
- 0: No effect
- 1: Clear the reset flags.

Bits 22:16 Reserved, must be kept at reset value.

Bits 15:12 **MSISSRANGE[3:0]**: MSIS range after Standby mode
This bitfield is set by software to chose the MSIS frequency at startup. It is used after exiting Standby mode until MSIRGSEL is set. After a NRST pin or a power-on reset or when exiting Shutdown mode, the range is always 4 MHz. MSISSRANGE can be written only when MSIRGSEL = 1.
- 0100: range 4 around 4M Hz (reset value)
- 0101: range 5 around 2 MHz
- 0110: range 6 around 1.33 MHz
- 0111: range 7 around 1 MHz
- 1000: range 8 around 3.072 MHz
- others: reserved

*Note: Changing this bitfield does not change the current MSIS frequency.*

Bits 11:8 **MSIKSRANGE[3:0]**: MSIK range after Standby mode
This bit is set by software to chose the MSIK frequency at startup. It is used after exiting Standby mode until MSIRGSEL is set. After a NRST pin or a power-on reset or when exiting Shutdown mode, the range is always 4 MHz. MSIKSRANGE can be written only when MSIRGSEL = 1.
- 0100: range 4 around 4M Hz (reset value)
- 0101: range 5 around 2 MHz
- 0110: range 6 around 1.33 MHz
- 0111: range 7 around 1 MHz
- 1000: range 8 around 3.072 MHz
- others: reserved

*Note: Changing this bitfield does not change the current MSIK frequency.*

Bits 7:0 Reserved, must be kept at reset value.
11.8.51 RCC secure configuration register (RCC_SECCFGR)

Address offset: 0x110
Reset value: 0x0000 0000
Access: no wait state; word, half-word, and byte access

When the system is secure (TZEN = 1), this register can be written only by a secure privileged access if SPRIV = 1, and by a secure privileged or unprivileged access if SPRIV = 0. A nonsecure write access generates an illegal access event and data is not written. This register can be read by secure or nonsecure, privilege or unprivileged access. When the system is not secure (TZEN = 0), this register is read as 0, and the register write is ignored.

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 |
|----------------|----------------|----------------|----------------|----------------|----------------|

| Res. Res. Res. RMVFSEC | HSI48SEC | ICLKSEC | PLL3SEC | PLL2SEC | PLL1SEC | SYSC | KYSEC | LSESC | LSISEC | MSI | HSESEC | HSISEC |
| rw rw rw rw rw rw rw rw rw rw rw rw rw rw |

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **RMVFSEC**: Remove reset flag security
- This bit is set and reset by software.
  - 0: nonsecure
  - 1: secure

Bit 11 **HSI48SEC**: HSI48 clock configuration and status bit security
- This bit is set and reset by software.
  - 0: nonsecure
  - 1: secure

Bit 10 **ICLKSEC**: Intermediate clock source selection security
- This bit is set and reset by software.
  - 0: nonsecure
  - 1: secure

Bit 9 **PLL3SEC**: PLL3 clock configuration and status bit security
- This bit is set and reset by software.
  - 0: nonsecure
  - 1: secure

Bit 8 **PLL2SEC**: PLL2 clock configuration and status bit security
- Set and reset by software.
  - 0: nonsecure
  - 1: secure

Bit 7 **PLL1SEC**: PLL1 clock configuration and status bit security
- This bit is set and reset by software.
  - 0: nonsecure
  - 1: secure
11.8.52 RCC privilege configuration register (RCC_PRIVCFGR)

Address offset: 0x114
Reset value: 0x0000 0000
Access: no wait state; word, half-word, and byte access

This register can be written only by a privileged access. It can be read by privileged or unprivileged access.

Bits 31:2 Reserved, must be kept at reset value.
Bit 1 **NSPRIV**: RCC nonsecure function privilege configuration
This bit is set and reset by software. It can be written only by privileged access, secure or nonsecure.
0: Read and write to RCC nonsecure functions can be done by privileged or unprivileged access.
1: Read and write to RCC nonsecure functions can be done by privileged access only.

Bit 0 **SPRIV**: RCC secure function privilege configuration
This bit is set and reset by software. It can be written only by a secure privileged access.
0: Read and write to RCC secure functions can be done by privileged or unprivileged access.
1: Read and write to RCC secure functions can be done by privileged access only.

12 Clock recovery system (CRS)

12.1 Introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means to evaluate the oscillator output frequency, based on comparison with a selectable synchronization signal. The CRS is capable of automatic trimming adjustments based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In this case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from the LSE oscillator output, or generated by user software.

12.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity:
  - LSE oscillator output
  - USB SOF packet reception
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster startup convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

12.4 CRS functional description

12.4.1 CRS block diagram

![Figure 41. CRS block diagram](image)

12.4.2 Synchronization input

The CRS synchronization (SYNC) source, selectable through the CRS_CFGR register, can be the signal from the LSE clock or the USB SOF signal. For better robustness of the SYNC input, a simple digital filter (2 out of 3 majority votes, sampled by the HSI48 clock) is implemented to filter out glitches. This source signal has a configurable polarity, and can be divided by a programmable binary prescaler, to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to Section 12.7.2.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.
12.4.3 Frequency error measurement

The frequency error counter is a 16-bit down/up counter, reloaded with the RELOAD value on each SYNC event. It starts counting down until it reaches the 0 value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit, where it eventually stops (if no SYNC event is received), and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the down-counting phase (before reaching the 0 value), it means that the actual frequency is lower than the target (the TRIM value must be incremented). When it is detected during the up-counting phase, it means that the actual frequency is higher (the TRIM value must be decremented).

![Figure 42. CRS counter behavior](image)

12.4.4 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:
- **TOLERANCE LIMIT**, given directly in the FELIM field of the CRS_CFGR register
- **WARNING LIMIT**, defined as 3 × FELIM value
- **OUTRANGE (error limit)**, defined as 128 × FELIM value
The result of this comparison is used to generate the status indication and also to control the automatic trimming which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode
- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated
  - TRIM value adjusted by one trimming step in AUTOTRIM mode
- When the frequency error is above or equal to the warning limit but below the error limit, a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode
- When the frequency error is above or equal to the error limit, the frequency is out of the trimming range. This can also happen when the SYNC input is not clean, or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

Note: If the actual value of the TRIM field is close to its limits and the automatic trimming can force it to overflow or underflow, the TRIM value is set to the limit, and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register) the TRIM field of CRS_CR is adjusted by hardware and is read-only.

12.4.5 CRS initialization and configuration

RELOAD value

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. This value is decreased by 1, to reach the expected synchronization on the 0 value. The formula is the following:

\[
RELOAD = \left(\frac{f_{TARGET}}{f_{SYNC}}\right) - 1
\]

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).

FELIM value

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of oscillator clock ticks. The following formula can be used:

\[
FELIM = \left(\frac{f_{TARGET}}{f_{SYNC}}\right) \times \text{STEP}[%] / 100\% / 2
\]
The result must be always rounded up to the nearest integer value to obtain the best
trimming response. If frequent trimming actions are not needed in the application, the
hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to \( \frac{f_{TARGET}}{f_{SYNC}} = 48000 \), and to a typical
trimming step size of 0.14%.

*Note:* The trimming step size depends upon the product, check the datasheet for accurate setting.

*Caution:* There is no hardware protection from a wrong configuration of the RELOAD and FELIM
fields, this can lead to an erratic trimming response. The expected operational mode
requires proper setup of the RELOAD value (according to the synchronization source
frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

### 12.5 CRS low-power modes

<table>
<thead>

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:8 TRIM[6:0]: HSI48 oscillator smooth trimming

The default value of the HSI48 oscillator smooth trimming is 64, which corresponds to the middle of the trimming interval.

Bit 7 SW_SYNC: Generate software SYNC event

This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.

0: No action
1: A software SYNC event is generated.

Bit 6 AUTOTRIMEN: Automatic trimming enable

This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to Section 12.4.4 for more details.

0: Automatic trimming disabled, TRIM bits can be adjusted by the user.
1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 CEN: Frequency error counter enable

This bit enables the oscillator clock for the frequency error counter.

0: Frequency error counter disabled
1: Frequency error counter enabled

When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

Bit 3 ESYNYCIE: Expected SYNC interrupt enable

0: Expected SYNC (ESYNCF) interrupt disabled
1: Expected SYNC (ESYNCF) interrupt enabled

Bit 2 ERRIE: Synchronization or trimming error interrupt enable

0: Synchronization or trimming error (ERRF) interrupt disabled
1: Synchronization or trimming error (ERRF) interrupt enabled
12.7.2 CRS configuration register (CRS_CFG)

This register can be written only when the frequency error counter is disabled (CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04
Reset value: 0x2022 BB7F

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>SYNCPOL: SYNC polarity selection</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This bit is set and cleared by software to select the input polarity for the SYNC signal source.</td>
</tr>
<tr>
<td>0</td>
<td>SYNC active on rising edge (default)</td>
</tr>
<tr>
<td>1</td>
<td>SYNC active on falling edge</td>
</tr>
</tbody>
</table>

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 SYNCSRC[1:0]: SYNC signal source selection

These bits are set and cleared by software to select the SYNC signal source (see Table 121 and Table 122):

00: crs_sync_in_1 selected as SYNC signal source
01: crs_sync_in_2 selected as SYNC signal source
10: crs_sync_in_3 selected as SYNC signal source
11: crs_sync_in_4 selected as SYNC signal source

Note: When using USB LPM (Link Power Management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the HSI48 oscillator on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE or reference clock on the GPIOs must be used as SYNC signal.

Bit 27 Reserved, must be kept at reset value.
Clock recovery system (CRS) RM0456

12.7.3 CRS interrupt and status register (CRS_ISR)

Address offset: 0x08
Reset value: 0x0000 0000

| TRIM | OVF | SYNCE | MISS | SYNC | ERRF | SYNCE | WARNF | SYNC | OKF |
| OVF | SYNCE | MISS | SYNC | ERRF | SYNCE | WARNF | SYNC | OKF |

Bits 26:24 SYNCDIV[2:0]: SYNC divider
These bits are set and cleared by software to control the division factor of the SYNC signal.
000: SYNC not divided (default)
001: SYNC divided by 2
010: SYNC divided by 4
011: SYNC divided by 8
100: SYNC divided by 16
101: SYNC divided by 32
110: SYNC divided by 64
111: SYNC divided by 128

Bits 23:16 FELIM[7:0]: Frequency error limit
FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to Section 12.4.4 for more details about FELIM evaluation.

Bits 15:0 RELOAD[15:0]: Counter reload value
RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to Section 12.4.3 for more details about counter behavior.

Bits 31:16 FECAP[15:0]: Frequency error capture
FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to Section 12.4.4 for more details about FECAP usage.

Bit 15 FEDIR: Frequency error direction
FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.
0: Up-counting direction, the actual frequency is above the target
1: Down-counting direction, the actual frequency is below the target

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 TRIMOVF: Trimming overflow or underflow
This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.
0: No trimming error signaled
1: Trimming error signaled
Bit 9  SYNCF: SYNC missed
This flag is set by hardware when the frequency error counter reaches value FELIM * 128 and no SYNC is detected, meaning either that a SYNC pulse was missed, or the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, hence some other action must be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC), and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.
0: No SYNC missed error signaled
1: SYNC missed error signaled

Bit 8  SYNCF: SYNC error
This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.
0: No SYNC error signaled
1: SYNC error signaled

Bits 7:4  Reserved, must be kept at reset value.

Bit 3  ESYNCF: Expected SYNC flag
This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCF bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCF bit in the CRS_ICR register.
0: No expected SYNC signaled
1: Expected SYNC signaled

Bit 2  ERRF: Error flag
This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCF and SYNECF bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRF bit in the CRS_ICR register, which clears the TRIMOVF, SYNECF and SYNECF bits.
0: No synchronization or trimming error signaled
1: Synchronization or trimming error signaled

Bit 1  SYNECF: SYNC warning flag
This flag is set by hardware when the measured frequency error is greater than or equal to FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNECF bit is set in the CRS_CR register. It is cleared by software by setting the SYNECF bit in the CRS_ICR register.
0: No SYNC warning signaled
1: SYNC warning signaled

Bit 0  SYNECKF: SYNC event OK flag
This flag is set by hardware when the measured frequency error is smaller than FELIM * 3. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNECKF bit is set in the CRS_CR register. It is cleared by software by setting the SYNECKF bit in the CRS_ICR register.
0: No SYNC event OK signaled
1: SYNC event OK signaled
12.7.4 CRS interrupt flag clear register (CRS_ICR)

Address offset: 0x0C
Reset value: 0x0000 0000

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 ESYNCC: Expected SYNC clear flag
Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register.

Bit 2 ERRC: Error clear flag
Writing 1 to this bit clears TRIMOVF, SYNCMISS and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register.

Bit 1 SYNCWARNC: SYNC warning clear flag
Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register.

Bit 0 SYNCOKC: SYNC event OK clear flag
Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register.

12.7.5 CRS register map

Table 125. CRS register map and reset values

| Offset | Register     | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Table 125. CRS register map and reset values (continued)
13 General-purpose I/Os (GPIO)

13.1 Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR), a 16 bits reset register (GPIOx_BRR) and a 32-bit set/reset register (GPIOx_BSRR).

In addition, all GPIOs have a 32-bit locking register (GPIOx_LCKR), two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL), a secure configuration register (GPIOx_SECCFGR) and a high-speed low-voltage register (GPIOx_HSLVR).

13.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_BSRR) for bitwise write access to GPIOx_ODR
- Lock mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions
- TrustZone security support

13.3 GPIO functional description

Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability
Each I/O port bit is freely programmable, however the I/O port registers must be accessed as 32-bit words, half-words, or bytes. The GPIOx_BSRR and GPIOx_BRR registers allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

The figure below shows the basic structure of a three-volt or five-volt tolerant GPIO (TT or FT). The Table 126 gives the possible port bit configurations.

Note: On a TT GPIO, the analog switch is not present and replaced by a direct connection. The analog bloc parasitic circuitry does not allow five-volt tolerance.
13.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in analog mode.

The debug pins are in AF pull-up/pull-down after reset:
- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDIO in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO/TRACESWO in floating state no pull-up/pull-down

PH3/BOOT0 is in input mode during the reset until at least the end of the option byte loading phase (see Section 13.3.15).

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, the high level is high-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, that can be activated or not depending on the value in the GPIOx_PUPDR register.
13.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there is no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to 16 alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:

- After reset, the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user must proceed as follows:

- **Debug function**: after each device reset, these pins are assigned as alternate function pins immediately usable by the debugger host.
- **GPIO**: configure the desired I/O as output, input, or analog in GPIOx_MODER.
- **Peripheral alternate function**:  
  - Connect the I/O to the desired AFx in one of GPIOx_AFRL or GPIOx_AFRH.
  - Select the type, pull-up/pull-down, and output speed via GPIOx_OTYPER, GPIOx_PUPDR, and GPIOx_OSPEEDR respectively.
  - Configure the desired I/O as an alternate function in GPIOx_MODER.
- **Additional functions**:  
  - For the ADC, DAC, OPAMP and COMP, configure the desired I/O in analog mode in GPIOx_MODER, and configure the required function in the ADC, DAC, OPAMP, and COMP registers.
  - For the additional functions like RTC, WKUPx, and oscillators, configure the required function in the related RTC, PWR, and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

13.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os:

- GPIOx_MODER is used to select the I/O mode (input, output, AF, analog).
- GPIOx_OTYPER and GPIOx_OSPEEDR are used to select the output type (push-pull or open-drain) and speed.
- GPIOx_PUPDR is used to select the push-up/pull-down whatever the I/O direction.

13.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx_IDR, x = A to J) and GPIOx_ODR, x = A to J).
GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into GPIOx_IDR, a read-only register.

13.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register that allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, BS(i) sets the corresponding ODR(i) bit. When written to 1, BR(i) resets the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: one or more bits can be modified in a single atomic AHB write access.

13.3.6 GPIO locking mechanism

The GPIO control registers can be frozen by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL, GPIOx_AFRH, and GPIOx_HSLVR.

To write GPIOx_LCKR, a specific write/read sequence must be applied. When the right LOCK sequence is applied to the bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the lock sequence is applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL, and GPIOx_AFRH).

The lock sequence can only be performed using a word (32-bit long) access to GPIOx_LCKR due to the fact that GPIOx_LCKR bit 16 must be set at the same time as the [15:0] bits.

13.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.
13.3.8 External interrupt/wake-up lines

All ports have external interrupt capability. To use external interrupt lines, the port can be configured in input, output, or alternate function mode (the port must not be configured in analog mode). Refer to Section 23: Extended interrupts and event controller (EXTI).

13.3.9 Input configuration

When the I/O port is programmed as input:
- The output buffer is disabled.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in GPIOx_PUPDR.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register provides the I/O state.

The figure below shows the input configuration of the I/O port bit.

**Figure 44. Input floating/pull-up/pull-down configurations**

13.3.10 Output configuration

When the I/O port is programmed as output:
- The output buffer is enabled:
  - Open-drain mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register leaves the port in Hi-Z (the P-MOS is never activated).
  - Push-pull mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register activates the P-MOS.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.
- A read access to the output data register gets the last written value.
The figure below shows the output configuration of the I/O port bit.

**Figure 45. Output configuration**

13.3.11 **Alternate function configuration**

When the I/O port is programmed as the alternate function:

- The output buffer can be configured in open-drain or push-pull mode.
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data).
- The Schmitt trigger input is activated.
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.

The figure below shows the alternate function configuration of the I/O port bit.

**Figure 46. Alternate function configuration**
13.3.12 **Analog configuration**

When the I/O port is programmed as analog configuration:
- The output buffer is disabled.
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled by hardware.
- Read access to the input data register gets the value 0.

The figure below shows the high-impedance, analog-input configuration of the I/O port bits.

**Figure 47. High-impedance analog configuration**

13.3.13 **Using the HSE or LSE oscillator pins as GPIOs**

When the HSE or LSE oscillator is switched off (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched on (by setting the HSEON or LSEON bit in the RCC_CSR register), the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input, and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

13.3.14 **Using the GPIO pins in the RTC supply domain**

The PC13/PC14/PC15 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to Section 63.3: RTC functional description.

13.3.15 **Using PH3 as GPIO**

PH3 may be used as boot pin (BOOT0) or as a GPIO. Depending on the nSWBOOT0 bit in the user option byte, PH3 switches from the input mode to the analog input mode:
- After the option byte loading phase if nSWBOOT0 = 1.
- After reset if nSWBOOT0 = 0.
13.3.16 Using PA11 and PA12 as GPIOs (STM32U59x/5Ax/5Fx/5Gx only)

PA11 and PA12 provide OTG_HS additional functions. There are constraints to use PA11 and PA12 as standard GPIOs or alternate functions. Refer to Section 10.7.12: USB power management in low-power modes (STM32U59x/5Ax/5Fx/5Gx only).

13.3.17 OPAMPx_VINM dedicated pins

The OPAMPx_VINM dedicated pins are three-volt tolerant and are supplied by VDDA. These pins do not feature a complete TT structure as shown in Figure 43, but a direct connection to OPAMPx. The OPAMPx_VINM dedicated pins are available on specific packages only (refer to the device datasheet for availability of these pins).

13.3.18 TrustZone security

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR. When the TrustZone is active (TZEN = 1), each I/O pin of GPIO port can be individually configured as secure through the GPIOx_SECCFGR register.

When the selected I/O pin is configured as secure, its corresponding configuration bits for alternate function, mode selection, I/O data are secure against a nonsecure access. In case of nonsecure access, these bits are RAZ/WI. The GPIO clock and reset control bits in the RCC are automatically configured as secure as soon as at least one I/O in the GPIO is secure.

The I/Os with peripherals functions are also conditioned by the peripheral security configuration (see Section 5: Global TrustZone controller (GTZC) for more details):

- For peripherals for which the I/O pin selection is done through alternate functions registers: if the peripheral is configured as secure, it cannot be connected to a nonsecure I/O pin. If this is not respected, the input data to the secure peripheral is forced to 0 (I/O input pin value is ignored) and the output pin value is forced to 0, thus avoiding any secure information leak through nonsecure I/Os.

- For I/Os with analog switches, directly controlled by peripherals (such as ADC for instance): If the I/O is secure, the I/O analog switch cannot be controlled by a nonsecure peripheral. If this is not respected, the switch remains open. This prevent the redirection of secure data to a nonsecure peripheral or I/O through analog path. Refer to Section 3: System security for more details.

- Some of the paths between I/Os “additional functions” and peripherals are not blocked if the I/O is secure and the peripheral is nonsecure. Therefore it is recommended to configure those peripherals as secure even when not used by the application. Refer to Section 3: System security for the list of concerned peripherals. When the path has a security control, it follows the same rule as I/O selection through alternate functions.

Refer to the device pins definition table in datasheet for more information about peripherals alternate functions and additional functions mapping.

After reset, all GPIO ports are secure.

Table 127 gives a summary of the I/O port secured bits following the security configuration bit in the GPIOx_SECCFGR register. When the I/O bit port is configured as secure:

- Secured bits: read and write operations are only allowed by a secure access. Non secure-read or write accesses on secured bits are RAZ/WI. There is no illegal access event generated.
• Nonsecure bits: no restriction. Read and write operations are allowed by both secure and nonsecure accesses.

When the TrustZone security is disabled (TZEN = 0 in FLASH_OPTR register), all registers bits are nonsecure. The GPIOx_SECCFG register is RAZ/WI.

1. The number of GPIOx ports varies in the STM32U5 Series devices. Refer to the product datasheet for availability of a particular port. If not present, consider the associated bits as reserved and keep them at the reset value.

13.3.19 Privileged and unprivileged modes

All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or nonsecure).

13.3.20 High-speed low-voltage mode (HSLV)

Some I/Os have the capability to increase their maximum speed at low voltage by configuring them in HSLV mode. The I/O HSLV bit controls whether the I/O output speed is optimized to operate at 3.3 V (default setting) or at 1.8 V (HSLV = 1).

Caution: The I/O HSLV configuration bit must not be set if the I/O supply (VDD or VDDIO2) is above 2.7 V. Setting it while the voltage is higher than 2.7 V can damage the device. The I/O HSLV bit can be set only when the corresponding option bit is activated (IO_VDD_HSLV or IO_VDDIO2_HSLV depending on the I/O supply, refer to Section 7.4: FLASH option bytes). There is no hardware protection associated to this feature so it is recommended to use it only as a static configuration for fixed I/O supply.

Caution: On STM32U59x/5Ax/5Fx/5Gx devices, HSLVy bits in GPIOx_HLSVR must be programmed with the same value within the following pairs: PF4/PF5, PI3/PI4, or PI6/PI7. Each of these pairs can be used as a differential clock for the OCTOSPIs or HSPI, but this caution applies even if these pairs are used for other purposes.
13.3.21 I/O compensation cell

The I/O commutation slew rate (t_{fall}/t_{rise}) can be adapted by software depending on process, voltage, and temperatures conditions, in order to reduce the I/O noise on power supply. Refer to Section 15: System configuration controller (SYSCFG) for more details.

13.4 GPIO registers

This section gives a detailed description of the GPIO registers.

The peripheral registers can be written in word, half word or byte mode.

The number of GPIOx ports varies in the STM32U5 Series devices. Refer to the product datasheet for availability of a particular port. If not present, consider the associated bits as reserved and keep them at the reset value.

13.4.1 GPIO port mode register (GPIOx_MODER) (x = A to J)

Address offset:0x00
Reset value: 0xABFF FFFF (for port A)
Reset value: 0xFFFF FEBF (for port B)
Reset value: 0xFFFF FFFF (for ports C..E)
Reset value: 0xFFFF FFFF (for port F on STM32U575/585/59x/5Ax/5Fx/5Gx)
Reset value: 0xFFFF FFF0 (for port G on STM32U535/545)
Reset value: 0xFFFF FFFF (for port G on STM32U575/585/59x/5Ax/5Fx/5Gx)
Reset value: 0x0000 00CF (for port H on STM32U535/545)
Reset value: 0xFFFF FFFF (for port H on STM32U575/585/59x/5Ax/5Fx/5Gx)
Reset value: 0x0000 FFFF (for port I on STM32U575/585)
Reset value: 0xFFFF FFFF (for port I on STM32U59x/5Ax/5Fx/5Gx)
Reset value: 0x00FF FFFF (for port J on STM32U59x/5Ax/5Fx/5Gx)

<tr>
<td></td>
<td>This field is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.</td>
</tr>
</tbody>
</table>

**Bits 31:0** OSPEEDy[1:0]: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output speed.

00: Low speed

01: Medium speed

10: High speed

11: Very-high speed

Note: Refer to the device datasheet for the frequency specifications, and the power supply and load conditions for each speed.

This field is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.
13.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A to J)

Address offset: 0x0C
Reset value: 0x6400 0000 (for port A)
Reset value: 0x0000 0100 (for port B)
Reset value: 0x0000 0000 (for the other ports)

Bits 31:0 PUPDy[1:0]: Port x configuration I/O pin y (y = 15 to 0)
These bits are written by software to configure the I/O pull-up or pull-down
00: No pull-up, pull-down
01: Pull-up
10: Pull-down
11: Reserved

Note: This field is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.

13.4.5 GPIO port input data register (GPIOx_IDR) (x = A to J)

Address offset: 0x10
Reset value: 0x0000 XXXX

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:0 IDy: Port x input data I/O pin y (y = 15 to 0)
These bits are read-only. They contain the input value of the corresponding I/O port.

Note: This bit is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.
13.4.6 GPIO port output data register (GPIOx_ODR) (x = A to J)

Address offset: 0x14
Reset value: 0x0000 0000

| Bits 31:16 | Reserved, must be kept at reset value. |
| Bits 15:0 | ODy: Port output data I/O pin y (y = 15 to 0) |
|           | These bits can be read and written by software. |
|           | Note: For atomic bit set/reset, these bits can be individually set and/or reset by writing to GPIOx_BSR or GPIOx_BRR (x = A to J). |
|           | This bit is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package. |

13.4.7 GPIO port bit set/reset register (GPIOx_BSR) (x = A to J)

Address offset: 0x18
Reset value: 0x0000 0000

| Bits 31:16 | BRy: Port x reset I/O pin y (y = 15 to 0) |
|           | These bits are write-only. A read to these bits returns the value 0x0000. |
|           | 0: No action on the corresponding ODy bit |
|           | 1: Resets the corresponding ODy bit |
|           | Note: If both BSy and BRy are set, BSy has priority. |
|           | This bit is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package. |

| Bits 15:0 | BSy: Port x set I/O pin y (y = 15 to 0) |
|           | These bits are write-only. A read to these bits returns the value 0x0000. |
|           | 0: No action on the corresponding ODy bit |
|           | 1: Sets the corresponding ODy bit |
|           | Note: The bit is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package. |
13.4.8  GPIO port configuration lock register (GPIOx_LCKR) (x = A to J)

Address offset: 0x1C
Reset value: 0x0000 0000

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

Note: A specific write sequence is used to write to GPIOx_LCKR. Only word access (32-bit long) is allowed during this locking sequence.

Each lock bit freezes a specific configuration register (control and alternate function registers).

<table>
<thead>
<tr>
<th>Bit 31:17</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 16</td>
<td>LCKK: Lock key</td>
</tr>
<tr>
<td>This bit can be read any time. It can only be modified using the lock key write sequence.</td>
<td></td>
</tr>
<tr>
<td>0: Port configuration lock key not active</td>
<td></td>
</tr>
<tr>
<td>1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.</td>
<td></td>
</tr>
<tr>
<td>- LOCK key write sequence:</td>
<td></td>
</tr>
<tr>
<td>WR LCKR[16] = 1 + LCKR[15:0]</td>
<td></td>
</tr>
<tr>
<td>WR LCKR[16] = 0 + LCKR[15:0]</td>
<td></td>
</tr>
<tr>
<td>WR LCKR[16] = 1 + LCKR[15:0]</td>
<td></td>
</tr>
<tr>
<td>- LOCK key read</td>
<td></td>
</tr>
<tr>
<td>RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)</td>
<td></td>
</tr>
</tbody>
</table>

Note: During the lock key write sequence, the value of LCK[15:0] must not change.
Any error in the lock sequence aborts the LOCK.
After the first lock sequence on any bit of the port, any read access on the LCKK bit returns 1 until the next MCU reset or peripheral reset.

