19.5.13 DMA2D background CLUT memory address register (DMA2D_BGCMAR)
Address offset: 0x030
Reset value: 0x0000 0000

Bits 31:0 MA[31:0]: Memory address
This field contains the address of the data used for the CLUT address dedicated to the background image. This register can only be written when no transfer is ongoing. Once the CLUT transfer has started, this register is read-only.
If the background CLUT format is 32-bit, the address must be 32-bit aligned.

19.5.14 DMA2D output PFC control register (DMA2D_OPFCCR)
Address offset: 0x034
Reset value: 0x0000 0000

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 RBS: Red Blue swap
This bit is used to swap the R and B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 AI: Alpha Inverted
This bit inverts the alpha value. Once the transfer has started, this bit is read-only.
0: Regular alpha
1: Inverted alpha
19.5.15 DMA2D output color register (DMA2D_OCOLR)

Address offset: 0x038
Reset value: 0x0000 0000

The same register is used to show the color values, with different formats depending on the color mode.

This register can only be written when transfers are disabled. Once the transfer has started, this register is read-only.

ARGB8888 or RGB888 color mode

| Bits 31:24 | ALPHA[7:0]: Alpha channel value of the output color in ARGB8888 mode (otherwise reserved) |
| Bits 23:16 | RED[7:0]: Red value of the output image in ARGB8888 or RGB888 mode |
| Bits 15:8  | GREEN[7:0]: Green value of the output image in ARGB8888 or RGB888 |
| Bits 7:0   | BLUE[7:0]: Blue value of the output image in ARGB8888 or RGB888 |
### 19.5.16 DMA2D output color register [alternate] (DMA2D_OCOLR)

Address offset: 0x038  
Reset value: 0x0000 0000  
The same register is used to show the color values, with different formats depending on the color mode.  
This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

**RGB565 color mode**

Bits 31:16: Reserved, must be kept at reset value.  
Bits 15:12: **ALPHA[3:0]**: Alpha channel of the output color value in ARGB4444  
Bits 11:8: **RED[3:0]**: Red value of the output image in ARGB4444 mode  
Bits 7:4: **GREEN[3:0]**: Green value of the output image in ARGB4444 mode  
Bits 3:0: **BLUE[3:0]**: Blue value of the output image in ARGB4444 mode

### 19.5.19 DMA2D output memory address register (DMA2D_OMAR)

Address offset: 0x003C  
Reset value: 0x0000 0000  
This field contains the address of the data used for the output FIFO. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.  
The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned and a 16-bit per pixel format must be 16-bit aligned.
### 19.5.20 DMA2D output offset register (DMA2D_OOR)

Address offset: 0x040  
Reset value: 0x0000 0000

<table>
<thead>

**LO[15:0]**

Bits 31:16  Reserved, must be kept at reset value.

**Bits 15:0 LO[15:0]: Line offset**

This field contains the line offset used for the output expressed in pixel when the LOM bit is reset and in byte when the LOM bit is set.

When expressed in pixels, only LO[13:0] is considered, LO[15:14] are ignored.

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.

### 19.5.21 DMA2D number of line register (DMA2D_NLR)

Address offset: 0x044  
Reset value: 0x0000 0000

<table>
<thead>
<tr>

</tbody>
</table>

**PL[13:0]**

Bits 31:30  Reserved, must be kept at reset value.

**Bits 29:16 PL[13:0]: Pixel per lines**

Number of pixels per lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

If any of the input image format is 4-bit per pixel, pixel per lines must be even.

**Bits 15:0 NL[15:0]: Number of lines**

Number of lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
19.5.22 DMA2D line watermark register (DMA2D_LWR)

</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 LW[15:0]: Line watermark

These bits allow the configuration of the line watermark for interrupt generation.
An interrupt is raised when the last pixel of the watermarked line has been transferred.
These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

19.5.23 DMA2D AHB master timer configuration register (DMA2D_AMTCR)

Address offset: 0x04C
Reset value: 0x0000 0000

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 DT[7:0]: Dead time

Dead time value in the AHB clock cycle inserted between two consecutive accesses on the AHB master port. These bits represent the minimum guaranteed number of cycles between two consecutive AHB accesses.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 EN: Enable
Enables the dead time functionality.
19.5.24 DMA2D foreground CLUT (DMA2D_FGCLUTx)

Address offset: 0x400 + 0x4 * x, (x = 0 to 255)
Reset value: 0xXXXX XXXX

Refer to Section 2.3 for the register boundary addresses.
20 Chrom-ART Accelerator controller (DMA2D)

This section only applies to STM32U5Fx/5Gx devices.

20.1 DMA2D introduction

The Chrom-ART Accelerator (DMA2D) is a specialized DMA dedicated to image manipulation. It can perform the following operations:

- Filling a part or the whole of a destination image with a specific color
- Copying a part or the whole of a source image into a part or the whole of a destination image
- Copying a part or the whole of a source image into a part or the whole of a destination image with a pixel format conversion
- Blending a part and/or two complete source images with different pixel format and copy the result into a part or the whole of a destination image with a different color format

All the classical color coding schemes are supported from 4-bit up to 32-bit per pixel with indexed or direct color mode, including block based YCbCr to handle JPEG decoder output. The DMA2D has its own dedicated memories for CLUTs (color look-up tables).

20.2 DMA2D main features

The main DMA2D features are:

- Single AHB master bus architecture
- AHB slave programming interface supporting 8-, 16-, 32-bit accesses (except for CLUT accesses which are 32-bit)
- User-programmable working area size
- User-programmable offset for sources and destination areas expressed in pixels or bytes
- User-programmable sources and destination addresses on the whole memory space
- Up to two sources with blending operation
- Alpha value that can be modified (source value, fixed value, or modulated value)
- User programmable source and destination color format
- Up to 12 color formats supported from 4-bit up to 32-bit per pixel with indirect or direct color coding
- Block based (8x8) YCbCr support with 4:4:4, 4:2:2 and 4:2:0 chroma sub-sampling factors
- 2 internal memories for CLUT storage in indirect color mode
- Automatic CLUT loading or CLUT programming via the CPU
- User programmable CLUT size
- Internal timer to control AHB bandwidth
- 6 operating modes: register-to-memory, memory-to-memory, memory-to-memory with pixel format conversion, memory-to-memory with pixel format conversion and blending, memory-to-memory with pixel format conversion, blending and fixed color foreground,
and memory-to memory with pixel format conversion, blending and fixed color background.
- Area filling with a fixed color
- Copy from an area to another
- Copy with pixel format conversion between source and destination images
- Copy from two sources with independent color format and blending
- Output buffer byte swapping to support refresh of displays through parallel interface
- Abort and suspend of DMA2D operations
- Watermark interrupt on a user programmable destination line
- Interrupt generation on bus error or access conflict
- Interrupt generation on process completion

20.3 DMA2D functional description

20.3.1 General description

The DMA2D controller performs direct memory transfer. As an AHB master, it can take the control of the AHB bus matrix to initiate AHB transactions.

The DMA2D can operate in the following modes:
- Register-to-memory
- Memory-to-memory
- Memory-to-memory with pixel format conversion
- Memory-to-memory with pixel format conversion and blending
- Memory-to-memory with pixel format conversion, blending and fixed color foreground
- Memory-to-memory with pixel format conversion, blending and fixed color background

The AHB slave port is used to program the DMA2D controller.

The block diagram of the DMA2D is shown in Figure 91.
20.3.2 DMA2D internal signals

The internal signals of the DMA2D are given in the table below:

20.3.3 DMA2D control

The DMA2D controller is configured through DMA2D_CR. The user application can perform the following operations:

- Select the operating mode.
- Enable/disable the DMA2D interrupt.
- Start/suspend/abort ongoing data transfers.

20.3.4 DMA2D foreground and background FIFOs

The DMA2D foreground (FG) FG FIFO and background (BG) FIFO fetch the input data to be copied and/or processed.

The FIFOs fetch the pixels according to the color format defined in their respective pixel format converter (PFC).

They are programmed through the following control registers:

- DMA2D foreground memory address register (DMA2D_FGMAR)
- DMA2D foreground offset register (DMA2D_FGOR)
- DMA2D background memory address register (DMA2D_BGMAR)
- DMA2D background offset register (DMA2D_BGBOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

When the DMA2D operates in register-to-memory mode, none of the FIFOs is activated.

When the DMA2D operates in memory-to-memory mode (no pixel format conversion nor blending operation), only the FG FIFO is activated, and acts as a buffer.

When the DMA2D operates in memory-to-memory operation with pixel format conversion (no blending operation), the BG FIFO is not activated.

20.3.5 DMA2D foreground and background PFC

DMA2D foreground pixel format converter (PFC) and background pixel format converter perform the pixel format conversion to generate a 32-bit per pixel value. The PFC can also modify the alpha channel.

The first PFC stage converts the color format. The original color format of the foreground and background pixels are configured through CM[3:0] in DMA2D_FGPFFCCR and DMA2D_BGPFCCR, respectively.

The supported input formats are given in the table below.

<table>
<thead>
<tr>
<th>CM[3:0]</th>
<th>Color mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>ARGB8888</td>
</tr>
<tr>
<td>0001</td>
<td>RGB888</td>
</tr>
<tr>
<td>0010</td>
<td>RGB565</td>
</tr>
<tr>
<td>0011</td>
<td>ARGB1555</td>
</tr>
<tr>
<td>0100</td>
<td>ARGB4444</td>
</tr>
<tr>
<td>0101</td>
<td>L8</td>
</tr>
</tbody>
</table>

Table 169. Supported color mode in input
The color format are coded as follows:

- Alpha value field: transparency
  0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.
- R field for Red
- G field for Green
- B field for Blue
- L field: luminance
  This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format was direct color mode (ARGB/RGB), the extension to 8-bit per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

If the original format is indirect color mode (L/AL), a CLUT is required, and each pixel format converter is associated with a 256 entry 32-bit CLUT.

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and defined in DMA2D_FGCOLR for foreground pixels, and in DMA2D_BGCOLR for background pixels.

The order of the fields in the system memory is defined in the table below.

### Table 170. Data order in memory

</tbody>
</table>
The 24-bit RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

Once the 32-bit value is generated, the alpha channel can be modified according to AM[1:0] in DMA2D_FGPFCCR or DMA2D_BGPFCCR, as shown in Table 171.

One of the following happens for the alpha channel:
- It is kept as it is (no modification).
- It is replaced by ALPHA[7:0] value in DMA2D_FGPFCCR/DMA2D_BGPFCCR.
- It is replaced by the original alpha value multiplied by ALPHA[7:0] in DMA2D_FGPFCCR/DMA2D_BGPFCCR divided by 255.

</tr>
</tbody>
</table>

*Note: To support the alternate format, the incoming alpha value can be inverted setting AI in DMA2D_FGPFCCR or DMA2D_BGPFCCR. This applies also to the Alpha value stored in the DMA2D_FGPFCCR or DMA2D_BGPFCCR, and in the CLUT. The R and B fields can also be swapped setting RBS in DMA2D_FGPFCCR or DMA2D_BGPFCCR. This applies also to the RGB order used in the CLUT, and in DMA2D_FGCOLR or DMA2D_BGCOLR.*

**20.3.6 DMA2D foreground and background CLUT interface**

The CLUT interface manages the CLUT memory access and the automatic loading of the CLUT.

Three kinds of accesses are possible:
- CLUT read by the PFC during pixel format conversion operation
- CLUT accessed through the AHB slave port when the CPU is reading or writing data into the CLUT
- CLUT written through the AHB master port when an automatic loading of the CLUT is performed

The CLUT memory loading can be done in two different ways:
- Automatic loading
  The following sequence must be followed to load the CLUT:
a) Program the CLUT address into DMA2D_FGCMAR (foreground CLUT) or DMA2D_BGCMAR (background CLUT).

b) Program the CLUT size with CS[7:0] field in DMA2D_FGPFCCR (foreground CLUT), or DMA2D_BGPFCCR (background CLUT).

c) Set START in DMA2D_FGPFCCR (foreground CLUT) or DMA2D_BGPFCCR (background CLUT) to start the transfer. During this automatic loading process, the CLUT is not accessible by the CPU. If a conflict occurs, a CLUT access error interrupt is raised assuming CAEIE = 1 in DMA2D_CR.

- Manual loading
  The application has to program the CLUT manually through the DMA2D AHB slave port to which the local CLUT memory is mapped. The foreground CLUT (FGCLUT) is located at address offset 0x0400 and the background CLUT (BGCLUT) at address offset 0x0800.

The CLUT format can be 24 or 32 bits. It is configured through CCM in DMA2D_FGPFCCR (foreground CLUT) or DMA2D_BGPFCCR (background CLUT) as shown in the table below.

Table 172. Supported CLUT color mode

20.3.7 DMA2D blender

The DMA2D blender blends the source pixels by pair to compute the resulting pixel. The blending is performed according to the following equation:

\[ \alpha_{\text{OUT}} = \frac{\alpha_{\text{FG}} \cdot \alpha_{\text{BG}}}{255} \]

\[ \alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \alpha_{\text{Mult}} \]

\[ C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{BG}} \cdot \alpha_{\text{Mult}}}{\alpha_{\text{OUT}}} \quad \text{with } C = R \text{ or } G \text{ or } B \]

Division is rounded to the nearest lower integer

No configuration register is required by the blender. The blender use depends on the DMA2D operating mode defined by MODE[2:0] in DMA2D_CR.

20.3.8 DMA2D output PFC

The output PFC performs the pixel format conversion from 32 bits to the output format defined by CM[2:0] in DMA2D_OPFCCR.

Supported output formats are given in the table below

<table>
<thead>
<tr>
<th>CM[2:0]</th>
<th>Color mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>ARGB8888</td>
</tr>
<tr>

<tr>
<td>011</td>
<td>ARGB1555</td>
</tr>
<tr>
<td>100</td>
<td>ARGB4444</td>
</tr>
</tbody>
</table>

Table 174. Supported color mode in output

Note: To support the alternate format, the calculated alpha value can be inverted setting AI bit in DMA2D_OPFCCR. This applies also to the Alpha value used in DMA2D_OCOLR. The R and B fields can also be swapped setting RBS in DMA2D_OPFCCR. This applies also to the RGB order used in DMA2D_OCOLR.

20.3.9 DMA2D output FIFO

The output FIFO programs the pixels according to the color format defined in the output PFC.

The destination area is defined through the following registers:

- DMA2D output memory address register (DMA2D_OMAR)
- DMA2D output offset register (DMA2D_OOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)
If the DMA2D operates in register-to-memory mode, the configured output rectangle is filled by the color specified in DMA2D_OCOLR which contains a fixed 32-, 24-, or 16-bit value. The format is selected by CM[2:0] in DMA2D_OPFCCR.

The data are stored into the memory in the order defined in the table below.

### Table 175. Data order in memory

<table>
<thead>
<tr>

<td>R₂[7:0]</td>
</tr>
</tbody>
</table>

The RGB888 aligned on 32 bits is supported through the ARGB8888 mode.

#### 20.3.10 DMA2D output FIFO byte reordering

The output FIFO bytes can be reordered to support display frame buffer update through a parallel interface (F(S)MC) directly from the DMA2D.

The reordering of bytes can be done using:
- RBS bit to swap red and blue component
- SB bit to swap byte two by two in the output FIFO

When the byte swapping is activated (SB = 1 in DMA2D_OPFCR), the number of pixel per line (PL field in DMA2D_NLR) must be even, and the output memory address (MA field in DMA2D_OMAR) must be even. The output line offset computed in bytes (resulting from LOM field in DMA2D_CR and LO field in DMA2D_OOR values) must also be even. If not a configuration error is detected.

### Table 176. Standard data order in memory

</tbody>
</table>

**16-bit mode (RGB565)**

This mode is supported without byte reordering by the DMA2D.
18/24-bit mode (RGB888)

This mode needs data reordering:

1. The red and the blue have to be swapped (setting the RBS bit).
2. MSB and the LSB bytes of an half-word must be swapped (setting SB bit).

Table 177. Output FIFO byte reordering steps

Setting the SB bit
20.3.11 DMA2D AHB master port timer

An 8-bit timer is embedded into the AHB master port to provide an optional limitation of the bandwidth on the crossbar. This timer is clocked by the AHB clock and counts a dead time between two consecutive accesses. This limits the bandwidth usage.

The timer enabling and dead time value are configured through DMA2D_AMPTCR.

20.3.12 DMA2D transactions

DMA2D transactions consist of a sequence of a given number of data transfers. Number of data and width can be programmed by software.

Each DMA2D data transfer is composed of up to four steps:
1. Data loading from the memory location pointed by DMA2D_FGMAR and pixel format conversion as defined in DMA2D_FGCR
2. Data loading from a memory location pointed by DMA2D_BGMAR and pixel format conversion as defined in DMA2D_BGCR
3. Blending of all retrieved pixels according to the alpha channels resulting of PFC operation on alpha values
4. Pixel format conversion of resulting pixels according to DMA2D_OCR and programming of data to the memory location addressed through DMA2D_OMAR

20.3.13 DMA2D configuration

Both source and destination data transfers can target peripherals and memories in the whole 4-Byte memory area, at addresses ranging between 0x0000 0000 and 0xFFFF FFFF.

The DMA2D can operate in any of the following modes selected through MODE[2:0] in DMA2D_CR:
- Register-to-memory
- Memory-to-memory
- Memory-to-memory with PFC
- Memory-to-memory with PFC and blending
- Memory-to-memory with PFC, blending and fixed FG color
- Memory-to-memory with PFC, blending and fixed BG color

Register-to-memory

The register-to-memory mode is used to fill a user defined area with a predefined color. The color format is set in DMA2D_OPFCCR.
The DMA2D does not perform any data fetching from any source. It just writes the color defined in DMA2D_OCOLR to the area located at the address pointed by DMA2D_OMAR and defined in DMA2D_NLR and DMA2D_OOR.

**Memory-to-memory**

In memory-to-memory mode, the DMA2D does not perform any graphical data transformation. The foreground input FIFO acts as a buffer, and data are transferred from the source memory location defined in DMA2D_FGMAR, to the destination memory location pointed by DMA2D_OMAR.

The color mode programmed by CM[3:0] in DMA2D_FGPFCCR defines the number of bits per pixel for both input and output.

The size of the area to be transferred is defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.

**Memory-to-memory with PFC**

In this mode, the DMA2D performs a pixel format conversion of the source data, and stores them in the destination memory location.

The size of the areas to be transferred are defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.

Data are fetched from the location defined in DMA2D_FGMAR, and processed by the foreground PFC. The original pixel format is configured through DMA2D_FGPFCCR.

If the original pixel format is direct-color mode, the color channels are all expanded to 8 bits.

If the pixel format is indirect color mode, the associated CLUT has to be loaded into the CLUT memory.

The CLUT loading can be done automatically by following the sequence below:

1. Set the CLUT address into DMA2D_FGCMAR.
2. Set the CLUT size with CS[7:0] in DMA2D_FGPFCCR.
3. Set the CLUT format (24 or 32 bits) with CCM in DMA2D_FGPFCCR.
4. Start the CLUT loading by setting START in DMA2D_FGPFCCR.

Once the CLUT loading is complete, CTCIF flag in DMA2D_IFR is raised, and an interrupt is generated if CTCIE is set in DMA2D_CR. The automatic CLUT loading process cannot work in parallel with classical DMA2D transfers.

The CLUT can also be filled by the CPU or by any other master through the AHB port. The access to the CLUT is not possible when a DMA2D transfer is ongoing, and uses the CLUT (indirect color format).

In parallel to the color conversion process, the alpha value can be added or changed depending on the value programmed in DMA2D_FGPFCCR. If the original image does not have an alpha channel, a default alpha value of 0xFF is automatically added to obtain a fully opaque pixel.

The alpha value is modified as follows according to AM[1:0] in DMA2D_FGPFCCR:

- It is unchanged.
- It is replaced by ALPHA[7:0] value in DMA2D_FGPFCCR.
- It is replaced by the original value multiplied by ALPHA[7:0] value in DMA2D_FGPFCCR divided by 255.
The resulting 32-bit data are encoded by the output PFC into the format specified by CM[2:0] in DMA2D_OPFCCR. The output pixel format cannot be the indirect mode since no CLUT generation process is supported.

Processed data are written into destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC and blending**

In this mode, two sources are fetched in the foreground and background FIFOs from the memory locations defined by DMA2D_FGMAR and DMA2D_BGMAR respectively.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory.

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended according to the equation below:

\[
\alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \alpha_{\text{Mult}}
\]

\[
\alpha_{\text{Mult}} = \frac{\alpha_{\text{FG}} \cdot \alpha_{\text{BG}}}{255}
\]

\[
C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{BG}} \cdot \alpha_{\text{Mult}}}{\alpha_{\text{OUT}}}
\]

**Division are rounded to the nearest lower integer**

The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and data are written into the destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC, blending and fixed color FG**

In this mode, only one source is fetched in the background FIFO from the memory location defined by DMA2D_BGMAR.

The value of the foreground color is given by DMA2D_FGCOLR, and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_FGPFCCR.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory.

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended together. The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format. Data are written into the destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC, blending and fixed color BG**

In this mode, only open source is fetched in the foreground FIFO from the memory location defined by DMA2D_FGMAR.
The value of the background color is given by DMA2D_BGCOLR, and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_BGPFCCR.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory.

Once each pixel has been converted into 32 bits by their respective PFCs, all pixels are blended together. The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format. Data are written into the destination memory location pointed by DMA2D_OMAR.

**Configuration error detection**

The DMA2D checks that the configuration is correct before any transfer. The configuration error interrupt flag is set by hardware when a wrong configuration is detected when a new transfer/automatic loading starts. An interrupt is then generated if CEIE = 1 in DMA2D_CR.

The wrong configurations that can be detected are listed below:

- Foreground CLUT automatic loading: MA bits in DMA2D_FGCMAR are not aligned with CCM in DMA2D_FGPFCCR.
- Background CLUT automatic loading: MA bits in DMA2D_BGCMAR are not aligned with CCM in DMA2D_BGPFCCR.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): MA bits in DMA2D_FGMAR are not aligned with CM in DMA2D_FGPFCCR.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): CM bits in DMA2D_FGPFCCR are invalid.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): PL bits in DMA2D_NLR are odd while CM is DMA2D_FGPFCCR is A4 or L4.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): LO bits in DMA2D_FGOR are odd while CM in DMA2D_BGPFCCR is A4 or L4, and LOM in DMA2D_CR is pixel mode.
- Memory transfer (only in blending mode, except in memory-to-memory with blending and fixed color FG): MA bits in DMA2D_BGMAR are not aligned with the CM in DMA2D_BGPFCCR.
- Memory transfer (only in blending and blending with fixed color FG): CM bits in DMA2D_BGPFCCR are invalid.
- Memory transfer (only in blending and blending with fixed color FG mode): PL bits in DMA2D_NLR odd while CM inDMA2D_BGPFCCR is A4 or L4.
- Memory transfer (only in blending and blending with fixed color FG): LO bits in DMA2D_BGOR are odd while CM inDMA2D_BGPFCCR is A4 or L4, and LOM in DMA2D_CR is pixel mode.
- Memory transfer (except in memory-to-memory): MA bits in DMA2D_OMAR are not aligned with CM in DMA2D_OPFCCR.
- Memory transfer (except in memory-to-memory): CM bits in DMA2D_OPFCCR are invalid.
• Memory transfer with byte swapping: PL bits in DMA2D_NLR are odd, or MA bits in DMA2D_OMAR are odd, or LO in bytes (resulting from LOM in DMA2D_CR and LO in DMA2D_OOR) are odd while SB = 1 in DMA2D_OPFCCR.
• Memory transfer: NL bits in DMA2D_NLR are all zeros.
• Memory transfer: PL bits in DMA2D_NLR are all zeros.
• Memory transfer: MODE bits in DMA2D_CR are invalid.
• YCbCr format: when a CLUT loading starts setting START in DMA2D_FGPFCCR
• YCbCr format: when memory-to-memory mode is selected
• YCbCr format: when YCbCr4:4:4 is selected, and the sum of number of pixel (PL) and line offset LO is not a multiple of 8 pixels
• YCbCr format: when YCbCr4:2:2 or YCbCr4:2:0 is selected, and the sum of number of pixel (PL) and line offset LO is not a multiple of 16 pixels

20.3.14 YCbCr support

The DMA2D foreground plane can support 8x8 block-based YCbCr as output by the JPEG decoder with different chroma subsampling factors.

The memory organization follows the standard JFIF rules:
• Each of the three color components must be coded on 8-bit.
• Each component must be arranged by blocks of 8x8 (64 bytes) called MCU.

Depending of the chroma subsampling factor, the MCU must be arranged in the memory as described in the table below.

<table>
<thead>
<tr>
<th>Sub-sampling</th>
<th>@</th>
<th>@ + 64</th>
<th>@ + 128</th>
<th>@ +192</th>
<th>@+256</th>
<th>@ + 320</th>
</tr>
</thead>
<tbody>
<tr>
<td>4:4:4</td>
<td>Y1</td>
<td>Cr1</td>
<td>Y2</td>
<td>Cb2</td>
<td>Cr2</td>
<td></td>
</tr>
<tr>
<td>4:2:2</td>
<td>Y1</td>
<td>Y2</td>
<td>Cb12</td>
<td>Cr12</td>
<td>Y3</td>
<td>Y4</td>
</tr>
<tr>
<td>4:2:0</td>
<td>Y1</td>
<td>Y2</td>
<td>Y3</td>
<td>Y4</td>
<td>Cb1234</td>
<td>Cr1234</td>
</tr>
</tbody>
</table>

The chroma subsampling factor is configured through CSS in DMA2D_FGPFCCR.

Once the DMA2D has started with the foreground configured in YCbCr color mode, the first two chroma MCUs are loaded in the foreground CLUT. Once the chroma MCUs are loaded, the DMA2D performs the loading of the Y MCU as for a classical color mode.

20.3.15 DMA2D transfer control (start, suspend, abort, and completion)

Once the DMA2D is configured, the transfer can be launched by setting START in DMA2D_CR. Once the transfer is completed, START is automatically reset, and TCIF flag is raised in DMA2D_ISR. An interrupt can be generated if TCIE is set in DMA2D_CR.

The user application can suspend the DMA2D at any time by setting SUSP in DMA2D_CR. The transaction can be aborted by setting ABORT in DMA2D_CR, or can be restarted by resetting SUSP in DMA2D_CR.

The user application can abort at any time an ongoing transaction by setting ABORT in DMA2D_CR. In this case, the TCIF flag is not raised.
Automatic CLUT transfers can also be aborted or suspended by using their own START bits in DMA2D_FGPFCCR and DMA2D_BGPCCR.

20.3.16 Watermark
A watermark can be programmed to generate an interrupt when the last pixel of a given line has been written to the destination memory area.

The line number is defined in LW[15:0] in DMA2D_LWR.

When the last pixel of this line has been transferred, TWIF flag is raised in DMA2D_ISR, and an interrupt is generated if TWIE is set in DMA2D_CR.

20.3.17 Error management
Two kinds of errors can be triggered:
- AHB master port errors signaled by TEIF flag in DMA2D_ISR
- Conflicts caused by CLUT access (CPU trying to access the CLUT while a CLUT loading or a DMA2D transfer is ongoing) signaled by CAEIF flag in DMA2D_ISR

Both flags are associated to their own interrupt enable flag in DMA2D_CR to generate an interrupt if need be (TEIE and CAEIE).

20.3.18 AHB dead time
To limit the AHB bandwidth use, a dead time between two consecutive AHB accesses can be programmed. This feature can be enabled by setting EN in DMA2D_AMTCR.

The dead-time value is stored in DT[7:0] in DMA2D_AMTCR. This value represents the guaranteed minimum number of cycles between two consecutive transactions on AHB bus.

The update of the dead-time value while the DMA2D is running is taken into account for the next AHB transfer.

20.4 DMA2D interrupts
An interrupt can be generated on the following events:
- Configuration error
- CLUT transfer complete
- CLUT access error
- Transfer watermark reached
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **MODE[2:0]: DMA2D mode**  
This bit is set and cleared by software. It cannot be modified while a transfer is ongoing.  
000: Memory-to-memory (FG fetch only)  
001: Memory-to-memory with PFC (FG fetch only with FG PFC active)  
010: Memory-to-memory with blending (FG and BG fetch with PFC and blending)  
011: Register-to-memory (no FG nor BG, only output stage active)  
100: Memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active)  
101: Memory-to-memory with blending and fixed color BG (FG fetch only with FG and BG PFC active)  
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **CEIE**: Configuration error (CE) interrupt enable  
This bit is set and cleared by software.  
0: CE interrupt disabled  
1: CE interrupt enabled

Bit 12 **CTCIE**: CLUT transfer complete (CTC) interrupt enable  
This bit is set and cleared by software.  
0: CTC interrupt disabled  
1: CTC interrupt enabled
Bit 11 **CAEIE**: CLUT access error (CAE) interrupt enable
   This bit is set and cleared by software.
   0: CAE interrupt disabled
   1: CAE interrupt enabled

Bit 10 **TWIE**: Transfer watermark (TW) interrupt enable
   This bit is set and cleared by software.
   0: TW interrupt disabled
   1: TW interrupt enabled

Bit 9 **TCIE**: Transfer complete (TC) interrupt enable
   This bit is set and cleared by software.
   0: TC interrupt disabled
   1: TC interrupt enabled

Bit 8 **TEIE**: Transfer error (TE) interrupt enable
   This bit is set and cleared by software.
   0: TE interrupt disabled
   1: TE interrupt enabled

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LOM**: Line offset mode
   This bit configures how the line offset is expressed (pixels or bytes) for the foreground, background and output.
   This bit is set and cleared by software. It cannot be modified while a transfer is ongoing.
   0: Line offsets expressed in pixels
   1: Line offsets expressed in bytes

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **ABORT**: Abort
   This bit can be used to abort the current transfer. This bit is set by software, and is automatically reset by hardware when START = 0.
   0: No transfer abort requested
   1: Transfer abort requested

Bit 1 **SUSP**: Suspend
   This bit can be used to suspend the current transfer. This bit is set and reset by software. It is automatically reset by hardware when START = 0.
   0: Transfer not suspended
   1: Transfer suspended

Bit 0 **START**: Start
   This bit can be used to launch the DMA2D according to parameters loaded in the various configuration registers. This bit is automatically reset by the following events:
   – at the end of the transfer
   – when the data transfer is aborted by the user by setting ABORT in this register
   – when a data transfer error occurs
   – when the data transfer has not started due to a configuration error, or another transfer operation already ongoing (automatic CLUT loading)
20.5.2  DMA2D interrupt status register (DMA2D_ISR)

Address offset: 0x004
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:6  Reserved, must be kept at reset value.

Bit 5  CEIF: Configuration error interrupt flag
This bit is set when START is set in DMA2D_CR, DMA2DFGPFCCR or DMA2D_BGPFCCR, and a wrong configuration has been programmed.

Bit 4  CTCIF: CLUT transfer complete interrupt flag
This bit is set when the CLUT copy from a system memory area to the internal DMA2D memory is complete.

Bit 3  CAEIF: CLUT access error interrupt flag
This bit is set when the CPU accesses the CLUT while the CLUT is being automatically copied from a system memory to the internal DMA2D.

Bit 2  TWIF: Transfer watermark interrupt flag
This bit is set when the last pixel of the watermarked line has been transferred.

Bit 1  TCIF: Transfer complete interrupt flag
This bit is set when a DMA2D transfer operation is complete (data transfer only).

Bit 0  TEIF: Transfer error interrupt flag
This bit is set when an error occurs during a DMA transfer (data transfer or automatic CLUT loading).

20.5.3  DMA2D interrupt flag clear register (DMA2D_IFCR)

Address offset: 0x008
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>

<td></td>
</tr>
</tbody>
</table>

Bits 31:6  Reserved, must be kept at reset value.

Bit 5  CCEIF: Clear configuration error interrupt flag
Programming this bit to 1 clears the CEIF flag in DMA2D_ISR.
20.5.4 **DMA2D foreground memory address register (DMA2D_FGMAR)**

Address offset: 0x00C

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

<table>
<thead>
<tr>
<th>MA[31:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>MA[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

Bits 31:0 **MA[31:0]**: Memory address, address of the data used for the foreground image

The address alignment must match the image format selected: a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned, and a 4-bit per pixel format must be 8-bit aligned.

20.5.5 **DMA2D foreground offset register (DMA2D_FGOR)**

Address offset: 0x010

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

<table>
<thead>
<tr>
<th>LO[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>

<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:0  **LO[15:0]: Line offset**

This field gives the line offset used for the foreground image, expressed:
- in pixels when LOM = 0 in DMA2D_CR. Only LO[13:0] bits are considered, LO[15:14] bits are ignored.
- in bytes when LOM = 1

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.
If the image format is 4-bit per pixel, the line offset must be even.

20.5.6 **DMA2D background memory address register (DMA2D_BGMAR)**

Address offset: 0x014
Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

</table>
Bits 17:16 **AM[1:0]**: Alpha mode
These bits select the alpha channel value to be used for the foreground image.
00: No modification of the foreground image alpha channel value
01: Replace original foreground image alpha channel value by ALPHA[7:0]
10: Replace original foreground image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value
Others: Reserved

Bits 15:8 **CS[7:0]**: CLUT size
These bits define the size of the CLUT used for the foreground image.
The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **START**: Start
This bit can be set to start the automatic loading of the CLUT. It is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user by setting ABORT in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic background CLUT transfer)

Bit 4 **CCM**: CLUT color mode
This bit defines the color format of the CLUT.
0: ARGB8888
1: RGB888

Bits 3:0 **CM[3:0]**: Color mode
These bits define the color format of the foreground image.
0000: ARGB8888

Bits 31:24 ALPHA[7:0]: Alpha value
These bits define a fixed alpha channel value which can replace the original alpha value, or be multiplied with the original alpha value according to the alpha mode selected with AM[1:0].

Bits 23:22 Reserved, must be kept at reset value.
Bit 21 **RBS**: Red/Blue swap
This bit allows to swap Red and Blue to support BGR or ABGR color formats.
- 0: Regular mode (RGB or ARGB)
- 1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted
This bit inverts the alpha value.
- 0: Regular alpha
- 1: Inverted alpha

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **AM[1:0]**: Alpha mode
These bits define which alpha channel value to be used for the background image.
- 00: No modification of the foreground image alpha channel value
- 01: Replace original background image alpha channel value by ALPHA[7: 0]
- 10: Replace original background image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value
Others: Reserved

Bits 15:8 **CS[7:0]**: CLUT size
These bits define the size of the CLUT used for the BG. The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **START**: Start
This bit is set to start the automatic loading of the CLUT. This bit is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user by setting ABORT bit in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already on going (data transfer or automatic background CLUT transfer)

Bit 4 **CCM**: CLUT color mode
These bits define the color format of the CLUT.
- 0: ARGB8888
- 1: RGB888

Bits 3:0 **CM[3:0]**: Color mode
These bits define the color format of the foreground image.

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 RBS: Red/Blue swap
This bit allows to swap Red and Blue to support BGR or ABGR color formats.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 AI: Alpha Inverted
This bit inverts the alpha value.
0: Regular alpha
1: Inverted alpha

Bits 19:9 Reserved, must be kept at reset value.
Bit 8  **SB**: Swap bytes
When this bit is set, the bytes in the output FIFO are swapped two by two. The number of pixels per line (PL) must be even, and the output memory address (OMAR) must be even.
0: Bytes in regular order in the output FIFO
1: Bytes swapped two by two in the output FIFO

Bits 7:3  Reserved, must be kept at reset value.

Bits 2:0  **CM[2:0]**: Color mode
These bits define the color format of the output image.
000: ARGB8888
001: RGB888
010: RGB565
011: ARG1555
100: ARG4444
Others: Reserved

## 20.5.15 DMA2D output color register (DMA2D_OCOLR)

Address offset: 0x038
Reset value: 0x0000 0000

The same register is used to show the color values, with different formats depending on the color mode.

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

ARG8888 or RGB888 color mode

</tbody>
</table>

Bits 31:0 MA[31:0]: Memory address

Address of the data used for the output FIFO.
The address alignment must match the image format selected: a 32-bit per pixel format must be 32-bit aligned and a 16-bit per pixel format must be 16-bit aligned.
20.5.20 DMA2D output offset register (DMA2D_OOR)

Address offset: 0x040
Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

<table>

</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 LO[15:0]: Line offset
This field gives the line offset used for the output, expressed:
- in pixels when LOM = 0 in DMA2D_CR. Only LO[13:0] bits are considered, LO[15:14] bits are ignored.
- in bytes when LOM = 1
This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

20.5.21 DMA2D number of line register (DMA2D_NLR)

Address offset: 0x044
Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

21 Chrom-GRC (GFXMMU)

This section only applies to STM32U599/5A9 and STM32U5Fx/5Gx devices.

21.1 Introduction

The graphic MMU is a graphical oriented memory management unit aimed to:
- Optimize memory usage according to the display shape
- Cache linear accesses to the frame buffer
- Prefetch data

21.2 GFXMMU main features

- Fully programmable display shape to physically store only the visible pixel
- Up to 4 virtual buffers
- Each virtual buffer have 3072 or 4096 bytes per line and 1024 lines
- Each virtual buffer can be physically mapped to any system memory
- Optional cache for linear accesses
- Cache can be locked to a virtual buffer
- Cache prefetch mechanism for linear accesses anticipation
- Interrupt in case of buffer overflow (1 per buffer)
- Interrupt in case of memory transfer error

21.3 GFXMMU implementation

21.4 GFXMMU functional and architectural description

The GFXMMU is composed of two main blocks:
- The MMU, responsible of address resolution
- The cache, responsible of data/address caching, prefetching and packing/unpacking

![Figure 94. GFXMMU block diagram](image)

21.4.1 Virtual memory

The GFXMMU provides a virtual memory space seen by the system masters\(^a\). This virtual memory space is divided into four virtual buffers.

**Virtual buffer**

A virtual buffer is seen by any system master as a continuous memory space representing a virtual frame buffer of 1024 lines.

Each line is divided into 192 or 256 16-byte blocks depending on the 192BM bit of the GFXMMU configuration register (GFXMMU_CR).

Depending on the display shape and size, only the necessary blocks are mapped to a physical memory location. This mapping is done programming the LUT entry for each line:
- The enable of the line
- The number of the first “visible” block
- The number of the last “visible” block
- The address offset of the line within the physical buffer

The “visible” blocks can be arranged in the physical buffer in a continuous way programming the address offset of each line.

\(^a\) Refer to section “System architecture” for system masters accessing GFXMMU.
The LUT is common to all the buffers i.e. all the buffers have the same “shape”.

**Figure 95. Virtual buffer**

Virtual buffer overview

For a frame buffer coded in 32 bpp or 16 bpp, the virtual buffer can be configured to have 192 or 256 blocks. This results in a virtual frame buffer of 768 x 1024 or 1024 x 1024 pixels for 32 bpp and 1536 x 1024 or 2048 x 1024 for 16 bpp.

For a frame buffer coded in 24 bpp, the virtual buffer must be configured to have 192 blocks to have an integer number of pixels per lines. This results in a virtual frame buffer of 1024 x 1024 pixels for 24 bpp.

Each buffer can be physically mapped anywhere in the physical memory thanks to:

- The physical buffer base address (PBBA) field of the GFXMMU buffer x configuration register (GFXMMU_BxCR). It configures the physical location of the 8-Mbyte area where the buffer is mapped.
- The physical buffer location respective to the physical buffer base address is defined by the physical buffer offset (PBO) field of the GFXMMU buffer x configuration register (GFXMMU_BxCR).
The buffer can not overflow the 8-Mbyte boundary of the zone defined by its base address. In case of overflow, the buffer x overflow flag (BxOF) of the GFXMMU status register (GFXMMU_SR) is set and an interrupt is generated if the buffer x overflow interrupt enable (BxOIE) bit of the GFXMMU configuration register (GFXMMU_CR) is set.

**Virtual buffer application use case**

As the physical locations are independently configurable, the four virtual buffers can be physically mapped to non continuous locations. This would allow for example to have the four buffers mapped on to four different SDRAM banks and avoid extra precharge cycles accessing the SDRAM.

As a consequence, one buffer must be used by the CPU/Chrom ART for frame buffer calculation while an other one must be used by the LTDC.

The two remaining buffers can be used as a graphical library requiring extra drawing buffers.

### 21.4.2 MMU architecture

The MMU block is responsible of the address resolution. It receives the 24-bit address and returns the physical 23-bit address and a valid signals to indicate the address is physically mapped or not. The MMU also checks overflow of a area boundary.
The MMU LUT is implemented as a 1024 x 35-bit RAM

**Figure 97. MMU block diagram**

**Line block decoder**

The line block decoder is generating the block number and the line number according to the address.

**Look up RAM**

The look up RAM is a 1024 x 35-bit RAM with the following fields:

- 1-bit line enable
- 8-bit first valid block
- 8-bit last valid block
- 18-bit for line offset

As the RAM is bigger than a word, each entry is split into two words on the memory map. The write access are done in two steps:

1. Write the first word with enable/first valid block/last valid block in the GFXMMU_LUTxL memory location (internally buffered).
2. Write the second word with line offset in the GFXMMU_LUTxH memory location (effective write into the memory together with the internally buffered value).

A write in the LUT can happen any time but it can lead to inconsistencies if a master is using the MMU at the same time. As the CPU has the priority during LUT programming, this may slow down MMU calculation.

There is no restriction during read operations, but this may slow down CPU as the MMU has the priority on LUT accesses.

**Block validation/comparator**

This block is checking if the block is valid.
A block is considered as valid (physically mapped) when:

- Line is enable.
- The block number is greater or equal to the first valid block.
- The block number is lower or equal to the last valid block.

When the block is valid, the physical address generated is considered as correct.

If the result of the MMU evaluation is not valid, the write operations are ignored, and read operations return the default 32-bit value stored in the default value (DV) field of the GFXMMU default value register (GFXMMU_DVR).

**Block offset address calculation within the buffer**

The block number is added to the line offset to get the offset of the block within the physical buffer.

As a consequence, the line offset stored in the LUT is given by the following formula:

\[
\text{Line offset} = [(\text{Number of visible blocks already used}) - (1^{st} \text{ visible block})] \times \text{block size}
\]

with:

- The maximum value for the line offset is when all the block of all the line are used. As the consequence the line offset for the last line can be maximum: 
  \[1023 \times 256 \times 16 = 0x3F:F00x\]
- The minimum value for the line offset is when the last block of the first line is the first valid block: 
  \[-255*16 = -0xFFx \text{ i.e } 0x3F:F01x\]

As the consequence the full range of the line offset entry of the LUT is used.

Carry is not taken into account as this stage to be able to perform negative offset calculations (values from 0x3F:F01x to 0x3F:FFFx)

As the block offset is within a 4-Mbyte buffer, the address generated is 22-bit wide.

**Block offset address calculation**

Once the offset of the block within the buffer as been calculated, this value is added to the offset of the block respective to the physical buffer base address.

The offset of the blocks are defined in registers as shown in **Figure 98**:

**Figure 98. Block validation/comparator implementation**

The resulting address and the buffer offset address must be on 23-bit.

The carry is taken into account to trigger address overflow. The carry is propagated to the GFXMMU status register (GFXMMU_SR) to set the buffer x overflow flag (BxOF).
Example of calculation

Consider the following configuration for virtual buffer 0:

- First visible block of line 0: block 7
- Number of visible block in line 0: 10
- First visible block of line 1: block 6
- Number of visible block in line 1: 12
- Address of the physical buffer: 0xC020:0000

The configuration must be:

- The base address of the physical buffer 0: 0xC000:0000
- The offset of buffer 0: 0x20:0000
- First visible block of line 0: block 7
- Last visible block of line 0: block 16
- Block 0 offset of line 0: (0 - 7) x 0x10 = -0x70 = 0x3F:FF90
- First visible block of line 1: block 6
- Last visible block of line 1: block 17
- Block 0 offset of line 1: (10 - 6) x 0x10 = (0xA - 0x6) x 0x10 = 0x40

As a consequence:

- the physical address of block 7 of line 0 is:
  0xC000:0000 + 0x20:0000 + (0x3F:FF90 + 0x70 without carry) = 0xC020:0000
- the physical address of block 16 of line 0 is:
  0xC000:0000 + 0x20:0000 + (0x3F:FF90 + 0x100 without carry) = 0xC020:0090
- the physical address of block 6 of line 1 is:
  0xC000:0000 + 0x20:0000 + (0x40 + 0x60 without carry) = 0xC020:00A0
- the physical address of block 17 of line 1 is:
  0xC000:0000 + 0x20:0000 + (0x40 + 0x110 without carry) = 0xC020:0150

21.4.3 Cache and prefetch mechanism

The GFXMMU integrated cache targets internal or external RAM devices storing the graphical frame buffer.

Master accessing the GFXMMU

Several masters are supposed to access memories through the GFXMMU:

- When the CPU is accessing the framebuffer, it is because it is performing a read/modify/write of a single pixel in the frame buffer. As a consequence the granularity of the R/M/W is less or equal to a word and a data cache is necessary. As the frame buffer is scanned linearly, it is realistic to says that the next data that is requested by the CPU within a buffer, is the next pixel. A prefetch mechanism can anticipate this efficiently.
- When Chrom ART or the LTDC are accessing the framebuffer, they are generating long accesses up to 128 bytes. A cache may not be necessary in this case as successive operation is done only once.
As a consequence the cache is aimed for CPU and must not be used together with DMA2D or LTDC. It is recommended to use the cache only with the CPU and manage coherency by software, flushing the cache when the CPU operations are finished.

On STM32U599/5A9, it is also recommended to use the cache with the GPU when the framebuffer is configured in RGB888 mode.

Cache enabling

The cache is enabled setting the CE (cache enable) bit of the GFXMMU control register (GFXMMU_CR).

Cache lock mechanism

It is possible to lock the cache by setting the cache lock bit (CL) and configuring the cache lock buffer (CLB) field of the GFXMMU configuration register (GFXMMU_CR).

When the cache is locked on a given buffer, all the other buffer cannot be cached.

An operation on the locked buffered can be cachable according to attribute of the master request, or can be always cachable setting the force caching (FC) bit of the GFXMMU configuration register (GFXMMU_CR). The force caching mechanism is only available when the cache is locked to a buffer. The force caching (FC) bit of the GFXMMU configuration register (GFXMMU_CR) is automatically reset when the cache lock (CL) bit of the GFXMMU configuration register (GFXMMU_CR) is reset.

Cache line size

A cache line size is 16 bytes.

Number of cache lines

The number of line is reduced as much as possible taking into account that CPU is performing linear accesses.

As a consequence three lines are needed:

- one line for the current access
- one line for the previous access (as pixels can be split into two 16-byte blocks)
- one line for the prefetched access

Prefetch mechanism

Because the CPU performs most of the time, linear accesses to the frame buffer, a prefetch mechanism is provided in order to automatically retrieve the next cache line from the memory.

The prefetch mechanism can be disabled setting the prefetch disable (PD) bit of the GFXMMU configuration register (GFXMMU_CR).

When the prefetch mechanism is disabled, only the TAG of the line dedicated for prefetching is updated but the data are retrieved from the memory.
Cache maintenance operation
When the cache is working in non force caching mode, this is the case when the force caching (FC) bit of the GFXMMU configuration register (GFXMMU_CR) is reset, then line eviction is done:

- Each time a non cachable access is performed on the buffer having data cached
- Each time a miss occurs

As a consequence the cache maintenance operation can be naturally automatic.
Nevertheless, it is possible to force a flush if the cache setting the force flush (FF) bit of the GFXMMU cache control register (GFXMMU_CCR). When flushing the cache, all the dirty entries are sent to the write buffer, and all the dirty bit of the TAGs are reset. But the entries are not invalidate.

It is also possible to invalidate the cache entries setting the force invalidate (FI) bit of the GFXMMU cache control register (GFXMMU_CCR). This does not send the dirty entries to the write buffer (modification done in the cache are lost). This just resets the ID field of the TAGs (unused state)

Setting the two force flush (FF) bits and forcing invalidate (FI) of the GFXMMU cache control register (GFXMMU_CCR) trigs the following operations:

- flush the cache, all the dirty entries are sent to the write buffer
- reset the dirty bit of the TAGs
- reset the ID field of the TAGs

When any of these two operations is done while the flash is having transaction already in the write buffer, the write buffer continues its operations.

The force flush (FF) and force invalidate (FI) are reset automatically when all the operations are finished (write buffer empty) creating a synchronization barrier.

21.4.4 Address cache
A specific cache can be activated to retain the latest MMU lookup results in order to reduce latencies due to the evaluation process. This address cache is only active on a selected virtual buffer.

This lookup cache is activated with address cache enable (ACE) bit in GFXMMU control register (GFXMMU_CR).

The cached virtual buffer is selected with address cache lock buffer (ACLB) bitfield in GFXMMU control register (GFXMMU_CR).
21.5 GFXMMU interrupts

An interrupt can be produced on the following events:

- Buffer 0 overflow
- Buffer 1 overflow
- Buffer 2 overflow
- Buffer 3 overflow
- AHB master error

Separate interrupt enable bits are available for flexibility.

Bits 31:23  Reserved, must be kept at reset value.

Bits 22:21 **ACLB[1:0]**: Address cache lock buffer
This field selects the virtual buffer on which the address cache is active.
00: Address cache locked on buffer 0
01: Address cache locked on buffer 1
10: Address cache locked on buffer 2
11: Address cache locked on buffer 3

Bit 20 **ACE**: Address cache enable
This bit enables the GFXMMU address cache.
0: Address cache is disabled
1: Address cache is enabled

Bits 19:18  Reserved, must be kept at reset value.

Bit 17 **OB**: Outer bufferability
This bit configure the bufferability of an access generated by the GFXMMU cache.
0: No bufferable
1: Bufferable

Bit 16 **OC**: Outer cachability
This bit configure the cachability of an access generated by the GFXMMU cache.
0: No cachable
1: Cachable

Bits 15:13  Reserved, must be kept at reset value.

Bit 12 **PD**: Prefetch disable
This bit disables the prefetch of the cache.
0: Prefetch enable
1: Prefetch disable

Bit 11 **FC**: Force caching
This bit force the caching into the cache regardless of the MPU attributes.
The cache must be enable (CE bit set).
0: Caching not forced
1: Caching forced
Bits 10:9 **CLB[1:0]**: Cache lock buffer
   This field select the buffer on which the cache is locked.
   00: Cache locked on buffer 0
   01: Cache locked on buffer 1
   10: Cache locked on buffer 2
   11: Cache locked on buffer 3

Bit 8 **CL**: Cache lock
   This bit lock the cache onto the buffer defined in the CLB field.
   0: Cache not locked
   1: Cache locked to a buffer

Bit 7 **CE**: Cache enable
   This bit enables the cache unit.
   0: Cache disable
   1: Cache enable

Bit 6 **192BM**: 192 Block mode
   This bit defines the number of blocks per line
   0: 256 blocks per line
   1: 192 blocks per line

Bit 5 Reserved, must be kept at reset value.

Bit 4 **AMEIE**: AHB master error interrupt enable
   This bit enables the AHB master error interrupt.
   0: Interrupt disable
   1: Interrupt enabled

Bit 3 **B3OIE**: Buffer 3 overflow interrupt enable
   This bit enables the buffer 3 overflow interrupt.
   0: Interrupt disable
   1: Interrupt enabled

Bit 2 **B2OIE**: Buffer 2 overflow interrupt enable
   This bit enables the buffer 2 overflow interrupt.
   0: Interrupt disable
   1: Interrupt enabled

Bit 1 **B1OIE**: Buffer 1 overflow interrupt enable
   This bit enables the buffer 1 overflow interrupt.
   0: Interrupt disable
   1: Interrupt enabled

Bit 0 **B0OIE**: Buffer 0 overflow interrupt enable
   This bit enables the buffer 0 overflow interrupt.
   0: Interrupt disable
   1: Interrupt enabled

21.6.4  GFXMMU cache control register (GFXMMU_CCR)

Address offset: 0x000C
Reset value: 0x0000 0000

Bit 2  **CB2OF**: Clear buffer 2 overflow flag
Writing 1 clears the buffer 2 overflow flag in the GFXMMU_SR register.

Bit 1  **CB1OF**: Clear buffer 1 overflow flag
Writing 1 clears the buffer 1 overflow flag in the GFXMMU_SR register.

Bit 0  **CB0OF**: Clear buffer 0 overflow flag
Writing 1 clears the buffer 0 overflow flag in the GFXMMU_SR register.

21.6.5  GFXMMU default value register (GFXMMU_DVR)

Address offset: 0x0010
Reset value: 0x0000 0000

Bits 31:2  Reserved, must be kept at reset value.

Bit 1  **FI**: Force invalidate
When set, the cache entries are invalidated. This bit is reset by hardware when the invalidation is complete. Write 0 has no effect.
0: Invalidation process complete
1: Force invalidation/invalidation process on going

Bit 0  **FF**: Force flush
When set, the cache entries are flushed. This bit is reset by hardware when the flushing is complete. Write 0 has no effect.
0: Flushing process complete
1: Force flush/flushing process on going

Bits 31:0  **DV[31:0]**: Default value
This field indicates the default 32-bit value which is returned when a master accesses a virtual memory location not physically mapped.

</table>
Refer to Section 2.3 on page 139 for the register boundary addresses.
22 Nested vectored interrupt controller (NVIC)

22.1 NVIC main features

- Up to 140 maskable interrupt channels (not including the 16 Cortex-M33 with FPU interrupt lines)
- 16 programmable priority levels (4 bits of interrupt priority used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of system control registers

The NVIC and the processor core interface are closely coupled, enabling low-latency interrupt processing and efficient processing of late arriving interrupts.

The NVIC registers are banked across secure and nonsecure states. All interrupts including the core exceptions are managed by the NVIC.

22.2 SysTick calibration value register

The Cortex-M33 with TrustZone mainline security extension embeds two SysTick timers.

When TrustZone is activated, the following SysTick timers are available:

- SysTick secure instance
- SysTick nonsecure instance

When TrustZone is disabled, only one SysTick timer is available.

The SysTick timer calibration value (STCALIB) is 0x3E8. It gives a reference time base of 1 ms based on a SysTick clock frequency of 1 MHz. In order to match the 1 ms time base for an application running at a given frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- When SysTick clock source is CPU clock HCLK
  reload value = (HCLK x STCALIB) - 1
- When SysTick clock source is external clock (HCLK/8)
  reload value = ((HCLK/8) x STCALIB) - 1

The HCLK refers to the AHB frequency value in MHz.

Example: SysTick clock source is CPU clock HCLK of 100 MHz, to match a time base of 1 ms:

  SysTick reload value = (100 x STCALIB) - 1 = 0x1869F
## 22.3 Interrupt and exception vectors

The grey rows in the table below describe the vectors without specific position.

1. Some interrupt lines are only available on some STM32U5 Series devices. Refer to the device datasheet for availability of associated peripheral. If not present, consider this interrupt line as reserved.

2. Reserved in STM32U575/585 rev. X devices. LSECSS and MSI_PLL_UNLOCK interrupt lines are available in all other revisions of STM32U575/585 and on all other STM32U5 Series devices.
23 Extended interrupts and event controller (EXTI)

The extended interrupts and event controller (EXTI) manages the individual CPU and system wake-up through configurable event inputs. It provides wake-up requests to the power control and generates an interrupt request to the CPU NVIC and events to the CPU event input. For the CPU, an additional event generation block (EVG) is needed to generate the CPU event signal.

The EXTI wake-up requests allow the system to be woken up from Stop modes.

The interrupt request and event request generation can be used also in Run modes.

The EXTI also includes the EXTI mux IO port selection.

23.1 EXTI main features

The EXTI main features are the following:

- 26 input events supported
- All event inputs allow the possibility to wake up the system.
- Events that do not have an associated wake-up flag in the peripheral, have a flag in the EXTI, and generate an interrupt to the CPU from the EXTI.
- Events can be used to generate a CPU wake-up event.

The configurable events have the following features:

- Selectable active trigger edge
- Interrupt pending status register bits independent for the rising and falling edge
- Individual interrupt and event generation mask, used for conditioning the CPU wake-up, interrupt, and event generation
- Software trigger possibility
- Secure events: The access to control and configuration bits of secure input events can be made secure and or privilege.
- EXTI IO port selection

23.2 EXTI block diagram

The EXTI consists of a register block accessed via an AHB interface, the event input trigger block, the masking block, and the EXTI mux as shown in Figure 99.

The register block contains all the EXTI registers.

The event input trigger block provides event input edge trigger logic.

The masking block provides the event input distribution to the different wake-up, interrupt and event outputs, and their masking.

The EXTI mux provides the IO port selection on to the EXTI event signal.

23.2.1 EXTI connections between peripherals and CPU

Some peripherals able to generate wake-up or interrupt events when the system is in Stop mode, are connected to the EXTI.

- Peripheral wake-up signals that generate a pulse or do not have an interrupt status bit in the peripheral, are connected to an EXTI configurable event input. For these events, the EXTI provides a status pending bit that requires to be cleared. It is the EXTI interrupt, associated with the status bit, that interrupts the CPU.
- All GPIO ports input to the EXTI multiplexer allow the selection of a port pin to wake up the system via a configurable event.

The EXTI configurable event interrupts are connected to the NVIC.

The dedicated EXTI/EVG CPU event is connected to the CPU rxev input.

The EXTI CPU wake-up signals are connected to the PWR and are used to wake up the system and the CPU subsystem bus clocks.

23.2.2 EXTI interrupt/event mapping

The EXTI lines are connected as shown in the table below.

1. Not available in STM32U535/545 devices.
2. Not available in STM32U535/545/59x/5Ax/5Fx/5Gx devices and STM32U575/585 rev. X devices. Available in all other revisions of STM32U575/585.
23.3 EXTI functional description

The events features are controlled from register bits as follows:

- Active trigger edge enabled
  - by rising edge selection in EXTI_RTSR1
  - by falling edge selection in EXTI_FTSR1
- Software trigger in EXTI_SWIER1
- Interrupt pending flag in EXTI_RPR1 and EXTI_FPR1
- CPU wake-up and interrupt enable in EXTI_IMR1
- CPU wake-up and event enable in EXTI_IMR1

23.3.1 EXTI configurable event input wake-up

The figure below is a detailed representation of the logic associated with configurable event inputs that wake up the CPU subsystem bus clocks and generate an EXTI pending flag and interrupt to the CPU, and/or a CPU wake-up event.

![Configurable event trigger logic CPU wake-up](image)

1. Only for the input events that support CPU rxev generation c_event.

The software interrupt event register allows configurable events to be triggered by software, writing the corresponding register bit, whatever the edge selection setting.

The configurable event active trigger edge (or both edges) is selected and enabled in the rising/falling edge selection registers.

The CPU has its dedicated wake-up (interrupt) mask register and a dedicated event mask registers. When the event is enabled, it is generated to the CPU. All events for the CPU are ORed together into a single CPU event signal. The event pending registers (EXTI_RPR and EXTI_FPR) are not set for an unmasked CPU event.

The configurable events have unique interrupt pending request registers. The pending register is only set for an unmasked interrupt. Each configurable event provides a common interrupt to the CPU. The configurable event interrupts must be acknowledged by software in the EXTI_RPR and/or EXTI_FPR registers.
When a CPU wake-up (interrupt) or CPU event is enabled, the asynchronous edge detection circuit is reset by the clocked delay and rising edge detect pulse generator. This guarantees that the EXTI hclk clock is woken up before the asynchronous edge detection circuit is reset.

Note: A detected configurable event interrupt pending request can be cleared by the CPU with the correct access permission. The system is not able to enter into low-power modes as long as an interrupt pending request is active.

### 23.3.2 EXTI mux selection

The EXTI mux allows the selection of GPIOs as interrupts and wake-up. GPIOs are connected via 16 EXTI mux lines to the first 16 EXTI events as configurable event. The selection of GPIO port as EXTI mux output is controlled in EXTI_EXTICRm.

![EXTI mux GPIO selection](image)

The EXTI mux outputs are available as output signals from the EXTI to trigger other peripherals, whatever the masking in EXTI_IMR and EXTI_EMR registers.

### 23.4 EXTI functional behavior

The configurable events are enabled by enabling at least one of the trigger edges. Once an event input is enabled, the CPU wake-up generation is conditioned by the CPU interrupt mask and CPU event mask.

<table>
<thead>
<tr>
<th>CPU interrupt enable (in EXTI_IMR.IMn)</th>
<th>CPU event enable (in EXTI_EMR.Emn)</th>
<th>Configurable event inputs (in EXTI_RPR,RPIFn and EXTI_FPR,FPIFn)</th>
<th>Exti(n) interrupt(1)</th>
<th>CPU event</th>
<th>CPU wake-up</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>No</td>
<td>Masked</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>No</td>
<td>Masked</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
For configurable event inputs, when the enabled edges occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding pending bits RPIFn in EXTI_RPR and/or FPIFn in EXTI_FPR is/are set: the CPU subsystem is woken up, and the CPU interrupt signal is activated. RPIFn and/or FPIFn must be cleared by the software writing them/it to one. This action clears the CPU interrupt.

For the configurable event inputs, an event request can be generated by software when writing a 1 in the software interrupt/event register EXTI_SWIER, allowing the generation of a rising edge on the event. The rising edge event pending bit is set in EXTI_RPR, whatever the setting in EXTI_RTSR.

### 23.5 EXTI event protection

The EXTI is able to protect event register bits from being modified by nonsecure and unprivileged accesses. The protection is individually activated per input event via the register bits in EXTI_SECCFGR and EXTI_PRIVCFGR. At EXTI level, the protection consists in preventing the following unauthorized write access:

- Change the settings of the secure and/or privileged configurable events.
- Change the masking of the secure and/or privileged input events.
- Clear pending status of the secure and/or privileged input events.

### Table 189. Register protection overview

</tr>
</tbody>
</table>
23.5.1 EXTI security protection

When security is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a secure access. A nonsecure write access is discarded and a read returns 0.

When input events are nonsecure, the security is disabled. The associated input event configuration and control bits can be modified and read by a secure access and nonsecure access.

The security configuration in registers EXTI_SECCFGR can be globally locked after reset by LOCK in EXTI_LOCKR.

23.5.2 EXTI privilege protection

When privilege is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a privileged access. An unprivileged write access is discarded, and a read access returns 0.

When input events are unprivileged, the privilege is disabled. The associated input event configuration and control bits can be modified and read by a privileged access and unprivileged access.

The privileged configuration in EXTI_PRIVCFGR registers can be globally locked after reset by LOCK in EXTI_LOCKR.
23.6 EXTI registers

The EXTI register map is divided in the following sections:

<table>
<thead>
<tr>
<th>Address offset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x000 - 0x01C</td>
<td>General configurable event [22:0] configuration</td>
</tr>
<tr>
<td>0x060 - 0x06C</td>
<td>EXTI IO port mux selection</td>
</tr>
<tr>
<td>0x070</td>
<td>EXTI protection lock configuration</td>
</tr>
<tr>
<td>0x080 - 0x0BC</td>
<td>CPU input event configuration</td>
</tr>
</tbody>
</table>

All registers can be accessed with word (32-bit), half-word (16-bit), and byte (8-bit) access.

23.6.1 EXTI rising trigger selection register (EXTI_RTSR1)

Address offset: 0x000
Reset value: 0x0000 0000

This register contains only bits for configurable events.

<table>
<thead>
<tr>
<th>Bits 31:26</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW RW RW RW RW RW RW RW RW RW RW RW RW RW RW</td>
<td>RT15 RT14 RT13 RT12 RT11 RT10 RT0</td>
</tr>
</tbody>
</table>

Bits 31:26: Reserved, must be kept at reset value.

Bits 25:0: **RTx**: Rising trigger event configuration bit of configurable event input x \(^{(1)}\) (x = 25 to 0)

- When EXTI_SECCFGR.SECx is disabled, RTx can be accessed with nonsecure and secure access.
- When EXTI_SECCFGR.SECx is enabled, RTx can only be accessed with secure access.
- Nonsecure write to this bit x is discarded and nonsecure read returns 0.
- When EXTI_PRIVCFGR.PRIVx is disabled, RTx can be accessed with unprivileged and privileged access.
- When EXTI_PRIVCFGR.PRIVx is enabled, RTx can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.

0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

**Note:** RT25, RT24, and RT23 bits are only available on some devices in the STM32U5 Series. Refer to the EXTI line connections table for its availability. If not present, consider this bit as reserved and keep at reset value.

1. The configurable event inputs are edge triggered. No glitch must be generated on these inputs. If a rising edge on the configurable event input occurs during writing of the register, the associated pending bit is not set. Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.
23.6.2 EXTI falling trigger selection register (EXTI_FTSR1)

Address offset: 0x004
Reset value: 0x0000 0000

This register contains only bits for configurable events.

<table>
<thead>
<tr>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **FTx:** Falling trigger event configuration bit of configurable event input \(x\) \(^{(1)}\) \(x = 25\) to 0

When EXTI_SECCFGR.SECx is disabled, FTx can be accessed with nonsecure and secure access.

When EXTI_SECCFGR.SECx is enabled, FTx can only be accessed with secure access. Nonsecure write to this FTx is discarded, nonsecure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.

0: Falling trigger disabled (for event and interrupt) for input line
1: Falling trigger enabled (for event and interrupt) for input line.

**Note:** FT25, FT24, and FT23 bits are only available on some devices in the STM32U5 Series. Refer to the EXTI line connections table for its availability. If not present, consider this bit as reserved and keep at reset value.

1. The configurable event inputs are edge triggered. No glitch must be generated on these inputs. If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set. Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

23.6.3 EXTI software interrupt event register (EXTI_SWIER1)

Address offset: 0x008
Reset value: 0x0000 0000

This register contains only bits for configurable events.

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 RPIFx: configurable event inputs x rising edge pending bit (x = 25 to 0)

- When EXTI_SECCFGR.SECx is disabled, RPIFx can be accessed with nonsecure and secure access.
- When EXTI_SECCFGR.SECx is enabled, RPIFx can only be accessed with secure access. Nonsecure write to this RPIFx is discarded, nonsecure read returns 0.
- When EXTI_PRIVCFGR.PRIVx is disabled, RPIFx can be accessed with nonprivileged and privileged access.
- When EXTI_PRIVCFGR.PRIVx is enabled, RPIFx can only be accessed with privileged access. Unprivileged write to this RPIFx is discarded, unprivileged read returns 0.