<table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HSLVy**: Port x high-speed low-voltage configuration (y = 15 to 0)
These bits are written by software to optimize the I/O speed when the I/O supply is low.
Each bit is active only if the corresponding IO_VDD_HSLV/IO_VDDIO2_HSLV user option bit is set. It must be used only if the I/O supply voltage is below 2.7 V.
Setting these bits when the I/O supply (VDD or VDDIO2) is higher than 2.7 V may be destructive.
0: I/O speed optimization disabled
1: I/O speed optimization enabled

**Note:** Not all I/Os support the HSLV mode. Refer to the I/O structure in the corresponding datasheet for the list of I/Os supporting this feature. Other I/Os HSLV configuration must be kept at reset value.
This bit is reserved and must be kept at reset value when the corresponding I/O is not available on the selected package.
13.4.13 GPIO secure configuration register (GPIOx_GPIOCGR) (x = A to J)

Address offset: 0x30
Reset value: 0x0000 FFFF (for ports A to E)
Reset value: 0x0000 FFFF (for port F on STM32U575/585/59x/5Ax/5Fx/5Gx)
Reset value: 0x0000 FFFC (for port G on STM32U535/545)
Reset value: 0x0000 FFFF (for port H on STM32U575/585/59x/5Ax/5Fx/5Gx)
Reset value: 0x0000 000B (for port I on STM32U535/545)
Reset value: 0x0000 FFFF (for port I on STM32U59x/5Ax/5Fx/5Gx)
Reset value: 0x0000 00FF (for port J on STM32U575/585/59x/5Ax/5Fx/5Gx)
Reset value: 0x0000 0FFF (for port J on STM32U59x/5Ax/5Fx/5Gx)

When the system is secure (TZEN = 1), this register provides write access security and can be written only by a secure access. It is used to configure a selected I/O as secure. A non-secure write access to this register is discarded.

When the system is not secure (TZEN = 0), this register is RAZ/WI.

| Bits 31:16 | Reserved, must be kept at reset value. |
| Bits 15:0 | SECy: I/O pin of Port x secure bit enable y (y = 15 to 0) |
| These bits are written by software to enable or disable the I/O port pin security. |
| 0: The I/O pin is nonsecure |
| 1: The I/O pin is secure. Refer to Table 127 for all corresponding secured bits. |

**Note:** The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Refer to Section 2.3 for the register boundary addresses.
14 Low-power general-purpose I/Os (LPGPIO)

14.1 Introduction

The low-power general-purpose input/output (LPGPIO) allows the I/O control in Stop mode (down to Stop 2 mode), using DMA in memory-to-memory transfer mode. LPGPIO is designed to be used in conjunction with the GPIO.

14.2 LPGPIO main features

- 16 I/Os control in low-power modes down to Stop 2 mode
- Secure clock and reset management
- Output data from output data register (LPGPIO_ODR)
- Input data to input data register (LPGPIO_IDR)
- Bit set and reset register (LPGPIO_BSRR) for bitwise write access to LPGPIO_ODR
- TrustZone security support

14.3 LPGPIO functional description

14.3.1 LPGPIO and GPIO configuration

The LPGPIO can control in input or output up to 16 I/Os thanks to LPGPIO_Py (y = 0 to 15) pins alternate functions. This control is still functional in Stop 2 mode, thanks to DMA transfers. The I/Os with a LPGPIO function must be configured as LPGPIO alternate function in GPIOx_MODER. Then the I/O value can be read in the LPGPIO input data register, and the I/O can be driven by the LPGPIO output data register or thanks to LPGPIO_BSRR/LPGPIO_BRR registers.

14.3.2 LPGPIO control registers

Each of the 16 I/Os controlled by the LPGPIO can be configured as input or output thanks to LPGPIO_MODER.

14.3.3 LPGPIO I/O data registers

The LPGPIO includes the following 16-bit data registers:

- LPGPIO_ODR that stores the data to be output (read/write accessible)
- LPGPIO_IDR that stores the data input through the I/O (read only)

14.3.4 LPGPIO I/O data bitwise handling

The 32-bit LPGPIO_BSRR is implemented to allow bitwise set and reset in LPGPIO_ODR.

Each LPGPIO_ODR bit has the following control bits in LPGPIO_BSRR:

- LPGPIO_BSRR(i): when writing 1 to it, this bit sets the LPGPIO_ODR(i) bit.
- LPGPIO_BSRR(i + 16): when writing 1 to it, this bit resets the LPGPIO_ODR(i) bit.

Note: Writing 0 to these bits has no effect on LPGPIO_ODR corresponding bits.
If there is an attempt to set and reset bits of the same index, the set action takes the priority.

Writing LPGPIO_BSRR register does not lock the LPGPIO_ODR bits, that can be anyway accessed directly. LPGPIO_BSRR provides a way to perform atomic bitwise handling.

The 16-bit LPGPIO_BRR allows individual bit reset. It is the same as LPGPIO_BSRR but with minimal pattern preparation:
- LPGPIO_BRR(i): when writing 1 to it, this bit resets the LPGPIO_ODR(i) bit.

14.3.5 Security protection

The LPGPIO includes a security mechanism, that allows or locks the access to the I/O configuration and data registers. This system is used to protect the I/O against the data corruption or observation.

The security mechanism within the LPGPIO is directly issued from GPIOx_SECCFGR. Therefore, no additional configuration is required.

The LPGPIO security means the following:
- When the executed code is secure, all bits can be accessed.
- When the executed code is nonsecure, only the bits concerning the nonsecure I/Os can be accessed.

A nonsecure access to a secure I/O register bit is silent fail:
- A nonsecure write to a secure I/O register bit is ignored (WI).
- A nonsecure read to a secure I/O register bit returns 0 (RAZ).
- No bus error is generated.

14.3.6 Secure clock and reset management

The LPGPIO clock and reset control bits in the RCC are automatically configured as secured as soon as at least one I/O with LPGPIO alternate function is secure (refer to the corresponding I/Os in GPIO_SECCFGR registers).

14.4 LPGPIO registers

This section gives a detailed description of the LPGPIO registers.

The peripheral registers can be written in word, half-word or byte mode.

14.4.1 LPGPIO port mode register (LPGPIO_MODER)

Address offset: 0x00

Reset value: 0x0000 0000

14.4.2 LPGPIO port input data register (LPGPIO_IDR)

Address offset: 0x10
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 \textbf{MODE}_y: Configuration I/O pin \( y \) (\( y = 15 \) to \( 0 \))
These bits are written by software to configure the I/O mode.
0: Input mode
1: Output mode

14.4.3 LPGPIO port output data register (LPGPIO_ODR)

Address offset: 0x14
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 \textbf{ID}_y: Input data I/O pin \( y \) (\( y = 15 \) to \( 0 \))
These bits are read-only. They contain the input value of the corresponding I/O port.

Note: For atomic bit set/reset, these OD bits can be individually set and/or reset by writing to the LPGPIO_BSRR or LPGPIO_BRR registers.
14.4.4 LPGPIO port bit set/reset register (LPGPIO_BSRR)

Refer to Section 2.3 for the register boundary addresses.
15 System configuration controller (SYSCFG)

15.1 SYSCFG main features

The STM32U5 Series devices feature a set of configuration registers. The main purposes of the system configuration controller are the following:

- Managing robustness feature
-Configuring FPU interrupts
- Enabling/disabling the FMP high-drive mode of some I/Os and voltage booster for I/Os analog switches
- Managing the I/O compensation cell
- Configuring register security access
- Configuring the OTG_HS PHY (only for STM32U59x/5Ax/5Fx/5Gx)
- Adjust the HSPI supply capacitance (only for STM32U59x/5Ax/5Fx/5Gx)
- Disable internal SRAMs cacheability by DCACHE2 (only for STM32U59x/5Ax/5Fx/5Gx)

15.2 SYSCFG functional description

15.2.1 I/O compensation cell management

The I/O compensation cell generates an 8-bit value for the I/O buffer (4 bits for N-MOS and 4 bits for P-MOS), which depends on PVT operating conditions (process, voltage, temperature). These bits are used to control the current slew-rate and output impedance in the I/O buffer. Three compensation cells are embedded, one for the I/Os supplied by VDD, one for the I/Os supplied by VDDIO2, and one dedicated to GPIOs with HSPI alternate functions (AF) capabilities.

By default, the compensation cells are disabled, and a fixed code is applied to all the I/Os. The HSI is used by the compensation cells and must be enabled before enabling the compensation cells in SYSCFG_CCCSR.

When enabled, the compensation cell tracks the PVT, and the 8-bit code PCVx and NCVx (x = 1 for I/Os supplied by VDD except the HSPI AF capabilities, x = 2 for I/Os supplied by VDDIO2 and x = 3 for I/Os with HSPI AF capabilities supplied by VDD) are available in SYSCFG_CCVR once the RDYx is set. If the CSx bit is cleared, the I/Ox receives the code from SYSCFG_CCVR, resulting from the compensation cell.

To optimize the trimming, the code can be adjusted through SYSCFG_CCCR. Three sets of bits are available: PCC1/NCC1 and PCC3/NCC3 for the VDD power rail, and PCC2/NCC2 for the VDDIO2 power rail. They can be selected independently through CS1, CS2, and CS3 bits in SYSCFG_CCCSR (see Figure 48).

To reduce the power consumption, it is recommended to copy the code from SYSCFG_CCVR to SYSCFG_CCCR. After the result is ready, set the CSx bit and disable the compensation cell.

Note: The compensation cell can be used only when 1.6 V ≤ VDDIOx ≤ 3.6 V.
15.2.2 **SYSCFG TrustZone security and privilege**

**SYSCFG TrustZone security**

When the TrustZone security is activated, the SYSCFG is able to secure registers from being modified by nonsecure accesses.

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.

A nonsecure read/write access to a secured register is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the SYSCFG illegal access event is enabled in the GTZC.

**Privileged/unprivileged mode**

The SYSCFG registers can be read and written by privileged and unprivileged accesses except the SYSCFG registers for CPU configuration: SYSCFG_CSLCKR, SYSCFG_FPUIMR and SYSCFG_CNSLCKR registers, and the FPUSEC bit in the SYSCFG_SECCFRGR.

An unprivileged access to a privileged register is RAZ/WI.
The table below shows the register security overview.

### Table 130. TrustZone security and privilege register accesses

</tbody>
</table>
15.2.3 Configuring the OTG_HS PHY
(only for STM32U59x/5Ax/5Fx/5Gx)

In order to use the OTG_HS PHY, the following configuration steps are required before the configuration of the OTG_HS:

1. Activate clocks in RCC clock gating registers for SYSCFG, OTG_HS, and OTG_HS PHY.
2. Configure desired clock settings for OTG_HS PHY using CLKSEL bitfield in SYSCFG_OTGHSPHYCR.
3. Adjust the disconnect threshold by writing 0b010 to COMPDISTUNE bitfield and the squelch threshold by writing 0b000 to SQRXTUNE bitfield in SYSCFG_OTGHSPHYTUNER2.
4. Enable the OTG_HS PHY by setting EN in SYSCFG_OTGHSPHYCR.

15.2.4 Adjusting HSPI supply capacitance
(only for STM32U59x/5Ax/5Fx/5Gx)

The HSPI supply capacitance can be adjusted using ENDCAP[1:0] in SYSCFG_CFGR1. If the HSPI alternate functions are not used, ENDCAP[1:0] must be left at its reset value.

15.2.5 Internal SRAMs cacheability by DCACHE2
(only for STM32U59x/5Ax/5Fx/5Gx)

Since DCACHE2 is only addressed by the GPU2D M0 port, and because vector graphic algorithms can manipulate data on the M1 port, it is recommended to clear SRAMCACHED in SYSCFG_CFGR1 before activating the GPU2D, to avoid any cache coherency issues. Also, since internal SRAMs are accessible in zero wait state through the bus matrix, no performance degradation is expected.
### 15.3 SYSCFG registers

#### 15.3.1 SYSCFG secure configuration register (SYSCFG_SECCFGR)

**Address offset:** 0x00  
**Reset value:** 0x0000 0000

When the system is secure (TZEN = 1), this register provides write access security and can be written only when the access is secure. It can be globally write-protected, or each bit of this register can be individually write-protected. A nonsecure write access is WI and generates an illegal access event. There are no read restrictions.

When the system is not secure (TZEN = 0), this register is RAZ/WI.

This register can be read and written by privileged and unprivileged access, except for FPUSEC that can be written only with privileged access.

</tbody>
</table>

**Bits 31:4** Reserved, must be kept at reset value.

**Bit 3** FPUSEC: FPU security  
0: SYSCFG_FPUIMR can be read and written by secure and nonsecure access.  
1: SYSCFG_FPUIMR can be read and written by secure access only.

**Bit 2** Reserved, must be kept at reset value.

**Bit 1** CLASSBSEC: Class B security  
0: SYSCFG_CFGR2 can be read and written by secure and nonsecure access.  
1: SYSCFG_CFGR2 can be read and written by secure access only.

**Bit 0** SYSCFGSEC: SYSCFG clock control, memory erase status and compensation cell registers security  
0: SYSCFG configuration clock in RCC registers, SYSCFG_MESR and SYSCFG_CCCSR, SYSCFG_CCVR and SYSCFG_CCCR can be read and written by secure and nonsecure access.  
1: SYSCFG configuration clock in RCC registers, SYSCFG_MESR and SYSCFG_CCCSR, SYSCFG_CCVR and SYSCFG_CCCR can be read and written by secure access only.
15.3.2 SYSCFG configuration register 1 (SYSCFG_CFGR1)

Address offset: 0x04
Reset value: 0x0000 0000 (for STM32U535/545/575/585)
Reset value: 0x1000 0000 (for STM32U59x/5Ax/5Fx/5Gx)

When the system is secure (TZEN = 1), this register can be a mix of secure and nonsecure bits depending on the ADC security configuration bit in GTZC peripheral and GPIO security bits. A nonsecure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN = 0), there is no access restriction. This register can be read and written by privileged and unprivileged access.

<table>
<thead>
<tr>
<th>Bit 31:29 Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>

- **Bit 28 SRAMCACHED**: Enable internal SRAMs cachability by DCACHE2
  - 0: SRAMx are not cached by DCACHE2
  - 1: SRAMx are cached by DCACHE2
  - *Note:* This bit is only available on some devices of the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

- **Bits 27:26 Reserved, must be kept at reset value.**

- **Bits 25:24 ENDCAP[1:0]**: Enable decoupling capacitance on HSPI supply
  - 00: Capacitance OFF
  - 01: 1/3 capacitance
  - 10: 2/3 capacitance
  - 11: Full capacitance
  - *Note:* This bitfield is only available on some devices of the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bitfield as reserved and keep it at reset value.

- **Bits 23:20 Reserved, must be kept at reset value.**

- **Bit 19 PB9_FMP**: Fast-mode Plus driving capability activation on PB9
  - This bit can be read and written only with secure access if PB9 is secure in GPIOB. This bit enables the Fm+ driving mode for PB9 when PB9 is not used by the I2C peripheral. This can be used to drive a LED for instance.
  - 0: PB9 pin operates in standard mode.
  - 1: Fm+ mode is enabled on PB9 pin and the speed control is bypassed.
Bit 18 **PB8\_FMP**: Fast-mode Plus driving capability activation on PB8

This bit can be read and written only with secure access if PB8 is secure in GPIOB. This bit enables the Fm+ driving mode for PB8 when PB8 is not used by I2C peripheral. This can be used to drive a LED for instance.

0: PB8 pin operates in standard mode.
1: Fm+ mode is enabled on PB8 pin and the speed control is bypassed.

Bit 17 **PB7\_FMP**: Fast-mode Plus driving capability activation on PB7

This bit can be read and written only with secure access if PB7 is secure in GPIOB. This bit enables the Fm+ driving mode for PB7 when PB7 is not used by I2C peripheral. This can be used to drive a LED for instance.

0: PB7 pin operates in standard mode.
1: Fm+ mode is enabled on PB7 pin and the speed control is bypassed.

Bit 16 **PB6\_FMP**: Fast-mode Plus driving capability activation on PB6

This bit can be read and written only with secure access if PB6 is secure in GPIOB. This bit enables the Fm+ driving mode for PB6 when PB6 is not used by the I2C peripheral. This can be used to drive a LED for instance.

0: PB6 pin operates in standard mode.
1: Fm+ mode is enabled on PB6 pin, and the speed control is bypassed.

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **ANASWVDD**: GPIO analog switch control voltage selection

This bit can be read and written only with secure access if ADC12 or ADC4 is secure in GTZC.

0: I/O analog switches are supplied by V_{DDA} or booster when booster is ON.
1: I/O analog switches are supplied by V_{DD}.

*Note: Refer to Table 131 for bit 9 setting.*

Bit 8 **BOOSTEN**: I/O analog switch voltage booster enable

This bit can be read and written only with secure access if ADC12 or ADC4 is secure in GTZC.

0: I/O analog switches are supplied by V_{DDA} voltage.
1: I/O analog switches are supplied by a dedicated voltage booster (supplied by V_{DD}).

*Note: Refer to Table 131 for bit 8 setting.*

Bits 7:0 Reserved, must be kept at reset value.

The table below describes when bit 8 (BOOSTEN) and bit 9 (ANASWVDD) must be set or reset depending on the voltage settings.

<table>
<thead>
<tr>
<th>V_{DD}</th>

*Table 131. BOOSTEN and ANASWVDD set/reset*
15.3.3 SYSCFG FPU interrupt mask register (SYSCFG_FPUIMR)

Address offset: 0x08
Reset value: 0x0000 001F

When the system is secure (TZEN = 1), this register can be protected against nonsecure access by setting the FPUSEC bit in the SYSCFG_SECCFGR register: a nonsecure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction. This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

<table>
<thead>
<tr>
<th>Bit 31-6</th>
<th>Bit 5-0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved</td>
<td>FPU_IE[5:0]</td>
</tr>
</tbody>
</table>

Bits 31-6 Reserved, must be kept at reset value.

Bits 5-0:
- **FPU_IE[5]**: Inexact interrupt enable (interrupt disable at reset)
- **FPU_IE[4]**: Input abnormal interrupt enable
- **FPU_IE[3]**: Overflow interrupt enable
- **FPU_IE[2]**: Underflow interrupt enable
- **FPU_IE[1]**: Divide-by-zero interrupt enable
- **FPU_IE[0]**: Invalid operation Interrupt enable

15.3.4 SYSCFG CPU nonsecure lock register (SYSCFG_CNSLCKR)

Address offset: 0x0C
Reset value: 0x0000 0000

This register is used to lock the configuration of nonsecure MPU and VTOR_NS registers. This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

<table>
<thead>
<tr>
<th>Bit 31-2</th>
<th>Bit 17-16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved</td>
<td>LOCKN_SMPU LOCKN_SVTO</td>
</tr>
</tbody>
</table>

Bits 31-2 Reserved, must be kept at reset value.
Bit 1 **LOCKNSMPU**: Nonsecure MPU registers lock  
This bit is set by software and cleared only by a system reset. When set, this bit disables write access to nonsecure MPU_CTRL_NS, MPU_RNR_NS and MPU_RBAR_NS registers.  
0: Nonsecure MPU registers write enabled  
1: Nonsecure MPU registers write disabled  

Bit 0 **LOCKNSVTOR**: VTOR_NS register lock  
This bit is set by software and cleared only by a system reset.  
0: VTOR_NS register write enabled  
1: VTOR_NS register write disabled  

**15.3.5 SYSCFG CPU secure lock register (SYSCFG_CSLCKR)**  
Address offset: 0x10  
Reset value: 0x0000 0000  
This register is used to lock the configuration of PRIS and BFHFNMINS in AIRCR register, SAU, secure MPU, and VTOR_S registers.  
When the system is secure (TZEN = 1), this register can be written only when the access is secure. A nonsecure read/write access is RAZ/WI and generates an illegal access event.  
When the system is not secure (TZEN = 0), this register is RAZ/WI. This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

### 15.3.6 SYSCFG configuration register 2 (SYSCFG_CFGR2)

Address offset: 0x14
Reset value: 0x0000 0000

When the system is secure (TZEN = 1), this register can be protected against nonsecure access by setting the CLASSBSEC bit in the SYSCFG_SECCFGR register. When CLASSBSEC bit is set, only secure access is allowed: nonsecure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction. This register can be read and written by privileged and unprivileged access.

15.3.7 SYSCFG memory erase status register (SYSCFG_MESR)

Address offset: 0x18

Power-on reset value: 0x0000 0000

System reset value: 0x0000 000X (bit 0 not affected by system reset)

When the system is secure (TZEN = 1), this register can be protected against nonsecure access by setting the SYSCFGSEC bit in the SYSCFG_SECCFGR register. When the SYSCFGSEC bit is set, only secure access is allowed: nonsecure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction. This register can be read and written by privileged and unprivileged access.

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   | IPMEE |   |   |   |   |   |   |   |   |   |   |   |
| rc_w1 |   |   |   |   |   |   |   |   |   |   | rc_w1 |   |   |   |   |   |   |   |   |   |   |   |
| 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   | IPMEE |   |   |   |   |   |   |   |   |   |   |   |
| rc_w1 |   |   |   |   |   |   |   |   |   |   | rc_w1 |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **IPMEE**: ICACHE and PKA SRAM erase status

This bit is set by hardware when ICACHE and PKA SRAM erase is completed after potential tamper detection (refer to Section 64: Tamper and backup registers (TAMP) for more details). This bit is cleared by software by writing 1 to it.

0: ICACHE and PKA SRAM erase on going if not yet cleared by software
1: ICACHE and PKA SRAM erase done

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **MCLR**: Erase status of device memories

This bit is set by hardware when SRAM2, BKPSRAM, ICACHE, DCACHE1/2, PKA SRAM erase is completed after power-on reset or tamper detection (refer to Section 64: Tamper and backup registers (TAMP) for more details). This bit is not reset by system reset and is cleared by software by writing 1 to it.

0: memory erase on going if not yet cleared by software
1: Memory erase done
15.3.8 SYCFG compensation cell control/status register (SYSCFG_CCCSR)

Address offset: 0x1C

Reset value: 0x0000 000A (for STM32U535/545/575/585 devices)
Reset value: 0x0000 002A (for STM32U59x/5Ax/5Fx/5Gx devices)

When the system is secure (TZEN = 1), this register can be protected against nonsecure access by setting the SYSCFGSEC bit in the SYSCFG_SECCFGR register. When the SYSCFGSEC bit is set, only secure access is allowed: nonsecure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction. This register can be read and written by privileged and unprivileged access.

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 RDY3: HSPI I/O compensation cell ready flag
This bit provides the compensation cell status of the HSPI I/Os supplied by VDD.
0: HSPI I/O compensation cell not ready
1: HSPI I/O compensation cell ready

Note: The HSI clock is required for the compensation cell to work properly. The compensation cell ready bit (RDY3) is not set if the HSI clock is not enabled. This compensation cell acts on the GPIOs with HSPI alternate functions but independently of this mode or AF configuration. Compensation cell 1 does not have effect on these GPIOs. This bit is only available on some devices in the STM32U5 Series; refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 9 RDY2: VDDIO2 I/O compensation cell ready flag
This bit provides the compensation cell status of the I/Os supplied by VDDIO2.
0: VDDIO2 I/O compensation cell not ready
1: VDDIO2 I/O compensation cell ready

Note: The HSI clock is required for the compensation cell to work properly. The compensation cell ready bit (RDY2) is not set if the HSI clock is not enabled.

Bit 8 RDY1: VDD I/Os compensation cell ready flag
This bit provides the compensation cell status of the I/Os supplied by VDD.
0: VDD I/O compensation cell not ready
1: VDD I/O compensation cell ready

Note: The HSI clock is required for the compensation cell to work properly. The compensation cell ready bit (RDY1) is not set if the HSI clock is not enabled.

Bits 7:6 Reserved, must be kept at reset value.
Bit 5  **CS3**: HSPI I/Os code selection
This bit selects the code to be applied for the compensation cell of the HSPI I/Os supplied by VDD.
0: HSPI I/O code from the cell (available in the SYSCFG_CCVR)
1: HSPI I/O code from the SYSCFG compensation cell code register (SYSCFG_CCCR)

*Note:* The compensation cell acts on the GPIOs with HSPI alternate functions but independently of this mode or AF configuration. Compensation cell 1 does not have effect on these GPIOs.
This bit is only available on some devices in the STM32U5 Series; refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 4  **EN3**: HSPI I/Os compensation cell enable
This bit enables the compensation cell of the HSPI I/Os supplied by VDD.
0: HSPI I/O compensation cell disabled
1: HSPI I/O compensation cell enabled

*Note:* The compensation cell acts on the GPIOs with HSPI alternate functions but independently of this mode or AF configuration. Compensation cell 1 does not have effect on these GPIOs.
This bit is only available on some devices in the STM32U5 Series; refer to the device datasheet for availability of its associated peripheral. If not present, consider this bit as reserved and keep it at reset value.

Bit 3  **CS2**: VDDIO2 I/O code selection
This bit selects the code to be applied for the compensation cell of the I/Os supplied by VDDIO2.
0: VDDIO2 I/O code from the cell (available in SYSCFG_CCVR)
1: VDDIO2 I/O code from SYSCFG_CCCR

Bit 2  **EN2**: VDDIO2 I/O compensation cell enable
This bit enables the compensation cell of the I/Os supplied by VDDIO2.
0: VDDIO2 I/O compensation cell disabled
1: VDDIO2 I/O compensation cell enabled

Bit 1  **CS1**: VDD I/O code selection
This bit selects the code to be applied for the compensation cell of the I/Os supplied by VDD.
0: VDD I/O code from the cell (available in the SYSCFG_CCVR)
1: VDD I/O code from the SYSCFG compensation cell code register (SYSCFG_CCCR)

Bit 0  **EN1**: VDD I/O compensation cell enable
This bit enables the compensation cell of the I/Os supplied by VDD.
0: VDD I/O compensation cell disabled
1: VDD I/O compensation cell enabled
15.3.9 SYSCFG compensation cell value register (SYSCFG_CCVR)

Address offset: 0x20
Reset value: 0x0000 0000

When the system is secure (TZEN = 1), this register can be protected against nonsecure access by setting the SYSCFGSEC bit in the SYSCFG_SECCFGR register. When the SYSCFGSEC bit is set, only secure access is allowed: nonsecure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction. This register can be read and written by privileged and unprivileged access.

| Bit 31:24 | Reserved, must be kept at reset value. |
| Bit 23:20 | **PCV3[3:0]**: PMOS compensation value of the HSPI I/Os supplied by VDD |
|           | This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when CS3 = 0 in SYSCFG_CCCSR. |
|           | **Note:** The compensation cell acts on the GPIOs with HSPI alternate functions but independently of this mode or AF configuration. Compensation cell 1 does not have effect on these GPIOs. |
|           | This bitfield is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bitfield as reserved and keep it at reset value. |
| Bit 19:16 | **NCV3[3:0]**: NMOS compensation value of the HSPI I/Os supplied by VDD |
|           | This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when CS3 = 0 in SYSCFG_CCCSR. |
|           | **Note:** The compensation cell acts on the GPIOs with HSPI alternate functions but independently of this mode or AF configuration. Compensation cell 1 does not have effect on these GPIOs. |
|           | This bitfield is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bitfield as reserved and keep it at reset value. |
| Bit 15:12 | **PCV2[3:0]**: PMOS compensation value of the I/Os supplied by VDDIO2 |
|           | This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when CS2 = 0 in SYSCFG_CCCSR. |
| Bit 11:8  | **NCV2[3:0]**: NMOS compensation value of the I/Os supplied by VDDIO2 |
|           | This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when CS2 = 0 in SYSCFG_CCCSR. |
Bits 7:4 **PCV1[3:0]**: PMOS compensation value of the I/Os supplied by V\textsubscript{DD}
This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when CS1 = 0 in SYSCFG\_CCCSR.

Bits 3:0 **NCV1[3:0]**: NMOS compensation value of the I/Os supplied by V\textsubscript{DD}
This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when CS1 = 0 in SYSCFG\_CCCSR

### 15.3.10 SYSCFG compensation cell code register (SYSCFG\_CCCR)

Address offset: 0x24

Reset value: 0x0000 7878 (for STM32U535/545/575/585 devices)

Reset value: 0x0078 7878 (for STM32U59x/5Ax/5Fx/5Gx devices)

When the system is secure (TZEN = 1), this register can be protected against nonsecure access by setting the SYSCFGSEC bit in the SYSCFG\_SECCFGR register. When SYSCFGSEC bit is set, only secure access is allowed: nonsecure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction. This register can be read and written by privileged and unprivileged access.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **PCC3[3:0]**: PMOS compensation code of the HSPI I/Os supplied by V\textsubscript{DD}

These bits are written by software to define an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when CS3 = 1 in SYSCFG\_CCCSR.

**Note:** The compensation cell acts on the GPIOs with HSPI alternate functions but independently of this mode or AF configuration. Compensation cell 1 does not have effect on these GPIOs.

This bitfield is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bitfield as reserved and keep it at reset value.

Bits 19:16 **NCC3[3:0]**: NMOS compensation code of the HSPI I/Os supplied by V\textsubscript{DD}

These bits are written by software to define an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when CS3 = 1 in SYSCFG\_CCCSR.

**Note:** The compensation cell acts on the GPIOs with HSPI alternate functions but independently of this mode or AF configuration. Compensation cell 1 does not have effect on these GPIOs.

This bitfield is only available on some devices in the STM32U5 Series. Refer to the device datasheet for availability of its associated peripheral. If not present, consider this bitfield as reserved and keep it at reset value.
Bits 15:12 **PCC2[3:0]**: PMOS compensation code of the I/Os supplied by VDDIO2  
These bits are written by software to define an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when CS2 = 1 in SYSCFG_CCCSR.

Bits 11:8 **NCC2[3:0]**: NMOS compensation code of the I/Os supplied by VDDIO2  
These bits are written by software to define an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when CS2 = 1 in SYSCFG_CCCSR.

Bits 7:4 **PCC1[3:0]**: PMOS compensation code of the I/Os supplied by VDD  
These bits are written by software to define an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when CS1 = 1 in SYSCFG_CCCSR.

Bits 3:0 **NCC1[3:0]**: NMOS compensation code of the I/Os supplied by VDD  
These bits are written by software to define an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when CS1 = 1 in SYSCFG_CCCSR.

### 15.3.11 SYSCFG RSS command register (SYSCFG_RSSCMDR)

**Address offset:** 0x2C  
**Power-on reset value:** 0x0000 0000  
**System reset:** not affected

When the system is secure (TZEN = 1), this register can be read and written only when the APB access is secure. Otherwise it is RAZ/WI.

When the system is not secure (TZEN = 0), this register is RAZ/WI. This register can be read and written by privileged and unprivileged access.

16 Peripherals interconnect matrix

16.1 Interconnect matrix introduction

Several peripherals have direct connections between them. This allows autonomous communication and or synchronization between peripherals, saving CPU resources, thus power supply consumption.

In addition, these hardware connections remove software latency and allow design of predictable system.

Depending on peripherals, these interconnections can operate in various power modes: Run, Sleep, Stop 0, Stop 1, and Stop 2 modes.
### 16.2 Connection summary

Table 133. Peripherals interconnect matrix\(^{(1)}\) \(\^{(2)}\)

2. "-" means no interconnect.
16.3 Interconnection details

16.3.1 Master to slave interconnection for timers

From timer (TIM1/2/3/4/5/8/15/16/17) to timer (TIM1/2/3/4/5/8/15)

Purpose

Some of the TIMx timers are linked together internally for timer synchronization or chaining.

When one timer is configured in master mode, it can reset, start, stop, or clock the counter of another timer configured in slave mode.

A description of the feature is provided in Section 55.4.23: Timer synchronization.

The synchronization modes are detailed in:
- Section 54.3.30 for advanced-control timers TIM1/TIM8
- Section 55.4.22 for general-purpose timers TIM2/TIM3/TIM4/TIM5
- Section 56.4.23 for the general-purpose timer TIM15

Triggering signals

The output (from master) is on signal TIMx_TRGO (and TIMx_TRGO2 for TIM1/8) following a configurable timer event. It can be also from signals tim16_oc1 and tim17_oc1 in case of TIM16/17. The input (to slave) is on signals TIMx_ITR0/1/2/3.

The possible master/slave connections are given in:
- Table 532 for advanced-control timers TIM1/8
- Table 557 for general-purpose timers TIM2/3/4/5
- Table 574 for the general-purpose timers TIM15

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:
- Table 546: Effect of low-power modes on TIM1/TIM8
- Table 566: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5
- Table 581: Effect of low-power modes on TIM15/TIM16/TIM17

16.3.2 Triggers to ADCs

From EXTI, timers (TIM1/2/3/4/5/8/15/16/17) and LP timers (LPTIM1/2/3/4) to ADC1/ADC2

From EXTI, timers (TIM1/2/6/15) and LP timers (LPTIM1/3) to ADC4

Purpose

A conversion, or a sequence of conversions, can be triggered either by software or by an external event (such as timer capture or input pins). For ADC12, if the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events can trigger a conversion with the selected polarity.

More details in:
- Section 33.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN[1:0], JEXTSEL, JEXTEN[1:0])
• EXTEN[1:0] defined in *ADC configuration register (ADC_CFRG1)*
• JEXTEN[1:0] defined in *ADC injected sequence register (ADC_JSRGR)*

General-purpose timers (TIM2/3/4/5), basic timer (TIM6), advanced-control timers (TIM1/8) and general-purpose timer (TIM15/16/17) can be used to generate the ADC triggering event through the timer outputs tim_oc and tim_trgo.

Low-power timers (LPTIM1/2/3/4) can be used to generate the ADC triggering event through the LPTIM channels (TIMx synchronization described in *Section 54.3.31: ADC triggers for TIM1/8*) in addition to the EXTI on channels 11 and 15.

The ADC4 do not have injected channels. The general-purpose timers (TIM2/15), basic timers (TIM6), and advanced-control timers (TIM1) can be used to generate the ADC triggering event through the timer outputs tim_oc and tim_trgo. Low-power timers (LPTIM1/3) can be used to generate the ADC triggering event through the LPTIM channels in addition to EXTI on channel 11 and 15.

**Triggering signals**

For ADC1/ADC2, the input triggering signals and the description of the interconnection between ADC1/ADC2, and timers, are given in:
• adc_ext_trgy: *Table 303: ADC1/ADC12 external triggers for regular channels*
• adc_jext_trgy: *Table 304: ADC1/ADC12 external triggers for injected channels*
• *Section 33.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN[1:0], JEXTSEL, JEXTEN[1:0])*
• *Section 33.4.25: Timing diagrams example (single/continuous modes, hardware/software triggers)*

For ADC4, the input triggering signals list and the description of the interconnection between ADC4 and timers, are given in:
• *Table 325: ADC interconnection*
• *Section 34.4.16: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN)*
• *Section 34.4.21: Example timing diagrams (single/continuous modes hardware/software triggers)*

**Active power mode**

This interconnection is active in Run and Sleep modes for all ADCs, and under Stop 0, Stop 1, and Stop 2 modes for ADC4 assuming that its trigger event line is active as well (such as LPTIM). The timers are active in Run and Sleep mode only. The effects of low-power modes are given in:
• *Table 546: Effect of low-power modes on TIM1/TIM8*
• *Table 566: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
• *Table 581: Effect of low-power modes on TIM15/TIM16/TIM17*
• *Section 34.5: ADC low-power modes for ADC4*
• *Table 593: STM32U5 Series LPTIM features*
• *Table 608: Effect of low-power modes on the LPTIM*
16.3.3 ADC analog watchdogs as triggers to timers

From ADC1/ADC4 to TIM1/3/8 on STM32U535/345/575/585.
From ADC1/ADC2/ADC4 to TIM1/3/4/8 on STM32U59x/5Ax/5Fx/5Gx.

Purpose

The internal analog watchdog output signals coming from ADC1/ADC2/ADC4, are connected to on-chip timers. ADC1/ADC2/ADC4 can provide trigger event through analog watchdog signals to advanced-control timers (TIM1/3/4/8) in order to reset, start, stop, or clock the counter.

Settings description of the ADC analog watchdog and timer trigger, are provided in:
- Section 54.3.6: External trigger input for TIM1/8
- Table 533 for the internal ADC1/ADC2/ADC4 sources connected to TIM1/8 (tim_etra) input multiplexer
- Table 559 for the internal ADC1/ADC2 sources connected to TIM3/4 (tim_etrb) input multiplexer
- Section 33.4.30 for the ADC1/ADC2/ADC_AWDy_OUT signal output generation
- Section 34.4.25 for the ADC4/ADC_AWDy_OUT signal output generation

Triggering signals

The output (from ADC) is on signals ADCn_AWDx_OUT, with n being the ADC instance and x = 1, 2, 3 (three watchdogs per ADC). The input (to timer) is on signal TIMx_ETR (external trigger).

Active power mode

ADC1/ADC2 and ADC4 are active in Run and Sleep modes.

The ADC4 conversion is functional and autonomous in Stop 0, Stop 1, and Stop 2 modes. This conversion can generate a wake-up interrupt and desired trigger action on timers.

16.3.4 Triggers to DAC

From timer (TIM1/2/4/5/6/7/8/15), Low-power timers (LPTIM1/3) and EXTI to DAC (DAC1/2)

Purpose

General-purpose timers (TIM2/4/5/15), basic timers (TIM6/7), advanced-control timers (TIM1/8), LP timers (LPTIM1/3) outputs channels (lptim1_ch1 and lptim3_ch1) and EXTI can be used as triggering event to start a DAC conversion.

Triggering signals

The output (from timer) on the TIMx_TRGO signal and from LP timers are directly connected to corresponding DAC inputs.

The selection of input triggers on DAC is provided in:
- Table 338: DAC interconnection
- Section 35.4.8: DAC trigger selection
Active power mode
This interconnect is active in Run, Sleep, Stop 0, Stop 1, and Stop 2 modes.

16.3.5 Triggers on MDF1 or ADF1
From EXTI, ADF1, timers (TIM1/3/4/6/7/8/16) and LP timer (LPTIM1), to MDF1
From EXTI and MDF1 to ADF1

Purpose
General-purpose timers (TIM3/4/16), basic timers (TIM6/7), advanced-control timers (TIM1/8), low-power timer (LPTIM1), EXTI (EXTI11/15) and ADF1 can be used to generate a triggering event on MDF1 module and start an A/C conversion. In addition, EXTI15 and MDF1 can trigger ADF1.
A description is given in:
- Section 39.4.2: MDF pins and internal signals
- Section 39.4.11: Start-up sequence examples

Triggering signals
The mdf_trgi[13:0] trigger inputs are the triggering input signals. The MDF and ADF trigger inputs connections are detailed in:
- Table 366: MDF trigger connections
- Table 387: ADF trigger connections

Active power mode
This interconnection remains active down to Stop 0 and Stop 1 modes for MDF1, and Stop 0, Stop 1, and Stop 2 modes for ADF1, assuming the trigger source remains active.

16.3.6 Timer break from MDF1
From MDF1 to advanced-control timer (TIM1/8)

Purpose
The MDF features an out-of-limit detectors (OLD) and a short circuit detector (SCD) functions. When a short-circuit or open-circuit errors (such as over current or over voltage) is detected an interrupt event or/and a break signal can be generated to TIM1/8.
This behavior is described in:
- Section 39.4.7: Short-circuit detectors (SCD)
- Section 39.4.9: Out-of-limit detector (OLD)
- Section 54.3.18: Using the break function
- Section 54.3.19: Bidirectional break inputs
Triggering signals

The mdf1_break[0:3] output signals are connected to break1 and break2 inputs signals of TIM1/8. The tables below gives the assignment of break signals:

• Table 367: MDF break connections
• Table 535: Timer break interconnect
• Table 536: Timer break2 interconnect

Active power mode

This interconnection is active under Run and Sleep modes. Refer to:

• Section 39.4.14: Autonomous mode
• Table 378: Effect of low-power modes on MDF

16.3.7 Clock sources to timers

From HSE, LSE, LSI, MSIK, HSI and MCO to timers (TIM1/2/3/4/5/8/15/16/17) and LP timers (LPTIM1/2/3)

Purpose

A timer input or timer counter can receive different clock sources and can be used to calibrate internal oscillator on a reference clock for example.

External clocks (HSE, LSE), internal clocks (LSI, MSI, HSI) and microcontroller output clock (MCO) can be used as input to timers:

• MSIK/HSI are assigned to advanced-control timers TIM1/8 as external trigger signals inputs (tim_etr3/ tim_etr4). MSIK/HSI can be selected as counter clock provided by an external clock source in mode2: external trigger input (tim_etr_in). Inputs assignment and clock selection description are detailed in:
  – Section 54.3.7: Clock selection for TIM1/8
  – Table 533: Interconnect to the tim_etr input multiplexer for STM32U535/545/575/585 for TIM1/8
• MSIK, HSI and LSI are assigned to general purpose timers TIM2/3/4/5 as external inputs signals. MSIK/HSI/LSI can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in) and mode2 (external trigger input tim_etr_in). Inputs assignment and clock selection description are detailed in:
  – Section 55.4.5: Clock selection for TIM2/3/4/5
  – External clock mode1: Table 553: Interconnect to the tim_ti1 input multiplexer for TIM5, tim_ti1_in1 (LSI) and tim_ti1_in2 (LSE)
  – External clock mode2: Table 559, tim_etr3 (MSIK), tim_etr4 (HSI) and tim_etr5 (MSIS) for TIM2/TIM3/TIM4/TIM5
• LSE, LSI, MSI and HSI are assigned to general purpose timers TIM15/16/17 as external inputs signals. LSE/LSI/MSI/HSI can be selected as counter clock provided by
an external clock source in mode1 (tim_t1 or tim_t2 signals). Inputs assignment and
clock selection description are detailed in:

- **Table 56.4.6: Clock selection** for TIM15/16/17. External clock mode1: external
  input pin (tim_t1 or tim_t2, if available)

- **Table 572: Interconnect to the tim_t1 input multiplexer**, tim_t1_in1 (LSE-TIM15),
  tim_t1_in5 (LSE-TIM16/17), tim_t1_in6 (LSI-TIM16/17), tim_t1_in7/8
  (MSI-TIM16/17), and tim_t1_in9 (HSI-TIM16/17)

- Microcontroller output clock (MCO) is connected as external input to general-purpose
  timers TIM16/17. This allows the calibration of the HSI16/MSI system clocks (with
  TIM15/16 and LSE) or LSI (with TIM16 and HSE). This is also used to precisely
  measure LSI (with TIM16 and HSI16) or MSI (with TIM16 and HSI16) oscillator
  frequency. When the low-speed external (LSE) oscillator is used, no additional
  hardware connections are required. This feature is given in:
  - **Section 11.4.23: Internal/external clock measurement with TIM15/TIM16/TIM17**
  - **Table 572: Interconnect to the tim_t1 input multiplexer** for TIM15/TIM16/TIM17

- LSI and LSE can be selected as input capture 2 to LPTIM1 as described in **Table 602:
  LPTIM1 input capture 2 connection**.

- HSI/256 can be selected as input capture 2 to LPTIM2 as described in **Table 603:
  LPTIM2 input capture 2 connection**.

- MSI/1024 and MSI/4 can be selected as input capture 2 to LPTIM3 as described
  in **Table 604: LPTIM3 input capture 2 connection**.

### Triggering signals

lptim_ic2_mux1 LPTIM input capture selection can be set in the LPTIM configuration
register 2 (LPTIM_CGR2). For timers, the internal clock signal can be selected as counter
clock provided by an external clock source in mode1 (tim_t1_in) and mode2 (external
trigger input tim_etr_in).

**Active power mode**

This feature is available under Run and Sleep modes.

#### 16.3.8 Triggers to low-power timers

From comparators (COMP1/2), EXTI, TAMP and RTC alarm to LP timers (LPTIM1/2/3/4)

**Purpose**

LPTIM1/2/3/4 counters may be started either by software or after the detection of an active
edge on one of the eight trigger inputs (see **Section 58.4.7: Trigger multiplexer**).

GPIO can also be selected as LPTIM input capture selection or LPTIM input selection,
according to the LPTIM configuration register 2 (LPTIM_CGR2).

**Triggering signals**

This trigger feature is described in **Section 58.4.7: Trigger multiplexer** and the following
sections. The input selection is described in **Table 598: LPTIM1/2/3/4 external trigger
connection**.
Active power mode
This interconnection remains active down to Stop 2 mode.

16.3.9 Blanking sources to comparators
From timers (TIM1/2/3/4/5/8/15/16/17) to comparators (COMP1/2)

Purpose
Advanced-control timers (TIM1/8) and general-purpose timers (TIM2/3/4/5/15/16/17) can be used as blanking window input to COMP1/2.

The blanking function is described in Section 37.4.6: Comparator output-blanking function.

The blanking sources are given in:
- COMP1 control and status register (COMP1_CSR), BLANKSEL[4:0]
- COMP2 control and status register (COMP2_CSR), BLANKSEL[4:0]

Triggering signals
Timer output signal TIMx_Ocx are the inputs to blanking source of COMP1/2.

Active power mode
This feature is available under Run and Sleep modes.

16.3.10 RTC wake-up as inputs to timers
From RTC to timers (TIM5/16/17)

Purpose
RTC wake-up interrupt can be used as input to general-purpose timers (TIM5/16/17) channel 1.

Triggering signals
RTC wake-up signal is connected to tim_ti1_in3 signal as described in Table 553: Interconnect to the tim_ti1 input multiplexer for TIM5.

RTC wake-up signal is connected to tim_ti1_in4 signal as described in Table 572: Interconnect to the tim_ti1 input multiplexer for TIM16/TIM17.

Active power mode
This interconnection is active down to Stop 3 mode. Timers are not active but the count is performed at wake-up.
16.3.11 OTG_FS/OTG_HS SOF as trigger to timers

From OTG_FS/OTG_HS SOF to TIM2

Purpose
The OTG_FS/OTG_HS SOF (start-of-frame) can generate a trigger to the general-purpose timer TIM2. The OTG_FS/OTG_HS connection to TIM2 is described in Table 557: TIMx internal trigger connection.

Triggering signals
The tim_itr11 internal signal is generated by the OTG_FS/OTG_HS SOF.

Active power mode
This interconnection is active in Run and Sleep modes.

16.3.12 Comparators as inputs, trigger or break signals to timers

From comparators to timers (TIM1/2/3/4/5/8/15/16/17)

Purpose
The comparators (COMP1/2) output values can be connected to timers (TIM1/2/3/4/5/8/15/16/17) input captures, TIMx_ETR or timer break signals. The connection to ETR is described in Section 54.3.6: External trigger input.

Comparators (COMP1/2) output values can also generate break input signals for timers (such as TIM1 or TIM8). The sources for break (tim_brk) channel are one of the following:

- external: connected to one of the TIMx_BKIN pin (as per selection done in the AFIO controller) with polarity selection and optional digital filtering
- internal: coming from comparators, tim_brk_cmpx input (refer to Section 54.3.2: TIM1/TIM8 pins and internal signals for product specific implementation).

Triggering signals
The tim_etra and tim_brk signals connected TIM1/8 (coming from COMP1/2) are given in:

- tim_etra (Table 533: Interconnect to the tim_etra input multiplexer for STM32U535/545/575/585): external trigger internal input bus
  These inputs can be used as trigger, external clock or for hardware cycle-by-cycle pulse width control.
- tim_brk (Table 535: Timer break interconnect and Table 536: Timer break2 interconnect)
  Section 54.3.6: External trigger input
  Section 54.3.18: Using the break function

For TIM2/3/4/5, the sources connected to the tim_ti[1:4] input multiplexers coming from comparators and some other peripherals, are given in:

- Table 553: Interconnect to the tim_ti1 input multiplexer
- Table 554: Interconnect to the tim_ti2 input multiplexer
- Table 556: Interconnect to the tim_ti4 input multiplexer
- Table 533: Interconnect to the tim_etra input multiplexer for STM32U535/545/575/585
• *Table 534: Interconnect to the timetr input multiplex for STM2U59x/5Ax/5Fx/5Gx*
• *Table 560: Interconnect to the timocref_clr input multiplexer*
• *Section 55.4.22: Timers and external trigger synchronization*
• *TIMx timer input selection register (TIMx_TISEL)(x = 2 to 5)*

For TIM15/16/17, the sources connected to timers coming from comparators and other peripherals are given in:

• *Table 573: Interconnect to the timti2 input multiplexer*
• *Table 575: Timer break interconnect*
• *Table 577: Interconnect to the ocref_clr input multiplexer*
• *Section 56.4.15: Using the break function*
• *Section 56.4.23: External trigger synchronization (TIM15 only)*

**Active power mode**

Run, Sleep, and wake-up capability in Stop 0, Stop 1, and Stop 2 modes for trigger sources. Input and break remain active in same low-power modes as timers activity, on Run and Sleep modes.

### 16.3.13 System errors as break signals to timers

From system errors to timers (TIM1/8/15/16/17)

**Purpose**

CSS, CPU lockup, SRAM2/3 ECC double errors, FLASH ECC double-error detection and PVD can generate system errors in the form of timer break toward timers (TIM1/8/15/16/17). The purpose of the break function is to protect power switches driven by PWM signals generated by the timers.

**Triggering signals**

The possible sources of break are described in:

• *Section 54.3.18: Using the break function* for TIM1/8
• *Section 56.4.15: Using the break function* for TIM15/16/17
• *Table 537: System break interconnect* for TIM1/8
• *Table 576: System break interconnect* for TIM15/16/17

**Active power mode**

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:

• *Table 546: Effect of low-power modes on TIM1/TIM8*
• *Table 566: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
• *Table 581: Effect of low-power modes on TIM15/TIM16/TIM17*

### 16.3.14 Timers generating IRTIM signal

From timers (TIM16/17) to IRTIM
The general-purpose timer (TIM16/17) output channels TIMx_OC1, are used to generate the waveform of the infrared signal output.

This functionality is described in Section 60: Infrared interface (IRTIM).

16.3.15 Triggers for communication peripherals

From LP timers (LPTIM1/2/3), comparators (COMP1/2), GPDMA1 transfer complete, LPDMA1 transfer complete, EXTI, RTC alarm and RTC wake-up to USART1/2/3/6, UART4/5, LPUART1, I2C1/2/3/4/5/6, and SPI1/2/3.

Purpose

LP timer (LPTIM1/3) output channels (lptim1_ch1, lptim1_ch2 and lptim3_ch1), comparator (COMP1/2) output channels (comp1_out and comp2_out), EXTI, RTC alarm and RTC wake-up, can be used as trigger to start a communication on the selected USART, UART, LPUART, I2C, or SPI peripheral.

A GPDMA1 transfer complete can trigger both the GPDMA1 regular or linked-list new transfers and communication on selected communication peripheral.

A LPDMA1 transfer complete can trigger both the LPDMA1 new transfers and the communication on selected peripheral.

Triggering signals

The outputs from triggers are directly connected to peripheral trigger inputs.

The selection of input triggers is detailed in:

- Table 670: USART interconnection (USART1/2/3/6 and UART4/5)
- Table 682: LPUART interconnections (LPUART1)
- Table 650: I2C1, I2C2, I2C4, I2C5, I2C6 interconnection and Table 651: I2C3 interconnection

The outputs (from timer) are directly connected to SPI1/2/3 inputs on signals spi_itrx (x = 6, 7). The selection of input triggers on SPI is provided in:

- Table 693: SPI interconnection (SPI1 and SPI2)
- Table 694: SPI interconnection (SPI3)

Active power mode

These interconnections remain active in Run, Sleep, and Stop modes if both source and communication line are autonomous under the mode. Refer to:

- Section 66.6: USART in low-power modes
- Section 65.5: I2C low-power modes
- Section 68.6: SPI low-power modes

16.3.16 Triggers to GPDMA/LPDMA

From EXTI, RTC (alarm/wake-up), TAMP (TAMP1/2/3), timers (TIM2/15), LP timers (LPTIM1/3/4), comparators (COMP1/2), LP/GPDMA1 transfer complete (gpdma1_chx_tc/lpdma1_chx_tc), ADC1/4 analog watchdog, and LTDC, DSI, DMA2D, GPU2D, JPEG, to LPDMA1 and GPDMA1
Purpose

A LP/GPDMA trigger can be assigned to a LP/GPDMA channel x. A programmed LP/GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event. The trigger mode can also be programmed to condition the LLI link transfer. More details are given in the sections below:

- Section 18.3.5: LPDMA triggers and Section 17.3.5: GPDMA triggers
- Section 18.4.12: LPDMA triggered transfer and Section 17.4.12: GPDMA triggered transfer
- LPDMA channel x transfer register 2 (LPDMA_CxTR2) and GPDMA channel x transfer register 2 (GPDMA_CxTR2) for more details on:
  - Trigger selection TRIGSEL[5:0] field
  - Trigger mode (LLI) defined by TRIGM[1:0].
  - Trigger polarity as defined by TRIGPOL[1:0]

Triggering signals

LPDMA trigger mapping is specified in Table 148: Programmed LPDMA1 trigger, according to LPDMA_CxTR2.TRIGSEL[5:0].

GPDMA trigger mapping is specified in Table 138: Programmed GPDMA1 trigger, according to GPDMA_CxTR2.TRIGSEL[5:0].

Active power mode

Assuming sources are active down to Stop modes, this interconnection remains functional in Stop 0 and Stop 1 modes for GPDMA, and Stop 0, Stop 1, and Stop 2 modes for LPDMA.

Refer to:
- Section 18.6: LPDMA in low-power modes
- Section 17.6: GPDMA in low-power modes

16.3.17 Internal analog signals to analog peripherals

From internal analog source to ADC (ADC1/2/4), comparators (COMP1/2) and OPAMP (OPAMP1/2)

Purpose

The internal reference voltage (VREFINT), the internal temperature sensor (VTS), and VBAT monitoring channel are connected to ADC (ADC1/2/4) input channels. In addition, the internal digital core voltage (VCORE) is connected/to ADC1/2/4 input channels.

DAC channels (DAC1_OUT/DAC2_OUT) and VREFINT are connected to comparators (COMP1/2).

OPAMP1/2 outputs can be connected to ADC1 or ADC4 input channels through the GPIO. DAC1_OUT1 can be connected to OPAMP1_VINP. DAC1_OUT2 can be connected to OPAMP2_VINP.

Refer to Table 337: DAC internal input/output signals for:
- dac_out1 analog output DAC channel1, output, for on-chip peripherals
- dac_out2 analog output DAC channel2, output, for on-chip peripherals
This is according to:

- **Section 33.2** and **Section 34.2: ADC main features**
- **Section 33.4.11: Channel selection (SQRx, JSQRx)**
- **Table 359: Operational amplifier possible connections**
- **Section 37.4.2: COMP pins and internal signals**

### Active power mode

These interconnections remain in Stop modes if the selected peripheral is kept active. Refer to:

- **Section 34.5: ADC low-power modes**
- **Section 37.5: COMP low-power modes**
- **Section 38.4: OPAMP low-power modes**

### 16.3.18 ADC data filtering by the MDF1

From ADC1/ADC2 to MDF1

**Purpose**

The MDF1 allows the connection of up to two ADCs to the filter path. For each filter, the DATSRC[1:0] field in the MDF digital filter configuration register x (MDF_DFLTxCICR) is used to select either data from the ADCs in:

- **Section 33.4.4: ADC connectivity**
- **Table 368: MDF ADC data connections**
  - mdf_adcitf1_dat[15:0] to adc1_dat
  - mdf_adcitf2_dat[15:0] to adc2_dat
- **Table 302: ADC1/ADC12 interconnection**
  - adcx_dat[15:0] (x = 1) to mdf1_adcx_dat[15:0] for STM32U535/545/575/585
  - adcx_dat[15:0] (x = 1, 2) mdf1_adcx_dat[15:0] for STM32U59x/5Ax/5Fx/5Gx
- **Section 39.5: MDF low-power modes**
  - Stop 0 and Stop 1 modes

**Active power mode**

This feature remains available down to Sleep mode.

### 16.3.19 Clock source for the DAC sample and hold mode

LSI/LSE to DAC1/2

**Purpose**

DAC1/2 can run in Stop mode. The sample and hold block and its associated registers use the LSI or LSE clock source (dac_hold_ck) in Stop mode.

**Table 337: DAC internal input/output signals:**

dac_hold_ck, Input, DAC low-power clock used in sample and hold mode
Active power mode
This feature remains available down to Stop 2 mode.

16.3.20 Triggers from graphic interfaces to timers
From DCMI, LTDC, DSI to timers (TIM2/TIM3/TIM4/TIM5) (for STM32U59x/5Ax/5Fx/5Gx) and GFXTIM (for STM32U5Fx/5Gx)

Purpose
DCMI, LTDC and DSI synchronization signals can be used as triggering event to start the timers.

Triggering signals
The inputs (to DCMI, LTDC, and DSI) are directly connected to the timers (TIM2/3/4/5). External trigger as described in Table 559: Interconnect to the tim_etr input multiplexer for the STM32U59x/5Ax/5Fx/5Gx.
GFXTIM input trigger as described in Table 613: GFXTIM trigger interconnections.

Active power mode
This feature remains available down to Sleep mode. Refer to Section 68.6: SPI low-power modes.

16.3.21 Internal tamper sources
From internal peripherals, clocks or monitoring to tamper.

Purpose
In order to detect any abnormal activity or tentative to corrupt the device, tampers are introduced and alert the system of such undesired event. Different actions can be taken in consequences.
List of tamper sources can be found in Table 637: TAMP interconnection.

Active power mode
This interconnection is active in all power modes if the tamper source is activated.

16.3.22 Output from tamper to RTC
From TAMP to RTC

Purpose
The RTC can timestamp a tamper event in order to retrieve history in time of such detection. The RTC can also control GPIOs and set a signal based on tamp or alarm status outside the MCU.
Refer to section Section 63.3.3: GPIOs controlled by the RTC and TAMP for more details.
Active power mode

This interconnection remains active in all power modes.

16.3.23 Encryption keys to AES/SAES

From TAMP backup registers, system flash memory to and in between SAES and AES

Purpose

The encryption mechanism requires an hardware key that must be stored in a protected non-volatile memory. Different approaches are implemented in order to load them in a non-readable way. Tamper backup registers or system flash memory can be used to store respectively BHK or RHUK, and to implement a dedicated bus to pass it to the SAES.

Refer to Section 50.4.9: SAES operation with wrapped keys for more details.

The AES encryption mechanism (faster than the SAES) can benefit from the sharing key of the SAES. Refer to Section 49.4.13: AES operation with shared keys for more details.