0: No rising edge trigger request occurred
1: Rising edge trigger request occurred

This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

Note: RPIF25, RPIF24, and RPIF23 bits are only available on some devices in the STM32U5 Series. Refer to the EXTI line connections table for its availability. If not present, consider this bit as reserved and keep at reset value.
23.6.5 EXTI falling edge pending register (EXTI_FPR1)

Address offset: 0x010
Reset value: 0x0000 0000

This register contains only bits for configurable events.

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 FPIFx: configurable event inputs x falling edge pending bit (x = 25 to 0)
- When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with nonsecure and secure access.
- When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access. Nonsecure write to this FPIFx is discarded, nonsecure read returns 0.
- When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privileged access.
- When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privileged access. Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.

0: No falling edge trigger request occurred
1: Falling edge trigger request occurred

This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

Note: FPIF25, FPIF24, and FPIF23 bits are only available on some devices in the STM32U5 Series. Refer to the EXTI line connections table for its availability. If not present, consider this bit as reserved and keep at reset value.

23.6.6 EXTI security configuration register (EXTI_SECCFGR1)

Address offset: 0x014
Reset value: 0x0000 0000

This register provides write access security, a nonsecure write access is ignored and causes the generation of an illegal access event. A nonsecure read returns the register data. This register contains only bits for security capable input events.

**Bits 31:24 EXTI{4*(m-1)+3}[7:0]: EXTI{4*(m-1)+3} GPIO port selection**

These bits are written by software to select the source input for EXTI{4*(m-1)+3} external interrupt.

- When EXTI_SECCFGR.SEC{4*(m-1)+3} is disabled, this field can be accessed with nonsecure and secure access.
- When EXTI_SECCFGR.SEC{4*(m-1)+3} is enabled, this field can only be accessed with secure access. Nonsecure write is discarded, and nonsecure read returns 0.
- When EXTI_PRIVCFGR.PRIV{4*(m-1)+3} is enabled, this field can only be accessed with privileged access. Nonprivileged write to this bit is discarded.
- When EXTI_PRIVCFGR.PRIV{4*(m-1)+3} is enabled, this field can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0x00: PA[{4*(m-1)+3}] pin
0x01: PB[{4*(m-1)+3}] pin
0x02: PC[{4*(m-1)+3}] pin
0x03: PD[{4*(m-1)+3}] pin
0x04: PE[{4*(m-1)+3}] pin
0x05: PF[{4*(m-1)+3}] pin
0x06: PG[{4*(m-1)+3}] pin
0x07: PH[{4*(m-1)+3}] pin
0x08: PI[{4*(m-1)+3}] pin
0x09: PJ[{4*(m-1)+3}] pin
Others: reserved
Bits 23:16  **EXTI(4*(m-1)+2)[7:0]**: EXTI(4*(m-1)+2) GPIO port selection

These bits are written by software to select the source input for the EXTI(4*(m-1)+2) external interrupt.

When EXTI_SECCFGR.SEC(4*(m-1)+2) is disabled, this field can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SEC(4*(m-1)+2) is enabled, this field can only be accessed with secure access. Nonsecure write is discarded, and nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIV(4*(m-1)+2) is disabled, this field can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIV(4*(m-1)+2) is enabled, this field can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0x03: PD[(4*(m-1)+2)] pin
0x04: PE[(4*(m-1)+2)] pin
0x05: PF[(4*(m-1)+2)] pin
0x06: PG[(4*(m-1)+2)] pin
0x07: PH[(4*(m-1)+2)] pin
0x08: PI[(4*(m-1)+2)] pin
0x09: PJ[(4*(m-1)+2)] pin
Others: reserved

Bits 15:8  **EXTI(4*(m-1)+1)[7:0]**: EXTI(4*(m-1)+1) GPIO port selection

These bits are written by software to select the source input for EXTI(4*(m-1)+1) external interrupt.

When EXTI_SECCFGR.SEC(4*(m-1)+1) is disabled, this field can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SEC(4*(m-1)+1) is enabled, this field can only be accessed with secure access. Nonsecure write is discarded and nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIV(4*(m-1)+1) is disabled, this field can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIV(4*(m-1)+1) is enabled, this field can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0x00: PA[(4*(m-1)+1)] pin
0x01: PB[(4*(m-1)+1)] pin
0x02: PC[(4*(m-1)+1)] pin
0x03: PD[(4*(m-1)+1)] pin

23.6.9 **EXTI lock register (EXTI_LOCKR)**

Address offset: 0x070

Reset value: 0x0000 0000

This register provides write access security: a nonsecure write access is ignored, a read access returns zero data, and both generates an illegal access event.

<table>
<thead>

Bits 31:1 Reserved, must be kept at reset value.

- **Bit 0 LOCK**: Global security and privilege configuration registers (EXTI_SECCFGR and EXTI_PRIVCFGR) lock
  - This bit is written once after reset.
  - 0: Security and privilege configuration open, can be modified.
  - 1: Security and privilege configuration locked, can no longer be modified.
### 23.6.10 EXTI CPU wake-up with interrupt mask register (EXTI_IMR1)

Address offset: 0x080  
Reset value: 0x0000 0000

This register contains bits for configurable events.

</tbody>
</table>

Bits 31:26 Reserved, must be kept at reset value.

**Bits 25:0 IMx:** CPU wake-up with interrupt mask on event input x \(^{(1)}\) (x = 25 to 0)

- When EXTI_SECCFGR.SECx is disabled, IMx can be accessed with nonsecure and secure access.
- When EXTI_SECCFGR.SECx is enabled, IMx can only be accessed with secure access.
- Nonsecure write to this bit is discarded and nonsecure read returns 0.
- When EXTI_PRIVCFGR.PRIVx is disabled, IMx can be accessed with privileged and unprivileged access.
- When EXTI_PRIVCFGR.PRIVx is enabled, IMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0: Wake-up with interrupt request from input event x is masked.  
1: Wake-up with interrupt request from input event x is unmasked.

**Note:** IM25, IM24, and IM23 bits are only available on some devices in the STM32U5 Series. Refer to the EXTI line connections table for its availability. If not present, consider this bit as reserved and keep at reset value.

---

1. The reset value for configurable event inputs is set to 0 in order to disable the interrupt by default.

### 23.6.11 EXTI CPU wake-up with event mask register (EXTI_EMR1)

</tbody>
</table>

Bits 31:26 Reserved, must be kept at reset value.
Bits 25:0 **EMx**: CPU wake-up with event generation mask on event input x (x = 25 to 0)

When EXTI_SECCFGR.SECx is disabled, EMx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, EMx can only be accessed with secure access.
Nonsecure write to this bit x is discarded and nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, EMx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, EMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.
0: Wake-up with event generation from line x is masked.
1: Wake-up with event generation from line x is unmasked.

Note: EM25, EM24, and EM23 bits are only available on some devices in the STM32U5 Series. Refer to the EXTI line connections table for its availability. If not present, consider this bit as reserved and keep at reset value.

### 23.6.12 EXTI register map

| Offset | Register name         | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Refer to Section 2.3 for the register boundary addresses.
24 Cyclic redundancy check calculation unit (CRC)

24.1 Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

24.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  \[X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^{8} + X^{7} + X^{5} + X^{4} + X^{2} + X + 1\]
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-, 16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of CRC_DR register that can be accessed by words, right-aligned half-words and right-aligned bytes
24.3 CRC functional description

24.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit accesses are allowed.

The duration of the computation depends on data width:
- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait states due to the previous CRC calculation.
The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register.

For example, 0x1A2B3C4D input data are used for CRC calculation as:
- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register.

The input data can be reversed to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register.

For example, 0x1A2B3C4D input data are used for CRC calculation as:
- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register.

The operation is done at bit level. For example, 0x11223344 output data are converted to 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

**Polynomial programmability**

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

Note: The type of an even polynomial is \( X + X^2 + \ldots + X^n \), while the type of an odd polynomial is \( 1 + X + X^2 + \ldots + X^n \).

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size cannot be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.
24.4 **CRC registers**

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes. For the other registers only 32-bit accesses are allowed.

### 24.4.1 CRC data register (CRC_DR)

Address offset: 0x00  
Reset value: 0xFFFF FFFF

|    | rw | rw | rw | rw | rw | rs |

Bits 31:8 Reserved, must be kept at reset value.

- Bit 7 **REV_OUT**: Reverse output data  
  0: Bit order not affected  
  1: Bit-reversed output format

Bits 6:5 **REV_IN[1:0]**: Reverse input data  
  00: Bit order not affected  
  01: Bit reversal done by byte  
  10: Bit reversal done by half-word  
  11: Bit reversal done by word

Bits 4:3 **POLYSIZE[1:0]**: Polynomial size  
  00: 32 bit polynomial  
  01: 16 bit polynomial  
  10: 8 bit polynomial  
  11: 7 bit polynomial

Bits 2:1 Reserved, must be kept at reset value.

- Bit 0 **RESET**: RESET bit  
  This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by hardware.
24.4.4 CRC initial value (CRC_INIT)

Address offset: 0x10
Reset value: 0xFFFF FFFF

Bits 31:0 CRC_INIT[31:0]: Programmable initial CRC value
This register is used to write the CRC initial value.

24.4.5 CRC polynomial (CRC_POL)

Address offset: 0x14
Reset value: 0x04C1 1DB7

Bits 31:0 POL[31:0]: Programmable polynomial
This register is used to write the coefficients of the polynomial to be used for CRC calculation.
If the polynomial size is less than 32 bits, the least significant bits have to be used to program the correct value.

Refer to Section 2.3 on page 139 for the register boundary addresses.
25 **CORDIC co-processor (CORDIC)**

25.1 **CORDIC introduction**

The CORDIC co-processor provides hardware acceleration of mathematical functions (mainly trigonometric ones) commonly used in motor control, metering, signal processing and many other applications.

It speeds up the calculation of these functions compared to a software implementation, making it possible the use of a lower operating frequency, or freeing up processor cycles in order to perform other tasks.

25.2 **CORDIC main features**

- 24-bit CORDIC rotation engine
- Circular and Hyperbolic modes
- Rotation and Vectoring modes
- Functions: sine, cosine, sinh, cosh, atan, atan2, tanh, modulus, square root, natural logarithm
- Programmable precision
- Low latency AHB slave interface
- Results can be read as soon as ready, without polling or interrupt
- DMA read and write channels
- Multiple register read/write by DMA

25.3 **CORDIC functional description**

25.3.1 **General description**

The CORDIC is a cost-efficient successive approximation algorithm for evaluating trigonometric and hyperbolic functions.

In trigonometric (circular) mode, the sine and cosine of an angle $\theta$ are determined by rotating the unit vector $[1, 0]$ through decreasing angles until the cumulative sum of the rotation angles equals the input angle $\theta$. The x and y cartesian components of the rotated vector then correspond, respectively, to the cosine and sine of $\theta$. Inversely, the angle of a vector $[x, y]$ corresponding to arctangent ($y / x$), is determined by rotating $[x, y]$ through successively decreasing angles to obtain the unit vector $[1, 0]$. The cumulative sum of the rotation angles gives the angle of the original vector.

The CORDIC algorithm can also be used for calculating hyperbolic functions (sinh, cosh, atanh), by replacing the successive circular rotations by steps along a hyperbole.

Other functions can be derived from the basic functions described above.

25.3.2 **CORDIC functions**

The first step when using the co-processor is to select the required function, by programming the FUNC field of the CORDIC_CR register accordingly.
Table 194 lists the functions supported by the CORDIC co-processor.

</tbody>
</table>

Several functions take two input arguments (ARG1 and ARG2) and some generate two results (RES1 and RES2) simultaneously. This is a side-effect of the algorithm and means that only one operation is needed to obtain two values. This is the case, for example, when performing polar-to-rectangular conversion: $\sin \theta$ also generates $\cos \theta$, $\cos \theta$ also generates $\sin \theta$. Similarly for rectangular-to-polar conversion ($\arctan2(x,y)$, modulus($x,y$)) and for hyperbolic functions ($\cosh \theta$, $\sinh \theta$).

Note: The exponential function, $\exp x$, can be obtained as the sum of $\sinh x$ and $\cosh x$. Furthermore, base $N$ logarithms, $\log_N x$, can be derived by multiplying $\ln x$ by a constant $K$, where $K = 1/\ln N$.

For certain functions (atan, log, sqrt) a scaling factor (see Section 25.3.4) can be applied to extend the range of the function beyond the maximum $[-1, 1]$ supported by the q1.31 fixed point format. The scaling factor must be set to 0 for all other circular functions, and to 1 for hyperbolic functions.

Cosine

Table 195. Cosine parameters

<table>
<thead>
<tr>

<tr>
<td>RES1</td>
<td>$m \cdot \cos \theta$</td>
<td>$[-1, 1]$</td>
</tr>
</tbody>
</table>
This function calculates the cosine of an angle in the range $-\pi$ to $\pi$. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle $\theta$ in radians. It must be divided by $\pi$ before programming ARG1.

The secondary argument is the modulus $m$. If $m$ is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the cosine of the angle, multiplied by the modulus.

The secondary result, RES2, is the sine of the angle, multiplied by the modulus.

**Sine**

<table>
<thead>
<tr>
<th>Parameter</th>

<td>$m \cdot \sin \theta$</td>
<td>[-1, 1]</td>
</tr>
<tr>
<td>SCALE</td>
<td>Not applicable</td>
<td>0</td>
</tr>
</tbody>
</table>

This function calculates the sine of an angle in the range $-\pi$ to $\pi$. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle $\theta$ in radians. It must be divided by $\pi$ before programming ARG1.

The secondary argument is the modulus $m$. If $m$ is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the sine of the angle, multiplied by the modulus.

The secondary result, RES2, is the cosine of the angle, multiplied by the modulus.

**Phase**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Range</th>

<td>y coordinate</td>
<td>[-1, 1]</td>
</tr>
<tr>
<td>RES1</td>
<td>Phase angle $\theta$ in radians, divided by $\pi$</td>
<td>[-1, 1]</td>
</tr>
</tbody>
</table>
This function calculates the phase angle in the range \(-\pi\) to \(\pi\) of a vector \(\mathbf{v} = [x, y]\) (also known as \(\text{atan2}(y, x)\)). It can also be used to perform rectangular to polar conversion.

The primary argument is the \(x\) coordinate, that is, the magnitude of the vector in the direction of the \(x\) axis. If \(|x| > 1\), a scaling must be applied in software to adapt it to the q1.31 range of \(\text{ARG1}\).

The secondary argument is the \(y\) coordinate, that is, the magnitude of the vector in the direction of the \(y\) axis. If \(|y| > 1\), a scaling must be applied in software to adapt it to the q1.31 range of \(\text{ARG2}\).

The primary result, \(\text{RES1}\), is the phase angle \(\theta\) of the vector \(\mathbf{v}\). \(\text{RES1}\) must be multiplied by \(\pi\) to obtain the angle in radians. Note that values close to \(\pi\) may sometimes wrap to \(-\pi\) due to the circular nature of the phase angle.

The secondary result, \(\text{RES2}\), is the modulus, given by: \(|\mathbf{v}| = \sqrt{x^2 + y^2}\). If \(|\mathbf{v}| > 1\) the result in \(\text{RES2}\) is saturated to 1.

**Modulus**

<table>
<thead>
<tr>

<td>0</td>
</tr>
</tbody>
</table>

This function calculates the magnitude, or modulus, of a vector \(\mathbf{v} = [x, y]\). It can also be used to perform rectangular to polar conversion.

The primary argument is the \(x\) coordinate, that is, the magnitude of the vector in the direction of the \(x\) axis. If \(|x| > 1\), a scaling must be applied in software to adapt it to the q1.31 range of \(\text{ARG1}\).

The secondary argument is the \(y\) coordinate, that is, the magnitude of the vector in the direction of the \(y\) axis. If \(|y| > 1\), a scaling must be applied in software to adapt it to the q1.31 range of \(\text{ARG2}\).

The primary result, \(\text{RES1}\), is the modulus, given by: \(|\mathbf{v}| = \sqrt{x^2 + y^2}\). If \(|\mathbf{v}| > 1\) the result in \(\text{RES1}\) is saturated to 1.

The secondary result, \(\text{RES2}\), is the phase angle \(\theta\) of the vector \(\mathbf{v}\). \(\text{RES2}\) must be multiplied by \(\pi\) to obtain the angle in radians. Note that values close to \(\pi\) may sometimes wrap to \(-\pi\) due to the circular nature of the phase angle.
### Arctangent

This function calculates the arctangent, or inverse tangent, of the input argument \( x \).

The primary argument, ARG1, is the input value, \( x = \tan \theta \). If \(|x| > 1\), a scaling factor of \( 2^{-n} \) must be applied in software such that \(-1 < x \cdot 2^{-n} < 1\). The scaled value \( x \cdot 2^{-n} \) is programmed in ARG1 and the scale factor \( n \) must be programmed in the SCALE parameter.

Note that the maximum input value allowed is \( \tan \theta = 128 \), which corresponds to an angle \( \theta = 89.55 \) degrees. For \(|x| > 128\), a software method must be used to find \( \tan^{-1} x \).

The secondary argument, ARG2, is unused.

The primary result, RES1, is the angle \( \theta = \tan^{-1} x \). RES1 must be multiplied by \( 2^n \cdot \pi \) to obtain the angle in radians.

The secondary result, RES2, is unused.

### Hyperbolic cosine

This function calculates the hyperbolic cosine of a hyperbolic angle \( x \). It can also be used to calculate the exponential functions \( e^x = \cosh x + \sinh x \), and \( e^{-x} = \cosh x - \sinh x \).

The primary argument is the hyperbolic angle \( x \). Only values of \( x \) in the range \(-1.118 \) to \(+1.118\) are supported. Since the minimum value of \( \cosh x \) is 1, which is beyond the range of the q1.31 format, a scaling factor of \( 2^n \) must be applied in software. The factor \( n = 1 \) must be programmed in the SCALE parameter.

The secondary argument is not used.

#### Table 200. Hyperbolic cosine parameters

</tr>
</tbody>
</table>

This function calculates the hyperbolic sine of a hyperbolic angle \( x \). It can also be used to calculate the exponential functions \( e^x = \cosh x + \sinh x \), and \( e^{-x} = \cosh x - \sinh x \).

The primary argument is the hyperbolic angle \( x \). Only values of \( x \) in the range \(-1.118\) to \(+1.118\) are supported. For all input values, a scaling factor of \( 2^{-n} \) must be applied in software, where \( n = 1 \). The scaled value \( x \cdot 0.5 \) is programmed in ARG1 and the factor \( n = 1 \) must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic sine, \( \sinh x \). RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic cosine, \( \cosh x \). RES2 must be multiplied by 2 to obtain the correct result.

**Hyperbolic arctangent**

<table>
<thead>
<tr>

</tbody>
</table>

This function calculates the hyperbolic arctangent of the input argument \( x \).

The primary argument is the input value \( x \). Only values of \( x \) in the \(-0.806\) to \(+0.806\) range are supported. The value \( x \) must be scaled by a factor \( 2^{-n} \), where \( n = 1 \). The scaled value \( x \cdot 2^{-n} \) must be programmed in ARG1 and the factor \( n = 1 \) must be programmed in the SCALE parameter.
x · 0.5 is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result is the hyperbolic arctangent, \(\text{atanh} \ x\). RES1 must be multiplied by 2 to obtain the correct value.

The secondary result is not used.

**Natural logarithm**

<table>
<thead>

</tr>
</tbody>
</table>

This function calculates the natural logarithm of the input argument \(x\).

The primary argument is the input value \(x\). Only values of \(x\) in the range 0.107 to 9.35 are supported. The value \(x\) must be scaled by a factor \(2^{-n}\), such that \(x \cdot 2^{-n} < 1 - 2^{-n}\). The scaled value \(x \cdot 2^{-n}\) is programmed in ARG1 and the factor \(n\) must be programmed in the SCALE parameter.

*Table 204* lists the valid scaling factors, \(n\), and the corresponding ranges of \(x\) and ARG1.

<table>
<thead>
<tr>
<th>(n)</th>

<td>0.4375 ≤ ARG1 ≤ 0.585</td>
</tr>
</tbody>
</table>

The secondary argument is not used.

The primary result is the square root of x. RES1 must be multiplied by 2ⁿ to obtain the correct value.

The secondary result is not used.

25.3.3 Fixed point representation

The CORDIC operates in fixed point signed integer format. Input and output values can be either q1.31 or q1.15.

In q1.31 format, numbers are represented by one sign bit and 31 fractional bits (binary decimal places). The numeric range is therefore -1 (0x80000000) to 1 - 2⁻³¹ (0x7FFFFFFF).

In q1.15 format, the numeric range is 1 (0x8000) to 1 - 2⁻¹⁵ (0x7FFF). This format has the advantage that two input arguments can be packed into a single 32-bit write, and two results can be fetched in one 32-bit read.

25.3.4 Scaling factor

Several of the functions listed in Section 25.3.2 specify a scaling factor, SCALE. This allows the function input range to be extended to cover the full range of values supported by the CORDIC, without saturating the input, output or internal registers. If the scaling factor is
required, it has to be calculated in software and programmed into the SCALE field of the CORDIC_CSR register. The input arguments must be scaled accordingly before programming the scaled values in the CORDIC_WDATA register. The scaling must also be undone on the results read from the CORDIC_RDATA register.

Note: The scaling factor entails a loss of precision due to truncation of the scaled value.

25.3.5 Precision

The precision of the result is dependent on the number of CORDIC iterations. The algorithm converges at a constant rate of one binary digit per iteration for trigonometric functions (sine, cosine, phase, modulus), see Figure 103.

For hyperbolic functions (hyperbolic sine, hyperbolic cosine, natural logarithm), the convergence rate is less constant due to the peculiarities of the CORDIC algorithm (see Figure 104). The square root function converges at roughly twice the speed of the hyperbolic functions (see Figure 105).

Figure 103. CORDIC convergence for trigonometric functions
Figure 104. CORDIC convergence for hyperbolic functions
The convergence rate decreases as the quantization error starts to become significant.

The CORDIC can perform four iterations per clock cycle. For each function, the maximum error remaining after every four iterations is shown in Table 207, together with the number of clock cycles required to reach that precision. From this table, the desired number of cycles can be determined and programmed in the PRECISION field of the CORDIC_CR register. The co-processor stops as soon as the programmed number of iterations has completed, and the result can be read immediately.

**Table 207. Precision vs. number of iterations**

<table>
<thead>
<tr>

<td>$2^{-19}$</td>
</tr>
</tbody>
</table>
The fastest way to use the co-processor is to pre-program the CORDIC_CSR register with the function to be performed (FUNC), the desired number of clock cycles (PRECISION), the size of the input and output values (ARGSIZE, RESSIZE), the number of input arguments (NARGS) and/or results (NRES), and the scaling factor (SCALE), if applicable. Subsequently, a calculation is triggered by writing the input arguments to the CORDIC_WDATA register. As soon as the correct number of input arguments has been written (and any ongoing calculation has finished) a new calculation is launched using these input arguments and the current CORDIC_CSR settings. There is no need to re-program the CORDIC_CSR register if there is no change.

If a dual 32-bit input argument is needed (ARGSIZE = 0, NARGS = 1), the primary input argument, ARG1, must be written first, followed by the secondary argument, ARG2. If the secondary argument remains unchanged for a series of calculations, the second write can be avoided, by reprogramming the number of arguments to one (NARGS = 0), once the first calculation has started. The secondary argument retains its programmed value as long as the function is not changed.

Note: ARG2 is set to +1 (0x7FFFFFFF) after a reset.

If two 16-bit arguments are used (ARGSIZE = 1) they must be packed into a 32-bit word, with ARG1 in the least significant half-word and ARG2 in the most significant half-word. The packed 32-bit word is then written to the CORDIC_WDATA register. Only one write is needed in this case (NARGS = 0).

For functions taking only one input argument, ARG1, it is recommended to set NARGS = 0. If NARGS = 1, a second write to CORDIC_WDATA must be performed to trigger the calculation. The ARG2 data in this case is not used.

### 25.3.6 Zero-overhead mode

The fastest way to use the co-processor is to pre-program the CORDIC_CSR register with the function to be performed (FUNC), the desired number of clock cycles (PRECISION), the size of the input and output values (ARGSIZE, RESSIZE), the number of input arguments (NARGS) and/or results (NRES), and the scaling factor (SCALE), if applicable.

Subsequently, a calculation is triggered by writing the input arguments to the CORDIC_WDATA register. As soon as the correct number of input arguments has been written (and any ongoing calculation has finished) a new calculation is launched using these input arguments and the current CORDIC_CSR settings. There is no need to re-program the CORDIC_CSR register if there is no change.

If a dual 32-bit input argument is needed (ARGSIZE = 0, NARGS = 1), the primary input argument, ARG1, must be written first, followed by the secondary argument, ARG2. If the secondary argument remains unchanged for a series of calculations, the second write can be avoided, by reprogramming the number of arguments to one (NARGS = 0), once the first calculation has started. The secondary argument retains its programmed value as long as the function is not changed.

Note: ARG2 is set to +1 (0x7FFFFFFF) after a reset.

If two 16-bit arguments are used (ARGSIZE = 1) they must be packed into a 32-bit word, with ARG1 in the least significant half-word and ARG2 in the most significant half-word. The packed 32-bit word is then written to the CORDIC_WDATA register. Only one write is needed in this case (NARGS = 0).

For functions taking only one input argument, ARG1, it is recommended to set NARGS = 0. If NARGS = 1, a second write to CORDIC_WDATA must be performed to trigger the calculation. The ARG2 data in this case is not used.
Once the calculation starts, any attempt to read the CORDIC_RDATA register inserts bus wait states until the calculation is completed, before returning the result. Hence it is possible for the software to write the input and immediately read the result without polling to see if it is valid. Alternatively, the processor can wait for the appropriate number of clock cycles before reading the result. This time can be used to program the CORDIC_CSR register for the next calculation and prepare the next input data, if needed. The CORDIC_CSR register can be re-programmed while a calculation is in progress, without affecting the result of the ongoing calculation. In the same way, the CORDIC_WDATA register can be updated with the next argument(s) once the previous arguments have been taken into account. The next arguments and settings remain pending until the previous calculation has completed.

When a calculation is finished, the result(s) can be read from the CORDIC_RDATA register. If two 32-bit results are expected (NRES = 1, RESSIZE = 0), the primary result (RES1) is read out first, followed by the secondary result (RES2). If only one 32-bit result is expected (NRES = 0, RESSIZE = 0), then RES1 is output on the first read.

If 16-bit results are expected (RESSIZE = 1), a single read to CORDIC_RDATA fetches both results packed into a 32-bit word. RES1 is in the lower half-word, and RES2 in the upper half-word. In this case, it is recommended to program NRES = 0. If NRES = 1, a second read of CORDIC_RDATA must be performed in order to free up the CORDIC for the next operation. The data from this second read must be discarded.

The next calculation starts when the expected number of results has been read, provided the expected number of arguments has been written. This means that at any time, there can be one calculation in progress, or waiting for the results to be read, and one operation pending. Any further access to CORDIC_WDATA while an operation is pending, cancels the pending operation and overwrite the data.

The following sequence summarizes the use of the CORDIC_IP in zero-overhead mode:

1. Program the CORDIC_CSR register with the appropriate settings
2. Program the argument(s) for the first calculation in the CORDIC_WDATA register. This launches the first calculation.
3. If needed, update the CORDIC_CSR register settings for the next calculation.
4. Program the argument(s) for the next calculation in the CORDIC_WDATA register.
5. Read the result(s) from the CORDIC_RDATA register. This triggers the next calculation.
6. Go to step 3.

### 25.3.7 Polling mode

When a new result is available in the CORDIC_RDATA register, the RRDY flag is set in the CORDIC_CSR register. The flag can be polled by reading the register. It is reset by reading the CORDIC_RDATA register (once or twice depending on the NRES field of the CORDIC_CSR register).

Polling the RRDY flag takes slightly longer than reading the CORDIC_RDATA register directly, since the result is not read as soon as it is available. However the processor and bus interface are not stalled while reading the CORDIC_CSR register, so this mode may be of interest if stalling the processor is not acceptable (e.g. if low latency interrupts must be serviced).
25.3.8 Interrupt mode

By setting the interrupt enable (IE) bit in the CORDIC_CSR register, an interrupt is generated whenever the RRDY flag is set. The interrupt is cleared when the flag is reset.

This mode allows the result of the calculation to be read under interrupt service routine, and hence given a priority relative to other tasks. However it is slower than directly reading the result, or polling the flag, due to the interrupt handling delays.

25.3.9 DMA mode

If the DMA write enable (DMAWEN) bit is set in the CORDIC_CSR register, and no operation is pending, a DMA write channel request is generated. The DMA controller can transfer a primary input argument (ARG1) from memory into the CORDIC_WDATA register. Writing into the register deasserts the DMA request. If NARGS = 1 in the CORDIC_CSR register, a second DMA write channel request is generated to transfer the secondary input argument (ARG2) into the CORDIC_WDATA register. When all input arguments have been written, and any ongoing calculation has been completed (by reading the results), a new calculation is started and another DMA write channel request is generated.

If the DMA read enable (DMAREN) bit is set in the CORDIC_CSR register, the RRDY flag going active generates a DMA read channel request. The DMA controller can then transfer the primary result (RES1) from the CORDIC_RDATA register to memory. Reading the register deasserts the DMA request. If NRES = 1 in the CORDIC_CSR register, a second DMA request is generated to read out the secondary result (RES2). When all results have been read, the RRDY flag is deasserted.

The DMA read and write channels can be enabled separately. If both channels are enabled, the CORDIC can autonomously perform repeated calculations on a buffer of data without processor intervention. This allows the processor to perform other tasks. The DMA controller is operating in memory-to-peripheral mode for the write channel, and peripheral-to-memory mode for the read channel. Note that the sequence is started by the processor setting the DMAWEN flag. Thereafter the DMA read and write requests are generated as fast as the CORDIC can process the data.

In some cases, the input data may be stored in memory, and the output is transferred at regular intervals to another peripheral, such as a digital-to-analog converter. In this case, the destination peripheral generates a DMA request each time it needs a new data. The DMA controller can directly fetch the next sample from the CORDIC_RDATA register (in this case the DMA controller is operating in memory-to-peripheral mode, even though the source is a peripheral register). The act of reading the result allows the CORDIC to start a new calculation, which in turn generates a DMA write channel request, and the DMA controller transfers the next input value to the CORDIC_WDATA register. The DMA write channel is enabled (DMAWEN = 1), but the read channel must not be enabled.

In a similar way, data coming from another peripheral, such as an ADC, can be transferred directly to the CORDIC_WDATA register (in peripheral-to-memory mode). The DMA write channel must not be enabled. The CORDIC processes the input data and generate a DMA read request when complete, if DMAREN = 1. The DMA controller then transfers the result from CORDIC_RDATA register to memory (peripheral-to-memory mode).

Note: No DMA request is generated to program the CORDIC_CSR register. DMA mode is therefore only useful when repeatedly performing the same function with the same settings. The scale factor cannot be changed during a series of DMA transfers.
Note: Each DMA request must be acknowledged, as a result of the DMA performing an access to the CORDIC_WDATA or CORDIC_RDATA register. If an extraneous access to the relevant register occurs before this, the acknowledge is asserted prematurely, and may block the DMA channel. Therefore, when the DMA read channel is enabled, CPU access to the CORDIC_RDATA register must be avoided. Similarly, the processor must avoid accessing the CORDIC_WDATA register when the DMA write channel is enabled.

25.4 CORDIC registers

The CORDIC registers can only be accessed in 32-bit word format

25.4.1 CORDIC control/status register (CORDIC_CSR)

Address offset: 0x00
Reset value: 0x0000 0050

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>RRDY: Result ready flag</th>
</tr>
</thead>
<tbody>
<tr>
<td>0: No new data in output register</td>
<td></td>
</tr>
<tr>
<td>1: CORDIC_RDATA register contains new data.</td>
<td></td>
</tr>
</tbody>
</table>

This bit is set by hardware when a CORDIC operation completes. It is reset by hardware when the CORDIC_RDATA register is read (NRES+1) times.
When this bit is set, if the IEN bit is also set, the CORDIC interrupt is asserted. If the DMAREN bit is set, a DMA read channel request is generated. While this bit is set, no new calculation is started.

| Bit 30:23 | Reserved, must be kept at reset value. |

<table>
<thead>
<tr>
<th>Bit 22</th>
<th>ARGSIZE: Width of input data</th>
</tr>
</thead>
<tbody>
<tr>
<td>0: 32-bit</td>
<td></td>
</tr>
<tr>
<td>1: 16-bit</td>
<td></td>
</tr>
</tbody>
</table>

ARGSIZE selects the number of bits used to represent input data.
If 32-bit data is selected, the CORDIC_WDATA register expects arguments in q1.31 format.
If 16-bit data is selected, the CORDIC_WDATA register expects arguments in q1.15 format.
The primary argument (ARG1) is written to the least significant half-word, and the secondary argument (ARG2) to the most significant half-word.