Active power mode

AES and SAES are operating under Run and Sleep modes.
17 General purpose direct memory access controller (GPDMA)

17.1 GPDMA introduction

The general purpose direct memory access (GPDMA) controller is a bus master and system peripheral.

The GPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

17.2 GPDMA main features

- Dual bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral
- Autonomous data transfers during low-power modes (see Section 17.3.2)
  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 16 concurrent GPDMA channels:
  - Per channel FIFO for queuing source and destination transfers
  (see Section 17.3.1)
  - Intra-channel GPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel GPDMA transfers chaining via programmable GPDMA input triggers connection to GPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level
- Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive burst transfers
- 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see Section 17.3.1)
- Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
- Programmable GPDMA request and trigger selection
- Programmable GPDMA half transfer and transfer complete events generation
- Pointer to the next linked-list item and its data structure in memory, with automatic update of the GPDMA linked-list control registers

- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags

- TrustZone support:
  - Support for secure and nonsecure GPDMA transfers, independently at a first channel level, and independently at a source/destination and link sublevels
  - Secure and nonsecure interrupts reporting, resulting from any of the respectively secure and nonsecure channels
  - TrustZone-aware AHB slave port, protecting any GPDMA secure resource (register, register field) from a nonsecure access

- Privileged/unprivileged support:
  - Support for privileged and unprivileged GPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

17.3 GPDMA implementation

17.3.1 GPDMA channels

A given GPDMA channel x is implemented with the following features and intended usage. To make the best use of the GPDMA performances, the table below lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested GPDMA transfer.
17.3.2 GPDMA autonomous mode in low-power modes

The GPDMA autonomous mode and wake-up feature are implemented in the device low-power modes as per the table below.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Low-power modes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomous mode and wake-up</td>
<td>GPDMA1 in Sleep, Stop 0 and Stop 1 modes</td>
</tr>
</tbody>
</table>

17.3.3 GPDMA requests

A GPDMA request from a peripheral can be assigned to a GPDMA channel x, via REQSEL[6:0] in GPDMA_CxTR2, provided that SWREQ = 0.

The GPDMA requests mapping is specified in the table below.

<table>
<thead>
<tr>
<th>GPDMA_CxTR2.REQSEL[6:0]</th>

17.3.4 GPDMA block requests

Some GPDMA requests must be programmed as a block request, and not as a burst request. Then BREQ in GPDMA_CxTR2 must be set for a correct GPDMA execution of the requested peripheral transfer at the hardware level.

17.3.5 GPDMA triggers

A GPDMA trigger can be assigned to a GPDMA channel x, via TRIGSEL[6:0] in GPDMA_CxTR2, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

17.4 GPDMA functional description

17.4.1 GPDMA block diagram

Figure 49. GPDMA block diagram

17.4.2 GPDMA channel state and direct programming without any linked-list

After a GPDMA reset, a GPDMA channel x is in idle state. When the software writes 1 in GPDMA_CxCR.EN, the channel takes into account the value of the different channel configuration registers (GPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

After enabling/starting a GPDMA channel transfer by writing 1 in GPDMA_CxCR.EN, a GPDMA channel interrupt on a complete transfer notifies the software that the GPDMA channel is back in idle state (EN is then deasserted by hardware) and that the channel is ready to be reconfigured then enabled again.

(1) Refer to the device implementation table for the number of channels.
The figure below illustrates this GPDMA direct programming without any linked-list (GPDMA_CxLLR = 0).

**Figure 50. GPDMA channel direct programming without linked-list (GPDMA_CxLLR = 0)**

### 17.4.3 GPDMA channel suspend and resume

The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.
Note that an ongoing GPDMA transfer can be a data transfer (a source/destination burst transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to GPDMA_CxCR.SUSP.

**Figure 51. GPDMA channel suspend and resume sequence**

Note: A suspend and resume sequence does not impact the GPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

### 17.4.4 GPDMA channel abort and restart

Alternatively, like for aborting a continuous GPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.
3. The software resets the channel by writing 1 to GPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the GPDMA_CxCR.EN bit, and the reset of the GPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram the hardware-modified GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR registers.
5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the GPDMA_CxCR.EN bit.

Figure 52. GPDMA channel abort and restart sequence

17.4.5 GPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

The base address in memory of the data structure of a next LLI_{n+1} of a channel x is the sum of the following:
- the link base address of the channel x (in GPDMA_CxLBAR)
- the link address offset (LA[15:2] field in GPDMA_CxLLR). The linked-list register GPDMA_CxLLR is the updated result from the data structure of the previous LLI_{n} of the channel x.

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the UT1, UT2, UB1, USA, UDA and ULL bits, plus UB2 and UT3, in GPDMA_CxLLR.
In linked-list mode, each GPDMA linked-list register (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3 or GPDMA_CxBR2) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the GPDMA_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

**Static linked-list data structure**

For example, when the update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3) in GPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel x (x = 0 to 11) contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR (see Figure 53) and including the first linked-list register file (LLI0) and the next LLIs (such as LLI1, LLI2) in the memory
- channel x(x = 12 to 15), contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2 (see Figure 54), and including the first linked-list register file (LLI0) and the next LLIs (such as LLI1, LLI2) in the memory

**Figure 53. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x**
Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register GPDMA_CxLLR is pointing to the updated value of the GPDMA_CxTR2 instead of the GPDMA_CxTR1 which is not to be modified (see Figure 55).

Example: if UT1 = UB1 = USA = 0 and if UT3 = UB2 = 0, when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for GPDMA_CxTR1, nor GPDMA_CxBR1, nor GPDMA_CxSAR, nor GPDMA_CxSAR, nor GPDMA_CxTR3, nor GPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for GPDMA_CxTR2, GPDMA_CxDAR, and GPDMA_CxLLR, as shown in Figure 56.
The user must program GPDMA_CxLLR for each LLI_n to be 32-bit aligned and not to exceed the 64-Kbyte addressable space pointed by GPDMA_CxLBAR.

### 17.4.6 Linked-list item transfer execution

A LLI_n transfer is the sequence of:

1. a data transfer: GPDMA executes the data transfer as described by the GPDMA internal register file (this data transfer can be void/null for LLI_0)
2. a conditional link transfer: GPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_n+1, as defined by the GPDMA_CxLLR value of the LLI_n.

**Note:** The initial data transfer as defined by the internal register file (LLI_0) can be null (GPDMA_CxBR1.BNDT[15:0] = 0) provided that the conditional update bit UB1 in GPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI in the memory to be executed).

Depending on the intended GPDMA usage, a GPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, GPDMA_CxCR.LSM = 0) or a GPDMA channel x can be programmed for a single execution of a LLI (link step mode, GPDMA_CxCR.LSM = 1), as described in the next sections.
17.4.7 GPDMA channel state and linked-list programming in run-to-completion mode

When GPDMA_CxCR.LSM = 0 (in full list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), a GPDMA channel x is initially programmed, started by writing 1 to GPDMA_CxCR.EN, and after completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI0, internal linked-list register file: GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2
  - the last LLI_N, described by the linked-list data structure in memory, as defined by the GPDMA_CxLLR reflecting the before last LLIN-1
- completed when GPDMA_CxLLR[31:0] = 0, GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLIN-1 transfer

GPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits GPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits GPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3).

The channel may never be completed when GPDMA_CxLLR.LSM = 0:

- If the last LLIN is recursive, pointing to itself as a next LLI:
  - either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value
  - or GPDMA_CxLLR.ULL = 0
- If LLIN is pointing to a previous LLI

In the typical run-to-completion mode, the allocation of a GPDMA channel, including its fine programming, is done once during the GPDMA initialization. In order to have a reserved data communication link and GPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

Figure 57 depicts the GPDMA channel execution and its registers programming in run-to-completion mode.

Note: Figure 57 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

End
Run-time inserting a LLI_{n} via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_{n} loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the GPDMA_CxTR2 in the data structure of the LLI_{n-1}:

- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[6:0] (see Section 17.3.5 for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_{n} in the memory and to generate a transfer complete event gpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_{n}.

The figure below depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_{n}.
17.4.8 GPDMA channel state and linked-list programming in link step mode

When GPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

A GPDMA channel transfer can be programmed at LLI level, started by writing 1 into GPDMA_CxCR.EN, and after completed at LLI level:
- The current LLI transfer is described with:
  - GPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - GPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]) and, for channel x (x = 12 to 15), the number of blocks at a 2D/repeated block level (BRC[10:0]+1) and the incrementing/decrementing mode for address offsets.
- GPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
- GPDMA_CxSAR/GPDMA_CxDAR define the source/destination transfer start address.
- GPDMA_CxTR3 for channel x (x = 12 to 15) defines the source/destination additional address offset between burst transfers.
- GPDMA_CxBR2 for channel x (x = 12 to 15) defines the source/destination additional address offset between blocks at a 2D/repeated block level.
- GPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.

- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0)
  - after the (conditional) update of the GPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If a LLI is recursive (pointing to itself as a next LLI, either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value, or GPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of GPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Figure 59 depicts the GPDMA channel execution mode, and its programming in link step mode.

Note: Figure 59 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after GPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in the figure below.

Figure 60. Building LLI_{n+1}: GPDMA dynamic linked-lists in link step mode

Run-time replacing a LLI_n with a new LLI_{n'}, in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI_{n'}, after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new LLI_{n'}, as shown in the figure below.
Run-time replacing a LLI<sub>n</sub> with a new LLI<sub>n'</sub> in link step mode (in the memory)

The software can build and insert a new LLI<sub>n'</sub> and LLI<sub>n+1'</sub> in the memory, after GPDMA executed the transfer from the LLI<sub>n-1</sub> and loaded a formerly elaborated LLI<sub>n</sub> from the memory, by overwriting partly the linked-list register file (GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new LLI<sub>n'</sub>) as shown in the figure below.
Figure 62. Replace with a new LLIn and LLIn+1 in memory in link step mode (option 1)

LSM = 1 with 1-stage linked-list programming:
Overwriting the (pre)loaded LLIn linked-list register file with a new LLIn and LLIn+1 in memory and
overwrite partly linked-list register file
(DMA_CxBR1.BNDT = 0 and DMA_CxLLR to point to new LLIn)
DMA executes LLIn-1 and load LLIn then CPU builds (LLIn and LLIn+1) and overwrite (BR1 and LLR)

DMA Channel

Executing LLIn transfer
Loading LLIn

Transfer complete interrupt

CPU

Build LLIn' and LLIn+1 in memory

Write DMA_CxBR1.BNDT = 0
Write DMA_CxLLR to point to new LLIn'

Enable DMA channel

Loading LLIn'

Transfer complete interrupt

Enable DMA channel

Executing LLIn+1 transfer
Loading LLIn+1

Transfer complete interrupt
Run-time replacing a LLIn with a new LLIn' in link step mode

Other software implementations exist. Meanwhile GPDMA executes the transfer from the LLIn-1 and loads a formerly elaborated LLIn from the memory (or even earlier), the software can do the following:
1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new LLIn' and a new LLIn+1'.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLIn-1 is then restricted to overwrite GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new LLIn', as shown in the figure below.

Figure 63. Replace with a new LLIn' and LLIn+1' in memory in link step mode (option 2)
17.4.9 GPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (GPDMA_CxCR.EN = 0) and update the execution mode (GPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLIn+1 in the memory to finally complete the channel by this LLIn+1 (clear the GPDMA_CxLLR of this LLIn+1), before that this LLIn+1 is loaded/used by the GPDMA channel
- abort and reconfigure the channel with a LSM update (see Section 17.4.4.)

In link step mode, the software can clear LSM after each a single execution of any LLI, during LLIn-1.

*Figure 64* shows the overall and unified GPDMA linked-list programming, whatever is the execution mode.

**Note:** *Figure 64 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.*

17.4.10 GPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see Section 17.3.1 for more details).

GPDMA burst

A programmed transfer at the lowest level is a GPDMA burst.

A GPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by the field SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by the field SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in the GPDMA_CxTR1 register.

The addressing mode after each data (named beat) of a GPDMA burst is defined by SINC and DINC in GPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a GPDMA source/destination burst (defined by GPDMA_CxSAR and GPDMA_CxDAR) must be aligned with the respective data width.

The table below lists the main characteristics of a GPDMA burst.

<table>
<thead>
<tr>
<th>SDW_LOG2[1:0]</th>
<th>Data width (bytes)</th>
<th>SINC/DINC</th>
<th>SBL_1[5:0]</th>
<th>Burst length (data/beats)</th>
<th>Next data/beat address</th>
<th>Next burst address</th>
<th>Burst address alignment</th>
</tr>
</thead>
<tbody>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.

The next burst address in the above table is the next source/destination default address pointed by GPDMA_CxSAR or GPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.
GPDMA burst with 2D addressing (channel x = 12 to 15)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by GPDMA_CxTR2.SAO[12:0]/DAO[12:0] and GPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by GPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and GPDMA_CxBR1.BRSDEC/BRDDEC

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by the figure below with a 2D destination buffer.
Programmable address jumps 1) after burst and 2) after block.
Example:
burst: \( I \) * words (DBL_1=I-1; DDW_LOG2='b10)
block: \( J \) * bursts (BNDT=J*4)
LLI: \( K \) * blocks (BRC=K-1)
GPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- one burst from the source to the FIFO over the allocated source master port, as defined by GPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by GPDMA_CxTR1.DAP

GPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

\[
\text{when FIFO level} \leq 2^{\text{dma_fifo_size}[x]} - (\text{SBL}_1[5:0]+1) \times 2^{\text{SDW_LOG2}[1:0]}
\]

where:

- \(\text{FIFO level}\) is the current filling level of the FIFO, in bytes.
- \(2^{\text{dma_fifo_size}[x]}\) is the half of the FIFO size of the channel \(x\), in bytes (see Section 17.3.1 for the implementation details and \(\text{dma_fifo_size}[x]\) value).
- \((\text{SBL}_1[5:0]+1) \times 2^{\text{SDW_LOG2}[1:0]}\) is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (GPDMA_CxCR.PRIOR[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

GPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

\[
\text{when FIFO level} \geq (\text{DBL}_1[5:0]+1) \times 2^{\text{DDW_LOG2}[1:0]}
\]

where:

- \(\text{FIFO level}\) is the current filling level of the FIFO, in bytes.
- \((\text{DBL}_1[5:0]+1) \times 2^{\text{DDW_LOG2}[1:0]}\) is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

GPDMA burst vs source block size, 1-Kbyte address boundary and FIFO size

The programmed source/destination GPDMA burst is implemented with an AHB burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel \(x\) is lower than the programmed source/destination burst size, the programmed source/destination GPDMA burst is implemented with a series of singles or bursts of a lower size, each transfer being of a size that is lower or equal than half of the FIFO size, without any user constraint.
- if the source block size (GPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (GPDMA_CxTR1.SD_W_LOG2[1:0]), the GPDMA modifies and shortens bursts into singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.
• if the source/destination burst transfer have crossed the 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.

• If the source/destination burst length exceeds 16 on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.

In any case, the GPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in GPDMA_CxSR) is compared to and updated with the effective transfer size, and the GPDMA re-arbitrates between each AHB single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

**Note:** In linked-list mode, the GPDMA read transfers related to the update of the linked-list parameters from the memory to the internal GPDMA registers, are scheduled over the link allocated port, as programmed by GPDMA_CxCR.LAP.

**GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment**

The data handling is controlled by GPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word or word, as per the SDW_LOG2[21:0] and DDW_LOG2[1:0] fields (see Table 140).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. Byte-based source reordering
   - If SBX = 1 and if source data width is a word, the two bytes of the unaligned half-word at the middle of each source data word are exchanged.

2. Data width conversion by packing, unpacking, padding or truncation, if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0 s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.

3. Byte-based destination re-ordering:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.

**Note:** Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding and a destination byte-based re-ordering.
The table below lists the possible data handling from the source to the destination.

\(^{(1)}\) Source and destination data streams are individual source and destination data.

\(^{(2)}\) PAM[1:0] values: 00 = privileged mode, 01 = normal mode, 10 = forced mode.
17.4.11 GPDMA transfer request and arbitration

GPDMA transfer request

As defined by GPDMA_CxTR2, a programmed GPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the GPDMA hardware peripheral request is driven by the REQSEL[6:0] field (see Section 17.3.3). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in GPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control registers update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory
Caution: The user must not assign a same input hardware peripheral GPDMA request via GPDMA_CxTR.REQSEL[6:0] to two different channels, if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

GPDMA transfer request for arbitration

A ready FIFO-based GPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (GPDMA_CxTR1.SAP) is arbitrated based on the channel priority (GPDMA_CxCxCR.PRI0[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

A ready FIFO-based GPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (GPDMA_CxTR1.DAP) is arbitrated based on the channel priority (GPDMA_CxCxCR.PRI0[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

An arbitrated GPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in memory to one of the linked-list registers (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3, GPDMA_CxBR2). Each 32-bit read from memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (GPDMA_CxCxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to-memory transfer (GPDMA_CxTR2.SWREQ = 1), or with a hardware request (GPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (GPDMA_CxTR2.SWREQ = 0 and GPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

GPDMA arbitration

The GPDMA arbitration is directed from the 4-grade assigned channel priority (GPDMA_CxCxCR.PRI0[1:0]). The arbitration policy, as illustrated in Figure 66, is defined by:

- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels
  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.

- three low-priority traffic classes (queues 0, 1 or 2) for non time-sensitive channels with priority 0, 1 or 2
  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.
Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.

Any queue 0, 1 or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.

Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1 and queue 2.

**Figure 66. GPDMA arbitration policy**

GPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as BQ3) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive GPDMA requests: req0 and req1. There are the following programming possibilities:
  - If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 \(B_{req0}\) is equal to the allocated bandwidth to req1 \(B_{req1}\).
    \[ B_{req0} = B_{req1} = \frac{1}{2} \times (1 - BQ3) \]
  - If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 \(B_{req0}\) is 3 times less than the allocated bandwidth to req1 \(B_{req1}\).
    \[ B_{req0} = B_{req1} = \frac{1}{2} \times \frac{1}{2} \times (1 - BQ3) = \frac{1}{4} \times (1 - BQ3) \]
    \[ B_{req0} = B_{req1} = (\frac{1}{2} + 1) \times \frac{1}{3} \times (1 - BQ3) = \frac{3}{4} \times (1 - BQ3) \]
  - If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 \(B_{req0}\) is 5 times less than the allocated bandwidth to req1 \(B_{req1}\).
    \[ B_{req0} = B_{req1} = \frac{1}{2} \times \frac{1}{3} \times (1 - BQ3) = \frac{1}{6} \times (1 - BQ3) \]
    \[ B_{req0} = B_{req1} = (\frac{1}{2} + 1 + 1) \times \frac{1}{3} \times (1 - BQ3) = \frac{5}{6} \times (1 - BQ3) \]

The above computed bandwidth calculation is based on a theoretical input request, always active for any GPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one GPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.
Example 2: application where the user distributes a same non-null N number of
GPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth
calculation is then the following:

- The allocated bandwidth to the set of requests of priority 0 (BP0) is
  \[ BP_0 = \frac{1}{3} \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{1}{9} \times (1 - B_{Q3}) \]

- The allocated bandwidth to the set of requests of priority 1 (BP1) is
  \[ BP_1 = \left( \frac{1}{3} + \frac{1}{2} \right) \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{5}{18} \times (1 - B_{Q3}) \]

- The allocated bandwidth to the set of requests of priority 2 (BP2) is
  \[ BP_2 = \left( \frac{1}{3} + \frac{1}{2} + 1 \right) \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{11}{18} \times (1 - B_{Q3}) \]

- The allocated bandwidth to any request n among the N requests of that
  priority Pi (i = 0 to 2) is \( B_n = \frac{1}{N} \times BP_i \)

- The allocated bandwidth to any request n of priority 0i (Bn, P0) is
  \[ B_{n, P0} = \frac{1}{N} \times \frac{1}{9} \times (1 - B_{Q3}) \]
  \[ B_{n, P1} = \frac{1}{N} \times \frac{5}{18} \times (1 - B_{Q3}) \]
  \[ B_{n, P2} = \frac{1}{N} \times \frac{11}{18} \times (1 - B_{Q3}) \]

In this example, when the master port bus bandwidth is not totally consumed by the
time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is
allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is
allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- \( I \) requests (\( I \geq 0 \)) assigned to priority 0
  - If \( I > 0 \), these requests are noted from \( i = 0 \) to \( I-1 \).

- \( J \) requests (\( J \geq 0 \)) assigned to priority 1
  - If \( J > 0 \), these requests are noted from \( j = 0 \) to \( J-1 \).

- \( K \) requests (\( K > 0 \)) assigned to priority 2
  - These requests are noted from \( k = 0 \) to \( K-1 \)

- \( L \) requests (\( L \geq 0 \)) assigned to priority 3
  - If \( L > 0 \), these requests are noted from \( l = 0 \) to \( L-1 \).

As \( B_{Q3} \) is the reserved bandwidth to time-sensitive requests, the bandwidth for each request
L with priority 3 is:

- \( B_l = B_{Q3} / L \) for \( L > 0 \) (else: \( B_l = 0 \))

The bandwidth for each non-time sensitive queue is:

- \( B_{Q0} = \frac{1}{3} \times (1 - B_{Q3}) \)
- \( B_{Q1} = \frac{1}{3} \times (1 - B_{Q3}) \)
- \( B_{Q2} = \frac{1}{3} \times (1 - B_{Q3}) \)

The bandwidth for the set of requests with priority 0 is:

- \( B_{P0} = I / (I + J + K) \times B_{Q0} \)

The bandwidth for each request i with priority 0 is:

- \( B_i = B_{P0} / I \) for \( L > 0 \) (else \( B_{P0} = 0 \))

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- \( B_{P1,Q0} = J / (I + J + K) \times B_{Q0} \)
The bandwidth for the set of requests with priority 1 and routed to queue 1 is:
- \( B_{P1,Q1} = \frac{J}{J + K} \times B_{Q1} \)

The total bandwidth for the set of requests with priority 1 is:
- \( B_{P1} = B_{P1,Q0} + B_{P1,Q1} \)

The bandwidth for each request \( j \) with priority 1 is:
- \( B_j = \frac{B_{P1}}{J} \) for \( J > 0 \) (else \( B_j = 0 \))

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:
- \( B_{P2,Q0} = \frac{K}{I + J + K} \times B_{Q0} \)

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:
- \( B_{P2,Q1} = \frac{K}{J + K} \times B_{Q1} \)

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:
- \( B_{P2,Q2} = B_{Q2} \)

The total bandwidth for the set of requests with priority 2 is:
- \( B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2} \)

The bandwidth for each request \( k \) with priority 2 is:
- \( B_k = \frac{B_{P2}}{K} \) (\( K > 0 \) in the general case)

Thus finally the maximum allocated residual bandwidths for any \( i \), \( j \), \( k \) non-time sensitive request are:
- in the general case (when there is at least one request \( k \) with a priority 2 (\( K > 0 \))):
  - \( B_i = \frac{1}{I} \times \frac{1}{3} \times \frac{1}{I + J + K} \times (1 - B_{Q3}) \)
  - \( B_j = \frac{1}{J} \times \frac{1}{3} \times [\frac{J}{I + J + K} + \frac{J}{J + K}] \times (1 - B_{Q3}) \)
  - \( B_k = \frac{1}{K} \times \frac{1}{3} \times [\frac{K}{I + J + K} + \frac{K}{J + K} + 1] \times (1 - B_{Q3}) \)
- in the specific case (when there is no request \( k \) with a priority 2 (\( K = 0 \))):
  - \( B_i = \frac{1}{I} \times \frac{1}{2} \times \frac{1}{I + J} \times (1 - B_{Q3}) \)
  - \( B_j = \frac{1}{J} \times \frac{1}{2} \times [\frac{J}{I + J} + 1] \times (1 - B_{Q3}) \)

Consequently, the GPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

### 17.4.12 GPDMA triggered transfer

A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGSEL[6:0] (see Section 17.3.5 for the trigger selection).

The triggered transfer, as defined by the trigger mode in GPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block for channel \( x \) (\( x = 12 \) to 15), or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see TRIGM[1:0] in GPDMA_CxTR2 for more details).
Trigger hit memorization and trigger overrun flag generation

The GPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[6:0] are not modified, and the channel is enabled.

Transferring a next LLI_{n+1}, that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[6:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

**Caution:** After a first new trigger hit_{n+1} is memorized, if another trigger hit_{n+2} is detected and if the hit_{n} triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

The figure below illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

**Figure 67. Trigger hit, memorization and overrun waveform**

<table>

**Note:** The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

17.4.13 GPDMA circular buffering with linked-list programming

**GPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel**

For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half transfer and complete transfer.
events/interrupts generation (GPDMA_CxCR.HTIE = 1 and GPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI\textsubscript{0} is configured for the first block transfer with the linear addressing channel. A continuously-executed LLI\textsubscript{1} is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). GPDMA automatically reloads the initially programmed GPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore GPDMA_CxBR1.

The figure below illustrates this programming with a linear addressing GPDMA channel and a source circular buffer.

**Figure 68. GPDMA circular buffer programming: update of the memory start address with a linear addressing channel**

![Diagram](diagram.png)

**Note:** With a 2D addressing channel, the user may use a single LLI with GPDMA_CxBR1.BRC[10:0] = 1, and program a negative memory block address offset with GDMA_CxBR2 and GDMA_CxBR1, in order to jump back to the memory source or the destination start address.

If circular buffering must be executed after some other transfers over the shared GPDMA channel \( x \), the before-last LLI\textsubscript{N-1} in memory is needed to configure the first block transfer. And the last LLI\textsubscript{N} restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).
The figure below illustrates this programming with a linear addressing shared GPDMA channel, and a source circular buffer.

**Figure 69. Shared GPDMA channel with circular buffering: update of the memory start address with a linear addressing channel**

17.4.14 **GPDMA secure/nonsecure channel**

The GPDMA controller is compliant with the TrustZone hardware architecture at channel level, partitioning all its resources so that they exist in one of the secure and nonsecure worlds at any given time.

Any channel $x$ is a secure or a nonsecure hardware resource, as configured by GPDMA_SECCFGR.SEC$x$.

When a channel $x$ is configured in secure state by a secure and privileged agent, the following access control rules are applied:

- A nonsecure read access to a register field of this channel is forced to return 0, except for GPDMA_SECCFGR, GPDMA_PRIVCFGR and GPDMA_RCFGLOCKR that are readable by a nonsecure agent.
- A nonsecure write access to a register field of this channel has no impact.

When a channel $x$ is configured in secure state, a secure agent can configure separately as secure or nonsecure the GPDMA data transfer from the source (GPDMA_CxTR1.SSEC) and the GPDMA data transfer to the destination (GPDMA_CxTR1.DSEC).

When a channel $x$ is configured in secure state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with secure transfers via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a secure bus that reflects GPDMA_SECCFGR, to keep the other peripherals informed of the secure/nonsecure state of each GPDMA channel $x$. 
The GPDMA also generates a security illegal access pulse signal on an illegal nonsecure access to a secure GPDMA register. This signal is routed to the TrustZone interrupt controller.

When the secure software must switch a channel from a secure state to a nonsecure state, the secure software must abort the channel or wait until the secure channel is completed before switching. This is needed to dynamically re-allocate a channel to a next nonsecure transfer as a nonsecure software is not allowed to do so and must have GPDMA_CxCR.EN = 0 before the nonsecure software can reprogram the GPDMA_CxCR for a next transfer. The secure software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

**17.4.15 GPDMA privileged/unprivileged channel**

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via GPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for GPDMA_PRIVCFGR, GPDMA_SECCFGR and GPDMA_RCFGLOCKR that are readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a privileged bus that reflects GPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each GPDMA channel x.

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have GPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the GPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

**17.4.16 GPDMA error management**

The GPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

**Data transfer error**

on a bus access (as a AHB single or a burst) to the source or the destination

- The source or destination target reports an AHB error.
• The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware). The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the data error (GPDMA_CxSR.DTEF = 1).

• After a GPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.

• After a GPDMA data transfer error, the user must issue a channel reset (set GPDMA_CxCR.RESET) to reset the hardware GPDMA channel data path and the content of the FIFO, before the user enables again the same channel for a next transfer.

**Link transfer error**

on a tentative update of a GPDMA channel register from the programmed LLI in the memory

• The linked-list memory reports an AHB error.

• The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware), the channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the link error (GPDMA_CxSR.ULEF = 1).

• After a GPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (GPDMA_CxLBAR and GPDMA_CxLLR), including the protection attributes.

• After a GPDMA link error, the user must explicitly write the linked-list register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2), before the user enables again the same channel for a next transfer.

**User setting error**

on a tentative execution of a GPDMA transfer with an unauthorized user setting:

• The programmed channel transfer is disabled (GPDMA_CxCR.EN forced and cleared by the GPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and a user setting error (GPDMA_CxSR.USEF = 1).

• After a GPDMA user setting error, the user must perform a debug session, taking care of the GPDMA channel programming. A user setting error can be caused by one of the following:
  – a programmed null source block size without a programmed update of this value from the next LLI1 (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxLLR.UB1 = 0)
  – a programmed non-null source block size being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  – when in packing/unpacking mode (if PAM[1] = 1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.DDW LOG2[1:0])
  – a programmed unaligned source start address, being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxSAR[2:0] versus GPDMA_CxTR1.SDW LOG2[1:0])
for channel x (x = 12 to 15): a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxTR3.SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])

for channel x (x = 12 to 15): a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR2.BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])

a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxDAR[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])

for channel x (x = 12 to 15): a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxTR3.DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])

for channel x (x = 12 to 15): a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR2.BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])

- a programmed double-word source data width (GPDMA_CxTR1.SDW_LOG2[1:0] = 11)

- a programmed double-word destination data width (GPDMA_CxTR1.DDW_LOG2[1:0] = 11)

- a programmed linked-list item LLI_{n+1} with a null data transfer (GPDMA_CxLLR.UB1 = 1 and GPDMA_CxBR1.BNDT = 0)

### 17.4.17 GPDMA autonomous mode

To save dynamic power consumption while the GPDMA executes the programmed linked-list transfers, the GPDMA hardware automatically manages its own clock gating and generates a clock request output signal to the RCC, whenever the device is in Run or low-power modes, provided that the RCC is programmed with the corresponding GPDMA enable control bits.

For more details about the RCC programming, refer to the RCC section of the reference manual.

For mode details about the availability of the GPDMA autonomous feature vs the device low-power modes, refer to Section 17.3.2.

The user can program and schedule the execution of a given GPDMA transfer at a LLI\_n level of a GPDMA channel x, with GPDMA_CxTR2 as follows:

- The software controls and conditions the input of a transfer with TRIGM[1:0], TRIGPOL[1:0], TRIGSEL[6:0], SWREQ and REQSEL[6:0] for the input trigger and request.

- The software controls and signals the output of a transfer with TCEM[1:0] for generating or not a transfer complete event, and generating or not an associated half data transfer event.

See GPDMA channel x transfer register 2 (GPDMA_CxTR2) for more details.

When used in low-power modes, this functionality enables a CPU wake-up on a specific transfer completion by the enabled GPDMA transfer complete interrupt (GPDMA_CxCR.TCIE = 1) or/and enables to continue with the autonomous GPDMA for operating another LLI_{n+1} transfer over the same channel.
The output channel x transfer complete event, gpdma_chx_tc, can be programmed as a selected input trigger for a channel if this event is looped-back and connected at the GPDMA level (see Section 17.3.5), allowing autonomous and fine GPDMA inter-channel transfer scheduling, without needing a cleared transfer complete flag (TCF).

A given GPDMA channel x asserts its clock request in one of the following conditions:

- if the next transfer to be executed is programmed as conditioned by a trigger (GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGM[1:0]), only when the trigger hit occurs.
- if the next transfer to be executed is not conditioned by a trigger:
  - if GPDMA_CxTR2.SWREQ = 0, only when the hardware request is asserted by the selected peripheral
  - if GPDMA_CxTR2.SWREQ = 1 (memory-to-memory, GPIO to/from memory), as soon as the GPDMA is enabled

The GPDMA channel x releases its clock request as soon as all the following conditions are met:

- The transfer to be executed is completed.
- The GPDMA channel x is not immediately ready and requested to execute the next transfer.
- If a channel x interrupt was raised, all the flags of the status register that can cause this interrupt, are cleared by a software agent.

When one channel asserts its clock request, the GPDMA asserts its clock request to the RCC. When none channel asserts its clock request, the GPDMA releases its clock request to the RCC.

### 17.5 GPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

**Note:** In debug mode, GPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, GPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

### 17.6 GPDMA in low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. GPDMA interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop(1)</td>
<td>The content of the GPDMA registers is kept when entering Stop mode. The content of the GPDMA registers can be autonomously updated by a next linked-list item from memory, to perform autonomous data transfers. GPDMA interrupts can cause the device to exit Stop mode(1).</td>
</tr>
<tr>
<td>Standby</td>
<td>The GPDMA is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

1. Refer to Section 17.3.2 to know if any Stop mode is supported.
17.7 GPDMA interrupts

There is one GPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 142. GPDMA interrupt requests

<table>

<td>GPDMA_CxCR.TOFIE</td>
<td>GPDMA_CxSR.TOF</td>
<td>Write 1 to GPDMA_CxFCR.TOF</td>
</tr>
</tbody>
</table>

A GPDMA channel x event may be:
- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal gpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:
- the corresponding interrupt event xx is enabled (GPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (GPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into GPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by GPDMA_CxTR2.TCEM[1:0] as follows:
- A transfer complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].
A half transfer event is an half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

A half-block transfer occurs when half of the source block size bytes (rounded-up integer of GPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2) is transferred to the destination.

See GPDMA channel x transfer register 2 (GPDMA_CxTR2) for more details.

A transfer error rises in one of the following situations:

- during a single/burst data transfer from the source or to the destination (DTEF)
- during an update of a GPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of a GPDMA channel with an unauthorized setting (USEF)

The user must perform a debug session to correct the GPDMA channel programming versus the USEF root causes list (see Section 17.4.16).

A trigger overrun is described in Trigger hit memorization and trigger overrun flag generation.

### 17.8 GPDMA registers

The GPDMA registers must be accessed with an aligned 32-bit word data access.

#### 17.8.1 GPDMA secure configuration register (GPDMA_SECCFGR)

Address offset: 0x00
Reset value: 0x0000 0000

A write access to this register must be secure and privileged. A read access is secure or nonsecure, privileged or unprivileged.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (when GPDMA_CxCR.EN = 0), to securely allocate individually any channel x to the secure or nonsecure world.

Bits 31:16  Reserved, must be kept at reset value.
Bits 15:0  **SECx**: secure state of channel x (x = 15 to 0)
0: nonsecure
1: secure

### 17.8.2 GPDMA privileged configuration register (GPDMA_PRIVCFGR)

Address offset: 0x04

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged, secure or nonsecure.

This register can mix secure and nonsecure information. If a channel x is configured as secure (GPDMA_SECCFGR.SECx = 1), the PRIVx bit can be written only by a secure (and privileged) agent.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (GPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

</table>

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **PRIVx**: privileged state of channel x (x = 15 to 0)
0: unprivileged
1: privileged

### 17.8.3 GPDMA configuration lock register (GPDMA_RCFGLOCKR)

Address offset: 0x08

Reset value: 0x0000 0000

This register can be written by a software agent with secure privileged attributes in order to individually lock at boot time the secure privileged attributes of any GPDMA.
General purpose direct memory access controller (GPDMA) RM0456

channel/resource (to lock the setting of GPDMA_CxSECCFGR and GPDMA_CxPRIVCFGR for any channel x at boot time).

A read access may be privileged or unprivileged, secure or nonsecure.

Note: If TZEN = 0, this register cannot be written.

17.8.4 GPDMA nonsecure masked interrupt status register (GPDMA_MISR)

Address offset: 0x0C
Reset value: 0x0000 0000

This register is a read register.

This is a nonsecure register, containing the masked interrupt status bit MISx for each nonsecure channel x (channel x configured with GPDMA_SECCFGR.SECx = 0). It is a logical OR of all the flags of GPDMA_CxSR, each source flag being enabled by the corresponding interrupt enable bit of GPDMA_CxCR.

Every bit is deasserted by hardware when writing 1 to the corresponding flag clear bit in GPDMA_CxFCR.

If a channel x is in secure state (GPDMA_SECCFGR.SECx = 1), a read access to the masked interrupt status bit MISx of this channel x returns zero.

This register may mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full nonsecure interrupt status. An unprivileged software is restricted to read the status of unprivileged (and nonsecure) channels, other privileged bit fields returning zero.
Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **MISx**: masked interrupt status of channel x (x = 15 to 0)
0: no interrupt occurred on channel x
1: an interrupt occurred on channel x

### 17.8.5  GPDMA secure masked interrupt status register (GPDMA_SMISR)

Address offset: 0x10
Reset value: 0x0000 0000

This is a secure read register, containing the masked interrupt status bit MISx for each secure channel x (GPDMA_SECCFGR.SECx = 1). It is a logical OR of all the GPDMA_CxSR flags, each source flag being enabled by the corresponding GPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when securely writing 1 to the corresponding GPDMA_CxFCR flag clear bit.

This register does not contain any information about a nonsecure channel.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full secure interrupt status. An unprivileged software is restricted to read the status of unprivileged and secure channels, other privileged bit fields returning zero.

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **MISx**: masked interrupt status of the secure channel x (x = 15 to 0)
0: no interrupt occurred on the secure channel x
1: an interrupt occurred on the secure channel x
17.8.6  **GPDMA channel x linked-list base address register (GPDMA_CxLBAR)**

Address offset: 0x50 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

This register is either secure or nonsecure depending on the secure state of the channel x (GPDMA_SECCFGGR.SECx).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the GPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit GPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

Bits 31:16  **LBA[31:16]**: linked-list base address of GPDMA channel x

Bits 15:0  Reserved, must be kept at reset value.

17.8.7  **GPDMA channel x flag clear register (GPDMA_CxFCR)**

Address offset: 0x5C + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This is a write register, secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGGR.SECx) and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

| TOF SUSPF USEF ULEF DTEF HTF TCF |
| w w w w w w w w |

Bits 31:15  Reserved, must be kept at reset value.
Bit 14 **TOF**: trigger overrun flag clear  
0: no effect  
1: corresponding TOF flag cleared  

Bit 13 **SUSPF**: completed suspension flag clear  
0: no effect  
1: corresponding SUSPF flag cleared  

Bit 12 **USEF**: user setting error flag clear  
0: no effect  
1: corresponding USEF flag cleared  

Bit 11 **ULEF**: update link transfer error flag clear  
0: no effect  
1: corresponding ULEF flag cleared  

Bit 10 **DTEF**: data transfer error flag clear  
0: no effect  
1: corresponding DTEF flag cleared  

Bit 9 **HTF**: half transfer flag clear  
0: no effect  
1: corresponding HTF flag cleared  

Bit 8 **TCF**: transfer complete flag clear  
0: no effect  
1: corresponding TCF flag cleared  

Bits 7:0 Reserved, must be kept at reset value.  

### 17.8.8 GPDMA channel x status register (GPDMA_CxSR)  
Address offset: 0x60 + 0x80 * x (x = 0 to 15)  
Reset value: 0x0000 0001  
This is a read register, reporting the channel status.  
This register is secure or nonsecure, depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of the channel (GPDMA_PRIVCFGPR.PRIVx).

</tbody>
</table>

Bits 31:24 Reserved, must be kept at reset value.
Bits 23:16 **FIFOL[7:0]**: monitored FIFO level
   Number of available write beats in the FIFO, in units of the programmed destination data width (see GPDMA_CxTR1.DDW_LOG2[1:0], in units of bytes, half-words, or words).
   
   Note: After having suspended an active transfer, the user may need to read FIFOL[7:0], additionally to GPDMA_CxBR1.BDNT[15:0] and GPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (GPDMA_CxSR.SUSPF = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag
   0: no trigger overrun event
   1: a trigger overrun event occurred

Bit 13 **SUSPF**: completed suspension flag
   0: no completed suspension event
   1: a completed suspension event occurred

Bit 12 **USEF**: user setting error flag
   0: no user setting error event
   1: a user setting error event occurred

Bit 11 **ULEF**: update link transfer error flag
   0: no update link transfer error event
   1: a master bus error event occurred while updating a linked-list register from memory

Bit 10 **DETF**: data transfer error flag
   0: no data transfer error event
   1: a master bus error event occurred on a data transfer

Bit 9 **HTF**: half transfer flag
   0: no half transfer event
   1: a half transfer event occurred
   
   A half transfer event is either a half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).
   
   A half block transfer occurs when half of the bytes of the source block size (rounded up integer of GPDMA_CxBR1.BNDT[15:0]/2) has been transferred to the destination.
   
   A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2)) has been transferred to the destination.

Bit 8 **TCF**: transfer complete flag
   0: no transfer complete event
   1: a transfer complete event occurred
   
   A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **IDLEF**: idle flag
   0: channel not in idle state
   1: channel in idle state
   
   This idle flag is deasserted by hardware when the channel is enabled (GPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).
   
   This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).
17.8.9 **GPDMA channel x control register (GPDMA_CxCR)**

Address offset: 0x64 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGPR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

<table>

| rw  | rw  | rw  | rw  | rw  | rw  | rw | rw | rw | rw | rw | rw | rw | rw | rw | 0  |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]**: priority level of the channel x GPDMA transfer versus others

- 00: low priority, low weight
- 01: low priority, mid weight
- 10: low priority, high weight
- 11: high priority

*Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.*

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 **LAP**: linked-list allocated port

This bit is used to allocate the master port for the update of the GPDMA linked-list registers from the memory.

- 0: port 0 (AHB) allocated
- 1: port 1 (AHB) allocated

*Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.*

Bit 16 **LSM**: Link step mode

- 0: channel executed for the full linked-list and completed at the end of the last LLI (GPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0). Then GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0.
- 1: channel executed once

First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0.

Secondly the next linked-list data structure is conditionally uploaded from memory as defined by GPDMA_CxLLR. Then channel execution is completed.

*Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.*

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: trigger overrun interrupt enable

- 0: interrupt disabled
- 1: interrupt enabled
Bit 13 **SUSPIE**: completed suspension interrupt enable
   0: interrupt disabled
   1: interrupt enabled

Bit 12 **USEIE**: user setting error interrupt enable
   0: interrupt disabled
   1: interrupt enabled

Bit 11 **ULEIE**: update link transfer error interrupt enable
   0: interrupt disabled
   1: interrupt enabled

Bit 10 **DTEIE**: data transfer error interrupt enable
   0: interrupt disabled
   1: interrupt enabled

Bit 9 **HTIE**: half transfer complete interrupt enable
   0: interrupt disabled
   1: interrupt enabled

Bit 8 **TCIE**: transfer complete interrupt enable
   0: interrupt disabled
   1: interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **SUSP**: suspend
   Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:
   Software must write 1 in order to suspend an active channel (channel with an ongoing GPDMA transfer over its master ports).
   The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in Figure 51.
   0: write: resume channel, read: channel not suspended
   1: write: suspend channel, read: channel suspended.

Bit 1 **RESET**: reset
   This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0).
   The reset is effective when the channel is in steady state, meaning one of the following:
   - active channel in suspended state (GPDMA_CxSR.SUSPF = 1 and GPDMA_CxSR.IDLEF = GPDMA_CxCR.EN = 1)
   - channel in disabled state (GPDMA_CxSR.IDLEF = 1 and GPDMA_CxCR.EN = 0).
   After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR) before enabling again the channel (see the programming sequence in Figure 52).
   0: no channel reset
   1: channel reset
Bit 0 **EN:** enable
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:
this bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).
Else, this bit can be asserted by software.
Writing 0 into this EN bit is ignored.
0: write: ignored, read: channel disabled
1: write: enable channel, read: channel enabled

17.8.10 **GPDMA channel x transfer register 1 (GPDMA_CxTR1)**

Address offset: 0x90 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFG.SECx) except for secure DSEC and SSEC, privileged or non-privileged, depending on the privileged state of the channel x in GPDMA_PRIVCFG.PRIVx.

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UT1 = 1.

Bit 31 **DSEC:** security attribute of the GPDMA transfer to the destination
If GPDMA_SECCFG.SECx = 1 and the access is secure:
0: GPDMA transfer nonsecure
1: GPDMA transfer secure
This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFG.SECx = 1. A secure write is ignored when GPDMA_SECCFG.SECx = 0.
When GPDMA_SECCFG.SECx is deasserted, this DSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the GPDMA transfer to the destination is nonsecure.
Bit 30  **DAP**: destination allocated port
This bit is used to allocate the master port for the destination transfer
0: port 0 (AHB) allocated
1: port 1 (AHB) allocated

*Note*: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 29:28  Reserved, must be kept at reset value.

Bit 27  **DHX**: destination half-word exchange
If the destination data size is shorter than a word, this bit is ignored.
If the destination data size is a word:
0: no halfword-based exchanged within word
1: the two consecutive (post PAM) half-words are exchanged in each destination word.

Bit 26  **DBX**: destination byte exchange
If the destination data size is a byte, this bit is ignored.
If the destination data size is not a byte:
0: no byte-based exchange within half-word
1: the two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20  **DBL_1[5:0]**: destination burst length minus 1, between 0 and 63
The burst length unit is one data named beat within a burst. If DBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width DDW_LOG2[1:0].

*Note*: If a burst transfer crossed a 1-Kbyte address boundary on an AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.
If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19  **DINC**: destination incrementing burst
0: fixed burst
1: contiguously incremented burst
The destination address, pointed by GPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18  Reserved, must be kept at reset value.

Bits 17:16  **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a burst, in bytes
00: byte
01: half-word (2 bytes)
10: word (4 bytes)
11: user setting error reported and no transfer issued

*Note*: Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.
A destination burst transfer must have an aligned address with its data width (start address GPDMA_CxDAR[2:0] and address offset GPDMA_CxTR3.DAO[2:0], versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.
**Bit 15  SSEC**: security attribute of the GPDMA transfer from the source
   If GPDMA_SECCFG.R.SECx = 1 and the access is secure:
   0: GPDMA transfer nonsecure
   1: GPDMA transfer secure
   This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFG.R.SECx = 1. A secure write is ignored when GPDMA_SECCFG.R.SECx = 0.
   When GPDMA_SECCFG.R.SECx is deasserted, this SSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the GPDMA transfer from the source is nonsecure.

**Bit 14  SAP**: source allocated port
   This bit is used to allocate the master port for the source transfer
   0: port 0 (AHB) allocated
   1: port 1 (AHB) allocated
   *Note:* This bit must be written when EN = 0. This bit is read-only when EN = 1.

**Bit 13  SBX**: source byte exchange within the unaligned half-word of each source word
   If the source data width is shorter than a word, this bit is ignored.
   If the source data width is a word:
   0: no byte-based exchange within the unaligned half-word of each source word
   1: the two consecutive bytes within the unaligned half-word of each source word are exchanged.

**Bits 12:11  PAM[1:0]**: padding/alignment mode
   If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.
   Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when source data width is higher than destination data width.
   Condition: PAM_1
   00: source data is transferred as right aligned, padded with 0s up to the destination data width
   01: source data is transferred as right aligned, sign extended up to the destination data width
   10-11: successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer
   Condition: PAM_2
   00: source data is transferred as right aligned, left-truncated down to the destination data width
   01: source data is transferred as left-aligned, right-truncated down to the destination data width
   10-11: source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

**Bit 10  Reserved**, must be kept at reset value.
Bits 9:4  **SBL_1[5:0]**: source burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If SBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width **SDW_LOG2[1:0]**.

**Note:** If a burst transfer crossed a 1-Byte address boundary on an AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3  **SINC**: source incrementing burst

0: fixed burst
1: contiguously incremented burst

The source address, pointed by GPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2  Reserved, must be kept at reset value.

Bits 1:0  **SDW_LOG2[1:0]**: binary logarithm of the source data width of a burst in bytes

00: byte
01: half-word (2 bytes)
10: word (4 bytes)
11: user setting error reported and no transfer issued

**Note:** Setting a 8-byte data width causes a user setting error to be reported and no transfer is issued.

A source block size must be a multiple of the source data width (GPDMA_CxBR1.BNDT[2:0] versus **SDW_LOG2[1:0]**). Otherwise, a user setting error is reported and no transfer is issued.

A source burst transfer must have an aligned address with its data width (start address GPDMA_CxSAR[2:0] versus **SDW_LOG2[1:0]**). Otherwise, a user setting error is reported and none transfer is issued.
17.8.11 GPDMA channel x transfer register 2 (GPDMA_CxTR2)

Address offset: 0x94 + 0x80 * x (x = 0 to 15)
Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGRx.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGx.PRIVx).

This register controls the transfer of a channel x.

This register must be written when LGPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory, if GPDMA_CxLLR.UT2 = 1.

Bits 31:30  **TCEM[1:0]:** transfer complete event mode

These bits define the transfer granularity for the transfer complete and half transfer complete events generation.

00: at block level (when GPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

**Note:** If the initial LLI1 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

01: channel x (x = 0 to 11), same as 00, channel x (x = 12 to 15), at 2D/repeated block level (when GPDMA_CxBR1.BRC[10:0] = 0 and GPDMA_CxBR1.BNDT[15:0] = 0). The complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

**Note:** If the initial LLI1 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer The LLI data transfer is a block transfer or a 2D/repeated block transfer for channel x (x = 12 to 15), if any data transfer.

**Note:** If the initial LLI1 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI1.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address GPDMA_CxLLR.LA[15:2] to zero and clears all the GPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26  Reserved, must be kept at reset value.

Bits 25:24  **TRIGPOL[1:0]:** trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[6:0].

00: no trigger (masked trigger event)
01: trigger on the rising edge
10: trigger on the falling edge
11: same as 00

Bit 23  Reserved, must be kept at reset value.

Bits 22:16  **TRIGSEL[6:0]:** trigger event input selection

These bits select the trigger event input of the GPDMA transfer (as per Section 17.3.5), with an active trigger event if TRIGPOL[1:0] ≠ 00.
Bits 15:14 **TRIGM[1:0]:** trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (GPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, a GPDMA transfer is conditioned by at least one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x = 12 to 15, for each block if a 2D/repeated block is configured with GPDMA_CxBR1.BRC[10:0] ≠ 0).

01: channel x (x = 0 to 11), same as 00; channel x (x =12 to 15), at 2D/repeated block level.

The first burst read of a 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger.

– If the peripheral is programmed as a source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is programmed as a destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and the first trigger hit.

The GPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[6:0] is not modified, and the channel is enabled.

Transferring a next LLI_n+1 that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[6:0] or TRIGPOL[1:0], resets the monitoring, trashin the memorized hit of the formerly defined LLI_n trigger.

After a first new trigger hit_n+1 is memorized, if another second trigger hit_n+2 is detected and if the hit_n triggered transfer is still not completed, hit_n+2 is lost and not memorized.

A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

**Note:** When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ = 0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1-Kbyte boundary address crossing): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bits 13:12 Reserved, must be kept at reset value.
Bit 11 **BREQ**: Block hardware request
If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:
0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.
1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see Section 17.3.3).

Bit 10 **DREQ**: destination hardware request
This bit is ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:
0: selected hardware request driven by a source peripheral (request signal taken into account by the GPDMA transfer scheduler over the source/read port)
1: selected hardware request driven by a destination peripheral (request signal taken into account by the GPDMA transfer scheduler over the destination/write port)

*Note:*

Bit 9 **SWREQ**: software request
This bit is internally taken into account when GPDMA_CxCR.EN is asserted.
0: no software request. The selected hardware request REQSEL[6:0] is taken into account.
1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[6:0] is ignored.

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:0 **REQSEL[6:0]**: GPDMA hardware request selection
These bits are ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per Section 17.3.3.

*Caution:* The user must not assign a same input hardware request (same REQSEL[6:0] value) to different active GPDMA channels (GPDMA_CxCR.EN = 1 and GPDMA_CxTR2.SWREQ = 0 for these channels). GPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.
17.8.12 GPDMA channel x block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 0 to 11)
Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGx.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:
- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the field BNDT[15:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

Bits 31:16 Reserved, must be kept at reset value.
17.8.13  **GPDMA channel x alternate block register 1 (GPDMA_CxBR1)**

Address offset: 0x98 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.

- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0].

- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is internally restored to the programmed value (infinite/continuous last LLI).
automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0] after each execution of this final LLI

- If GPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

| Bit 27 | Reserved, must be kept at reset value. |
Bits 26:16  **BRC[10:0]**: Block repeat counter

This field contains the number of repetitions of the current block (0 to 2047).
When the channel is enabled, this field becomes read-only. After decrements, this field indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):
- If GPDMA_CxLLR.UB1 = 1, all GPDMA_CxBR1 fields are updated by the next LLI in the memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.
- If all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- If GPDMA_CxLLR = 0, this field is kept as zero following the last LLI and data transfer.

Bits 15:0  **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):
- If GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.
- If all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- If GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

**Note:** A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (GPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.
17.8.14 GPDMA channel x source address register (GPDMA_CxSAR)

Address offset: 0x9C + 0x80 * x (x = 0 to 15)
Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.USA = 1.

SA[31:16]
SA[15:0]
Bits 31:0  **SA[31:0]:** source address

This field is the pointer to the address from which the next data is read. During the channel activity, depending on the source addressing mode (GPDMA_CxTR1.SINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read. During the channel activity, this address is updated after each completed source burst, consequently to:

– the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.SBL_1[5:0] and GPDMA_CxTR1.SDW_LOG2[21:0]

– the additional source incremented/decremented offset value as programmed by GPDMA_CxBR1.SDEC and GPDMA_CxTR3.SAO[12:0].

– once/if completed source block transfer, for a channel x with 2D addressing capability (x = 12 to 15), additional block repeat source incremented/decremented offset value as programmed by GPDMA_CxBR1.BRSDEC and GPDMA_CxBR2.BRSAO[15:0].

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.USA = 1.

**Note:** A source address must be aligned with the programmed data width of a source burst (SA[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.
17.8.15 GPDMA channel x destination address register (GPDMA_CxDAR)

Address offset: $0xA0 + 0x80 * x$ ($x = 0$ to $15$)

Reset value: $0x0000 0000$

This register is secure or nonsecure depending on the secure state of channel $x$ (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel $x$ (GPDMA_PRIVCFGPR.PRIx).

This register configures the destination start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UDA = 1.

Bits 31:0 DA[31:0]: destination address

This field is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (GPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.DDW_LOG2[21:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:

- the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.DBL_1[5:0] and GPDMA_CxTR1.DDW_LOG2[1:0]
- the additional destination incremented/decremented offset value as programmed by GPDMA_CxBR1.DDEC and GPDMA_CxTR3.DAO[12:0].
- once/if completed destination block transfer, for a channel $x$ with 2D addressing capability ($x = 12$ to $15$), the additional block repeat destination incremented/decremented offset value as programmed by GPDMA_CxBR1.BRDDEC and GPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst (DA[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.
17.8.16  GPDMA channel x transfer register 3 (GPDMA_CxTR3)

Address offset: 0xA4 + 0x80 * x (x = 12 to 15)
Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGPR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UT3 = 1.

</tr>
</tbody>
</table>

Bits 31:29  Reserved, must be kept at reset value.

Bits 28:16  DAO[12:0]: destination address offset increment

The destination address, pointed by GPDMA_CxDAR, is incremented or decremented (depending on GPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.DINC = 1).

Note: A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

Bits 15:13  Reserved, must be kept at reset value.

Bits 12:0  SAO[12:0]: source address offset increment

The source address, pointed by GPDMA_CxSAR, is incremented or decremented (depending on GPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.SINC = 1).

Note: A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size, and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.
17.8.17 **GPDMA channel x block register 2 (GPDMA_CxBR2)**

Address offset: 0xA8 + 0x80 * x (x = 12 to 15)
Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UB2 = 1.

17.8.18  

**GPDMA channel x linked-list address register (GPDMA_CxLLR)**

Address offset: 0xCC + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGPR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

**Bit 31 UT1**: Update GPDMA_CxTR1 from memory
This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.
0: no GPDMA_CxTR1 update
1: GPDMA_CxTR1 update

**Bit 30 UT2**: Update GPDMA_CxTR2 from memory
This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.
0: no GPDMA_CxTR2 update
1: GPDMA_CxTR2 update

**Bit 29 UB1**: Update GPDMA_CxBR1 from memory
This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: GPDMA_CxBR1 update

**Bit 28 USA**: update GPDMA_CxSAR from memory
This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.
0: no GPDMA_CxSAR update
1: GPDMA_CxSAR update
Bit 27  **UDA**: Update GPDMA\_CxDAR register from memory  
This bit is used to control the update of GPDMA\_CxDAR from the memory during the link transfer.  
0: no GPDMA\_CxDAR update  
1: GPDMA\_CxDAR update

Bit 26  **UT3**: Update GPDMA\_CxTR3 from memory  
This bit controls the update of GPDMA\_CxTR3 from the memory during the link transfer.  
0: no GPDMA\_CxTR3 update  
1: GPDMA\_CxTR3 update

Bit 25  **UB2**: Update GPDMA\_CxBR2 from memory  
This bit controls the update of GPDMA\_CxBR2 from the memory during the link transfer.  
0: no GPDMA\_CxBR2 update  
1: GPDMA\_CxBR2 update

Bits 24:17  Reserved, must be kept at reset value.

Bit 16  **ULL**: Update GPDMA\_CxLLR register from memory  
This bit is used to control the update of GPDMA\_CxLLR from the memory during the link transfer.  
0: no GPDMA\_CxLLR update  
1: GPDMA\_CxLLR update

Bits 15:2  **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure  
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:20] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.  
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA\_CxTR1, GPDMA\_CxTR2, GPDMA\_CxBR1, GPDMA\_CxSAR, GPDMA\_CxDAR, and GPDMA\_CxLLR).  
**Note:** The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0  Reserved, must be kept at reset value.