<table>
<thead>
<tr>
<th>Bit 21</th>
<th>RESSIZE: Width of output data</th>
</tr>
</thead>
<tbody>
<tr>
<td>0: 32-bit</td>
<td></td>
</tr>
<tr>
<td>1: 16-bit</td>
<td></td>
</tr>
</tbody>
</table>

RESSIZE selects the number of bits used to represent output data.
If 32-bit data is selected, the CORDIC_RDATA register contains results in q1.31 format.
If 16-bit data is selected, the least significant half-word of CORDIC_RDATA contains the primary result (RES1) in q1.15 format, and the most significant half-word contains the secondary result (RES2), also in q1.15 format.
Bit 20 **NARGS**: Number of arguments expected by the CORDIC_WDATA register
- 0: Only one 32-bit write (or two 16-bit values if ARGSIZE = 1) is needed for the next calculation.
- 1: Two 32-bit values must be written to the CORDIC_WDATA register to trigger the next calculation.
Reads return the current state of the bit.

Bit 19 **NRES**: Number of results in the CORDIC_RDATA register
- 0: Only one 32-bit value (or two 16-bit values if RESSIZE = 1) is transferred to the CORDIC_RDATA register on completion of the next calculation. One read from CORDIC_RDATA resets the RRDY flag.
- 1: Two 32-bit values are transferred to the CORDIC_RDATA register on completion of the next calculation. Two reads from CORDIC_RDATA are necessary to reset the RRDY flag.
Reads return the current state of the bit.

Bit 18 **DMAWEN**: Enable DMA write channel
- 0: Disabled. No DMA write requests are generated.
- 1: Enabled. Requests are generated on the DMA write channel whenever no operation is pending.
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 17 **DMAREN**: Enable DMA read channel
- 0: Disabled. No DMA read requests are generated.
- 1: Enabled. Requests are generated on the DMA read channel whenever the RRDY flag is set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 16 **IEN**: Enable interrupt
- 0: Disabled. No interrupt requests are generated.
- 1: Enabled. An interrupt request is generated whenever the RRDY flag is set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **SCALE[2:0]**: Scaling factor
The value of this field indicates the scaling factor applied to the arguments and/or results. A value n implies that the arguments have been multiplied by a factor $2^{-n}$, and/or the results need to be multiplied by $2^n$. Refer to Section 25.3.2 for the applicability of the scaling factor for each function and the appropriate range.

Bits 7:4 **PRECISION[3:0]**: Precision required (number of iterations)
- 0: reserved
- 1 to 15: (Number of iterations)/4
To determine the number of iterations needed for a given accuracy refer to Table 207. Note that for most functions, the recommended range for this field is 3 to 6.
25.4.2 CORDIC argument register (CORDIC_WDATA)

Address offset: 0x04
Reset value: 0xXXXX XXXX

Bits 3:0 \textbf{FUNC[3:0]}: Function
0: Cosine
1: Sine
2: Phase
3: Modulus
4: Arctangent
5: Hyperbolic cosine
6: Hyperbolic sine
7: Arctanh
8: Natural logarithm
9: Square Root
10 to 15: reserved

Bits 31:0 \textbf{ARG[31:0]}: Function input arguments
This register is programmed with the input arguments for the function selected in the CORDIC_CSR register FUNC field.
If 32-bit format is selected (CORDIC_CSR.ARGSIZE = 0) and two input arguments are required (CORDIC_CSR.NARGS = 1), two successive writes are required to this register.
The first writes the primary argument (ARG1), the second writes the secondary argument (ARG2).
If 32-bit format is selected and only one input argument is required (NARGS = 0), only one write is required to this register, containing the primary argument (ARG1).
If 16-bit format is selected (CORDIC_CSR.ARGSIZE = 1), one write to this register contains both arguments. The primary argument (ARG1) is in the lower half, ARG[15:0], and the secondary argument (ARG2) is in the upper half, ARG[31:16]. In this case, NARGS must be set to 0.
Refer to Section 25.3.2 for the arguments required by each function, and their permitted range.

When the required number of arguments has been written, the CORDIC evaluates the function designated by CORDIC_CSR.FUNC using the supplied input arguments, provided any previous calculation has completed. If a calculation is ongoing, the ARG1 and ARG2 values are held pending until the calculation is completed and the results read. During this time, a write to the register cancels the pending operation and overwrite the argument data.
25.4.3 CORDIC result register (CORDIC_RDATA)

Address offset: 0x08
Reset value: 0x0000 0000

Bits 31:0 RES[31:0]: Function result

If 32-bit format is selected (CORDIC_CSR.RESSIZE = 0) and two output values are expected (CORDIC_CSR.NRES = 1), this register must be read twice when the RRDY flag is set. The first read fetches the primary result (RES1). The second read fetches the secondary result (RES2) and resets RRDY.

If 32-bit format is selected and only one output value is expected (NRES = 0), only one read of this register is required to fetch the primary result (RES1) and reset the RRDY flag.

If 16-bit format is selected (CORDIC_CSR.RESSIZE = 1), this register contains the primary result (RES1) in the lower half, RES[15:0], and the secondary result (RES2) in the upper half, RES[31:16]. In this case, NRES must be set to 0, and only one read performed. A read from this register resets the RRDY flag in the CORDIC_CSR register.

25.4.4 CORDIC register map

Refer to Section 2.3 for the register boundary addresses.
26 Filter math accelerator (FMAC)

26.1 FMAC introduction

The filter math accelerator unit performs arithmetic operations on vectors. It comprises a multiplier/accumulator (MAC) unit, together with address generation logic which allows it to index vector elements held in local memory.

The unit includes support for circular buffers on input and output, which allows digital filters to be implemented. Both finite and infinite impulse response filters can be realized.

The unit allows frequent or lengthy filtering operations to be offloaded from the CPU, freeing up the processor for other tasks. In many cases it can accelerate such calculations compared to a software implementation, resulting in a speed-up of time critical tasks.

26.2 FMAC main features

- 16 x 16-bit multiplier
- 24 + 2-bit accumulator with addition and subtraction
- 16-bit input and output data
- 256 x 16-bit local memory
- Up to three areas can be defined in memory for data buffers (two input, one output), defined by programmable base address pointers and associated size registers
- Input and output buffers can be circular
- Filter functions: FIR, IIR (direct form 1)
- Vector functions: Dot product, convolution, correlation
- AHB slave interface
- DMA read and write data channels
26.3 FMAC functional description

26.3.1 General description

The FMAC is shown in Figure 106.

The unit is built around a fixed point multiplier and accumulator (MAC). The MAC can take two 16-bit input signed values from memory, multiply them together and add them to the contents of the accumulator. The address of the input values in memory is determined using a set of pointers. These pointers can be loaded, incremented, decremented or reset by the internal hardware. The pointer and MAC operations are controlled by a built-in sequencer in order to execute the requested operation.

To calculate a dot product, the two input vectors are loaded into the local memory by the processor or DMA controller, and the requested operation is selected and started. Each pair of input vector elements is fetched from memory, multiplied together and accumulated. When all the vector elements have been processed, the contents of the accumulator are stored in the local memory, from where they can be read out by the processor or DMA.

The finite impulse response (FIR) filter operation (also known as convolution) consists in repeatedly calculating the dot product of the coefficient vector and a vector of input samples, the latter being shifted by one sample delay, with the least recent sample being discarded and a new sample added, at each repetition.

The infinite impulse response (IIR) filter operation is the convolution of the feedback coefficients with the previous output samples, added to the result of the FIR convolution.

A more detailed description of the filter operations is given in Section 26.3.6: Filter functions.
26.3.2 Local memory and buffers

The unit contains a 256 x 16-bit read/write memory which is used for local storage:

- Input values (the elements of the input vectors) are stored in two buffers, X1 and X2.
- Output values (the results of the operations) are stored in another buffer, Y.
- The locations and sizes of the buffers are designated as follows:
  - x1_base: the base address of the X1 buffer
  - x2_base: the base address of the X2 buffer
  - y_base: the base address of the Y buffer
  - x1_buf_size: the number of 16-bit addresses allocated to the X1 buffer
  - x2_buf_size: the number of 16-bit addresses allocated to the X2 buffer
  - y_buf_size: the number of 16-bit addresses allocated to the Y buffer.

These parameters are programmed in the corresponding registers when configuring the unit.

The CPU (or DMA controller) can initialize the contents of each buffer using the Initialization functions (Section 26.3.5: Initialization functions) and writing to the write data register. The data is transferred to the location within the target buffer indicated by a write pointer. After each new write, the write pointer is incremented. When the write pointer reaches the end of the allocated buffer space, it wraps back to the base address. This feature is used to load the elements of a vector prior to an operation, or to initialize a filter and load filter coefficients.

Buffer configuration

The buffer sizes and base address offsets must be configured in the X1, X2 and Y buffer configuration registers. For each function, the required buffer size is specified in the function description in Section 26.3.6: Filter functions. The base addresses can be chosen anywhere in internal memory, provided that all buffers fit within the internal memory address range (0x00 to 0xFF), that is, base address + buffer size must be less than 256.

There is no constraint on the size and location of the buffers (they can overlap or even coincide exactly). For filter functions it is recommended not to overlap buffers as this can lead to erroneous behavior.

When circular buffer operation is required, an optional “headroom”, d, can be added to the buffer size. Furthermore, a watermark level can be set, to regulate the CPU or DMA activity. The value of d and the watermark level must be chosen according to the application performance requirements. For maximum throughput, the input buffer must never go empty, so d must be somewhat greater than the watermark level, allowing for any interrupt or DMA latency. On the other hand, if the input data can not be provided as fast as the unit can process them, the buffer can be allowed to empty waiting for the next data to be written, so d can be equal to the watermark level (to ensure that no overflow occurs on the input).

26.3.3 Input buffers

The X1 and X2 buffers are used to store data for input to the MAC. Each multiplication takes a value from the X1 buffer and a value from the X2 buffer and multiplies them together. A pointer in the control unit generates the read address offset (relative to the buffer base address) for each value. The pointers are managed by hardware according to the current function.
The X1 buffer can be used as a circular buffer, in which case new data are continually transferred into the input buffer whenever space is available. Pre-loading this buffer is optional for digital filters, since if no input samples have been written in the buffer when the operation is started, it is flagged as empty, which triggers the CPU or DMA to load new samples until there are enough to begin operation. Pre-loading is nevertheless useful in the case of a vector operation, that is, the input data is already available in system memory and circular operation is not required.
The X2 buffer can only be used in vector mode (that is not circular), and needs to be pre-loaded, except if the contents of the buffer do not change from one operation to the next. For filter functions, the X2 buffer is used to store the filter coefficients.

When operating as a circular buffer, the space allocated to the buffer (x1_buf_size) must generally be bigger than the number of elements in use for the current calculation, so that there are always new values available in the buffer. Figure 108 illustrates the layout of the buffer for a filter operation. While calculating an output sample y[n], the unit uses a set of N+1 input samples, x[n-N] to x[n]. When this is finished, the unit starts the calculation of y[n+1], using the set of input samples x[n-N+1] to x[n+1]. The least-recent input sample, x[n-N], drops out of the input set, and a new sample, x[n+1], is added to it.

The processor, or DMA controller, must ensure that the new sample x[n+1] is available in the buffer space when required. If not, the buffer is flagged as empty, which stalls the execution of the unit until a new sample is added. No underflow condition is signaled on the X1 buffer.
Note: If the flow of samples is controlled by a timer or other peripheral such as an ADC, the buffer regularly goes empty, since the filter processes each new sample faster than the source can provide it. This is an essential feature of filter operation.

If the number of free spaces in the buffer is less than the watermark threshold programmed in the FULL_WM bitfield of the FMAC_X1BUFCFG register, the buffer is flagged as full. As long as the full flag is not set, interrupts are generated, if enabled, to request more data for the buffer. The watermark allows several data to be transferred under one interrupt, without danger of overflow. Nevertheless, if an overflow does occur, the OVFL error flag is set and the write data is ignored. The write pointer is not incremented in the event of an overflow.

The operation of the X1 buffer during a filtering operation is illustrated in Figure 109. This example shows an 8-tap FIR filter with a watermark set to four.

**Figure 109. Circular input buffer operation**

26.3.4 Output buffer

The Y (output) buffer is used to store the output of an accumulation. Each new output value is stored in the buffer until it is read by the processor or DMA controller. Each time a read access is made to the read data register, the read data is fetched from the address indicated by the read pointer. This pointer is incremented after each read, and wraps back to the base address when it reaches the end of the allocated Y buffer space.
The Y buffer can also operate as a circular buffer. If the address for the next output value is the same as that indicated by the read pointer (an unread sample), then the buffer is flagged as full and execution stalled until the sample is read.

In the case of IIR filters, the Y buffer is used to store the set of \( M \) previous output samples, \( y[n-M] \) to \( y[n-1] \), used for calculating the next output sample \( y[n] \). Each time a new sample is added to the set, the least recent sample \( y[n-M] \) drops out.

If the number of unread data in the buffer is less than the watermark threshold programmed in the EMPTY_WM bitfield of the FMAC_YBUFCFG register, the buffer is flagged as empty. As long as the empty flag is not set, interrupts or DMA requests are generated, if enabled, to request reads from the buffer. The watermark allows several data to be transferred under one interrupt, without danger of underflow. Nevertheless, if an underflow does occur, the UNFL error flag is set. In this case, the read pointer is not incremented and the read operation returns the content of the memory at the read pointer address.

The operation of the Y buffer in circular mode is illustrated in Figure 111. This example shows a 7-tap IIR filter with a watermark set to four.
26.3.5 Initialization functions

The following functions initialize the FMAC unit. They are triggered by writing the appropriate value in the FUNC bitfield of the FMAC_PARAM register, with the START bit set. The P and Q bitfields must also contain the appropriate parameter values for each function as detailed below. The R bitfield is not used. When the function completes, the START bit is automatically reset by hardware.

During initialization, it is recommended that the DMA requests and interrupts be disabled. The transfer of data into the FMAC memory can be done by software or by memory-to-memory DMA transfers, since no flow control is required.

Load X1 buffer

This function pre-loads the X1 buffer with N values, starting from the address in X1_BASE. Successive writes to the FMAC_WDATA register load the write data into the X1 buffer and increment the write address. The write pointer points to the address X1_BASE + N when the function completes.

The function can be used to pre-load the buffer with the elements of a vector, or to initialize the input storage elements of a filter.

Parameters

- The parameter P contains the number of values, N, to be loaded into the X1 buffer.
- The parameters Q and R are not used.

The function completes when N writes have been performed to the FMAC_WDATA register.

**Figure 111. Circular output buffer operation**

Filter using seven samples y[n-7] to y[n-1]  Filter finishes current output sample. No free space in buffer, so full flag is set and execution stalled.

Four samples are read out. Read pointer is incremented by 4 and wraps to beginning of buffer space. Space now available in buffer so execution resumes.

Four more samples are read out. Read pointer is incremented by 4. Number of unread samples in buffer is less than watermark, so empty flag is set.
Load X2 buffer

This function pre-loads the X2 buffer with N + M values, starting from the address in X2_BASE. Successive writes to the FMAC_WDATA register load the write data into the X2 buffer and increment the write address.

The function can be used to pre-load the buffer with the elements of a vector, or the coefficients of a filter. In the case of an IIR, the N feed-forward and M feed-back coefficients are concatenated and loaded together into the X2 buffer. The total number of coefficients is equal to N + M. For an FIR, there are no feedback coefficients, so M = 0.

Parameters

- The parameter P contains the number of values, N, to be loaded into the X2 buffer starting from address X2_BASE.
- The parameter Q contains the number of values, M, to be loaded into the X2 buffer starting from address X2_BASE + N.
- The parameter R is not used.

The function completes when N + M writes have been performed to the FMAC_WDATA register.

Load Y buffer

This function pre-loads the Y buffer with N values, starting from the address in Y_BASE. Successive writes to the FMAC_WDATA register load the write data into the Y buffer and increment the write address. The read pointer points to the address Y_BASE + N when the function completes.

The function can be used to pre-load the feedback storage elements of an IIR filter.

Parameters

- The parameter P contains the number of values to be loaded into the Y buffer.
- The parameters Q and R are not used.

The function completes when N writes have been performed to the FMAC_WDATA register.

26.3.6 Filter functions

The following filter functions are supported by the FMAC unit. These functions are triggered by writing the corresponding value in the FUNC bitfield of the FMAC_PARAM register with the START bit set. The P, Q and R bitfields must also contain the appropriate parameter values for each function as detailed below. The filter functions continue to run until the START bit is reset by software.

Convolution (FIR filter)

\[ Y = B \ast X \]

\[ y_n = 2^R \cdot \sum_{k=0}^{N} b_k x_{n-k} \]

This function performs a convolution of a vector B of length N+1 and a vector X of indefinite length. The elements of Y for incrementing values of n are calculated as the dot product,
\( y_n = B \cdot X_n \), where \( X_n = [x_{n-N},...,x_n] \) is composed of the \( N+1 \) elements of \( X \) at indexes \( n - N \) to \( n \).

This function corresponds to a finite impulse response (FIR) filter, where vector \( B \) contains the filter coefficients and vector \( X \) the sampled data.

The structure of the filter (direct form) is shown in Figure 112.

**Figure 112. FIR filter structure**

Note that the cross correlation vector can be calculated by reversing the order of the coefficient vector \( B \).

**Input:**
- \( X1 \) buffer contains the elements of vector \( X \). It is a circular buffer of length \( N + 1 + d \).
- \( X2 \) buffer contains the elements of vector \( B \). It is a fixed buffer of length \( N + 1 \).

**Output:**
- \( Y \) buffer contains the output values, \( y_n \). It is a circular buffer of length \( d \).
Parameters:

- The parameter P contains the length, N+1, of the coefficient vector \( B \) in the range [2:127].
- The parameter R contains the gain to be applied to the accumulator output. The value output to the Y buffer is multiplied by \( 2^R \), where R is in the range [0:7]
- The parameter Q is not used.

The function completes when the START bit in the FMAC_PARAM register is reset by software.

IIR filter

\[ Y = B^T X + A^T Y' \]

\[ y_n = 2^R \cdot \left( \sum_{k=0}^{N} b_k x_{n-k} + \sum_{k=1}^{M} a_k y_{n-k} \right) \]

This function implements an infinite impulse response (IIR) filter. The filter output vector \( Y \) is the convolution of a coefficient vector \( B \) of length N+1 and a vector \( X \) of indefinite length, plus the convolution of the delayed output vector \( Y' \) with a second coefficient vector \( A \), of length M. The elements of \( Y \) for incrementing values of n are calculated as \( y_n = B^T X_n + A^T Y_{n-1} \), where \( X_n = [x_{n-N},...,x_n] \) comprises the N+1 elements of \( X \) at indexes n - N to n, while \( Y_{n-1} = [y_{n-M},...,y_{n-1}] \) comprises the M elements of \( Y \) at indexes n - M to n - 1. The structure of the filter (direct form 1) is shown in Figure 113.
Figure 113. IIR filter structure (direct form 1)

Input:
- X1 buffer contains the elements of vector $X$. It is a circular buffer of length $N + 1 + d$.
- X2 buffer contains the elements of coefficient vectors $B$ and $A$ concatenated $(b_0, b_1, b_2..., b_N, a_1, a_2, ..., a_M)$. It is a fixed buffer of length $M+N+1$.

Output:
- Y buffer contains the output values, $y_n$. It is a circular buffer of length $M + d$.

Parameters
- The parameter $P$ contains the length, $N + 1$, of the coefficient vector $B$ in the range $[2:64]$.
- The parameter $Q$ contains the length, $M$, of the coefficient vector $A$ in the range $[1:63]$.
- The parameter $R$ contains the gain to be applied to the accumulator output. The value output to the Y buffer is multiplied by $2^R$, where $R$ is in the range $[0:7]$. 
The function completes when the START bit in the FMAC_PARAM register is reset by software.

26.3.7 Fixed point representation

The FMAC operates in fixed point signed integer format. Input and output values are q1.15.

In q1.15 format, numbers are represented by one sign bit and 15 fractional bits (binary decimal places). The numeric range is therefore -1 (0x8000) to 1 - 2^{-15} (0x7FFF).

The accumulator has 26 bits, of which 22 are fractional and 4 are integer/sign (q4.22). This allows it to support partial accumulation sums in the range -8 (0x8000000) to +7.99999976 (0x1FFFFFF). A programmable gain from 0dB to 42dB in steps of 6dB can be applied at the output of the accumulator.

Note that the content of the accumulator is not saturated if the numeric range is exceeded. Partial sums whose value is greater than +7.99999976 or less than -8, wrap but this is harmless provided subsequent accumulations undo the wrapping. Nevertheless, the SAT flag in the FMAC_SR register is set if wrapping occurs, and generates an interrupt if the SATIEN bit is set in the FMAC_CR register. This helps in debugging the filter.

The data output by the accumulator can optionally be saturated, after application of the programmable gain, by setting the CLIPEN bit in the FMAC_CR register. If this bit is set, then any value which exceeds the numeric range of the q1.15 output, is set to 1 - 2^{-15} or -1, according to the sign. If clipping is not enabled, the unused accumulator bits after applying the gain is simply truncated.

26.3.8 Implementing FIR filters with the FMAC

The FMAC supports FIR filters of length N, where N is the number of taps or coefficients. The minimum local memory requirement for a FIR filter of length N is 2N + 1:

- N coefficients
- N input samples
- 1 output sample

Since the local memory size is 256, the maximum value for N is 127.

If maximum throughput is required, it may be necessary to allocate a small amount of extra space, d1 and d2, to the input and output sample buffers respectively, to ensure that the filter never stalls waiting for a new input sample, or waiting for the output sample to be read. In this case, the local memory requirement is 2N + d1 + d2.

The buffers must be configured as follows:

- X1_BUF_SIZE = N + d1;
- X2_BUF_SIZE = N;
- Y_BUF_SIZE = d2 (or 1 if no extra space is required)

The buffer base addresses can be allocated anywhere, but the X2 buffer must not overlap with the others, or else the coefficients are overwritten. An example configuration is:

- X2_BASE = 0;
- X1_BASE = N;
- Y_BASE = 2N + d1
However, if the memory space is limited, the X1 and Y buffer areas can be overlapped, such that each output sample takes the place of the oldest input sample, which is no longer required:

- X2_BASE = 0;
- X1_BASE = N;
- Y_BASE = N

In this case, Y_BUF_SIZE = X1_BUF_SIZE = N + d1, so that the buffers remain in sync.

**Note:** The FULL_WM bitfield of X1 buffer configuration register must be programmed with a value less than or equal to log2(d1), otherwise the buffer is flagged full before N input samples have been written, and no more samples are requested. Similarly, the EMPTY_WM bitfield of the Y buffer configuration register must be less than or equal to log2(d2).

The filter coefficients must be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of N. There is no point in pre-loading the Y buffer, since for the FIR filter there is no feedback path.

After configuring and initializing the buffers, the FMAC_CR register must be programmed according to the method used for writing and reading data to and from the FMAC memory.

Three methods are supported:

- Polling: No DMA request or Interrupt request is generated. Software must check that the X1_FULL flag is low before writing to WDATA, or that the Y_EMPTY flag is low before reading from RDATA.
- Interrupt: The interrupt request is asserted while the X1_FULL flag is low, for writes, or when the Y_EMPTY flag is low, for reads.
- DMA: DMA requests are asserted on the DMA write channel while the X1_FULL flag is low, and on the read channel while the Y_EMPTY flag is low.

Different methods can be used for read and for write. However it is not recommended to use both interrupts and DMA requests for the same operation(a). The valid combinations are listed in **Table 209**.

a. If both interrupts and DMA requests are enabled then only DMA must perform the transfer.
The filter is started by writing to the FMAC_PARAM register with the following bitfield values:

- FUNC = 8 (FIR filter);
- \( P = N \) (number of coefficients);
- \( Q = \text{"Don't care"} \);
- \( R = \text{Gain} \);
- \( \text{START} = 1 \);

If less than \( N + d - 2^\text{FULL_WM} \) values have been pre-loaded in the X1 buffer, the X1FULL flag remains low. If the WIEN bit is set in the FMAC_CR register, then the interrupt request is asserted immediately to request the processor to write \( 2^{\text{FULL_WM}} \) additional samples into the buffer, via the FMAC_WDATA register. It remains asserted until the X1FULL flag goes high in the FMAC_SR register. The interrupt service routine must check the X1FULL flag after every \( 2^{\text{FULL_WM}} \) writes to the FMAC_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMAWEN bit is set in the FMAC_CR register, DMA write channel requests are generated until the X1FULL flag goes high.

The filter calculates the first output sample when at least \( N \) samples have been written into the X1 buffer (including any pre-loaded samples).

When \( 2^{\text{EMPTY_WM}} \) output samples have been written into the Y buffer, the YEMPTY flag in the FMAC_SR register goes low. If the RIEN bit is set in the FMAC_CR register, the interrupt request is asserted to request the processor to read \( 2^{\text{EMPTY_WM}} \) samples from the buffer, via the FMAC_RDATA register. It remains asserted until the YEMPTY flag goes high. The interrupt service routine must check the YEMPTY flag after every \( 2^{\text{EMPTY_WM}} \) reads from the FMAC_RDATA register, and repeat the transfer until the flag goes high. If the DMAREN bit is set in the FMAC_CR, DMA read channel requests are generated until the YEMPTY flag goes high.

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.

### Implementing IIR filters with the FMAC

The FMAC supports IIR filters of length \( N \), where \( N \) is the number of feed-forward taps or coefficients. The number of feedback coefficients, \( M \), can be any value from 1 to \( N-1 \). Only direct form 1 implementations can be realized, so filters designed for other forms need to be converted.

The minimum memory requirement for an IIR filter with \( N \) feed-forward coefficients and \( M \) feed-back coefficients is \( 2N + 2M \):

- \( N + M \) coefficients
- \( N \) input samples
- \( M \) output samples

If \( M = N-1 \), then the maximum filter length that can be implemented is \( N = 64 \).

As for the FIR, for maximum throughput, a small amount of additional space, \( d1 \) and \( d2 \), is allowed in the input and output buffer size respectively, making the total memory requirement \( 2M + 2N + d1 + d2 \).

The buffers must be configured as follows:

- \( \text{X1_BUF_SIZE} = N + d1 \);
- \( \text{X2_BUF_SIZE} = N + M \);
- \( \text{Y_BUF_SIZE} = M + d2 \);
The buffer base addresses can be allocated anywhere, but must not overlap. An example configuration is given below:

- \( X_2 \_\text{BASE} = 0 \);
- \( X_1 \_\text{BASE} = N + M \);
- \( Y \_\text{BASE} = 2N + M + d_1 \);

**Note:** The \( \text{FULL} \_\text{WM} \) bitfield of X1 buffer configuration register must be programmed with a value less than or equal to \( \log_2(d_1) \), otherwise the buffer is flagged full before \( N \) input samples have been written, and no more samples are requested. Similarly, the \( \text{EMPTY} \_\text{WM} \) bitfield of the Y buffer configuration register must be less than or equal to \( \log_2(d_2) \).

The filter coefficients (N feed-forward followed by M feedback) must be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of \( N \). The Y buffer can optionally be pre-loaded with any number of values up to a maximum of \( M \). This has the effect of initializing the feedback delay line.

After configuring the buffers, the FMAC\_CR register must be programmed in the same way as for the FIR filter (see Section 26.3.8: Implementing FIR filters with the FMAC).

The filter is started by writing to the FMAC\_PARAM register with the following bitfield values:

- \( \text{FUNC} = 9 \) (IIR filter);
- \( P = N \) (number of feed-forward coefficients);
- \( Q = M \) (number of feed-back coefficients);
- \( R = \text{Gain} \);
- \( \text{START} = 1 \);

If less than \( N + d - 2^{\text{FULL} \_\text{WM}} \) values have been pre-loaded in the X1 buffer, the X1FULL flag remains low. If the WIEN bit is set in the FMAC\_CR register, then the interrupt request is asserted immediately to request the processor to write \( 2^{\text{FULL} \_\text{WM}} \) additional samples into the buffer, via the FMAC\_WDATA register. It remains asserted until the X1FULL flag goes high in the FMAC\_SR register. The interrupt service routine must check the X1FULL flag after every \( 2^{\text{FULL} \_\text{WM}} \) writes to the FMAC\_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMAWEN bit is set in the FMAC\_CR register, DMA write channel requests are generated until the X1FULL flag goes high.

The filter calculates the first output sample when at least \( N \) samples have been written into the X1 buffer (including any pre-loaded samples). The first sample is calculated using the first \( N \) samples in the X1 buffer, and the first \( M \) samples in the Y buffer (whether or not they are preloaded. The first output sample is written into the Y buffer at \( Y \_\text{BASE} + M \).

When \( 2^{\text{EMPTY} \_\text{WM}} \) new output samples have been written into the Y buffer, the YEMPTY flag in the FMAC\_SR register goes low. If the RIEN bit is set in the FMAC\_CR register, the interrupt request is asserted to request the processor to read \( 2^{\text{EMPTY} \_\text{WM}} \) samples from the buffer, via the FMAC\_RDATA register. It remains asserted until the YEMPTY flag goes high. The interrupt service routine must check the YEMPTY flag after every \( 2^{\text{EMPTY} \_\text{WM}} \) reads from the FMAC\_RDATA register, and repeat the transfer until the flag goes high. If the DMAREN bit is set in the FMAC\_CR, DMA read channel requests are generated until the YEMPTY flag goes high.

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.
26.3.10 Examples of filter initialization

The example in Figure 114 illustrates an X1 buffer pre-load with four samples \((P = 4)\). The buffer size is six \((X1\_BUF\_SIZE = 6)\). The initialization is launched by programming the FMAC\_PARAM register with the START bit set. The four samples are then written to FMAC\_WDATA, and transferred into local memory from X1\_BASE onwards. The START bit resets after the fourth sample has been written. At this point, the X1 buffer contains the four samples, in order of writing, and the write pointer (next empty space) is at X1\_BASE + 0x4.

![Figure 114. X1 buffer initialization](MSv47128V1)
26.3.11 Examples of filter operation

![Diagram showing filter operation](image)

The example in Figure 115 illustrates the beginning of a filter operation. The filter has four taps (P=4). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in Figure 114. So the filter starts calculating the first output sample, y[0], immediately after the START bit is set. Since the X1FULL flag is not set (due to two uninitialized spaces in the X1 buffer), the interrupt is asserted straight away, to request new data. The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer.

In the mean time, the FMAC finishes calculating the first output sample, y[0], and writes it into the Y buffer, causing the Y_EMPTY flag to go low. At the same time, the x[0] sample is discarded, as it is no longer required, freeing up its location in memory (at X1_BASE). The FMAC can immediately start work on the second output sample, y[1], since all the required input samples x[1:5] are present in the X1 buffer.

Since the Y_EMPTY flag is low, the interrupt remains active after the processor finishes writing x[5]. The processor reads y[0] from the FMAC_RDATA register, freeing up its location in the Y buffer. There are now no samples in the output buffer since y[1] is still being calculated, so the Y_EMPTY flag goes high. Nevertheless, the interrupt remains active, because there is still free space in the X1 buffer, which the processor next fills with x[6], and so on.

**Note:** In this example, the processor can fill the input buffer more quickly than the FMAC can process them, so the X1_full flag regularly goes active. However, it struggles to read the Y buffer fast enough, so the FMAC stalls regularly waiting for space to be freed up in the Y buffer. This means the filter is not executing at maximum throughput. The reason is that the...
Filter length is small and the processor relatively slow, in this example. So increasing the Y buffer size would not help.

Figure 116. Filtering example 2

The example in Figure 116 illustrates the beginning of the same filter operation, but this time the filter has six taps (P=6). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in Figure 114. Because there are not enough samples in the input buffer, the X1FULL flag is not set, so the interrupt is asserted straight away, to request new data. The FMAC is stalled.

The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer. As soon as there are six unused samples in the X1 buffer, the X1_FULL flag goes active (since the buffer size is six), causing the interrupt to go inactive. The FMAC starts calculating the first output sample, y[0]. Since this requires all six input samples, there are no free spaces in the X1 buffer and so the X1_FULL flag remains active. Only when the FMAC finishes calculating y[0] and writes it into the Y buffer, can x[0] be discarded, freeing up a space in the X1 buffer, and deasserting X1_FULL. At the same time, the Y_EMPTY flag goes inactive. Both these flag states cause the interrupt to be asserted, requesting the processor to write a new input sample, first of all, and then read the output sample just calculated. The FMAC remains stalled until a new input sample is written.

In this example, the processor has to wait for the FMAC to finish calculating the current output sample, before it can write a new input sample, and therefore the X1 buffer regularly goes empty, stalling the FMAC. This can be avoided by allowing some extra space in the input buffer.
26.3.12 Filter design tips

The FMAC architecture imposes some constraints detailed below, on the design of digital filters.

1. Implementation of direct form 2, or transposed forms, is not efficient. Filters which have been designed for such forms must be converted to direct form 1.