### 17.8.20 GPDMA register map

#### Table 143. GPDMA register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Refer to Section 2.3 for the register boundary addresses.
18 Low-power direct memory access controller (LPDMA)

18.1 LPDMA introduction
The low-power direct memory access (LPDMA) controller is a bus master and system peripheral.

The LPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

18.2 LPDMA main features
- Single bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral
- Autonomous data transfers during Sleep and Stop modes
- Transfers arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 4 concurrent LPDMA channels:
  - Intra-channel LPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel LPDMA transfers chaining via programmable LPDMA input triggers connection to LPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level
  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive single transfers
  - Programmable LPDMA request and trigger selection
  - Programmable LPDMA half-transfer and transfer-complete events generation
- Pointer to the next linked-list item and its data structure in memory, with automatic update of the LPDMA linked-list control registers

- **Debug:**
  - Channel suspend and resume support
  - Channel status reporting and event flags

- **TrustZone support**
  - Support for secure and nonsecure LPDMA transfers, independently at a first channel level, and independently at a source/destination and link sub-levels
  - Secure and nonsecure interrupts reporting, resulting from any of the respectively secure and nonsecure channels
  - TrustZone-aware AHB slave port, protecting any LPDMA secure resource (register, register field) from a nonsecure access

- **Privileged/unprivileged support:**
  - Support for privileged and unprivileged LPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

### 18.3 LPDMA implementation

#### 18.3.1 LPDMA channels

A given LPDMA channel \( x \) is implemented with the hardware parameters as per the table below.

<table>
<thead>
<tr>
<th>Channel ( x )</th>
<th>Hardware parameters</th>
<th>Features</th>
</tr>
</thead>
</table>
| \( x = 0 \) to \( 3 \) | \( \text{dma\_fifo\_size}[x] \) | \( \text{dma\_addressing}[x] \) | Channel \( x \) (\( x = 0 \) to \( 3 \)) is implemented with:
  - no FIFO. Only a single source transfer cell is internally registered.
  - fixed/contiguously incremented addressing |
| 0 | 0 | |

#### 18.3.2 LPDMA autonomous mode in low-power modes

The LPDMA autonomous mode and wake-up feature is implemented in the device low-power modes as per the table below.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Low-power modes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomous mode and wake-up</td>
<td>LPDMA1 in Sleep, Stop 0, Stop 1 and Stop 2 modes</td>
</tr>
</tbody>
</table>
18.3.3 LPDMA requests

A LPDMA request from a peripheral can be assigned to a LPDMA channel x, via the REQSEL[4:0] field in the LPDMA channel x transfer register 2 (LPDMA_CxTR2), provided that SWREQ = 0.

The LPDMA requests mapping is specified in the table below.

<table>
<thead>
<tr>
<th>LPDMA_CxTR2.REQSEL[4:0]</th>
<th>Selected LPDMA request</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>lpuart1_rx_dma</td>
</tr>
<tr>
<td>1</td>

</tr>
<tr>
<td>16</td>
<td>lptim3_ue_dma</td>
</tr>
</tbody>
</table>

18.3.4 LPDMA block requests

Some LPDMA requests must be programmed as a block request, and not as a single request. Then the BREQ bit in LPDMA channel x transfer register 2 (LPDMA_CxTR2) must be set for a correct LPDMA execution of the requested peripheral transfer at the hardware level.

The LPDMA block requests are listed in the table below.

<table>
<thead>
<tr>
<th>LPDMA block requests</th>
</tr>
</thead>
<tbody>
<tr>
<td>lptim1_ue_dma</td>
</tr>
<tr>
<td>lptim3_ue_dma</td>
</tr>
</tbody>
</table>
18.3.5 LPDMA triggers

A LPDMA trigger can be assigned to a LPDMA channel x, via the TRIGSEL[4:0] field in the LPDMA channel x transfer register 2 (LPDMA_CxTR2), provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

The LPDMA triggers mapping is specified in the table below.

<table>
<thead>
<tr>
<th>LPDMA_CxTR2.TRIGSEL[4:0]</th>

### 18.4 LPDMA functional description

#### 18.4.1 LPDMA block diagram

The LPDMA block diagram is illustrated in the figure below.

**Figure 70. LPDMA block diagram**

#### 18.4.2 LPDMA channel state and direct programming without any linked-list

After a LPDMA reset, a LPDMA channel x is in idle state. When the software writes 1 into the LPDMA_CxCR.EN enable control bit, the channel takes into account the value of the different channel configuration registers (LPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

---

**Table 148. Programmed LPDMA1 trigger (continued)**

<table>
<thead>
<tr>
<th>LPDMA_CxTR2.TRIGSEL[4:0]</th>
<th>Selected LPDMA trigger</th>
</tr>
</thead>
<tbody>
<tr>
<td>30</td>
<td>tim2_trgo</td>
</tr>
<tr>
<td>31</td>
<td>tim15_trgo</td>
</tr>
</tbody>
</table>

(1) Refer to the device implementation table for the number of channels.
After enabling/starting a LPDMA channel transfer by writing 1 into the LPDMA_CxCR.EN bit, a LPDMA channel interrupt on a complete transfer notifies the software that the LPDMA channel is back in idle state (EN is then de-asserted by hardware) and that the channel is ready to be reconfigured then enabled again.

The figure below illustrates this LPDMA direct programming without any linked-list (LPDMA_CxLLR = 0).

Figure 71. LPDMA channel direct programming without linked-list (LPDMA_CxLLR = 0)
18.4.3 LPDMA channel suspend and resume

The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the LPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag LPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to LPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing LPDMA transfer over its master port. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.

Note that an ongoing LPDMA transfer can be a data transfer (a read-followed-by-write single transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to LPDMA_CxCR.SUSP.

The suspend and resume sequence is illustrated in the figure below.

![Figure 72. LPDMA channel suspend and resume sequence](image)

Note: A suspend and resume sequence does not impact the LPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

18.4.4 LPDMA channel abort and restart

Alternatively, like for aborting a continuous LPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the LPDMA_CxCR.SUSP bit.
2. The software polls suspended flag LPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to LPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing LPDMA transfer over its master port.

3. The software resets the channel by writing 1 to LPDMA_CxCR.RESET. This causes the reset of the channel internal state, the reset of the LPDMA_CxCR.EN bit, and the reset of the LPDMA_CxCR.SUSP bit.

4. The software safely reconfigures the channel. The software must reprogram the hardware-modified LPDMA_CxBR1, LPDMA_CxSAR, and LPDMA_CxDAR registers.

5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the LPDMA_CxCR.EN bit.

The abort and restart sequence is illustrated in the figure below.

![Figure 73. LPDMA channel abort and restart sequence](MSv62628V1)

### 18.4.5 LPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.
The base address in memory of the data structure of a next LLI\(_{n+1}\) of a channel \(x\) is the sum of the following:

- the link base address of the channel \(x\) (in LPDMA\(_{Cx}\)LBAR)
- the link address offset (LA[15:2] field in LPDMA\(_{Cx}\)LLR)

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the UT1, UT2, UB1, USA, UDA and ULL bits of the LPDMA\(_{Cx}\)LLR register.

In linked-list mode, each LPDMA linked-list register (LPDMA\(_{Cx}\)TR1, LPDMA\(_{Cx}\)TR2, LPDMA\(_{Cx}\)BR1, LPDMA\(_{Cx}\)SAR, LPDMA\(_{Cx}\)DAR or LPDMA\(_{Cx}\)LLR) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the LPDMA\(_{Cx}\)LLR register that was conditionally updated from the linked-list data structure of the previous LLI.

**Static linked-list data structure**

For example, when the update bits (UT1, UT2, UB1, USA, UDA and ULL) of the LPDMA\(_{Cx}\)LLR register are all asserted, the linked-list data structure in memory is maximal with six contiguous 32-bit locations, including LPDMA\(_{Cx}\)TR1, LPDMA\(_{Cx}\)TR2, LPDMA\(_{Cx}\)BR1, LPDMA\(_{Cx}\)SAR, LPDMA\(_{Cx}\)DAR and LPDMA\(_{Cx}\)LLR (see the figure below) and including the first linked-list register file (LLI\(_0\)) and the next LLIs (LLI\(_1\), LLI\(_2\),...) in the memory.

![Figure 74. Static linked-list data structure (all Uxx = 1) of channel \(x\)](image)
**Dynamic linked-list data structure**

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register LPDMA_CxLLR is pointing to the updated value of the LPDMA_CxTR2 instead of the LPDMA_CxTR1 which is not to be modified.

Example: if UT1 = UB1 = USA = 0, and if UT2 = UDA = ULL = 1, the next LLI does not contain an updated value for LPDMA_CxTR1, nor LPDMA_CxBR1, nor LPDMA_CxSAR. The next LLI contains an updated value for LPDMA_CxTR2, LPDMA_CxDAR, and LPDMA_CxLLR, as shown in the figure below.

![Figure 75. LPDMA dynamic linked-list data structure of an addressing channel x](image)

The user must program LPDMA_CxLLR for each LLI to be 32-bit aligned and not to exceed the 64-Kbyte addressable space pointed by LPDMA_CxLBAR.

### 18.4.6 Linked-list item transfer execution

A LLI transfer is the sequence of:

1. a data transfer: LPDMA executes the data transfer as described by the LPDMA internal register file (this data transfer can be void/null for LLI0)
2. a conditional link transfer: LPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI+1, as defined by the LPDMA_CxLLR value of the LLI.

*Note:* The initial data transfer as defined by the internal register file (LLI0) can be null (LPDMA_CxBR1.BNDT[15:0] = 0) provided that the conditional update bit UB1 in LPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI in the memory to be executed).

Depending on the intended LPDMA usage, a LPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, LPDMA_CxCR.LSM = 0) or a LPDMA channel x can be programmed for a single execution of a LLI (link step mode, LPDMA_CxCR.LSM = 1), as described in the next paragraphs.
18.4.7 LPDMA channel state and linked-list programming in run-to-completion mode

When LPDMA_CxCR.LSM = 0, a LPDMA channel x is initially programmed, started by writing 1 to LPDMA_CxCR.EN, and after (possibly) completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI₀, internal linked-list register file: LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR
  - the last LLIₙ, described by the linked-list data structure in memory, as defined by the LPDMA_CxLLR reflecting the before last LLIₙ₋₁
- completed when LPDMA_CxLLR[31:0] = 0 and LPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLIₙ₋₁ transfer

LPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits LPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits Uxx of LPDMA_CxLLR are null (UT1, UT2, UB1, USA, UDA, ULL).

The channel may never be completed when LPDMA_CxLLR.LSM = 0:

- If the last LLIₙ is recursive, pointing to itself as a next LLI:
  - either LPDMA_CxLLR.ULL = 1 and LPDMA_CxLLR.LA[15:2] is updated by the same value
  - or LPDMA_CxLLR.ULL = 0
- If LLIₙ is pointing to a previous LLI.

In the typical run-to-completion mode, the allocation of a LPDMA channel, including its fine programming, is done once during the LPDMA initialization. In order to have a reserved data communication link and LPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

Figure 76 depicts the LPDMA channel execution and its registers programming in run-to-completion mode.

Note: Figure 76 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in LPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.
Figure 76. LPDMA channel execution and linked-list programming in run-to-completion mode (LPDMA_CxCR.LSM = 0)

Channel state = Idle

    - Setting DTEF = 1
      - Disabling DMA channel

End
Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the LPDMA_CxTR2 in the data structure of the LLI_{n-1}:

- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[4:0] (see Section 18.3.5 for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory and to generate a transfer complete event lpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

Figure 77 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

CPU
18.4.8 LPDMA channel state and linked-list programming in link step mode

When LPDMA_CxCR.LSM = 1, a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

A LPDMA channel transfer can be programmed at LLI level, started by writing 1 into LPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI\(n\) transfer is described with:
  - LPDMA_CxTR1 defines the source/destination elementary single transfers.
  - LPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]).
  - LPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
  - LPDMA_CxSAR/LPDMA_CxDAR defines the source/destination transfer start address.
  - LPDMA_CxLLR defines the data structure and the address offset of the next LLI\(n+1\) in the memory.

- The current LLI\(n\) transfer is completed after the single execution of the current LLI\(n\):
  - after the (conditional) data transfer completion (when LPDMA_CxBR1.BNDT[15:0] = 0)
  - after the (conditional) update of the LPDMA link register file from the data structure of the next LLI\(n+1\) in memory

**Note:** If a LLI is recursive (pointing to itself as a next LLI, either LPDMA_CxLLR.ULL = 1 and LPDMA_CxLLR.LA[15:2] is updated by the same value, or LPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

*Figure 78* depicts the LPDMA channel execution mode, and its programming in link step mode.

**Note:** *Figure 78* is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in LPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.
Figure 78. LPDMA channel execution and linked-list programming in link step mode (LPDMA_CxCR.LSM = 1)

Channel state = Idle
- Initialize DMA channel
- Enable DMA channel
- Reconfigure DMA channel

Channel state = Active
- Valid user setting ?
  - Y: Setting USEF = 1 Disabling DMA channel
  - N: Setting DTEF = 1 Disabling DMA channel
- BNDT ≠ 0 ?
  - Y: Executing once the data transfer from the register file
  - N: Setting ULEF = 1 Disabling DMA channel
- No transfer error ?
  - Y: Loading next LLI into the register file
  - N: Valid user setting ?
    - Y: Setting TCF = 1 Disabling DMA channel
    - N: Setting USEF = 1 Disabling DMA channel
- LLR ≠ 0 ?
  - Y: No transfer error ?
    - Y: Setting ULEF = 1 Disabling DMA channel
    - N: Valid user setting ?
      - Y: Setting TCF = 1 Disabling DMA channel
      - N: Setting USEF = 1 Disabling DMA channel
  - N: End
The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI<sub>n</sub> (all update bits of LPDMA_CxLLR have a static value, LLI<sub>n</sub>.LLR.LA = LLI<sub>n-1</sub>.LLR.LA + constant).

Run-time adding a LLI<sub>n+1</sub> in link step mode

During run-time, the software can defer the elaboration of the LLI<sub>n+1</sub> (and next LLIs), until/after LPDMA executed the transfer from the LLI<sub>n-1</sub> and loaded the LLI<sub>n</sub> from the memory, as shown in the figure below.

**Figure 79. Building LLI<sub>n+1</sub>: LPDMA dynamic linked-lists in link step mode**

Run-time replacing a LLI<sub>n</sub> with a new LLI<sub>n'</sub>, in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI<sub>n'</sub>, after LPDMA executed the transfer from the LLI<sub>n-1</sub> and loaded a formerly elaborated LLI<sub>n</sub> from the memory by overwriting directly the linked-list register file with the new LLI<sub>n'</sub>, as shown in **Figure 80**.
Run-time replacing a LLI\textsubscript{n} with a new LLI\textsubscript{n}’ in link step mode (in the memory)

The software can build and insert a new LLI\textsubscript{n}’ and LLI\textsubscript{n+1}’ in the memory, after LPDMA executed the transfer from the LLI\textsubscript{n-1} and loaded LLI\textsubscript{n}, then CPU builds and overwrites LLI\textsubscript{n+1} as shown in Figure 81.
Figure 81. Replace with a new \( \text{LLI}_n \) and \( \text{LLI}_{n+1} \) in memory in link step mode (option 1)

LSM = 1 with 1-stage linked-list programming:
Overwriting the (pre)loaded \( \text{LLI}_n \) linked-list register file with a new \( \text{LLI}_n \) and \( \text{LLI}_{n+1} \) in memory and overwrite partly linked-list register file

\((\text{DMA}_c\text{BR}1.\text{BNDT} = 0 \text{ and } \text{DMA}_c\text{LLR} \text{ to point to new } \text{LLI}_n)\)

DMA executes \( \text{LLI}_{n-1} \) and load \( \text{LLI}_n \) then CPU builds (\( \text{LLI}_n \) and \( \text{LLI}_{n+1} \)) and overwrite (BR1 and LLR)

1. **DMA Channel**
   - Executing \( \text{LLI}_{n-1} \) data transfer
   - Loading \( \text{LLI}_n \)
   - Transfer complete interrupt

2. **CPU**
   - Build \( \text{LLI}_n \) and \( \text{LLI}_{n+1} \) in memory
   - Write \( \text{DMA}_c\text{BR}1.\text{BNDT} = 0 \)
   - Write \( \text{DMA}_c\text{LLR} \) to point to new \( \text{LLI}_n \)
   - Enable DMA channel

3. **DMA Channel**
   - Loading \( \text{LLI}_n \)
   - Transfer complete interrupt
   - Enable DMA channel

4. **DMA Channel**

   - Transfer complete interrupt
Run-time replacing a LLIn with a new LLIn' in link step mode

Other software implementations exist. Meanwhile LPDMA executes the transfer from the LLIn-1 and loads a formerly elaborated LLIn from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new LLIn' and a new LLIn+1'.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLIn-1 is then restricted to overwrite LPDMA_CxBR1.BNDT[15:0] to be null and LPDMA_CxLLR to point to new LLIn', as shown in Figure 82.

**Figure 82. Replace with a new LLIn' and LLIn+1' in memory in link step mode (option 2)**

---

**Diagram Description:**

- **DMA channel**
  - Executing LLIn-1 data transfer
    - Loading LLIn
  - Transfer complete interrupt
  - Overwriting the (pre)loaded LLIn linked-list register file by building new LLIn' and LLIn+1' in memory while disabling (temporary) channel interrupt at NVIC level, and overwriting DMA_CxBR1.BNDT = 0 and DMA_CxLLR to point to new LLIn'.
  - DMA executes LLIn-1 and loading LLIn while CPU builds (LLIn' and LLIn+1'), then CPU overwrites (BR1 and LLR)

- **CPU**
  - Disable NVIC DMA irq channel
  - Build LLIn' & LLIn+1' in memory
  - Enable NVIC DMA irq channel
  - Write DMA_CxBR1.BNDT = 0
  - Write DMA_CxLLR to point to new LLIn'
  - Enable DMA channel

**Legend:**

- LSM = 1 with 1-stage linked-list programming:
- MSv62637V1
18.4.9 LPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (LPDMA_CxCR.EN = 0) and update the execution mode (LPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the LPDMA_CxLLR of this LLI_{n+1}), before that this LLI_{n+1} is loaded/used by the LPDMA channel
- abort and reconfigure the channel with a LSM update (see Section 18.4.4)

In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 83 shows the overall and unified LPDMA linked-list programming, whatever is the execution mode.

Note: Figure 83 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in LPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

18.4.10 LPDMA direct transfers

There is a single transfer operation mode called the direct mode. Any LPDMA channel is used in direct mode. Any channel is implemented without any FIFO (for every channel \( x \), \( \text{dma_fifo_size}[x] = 0 \)).

**LPDMA single**

A programmed transfer at the lowest level is called a LPDMA single.

A LPDMA single data width is 1, 2 or 4 bytes, as defined by the \( \text{SDW_LOG2}[1:0] \) and \( \text{DDW_LOG2}[1:0] \) fields of LPDMA_CxTR1 (respectively for source and destination).

*Note:* The user must not assign a 8-byte data width \( (\text{SDW_LOG2}[1:0] = 0b11 \) or \( \text{DDW_LOG2}[1:0] = 0b11) \) else a user setting is reported and no transfer is issued.

The addressing mode after each data of a LPDMA single is defined by the SINC and DINC bits of LPDMA_CxTR1 (respectively for source and destination): either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a LPDMA source/destination single (defined by LPDMA_CxSAR and LPDMA_CxDAR) must be aligned with the respective data width.

The table below lists the main characteristics of a LPDMA single.

The next single address in the table is the next source/destination address, pointed by LPDMA_CxSAR and LPDMA_CxDAR, once the programmed source/destination single is completed.

</table>

In direct mode, a LPDMA single is an AHB single transfer.
LPDMA data handling: byte-based padding/truncation, sign extension and left/right alignment

The user can configure some data manipulation between a transferred data from the source and its transfer to the destination. Data handling is controlled by the LPDMA_CxTR1 register:

- If destination data width = source data width (DDW_LOG2[1:0] = SDW_LOG2[1:0]), the source data is copied as is and transferred to the destination.
- Else, depending on PAM:
  - If destination data width > source data width, the source data can be either right-aligned and padded with 0s, or sign extended up to the destination data width.
  - If destination data width < source data width, the source data can be either right-aligned and left-truncated down to the destination data width, or left-aligned and right-truncated down to the destination data width.

There is no data manipulation between two distinct transferred data from the source, before the generation of the destination transfer.

The table below lists possible data handling from the source to the destination.

1. Data stream is timely ordered starting from the byte with the lowest index a.k.a B0.
2. RA = right aligned. LA = left aligned. RT= right truncated. LT = left truncated.
3. 0P = zero bit padding up to the destination data width.
4. SE = sign bit extended up to the destination data width.
18.4.11 LPDMA transfer request and arbitration

LPDMA transfer request

As defined by LPDMA_CxTR2, a programmed LPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the LPDMA hardware peripheral request is driven by the REQSEL[4:0] field (see Section 18.3.4). The selected hardware request can be one of the following:
  - a hardware request from a peripheral configured in LPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - a hardware request from a peripheral for its control registers update from the memory
  - a hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign a same input hardware peripheral LPDMA request via LPDMA_CxTR.REQSEL[4:0] to two different channel if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

LPDMA transfer request for arbitration

For a given channel, a LPDMA requested data transfer from the source address to the destination address is arbitrated versus simultaneous requested LPDMA transfers from other channels, in order to be scheduled over the AHB master port. A LPDMA data transfer is atomic to the LPDMA arbitration: it consists of an AHB read single, immediately followed by an AHB write single. It is granted by the arbiter once for both AHB transfers, based on the channel priority defined by LPDMA_CxCR.PRIO[1:0].

An arbitrated LPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in the memory to one of the linked-list registers (LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR or LPDMA_CxLLR). Each 32-bit read from the memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the master port.

The re arbitration occurs after each granted single transfer:

- whatever how the requested data transfer is programmed:
  - with a software request for a memory-to-memory transfer (LPDMA_CxTR2.SWREQ = 1)
  - with a hardware request (LPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer
- whatever the hardware request type

When the requested data transfer is programmed with a hardware request from a peripheral (LPDMA_CxTR2.SWREQ = 0), the first memory read of a block is gated by the occurrence of the corresponding and selected hardware request, whatever the peripheral is source or destination of the transfer. This first read request to the memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).
**LPDMA arbitration**

The LPDMA arbitration is directed from the 4-grade assigned channel priority (LPDMA_CxCR_PRIO[1:0]). The arbitration policy, as illustrated in Figure 84, is defined by:

- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels
  
  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single transfers are round-robin arbitrated.

- three low-priority traffic classes (queues 0, 1 or 2) for non time-sensitive channels with priority 0, 1 or 2
  
  Each requested single transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.
  - Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
  - Any queue 0, 1 or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
  - Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1 and queue 2.

**Figure 84. LPDMA arbitration policy**

1. RRA: round-robin arbitration
2. FPA: fixed-priority arbitration

**LPDMA arbitration and bandwidth**

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as $B_Q3$) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).
The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1:** basic application with two non time-sensitive LPDMA requests: req0 and req1. There are the following programming possibilities:
  - If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 ($B_{req0}$) is **equal** to the allocated bandwidth to req1($B_{req1}$).
    \[
    B_{req0} = B_{req1} = 1/2 \times (1 - B_{Q3})
    \]
  - If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 ($B_{P0}$) is **3 times less** than the allocated bandwidth to req1 ($B_{P1}$).
    \[
    B_{req0} = B_{P0} = 1/2 \times 1/2 \times (1 - B_{Q3}) = 1/4 \times (1 - B_{Q3})
    \]
    \[
    B_{req1} = B_{P1} = (1/2 + 1) \times 1/3 \times (1 - B_{Q3}) = 3/4 \times (1 - B_{Q3})
    \]
  - If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 ($B_{P0}$) is **5 times less** than the allocated bandwidth to req1 ($B_{P2}$).
    \[
    B_{req0} = B_{P0} = 1/2 \times 1/3 \times (1 - B_{Q3}) = 1/6 \times (1 - B_{Q3})
    \]
    \[
    B_{req1} = B_{P2} = (1/2 + 1 + 1) \times 1/3 \times (1 - B_{Q3}) = 5/6 \times (1 - B_{Q3})
    \]

The above computed bandwidth calculation is based on a theoretical input request, always active for any LPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one LPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.

- **Example 2:** application where the user distributes a same non-null $N$ number of LPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 ($B_{P0}$) is
    \[
    B_{P0} = 1/3 \times 1/3 \times (1 - B_{Q3}) = 1/9 \times (1 - B_{Q3})
    \]
  - The allocated bandwidth to the set of requests of priority 1 ($B_{P1}$) is
    \[
    B_{P1} = (1/3 + 1/2) \times 1/3 \times (1 - B_{Q3}) = 5/18 \times (1 - B_{Q3})
    \]
  - The allocated bandwidth to the set of requests of priority 2 ($B_{P2}$) is
    \[
    B_{P2} = (1/3 + 1/2 + 1) \times 1/3 \times (1 - B_{Q3}) = 11/18 \times (1 - B_{Q3})
    \]
  - The allocated bandwidth to any request $n$ ($B_{n}$) among the $N$ requests of that priority $Pi$ $(i = 0 \text{ to } 2)$ is $B_{n} = 1/N \times B_{Pi}$
    \[
    B_{n, P0} = 1/N \times 1/9 \times (1 - B_{Q3})
    \]
    \[
    B_{n, P1} = 1/N \times 5/18 \times (1 - B_{Q3})
    \]
    \[
    B_{n, P2} = 1/N \times 11/18 \times (1 - B_{Q3})
    \]

In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.
More generally, assume that the following requests are present:

- I requests \((I \geq 0)\) assigned to priority 0
  
  If \(I > 0\), these requests are noted from \(i = 0\) to \(I-1\).

- J requests \((J \geq 0)\) assigned to priority 1
  
  If \(J > 0\), these requests are noted from \(j = 0\) to \(J-1\).

- K requests \((K > 0)\) assigned to priority 2
  
  These requests are noted from \(k = 0\) to \(K-1\)

- L requests \((L \geq 0)\) assigned to priority 3
  
  If \(L > 0\), these requests are noted from \(l = 0\) to \(L-1\).

As \(B_{Q3}\) is the reserved bandwidth to time-sensitive requests, the bandwidth for each request \(L\) with priority 3 is:

- \(B_l = B_{Q3} / L\) for \(L > 0\) (else: \(B_l = 0\))

The bandwidth for each non-time sensitive queue is:

- \(B_{Q0} = 1/3 \times (1 - B_{Q3})\)
- \(B_{Q1} = 1/3 \times (1 - B_{Q3})\)
- \(B_{Q2} = 1/3 \times (1 - B_{Q3})\)

The bandwidth for the set of requests with priority 0 is:

- \(B_{P0} = I / (I + J + K) \times B_{Q0}\)

The bandwidth for each request \(i\) with priority 0 is:

- \(B_i = B_{P0} / I\) for \(L > 0\) (else \(B_i = 0\))

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- \(B_{P1,Q0} = J / (I + J + K) \times B_{Q0}\)

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- \(B_{P1,Q1} = J / (J + K) \times B_{Q1}\)

The bandwidth for each request \(j\) with priority 1 is:

- \(B_j = B_{P1} / J\) for \(J > 0\) (else \(B_j = 0\))

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- \(B_{P2,Q0} = K / (I + J + K) \times B_{Q0}\)

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- \(B_{P2,Q1} = K / (J + K) \times B_{Q1}\)

The bandwidth for each request \(k\) with priority 2 is:

- \(B_k = B_{P2} / K\) (\(K>0\) in the general case)
Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 (K > 0)):
  - \( B_i = \frac{1}{I} * \frac{1}{3} * \frac{I}{(I + J + K)} * (1 - B_{Q3}) \)
  - \( B_j = \frac{1}{J} * \frac{1}{3} * \left[ \frac{J}{(I + J + K)} + \frac{J}{(J + K)} \right] * (1 - B_{Q3}) \)
  - \( B_k = \frac{1}{K} * \frac{1}{3} * \left[ \frac{K}{(I + J + K)} + \frac{K}{(J + K)} + 1 \right] * (1 - B_{Q3}) \)

- in the specific case (when there is no request k with a priority 2 (K = 0)):
  - \( B_i = \frac{1}{I} * \frac{1}{2} * \frac{I}{(I + J)} * (1 - B_{Q3}) \)
  - \( B_j = \frac{1}{J} * \frac{1}{2} * \left[ \frac{J}{(I + J)} + 1 \right] * (1 - B_{Q3}) \)

Consequently, the LPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

18.4.12 LPDMA triggered transfer

A programmed LPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by LPDMA_CxTR2.TRIGPOL[1:0] and LPDMA_CxTR2.TRIGSEL[4:0] (see Section 18.3.5 for the trigger selection).

The triggered transfer, as defined by the trigger mode in LPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first single read of a block, or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see the TRIGM[1:0] description in LPDMA channel x transfer register 2 (LPDMA_CxTR2) for more details).

Trigger hit memorization and trigger overrun flag generation

The LPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[4:0] are not modified, and the channel is enabled.