2. Cascaded filters must either be combined into a single stage, or implemented as separate filters. In the latter case, multiple sets of filter coefficients can be pre-loaded into the memory, one set per stage, and only the X2_BASE address changed to select which set is used. The most efficient method of implementing a multi-stage filter is to pre-load a large X1 buffer with input samples, run the IIR filter function on it using the first stage coefficients, and store the output samples back in memory. Then change the X2_BASE pointer to point to the 2nd stage coefficients, and reload the input buffer with the output of the first stage (with a gain if required), before running the IIR function again. The procedure is repeated for all stages. Once the final stage samples have been transferred back into system memory, the input buffer can be loaded with the next set of input samples, and a new round of calculations started. Note that the N sample input buffer of each stage must be pre-loaded first of all with the N-1 last inputs from the previous round, plus one new sample, in order to keep continuity between each round. Similarly, the output buffer of each stage must be loaded with the last M samples from the previous round, for the same reason.

3. The use of direct form 1 for IIR designs can lead to large positive or negative partial sums in the accumulator, if for example a large step occurs on the input, or some of the filter coefficients’ absolute values are >1. Since the accumulator is limited to 26 bits, the biggest value that it can handle without wrapping (changing sign) is 0x1FFFFFF positive or 0x2000000 negative. This corresponds to 3.99999988 and -4 respectively in q3.23 fixed point format. Wrapping does not represent a problem provided the wrapping is “undone” before the end of the accumulation. However this is not always the case when a filter is starting up and can lead to unexpected results. Consider pre-loading the output buffer with suitable values to avoid this.

4. The IIR filter has feed-forward (numerator) coefficients \([b_0, b_1, ..., b_{N-1}]\), and feed-back (denominator) coefficients \([1, a_1, ..., a_M]\). Many IIR filters require some of the denominator coefficients to have an absolute value greater than 1 to achieve a steep roll-off in the frequency response. Given that the coefficients are coded in fixed point q1.15 format, this is not possible. Nevertheless, by scaling the denominator coefficients by a factor \(2^R\), such that \(2^{-R}[1, a_1, ..., a_M]\) are all less than 1, such filters can be implemented. However an inverse gain of \(2^R\) must be applied at the output of the accumulator to compensate the scaling. This has an adverse effect on the signal-to-noise ratio.
## 26.4 FMAC registers

### 26.4.1 FMAC X1 buffer configuration register (FMAC_X1BUFCFG)

Address offset: 0x00  
Reset value: 0x0000 0000  
Access: word access

This register can only be modified if START = 0 in the FMAC_PARAM register.

| Bit 31-26 | Reserved, must be kept at reset value. |
| Bit 25-24 | **FULL_WM[1:0]**: Watermark for buffer full flag |
|           | Defines the threshold for setting the X1 buffer full flag when operating in circular mode. The flag is set if the number of free spaces in the buffer is less than $2^{\text{FULL_WM}}$. |
|           | 0: Threshold = 1 |
|           | 1: Threshold = 2 |
|           | 2: Threshold = 4 |
|           | 3: Threshold = 8 |
|           | Setting a threshold greater than 1 allows several data to be transferred into the buffer under one interrupt. |
|           | Threshold must be set to 1 if DMA write requests are enabled (DMAWEN = 1 in FMAC_CR register). |

| Bit 23-16 | Reserved, must be kept at reset value. |
| Bit 15-8  | **X1_BUF_SIZE[7:0]**: Allocated size of X1 buffer in 16-bit words |
|           | The minimum buffer size is the number of feed-forward taps in the filter (+ the watermark threshold - 1). |

| Bit 7-0   | **X1_BASE[7:0]**: Base address of X1 buffer |

### 26.4.2 FMAC X2 buffer configuration register (FMAC_X2BUFCFG)

Address offset: 0x04  
Reset value: 0x0000 0000  
Access: word access

| Bit 31-26 | Reserved, must be kept at reset value. |
| Bit 25-24 | **X2_BUF_SIZE[7:0]**: Allocated size of X2 buffer in 16-bit words |
|           | The minimum buffer size is the number of feed-forward taps in the filter (+ the watermark threshold - 1). |

| Bit 15-8  | **X2_BASE[7:0]**: Base address of X2 buffer |
26.4.3 FMAC Y buffer configuration register (FMAC_YBUFCFG)

Address offset: 0x08
Reset value: 0x0000 0000
Access: word access

This register can only be modified if START = 0 in the FMAC_PARAM register.

<table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **X2_BUF_SIZE[7:0]**: Size of X2 buffer in 16-bit words
This bitfield can not be modified when a function is ongoing (START = 1).

Bits 7:0 **X2_BASE[7:0]**: Base address of X2 buffer
The X2 buffer base address can be modified while START=1, for example to change coefficient values. The filter must be stalled when doing this, since changing the coefficients while a calculation is ongoing affects the result.

Bits 7:0 **EMPTY_WM[1:0]**: Watermark for buffer empty flag
Defines the threshold for setting the Y buffer empty flag when operating in circular mode. The flag is set if the number of unread values in the buffer is less than \(2^{\text{EMPTY_WM}}\).

0: Threshold = 1
1: Threshold = 2
2: Threshold = 4
3: Threshold = 8
Setting a threshold greater than 1 allows several data to be transferred from the buffer under one interrupt.
Threshold must be set to 1 if DMA read requests are enabled (DMAREN = 1 in FMAC_CR register).

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **Y_BUF_SIZE[7:0]**: Size of Y buffer in 16-bit words
For FIR filters, the minimum buffer size is 1 (+ the watermark threshold). For IIR filters the minimum buffer size is the number of feedback taps (+ the watermark threshold).

Bits 7:0 **Y_BASE[7:0]**: Base address of Y buffer
26.4.4  **FMAC parameter register (FMAC_PARAM)**

</tbody>
</table>
Bit 2 **OVFLIEN**: Enable overflow error interrupts  
0: Disabled. No interrupts are generated upon overflow detection.  
1: Enabled. An interrupt request is generated if the OVFL flag is set  
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 1 **WIEN**: Enable write interrupt  
0: Disabled. No write interrupt requests are generated.  
1: Enabled. An interrupt request is generated while the X1 buffer FULL flag is not set.  
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 0 **RIEN**: Enable read interrupt  
0: Disabled. No read interrupt requests are generated.  
1: Enabled. An interrupt request is generated while the Y buffer EMPTY flag is not set.  
This bit is set and cleared by software. A read returns the current state of the bit.

- **Bits 31:11**: Reserved, must be kept at reset value.

- **Bit 10 SAT**: Saturation error flag  
  Saturation occurs when the result of an accumulation exceeds the numeric range of the accumulator.  
  0: No saturation detected  
  1: Saturation detected. If the SATIEN bit is set, an interrupt is generated.  
  This flag is cleared by a reset of the unit.

- **Bit 9 UNFL**: Underflow error flag  
  An underflow occurs when a read is made from FMAC_RDATA when no valid data is available in the Y buffer.  
  0: No underflow detected  
  1: Underflow detected. If the UNFLIEN bit is set, an interrupt is generated.  
  This flag is cleared by a reset of the unit.

- **Bit 8 OVFL**: Overflow error flag  
  An overflow occurs when a write is made to FMAC_WDATA when no free space is available in the X1 buffer.  
  0: No overflow detected  
  1: Overflow detected. If the OVFLIEN bit is set, an interrupt is generated.  
  This flag is cleared by a reset of the unit.

- **Bits 7:2**: Reserved, must be kept at reset value.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RDATA[15:0]**: Read data

When a read access to this register occurs, the read data are the contents of the Y output buffer at the address offset indicated by the READ pointer. The pointer address is automatically incremented after each read access.
Refer to Section 2.3 for the register boundary addresses.
27 Flexible static memory controller (FSMC)

This section only applies to STM32U575/585/59x/5Ax/5Fx/5Gx devices.

27.1 Introduction

The flexible static memory controller (FSMC) includes two memory controllers:
- The NOR/PSRAM memory controller
- The NAND memory controller

This memory controller is also named flexible memory controller (FMC).

27.2 FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, and NAND flash memory. Its main purposes are:
- to translate AHB transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique chip select. The FMC performs only one access at a time to an external device.

The main features of the FMC controller are the following:
- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR flash memory/OneNAND flash memory
  - PSRAM (4 memory banks)
  - Ferroelectric RAM (FRAM)
  - NAND flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with parallel LCD modules, supporting Intel 8080 and Motorola 6800 modes.
- Burst mode support for faster access to synchronous devices such as NOR flash memory, PSRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-,16-bit wide data bus
- Independent chip select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth

The Write FIFO is common to all memory controllers and consists of:
- a Write Data FIFO which stores the AHB data to be written to the memory (up to 32 bits) plus one bit for the AHB transfer (burst or not sequential mode)
- a Write Address FIFO which stores the AHB address (up to 28 bits) plus the AHB data size (up to 2 bits). When operating in burst mode, only the start address is stored
except when crossing a page boundary (for PSRAM). In this case, the AHB burst is
broken into two FIFO entries.

At startup the FMC pins must be configured by the user application. The FMC I/O pins which
are not used by the application can be used for other purposes.

The FMC registers that define the external device type and associated characteristics are
usually set at boot time and do not change until the next reset or power-up.

However, only a few bits can be changed on-the-fly:

• MBKEN, FMCEN, WEN bits in FMC_BCRx register
• ECCEN and PBKEN bits in the FMC_PCR register
• IFS, IRS and ILS bits in the FMC_SR register

Follow the below sequence to modify parameters while the FMC is enabled:
1. First disable the FMC controller to prevent further accesses to any memory controller
   while the register is modified.
2. Update all required configurations.
3. Enable the FMC controller again.

27.3 FMC block diagram

The FMC consists of the following main blocks:
• The AHB interface (including the FMC configuration registers)
• The NOR flash/PSRAM/SRAM controller

The block diagram is shown in the figure below.
27.4 AHB interface

The AHB slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AHB transactions are translated into the external device protocol. In particular, if the selected external memory is 16- or 8-bit wide, 32-bit wide transactions on the AHB are split into consecutive 16- or 8-bit accesses. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses except in case of Access mode D when the Extended mode is enabled.

The FMC generates an AHB error in the following conditions:
- When reading or writing to a FMC bank (Bank 1 to 4) which is not enabled.
- When reading or writing to the NOR flash bank while the FACCEN bit is reset in the FMC_BCRx register.

The effect of an AHB error depends on the AHB master which has attempted the R/W access:
- If the access has been attempted by the Cortex®-M33 CPU, a hard fault interrupt is generated.
- If the access has been performed by a DMA controller, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

The AHB clock (HCLK) is the reference clock for the FMC.

27.4.1 Supported memories and transactions

General transaction rules

The requested AHB transaction data size can be 8-, 16- or 32-bit wide whereas the accessed external device has a fixed data width. This may lead to inconsistent transfers.

Therefore, some simple transaction rules must be followed:
- AHB transaction size and memory data size are equal
  There is no issue in this case.
- AHB transaction size is greater than the memory size:
  In this case, the FMC splits the AHB transaction into smaller consecutive memory accesses to meet the external data width. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses. If the bus turnaround timings is configured to any other value than 0, the FMC chip select (FMC_NEx) toggles between the consecutive accesses. This feature is required when interfacing with FRAM memory.
- AHB transaction size is smaller than the memory size:
  The transfer may or not be consistent depending on the type of external device:
  - Accesses to devices that have the byte select feature (SRAM, ROM, PSRAM)
    In this case, the FMC allows read/write transactions and accesses to the right data through its byte lanes NBL[1:0].
    Bytes to be written are addressed by NBL[1:0].
    All memory bytes are read (NBL[1:0] are driven low during read transaction) and the useless ones are discarded.
– Accesses to devices that do not have the byte select feature (NOR and NAND flash memories)

This situation occurs when a byte access is requested to a 16-bit wide flash memory. Since the device cannot be accessed in Byte mode (only 16-bit words can be read/written from/to the flash memory), Write transactions and Read transactions are allowed (the controller reads the entire 16-bit memory word and uses only the required byte).

**Wrap support for NOR flash/PSRAM**

Wrap burst mode for synchronous memories is not supported. The memories must be configured in Linear burst mode of undefined length.

**Configuration registers**

The FMC can be configured through a set of registers. Refer to Section 27.6.6, for a detailed description of the NOR flash/PSRAM controller registers. Refer to Section 27.7.7, for a detailed description of the NAND flash registers.

### 27.5 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see Figure 118):

- Bank 1 used to address up to 4 NOR flash memory or PSRAM devices. This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated chip selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4

- Bank 3 used to address NAND flash memory devices. The MPU memory attribute for this space must be reconfigured by software to Device.

For each bank the type of memory to be used can be configured by the user application through the Configuration register.
27.5.1 NOR/PSRAM address mapping

HADDR[27:26] bits are used to select one of the four memory banks as shown in Table 211.

Table 211. NOR/PSRAM bank selection

<table>
<thead>
<tr>
<th>HADDR<a href="1">27:26</a></th>
<th>Selected bank</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Bank 1 - NOR/PSRAM 1</td>
</tr>
<tr>
<td>01</td>
<td>Bank 1 - NOR/PSRAM 2</td>
</tr>
<tr>
<td>10</td>
<td>Bank 1 - NOR/PSRAM 3</td>
</tr>
<tr>
<td>11</td>
<td>Bank 1 - NOR/PSRAM 4</td>
</tr>
</tbody>
</table>

1. HADDR are internal AHB address lines that are translated to external memory.

The HADDR[25:0] bits contain the external memory address. Since HADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

Table 212. NOR/PSRAM External memory address

<table>
<thead>
<tr>
<th>Memory width(1)</th>
<th>Data address issued to the memory</th>
<th>Maximum memory capacity (bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>8-bit</td>
<td>HADDR[25:0]</td>
<td>64 Mbytes x 8 = 512 Mbits</td>
</tr>
<tr>
<td>16-bit</td>
<td>HADDR[25:1] &gt;&gt; 1</td>
<td>64 Mbytes/2 x 16 = 512 Mbits</td>
</tr>
</tbody>
</table>

1. In case of a 16-bit external memory width, the FMC internally uses HADDR[25:1] to generate the address for external memory FMC_A[24:0].

Whatever the external memory width, FMC_A[0] must be connected to external memory address A[0].
27.5.2  NAND flash memory address mapping

The NAND bank is divided into memory areas as indicated in Table 213.

Table 213. NAND memory mapping and timing registers

<table>
<thead>
<tr>
<th>Start address</th>
<th>End address</th>
<th>FMC bank</th>
<th>Memory space</th>
<th>Timing register</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x8800 0000</td>
<td>0x8BFF FFFF</td>
<td>Bank 3 - NAND flash</td>
<td>Attribute</td>
<td>FMC_PATT (0x8C)</td>
</tr>
<tr>
<td>0x8000 0000</td>
<td>0x83FF FFFF</td>
<td></td>
<td>Common</td>
<td>FMC_PMEM (0x88)</td>
</tr>
</tbody>
</table>

For NAND flash memory, the common and attribute memory spaces are subdivided into three sections (see in Table 214 below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)

Table 214. NAND bank selection

<table>
<thead>
<tr>
<th>Section name</th>
<th>HADDR[17:16]</th>
<th>Address range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address section</td>
<td>1X</td>
<td>0x020000-0x03FFFF</td>
</tr>
<tr>
<td>Command section</td>

<td>0x010000-0x01FFFF</td>
</tr>
<tr>
<td>Data section</td>
<td>00</td>
<td>0x000000-0x0FFFF</td>
</tr>
</tbody>
</table>

The application software uses the 3 sections to access the NAND flash memory:

- **To sending a command to NAND flash memory**, the software must write the command value to any memory location in the command section.
- **To specify the NAND flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- **To read or write data**, the software reads or writes the data from/to any memory location in the data section.

Since the NAND flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

27.6  NOR flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM, FRAM and ROM
  - 8 bits
  - 16 bits
• PSRAM (CellularRAM™)
  – Asynchronous mode
  – Burst mode for synchronous accesses
  – Multiplexed or non-multiplexed
• NOR flash memory
  – Asynchronous mode
  – Burst mode for synchronous accesses
  – Multiplexed or non-multiplexed

The FMC outputs a unique chip select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:
• Programmable wait states (up to 15)
• Programmable bus turnaround cycles (up to 15)
• Programmable output enable and write enable delays (up to 15)
• Independent read and write timings and protocol to support the widest variety of memories and timings
• Programmable continuous clock (FMC_CLK) output.

The FMC Clock (FMC_CLK) is a submultiple of the HCLK clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC_BCR1 register:
• If the CCLKEN bit is reset, the FMC generates the clock (CLK) only during synchronous accesses (Read/write transactions).
• If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC_CLK continuous clock, Bank 1 must be configured in Synchronous mode (see Section 27.6.6: NOR/PSRAM controller registers). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AHB data size has to be the same as the memory data width (MWID) otherwise the FMC_CLK frequency is changed depending on AHB data transaction (refer to Section 27.6.5: Synchronous transactions for FMC_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see Section 27.6.6: NOR/PSRAM controller registers).

The programmable memory parameters include access times (see Table 215) and support for wait management (for PSRAM and NOR flash accessed in Burst mode).

27.6.3 General timing rules

Signals synchronization

- All controller output signals change on the rising edge of the internal clock (HCLK)
- In Synchronous mode (read or write), all output signals change on the rising edge of HCLK. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADV/ NADVH /NBLL/ Address valid outputs change on the falling edge of FMC_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC_CLK clock.

27.6.4 NOR flash/PSRAM controller asynchronous transactions

Asynchronous static memories (NOR flash, PSRAM, SRAM, FRAM)

- Signals are synchronized by the internal clock HCLK. This clock is not issued to the memory
• The FMC always samples the data before de-asserting the NOE signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns)

• If the Extended mode is enabled (EXTMOD bit is set in the FMC_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.

• If the Extended mode is disabled (EXTMOD bit is reset in the FMC_BCRx register), the FMC can operate in mode 1 or mode 2 as follows:
  – Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01 in the FMC_BCRx register)
  – Mode 2 is the default mode when NOR memory type is selected (MTYP = 0x10 in the FMC_BCRx register).

**Mode 1 - SRAM/FRAM/PSRAM (CRAM)**

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC_BCRx, and FMC_BTRx/FMC_BWTRx registers.

*Figure 119. Mode 1 read access waveforms*
The DATAHLD time at the end of the read and write transactions guarantee the address and data hold time after the NOE/NWE rising edge. The DATAST value must be greater than zero (DATAST > 0).

WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCEWAIT bit has to be set in FMC_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

</tr>
</tbody>
</table>
The data setup phase must be programmed so that WAIT can be detected 4 HCLK cycles before the end of the memory transaction. The following cases must be considered:

1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:
   \[
   \text{DATAST} \geq (4 \times \text{HCLK}) + \text{max}_-\text{wait_assertion_time}
   \]

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):
   if
   \[
   \text{max}_-\text{wait_assertion_time} > \text{address_phase} + \text{hold_phase}
   \]
   then:
   \[
   \text{DATAST} \geq (4 \times \text{HCLK}) + (\text{max}_-\text{wait_assertion_time} - \text{address_phase} - \text{hold_phase})
   \]
   otherwise
   \[
   \text{DATAST} \geq 4 \times \text{HCLK}
   \]

where max_wait_assertion_time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

Figure 132 and Figure 133 show the number of HCLK clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

**Figure 132. Asynchronous wait during a read access waveforms**

1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.
CellularRAM™ (PSRAM) refresh management

The CellularRAM™ does not enable maintaining the chip select signal (NE) low for longer than the tCEM timing specified for the memory device. This timing can be programmed in the FMC_PCSCNTR register. It defines the maximum duration of the NE low pulse in HCLK cycles for asynchronous accesses and FMC_CLK cycles for synchronous accesses.

27.6.5 Synchronous transactions

The memory clock, FMC_CLK, is a submultiple of HCLK. It depends on the value of CLKDIV and the MWID/ AHB data size, following the formula given below:

Whatever MWID size: 16 or 8-bit, the FMC_CLK divider ratio is always defined by the programmed CLKDIV value.

Example:
- If CLKDIV=1, MWID = 16 bits, AHB data size=8 bits, FMC_CLK=HCLK/2.

NOR flash memories specify a minimum time from NADV assertion to CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR flash configuration.
register. The FMC does not include the clock cycle when NADV is low in the data latency count.

**Caution:** Some NOR flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR flash latency and the FMC DATLAT parameter can be either:

- NOR flash latency = (DATLAT + 2) CLK clock cycles
- or NOR flash latency = (DATLAT + 3) CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

**Single-burst transfer**

When the selected bank is configured in Burst mode for synchronous accesses, if for example an AHB single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AHB transfer is 16 bits), or length 2 (if the AHB transfer is 32 bits) and de-assert the chip select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

**Cross boundary page for CellularRAM™ 1.5**

CellularRAM™ 1.5 does not allow burst access to cross the page boundary. The FMC controller is used to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC_BCR1 register following the memory page size.

**Wait management**

For synchronous NOR flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the chip select and output enable signals valid. It does not consider the data as valid.

In Burst mode, there are two timing configurations for the NOR flash NWAIT signal:

- The flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The flash memory asserts the NWAIT signal during the wait state
The FMC supports both NOR flash wait state configurations, for each chip select, thanks to the WAITCFG bit in the FMC_BCRx registers ($x = 0..3$).

**Figure 134. Wait configuration waveforms**

[Diagram showing waveforms for HCLK, CLK, A[25:16], NADV, NWAIT (WAITCFG = 0), NWAIT (WAITCFG = 1), and A/D[15:0] with memory transaction = burst of 4 half words.]
Figure 135. Synchronous multiplexed read mode waveforms - NOR, PSRAM (CRAM)

1. Byte lane outputs (NBL are not shown; for NOR access, they are held high, and, for PSRAM (CRAM) access, they are held low.

### 27.6.6 NOR/PSRAM controller registers

**SRAM/NOR-flash chip-select control register for bank x (FMC_BCRx) (x = 1 to 4)**

Address offset: $0x00 + 0x8 \times (x - 1)$, (x = 1 to 4)

Reset value: $0x0000\ 30DB, \ 0x0000\ 30D2, \ 0x0000\ 30D2, \ 0x0000\ 30D2$

This register contains the control information of each memory bank, used for SRAMs, PSRAM, FRAM and NOR flash memories.

<table>
<thead>
<tr>

<tr>
<td><strong>Note:</strong></td>
<td>The FMCEN bit of the FMC_BCR2..4 registers is don’t care. It is only enabled through the FMC_BCR1 register.</td>
</tr>
</tbody>
</table>

| Bits 30:24 | Reserved, must be kept at reset value. |

| Bits 23:22 | NBLSET[1:0]: Byte lane (NBL) setup |
|           | These bits configure the NBL setup timing from NBLx low to chip select NEx low. |
|           | 00: NBL setup time is 0 AHB clock cycle |
|           | 01: NBL setup time is 1 AHB clock cycle |
|           | 10: NBL setup time is 2 AHB clock cycles |
|           | 11: NBL setup time is 3 AHB clock cycles |

| Bit 21 | WFDIS: Write FIFO disable |
|        | This bit disables the Write FIFO used by the FMC controller. |
|        | 0: Write FIFO enabled (Default after reset) |
|        | 1: Write FIFO disabled |
| **Note:** | The WFDIS bit of the FMC_BCR2..4 registers is don’t care. It is only enabled through the FMC_BCR1 register. |
Bit 20  **CCLKEN**: Continuous clock enable  
This bit enables the FMC_CLK clock output to external memory devices.  
0: The FMC_CLK is only generated during the synchronous memory access (read/write transaction). The FMC_CLK clock ratio is specified by the programmed CLKDIV value in the FMC_BCRx register (default after reset).  
1: The FMC_CLK is generated continuously during asynchronous and synchronous access. The FMC_CLK clock is activated when the CCLKEN is set.  

**Note**: The CCLKEN bit of the FMC_BCR2..4 registers is don’t care. It is only enabled through the FMC_BCR1 register. Bank 1 must be configured in Synchronous mode to generate the FMC_CLK continuous clock.  

**Note**: If CCLKEN bit is set, the FMC_CLK clock ratio is specified by CLKDIV value in the FMC_BTR1 register. CLKDIV in FMC_BWTR1 is don’t care.  

**Note**: If the Synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC_BTR2..4 and FMC_BWTR2..4 registers for other banks has no effect.)  

Bit 19  **CBURSTRW**: Write burst enable  
For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC_BCRx register.  
0: Write operations are always performed in Asynchronous mode.  
1: Write operations are performed in Synchronous mode.  

Bits 18:16  **CPSIZE[2:0]**: CRAM page size  
These are used for CellularRAM™ 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC controller splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).  
000: No burst split when crossing page boundary (default after reset)  
001: 128 bytes  
010: 256 bytes  
011: 512 bytes  
100: 1024 bytes  
Others: reserved  

Bit 15  **ASYNCWAIT**: Wait signal during asynchronous transfers  
This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.  
0: NWAIT signal is not taken into account when running an asynchronous protocol (default after reset).  
1: NWAIT signal is taken into account when running an asynchronous protocol.  

Bit 14  **EXTMOD**: Extended mode enable  
This bit enables the FMC to program the write timings for non multiplexed asynchronous accesses inside the FMC_BWTR register, thus resulting in different timings for read and write operations.  
0: values inside FMC_BWTR register are not taken into account (default after reset)  
1: values inside FMC_BWTR register are taken into account  

**Note**: When the Extended mode is disabled, the FMC can operate in mode 1 or mode 2 as follows:  
– **Mode 1** is the default mode when the SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01)  
– **Mode 2** is the default mode when the NOR memory type is selected (MTYP = 0x10).
Bit 13 **WAITEN**: Wait enable bit

This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in Synchronous mode.

0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed flash latency period).
1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset).

Bit 12 **WREN**: Write enable bit

This bit indicates whether write operations are enabled/disabled in the bank by the FMC.

0: Write operations are disabled in the bank by the FMC, an AHB error is reported.
1: Write operations are enabled for the bank by the FMC (default after reset).

Bit 11 **WAITCFG**: Wait timing configuration

The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in Synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:

0: NWAIT signal is active one data cycle before wait state (default after reset).
1: NWAIT signal is active during wait state (not used for PSRAM).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **WAITPOL**: Wait signal polarity bit

Defines the polarity of the wait signal from memory used for either in Synchronous or Asynchronous mode.

0: NWAIT active low (default after reset)
1: NWAIT active high

Bit 8 **BURSTEN**: Burst enable bit

This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode.

0: Burst mode disabled (default after reset). Read accesses are performed in Asynchronous mode.
1: Burst mode enable. Read accesses are performed in Synchronous mode.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FACCEN**: Flash access enable

Enables NOR flash memory access operations.

0: Corresponding NOR flash memory access is disabled.
1: Corresponding NOR flash memory access is enabled (default after reset).

Bits 5:4 **MWID[1:0]**: Memory data bus width

Defines the external memory device width, valid for all type of memories.

00: 8 bits
01: 16 bits (default after reset)
10: reserved
11: reserved

Bits 3:2 **MTYP[1:0]**: Memory type

Defines the type of external memory attached to the corresponding memory bank.

00: SRAM/FRAM (default after reset for Bank 2...4)
01: PSRAM (CRAM) / FRAM
10: NOR flash/OneNAND flash (default after reset for Bank 1)
11: reserved
Bit 1 **MUXEN**: Address/data multiplexing enable bit
When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:
0: Address/data non multiplexed
1: Address/data multiplexed on databus (default after reset)

Bit 0 **MBKEN**: Memory bank enable bit
Enables the memory bank. After reset Bank1 is enabled, all others are disabled. Accessing a disabled bank causes an ERROR on AHB bus.
0: Corresponding memory bank is disabled.
1: Corresponding memory bank is enabled.

**SRAM/NOR-flash chip-select timing register for bank x (FMC_BTRx)**
Address offset: 0x04 + 0x8 * (x - 1), (x = 1 to 4)
Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR flash memories. If the EXTMOD bit is set in the FMC_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC_BWTRx registers).

Bits 31:30 **DATAHLD[1:0]**: Data hold phase duration
These bits are written by software to define the duration of the data hold phase in HCLK cycles (refer to Figure 119 to Figure 131), used in asynchronous accesses:
For read accesses
00: DATAHLD phase duration = 0 × HCLK clock cycle (default)
01: DATAHLD phase duration = 1 × HCLK clock cycle
10: DATAHLD phase duration = 2 × HCLK clock cycle
11: DATAHLD phase duration = 3 × HCLK clock cycle
For write accesses
00: DATAHLD phase duration = 1 × HCLK clock cycle (default)
01: DATAHLD phase duration = 2 × HCLK clock cycle
10: DATAHLD phase duration = 3 × HCLK clock cycle
11: DATAHLD phase duration = 4 × HCLK clock cycle

Bits 29:28 **ACCMOD[1:0]**: Access mode
Specifies the asynchronous access modes as shown in the timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.
00: Access mode A
01: Access mode B
10: Access mode C
11: Access mode D
Bits 27:24 **DATLAT[3:0]**: (see note below bit descriptions): Data latency for synchronous memory
For synchronous access with read/write Burst mode enabled (BURSTEN / CBURSTRW bits set), defines the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:
This timing parameter is not expressed in HCLK periods, but in FMC_CLK periods.
For asynchronous access, this value is don't care.
0000: Data latency of 2 CLK clock cycles for first burst access
1111: Data latency of 17 CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]**: Clock divide ratio (for FMC_CLK signal)
Defines the period of FMC_CLK clock output signal, expressed in number of HCLK cycles:
0000: FMC_CLK period= 1x HCLK period
0001: FMC_CLK period = 2 × HCLK periods
0010: FMC_CLK period = 3 × HCLK periods
1111: FMC_CLK period = 16 × HCLK periods (default value after reset)
In asynchronous NOR flash, SRAM or PSRAM accesses, this value is don't care.

Note: Refer to Section 27.6.5: Synchronous transactions for FMC_CLK divider ratio formula

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration
These bits are written by software to add a delay at the end of current read or write transaction to next transaction on the same bank.
This delay is used to match the minimum time between consecutive transactions (tEHENTS from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access (tEHQZ, chip enable high to output Hi-Z). This delay is recommended for mode D and muxed mode. For non-muxed memory, the bus turnaround delay can be set to minimum value.
(BUSTURN + 1)HCLK period ≥ max(tEHENTS min, tEHQZ max)
For FRAM memories, the bus turnaround delay must be configured to match the minimum tPC (precharge time) timings. The bus turnaround delay is inserted between any consecutive transactions on the same bank (read/read, write/write, read/write and write/read) to match the tPC memory timing. The chip select is toggling between any consecutive accesses.
(BUSTURN + 1)HCLK period ≥ tPC min
0000: BUSTURN phase duration = 1 HCLK clock cycle added
...1111: BUSTURN phase duration = 16 x HCLK clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]**: Data-phase duration
These bits are written by software to define the duration of the data phase (refer to Figure 119 to Figure 131), used in asynchronous accesses:
0000 0000: Reserved
0000 0001: DATAST phase duration = 1 × HCLK clock cycles
0000 0010: DATAST phase duration = 2 × HCLK clock cycles
...
1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)
For each memory type and access mode data-phase duration, refer to the respective figure (Figure 119 to Figure 131).
Example: Mode 1, write access, DATAST=1: Data-phase duration= DATAST+1 = 2 HCLK clock cycles.

Note: In synchronous accesses, this value is don't care.
Note: PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to prolong the latency as needed.

With PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.

This method can be used also with the latest generation of synchronous flash memories that issue the NWAIT signal, unlike older flash memories (check the datasheet of the specific flash memory being used).

SRAM/NOR-flash write timing registers x (FMC_BWTRx)

Address offset: 0x104 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR flash memories. When the EXTMOD bit is set in the FMC_BCRx register, then this register is active for write access.
Bits 31:30 **DATAHLD[1:0]**: Data hold phase duration
These bits are written by software to define the duration of the data hold phase in HCLK cycles (refer to Figure 119 to Figure 131), used in asynchronous write accesses:
- 00: DATAHLD phase duration = 1 × HCLK clock cycle (default)
- 01: DATAHLD phase duration = 2 × HCLK clock cycle
- 10: DATAHLD phase duration = 3 × HCLK clock cycle
- 11: DATAHLD phase duration = 4 × HCLK clock cycle

Bits 29:28 **ACCMOD[1:0]**: Access mode.
Specifies the asynchronous access modes as shown in the next timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.
- 00: Access mode A
- 01: Access mode B
- 10: Access mode C
- 11: Access mode D

Bits 27:20 Reserved, must be kept at reset value.