Transferring a next LLI_{n+1}, that updates the LPDMA_CxTR2 with a new value for any of TRIGSEL[4:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_{n} trigger.

Caution: After a first new trigger hit_{n+1} is memorized, if another trigger hit_{n+2} is detected and if the hit_{n} triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (LPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if LPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.
The figure below illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

**Figure 85. Trigger hit, memorization and overrun waveform**

Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

### 18.4.13 LPDMA circular buffering with linked-list programming

**LPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers**

For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half transfer and complete transfer events/interrupts generation (LPDMA_CxCR.HTIE = 1 and LPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI0 is configured for the first block transfer. A continuously-executed LLI1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). LPDMA automatically reloads the initially programmed LPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore LPDMA_CxBR1.
The figure below illustrates this programming with a LPDMA channel and a source circular buffer.

Figure 86. LPDMA circular buffer programming: update of the memory start address

If circular buffering must be executed after some other transfers over the shared LPDMA channel x, the before-last LLIN+1 in memory is needed to configure the first block transfer. And the last LLIN restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).
The figure below illustrates this programming with a shared LPDMA channel, and a source circular buffer.

**Figure 87. Shared LPDMA channel with circular buffering: update of the memory start address**

---

**18.4.14 LPDMA secure/nonsecure channel**

The LPDMA controller is compliant with the TrustZone hardware architecture at channel level, partitioning all its resources so that they exist in one of the secure and nonsecure worlds at any given time.

Any channel \( x \) is a secure or a nonsecure hardware resource, as configured by LPDMA_SECCFG.R.SEC\( x \).

When a channel \( x \) is configured in secure state by a secure and privileged agent, the following access control rules are applied:

- A nonsecure read access to a register field of this channel is forced to return 0, except for LPDMA_SECCFG.R, LPDMA_PRIVCFG.R, LPDMA_RCFGLOCK.R that are readable by a nonsecure agent.
- A nonsecure write access to a register field of this channel has no impact.

When a channel \( x \) is configured in secure state, a secure agent can configure separately as secure or nonsecure the LPDMA data transfer from the source (LPDMA_CxTR1.SSEC) and the LPDMA data transfer to the destination (LPDMA_CxTR1.DSEC).

When a channel \( x \) is configured in secure state and in linked-list mode, the loading of the next linked-list data structure from the LPDMA memory into its register file, is automatically performed with secure transfers via the master port.

LPDMA generates the DMA channel state versus security, reflecting LPDMA_SECCFG.R, to keep the other peripherals informed of the secure/nonsecure state of each LPDMA channel \( x \).
LPDMA also generates a security illegal access pulse signal on an illegal nonsecure access to a secure LPDMA register. This signal is routed to the TrustZone interrupt controller.

When the secure software must switch a channel from a secure state to a nonsecure state, the secure software must abort the channel or wait until the secure channel is completed before switching. This is needed to dynamically re-allocate a channel to a next nonsecure transfer as a nonsecure software is not allowed to do so and must have LPDMA_CxCR.EN = 0 before the nonsecure software can reprogram the LPDMA_CxCR for a next transfer. The secure software may reset not only the channel x (LPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

18.4.15 LPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via LPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for LPDMA_PRIVCFGR, LPDMA_SECCFGR, that are readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the LPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the master port.

LPDMA generates a DMA channel state versus privilege, reflecting LPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each DMA channel x.

Additionally, the LPDMA generates the privileged illegal access pulse signal on an illegal unprivileged access to a privileged LPDMA register. This signal may be used or not, depending on the product (see the system security section for more details).

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have LPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the LPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (LPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.
18.4.16 LPDMA error management

LPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

**Data transfer error**

On a bus access (as a AHB single) to the source or the destination:

- The source or destination target reports an AHB error.
- The programmed channel transfer is stopped (LPDMA_CxCR.EN cleared by the LPDMA hardware). The channel status register reports an idle state (LPDMA_CxSR.IDLEF = 1) and the data error (LPDMA_CxSR.DTEF = 1).
- After a LPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After a LPDMA data transfer error, the user must issue a channel reset (set LPDMA_CxCR.RESET) to reset the hardware LPDMA channel data path before the user enables again the same channel for a next transfer.

**Link transfer error**

On a tentative update of a LPDMA channel register from the programmed LLI in the memory:

- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (LPDMA_CxCR.EN cleared by the LPDMA hardware), the channel status register reports an idle state (LPDMA_CxSR.IDLEF = 1) and the link error (LPDMA_CxSR.ULEF = 1).
- After a LPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (LPDMA_CxLBAR and LPDMA_CxLLR), including the protection attributes.
- After a LPDMA link error, the user must explicitly write the linked-list register file (LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR), before the user enables again the same channel for a next transfer.

**User setting error**

On a tentative execution of a LPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (LPDMA_CxCR.EN forced and cleared by the LPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (LPDMA_CxSR.IDLEF = 1) and a user setting error (LPDMA_CxSR.USEF = 1).
- After a LPDMA user setting error, the user must perform a debug session, taking care of the LPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI1 (LPDMA_CxBR1.BNDT[15:0] = 0 and LPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source single transfer (LPDMA_CxBR1.BNDT[2:0] versus LPDMA_CxTR1.SDW_LOG2[1:0])
– a programmed unaligned source start address, being not a multiple of the programmed data width of a source single transfer (LPDMA_CxSAR[2:0] versus LPDMA_CxTR1.SDW_LOG2[1:0])
– a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination single transfer (LPDMA_CxDAR[2:0] versus LPDMA_CxTR1.DDW_LOG2[1:0])
– a programmed double-word source data width (LPDMA_CxTR1.SDW_LOG2[1:0] = 0b11)
– a programmed double-word destination data width (LPDMA_CxTR1.DDW_LOG2[1:0] = 0b11)
– a programmed linked-list item LLI_{n+1} with a null data transfer (LPDMA_CxLLR.UB1 = 1 and LPDMA_CxBR1.BNDT = 0)

18.4.17 LPDMA autonomous mode

To save dynamic power consumption while LPDMA executes the programmed linked-list transfers, LPDMA hardware automatically manages its own clock gating and generates a clock request output signal to the RCC, whenever the device is in Run, Sleep or Stop mode, provided that the RCC is programmed with the corresponding LPDMA enable control bits.

For more details about the RCC programming, refer to the RCC section of the reference manual.

For mode details about the availability of the LPDMA autonomous feature vs the device low-power modes, refer to Section 18.3.2.

The user can program and schedule the execution of a given LPDMA transfer at a LLI_{n} level of a LPDMA channel x, with LPDMA_CxTR2 as follows:

- The software controls and conditions the input of a transfer with TRIGM[1:0], TRIGPOL[1:0], TRIGSEL[4:0], SWREQ and REQSEL[4:0] for the input trigger and request.
- The software controls and signals the output of a transfer with TCEM[1:0] for generating or not a transfer complete event, and generating or not an associated half data transfer event).

See LPDMA channel x transfer register 2 (LPDMA_CxTR2) for more details.

The output channel x transfer complete event, lpdma_chx_tc, can be programmed as a selected input trigger for a channel if this event is looped-back and connected at the LPDMA level (see Section 18.3.5), allowing autonomous and fine DMA inter-channel transfer scheduling, without needing a cleared transfer complete flag (TCF).

A given LPDMA channel x asserts its clock request in one of the following conditions:

- if the next transfer to be executed is programmed as conditioned by a trigger (LPDMA_CxTR2.TRIGPOL[1:0] and LPDMA_CxTR2.TRIGM[1:0]), only when the trigger hit occurs.
- if the next transfer to be executed is not conditioned by a trigger:
  - if LPDMA_CxTR2.SWREQ = 0, only when the hardware request is asserted by the selected peripheral
  - if LPDMA_CxTR2.SWREQ = 1 (memory-to-memory, GPIO to/from memory), as soon as the GPDMA is enabled
The LPDMA channel x releases its clock request as soon as all the following conditions are met:
- The transfer to be executed is completed.
- The LPDMA channel x is not immediately ready and requested to execute the next transfer.
- If a channel x interrupt was raised, all the flags of the status register that can cause this interrupt, are cleared by a software agent.

When one channel asserts its clock request, the LPDMA asserts its clock request to the RCC. When none channel asserts its clock request, the LPDMA releases its clock request to the RCC.

18.5 LPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, LPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, LPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

18.6 LPDMA in low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. LPDMA interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop$^{(1)}$</td>
<td>The content of the LPDMA registers is kept when entering Stop mode. The content of the LPDMA registers can be autonomously updated by a next linked-list item from memory, to perform autonomous data transfers. LPDMA interrupts can cause the device to exit Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The LPDMA is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

1. Refer to Section 18.3.2 to know which Stop mode is supported.
18.7 LPDMA interrupts

There is one LPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

<table>
<thead>

<td>LPDMA_CxCR.TOFIE</td>
<td>LPDMA_CxSR.TOF</td>
<td>Write 1 to LPDMA_CxFCR.TOF</td>
</tr>
</tbody>
</table>

A LPDMA channel x event may be:
- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

**Note:** When a channel x transfer complete event occurs, the output signal lpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:
- the corresponding interrupt event xx is enabled (LPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (LPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into LPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by LPDMA_CxTR2.TCEM[1:0] as follows:
- A transfer complete event is a block transfer complete or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode LPDMA_CxTR2.TCEM[1:0].
- A half transfer event is a half block transfer. A half-block transfer occurs when half of the source block size bytes (rounded-up integer of LPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

See *LPDMA channel x transfer register 2 (LPDMA_CxTR2)* for more details.
A transfer error rises in one of the following situations:
• during a single data transfer from the source or to the destination (DTEF)
• during an update of a LPDMA channel register from the programmed LLI in memory (ULEF)
• during a tentative execution of a LPDMA channel with an unauthorized setting (USEF)

The user must perform a debug session to correct the LPDMA channel programming versus the USEF root causes list (see Section 18.4.16).

A trigger overrun is described in Trigger hit memorization and trigger overrun flag generation.

18.8 LPDMA registers
The LPDMA registers must be accessed with an aligned 32-bit word data access.

18.8.1 LPDMA secure configuration register (LPDMA_SECCFGR)
Address offset: 0x000
Reset value: 0x0000 0000

A write access is ignored at bit level if the corresponding channel x is locked (LPDMA_RCFGLOCKR.LOCKx = 1).

A write access to this register must be secure and privileged. A read access is secure or nonsecure, privileged or unprivileged.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a LPDMA channel (when LPDMA_CxCR.EN = 0), to securely allocate individually any channel x to the secure or nonsecure world.

```
18.8.2 LPDMA privileged configuration register (LPDMA_PRIVCFGR)

Address offset: 0x004
Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged, secure or nonsecure.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register can mix secure and nonsecure information. If a channel x is configured as secure (LPDMA_SECCFGR.SECx = 1), the PRIVx bit can be written only by a secure (and privileged) agent.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a LPDMA channel (LPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **PRIVx**: privileged state of channel x (x = 3 to 0)

0: unprivileged
1: privileged
18.8.3 LPDMA configuration lock register (LPDMA_RCFGLOCKR)

Address offset: 0x008
Reset value: 0x0000 0000

This register can be written by a software agent with secure privileged attribute in order to individually lock, for example at boot time, the secure privileged attributes of any DMA channel/resource (to lock the setting of LPDMA_SECCFGR, LPDMA_PRIVCFGR for any channel x, for example at boot time).

A read access may be privileged or unprivileged, secure or nonsecure.

Note: If TZEN = 0, this register cannot be written.

<table>

</tbody>
</table>

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **LOCKx**: lock the configuration of LPDMA_SECCFGR.SECx, LPDMA_PRIVCFGR.PRIVx until a global DMA reset (x = 3 to 0)

This bit is cleared after reset and, once set, it cannot be reset until a global DMA reset.

0: secure privilege configuration of the channel x is writable.
1: secure privilege configuration of the channel x is not writable.

18.8.4 LPDMA nonsecure masked interrupt status register (LPDMA_MISR)

Address offset: 0x00C
Reset value: 0x0000 0000

This register is a read register.

This is a nonsecure register, containing the masked interrupt status bit MISx for each nonsecure channel x (channel x configured with LPDMA_SECCFGR.SECx = 0). It is a logical OR of all the flags of LPDMA_CxSR, each source flag being enabled by the corresponding interrupt enable bit of LPDMA_CxCR.

Every bit is de-asserted by hardware when writing 1 to the corresponding flag clear bit in LPDMA_CxCR.

If a channel x is in secure state (LPDMA_SECCFGR.SECx = 1), a read access to the masked interrupt status bit MISx of this channel x returns zero.

This register may mix privileged and unprivileged information, depending on the privileged state of each channel LPDMA_PRIVCFGR.PRIVx. A privileged software can read the full nonsecure interrupt status. An unprivileged software is restricted to read the status of unprivileged (and nonsecure) channel(s), other privileged bit fields returning zero.
Low-power direct memory access controller (LPDMA)

18.8.5 LPDMA secure masked interrupt status register (LPDMA_SMISR)

Address offset: 0x010
Reset value: 0x0000 0000

This is a secure read register, containing the masked interrupt status bit MISx for each secure channel x (LPDMA_SECCFG.R.SECx = 1). It is a logical OR of all the LPDMA_CxSR flags, each source flag being enabled by the corresponding LPDMA_CxCR interrupt enable bit.

Every bit is de-asserted by hardware when securely writing 1 to the corresponding LPDMA_CxFCR flag clear bit.

This register does not contain any information about a nonsecure channel.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel LPDMA_PRIVCFG.PRIVx. A privileged software can read the full secure interrupt status. An unprivileged software is restricted to read the status of unprivileged and secure channels, other privileged bit fields returning zero.

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 MISx: masked interrupt status of channel x (x = 3 to 0)
- 0: no interrupt occurred on nonsecure channel x
- 1: an interrupt occurred on nonsecure channel x

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 MISx: masked interrupt status of the secure channel x (x = 3 to 0)
- 0: no interrupt occurred on the secure channel x
- 1: an interrupt occurred on the secure channel x
18.8.6 LPDMA channel x linked-list base address register (LPDMA_CxLBAR)

Address offset: 0x050 + 0x80 * x (x = 0 to 3)
Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x LPDMA_PRIVCFGR.PRIVx.

This register is either secure or nonsecure depending on the secure state of the channel x (LPDMA_SECCFGR.SECx).

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the LPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit LPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

## 18.8.8  LPDMA channel x status register (LPDMA_CxSR)  

Address offset: 0x060 + 0x80 * x (x = 0 to 3)  
Reset value: 0x0000 0001  

This is a read register, reporting the channel status.  

This register is secure or nonsecure, depending on the secure state of channel x  
(LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged  
state of the channel (LPDMA_PRIVCFGR.PRIVx).  

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |  

Bits 31:15  Reserved, must be kept at reset value.  

Bit 14  **TOF**: trigger overrun flag clear  
0: no effect  
1: clears the corresponding TOF flag
Bit 13 **SUSPF**: completed suspension flag
- 0: no completed suspension event
- 1: a completed suspension event occurred

Bit 12 **USEF**: user setting error flag
- 0: no user setting error event
- 1: a user setting error event occurred

Bit 11 **ULEF**: update link transfer error flag
- 0: no update link transfer error event
- 1: a master bus error event occurred while updating a linked-list register from memory

Bit 10 **DTEF**: data transfer error flag
- 0: no data transfer error event
- 1: a master bus error event occurred on a data transfer

Bit 9 **HTF**: half transfer flag
- 0: no half transfer event
- 1: a half transfer event occurred

A half transfer event is a half block transfer that occurs when half of the bytes of the source block size (rounded-up integer of LPDMA_CxBR1.BNDT[15:0] / 2) has been transferred to the destination.

Bit 8 **TCF**: transfer complete flag
- 0: no transfer complete event
- 1: a transfer complete event occurred

A transfer complete event is a block transfer complete or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode LPDMA_CxTR2.TCEM[1:0].

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **IDLEF**: idle flag
- 0: channel not in idle state
- 1: channel in idle state

This idle flag is de-asserted by hardware when the channel is enabled (LPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).

This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).
18.8.9 LPDMA channel x control register (LPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 3)
Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of the channel x (LPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 PRIO[1:0]: priority level of the channel x LPDMA transfer versus others
- 00: low priority, low weight
- 01: low priority, mid weight
- 10: low priority, high weight
- 11: high priority

*Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.*

Bits 21:17 Reserved, must be kept at reset value.

Bit 16 LSM: Link step mode
- 0: channel executed for the full linked-list and completed at the end of the last LLI (LPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0). Then LPDMA_CxBR1.BNDT[15:0] = 0.
- 1: channel executed once for the current LLI
First the block transfer is executed as defined by the current internal register file until LPDMA_CxBR1.BNDT[15:0] = 0). Secondly the next linked-list data structure is conditionally uploaded from memory as defined by LPDMA_CxLLR. Then channel execution is completed.

*Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.*

Bit 15 Reserved, must be kept at reset value.

Bit 14 TOIE: trigger overrun interrupt enable
- 0: interrupt disabled
- 1: interrupt enabled

Bit 13 SUSPIE: completed suspension interrupt enable
- 0: interrupt disabled
- 1: interrupt enabled

Bit 12 USEIE: user setting error interrupt enable
- 0: interrupt disabled
- 1: interrupt enabled
Bit 11 **ULEIE**: update link transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 10 **DTEIE**: data transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 9 **HTIE**: half transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 8 **TCIE**: transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **SUSP**: suspend
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:
Software must write 1 in order to suspend an active channel (with an ongoing DMA transfer over its master ports).
The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in Figure 72.
0: write: resume channel, read: channel not suspended
1: write: suspend channel, read: channel suspended.

Bit 1 **RESET**: reset
This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0). The reset is effective when the channel is in steady state, meaning one of the following:
- active channel in suspended state (LPDMA_CxSR.SUSPF = 1 and LPDMA_CxSR.IDLEF = LPDMA_CxCR.EN = 1)
- channel in disabled state (LPDMA_CxSR.IDLEF = 1 and LPDMA_CxCR.EN = 0).
After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (LPDMA_CxBR1, LPDMA_CxSAR and LPDMA_CxDAR) before enabling again the channel (see the programming sequence in Figure 73).
0: no channel reset
1: channel reset

Bit 0 **EN**: enable
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:
this bit is de-asserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example: if LSM = 1 at the end of a single execution of the LLI).
Else, this bit can be asserted by software.
Writing 0 into this EN bit is ignored.
0: write: ignored, read: channel disabled
1: write: enable channel, read: channel enabled
18.8.10 LPDMA channel x transfer register 1 (LPDMA_CxTR1)

Address offset: 0x090 + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (LPDMA_SECCFGR.SECx) except for secure DSEC and SSEC, privileged or non-privileged, depending on the privileged state of the channel x in LPDMA_PRIVCFGR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has de-asserted LPDMA_CxCR.EN. A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.UT1 = 1.

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>DSEC: security attribute of the LPDMA transfer to the destination</th>

<td>0: fixed single</td>
</tr>
<tr>
<td></td>
<td>1: contiguously incremented single</td>
</tr>
<tr>
<td></td>
<td>The destination address, pointed by LPDMA_CxDAR, is kept constant after a single transfer, or is incremented by the offset value corresponding to a contiguous data after a single transfer.</td>
</tr>
</tbody>
</table>

| Bit 18 | Reserved, must be kept at reset value. |
Bits 17:16 **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a single in bytes
- **00**: byte
- **01**: half-word (2 bytes)
- **10**: word (4 bytes)
- **11**: user setting error reported and no transfer issued

*Note:* Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

A destination single transfer must have an aligned address with its data width (start address LPDMA_CxDAR[2:0] versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and none transfer is issued.

Bit 15 **SSEC**: security attribute of the LPDMA transfer from the source

If LPDMA_SECCFGR.SECx = 1 and the access is secure:
- **0**: LPDMA transfer nonsecure
- **1**: LPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when LPDMA_SECCFGR.SECx =1 . A secure write is ignored when LPDMA_SECCFGR.SECx = 0.

When LPDMA_SECCFGR.SECx is de-asserted, this SSEC bit is also de-asserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the LPDMA transfer from the source is nonsecure.

Bits 14:12 Reserved, must be kept at reset value.

Bit 11 **PAM**: padding/alignment mode

If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a single destination transfer is equal to the data width of a single source transfer, this bit is ignored.

Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when destination data width is higher than source data width.

**Condition: PAM_1**
- **0**: source data is transferred as right aligned, padded with 0s up to the destination data width
- **1**: source data is transferred as right aligned, sign extended up to the destination data width

**Condition: PAM_2**
- **0**: source data is transferred as right aligned, left-truncated down to the destination data width
- **1**: source data is transferred as left-aligned, right-truncated down to the destination data width

Bits 10:4 Reserved, must be kept at reset value.

Bit 3 **SINC**: source incrementing single

- **0**: fixed single
- **1**: contiguously incremented single

The source address, pointed by LPDMA_CxSAR, is kept constant after a single transfer or is incremented by the offset value corresponding to a contiguous data after a single transfer.

Bit 2 Reserved, must be kept at reset value.
Low-power direct memory access controller (LPDMA)

18.8.11 LPDMA channel x transfer register 2 (LPDMA_CxTR2)

Address offset: 0x094 + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory, if LPDMA_CxLLR.UT2 = 1.

Bits 1:0 SDW_LOG2[1:0]: binary logarithm of the source data width of a single in bytes

00: byte
01: half-word (2 bytes)
10: word (4 bytes)
11: user setting error reported and no transfer issued

Note: Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

A source block size must be a multiple of the source data width (LPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source single transfer must have an aligned address with its data width (start address LPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
rw        | rw   | rw   | rw   | rw   |     | rw | rw   | rw   | rw   | rw   | rw        | rw        | rw        | rw        |          |
Bits 31:30 **TCEM[1:0]**: transfer complete event mode

These bits define the transfer granularity for the transfer complete and half transfer complete events generation.

00: at block level (when LPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

**Note:** If the initial LLI0 data transfer is null/void (directly programmed by the internal register file with LPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

01: same as 00

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer (the LLI data transfer being a block transfer), if any data transfer.

**Note:** If the initial LLI0 data transfer is null/void (i.e. directly programmed by the internal register file with LPDMA_CxBR1.BNDT[15:0] = 0), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address LPDMA_CxLLR.LA[15:2] to zero and clears all the LPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[4:0].

00: no trigger (masked trigger event)

01: trigger on the rising edge

10: trigger on the falling edge

11: same as 00

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **TRIGSEL[4:0]**: trigger event input selection

These bits select the trigger event input of the LPDMA transfer (as per Section 18.3.5), with an active trigger event if TRIGPOL[1:0] = 00.
Bits 15:14 TRIGM[1:0]: trigger mode

These bits define the transfer granularity for its conditioning by the trigger.
If the channel x is enabled (LPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 0b00 or 0b11, these TRIGM[1:0] bits are ignored.
Else, a DMA transfer is conditioned by at least one trigger hit:
00: at block level: the first single read of each block transfer is conditioned by one hit trigger.
01: same as 00
10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.
11: at programmed single level: each programmed single read is conditioned by one hit trigger.

The LPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 0b01 or respectively TRIGPOL[1:0] = 0b10).
The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[4:0] is not modified, and the channel is enabled.

Transferring a next LLI_{n+1} that updates the LPDMA_CxTR2 with a new value for any of TRIGSEL[4:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_{n} trigger.

After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_{n} triggered transfer is still not completed, hit_{n+2} is lost and not memorized, and a trigger overrun flag is reported (LPDMA_CxSR.TOF = 1), an interrupt is generated if enabled (LPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 BREQ: block hardware request

If the channel x is activated (LPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:
0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a single level.
1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see Section 18.3.4).

Bit 10 Reserved, must be kept at reset value.

Bit 9 SWREQ: software request

This bit is internally taken into account when LPDMA_CxCR.EN is asserted.
0: no software request. The selected hardware request REQSEL[4:0] is taken into account.
1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[4:0] is ignored.

Bits 8:5 Reserved, must be kept at reset value.

Bits 4:0 REQSEL[4:0]: DMA hardware request selection

These bits are ignored if channel x is activated (LPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per Section 18.3.3.

Caution: The user must not assign a same input hardware request (same REQSEL[4:0] value) to different active DMA channels (LPDMA_CxCR.EN = 1 and LPDMA_CxTR2.SWREQ = 0 for these channels). DMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.
18.8.12  LPDMA channel x block register 1 (LPDMA_CxBR1)

Address offset: 0x098 + 0x80 * x (x = 0 to 3)
Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- If LPDMA_CxLLR.UB1 = 1, this register is automatically updated by DMA from the next LLI in memory.
- If LPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed values for the field BNDT[15:0].
- If all the update bits LPDMA_CxLLR.Uxx are null and if LPDMA_CxLLR.LA[15:0] # 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI.
- If LPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

Bits 31:16  Reserved, must be kept at reset value.
18.8.13 **LPDMA channel x source address register (LPDMA_CxSAR)**

Address offset: 0x09C + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVCFGPR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next single transfer from the source.

This register must be written when the channel is completed (then the hardware has de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.USA = 1.

**Note:** A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus LPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.
18.8.14 LPDMA channel x destination address register (LPDMA_CxDAR)

Address offset: 0x0A0 + 0x80 * x (x = 0 to 3)
Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next single transfer to the destination.

This register must be written when the channel is completed (then the hardware has de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination single (DA[32:0] versus LPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

Bits 31:0 DA[31:0]: destination address

This field is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (LPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (LPDMA_CxTR1.DDW_LOG2[1:0]) after each single destination data, reflecting the next address from which data is written.

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by LPDMA from the memory, provided the LLI is set with LPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination single (DA[2:0] versus LPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.
18.8.15 LPDMA channel x linked-list address register (LPDMA_CxLLR)

Address offset: 0x0CC + 0x80 * x (x = 0 to 3)
Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (LPDMA_SECCFGREG_SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVCFGREG_PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.ULL = 1.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16

Bit 31 UT1: Update LPDMA_CxTR1 from memory
This bit controls the update of the LPDMA_CxTR1 register from the memory during the link transfer.
0: no LPDMA_CxTR1 update
1: LPDMA_CxTR1 update

Bit 30 UT2: Update LPDMA_CxTR2 from memory
This bit controls the update of the LPDMA_CxTR2 register from the memory during the link transfer.
0: no LPDMA_CxTR2 update
1: LPDMA_CxTR2 update

Bit 29 UB1: Update LPDMA_CxBR1 from memory
This bit controls the update of the LPDMA_CxBR1 register from the memory during the link transfer.
0: no LPDMA_CxBR1 update
1: LPDMA_CxBR1 update from memory and internally restored to the previous programmed value

Bit 28 USA: update LPDMA_CxSAR from memory
This bit controls the update of the LPDMA_CxSAR register from the memory during the link transfer.
0: no LPDMA_CxSAR update
1: LPDMA_CxSAR update

Bit 27 UDA: Update LPDMA_CxDAR register from memory
This bit is used to control the update of the LPDMA_CxDAR register from the memory during the link transfer.
0: no LPDMA_CxDAR update
1: LPDMA_CxDAR update
Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update LPDMA_CxLLR register from memory
This bit is used to control the update of the LPDMA_CxLLR register from the memory during the link transfer.
0: no LPDMA_CxLLR update
1: LPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:20] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list DMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list DMA internal register file (LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR).

*Note*: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

Refer to Section 2.3 for the register boundary addresses.
19 Chrom-ART Accelerator controller (DMA2D)

This section only applies to STM32U575/585/59x/5Ax devices.

19.1 DMA2D introduction

The Chrom-ART Accelerator (DMA2D) is a specialized DMA dedicated to image manipulation. It can perform the following operations:

- fill a part or the whole of a destination image with a specific color
- copy a part or the whole of a source image into a part or the whole of a destination image
- copy a part or the whole of a source image into a part or the whole of a destination image with a pixel format conversion
- blend a part and/or two complete source images with different pixel format and copy the result into a part or the whole of a destination image with a different color format

All the classical color coding schemes are supported from 4-bit up to 32-bit per pixel with indexed or direct color mode. The DMA2D has its own dedicated memories for CLUTs (color look-up tables).

19.2 DMA2D main features

The main DMA2D features are:

- Single AHB master bus architecture
- AHB slave programming interface supporting 8/16/32-bit accesses (except for CLUT accesses which are 32-bit)
- User programmable working area size
- User programmable offset for sources and destination areas expressed in pixels or bytes
- User programmable sources and destination addresses on the whole memory space
- Up to 2 sources with blending operation
- Alpha value can be modified (source value, fixed value or modulated value)
- User programmable source and destination color format
- Up to 11 color formats supported from 4-bit up to 32-bit per pixel with indirect or direct color coding
- 2 internal memories for CLUT storage in indirect color mode
- Automatic CLUT loading or CLUT programming via the CPU
- User programmable CLUT size
- Internal timer to control AHB bandwidth
- 6 operating modes: register-to-memory, memory-to-memory, memory-to-memory with pixel format conversion, memory-to-memory with pixel format conversion and blending, memory-to-memory with pixel format conversion, blending and fixed color foreground, and memory-to-memory with pixel format conversion, blending and fixed color background.
- Area filling with a fixed color
• Copy from an area to another
• Copy with pixel format conversion between source and destination images
• Copy from two sources with independent color format and blending
• Output buffer byte swapping to support refresh of displays through parallel interface
• Abort and suspend of DMA2D operations
• Watermark interrupt on a user programmable destination line
• Interrupt generation on bus error or access conflict
• Interrupt generation on process completion

19.3 DMA2D functional description

19.3.1 DMA2D block diagram

The DMA2D controller performs direct memory transfer. As an AHB master, it can take the control of the AHB bus matrix to initiate AHB transactions.

The DMA2D can operate in the following modes:
• Register-to-memory
• Memory-to-memory
• Memory-to-memory with pixel format conversion
• Memory-to-memory with pixel format conversion and blending
• Memory-to-memory with pixel format conversion, blending and fixed color foreground
• Memory-to-memory with pixel format conversion, blending and fixed color background

The AHB slave port is used to program the DMA2D controller.
The block diagram of the DMA2D is shown in the figure below.

**Figure 88. DMA2D block diagram**

The internal signals of the DMA2D are given in the table below.

1. Only available on STM32U59x/5Ax products.
19.3.3 DMA2D control

The DMA2D controller is configured through the DMA2D control register (DMA2D_CR). The user application can perform the following operations:
- Select the operating mode.
- Enable/disable the DMA2D interrupt.
- Start/suspend/abort ongoing data transfers.

19.3.4 DMA2D foreground and background FIFOs

The DMA2D foreground (FG) FG FIFO and background (BG) FIFO fetch the input data to be copied and/or processed.

These FIFOs fetch the pixels according to the color format defined in their respective pixel format converter (PFC). They are programmed through a set of control registers:
- DMA2D foreground memory address register (DMA2D_FGMAR)
- DMA2D foreground offset register (DMA2D_FGOR)
- DMA2D background memory address register (DMA2D_BGMAR)
- DMA2D background offset register (DMA2D_BGBOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

When the DMA2D operates in register-to-memory mode, none of the FIFOs is activated.

When the DMA2D operates in memory-to-memory mode (no pixel format conversion nor blending operation), only the FG FIFO is activated and acts as a buffer.

When the DMA2D operates in memory-to-memory operation with pixel format conversion (no blending operation), the BG FIFO is not activated.

19.3.5 DMA2D foreground and background pixel format converter (PFC)

DMA2D foreground pixel format converter (PFC) and background pixel format converter perform the pixel format conversion to generate a 32-bit per pixel value. The PFC can also modify the alpha channel.

The first stage of the converter converts the color format. The original color format of the foreground pixel and background pixels are configured through the CM[3:0] bits of the DMA2D_FGPFCCR and DMA2D_BGPFCCR, respectively.

The supported input formats are given in the table below.

<table>
<thead>
<tr>
<th>CM[3:0]</th>
<th>Color mode</th>
</tr>

<td>L8</td>
</tr>
</tbody>
</table>

Table 156. Supported color mode in input
The color format is coded as follows:

- **Alpha value field**: transparency
  
  0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.

- **R field for Red**

- **G field for Green**

- **B field for Blue**

- **L field**: luminance
  
  This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format is direct color mode (ARGB/RGB), the extension to 8 bits per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format is indirect color mode (L/AL), a CLUT is required and each pixel format converter is associated with a 256 entry 32-bit CLUT.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and is defined in the DMA2D_FGCOLR for foreground pixels and in the DMA2D_BGCOLR register for background pixels.

The order of the fields in the system memory is defined in the table below.

### Table 156. Supported color mode in input (continued)

</tbody>
</table>
The 24-bit RGB888 aligned on 32 bits is supported through the ARGB8888 mode.

Once the 32-bit value is generated, the alpha channel can be modified according to AM[1:0] in DMA2D_FGPFCCR/DMA2D_BGPFCCR registers as shown in the table below.

The alpha channel can be:
- kept as it is (no modification)
- replaced by the ALPHA[7:0] value of DMA2D_FGPFCCR/DMA2D_BGPFCCR
- replaced by the original alpha value multiplied by the ALPHA[7:0] value of DMA2D_FGPFCCR/DMA2D_BGPFCCR divided by 255.

<td>Reserved</td>
</tr>
</tbody>
</table>

Note: To support the alternate format, the incoming alpha value can be inverted setting AI in DMA2D_FGPFCCR/DMA2D_BGPFCCR registers. This applies also to the Alpha value stored in the DMA2D_FGPFCCR/DMA2D_BGPFCCR and in the CLUT.

The R and B fields can also be swapped setting RBS in DMA2D_FGPFCCR/DMA2D_BGPFCCR registers. This applies also to the RGB order used in the CLUT and in the DMA2D_FGCOLR/DMA2D_BGCOLOR registers.

19.3.6 DMA2D foreground and background CLUT interface

The CLUT interface manages the CLUT memory access and the automatic loading of the CLUT.

Three access types are possible:
- CLUT read by the PFC during pixel format conversion operation
- CLUT accessed through the AHB slave port when the CPU is reading or writing data into the CLUT
- CLUT written through the AHB master port when an automatic loading of the CLUT is performed
The CLUT memory loading can be done in two different ways:

- **Automatic loading**
  The following sequence must be followed to load the CLUT:
  - a) Program the CLUT address in DMA2D_FGCMAR (foreground CLUT) or DMA2D_BGCMAR (background CLUT).
  - b) Program the CLUT size with CS[7:0] in DMA2D_FGPFCR (foreground CLUT) or DMA2D_BGPFCR (background CLUT).
  - c) Set the START bit in DMA2D_FGPFCR (foreground CLUT) or DMA2D_BGPFCR (background CLUT) to start the transfer. During this automatic loading process, the CLUT is not accessible by the CPU. If a conflict occurs, a CLUT access error interrupt is raised assuming CAEIE = 1 in DMA2D_CR.

- **Manual loading**
  The application has to program the CLUT manually through the DMA2D AHB slave port to which the local CLUT memory is mapped. The foreground CLUT (FGCLUT) is located at address offset 0x0400 and the background CLUT (BGCLUT) at address offset 0x0800.

The CLUT format is 24 or 32 bits. It is configured through the CCM bit in DMA2D_FGPFCR (foreground CLUT) or DMA2D_BGPFCR (background CLUT) as shown in the table below.

### Table 159. Supported CLUT color mode

</tbody>
</table>
19.3.7 DMA2D blender

The DMA2D blender blends the source pixels by pair to compute the resulting pixel. The blending is performed according to the following equation:

\[
\alpha_{\text{Mult}} = \frac{\alpha_{FG} \cdot \alpha_{BG}}{255}
\]

\[
\alpha_{OUT} = \alpha_{FG} + \alpha_{BG} - \alpha_{\text{Mult}}
\]

\[
C_{OUT} = \frac{C_{FG} \cdot \alpha_{FG} + C_{BG} \cdot \alpha_{BG} - C_{BG} \cdot \alpha_{\text{Mult}}}{\alpha_{OUT}}
\]

with \( C = R \) or \( G \) or \( B \)

Division is rounded to the nearest lower integer

No configuration register is required by the blender. The blender use depends on the DMA2D operating mode defined by MODE[2:0] in DMA2D_CR.

19.3.8 DMA2D output PFC

The output PFC performs the pixel format conversion from 32 bits to the output format defined by CM[2:0] in DMA2D_OPFCCR.

The supported output formats are given in the table below.

<table>
<thead>
<tr>
<th>CM[2:0]</th>
<th>Color mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>ARGB8888</td>
</tr>
<tr>
<td>001</td>
<td>RGB888</td>
</tr>
<tr>
<td>010</td>
<td>RGB565</td>
</tr>
<tr>
<td>011</td>
<td>ARGB1555</td>
</tr>
<tr>
<td>100</td>
<td>ARGB4444</td>
</tr>
</tbody>
</table>

Note: To support the alternate format, the calculated alpha value is inverted setting AI bit in DMA2D_OPFCCR. This applies also to the alpha value used in DMA2D_OCOLR. The R and B fields can also be swapped setting RBS in DMA2D_OPFCCR. This applies also to the RGB order used in DMA2D_OCOLR.

19.3.9 DMA2D output FIFO

The output FIFO programs the pixels according to the color format defined in the output PFC.

The destination area is defined through a set of control registers:
- DMA2D output memory address register (DMA2D_OMAR)
• DMA2D output offset register (DMA2D_OOR)
• DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

If the DMA2D operates in register-to-memory mode, the configured output rectangle is filled by the color specified in DMA2D_OCOLR which contains a fixed 32-, 24-, or 16-bit value. The format is selected by CM[2:0] in DMA2D_OPFCCR.

The data are stored into the memory in the order defined in the table below.

### Table 162. Data order in memory

<table>
<thead>
<tr>
<th>Color mode</th>
<th>@ + 3</th>
<th>@ + 2</th>
<th>@ + 1</th>
<th>@ + 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARGB8888</td>
<td>R0[7:0]</td>
<td>G0[7:0]</td>
<td>B0[7:0]</td>

</tr>
<tr>
<td>RGB888</td>
<td>B1[7:0]</td>
<td>R0[7:0]</td>
<td>G0[7:0]</td>
<td>B0[7:0]</td>
</tr>
<tr>
<td></td>
<td>R3[7:0]</td>
<td>G3[7:0]</td>
<td>B3[7:0]</td>
<td>R2[7:0]</td>
</tr>
</tbody>
</table>

The RGB888 aligned on 32 bits is supported through the ARGB8888 mode.

### 19.3.10 DMA2D output FIFO byte reordering

The output FIFO bytes are reordered to support display frame buffer update through a parallel interface (F(S)MC) directly from the DMA2D.

The reordering of bytes can be done using:
• RBS bit to swap Red and Blue component
• SB bit to swap byte two-by-two in the output FIFO

When the byte swapping is activated (SB = 1 in DMA2D_OPFCCR), the number of pixel per line (PL field in DMA2D_NLR) must be even, the output memory address (MA field in DMA2D_OMAR) must be even, and the output line offset computed in bytes (resulting from LOM field in DMA2D_CR and LO field in DMA2D_OOR values) must be even.

If not, a configuration error is detected.

### Table 163. Standard data order in memory

<table>
<thead>
<tr>
<th>Color Mode</th>

<td>R3[7:0]</td>
<td>G3[7:0]</td>
<td>B3[7:0]</td>
<td>R2[7:0]</td>
</tr>
</tbody>
</table>

### 16-bit mode (RGB565)

This mode is supported without byte reordering by the DMA2D.
18/24-bit mode (RGB888)

This mode needs data reordering.

1. Red and the Blue have to be swapped (setting the RBS bit).
2. MSB and the LSB bytes of a half-word have to be swapped (setting the SB bit).

Table 164. Output FIFO byte reordering steps

</table>
19.3.11 DMA2D AHB master port timer

An 8-bit timer is embedded into the AHB master port to provide an optional limitation of the bandwidth on the crossbar.

This timer is clocked by the AHB clock and counts a dead time between two consecutive accesses. This limits the bandwidth availability.

The timer enabling and the dead time value are configured through the AHB master port timer configuration register (DMA2D_AMPTCR).

19.3.12 DMA2D transactions

DMA2D transactions consist of a sequence of a given number of data transfers. The number of data and the width can be programmed by software.

Each DMA2D data transfer is composed of up to four steps:
1. Data loading from the memory location pointed by DMA2D_FGMAR and pixel format conversion as defined in DMA2D_FGCR
2. Data loading from a memory location pointed by DMA2D_BGMAR and pixel format conversion as defined in DMA2D_BGCR
3. Blending of all retrieved pixels according to the alpha channels resulting of the PFC operation on alpha values
4. Pixel format conversion of the resulting pixels according to DMA2D_OCR and programming of the data to the memory location addressed through DMA2D_OMAR

19.3.13 DMA2D configuration

Both source and destination data transfers can target peripherals and memories in the whole 4 Gbyte memory area, at addresses ranging between 0x0000 0000 and 0xFFFF FFFF.

The DMA2D can operate in any of the following modes selected through MODE[2:0] in DMA2D_CR:
- Register-to-memory
- Memory-to-memory
- Memory-to-memory with PFC
- Memory-to-memory with PFC and blending
- Memory-to-memory with PFC, blending and fixed FG color
- Memory-to-memory with PFC, blending and fixed BG color

</table>
Register-to-memory

The register-to-memory mode is used to fill a user defined area with a predefined color.
The color format is set in DMA2D_OPFCCR.
The DMA2D does not perform any data fetching from any source. It just writes the color defined in DMA2D_OCOLR to the area located at the address pointed by DMA2D_OMAR, and defined in DMA2D_NLR and DMA2D_OOR.

Memory-to-memory

In memory-to-memory mode, the DMA2D does not perform any graphical data transformation. The foreground input FIFO acts as a buffer and the data are transferred from the source memory location defined in DMA2D_FGMAR to the destination memory location pointed by DMA2D_OMAR.
The color mode programmed by CM[3:0] in DMA2D_FGPFCCR defines the number of bits per pixel for both input and output.
The size of the area to be transferred is defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.

Memory-to-memory with PFC

In this mode, the DMA2D performs a pixel format conversion of the source data and stores them in the destination memory location.
The size of the areas to be transferred are defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.
Data are fetched from the location defined in DMA2D_FGMAR and processed by the foreground PFC. The original pixel format is configured through DMA2D_FGPFCCR.
If the original pixel format is direct color mode, then the color channels are all expanded to 8 bits.
If the pixel format is indirect color mode, the associated CLUT has to be loaded into the CLUT memory.
The CLUT loading can be done automatically by following the sequence below:
1. Set the CLUT address into DMA2D_FGCMAR.
2. Set the CLUT size with CS[7:0] bits in DMA2D_FGPFCCR.
3. Set the CLUT format (24 or 32 bits) with CCM in DMA2D_FGPFCCR.
4. Start the CLUT loading by setting START in DMA2D_FGPFCCR.
Once the CLUT loading is complete, the CTCIF flag in DMA2D_IFR is raised, and an interrupt is generated if CTCIE = 1 in DMA2D_CR. The automatic CLUT loading process can not work in parallel with classical DMA2D transfers.
The CLUT can also be filled by the CPU or by any other master through the APB port. The access to the CLUT is not possible when a DMA2D transfer is ongoing and uses the CLUT (indirect color format).
In parallel to the color conversion process, the alpha value is added or changed depending on the value programmed in DMA2D_FGPFCCR. If the original image does not have an
alpha channel, a default alpha value of 0xFF is automatically added to obtain a fully opaque pixel. The alpha value is modified according to AM[1:0] in DMA2D_FGPFCR:

- It can be unchanged.
- It can be replaced by the value defined by ALPHA[7:0] in DMA2D_FGPFCR.
- It can be replaced by the original value multiplied by ALPHA[7:0] divided by 255.

The resulting 32-bit data are encoded by the OUT PFC into the format specified by CM[2:0] in DMA2D_OPFCCR. The output pixel format cannot be the indirect mode since no CLUT generation process is supported.

The processed data are written into the destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC and blending**

In this mode, two sources are fetched in the foreground and background FIFOs from the memory locations defined by DMA2D_FGMAR and DMA2D_BGMAR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory.

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended according to the equation below:

\[
\alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \frac{\alpha_{\text{MULT}} \cdot \alpha_{\text{FG}} - \alpha_{\text{BG}}}{255}
\]

\[
C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{BG}} \cdot \alpha_{\text{MULT}}}{\alpha_{\text{OUT}}}
\]

Division are rounded to the nearest lower integer

The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC, blending and fixed color FG**

In this mode, only one source is fetched in the background FIFO from the memory location defined by DMA2D_BGMAR.

The value of the foreground color is given by DMA2D_FGCOLR and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_FGPFCR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory.
Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended together, and the resulting 32-bit pixel value is encoded by the output PFC according to the specified output format. Data are written into the destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC, blending and fixed color BG**

In this mode, only one source is fetched in the foreground FIFO from the memory location defined by DMA2D_FGMAR.

The value of the background color is given by DMA2D_BGCOLR and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_BGPFCR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory.

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended together, and the resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D_OMAR.

**Configuration error detection**

The DMA2D checks that the configuration is correct before any transfer. The configuration error interrupt flag is set by hardware when a wrong configuration is detected when a new transfer/automatic loading starts. An interrupt is then generated if CEIE = 1 in DMA2D_CR.

The wrong configurations that can be detected are listed below:

- Foreground CLUT automatic loading: MA bits in DMA2D_FGCMAR are not aligned with CCM in DMA2D_FGPFCCR.
- Background CLUT automatic loading: MA bits in DMA2D_BGCMAR are not aligned with CCM in DMA2D_BGPFCR.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): MA bits in DMA2D_FGMAR are not aligned with CM in DMA2D_FGPFCCR.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): CM bits in DMA2D_FGPFCCR are invalid.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): PL bits in DMA2D_NLR are odd while CM in DMA2D_FGPFCCR is A4 or L4.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): LO bits in DMA2D_FGOR are odd while CM in DMA2D_FGPFCCR is A4 or L4, and LOM bit in DMA2D_CR is pixel mode.
- Memory transfer (only in blending mode and except in memory-to-memory mode with blending and fixed color FG): MA bits in DMA2D_BGMAR are not aligned with CM in DMA2D_BGPFCR.
- Memory transfer: (only in blending mode and in blending with fixed color FG mode): CM bits in DMA2D_BGPFCR are invalid.
• Memory transfer (only in blending mode and in blending with fixed color FG mode):
  PL bits in DMA2D_NLR odd while CM in DMA2D_BGPFFCCR is A4 or L4.
• Memory transfer (only in blending mode and in blending with fixed color FG mode):
  LO bits in DMA2D_BGQR are odd while CM in DMA2D_BGPFFCCR is A4 or L4, and
  LOM bit in DMA2D_CR is pixel mode.
• Memory transfer (except in memory-to-memory mode and except
  in memory-to-memory mode with blending and fixed color FG): MA bits in
  DMA2D_OMAR are not aligned with CM bits in DMA2D_OPFCR.
• Memory transfer (except in memory to memory mode): CM bits in DMA2D_OPFCR
  are invalid.
• Memory transfer with byte swapping: PL bits in DMA2D_NLR are odd or MA bits in
  DMA2D_OMAR are odd, or LO in bytes (resulting from LOM in DMA2D_CR and LO
  bits in DMA2D_OOR) are odd while SB = 1 in DMA2D_OPFCR.
• Memory transfer: NL = 0x0 in DMA2D_NLR
• Memory transfer: PL = 0x0 in DMA2D_NLR
• Memory transfer: MODE bits in DMA2D_CR are invalid.

19.3.14 DMA2D transfer control (start, suspend, abort and completion)

Once the DMA2D is configured, the transfer can be launched by setting START
in DMA2D_CR. Once the transfer is completed, START is automatically reset and TCIF flag
in DMA2D_ISR is raised. An interrupt can be generated if TCIE is set in DMA2D_CR.

The user application can suspend the DMA2D at any time by setting SUSP in DMA2D_CR.
The transaction can then be aborted by setting ABORT in DMA2D_CR, or can be restarted
by resetting SUSP in DMA2D_CR.

The user application can abort at any time an ongoing transaction by setting ABORT
in DMA2D_CR. In this case, the TCIF flag is not raised.

Automatic CLUT transfers can also be aborted or suspended by using ABORT or SUSP
in DMA2D_CR.

19.3.15 Watermark

A watermark can be programmed to generate an interrupt when the last pixel of a given line
has been written to the destination memory area.

The line number is defined by LW[15:0] in DMA2D_LWR.

When the last pixel of this line has been transferred, the TWIF flag in DMA2D_ISR is raised,
and an interrupt is generated if TWIE is set in DMA2D_CR.

19.3.16 Error management

Two kind of errors can be triggered:
• AHB master port errors signaled by TEIF in DMA2D_ISR
• conflicts caused by a CLUT access (CPU trying to access the CLUT while a CLUT
  loading or a DMA2D transfer is ongoing) signaled by CAEIF in DMA2D_ISR.

Both flags are associated to their own interrupt enable flag in DMA2D_CR to generate an
interrupt if need be (TEIE and CAEIE).
19.3.17 **AHB dead time**

To limit the AHB bandwidth use, a dead time between two consecutive AHB accesses can be programmed.

This feature can be enabled by setting EN in DMA2D_AMTCR.

The dead time value is stored into DT[7:0] in DMA2D_AMTCR. This value represents the guaranteed minimum number of cycles between two consecutive transactions on the AHB bus.

The update of the dead time value while the DMA2D runs is taken into account for the next AHB transfer.

19.4 **DMA2D interrupts**

An interrupt can be generated on the following events:

- Configuration error
- CLUT transfer complete
- CLUT access error
- Transfer watermark reached
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

19.5 DMA2D registers

19.5.1 DMA2D control register (DMA2D_CR)

Address offset: 0x000
Reset value: 0x0000 0000

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **MODE[2:0]: DMA2D mode**

These bits are set and cleared by software. They cannot be modified while a transfer is ongoing.

000: Memory-to-memory (FG fetch only)
001: Memory-to-memory with PFC (FG fetch only with FG PFC active)
010: Memory-to-memory with blending (FG and BG fetch with PFC and blending)
011: Register-to-memory (no FG nor BG, only output stage active)
100: Memory-to-memory with Blending and fixed color FG (BG fetch only with FG and BG PFC active)
101: Memory-to-memory with Blending and fixed color BG (BG fetch only with FG and BG PFC active)
others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **CEIE**: Configuration error interrupt enable
This bit is set and cleared by software.
0: CE interrupt disabled
1: CE interrupt enabled

Bit 12 **CTCIE**: CLUT transfer complete interrupt enable
This bit is set and cleared by software.
0: CTC interrupt disabled
1: CTC interrupt enabled

Bit 11 **CAEIE**: CLUT access error interrupt enable
This bit is set and cleared by software.
0: CAE interrupt disabled
1: CAE interrupt enabled

Bit 10 **TWIE**: Transfer watermark interrupt enable
This bit is set and cleared by software.
0: TW interrupt disabled
1: TW interrupt enabled
Bit 9 **TCIE**: Transfer complete interrupt enable
This bit is set and cleared by software.
0: TC interrupt disabled
1: TC interrupt enabled

Bit 8 **TEIE**: Transfer error interrupt enable
This bit is set and cleared by software.
0: TE interrupt disabled
1: TE interrupt enabled

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LOM**: Line offset mode
This bit configures how is expressed the line offset (pixels or bytes) for the foreground, background and output.
This bit is set and cleared by software. It can not be modified while a transfer is ongoing.
0: Line offsets expressed in pixels
1: Line offsets expressed in bytes

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **ABORT**: Abort
This bit can be used to abort the current transfer. This bit is set by software and is automatically reset by hardware when the START bit is reset.
0: No transfer abort requested
1: Transfer abort requested

Bit 1 **SUSP**: Suspend
This bit can be used to suspend the current transfer. This bit is set and reset by software. It is automatically reset by hardware when the START bit is reset.
0: Transfer not suspended
1: Transfer suspended

Bit 0 **START**: Start
This bit can be used to launch the DMA2D according to the parameters loaded in the various configuration registers. This bit is automatically reset by the following events:
- at the end of the transfer
- when the data transfer is aborted by the user application (setting ABORT in DMA2D_CR)
- when a data transfer error occurs
- when the data transfer has not started due to a configuration error or another transfer operation already ongoing (automatic CLUT loading).

### 19.5.2 DMA2D interrupt status register (DMA2D_ISR)

19.5.3 DMA2D interrupt flag clear register (DMA2D_IFCR)

Address offset: 0x008
Reset value: 0x0000 0000

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CCEIF**: Clear configuration error interrupt flag
Programming this bit to 1 clears CEIF in DMA2D_ISR.

Bit 4 **CCTCIF**: Clear CLUT transfer complete interrupt flag
Programming this bit to 1 clears CTCIF in DMA2D_ISR.

Bit 3 **CAECIF**: Clear CLUT access error interrupt flag
Programming this bit to 1 clears CAEIF in DMA2D_ISR.

Bit 2 **CTWIF**: Clear transfer watermark interrupt flag
Programming this bit to 1 clears TWIF in DMA2D_ISR.

Bit 1 **CTCIF**: Clear transfer complete interrupt flag
Programming this bit to 1 clears TCIFF in DMA2D_ISR.

Bit 0 **CTEIF**: Clear Transfer error interrupt flag
Programming this bit to 1 clears TEIF in DMA2D_ISR.
19.5.4 DMA2D foreground memory address register (DMA2D_FGMAR)

</tbody>
</table>

Bits 31:0 MA[31:0]: Memory address
This field contains the address of the data used for the foreground image. This register can only be written when data transfers are disabled. Once the data transfer has started, this register is read-only.
The address alignment must match the image format selected: for example, a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

19.5.5 DMA2D foreground offset register (DMA2D_FGOR)

<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:0 LO[15:0]: Line offset
The line offset used for the foreground image, expressed in pixel when the LOM bit is reset and in byte when the LOM bit is set.
When expressed in pixels, only LO[13:0] is considered, LO[15:14] are ignored.
This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.
These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.
If the image format is 4-bit per pixel, the line offset must be even.
19.5.6 DMA2D background memory address register (DMA2D_BGMAR)

Address offset: 0x014
Reset value: 0x0000 0000

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 |
|-------------------|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    |
| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |

Bits 31:0 **MA[31:0]**: Memory address
This field contains the address of the data used for the background image. This register can only be written when data transfers are disabled. Once a data transfer has started, this register is read-only.
The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

19.5.7 DMA2D background offset register (DMA2D_BGOR)

Address offset: 0x018
Reset value: 0x0000 0000

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 |
|-------------------|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    |
| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset
This field contains the line offset used for the background image, expressed in pixel when the LOM bit is reset, and in byte when the LOM bit is set.
When expressed in pixels, only LO[13:0] is considered, LO[15:14] are ignored.
This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.
These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.
If the image format is 4-bit per pixel, the line offset must be even.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **RED[7:0]**: Red value
These bits define the Red value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
These bits can also be used for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.
Bits 15:8 **GREEN[7:0]**: Green value
These bits define the Green value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
These bits can also be used for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

Bits 7:0 **BLUE[7:0]**: Blue value
These bits define the Blue value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
These bits can also be used for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

### 19.5.10 DMA2D background PFC control register (DMA2D_BGPFCCR)

Address offset: 0x024
Reset value: 0x0000 0000

<table>
<thead>

</tr>
</tbody>
</table>

Bits 31:24 **ALPHA[7:0]**: Alpha value
These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied with the original alpha value according to the alpha mode selected with AM[1:0]. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red Blue swap
This bit is used to swap the R and B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha inverted
This bit inverts the alpha value. Once the transfer has started, this bit is read-only.
0: Regular alpha
1: Inverted alpha

Bits 19:18 Reserved, must be kept at reset value.
Bits 17:16 AM[1:0]: Alpha mode
These bits define which alpha channel value to be used for the background image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
00: No modification of the foreground image alpha channel value
01: Replace original background image alpha channel value by ALPHA[7:0]
10: Replace original background image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value
Other: Reserved

Bits 15:8 CS[7:0]: CLUT size
These bits define the size of the CLUT used for the BG. Once the CLUT transfer has started, this field is read-only.
The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 START: Start
This bit is set to start the automatic loading of the CLUT. This bit is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user application by setting ABORT in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic foreground CLUT transfer).

Bit 4 CCM: CLUT color mode
These bits define the color format of the CLUT. This register can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.
0: ARGB8888
1: RGB888
Other: Reserved

Bits 3:0 CM[3:0]: Color mode
These bits define the color format of the foreground image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
0000: ARGB8888
0001: RGB888
0010: RGB565
0011: ARGB1555
0100: ARGB4444
0101: L8
0110: AL44
0111: AL88
1000: L4
1001: A8
1010: A4
Other: Reserved
### 19.5.11 DMA2D background color register (DMA2D_BGCOLR)

Address offset: 0x028  
Reset value: 0x0000 0000

| Bits 31:24 | Reserved, must be kept at reset value. |
| Bits 23:16 | **RED[7:0]**: Red value |
|            | These bits define the Red value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only. |
|            | These bits are also used for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode. |
| Bits 15:8  | **GREEN[7:0]**: Green value |
|            | These bits define the green value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only. |
|            | These bits are also used for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode. |
| Bits 7:0   | **BLUE[7:0]**: Blue value |
|            | These bits define the blue value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only. |
|            | These bits are also used for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode. |

### 19.5.12 DMA2D foreground CLUT memory address register (DMA2D_FGCMAR)

Address offset: 0x02C  
Reset value: 0x0000 0000

| Bits 31:16 | **MA[31:16]** |
| Bits 15:0  | **MA[15:0]** |

---

RM0456 Rev 5  
841/3637
Bits 31:0 MA[31:0]: Memory address
This field contains the address of the data used for the CLUT address dedicated to the foreground image. This register can only be written when no transfer is ongoing. Once the CLUT transfer has started, this register is read-only.
If the foreground CLUT format is 32-bit, the address must be 32-bit aligned.