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration
These bits are written by software to add a delay at the end of current write transaction to next transaction on the same bank.
For FRAM memories, the bus turnaround delay must be configured to match the minimum tPC (precharge time) timings. The bus turnaround delay is inserted between any consecutive transactions on the same bank (read/read, write/write, read/write and write/read). The chip select is toggling between any consecutive accesses.
(BUSTURN + 1)HCLK period ≥ tPC min
- 0000: BUSTURN phase duration = 1 HCLK clock cycle added
- ... 1111: BUSTURN phase duration = 16 × HCLK clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]**: Data-phase duration.
These bits are written by software to define the duration of the data phase (refer to Figure 119 to Figure 131), used in asynchronous SRAM, PSRAM and NOR flash memory accesses:
- 0000 0000: Reserved
- 0000 0001: DATAST phase duration = 1 × HCLK clock cycles
- 0000 0010: DATAST phase duration = 2 × HCLK clock cycles
- ... 1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)

Bits 7:4 **ADDHLD[3:0]**: Address-hold phase duration.
These bits are written by software to define the duration of the address hold phase (refer to Figure 128 to Figure 131), used in asynchronous multiplexed accesses:
- 0000: Reserved
- 0001: ADDHLD phase duration = 1 × HCLK clock cycle
- 0010: ADDHLD phase duration = 2 × HCLK clock cycle
- ... 1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)

*Note: In synchronous NOR flash accesses, this value is not used, the address hold phase is always 1 flash clock period duration.*
Flexible static memory controller (FSMC) RM0456

PSRAM chip select counter register (FMC_PCSCNTR)

Address offset: 0x20
Reset value: 0x0000 0000

This register contains the PSRAM chip select counter value for Synchronous and Asynchronous modes. The chip select counter is common to all banks and can be enabled separately on each bank. During PSRAM read or write accesses, this value is loaded into a timer which is decremented while the NE signal is held low. When the timer reaches 0, the PSRAM controller splits the current access, toggles NE to allow PSRAM device refresh, and restarts a new access. The programmed counter value guarantees a maximum NE pulse width \( t_{CEM} \) as specified for PSRAM devices. The counter is reloaded and starts decrementing each time a new access is started by a transition of NE from high to low.

Bits 3:0 **ADDSET[3:0]**: Address setup phase duration.
These bits are written by software to define the duration of the address setup phase in HCLK cycles (refer to *Figure 119 to Figure 131*), used in asynchronous accesses:
0000: ADDSET phase duration = 0 × HCLK clock cycle
... 1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)

*Note:* In synchronous accesses, this value is not used, the address setup phase is always 1 flash clock period duration. In muxed mode, the minimum ADDSET value is 1.

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 | CNTB4EN CNTB3EN CNTB2EN CNTB1EN |

| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |  |

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **CNTB4EN**: Counter Bank 4 enable
This bit enables the chip select counter for PSRAM/NOR Bank 4.
0: Counter disabled for Bank 4
1: Counter enabled for Bank 4

Bit 18 **CNTB3EN**: Counter Bank 3 enable
This bit enables the chip select counter for PSRAM/NOR Bank 3.
0: Counter disabled for Bank 3.
1: Counter enabled for Bank 3

Bit 17 **CNTB2EN**: Counter Bank 2 enable
This bit enables the chip select counter for PSRAM/NOR Bank 2.
0: Counter disabled for Bank 2
1: Counter enabled for Bank 2

Bit 16 **CNTB1EN**: Counter Bank 1 enable
This bit enables the chip select counter for PSRAM/NOR Bank 1.
0: Counter disabled for Bank 1
1: Counter enabled for Bank 1
27.7 NAND flash controller

The FMC generates the appropriate signal timings to drive the following types of device:

- 8- and 16-bit NAND flash memories

The NAND bank is configured through dedicated registers (Section 27.7.7). The programmable memory parameters include access timings (shown in Table 241) and ECC configuration.

<table>

27.7.1 External memory interface signals

The following tables list the signals that are typically used to interface NAND flash memory.

Note: The prefix “N” identifies the signals which are active low.

### 8-bit NAND flash memory

<table>
<thead>
<tr>
<th>FMC signal name</th>
<th>I/O</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>A[17]</td>
<td>O</td>
<td>NAND flash address latch enable (ALE) signal</td>

27.7.3 Timing diagrams for NAND flash memory

The NAND flash memory bank is managed through a set of registers:

- Control register: FMC_PCR
- Interrupt status register: FMC_SR
- ECC register: FMC_ECCR
- Timing register for Common memory space: FMC_PMEM
- Timing register for Attribute memory space: FMC_PATT

Each timing configuration register contains three parameters used to define number of HCLK cycles for the three phases of any NAND flash access, plus one parameter that defines the timing for starting driving the data bus when a write access is performed. Figure 137 shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.

![Figure 137. NAND flash controller waveforms for common memory access](image)

1. NOE remains high (inactive) during write accesses. NWE remains high (inactive) during read accesses.
2. For write access, the hold phase delay is (MEMHOLD) HCLK cycles and for read access is (MEMHOLD + 2) HCLK cycles.
27.7.4 NAND flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND flash memory device are driven by address signals from the FMC controller. This means that to send a command or an address to the NAND flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC_PCR and FMC_PMEM (and for some devices, FMC_PATT, see Section 27.7.5: NAND flash prewait functionality) registers according to the characteristics of the NAND flash memory (PWID bits for the data bus width of the NAND flash, PTYP = 1, PWAITEN = 0 or 1 as needed, see Section 27.5.2: NAND flash memory address mapping for timing configuration).

2. The CPU performs a byte write to the common memory space, with data byte equal to one flash command byte (for example 0x00 for Samsung NAND flash devices). The LE input of the NAND flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.

3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND flash memories) in the common memory or attribute space. The ALE input of the NAND flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used to implement the prewait functionality needed by some NAND flash memories (see details in Section 27.7.5: NAND flash prewait functionality).

4. The controller waits for the NAND flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).

5. The CPU can then perform byte read operations from the common memory space to read the NAND flash page (data field + Spare field) byte by byte.

6. The next NAND flash page can be read without any CPU command or address write operation. This can be done in three different ways:
   - by simply performing the operation described in step 5
   - a new random address can be accessed by restarting the operation at step 3
   - a new command can be sent to the NAND flash device by restarting at step 2

27.7.5 NAND flash prewait functionality

Some NAND flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see Figure 138).
1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7~A0 at address 0x7002 0000.
3. CPU wrote byte A16~A9 at address 0x7002 0000.
4. CPU wrote byte A24~A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x7802 0000: FMC performs a write access using FMC_PATT timing definition, where ATTHOLD ≥ 7 (providing that (7+1) × HCLK = 112 ns > tWB max). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND flash memories where NCE is not don’t care).

When this functionality is required, it can be ensured by programming the MEMHOLD value to meet the tWB timing. However any CPU read access to the NAND flash memory has a hold delay of (MEMHOLD + 2) HCLK cycles and CPU write access has a hold delay of (MEMHOLD) HCLK cycles inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the tWB timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND flash read and write accesses, except when writing the last address byte to the NAND flash device, where the CPU must write to the attribute memory space.

27.7.6 Computation of the error correction code (ECC) in NAND flash memory

The FMC NAND Card controller includes two error correction code computation hardware blocks, one per memory bank. They reduce the host CPU workload when processing the ECC by software.
These two ECC blocks are identical and associated with Bank 2 and Bank 3. As a consequence, no hardware ECC computation is available for memories connected to Bank 4.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1024, 2048, 4096 or 8192 bytes read or written from/to the NAND flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND flash data bus and read/write signals (NCE and NWE) each time the NAND flash memory bank is active.

The ECC operates as follows:

- When accessing NAND flash memory bank 2 or bank 3, the data present on the D[15:0] bus is latched and used for ECC computation.
- When accessing any other address in NAND flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND flash memory by the host CPU, the FMC_ECCR registers must be read to retrieve the computed value. Once read, they must be cleared by resetting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to one in the FMC_PCR registers.

To perform an ECC computation:
1. Enable the ECCEN bit in the FMC_PCR register.
2. Write data to the NAND flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Read the ECC value available in the FMC_ECCR register and store it in a variable.
4. Clear the ECCEN bit and then enable it in the FMC_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
5. Read the new ECC value available in the FMC_ECCR register.
6. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

1032/3637   RM0456 Rev 5
Bits 31:20 Reserved, must be kept at reset value.

Bits 19:17 **ECCPS[2:0]**: ECC page size
- Defines the page size for the extended ECC:
  - 000: 256 bytes
  - 001: 512 bytes
  - 010: 1024 bytes
  - 011: 2048 bytes
  - 100: 4096 bytes
  - 101: 8192 bytes

Bits 16:13 **TAR[3:0]**: ALE to RE delay
- Sets time from ALE low to RE low in number of AHB clock cycles (HCLK).
  - Time is: \( t_{ar} = (TAR + SET + 2) \times THCLK \) where THCLK is the HCLK clock period
  - 0000: 1 HCLK cycle (default)
  - 1111: 16 HCLK cycles

*Note: SET is MEMSET or ATTSET according to the addressed space.*

Bits 12:9 **TCLR[3:0]**: CLE to RE delay
- Sets time from CLE low to RE low in number of AHB clock cycles (HCLK).
  - Time is: \( t_{clr} = (TCLR + SET + 2) \times THCLK \) where THCLK is the HCLK clock period
  - 0000: 1 HCLK cycle (default)
  - 1111: 16 HCLK cycles

*Note: SET is MEMSET or ATTSET according to the addressed space.*

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **ECCEN**: ECC computation logic enable bit
- 0: ECC logic is disabled and reset (default after reset),
- 1: ECC logic is enabled.

Bits 5:4 **PWID[1:0]**: Data bus width
- Defines the external memory device width.
  - 00: 8 bits
  - 01: 16 bits (default after reset).
  - 10: reserved.
  - 11: reserved.

Bit 3 **PTYP**: Memory type
- Defines the type of device attached to the corresponding memory bank:
  - 0: Reserved, must be kept at reset value
  - 1: NAND flash (default after reset)

Bit 2 **PBKEN**: NAND flash memory bank enable bit
- Enables the memory bank. Accessing a disabled memory bank causes an ERROR on AHB bus
  - 0: Corresponding memory bank is disabled (default after reset)
  - 1: Corresponding memory bank is enabled

Bit 1 **PWAITEN**: Wait feature enable bit
- Enables the Wait feature for the NAND flash memory bank:
  - 0: disabled
  - 1: enabled

Bit 0 Reserved, must be kept at reset value.
**FIFO status and interrupt register (FMC_SR)**

Address offset: 0x84

Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data from the AHB.

This is used to quickly write to the FIFO and free the AHB for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

  - 0: Interrupt rising edge detection request disabled
  - 1: Interrupt rising edge detection request enabled

- **Bit 2 IFS**: Interrupt falling edge status
  - The flag is set by hardware and reset by software.
  - 0: No interrupt falling edge occurred
  - 1: Interrupt falling edge occurred
  - *Note*: *If this bit is written by software to 1 it is set.*

- **Bit 1 ILS**: Interrupt high-level status
  - The flag is set by hardware and reset by software.
  - 0: No Interrupt high-level occurred
  - 1: Interrupt high-level occurred
**Bit 0** **IRS:** Interrupt rising edge status
   The flag is set by hardware and reset by software.
   0: No interrupt rising edge occurred
   1: Interrupt rising edge occurred
   *Note:* If this bit is written by software to 1 it is set.

### Common memory space timing register (FMC_PMEM)

Address offset: Address: 0x88  
Reset value: 0xFCFC FCFC

The FMC_PMEM read/write register contains the timing information for NAND flash memory bank. This information is used to access either the common memory space of the NAND flash for command, address write access and data read/write access.

</tbody>
</table>
| Bits 31:24 **MEMHIZ[7:0]:** Common memory x data bus Hi-Z time
   Defines the number of HCLK clock cycles during which the data bus is kept Hi-Z after the start of a NAND flash write access to common memory space on socket. This is only valid for write transactions:
   0000 0000: 1 HCLK cycle
   1111 1110: 255 HCLK cycles
   1111 1111: reserved.

| Bits 23:16 **MEMHOLD[7:0]:** Common memory hold time
   Defines the number of HCLK clock cycles for write access and HCLK (+2) clock cycles for read access during which the address is held (and data for write accesses) after the command is deasserted (NWE, NOE), for NAND flash read or write access to common memory space on socket x:
   0000 0000: reserved.
   0000 0001: 1 HCLK cycle for write access / 3 HCLK cycles for read access
   1111 1110: 254 HCLK cycles for write access / 256 HCLK cycles for read access
   1111 1111: reserved.

| Bits 15:8 **MEMWAIT[7:0]:** Common memory wait time
   Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for NAND flash read or write access to common memory space on socket. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:
   0000 0000: reserved
   0000 0001: 2HCLK cycles (+ wait cycle introduced by deasserting NWAIT)
   1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)
   1111 1111: reserved.
Attribute memory space timing register (FMC_PATT)

Address offset: 0x8C
Reset value: 0xFCFC FCFC

The FMC_PATT read/write register contains the timing information for NAND flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to Section 27.7.5: NAND flash prewait functionality).

Bits 7:0 **ATTSET[7:0]: Attribute memory setup time**

Defines the number of HCLK (+1) clock cycles to set up address before the command
assertion (NWE, NOE), for NAND flash read or write access to attribute memory space on
socket:

- 0000 0000: 1 HCLK cycle
- 1111 1110: 255 HCLK cycles
- 1111 1111: reserved.

**ECC result registers (FMC_ECCR)**

Address offset: 0x94

Reset value: 0x0000 0000

This register contain the current error correction code value computed by the ECC
computation modules of the FMC NAND controller. When the CPU reads the data from a
NAND flash memory page at the correct address (refer to Section 27.7.6: Computation of
the error correction code (ECC) in NAND flash memory), the data read/written from/to the
NAND flash memory are processed automatically by the ECC computation module. When X
bytes have been read (according to the ECCPS field in the FMC_PCR registers), the CPU
must read the computed ECC value from the FMC_ECC registers. It then verifies if these
computed parity data are the same as the parity value recorded in the spare area, to
determine whether a page is valid, and, to correct it otherwise. The FMC_ECCR register
must be cleared after being read by setting the ECCEN bit to 0. To compute a new data
block, the ECCEN bit must be set to 1.

Refer to Section 2.3 on page 139 for the register boundary addresses.
28 Octo-SPI interface (OCTOSPI)

28.1 Introduction

The OCTOSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- indirect mode: all the operations are performed using the OCTOSPI registers to preset commands, addresses, data, and transfer parameters.
- automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting. This feature is only available in regular-command protocol.
- memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The OCTOSPI supports the following protocols with associated frame formats:

- the regular-command frame format with the command, address, alternate byte, dummy cycles, and data phase
- the HyperBus™ frame format

28.2 OCTOSPI main features

- Functional modes: indirect, automatic status-polling, and memory-mapped
- Read and write support in memory-mapped mode
- External (P)SRAM memory support
- Support for single, dual, quad, and octal communication
- Dual memory configuration, where eight bits can be sent/received simultaneously by accessing two quad memories in parallel
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- Asynchronous bus clock versus kernel clock support
- 8-, 16-, and 32-bit data accesses allowed
- DMA protocol support
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AHB interface with transaction acceptance limited to one: the interface accepts the next transfer on AHB bus only once the previous is completed on memory side.

28.4.3 OCTOSPI interface to memory modes

The OCTOSPI supports the following protocols:
- regular-command protocol
- HyperBus protocol

The OCTOSPI uses from 6 to 12 signals to interface with a memory, depending on the functional mode:
- NCS: chip-select
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS: data strobe used only in regular-command protocol as input only
- IO[3:0]: data bus LSB
- IO[7:4]:
  - data bus MSB used in dual-quad and octal configurations
  - data bus can be used as possible remap for quad-SPI mode
28.4.4 OCTOSPI regular-command protocol

When in regular-command protocol, the OCTOSPI communicates with the external device using commands. Each command can include the following phases:

- Instruction phase
- Address phase
- Alternate-byte phase
- Dummy-cycle phase
- Data phase

Any of these phases can be configured to be skipped but, in case of single-phase command, the only use case supported is instruction-phase-only.

The NCS falls before the start of each command and rises again after each command finishes.

In memory-mapped mode, both read and write operations are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

![Figure 145. SDR read command in octal configuration](image)

The specific regular-command protocol features are configured through the registers in the 0x0100-0x01FC offset range.

**Instruction phase**

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured by ISIZE[1:0] in OCTOSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of OCTOSPI_IR.

The instruction phase can optionally send:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode).

This can be configured using IMODE[2:0] of OCTOSPI_CCR.

The instruction can be sent in DTR mode on each rising and falling edge of the clock, by setting IDTR in OCTOSPI_CCR.

When IMODE[2:0] = 000 in OCTOSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.
In memory-mapped mode, the instruction used for the write operation is specified in OCTOSPI_WIR, and the instruction format is specified in OCTOSPI_WCCR. The instruction used for the read operation and the instruction format are specified in OCTOSPI_IR and OCTOSPI_CCR.

**Address phase**

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured by ADSIZE[1:0] in OCTOSPI_CCR.

In indirect and automatic status-polling modes, the address bytes to be sent are specified by ADDRESS[31:0] in OCTOSPI_AR. In memory-mapped mode, the address is given directly via the AHB (from any master in the system).

The address phase can send:
- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ADMODE[2:0] in OCTOSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR in OCTOSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In memory-mapped mode, the address format for the write operation is specified in OCTOSPI_WCCR. The address format for the read operation is specified in OCTOSPI_CCR.

**Alternate-byte phase**

In the alternate-byte phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured by ABSIZE[1:0] in OCTOSPI_CCR. The bytes to be sent are specified in OCTOSPI_ABR.

The alternate-byte phase can send:
- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ABMODE[2:0] in OCTOSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR in OCTOSPI_CCR.

When ABMODE[2:0] = 000, the alternate-byte phase is skipped and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the dual-SPI mode is used and only two cycles are used for the alternate bytes.
In this case, the firmware can use the quad-SPI mode (ABMODE[2:0] = 011) and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in OCTOSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 5:4 of ALTERNATE[31:0] while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In memory-mapped mode, the alternate bytes used for the write operation are specified in OCTOSPI_WABR, and the alternate byte format is specified in OCTOSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in OCTOSPI_ABR and OCTOSPI_CCR.

**Dummy-cycle phase (memory latency)**

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when the higher clock frequencies are used. The number of cycles given during this phase is specified by DCYC[4:0] in OCTOSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual-SPI, the quad-SPI, or the octal-SPI mode, to receive data from the external device.

In memory-mapped mode, the dummy cycles for the write operations are specified in OCTOSPI_WTCR. The dummy cycles for the read operation are specified in OCTOSPI_TCR.

**Data phase**

During the data phase, any number of bytes can be sent to or received from the external device.

In indirect mode, the number of bytes to be sent/received is specified in OCTOSPI_DLR. In this mode, the data to be sent to the external device must be written to OCTOSPI_DR, while in indirect-read mode the data received from the external device is obtained by reading OCTOSPI_DR.

In automatic status-polling mode, the number of bytes to be received is specified in OCTOSPI_DLR, and the data received from the external device can be obtained by reading OCTOSPI_DR.

In memory-mapped mode, the data read or written, is sent or received directly over the AHB to the Cortex core or to a DMA.

The data phase can send/receive:
- 1 bit at a time (over IO0/IO1 (SO/SI respectively) in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using DMODE[2:0] in OCTOSPI_CCR.
The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR in OCTOSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in indirect-write mode.

In memory-mapped mode, the data format for the write operation is specified in OCTOSPI_WCCR. The data format for the read operation is specified in OCTOSPI_CCR.

**DQS use**

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.

The DQS management can be enabled by setting DQSE in OCTOSPI_CCR.

![Figure 146. DTR read in octal-SPI mode with DQS (Macronix mode) example](image)

### 28.4.5 OCTOSPI regular-command protocol signal interface

#### Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (whose I/Os are shared with IO0). The data received from the external device arrives via SI (whose I/Os are shared with IO1).

The different phases can each be configured separately to use this single-SPI mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in single-SPI mode:
- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0 (to deactivate the "write protect" function).
- IO3 is in output mode and forced to 1 (to deactivate the "hold" function).
- IO4 to IO7 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.
Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in dual-SPI mode:
- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 010, IO0/IO1 are always high-impedance.

Quad-SPI mode

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the quad-SPI mode by setting to 011 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in quad-SPI mode:
- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 011, IO0 to IO3 are all high-impedance.

Octal-SPI mode

In regular octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the octal-SPI mode by setting to 100 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase that is configured in octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 100, IO[0:7] are all high-impedance.

Single-data rate (SDR) mode

By default, all the phases operate in SDR mode.

In this mode, when the OCTOSPI drives the IO0/SO, IO1 to IO7 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the OCTOSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in OCTOSPI_TCR), the signals are sampled using the following (rising) edge of CLK.
Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte, and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in OCTOSPI_CCR.

In memory-mapped mode, the DTR mode for each phase of the write operations is specified in OCTOSPI_WCCR. The DTR mode for each phase of the read operations is specified in OCTOSPI_CCR.

In DTR mode, when the OCTOSPI drives the IO0/SO and IO1to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the OCTOSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in OCTOSPI_CCR, the software must clear SSHIFT in OCTOSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

In DTR mode, it is recommended to set DHQC of OCTOSPI_TCR, to shift the outputs by a quarter of cycle and avoid holding issues on the memory side.

Note: DHQC must not be set when the prescaler value is 0, as this action leads to unpredictable behavior.

Dual-quad configuration

When DMM = 1 in OCTOSPI_CR, the OCTOSPI is in dual-memory configuration: if DMODE = 011, two external Quad-SPI devices (device A and device B) are used in order to
send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.

The dual-quad configuration can be used in conjunction with the single-SPI, dual-SPI, and quad-SPI modes, as well as with either the SDR or DTR mode.

The device size, as specified by DEVSIZE[4:0] in OCTOSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the OCTOSPI gives for address X is the byte at the address X/2 of device A, and the byte that the OCTOSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the OCTOSPI must be configured with a data length of 2 bytes (16 bits), and the OCTOSPI receives one byte from each device.

If each device gives a status of 16 bits, then the OCTOSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The fourth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in OCTOSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

28.4.6 HyperBus protocol

The OCTOSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins depending on the operating voltage:

- IO[7:0] as bidirectional data bus
- RWDS for read and write data strobe and latency insertion (mapped on DQS pin)
- NCS
- CLK
- NCLK for 1.8 V operations (to support this mode, the device must be powered with 1.8 V)

The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.
The HyperBus frame is composed of the following phases:

- Command/address phase
- Data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.

**Figure 149. Example of HyperBus read operation**

The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

**Command/address phase**

During this initial phase, the OCTOSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

**Table 252. Command/address phase description**

The address space is configured through the memory type MTYP[2:0] in OCTOSPI_DCR1. The total size of the device is configured in DEVSIZE[4:0] of OCTOSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

**Note:** Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.
Read/write operation with initial latency

The HyperBus read and write operations need to respect two timings:

- $t_{RWR}$: minimal read/write recovery time for the device (defined by TRWR[7:0] in OCTOSPI_HLCR)
- $t_{ACC}$: access time for the device (defined by TACC[7:0] in OCTOSPI_HLCR) according to the memory latency

During the read operation, the RWDS is used by the device, in two ways (see Figure 149):

- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation, the RWDS is used:

- by the device, during the command/address phase, to request an additional latency.
- by the OCTOSPI, during the data phase, for write data masking.

**Figure 150. HyperBus write operation with initial latency**
Read/write operation with additional latency

If the device needs an additional latency (during refresh period of an SDRAM for example), RWDS must be tied to one during one of the RWDS signals, during the command/address phase.

An additional $t_{ACC}$ duration is added by the OCTOSPI to meet the device request.

**Figure 151. HyperBus read operation with additional latency**

**Figure 152. HyperBus write operation with additional latency**

Fixed-latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.

The latency can be forced to $2 \times t_{ACC}$ by setting LM in OCTOSPI_HLCR.

In this OCTOSPI latency mode, the state of the RWDS signal is not taken into account by the OCTOSPI, and an additional latency is always added, leading to a fixed $2 \times t_{ACC}$ latency time.
Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in OCTOSPI_HLCR.

Figure 153. HyperBus write operation with no latency (register write)

Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the $t_{ACC}$ time.

Figure 154. HyperBus read operation page crossing with latency

28.4.7 Specific features

The OCTOSPI supports some specific features, such as:

- Wrap support
- NCS boundary and refresh
- Communication regulation

Wrap support

The OCTOSPI supports a hybrid wrap as defined by the HyperBus protocol. A hybrid wrap is also supported in the regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.
The wrap size supported by the target memory is configured by WRAPSIZE in OCTOSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 4 bytes. Wrapped reads are supported for both HyperBus and regular-command protocols. To enable wrapped-read accesses, the dedicated OCTOSPI_WPxxx registers must be programmed according to the wrapped-read access characteristics. These registers apply for both HyperBus and regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

Note: The wrap operation cannot be interrupted by a refresh. The refresh event is only considered after the wrap completion.

NCS boundary and refresh

Two processes can be activated to regulate the OCTOSPI transactions:

- NCS boundary
- Refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with, is configured by CSBOUND[4:0] in OCTOSPI_DCR3: it is equal to $2^{CSBOUND}$.

As an example, if CSBOUND[4:0] = 0x4, the boundary is set to $2^4 = 16$ bytes. The NCS is then released each time the LSB address is equal to 0xF, and each time a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled. A minimum value of three is recommended.

The NCS boundary feature cannot be used for flash memory devices in write mode since a command is necessary to program another page of the flash memory.

The refresh feature limits the duration of the transactions to the value programmed by REFRESH[31:0] in OCTOSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command/address/alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

Communication regulation

The communication regulation feature limits the maximum length of a transaction to the value programmed by MAXTRAN[7:0] in OCTOSPI_DCR3.

If the number of clock cycles reaches the MAXTRAN + 1 value, and if the second OCTOSPI requests access, the NCS is released and a new transaction is issued to address the next data. If the second OCTOSPI does not request an access, the transaction is not stopped and the NCS is not released.

If MAXTRAN[7:0] = 0, no limitation occurs.

The MAXTRAN[7:0] value must be greater than the minimal transaction size in terms of number of cycles including the command, address, alternate, and dummy phases.
Note: The communication regulation feature cannot be used in write mode for the flash memory devices that require extra command to reenable the write operation after the NCS is active again.

If NCS boundary, refresh, and communication regulation are enabled at the same time, the NCS is released on the first condition met.

Restarting after an interrupted transfer

When a read or write operation is interrupted by a timeout or communication regulation feature, the Octo-SPI interface, as soon as possible after getting back the port ownership, reissues the initial command sequence together with the address following the last address actually accessed before interruption. The transfer initially set goes on and ends seamlessly.

28.4.8 OCTOSPI operating mode introduction

The OCTOSPI has the following operating modes regardless of the low-level protocol used (either regular-command or HyperBus):

- indirect mode (read or write)
- automatic status-polling mode (only in regular-command protocol)
- memory-mapped mode

28.4.9 OCTOSPI indirect mode

In indirect mode, the commands are started by writing to the OCTOSPI registers, and data are transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 00 in OCTOSPI_CR, the OCTOSPI is in indirect-write mode: bytes are sent to the external device during the data phase. Data are provided by writing to OCTOSPI_DR.

When FMODE[1:0] = 01, the OCTOSPI is in indirect-read mode: bytes are received from the external device during the data phase. Data are recovered by reading OCTOSPI_DR.

In indirect mode, when the OCTOSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

Note: The OCTOSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.

The number of bytes to be read/written is specified in OCTOSPI_DLR:

- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the OCTOSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in OCTOSPI_CCR.
- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the OCTOSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, the TCF bit is set in OCTOSPI_SR, and an interrupt is generated if TCIE = 1 in OCTOSPI_CR. In the
case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in OCTOSPI_DCR1.

**Triggering the start of a transfer in regular-command protocol**

Depending on the OCTOSPI configuration, there are three different ways to trigger the start of a transfer in indirect mode when using the regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in indirect mode, a transfer starts when one of the following sequence of events occurs:

- if no address is necessary (ADMODE[2:0] = 000) and if no data need to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in OCTOSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data need to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in OCTOSPI_AR
- if data need to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in OCTOSPI_DR

A write to OCTOSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in OCTOSPI_SR.

**Triggering the start of a transfer in HyperBus protocol**

Depending on the OCTOSPI configuration, there are different ways to trigger the start of a command in indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (OCTOSPI_AR) with ADMODE[2:0] ≠ 000 in indirect read mode (FMODE[1:0] = 01).
- when a write is performed to DATA[31:0] (OCTOSPI_DR) in indirect-write mode (when FMODE = 00).
- when a (dummy) write is performed to INSTRUCTION[31:0] (OCTOSPI_IR) for indirect read mode (with ADMODE[2:0] = 000 and FMODE = 01).

As soon as a transfer is started, the BUSY bit (OCTOSPI_SR[5]) is automatically set.

**FIFO and data management**

Data in indirect mode passes through a 32-byte FIFO that is internal to the OCTOSPI. FLEVEL in OCTOSPI_SR indicates how many bytes are currently being held in the FIFO.

AHB burst transactions are supported. Data of the burst are successively written in OCTOSPI_DR, and immediately transferred in the internal FIFO.

In indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in OCTOSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).
The byte/half-word accesses to OCTOSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

28.4.10 OCTOSPI automatic status-polling mode

In automatic status-polling mode, the OCTOSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value. The automatic status-polling mode must be used only in regular-command protocol. For HyperBus protocol, it is not exploitable since the read status register into the HyperFlash memory must be performed in two steps (a write operation followed by a read operation).

The access to the device begins in the same manner as in indirect-read mode. BUSY in OCTOSPI_SR goes high at this point and stays high even between the periodic accesses.

The content of MASK[31:0] in OCTOSPI_PSMAR is used to mask the data from the external device in automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in OCTOSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in OCTOSPI_CR, the AND-match mode is activated: SMF is set in OCTOSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in OCTOSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in OCTOSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the OCTOSPI is disabled (EN = 0).

OCTOSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in OCTOSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In automatic status-polling mode, variable latency is not supported. The memory must then be configured in fixed latency.
28.4.11 OCTOSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

*Note:* No more than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256 Mbytes range, then an AHB error is given. The effect of this error depends on the AHB master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated, and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the OCTOSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations end up quickly since their results were prefetched.

By default, the OCTOSPI never stops its prefetch operation. It either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time.

Since external devices tend to consume more when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in OCTOSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in OCTOSPI_LPTR, when x cycles have elapsed without access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

28.4.12 OCTOSPI configuration introduction

The OCTOSPI configuration is done in three steps:

1. OCTOSPI system configuration
2. OCTOSPI device configuration
3. OCTOSPI mode configuration

28.4.13 OCTOSPI system configuration

The OCTOSPI is configured using OCTOSPI_CR. The user must program:

- the functional mode with FMODE[1:0]
- the automatic status-polling mode behavior if needed with PMM and APMS
- the FIFO level with FTHRES
- the DMA use with DMAEN
- the timeout counter use with TCEN
- the dual-memory configuration, if needed, with DMM

In case of an interrupt use, the respective enable bit can also be set during this phase.
If the timeout counter is used, the timeout value is programmed in OCTOSPI_LPTR.

The DMA channel must not be enabled during the OCTOSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and OCTOSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

28.4.14 OCTOSPI device configuration

The parameters related to the external device targeted are configured through OCTOSPI_DCR1 and OCTOSPI_DCR2. The user must program:

- the device size with DEVSIZE[4:0]
- the chip-select minimum high time with CSHT[5:0]
- the clock mode with FRCK and CKMODE
- the device frequency with PRESCALER[7:0]

MTYP[2:0] defines the memory type to be used for 8-line modes:

- Micron mode with D0/D1 ordering in 8-data-bit mode (DMODE[2:0] = 100)
- Macronix mode with D1/D0 ordering in 8-data-bit mode (DMODE[2:0] = 100).
  MTYP[2:0] = 001 targets Octaflash memory whereas MTYP[2:0] = 011 addresses OctaRAM™ memory having specific address phase (address is built with row and column to fit with Macronix requirements).
- HyperBus memory mode: the protocol follows the HyperBus specification.
- HyperBus register mode, addressing register space: the memory-mapped accesses in this mode must be noncachable, or the indirect-read/write modes must be used.

DEVSIZE[4:0] defines the size of external memory using the following formula:

\[ \text{Number of bytes in the device} = 2^{\text{DEVSIZE}+1} \]

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

If DMM = 1, DEVSIZE[4:0] indicates the total capacity of the two devices together.

When the OCTOSPI executes two commands, one immediately after the other, it raises the chip-select signal (NCS) high between the two commands for only one CLK cycle by default.

If the external device requires more time between commands, the chip-select high time CSHT[5:0] can be used to specify the minimum number of CLK cycles for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

In HyperBus protocol, the device timing (tACC and tRWR) and the latency mode must be configured in OCTOSPI_HLCR.
28.4.15 OCTOSPI regular-command mode configuration

Indirect mode configuration

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected, and data can be read from the external device.

When the OCTOSPI is used in indirect mode, the frames are constructed in the following way:
1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the frame timing in OCTOSPI_TCR.
3. Specify the frame format in OCTOSPI_CCR.
4. Specify the instruction in OCTOSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
6. Specify the targeted address in OCTOSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

If neither the address register (OCTOSPI_AR) nor the data register (OCTOSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

Automatic status-polling mode configuration

The automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and data are retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored, and only 4 bytes are read. The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, the following can be processed:
• Set SMF (an interrupt is generated if enabled).
• Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR, and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The OCTOSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in OCTOSPI_DR.

When the OCTOSPI is used in automatic status-polling mode, the frames are constructed in the following way:
1. Specify the input mask in OCTOSPI_PSMKR.
2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the frame timing in OCTOSPI_TCR.
6. Specify the frame format in OCTOSPI_CCR.
7. Specify the instruction in OCTOSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
9. Specify the optional targeted address in OCTOSPI_AR.

If the address register (OCTOSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

**Memory-mapped mode configuration**

In memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled. The indirect-write mode fulfills this operation, possibly in conjunction with the automatic status-polling mode.

The memory-mapped mode is entered by setting FMODE[1:0] = 11 in OCTOSPI_CR.

The programmed instruction and frame are sent when an AHB master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in memory-mapped mode.

When the OCTOSPI is used in memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in OCTOSPI_TCR for read operation.
2. Specify the frame format in OCTOSPI_CCR for read operation.
3. Specify the instruction in OCTOSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR for read operation.
5. Specify the frame timing in OCTOSPI_WTCR for write operation.
6. Specify the frame format in OCTOSPI_WCCR for write operation.
7. Specify the instruction in OCTOSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_WABR for write operation.

All configuration operations must be completed (ensured by checking BUSY = 0) before the first access to the memory area: any register write operation when BUSY = 1 has no effect and is not signaled with an error response. On the first access, the OCTOSPI becomes
bus, and no further configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

**OCTOSPI delayed data sampling when no DQS is used**

By default, when no DQS is used, the OCTOSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in OCTOSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

**OCTOSPI delayed data sampling when DQS is used**

When external DQS is used as a sampling clock, it can be shifted in time to compensate the data propagation delay. This shift is performed by an external delay block located outside the OCTOSPI. The control of this feature depends on the device implementation (see the product reference manual for more details).

In configurations where delay does not need to be compensated, the external delay block can be bypassed by setting DLYBYP in OCTOSPI_DCR1.

**Sending the instruction only once (SIOO)**

A flash memory can provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. The user can take advantage of this type of features using SIOO in OCTOSPI_CCR.

SIOO is valid for memory-mapped mode only. If this bit is set, the instruction is sent only for the first command following a write to OCTOSPI_CCR.

Subsequent command sequences skip the instruction phase, until there is a write to OCTOSPI_CCR. SIOO has no effect when IMODE[1:0] = 00 (no instruction).

The SIOO mode is not supported when any of the communication regulations, NCS boundary, or refresh features are used.

**28.4.16 OCTOSPI HyperBus protocol configuration**

**Indirect mode configuration (HyperBus)**

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected where data can be read from the external device. ADMODE must be configured with a value different from 000 (for instance ADMODE = 100).

When the OCTOSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the targeted address in OCTOSPI_AR.
3. Enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

In indirect-read mode, the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.
In indirect-write mode, the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

**Memory-mapped mode configuration (HyperBus)**

In memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

The memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AHB master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in memory-mapped mode.

All the configuration operation must be completed before the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no configuration is allowed.

Then, the only way to get BUSY low is to clear the ENABLE bit, or to abort by setting the ABORT bit.

### 28.4.17 OCTOSPI error management

An error can be generated in the following cases:

- in indirect or automatic status-polling mode, when a wrong address has been programmed in OCTOSPI_AR (according to the device size defined by DEVSIZE[4:0]): this sets TEF and an interrupt is generated if enabled.
- in indirect mode, if the address plus the data length exceed the device size: TEF is set as soon as the access is triggered.
- in memory-mapped mode when an out-of-range access is done by an AHB master: this generates an AHB error as a response to the faulty AHB request.
- when the memory-mapped mode is disabled: an access to the memory-mapped area generates an AHB error as a response to the faulty AHB request.

The OCTOSPI generates an AHB slave error in the following situations:

- The memory-mapped mode is disabled and an AHB read request occurs.
- A read or write address exceeds the size of the external memory.
- An abort is received while a read or write burst is ongoing.
- The OCTOSPI is disabled while a read or write burst is ongoing.
- A write wrap burst is received.
- A write request is received while DQSE = 0 in OCTOSPI_WCCR in octal DTR mode or in dual-memory configuration.
- Write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means that the HSIZE is different from 4 bytes (only for memory-mapped mode).
- Illegal wrap size when receiving read wrap burst with size different from 4 bytes (only for memory-mapped mode).
28.4.18 OCTOSPI BUSY and ABORT

Once the OCTOSPI starts an operation with the external device, BUSY is automatically set in OCTOSPI_SR.

In indirect mode, BUSY is reset once the OCTOSPI has completed the requested command sequence and the FIFO is empty.

In automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on an abort.

Any operation can be aborted by setting ABORT in OCTOSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers. When DMA is enabled to handle the data read or write operations in OCTOSPI_DR, it is recommended to disable the DMA channel before aborting the OCTOSPI.

Note: Some devices may misbehave if a write operation to a status register is aborted.

28.4.19 OCTOSPI reconfiguration or deactivation

Before any OCTOSPI reconfiguration, the software must ensure that all the transactions are completed:

- After a memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a memory-mapped read, the software must perform a synchronization barrier than an abort.

28.4.20 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 (clock mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

![Figure 155. NCS when CKMODE = 0 (T = CLK period)](image-url)
When CKMODE = 1 (clock mode 3: CLK goes high when no operation is in progress) and when in SDR mode, NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

**Figure 156. NCS when CKMODE = 1 in SDR mode (T = CLK period)**

![Diagram](MSv44101V1)

When the CKMODE = 1 (clock mode 3) and DDTR = 1 (data DTR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge (see the figure below). Because the DTR operations must finish with a falling edge, CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

**Figure 157. NCS when CKMODE = 1 in DTR mode (T = CLK period)**

![Diagram](MSv44102V1)

When the FIFO stays full during a read operation, or if the FIFO stays empty during a write operation, the operation stalls and CLK stays low until the software services the FIFO. If an abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later (see the figure below).

**Figure 158. NCS when CKMODE = 1 with an abort (T = CLK period)**

![Diagram](MSv44103V1)
### 28.5 Address alignment and data number

The table below summarizes the effect of the address alignment and programmed data number depending on the use case.

<table>

4. Extra data at transfer start.
5. Extra data at transfer end.
6. WDM = write data mask.
### 28.6 OCTOSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available to provide more flexibility.

<table>
<thead>
<tr>

<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **FMODE[1:0]**: Functional mode

This bitfield defines the OCTOSPI functional mode of operation.

00: Indirect-write mode

01: Indirect-read mode

10: Automatic status-polling mode (relevant in regular-command protocol only)

11: Memory-mapped mode

If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value. If FMODE[1:0] and FTHRES[4:0] are wrongly updated while DMAEN = 1, the DMA request signal automatically goes to inactive state.

*Note: This bitfield can be modified only when BUSY = 0.*
Bits 27:24 Reserved, must be kept at reset value.

Bit 23 **PMM**: Polling match mode

This bit indicates which method must be used to determine a match during the automatic status-polling mode.

- 0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.
- 1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.

*Note:* This bit can be modified only when BUSY = 0.

Bit 22 **APMS**: Automatic status-polling mode stop

This bit determines if the automatic status-polling mode is stopped after a match.

- 0: Automatic status-polling mode is stopped only by abort or by disabling the OCTOSPI.
- 1: Automatic status-polling mode stops as soon as there is a match.

*Note:* This bit can be modified only when BUSY = 0.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE**: Timeout interrupt enable

This bit enables the timeout interrupt.

- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 19 **SMIE**: Status-match interrupt enable

This bit enables the status-match interrupt.

- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable

This bit enables the FIFO threshold interrupt.

- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable

This bit enables the transfer complete interrupt.

- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable

This bit enables the transfer error interrupt.

- 0: Interrupt disabled
- 1: Interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.
Bits 12:8 FTHRES[4:0]: FIFO threshold level
This bitfield defines, in indirect mode, the threshold number of bytes in the FIFO that causes
the FIFO threshold flag FTF in OCTOSPI_SR, to be set.
00000: FTF is set if there are one or more free bytes available to be written to in the FIFO
in indirect-write mode, or if there are one or more valid bytes can be read from the FIFO
in indirect-read mode.
00001: FTF is set if there are two or more free bytes available to be written to in the FIFO
in indirect-write mode, or if there are two or more valid bytes can be read from the FIFO
in indirect-read mode.
...11111: FTF is set if there are 32 free bytes available to be written to in the FIFO in
indirect-write mode, or if there are 32 valid bytes can be read from the FIFO in indirect-read
mode.
Note: If DMAEN = 1, the DMA controller for the corresponding channel must be disabled
before changing the FTHRES[4:0] value.

Bit 7 MSEL: External memory select
This bit selects the external memory to be addressed in single-, dual-, quad-SPI mode in
single-memory configuration (when DMM = 0).
0: External memory 1 selected (data exchanged over IO[3:0])
1: External memory 2 selected (data exchanged over IO[7:4])
This bit is ignored when DMM = 1 or when octal-SPI mode is selected.

Bit 6 DMM: Dual-memory configuration
This bit activates the dual-memory configuration, where two external devices are used
simultaneously to double the throughput and the capacity
0: Dual-memory configuration disabled
1: Dual-memory configuration enabled
Note: This bit can be modified only when BUSY = 0.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 TCEN: Timeout counter enable
This bit is valid only when the memory-mapped mode (FMODE[1:0] = 11) is selected. This bit
enables the timeout counter.
0: The timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely
after an access in memory-mapped mode.
1: The timeout counter is enabled, and thus the chip-select is released in the memory-
mapped mode after TIMEOUT[15:0] cycles of external device inactivity.
Note: This bit can be modified only when BUSY = 0.

Bit 2 DMAEN: DMA enable
In indirect mode, the DMA can be used to input or output data via OCTOSPI_DR. DMA
transfers are initiated when FTF is set.
0: DMA disabled for indirect mode
1: DMA enabled for indirect mode
Note: Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with
the DMA. Do not write this bit during DMA operation.

Bit 1 ABORT: Abort request
This bit aborts the ongoing command sequence. It is automatically reset once the abort is
completed. This bit stops the current transfer.
0: No abort requested
1: Abort requested
Note: This bit is always read as 0.
Bit 0 **EN**: Enable
This bit enables the OCTOSPI.
0: OCTOSPI disabled
1: OCTOSPI enabled

Note: The DMA request can be aborted without having received the ACK in case this EN bit is cleared during the operation.
In case this bit is set to 0 during a DMA transfer, the REQ signal to DMA returns to inactive state without waiting for the ACK signal from DMA to be active.

### 28.7.2 OCTOSPI device configuration register 1 (OCTOSPI_DCR1)

Address offset: 0x0008
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

</tbody>
</table>

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **MTYP[2:0]**: Memory type
This bitfield indicates the type of memory to be supported.
000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. regular-command protocol in single-, dual-, quad- and octal-SPI modes.
Note: In this mode, DQS signal polarity is inverted with respect to the memory clock signal.
This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron.
001: Macronix mode, D1/D0 ordering in DTR 8-data-bit mode. regular-command protocol in single-, dual-, quad- and octal-SPI modes.
010: Standard mode
011: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. regular-command protocol in single-, dual-, quad- and octal-SPI modes with dedicated address mapping.
100: HyperBus memory mode, the protocol follows the HyperBus specification.
101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be non-cacheable, or indirect-read/write modes must be used.
Others: Reserved

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **DEVSIZE[4:0]**: Device size
This bitfield defines the size of the external device using the following formula:
Number of bytes in device = 2**(DEVSIZE+1).
DEVSIZE + 1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 Gbytes (addressed using 32-bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.
In regular-command protocol, if DMM = 1, DEVSIZE[4:0] indicates the capacity of one of the two external devices.
**28.7.3 OCTOSPI device configuration register 2 (OCTOSPI_DCR2)**

Address offset: 0x000C

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

<table>
<thead>
<tr>
<th>Bits 31:19</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Bits 15:14</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>

**Bits 13:8** **CSHT[5:0]: Chip-select high time**

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.

0x0: NCS stays high for at least 1 cycle between external device commands.

0x1: NCS stays high for at least 2 cycles between external device commands.

...  
0x3F: NCS stays high for at least 64 cycles between external device commands.

**Bits 7:4** Reserved, must be kept at reset value.

**Bit 3** **DLYBYP: Delay block bypass**

0: The internal sampling clock (called feedback clock) or the DQS data strobe external signal is delayed by the delay block (for more details on this block, refer to the dedicated section of the reference manual as it is not part of the OCTOSPI peripheral).

1: The delay block is bypassed, so the internal sampling clock or the DQS data strobe external signal is not affected by the delay block. The delay is shorter than when the delay block is not bypassed, even with the delay value set to minimum value in delay block.

**Bit 2** Reserved, must be kept at reset value.

**Bit 1** **FRCK: Free running clock**

0: CLK is not free running.

1: CLK is free running (always provided).

*Note: Free running clock mode is intended for delay calibration only. No memory or other device access is possible when FRCK is set.*

**Bit 0** **CKMODE: Clock mode 0/mode 3**

This bit indicates the level taken by the CLK between commands (when NCS = 1).

0: CLK must stay low while NCS is high (chip-select released). This is referred to as clock mode 0.

1: CLK must stay high while NCS is high (chip-select released). This is referred to as clock mode 3.
Bits 18:16 **WRAPSIZE[2:0]**: Wrap size

This bitfield indicates the wrap size to which the memory is configured. For memories which have a separate command for wrapped instructions, this bitfield indicates the wrap-size associated with the command held in the OCTOSPI1_WPIR register.

000: Wrapped reads are not supported by the memory.
010: External memory supports wrap size of 16 bytes.
011: External memory supports wrap size of 32 bytes.
100: External memory supports wrap size of 64 bytes.
101: External memory supports wrap size of 128 bytes.
Others: Reserved

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **PRESCALER[7:0]**: Clock prescaler

This bitfield defines the scaler factor for generating the CLK based on the kernel clock 
(value + 1).

0: FCLK = FKERNEL, kernel clock used directly as OCTOSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the OCTOSPI a kernel clock that has 50% duty-cycle.
1: FCLK = FKERNEL/2
2: FCLK = FKERNEL/3
... 
255: FCLK = FKERNEL/256

For odd clock division factors, the CLK duty cycle is not 50 %. The clock signal remains low one cycle longer than it stays high.

28.7.4 OCTOSPI device configuration register 3 (OCTOSPI_DCR3)

Address offset: 0x0010
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary

This bitfield enables the transaction boundary feature. When active, a minimum value of 3 is recommended. The NCS is released on each boundary of $2^{CSBOUND}$ bytes.

0: NCS boundary disabled
Others: NCS boundary set to $2^{CSBOUND}$ bytes

Bits 15:8 Reserved, must be kept at reset value.
28.7.5 OCTOSPI device configuration register 4 (OCTOSPI_DCR4)

</table>

Bits 31:0 REFRESH[31:0]: Refresh rate
This bitfield enables the refresh rate feature. The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads. These two values can be extended with few clock cycles when refresh occurs during a byte transmission in single-, dual- or quad-SPI mode, because the byte transmission must be completed.

0: Refresh disabled
Others: Maximum communication length is set to REFRESH + 1 clock cycles.

Note: REFRESH count is based on the divided clock period: if OCTOSPI_DCR2 PRESCALER bitfield is changed, the REFRESH field must be updated accordingly.

28.7.6 OCTOSPI status register (OCTOSPI_SR)

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 FLEVEL[5:0]: FIFO level
This bitfield gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full.

In automatic status-polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.
Bit 5 **BUSY**: Busy  
This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag  
This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag  
This bit is set in automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (OCTOSPI_PSMAR). It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag  
In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete. It is cleared automatically as soon as the threshold condition is no longer true. In automatic status-polling mode, this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag  
This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted. It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag  
This bit is set in indirect mode when an invalid address is being accessed in indirect mode. It is cleared by writing 1 to CTEF.

### 28.7.7 OCTOSPI flag clear register (OCTOSPI_FCR)

Address offset: 0x0024  
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:0 DL[31:0]: Data length

Number of data to be retrieved (value+1) in indirect and automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for automatic status-polling mode.

All 1’s in indirect mode means undefined length, where OCTOSPI continues until the end of the memory, as defined by DEVSIZE.
0x0000_0000: 1 byte is to be transferred.
0x0000_0001: 2 bytes are to be transferred.
0x0000_0002: 3 bytes are to be transferred.
0x0000_0003: 4 bytes are to be transferred.
...
0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.
0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.
0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F.

DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.

This bitfield has no effect in memory-mapped mode.

28.7.9 OCTOSPI address register (OCTOSPI_AR)

Address offset: 0x0048
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0 and FMODE ≠ 11.

<table>

<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

Bits 31:0 DATA[31:0]: Data
Data to be sent/received to/from the external SPI device
In indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.
In indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.
In automatic status-polling mode, this register contains the last data read from the external device (without masking).
Word, half-word, and byte accesses to this register are supported. In indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes.
Similarly, in indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].

28.7.11 OCTOSPI polling status mask register (OCTOSPI_PSMKR)

Address offset: 0x0080
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.

<table>
<thead>

</tr>
</tbody>
</table>

Bits 31:0 MASK[31:0]: Status mask
Mask to be applied to the status bytes received in automatic status-polling mode
For bit n:
0: Bit n of the data received in automatic status-polling mode is masked and its value is not considered in the matching logic.
1: Bit n of the data received in automatic status-polling mode is unmasked and its value is considered in the matching logic.
28.7.12  OCTOSPI polling status match register (OCTOSPI_PSMAR)

Address offset: 0x0088
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:0 ADSIZE[1:0]: AD size
Bits 14:13 ADTR: AD transfer size
Bits 12:11 ABTR: AB transfer size
Bits 10:9 ADMODE[2:0]: AD mode
Bits 8:7 IDTR: ID mode
Bits 6:5idi| 1080/3637 | RM0456 Rev 5 |
Bit 31  **SIOO**: Send instruction only once mode  
This bit has no effect when IMODE = 00 (see *Sending the instruction only once (SIOO)*).  
0: Send instruction on every transaction  
1: Send instruction only for the first command  

Bit 30  Reserved, must be kept at reset value.  

Bit 29  **DQSE**: DQS enable  
This bit enables the data strobe management.  
0: DQS disabled  
1: DQS enabled  

Bit 28  Reserved, must be kept at reset value.  

Bit 27  **DDTR**: Data double transfer rate  
This bit sets the DTR mode for the data phase.  
0: DTR mode disabled for data phase  
1: DTR mode enabled for data phase  

Bits 26:24  **DMODE[2:0]**: Data mode  
This bitfield defines the data phase mode of operation.  
000: No data  
001: Data on a single line  
010: Data on two lines  
011: Data on four lines  
100: Data on eight lines  
Others: Reserved  

Bits 23:22  Reserved, must be kept at reset value.  

Bits 21:20  **ABSIZE[1:0]**: Alternate-byte size  
This bitfield defines the alternate-byte size.  
00: 8-bit alternate bytes  
01: 16-bit alternate bytes  
10: 24-bit alternate bytes  
11: 32-bit alternate bytes  

Bit 19  **ABDTR**: Alternate-byte double transfer rate  
This bit sets the DTR mode for the alternate-byte phase.  
0: DTR mode disabled for the alternate-byte phase  
1: DTR mode enabled for the alternate-byte phase  

Bits 18:16  **ABMODE[2:0]**: Alternate-byte mode  
This bitfield defines the alternate-byte phase mode of operation.  
000: No alternate bytes  
001: Alternate bytes on a single line  
010: Alternate bytes on two lines  
011: Alternate bytes on four lines  
100: Alternate bytes on eight lines  
Others: Reserved  

Bits 15:14  Reserved, must be kept at reset value.  

Bit 13  **ABDTR**: Alternate-byte data ready (ABDTR)  
This bit indicates whether the alternate-byte data is ready or not.  
0: Alternate-byte data not ready  
1: Alternate-byte data ready  

Bit 12  **DTR**: Data transfer ready (DTR)  
This bit indicates whether the data is ready or not.  
0: Data not ready  
1: Data ready  

Bit 11  **ABDTR**: Alternate-byte double transfer rate  
This bit sets the DTR mode for the alternate-byte phase.  
0: DTR mode disabled for the alternate-byte phase  
1: DTR mode enabled for the alternate-byte phase  

Bit 10  **ABMODE[2:0]**: Alternate-byte mode  
This bitfield defines the alternate-byte phase mode of operation.  
000: No alternate bytes  
001: Alternate bytes on a single line  
010: Alternate bytes on two lines  
011: Alternate bytes on four lines  
100: Alternate bytes on eight lines  
Others: Reserved  

Bit 9  **DTR**: Data transfer ready (DTR)  
This bit indicates whether the data is ready or not.  
0: Data not ready  
1: Data ready  

Bit 8  **DQSE**: DQS enable  
This bit enables the data strobe management.  
0: DQS disabled  
1: DQS enabled  

Bit 7  **DDTR**: Data double transfer rate  
This bit sets the DTR mode for the data phase.  
0: DTR mode disabled for data phase  
1: DTR mode enabled for data phase  

Bits 6:4  **DMODE[2:0]**: Data mode  
This bitfield defines the data phase mode of operation.  
000: No data  
001: Data on a single line  
010: Data on two lines  
011: Data on four lines  
100: Data on eight lines  
Others: Reserved  

Bits 3:0  **ABSIZE[1:0]**: Alternate-byte size  
This bitfield defines the alternate-byte size.  
00: 8-bit alternate bytes  
01: 16-bit alternate bytes  
10: 24-bit alternate bytes  
11: 32-bit alternate bytes  

Bit 0  **SIOO**: Send instruction only once mode  
This bit has no effect when IMODE = 00 (see *Sending the instruction only once (SIOO)*).  
0: Send instruction on every transaction  
1: Send instruction only for the first command
Bits 13:12 **ADSIZE[1:0]**: Address size

This bitfield defines the address size.

- 00: 8-bit address
- 01: 16-bit address
- 10: 24-bit address
- 11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate

This bit sets the DTR mode for the address phase.

- 0: DTR mode disabled for the address phase
- 1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode

This bitfield defines the address phase mode of operation.

- 000: No address
- 001: Address on a single line
- 010: Address on two lines
- 011: Address on four lines
- 100: Address on eight lines
- Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size

This bitfield defines instruction size.

- 00: 8-bit instruction
- 01: 16-bit instruction
- 10: 24-bit instruction
- 11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate

This bit sets the DTR mode for the instruction phase.

- 0: DTR mode disabled for the instruction phase
- 1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode

This bitfield defines the instruction phase mode of operation.

- 000: No instruction
- 001: Instruction on a single line
- 010: Instruction on two lines
- 011: Instruction on four lines
- 100: Instruction on eight lines
- Others: Reserved
28.7.15 OCTOSPI timing configuration register (OCTOSPI_TCR)

Address offset: 0x0108
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bit 31  Reserved, must be kept at reset value.

Bit 30  SSHIFT: Sample shift
- By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
- This bit allows the data to be sampled later in order to consider the external signal delays.
  0: No shift
  1: 1/2 cycle shift
- The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bit 29  Reserved, must be kept at reset value.

Bit 28  DHQC: Delay hold quarter cycle
  0: No delay hold
  1: 1/4 cycle hold

Bits 27:5  Reserved, must be kept at reset value.

Bits 4:0  DCYC[4:0]: Number of dummy cycles
- This bitfield defines the duration of the dummy phase according to the memory latency.
- In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).
- It is recommended to have at least six dummy cycles when using memories with DQS activated.

28.7.16 OCTOSPI instruction register (OCTOSPI_IR)

Address offset: 0x0110
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:0 TIMEOUT[15:0]: Timeout period
After each access in memory-mapped mode, the OCTOSPI prefetches the subsequent bytes and hold them in the FIFO.
This bitfield indicates how many CLK cycles the OCTOSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.
28.7.19 OCTOSPI wrap communication configuration register (OCTOSPI_WPCCR)

Address offset: 0x0140

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
   This bit enables the data strobe management.
   0: DQS disabled
   1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
   This bit sets the DTR mode for the data phase.
   0: DTR mode disabled for the data phase
   1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
   This bitfield defines the data phase mode of operation.
   000: No data
   001: Data on a single line
   010: Data on two lines
   011: Data on four lines
   100: Data on eight lines
   Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
   This bitfield defines the alternate-byte size.
   00: 8-bit alternate bytes
   01: 16-bit alternate bytes
   10: 24-bit alternate bytes
   11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double transfer rate
   This bit sets the DTR mode for the alternate-byte phase.
   0: DTR mode disabled for the alternate-byte phase
   1: DTR mode enabled for the alternate-byte phase
Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
- 000: no alternate bytes
- 001: alternate bytes on a single line
- 010: alternate bytes on two lines
- 011: alternate bytes on four lines
- 100: alternate bytes on eight lines
- Others: reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
- 00: 8-bit address
- 01: 16-bit address
- 10: 24-bit address
- 11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
- 0: DTR mode disabled for address phase
- 1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
- 000: No address
- 001: Address on a single line
- 010: Address on two lines
- 011: Address on four lines
- 100: Address on eight lines
- Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
- 00: 8-bit instruction
- 01: 16-bit instruction
- 10: 24-bit instruction
- 11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
- 0: DTR mode disabled for the instruction phase
- 1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
- 000: No instruction
- 001: Instruction on a single line
- 010: Instruction on two lines
- 011: Instruction on four lines
- 100: Instruction on eight lines
- Others: Reserved
28.7.20 OCTOSPI wrap timing configuration register (OCTOSPI_WPTCR)

Address offset: 0x0148
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

<table>
<thead>

</tbody>
</table>

Bit 31  Reserved, must be kept at reset value.

Bit 30  S SHIFT: Sample shift
By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The firmware must assure that S SHIFT=0 when the data phase is configured in DTR mode (when DDTR = 1).

Bit 29  Reserved, must be kept at reset value.

Bit 28  DHQC: Delay hold quarter cycle
Add a quarter cycle delay on the outputs in DTR communication to match hold requirement.
0: No quarter cycle delay
1: 1/4 cycle delay inserted

Bits 27:5  Reserved, must be kept at reset value.

Bits 4:0  DCYC[4:0]: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31). It is recommended to have at least 5 dummy cycles when using memories with DQS activated.

28.7.21 OCTOSPI wrap instruction register (OCTOSPI_WPIR)

Address offset: 0x0150
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

#### Field Descriptions

- **Bits 31:24** Reserved, must be kept at reset value.
- **Bits 23:16** **TRWR[7:0]**: Read-write minimum recovery time
  - Device read-to-write/write-to-read minimum recovery time expressed in number of communication clock cycles
- **Bits 15:8** **TACC[7:0]**: Access time
  - Device access time according to the memory latency, expressed in number of communication clock cycles
- **Bits 7:2** Reserved, must be kept at reset value.
- **Bit 1** **WZL**: Write zero latency
  - This bit enables zero latency on write operations.
  - 0: Latency on write accesses
  - 1: No latency on write accesses
- **Bit 0** **LM**: Latency mode
  - This bit selects the latency mode.
  - 0: Variable initial latency
  - 1: Fixed latency

Refer to Section 2.3 for the register boundary addresses.
29 OCTOSPI I/O manager (OCTOSPIM)

This section does not apply to STM32U535/545 devices.

29.1 Introduction

The OCTOSPI I/O manager is a low-level interface that enables an efficient OCTOSPI pin assignment with a full I/O matrix (before alternate function map), and multiplex of single/dual/quad/octal SPI interfaces over the same bus.

29.2 OCTOSPIM main features

- Supports up to two single/dual/quad/octal SPI interfaces
- Supports up to two ports for pin assignment
- Fully programmable I/O matrix for pin assignment by function (data/control/clock)

29.3 OCTOSPIM implementation

The table below describes the OCTOSPIM implementation.

<table>
<thead>
<tr>
<th>OCTOSPI feature</th>
<th>Available on the devices</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supports up to two single/dual/quad interfaces</td>
<td>X</td>
</tr>
<tr>
<td>Fully I/O multiplexing capability</td>
<td>X</td>
</tr>
<tr>
<td>Supports time-multiplexed mode</td>
<td>X</td>
</tr>
<tr>
<td>Supports high-speed interface</td>
<td>-</td>
</tr>
<tr>
<td>Chip select selection if OCTOSPI provides dual chip select</td>
<td>-</td>
</tr>
<tr>
<td>Supports 16-bit data interface and dual-octal mode</td>
<td>-</td>
</tr>
</tbody>
</table>

29.4 OCTOSPIM functional description

29.4.1 OCTOSPIM block diagram

The block diagram of the OCTOSPI I/O manager is shown in Figure 159.
1. The number of ports (n) is 2.
2. Arbitration is possible for both I/O matrix input ports.

### 29.4.2 OCTOSPIM input/output pins

<table>
<thead>

</tbody>
</table>

1. x = 1 to 2.
29.4.3 OCTOSPIM matrix

The OCTOSPI I/O manager matrix allows the user to set a fully programmable premapping of functions:

- Any OCTOSPIM_Pn_CLK / OCTOSPIM_Pn_NCLK pair can be mapped independently to OCTOSPI1_CLK/OCTOSPI1_NCLK or OCTOSPI2_CLK/OCTOSPI2_NCLK
- Any OCTOSPIM_Pn_DQS can be mapped independently to OCTOSPI1_DQS or OCTOSPI2_DQS
- Any OCTOSPIM_Pn_NCS can be mapped independently to OCTOSPI1_NCS or OCTOSPI2_NCS
- Any OCTOSPIM_Pn_IO[3:0] and OCTOSPIM_Pn_IO[7:4] can be mapped independently to OCTOSPI1_IO[3:0], OCTOSPI1_IO[7:4], OCTOSPI2_IO[3:0] or OCTOSPI2_IO[7:4]

For each OCTOSPI I/O manager port, individual signal enables and mapping are configured through the corresponding OCTOSPI I/O manager Port n configuration register (OCTOSPIM_PnCR).

When several I/O pins have the same configuration and are enabled at the same time, the result can be unpredictable.

In the default out-of-reset configuration, the OCTOSPI1 and OCTOSPI2 signals are mapped, respectively, on Port 1 and on Port 2.

The OCTOSPIM configuration can be changed only when all OCTOSPIs are disabled.

29.4.4 OCTOSPIM multiplexed mode

When this mode is set, the OCTOSPIs are time-multiplexed over the same bus. They get the ownership of the bus (in turn) through a request/acknowledge protocol with REQ/ACK signals.

The time-multiplexing is enabled by setting the MUXEN bit of the configuration register OCTOSPIM_CR.

The fairness counter (MAXTRAN) of each OCTOSPI can be used to manage accurately the maximum duration for which a given OCTOSPI takes the bus: this feature ensures a maximum bus access latency for the other OCTOSPI(s). When the bus is released by one OCTOSPI, an arbitration phase occurs, which is round-robin: when another OCTOSPI requests the bus, it gets it.

When the multiplexed mode is enabled, either the fairness counter or the refresh timeout counter of both OCTOSPI interfaces must be activated.

OCTOSPIn_NCS are not part of the multiplexing. Only OCTOSPIn_IOs, OCTOSPIn_DQS and OCTOSPIn_CLK / OCTOSPIn_NCLK are multiplexed.

When the multiplexed mode is used, only clock mode 0 is supported on the OCTOSPIs.

Due to arbitration and bus sharing, the auto polling interval time of the OCTOSPI, when used, may increase.

Minimum switching duration

The minimum number of cycles needed to switch from an OCTOSPI to another can be configured.
This internal timer guarantees a latency between the falling edge of the REQ signal of the active OCTOSPI (the active one releases the bus), and the rising edge of the ACK signal to the requesting OCTOSPI (the bus is granted to the requesting one).

The REQ2ACK_TIME field of the configuration register OCTOSPIM_CR defines the duration.

**Pin mapping in multiplexed mode**

In multiplexed mode, the mapping of the bus is done as described below:

- OCTOSPI1_NCS and OCTOSPI2_NCS work in the same way, then in Non-multiplexed mode they have to be assigned to their respective OCTOSPIM_Pn_NCS.
- All the other signals are seen by the I/O matrix as if they were seen from OCTOSPI1.
# 29.5 OCTOSPIM registers

## 29.5.1 OCTOSPIM control register (OCTOSPIM\_CR)

Address offset: 0x0000  
Reset value: 0x0000 0000

| Bit 31:24 | Reserved, must be kept at reset value. |
| Bit 23:16 | **REQ2ACK\_TIME[7:0]** | REQ to ACK time  
In multiplexed mode (MUXEN = 1), this field defines the time between two transactions. The value is the number of OCTOSPI clock cycles - 1  
Bits 15:1 | Reserved, must be kept at reset value.  
Bit 0 | MUXEN: Multiplexed mode enable  
This bit enables the multiplexing of the two OCTOSPIs.  
0: No multiplexing, hence no arbitration  
1: OCTOSPI1 and OCTOSPI2 are multiplexed over the same bus.

## 29.5.2 OCTOSPIM Port n configuration register (OCTOSPIM\_PnCR)

Address offset: 0x0000 + 0x4 * n (n = 1 to 2)  
Reset value: 0x0301 0111, 0x0705 0333

| Bit 31:27 | Reserved, must be kept at reset value. |
| Bit 26:25 | **IOHSRC[1:0]** | IO[7:4] source for Port n  
This bits select the source of Port n IO[7:4].  
00: OCTOSPI1\_IO[3:0] in non multiplexed mode / multiplexed\_IO[3:0] in multiplexed mode  
10: OCTOSPI2\_IO[3:0] in non multiplexed mode / unused in multiplexed mode  
11: OCTOSPI2\_IO[7:4] in non multiplexed mode / unused in multiplexed mode |
Bit 24  **IOHEN**: IO[7:4] enable for Port n  
This bit enables the Port n IO[7:4].  
0: IO[7:4] for Port n disabled  
1: IO[7:4] for Port n enabled

Bits 23:19  Reserved, must be kept at reset value.

Bits 18:17  **IOLSRC[1:0]**: IO[3:0] source for Port n  
This bits select the source of Port n IO[3:0].  
00: OCTOSPI1_IO[3:0] in non multiplexed mode / multiplexed_IO[3:0] in multiplexed mode  
10: OCTOSPI2_IO[3:0] in non multiplexed mode / unused in multiplexed mode  
11: OCTOSPI2_IO[7:4] in non multiplexed mode / unused in multiplexed mode

Bit 16  **IOLEN**: IO[3:0] enable for Port n  
This bit enables the Port n IO[3:0].  
0: IO[3:0] for Port n disabled  
1: IO[3:0] for Port n enabled

Bits 15:10  Reserved, must be kept at reset value.

Bit 9  **NCSSRC**: NCS source for Port n  
This bit selects the source of Port n NCS.  
0: OCTOSPI1_NCS  
1: OCTOSPI2_NCS

Bit 8  **NCSEN**: NCS enable for Port n  
This bit enables the Port n NCS.  
0: NCS for Port n is disabled  
1: NCS for Port n is enabled

Bits 7:6  Reserved, must be kept at reset value.

Bit 5  **DQSSRC**: DQS source for Port n  
This bit selects the source of Port n DQS.  
0: OCTOSPI1_DQS in non multiplexed mode / multiplexed_DQS in multiplexed mode  
1: OCTOSPI2_DQS in non multiplexed mode / unused port in multiplexed mode

Bit 4  **DQSEN**: DQS enable for Port n  
This bit enables the Port n DQS.  
0: DQS for Port n is disabled  
1: DQS for Port n is enabled

Bits 3:2  Reserved, must be kept at reset value.

Bit 1  **CLKSRC**: CLK/NCLK source for Port n  
This bit selects the source of Port n CLK/NCLK.  
0: OCTOSPI1_CLK/NCLK in non multiplexed mode / multiplexed_CLK/CLKn in multiplexed mode  
1: OCTOSPI2_CLK/NCLK in non multiplexed mode / unused port in multiplexed mode

Bit 0  **CLKEN**: CLK/NCLK enable for Port n  
This bit enables the Port n CLK/NCLK.  
0: CLK/NCLK for Port n is disabled  
1: CLK/NCLK for Port n is enabled

Refer to Section 2.3 on page 139 for the register boundary addresses.
30 Hexadeca-SPI interface (HSPI)

30.1 Introduction

The HSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- indirect mode: all the operations are performed using the HSPI registers to preset commands, addresses, data, and transfer parameters.
- automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting. This feature is only available in regular-command protocol.
- memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The HSPI supports the following protocols with associated frame formats:

- the regular-command frame format with the command, address, alternate byte, dummy cycles, and data phase
- the HyperBus™ frame format

30.2 HSPI main features

- Functional modes: indirect, automatic status-polling, and memory-mapped
- Read and write support in memory-mapped mode
- Support for single, dual, quad, and octal communication
- Dual-memory configuration, where 8 bits can be sent/received simultaneously by accessing two quad or two octal memories in parallel
- HSPI mode accessing a single 16-bit memory
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- 8-, 16-, and 32-bit data accesses allowed
- DMA protocol support
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AHB interface with transaction acceptance limited to one: the interface accepts the next transfer on AHB bus only once the previous is completed on memory side.

30.4.3 HSPI interface to memory modes

The HSPI supports the following protocols:

- regular-command protocol
- HyperBus protocol

The HSPI uses from 6 to 21 signals to interface with a memory, depending on the functional mode:

- NCS: chip-select
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS0, DQS1: data strobe used only in regular-command protocol
- IO[3:0]: data bus LSB
- IO[7:4]:
  - data bus MSB used in dual-quad and octal configurations
  - data bus used as possible remap for quad-SPI mode
- IO[15:8]:
  - data bus MSB used in dual-quad, dual-octal and 16-bit configurations
  - data bus used as possible remap for octal-SPI mode
  - IO[15:12] and IO[11:8] can also be used as possible remap for quad-SPI mode

30.4.4 HSPI regular-command protocol

When in regular-command protocol, the HSPI communicates with the external device using commands. Each command can include the following phases:

- instruction phase
- address phase
- alternate-byte phase
- dummy-cycle phase
- data phase

Only the data phase uses 16 bits. Instruction, address, and alternate phases use only the eight LSB of the bus as for octal configuration.

Any of these phases can be configured to be skipped, but single-phase commands supported are only those with instruction phase.

The NCS falls before the start of each command and rises again after each command finishes.

In memory-mapped mode, both read and write operation are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).
1. Data (such as D0, D1, D2) are sent in 16-bit configuration mode over IO[15:0]. Only the command and address are sent over IO[7:0] as for octal mode.

The specific regular-command protocol features are configured through the registers in the 0x0100-0x01FC offset range.

**Instruction phase**

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured in ISIZE[1:0] of HSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of HSPI_IR.

The instruction phase can optionally send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode, or in 16-bit SPI mode)

This can be configured using IMODE[2:0] of HSPI_CCR.

The instruction can be sent in DTR (double-transfer rate) mode on each rising and falling edge of the clock, by setting IDTR in HSPI_CCR.

When IMODE[2:0] = 000 in HSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

When in memory-mapped mode, the instruction used for the write operation is specified in HSPI_WIR and the instruction format is specified in HSPI_WCCR. The instruction used for the read operation and the instruction format are specified in HSPI_IR and HSPI_CCR.

**Address phase**

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured in ADSIZE[1:0] of HSPI_CCR.

In indirect and automatic status-polling modes, the address bytes to be sent are specified in ADDRESS[31:0] of HSPI_AR. In memory-mapped mode, the address is given directly via the AHB (from any master in the system).

The address phase can send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode, or in 16-bit SPI mode)
This can be configured using ADMODE[2:0] of HSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR in HSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In memory-mapped mode, the address format for the write operation is specified in HSPI_WCCR. The address format for the read operation is specified in HSPI_CCR.

---

**Warning:** Some memory specifications consider that each address corresponds to a 16-bit value. HSPI considers that each address corresponds to an 8-bit value. So the software needs to multiple the address by two when accessing the memory registers.

---

**Alternate-byte phase**

In the alternate-bytes phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured in ABSIZE[1:0] of HSPI_CCR. The bytes to be sent are specified in HSPI_ABR.

The alternate-byte phase can send:
- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode, or in 16-bit SPI mode)

This can be configured using ABMODE[2:0] of HSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR of HSPI_CCR.

When ABMODE[2:0] = 000, the alternate-bytes phase is skipped and the command sequence proceeds directly to the next phase, if any.

Only a single nibble may need to be sent during the alternate-byte phase rather than a full byte, such as when the dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the quad-SPI mode (ABMODE[2:0] = 011), and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in HSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 5:4 of ALTERNATE[31:0], while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In memory-mapped mode, the alternate bytes used for the write operation are specified in HSPI_WABR, and the alternate byte format is specified in HSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in HSPI_ABR and HSPI_CCR.
Dummy-cycle phase (memory latency)

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when the higher clock frequencies are used. The number of cycles given during this phase is specified in DCYC[4:0] of HSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual-, quad-, octal-, or 16-bit SPI mode, to receive data from the external device.

In memory-mapped mode, the dummy cycles for the write operations are specified in HSPI_WTCR. The dummy cycles for the read operation are specified in HSPI_TCR.

Data phase

During the data phase, any number of bytes can be sent to or received from the external device.

In indirect mode, the number of bytes to be sent/received is specified in HSPI_DLR. In this mode, the data to be sent to the external device must be written to HSPI_DR. In indirect-read mode, the data received from the external device is obtained by reading HSPI_DR.

In automatic status-polling mode, the number of bytes to be received is specified in HSPI_DLR, and the data received from the external device can be obtained by reading HSPI_DR.

In memory-mapped mode, the data read or written, is sent or received directly over the AHB to the Cortex core or to a DMA.

The data phase can send/receive:
- 1 bit at a time (over IO0/IO1 (SO/SI respectively) in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)
- 16 bits at a time (over IO0 to IO15 in 16-bit SPI mode)

This can be configured using DMODE[2:0] of HSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR of HSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in indirect-write mode.

In memory-mapped mode, the data format for the write operation is specified in HSPI_WCCR. The data format for the read operation is specified in HSPI_CCR.

DQS use

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.
The DQS management can be enabled by setting DQSE of HSPI_CCR.

**Figure 166. DTR read in octal-SPI mode with DQS (Macronix mode) example**

### 30.4.5 HSPI regular-command protocol signal interface

#### Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (whose I/Os are shared with IO0). The data received from the external device arrives via SI (whose I/Os are shared with IO1).

The different phases can each be configured separately to use this single-bit mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in HSPI_CCR and HSPI_WCCR.

In each phase configured in single-SPI mode:
- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0 (to deactivate the “write protect” function).
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO15 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

#### Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in HSPI_CCR and HSPI_WCCR.

In each phase configured in dual-SPI mode:
- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO15 are in output mode and forced to 0.
In the dummy phase when DMODE[2:0] = 010, IO0/IO1 are always high-impedance.

**Quad-SPI mode**

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the quad-SPI mode by setting to 011 the IMODE, ADMODE, ABMODE, and DMODE fields in HSPI_CCR and HSPI_WCCR.

In each phase configured in quad-SPI mode:
- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO15 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 011, IO0 to IO3 are all high-impedance.

**Octal-SPI mode**

In regular octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the octal-SPI mode by setting to 100 the IMODE, ADMODE, ABMODE, and DMODE fields in HSPI_CCR and HSPI_WCCR.

In each phase that is configured in octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 100, IO[0:7] are all high-impedance.

**HSPI mode**

In HSPI mode, the 16 bits are sent/received simultaneously over the IO[0:15] signals during the data phase.

The following phases must be configured separately to use the HSPI mode:
1. Set to 100 the IMODE, ADMODE, and ABMODE fields (in HSPI_CCR and HSPI_WCCR).
2. Set to 101 the DMODE fields (in HSPI_CCR and HSPI_WCCR).

In each phase that is configured in HSPI mode, IO[0:15] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 101, IO[0:15] are all high-impedance.

IO[8:15] are used only in HSPI mode. If none of the phases are configured to use this mode, then the pins corresponding to IO[8:15] can be used for other functions, even while the HSPI is active.

**Single-data rate (SDR) mode**

By default, all the phases operate in single-data rate (SDR) mode.

In SDR mode, when the HSPI drives the IO0/S0 and IO1 to IO15 signals, these signals transition only with the falling edge of CLK.
When receiving data in SDR mode, the HSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in HSPI_TCR), the signals are sampled using the following (rising) edge of CLK.

**Figure 167. SDR write command in octal-SPI mode example.**

### Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte, and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in HSPI_CCR.

In memory-mapped mode, the DTR mode for each phase of the write operations is specified in HSPI_WCCR. The DTR mode for each phase of the read operations is specified in HSPI_CCR.

In DTR mode, when the HSPI drives the IO0/SO and IO1 to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

In DTR mode, when the HSPI drives the IO0 to IO15 signals in the data phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the HSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in HSPI_CCR, the software must clear SSHIFT in HSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

**Figure 168. DTR write in octal-SPI mode (Macronix mode) example**

### Dual-quad configuration

When DMM = 1 in HSPI_CR, the HSPI is in dual-memory configuration: if DMODE = 011, two external quad-SPI devices (device A and device B) are used in order to send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.
The dual-quad configuration can be used in conjunction with the single-SPI, dual-SPI, and quad-SPI modes, as well as with either SDR or DTR mode.

The device size, as specified in DEVSIZE[4:0] of HSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the HSPI gives for address X is the byte at the address X/2 of device A, and the byte that the HSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the HSPI must be configured with a data length of 2 bytes (16 bits), and the HSPI receives one byte from each device.

If each device gives a status of 16 bits, then the HSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The forth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in HSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

**Dual-octal configuration**

When DMM = 1 in HSPI_CR, the HSPI is in dual-memory configuration: when DMODE = 100, two external octal-SPI devices (device A and device B) are used in order to receive 32 bits in DTR mode every cycle, effectively doubling the throughput as well as the capacity.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO7 signals.

The dual-octal configuration can be used in DTR mode exclusively in conjunction with the single-SPI, dual-SPI, quad-SPI and octal-SPI modes.

The device size, as specified in DEVSIZE[4:0] of HSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the HSPI gives for address X is the byte at the address X/2 of device A, and the byte that the HSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-octal DTR mode, twice as many bytes must be read compared to the same read in regular DTR mode: if each device gives twice eight valid bits after the instruction for fetching the status register, then the HSPI must
be configured with a data length of 4 bytes. The LSB is the LSB of device A, and the third byte is the LSB of device B.

If each device gives a status of 16 bits, then the HSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-octal DTR mode. In such case, the order of retrieved status bits is as follows:

- first byte: LSB of device A
- second byte: second byte of device A
- third byte: LSB of device B
- fourth byte: second byte of device B

In indirect mode using DTR mode, a number of bytes multiple of four must always be accessed in HSPI mode. For this reason, bit 0 and bit 1 of the DL[31:0] bitfield in HSPI_DLR are stuck at 0 when DMODE[2:0] = 101.

In dual-octal configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycles phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

Note: The variable latency is not supported in dual-octal configuration.

### HSPI mode

When DMODE[2:0] = 0b101 in HSPI_CCR, the HSPI is in single 16-bit-memory configuration: when DMODE[2:0] = 0b101 with DMM value ignored in that case. A single external HSPI device is used in order to send/receive 16 bits (or 32 bits in DTR mode) every cycle, effectively doubling the throughput.

The device provides/receives two separate DQS signals: DQS0 for the eight LSBs and DQS1 for the eight MSBs.

The HSPI mode can be used in conjunction with the single-SPI, dual-SPI, quad-SPI and octal-SPI modes, as well as with either the SDR or the DTR mode.

The device size, as specified in DEVSIZE[4:0] of HSPI_DCR1, must reflect the total external device capacity.

In SDR mode, a number of bytes multiple of two must always be accessed in HSPI mode. For this reason, bit 0 of DL[31:0] in HSPI_DLR is stuck at 0 when DMODE = 101.

In DTR mode, a number of bytes multiple of four must always be accessed in HSPI mode. For this reason, bit 0 and 1 of DL[31:0] in HSPI_DLR are stuck at 0 when DMODE = 101.

### 30.4.6 HyperBus protocol

The HSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins in 8-bit data mode, or 19 to 20 pins in 16-bit data mode depending on the operating voltage:

- IO[7:0] as bidirectional data bus for 8-bit data mode and IO[15:0] as bidirectional data bus for 16-bit data mode
- RWDS for read and write data strobe and latency insertion (mapped on DQS pin)
- NCS
**Hexadeca-SPI interface (HSPI)**

- **CLK**
- **NCLK** for 1.8 V operations (to support this mode, the device must be powered with 1.8 V)

The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:
- command/address phase
- data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.

**Figure 169. Example of HyperBus read operation (8-bit data mode)**

The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

**Command/address phase**

During this initial phase, the HSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

### Table 263. Command/address phase description

</table>
The address space is configured through the memory type MTYP[2:0] of HSPI_DCR1. The total size of the device is configured in DEVSIZE[4:0] of HSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

**Warning:** Some memory specifications consider that each address corresponds to a 16-bit value. The HSPI considers that each address corresponds to an 8-bit value. So, the software needs to multiple the address by two when accessing the memory registers.

### Read/write operation with initial latency

The HyperBus read and write operations need to respect two timings:
- $t_{\text{RWR}}$: minimal read/write recovery time for the device (defined by TRWR[7:0] in HSPI_HLCR)
- $t_{\text{ACC}}$: access time for the device (defined in TACC[7:0] of HSPI_HLCR) according to the memory latency

During the read operation, the RWDS is used by the device, in two ways (see Figure 169):
- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation, the RWDS is used:
- by the device, during the command/address phase, to request an additional latency.
- by the HSPI, during the data phase, for write data masking.

*Figure 170. HyperBus write operation with initial latency (8-bit data mode)*
**Read/write operation with additional latency**

If the device needs an additional latency (during refresh period of an SDRAM for example), RWDS must be tied to one during one of the RWDS signals, during the command/address phase.

An additional \( t_{\text{ACC}} \) duration is added by the HSPI to meet the device request.

**Figure 171. HyperBus read operation with additional latency (8-bit data mode)**

![HyperBus read operation with additional latency](image1)

**Figure 172. HyperBus write operation with additional latency (8-bit data mode)**

![HyperBus write operation with additional latency](image2)

**Fixed latency mode**

Some devices or some applications may not want to operate with a variable latency time as described above.

The latency can be forced to \( 2 \times t_{\text{ACC}} \) by setting LM of HSPI_HLCR.

In this HSPI latency mode, the state of the RWDS signal is not taken into account by the HSPI and an additional latency is always added leading to a fixed \( 2 \times t_{\text{ACC}} \) latency time.
Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in HSPI_HLCR.

**Figure 173. HyperBus write operation with no latency (register write)**

Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the tACC time.

**Figure 174. HyperBus read operation page crossing with latency (8-bit data mode)**

16-bit data transfer using HyperBus

In HyperBus protocol, the HSPI supports a dual-octal configuration (16-bit data transfers) when DMM = 1 in HSPI_CR: one octal HyperBus memory is connected to IO0-IO7 and another is connected to IO8-IO15. These memories share all signals except RWDS that are dedicated.

For 16-bit data transfers, DMODE[2:0] must be to equal to 101. Any other value in DMODE[2:0] correspond to 8-bit data transfer (quad-, dual-, and single-bit data transfer do not exist in HyperBus protocol). Command-address phase is always using 8 bits in HyperBus protocol (from IO8-IO15). Only the data is on 16-bit for write or read operations accessing the memory space (from IO0-IO15) as shown for instance in *Figure 175*. For the memory register accesses, the data is on 8-bit (from IO0 to IO7, IO8 to IO15 being not used but driven by the controller) as shown in *Figure 173*. 
The behavior of the interface at protocol-level is exactly the same as for HyperBus octal configuration, as described above, except that the variable latency is not supported in dual-octal HyperBus configuration. LM in HSPI_HLCR must be set.

**Figure 175. HyperBus write operation with initial latency (16-bit mode)**

### 30.4.7 Specific features

The HSPI supports some specific features, such as:

- wrap support
- NCS boundary and refresh

#### Wrap support

The HSPI supports an hybrid wrap as defined by the HyperBus protocol. A hybrid wrap is also supported in the regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in HSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 4 bytes. Wrapped reads are supported for both HyperBus and regular-command protocols. To enable wrapped-read accesses, the dedicated registers HSPI_WPxxx must be programmed according to the wrapped-read access characteristics. The dedicated HSPI_WPxxx registers apply for both HyperBus and regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

**Note:** Hybrid wrap requires that the non-wrapped registers (HSPI_CCR, HSPI_TCR, HSPI_IR) are set according to the memory configuration to satisfy its correct data prefetch (initiated after the wrap command).

The wrap operation cannot be interrupted by a refresh. The refresh event is only considered after the wrap completion.
NCS boundary and refresh

Two processes can be activated to regulate the HSPI transactions:

- NCS boundary
- refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with is configured in CSBOUND[4:0] of HSPI_DCR3 and it is equal to $2^{\text{CSBOUND}}$.

As an example, if CSBOUND[4:0] = 0x4, the boundary is set to $2^4 = 16$ bytes. As a consequence, the NCS is released each time that the LSB address is equal to 0xF, and each time that a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled. A minimum value of three is recommended.

The NCS boundary feature cannot be used for flash memory devices in write mode since a command is necessary to program another page of the flash memory.

The refresh feature limits the duration of the transactions to the value programmed in REFRESH[31:0] of HSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command, address, alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

Restarting after an interrupted transfer

When a read or write operation is interrupted by a timeout, the HSPI interface, as soon as possible after getting back the port ownership, re-issues the initial command sequence together with the address following the last address actually accessed before interruption. The transfer initially set goes on and ends seamlessly.

30.4.8 HSPI operating modes introduction

The HSPI has the following operating modes regardless of the low-level protocol used (either regular-command or HyperBus):

- indirect mode (read or write)
- automatic status-polling mode (only in regular-command protocol)
- memory-mapped mode

30.4.9 HSPI indirect mode

In indirect mode, the commands are started by writing to the HSPI registers, and the data is transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 00 in HSPI_CR, the HSPI is in indirect-write mode: bytes are sent to the external device during the data phase. Data are provided by writing to HSPI_DR.

When FMODE[1:0] = 01, the HSPI is in indirect-read mode: bytes are received from the external device during the data phase. Data are recovered by reading HSPI_DR.
In indirect mode, when the HSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

**Note:** The HSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.

The number of bytes to be read/written is specified in HSPI_DLR:
- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the HSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in HSPI_CCR.
- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the HSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, TCF bit is set in HSPI_SR and an interrupt is generated if TCIE = 1 in HSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in HSPI_DCR1.

**Triggering the start of a transfer in regular-command protocol**

Depending on the HSPI configuration, there are three different ways to trigger the start of a transfer in indirect mode when using regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in indirect mode, a transfer starts when one of the following sequence of events occurs:
- if no address is necessary (ADMODE[2:0] = 000) and if no data needs to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in HSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data needs to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in HSPI_AR
- if data needs to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in HSPI_DR

A write to HSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in HSPI_SR.

**Triggering the start of a transfer in HyperBus protocol**

Depending on the HSPI configuration, there are different ways to trigger the start of a command in indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in indirect mode is triggered by one of the following register settings, when it is the last one to be executed:
- when a write is performed to ADDRESS[31:0] (HSPI_AR) with ADMODE[2:0] ≠ 000 in indirect read mode (FMODE[1:0] = 01)
- when a write is performed to DATA[31:0] (HSPI_DR) in indirect-write mode (when FMODE = 00)
• when a (dummy) write is performed to INSTRUCTION[31:0] (HSPI_IR) for indirect read mode (with ADMODE[2:0] = 000 and FMODE = 01)

As soon as a transfer is started, the BUSY bit (HSPI_SR[5]) is automatically set.

**FIFO and data management**

Data in indirect mode pass through a 64-byte FIFO that is internal to the HSPI. FLEVEL in HSPI_SR indicates how many bytes are currently being held in the FIFO.

In indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in the HSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to the HSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

In indirect-read mode, when the FIFO becomes full, the HSPI temporarily stops reading bytes from the external device to avoid an overrun. Note that the reading of the external device does not restart until 4 bytes become vacant in the FIFO (when FLEVEL ≤ (FIFO_size - 4). Thus, when FTHRES ≥ (FIFO_size - 3), the application must be sure to read enough bytes to assure that the HSPI starts retrieving data from the external device again. Otherwise, the FTF flag stays at 0 as long as FLEVEL < FTHRES.

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

**30.4.10 HSPI automatic status-polling mode**

In automatic status-polling mode, the HSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.

The automatic status-polling mode must be used only in regular-command protocol. For HyperBus protocol, it is not exploitable since the read status register into the HyperFlash memory must be performed in two steps (a write operation followed by a read operation).

The access to the device begins in the same manner as in indirect-read mode. BUSY in HSPI_SR goes high at this point, and stays high even between the periodic accesses.
The content of MASK[31:0] in HSPI_PSMAR is used to mask the data from the external device in automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in HSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in HSPI_CR, the AND-match mode is activated: SMF is set in HSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in HSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in HSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the HSPI is disabled (EN = 0).

HSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in HSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In automatic status-polling mode, variable latency is not supported. As a consequence, the memory must be configured in fixed latency.

30.4.11 HSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

*Note:* No more than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256-Mbyte range, then an AHB error is given. The effect of this error depends on the AHB master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated, and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the HSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations end up quickly since their results were prefetched.

By default, the HSPI never stops its prefetch operation, it either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time.

Since external devices tend to consume more when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in HSPI_CR); the NCS is released after a period defined by TIMEOUT[15:0] in HSPI_LPTR, when x cycles have elapsed without an access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.
It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

30.4.12 HSPI configuration introduction

The HSPI configuration is done in three steps:
1. HSPI system configuration
2. HSPI device configuration
3. HSPI mode configuration

30.4.13 HSPI system configuration

The HSPI is configured using HSPI_CR. The user must program:
- the functional mode with FMODE[1:0]
- the automatic status-polling mode behavior if needed with PMM and APMS
- the FIFO level with FTHRES
- DMA use with DMAEN
- the timeout counter use with TCEN
- the dual-memory configuration, if needed, with DMM

In case of an interrupt use, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in HSPI_LPTR.

The DMA channel must not be enabled during the HSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and HSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

30.4.14 HSPI device configuration

The parameters related to the external device targeted are configured through HSPI_DCR1 and HSPI_DCR2. The user must program:
- the device size with DEVSIZE[4:0]
- the chip-select minimum high time with CSHT[5:0]
- the device frequency with PRESCALER[7:0]

MTYP[2:0] defines the memory type to be used for 8-line modes:
- Micron mode with D0/D1 ordering in 8-data-bit mode (DMODE[2:0] = 100)
- Macronix mode with D1/D0 ordering in 8-data-bit mode (DMODE[2:0] = 100). There are two distinct configurations for Macronix memories. MTYP[2:0] = 001 targets Octaflash memory whereas MTYP[2:0] = 011 addresses OctaRAM™ memory having specific address phase (address is built with row and column to fit with Macronix requirements).
- HyperBus memory mode: the protocol follows the HyperBus specification.
- HyperBus register mode, addressing register space: the memory-mapped accesses in this mode must be noncacheable, or the indirect read/write modes must be used.

For memory coming from APmemory, select MTYP[2:0] = 6 to fit with the memory provider requirements (address bit management).
DEVSIZE[4:0] defines the size of external memory using the following formula:

\[
\text{Number of bytes in the device} = 2^{\text{DEVSIZE}+1}
\]

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

If DMM = 1, DEVSIZE[4:0] indicates the total capacity of the two devices together.

When the HSPI executes two commands, one immediately after the other, it raises the NCS high between the two commands, at least one CLK cycle by default.

If the external device requires more time between commands, CSHT[5:0] can be used to specify the minimum number of CLK cycles (up to 64) for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

In HyperBus protocol, the device timing (\(t_{\text{ACC}}\) and \(t_{\text{RWR}}\)) and the Latency mode must be configured in HSPI_HLCR.

### 30.4.15 HSPI regular-command mode configuration

#### Indirect mode configuration

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected and data can be read from the external device.

When the HSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in HSPI_DLR.
2. Specify the frame timing in HSPI_TCR.
3. Specify the frame format in HSPI_CCR.
4. Specify the instruction in HSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in HSPI_ABR.
6. Specify the targeted address in HSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through HSPI_DR (if no DMA usage).

If neither the address register (HSPI_AR) nor the data register (HSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as HSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to HSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the communication start is triggered by a write in the FIFO through HSPI_DR.

#### Automatic status-polling mode configuration

The automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and the data is retrieved periodically.
The maximum amount of data read in each frame is 4 bytes. If more data is requested in HSPI_DLR, it is ignored, and only 4 bytes are read. The periodicity is specified in HSPI_PIR.

Once the status data has been retrieved, the following can be processed:
- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in HSPI_PSMKR, and can be ORed or ANDed with the value stored in HSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The HSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in HSPI_DR.

When the HSPI is used in automatic status-polling mode, the frames are constructed in the following way:
1. Specify the input mask in HSPI_PSMKR.
2. Specify the comparison value in HSPI_PSMAR.
3. Specify the read period in HSPI_PIR.
4. Specify a number of data bytes to read in HSPI_DLR.
5. Specify the frame timing in HSPI_TCR.
6. Specify the frame format in HSPI_CCR.
7. Specify the instruction in HSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in HSPI_ABR.
9. Specify the optional targeted address in HSPI_AR.

If the address register (HSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as HSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to HSPI_AR.

**Memory-mapped mode configuration**

In memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled. The indirect-write mode fulfills this operation, possibly in conjunction with the automatic status-polling mode.

Memory-mapped mode is entered by setting FMODE[1:0] = 11 in HSPI_CR.

The programmed instruction and frame are sent when an AHB master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to HSPI_DR in this mode returns zero.

The data length register (HSPI_DLR) has no meaning in memory-mapped mode.
When the HSPI is used in memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in HSPI_TCR for read operation.
2. Specify the frame format in HSPI_CCR for read operation.
3. Specify the instruction in HSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in HSPI_ABR for read operation.
5. Specify the frame timing in HSPI_WTCR for write operation.
6. Specify the frame format in HSPI_WCCR for write operation.
7. Specify the instruction in HSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in HSPI_WABR for write operation.

All the configuration operations must be completed (ensured by checking BUSY = 0) before the first access to the memory area: any register write operation when BUSY = 1 have no effect and is not signaled with an error response. On the first access, the HSPI becomes busy, and no further configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

**HSPI delayed data sampling when no DQS is used**

By default, when no DQS is used, the HSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in HSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

**HSPI delayed data sampling when DQS is used**

When external DQS is used as a sampling clock, it is shifted precisely by one quarter of the SPI clock cycle, for all frequencies above freq_min, to compensate the data propagation delay in the “high-speed interface” when the product embeds one.

### 30.4.16 HSPI HyperBus protocol configuration

**Indirect mode configuration (HyperBus)**

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected where data can be read from the external device. ADMODE must be configured with a value different from 000 (for instance ADMODE = 100).

When the HSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in HSPI_DLR.
2. Specify the targeted address in HSPI_AR.
3. Enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through HSPI_DR (if no DMA usage).

In indirect-read mode, the command sequence starts as soon as the address is updated with a write to HSPI_AR.
In indirect-write mode, the communication start is triggered by a write in the FIFO through HSPI_DR.

**Memory-mapped mode configuration (HyperBus)**

In memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

The memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AHB master is accessing the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to HSPI_DR in this mode returns zero.

The data length register (HSPI_DLR) has no meaning in memory-mapped mode.

All the configuration operation must be completed before the first access to the memory area. On the first access, the HSPI becomes busy, and no configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

### 30.4.17 HSPI error management

An error can be generated in the following cases:

- in indirect or automatic status-polling mode, when a wrong address has been programmed in HSPI_AR (according to the device size defined by DEVSIZE[4:0]). This sets TEF and an interrupt is generated if enabled.
- in indirect mode, if the address plus the data length exceed the device size. TEF is set as soon as the access is triggered.
- in memory-mapped mode when an out-of-range access is done by an AHB master, it generates an AHB error as a response to the faulty AHB request.
- when the memory-mapped mode is disabled, an access to the memory-mapped area generates an AHB error as a response to the faulty AHB request.

The HSPI generates an AHB slave error in the following situations:

- The memory-mapped mode is disabled and an AHB read request occurs.
- Read or write address exceeds the size of the external memory.
- Abort is received while a read or write burst is ongoing.
- The HSPI is disabled while a read or write burst is ongoing.
- A write wrap burst is received.
- A write request is received while DQSE = 0 in HSPI_WCCR in octal DTR mode or in dual-memory configuration.
- A write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means HSIZE is different from 4 bytes (only for memory-mapped mode).
- an illegal wrap size when receiving read wrap burst with size different from 48 bytes (only for memory-mapped mode).
30.4.18 HSPI high-speed interface and calibration

To reach higher frequencies, a dedicated high-speed interface is inserted between the HSPI (or the I/O manager in case the product embeds one), and the I/O pads.

The following is valid for all data bus sizes 1, 2, 4, 8 or 16 bits.

The high-speed interface block embeds resynchronization registers that are clocked by delayed clock created from a DLL (delay locked loop) also located in the high-speed interface. The high-speed interface features are controlled by registers located in the HSPI.

The purpose of resynchronization is primary to shift data or data strobe by one quarter of octal bus clock period, with a correct timing accuracy. DLL must be calibrated versus this clock period.

The calibration process is automatically enabled when one of the three conditions below is met:

- The HSPI exits reset state.
- A value is written in PRESCALER[7:0] of HSPI_DCR2.
- A value is written in HSPI_CCR.

The calibration process starts when the two following conditions are both met:

- The calibration has been enabled by one of the three conditions above.
- An action that sets BUSY = 1 is performed. For example the first transfer to memory after calibration is enabled. When the calibration is completed, BUSY returns to 0.

In case a periodic recalibration is needed (for example to take in account possible variations in temperature or power supply on a long duration), this recalibration must be triggered by writing periodically in PRESCALER[7:0] of HSPI_DCR2, while BUSY = 0.

Once the calibration is completed, the value of the SPI bus clock period, expressed in number of unitary delay, is available to user in COARSE[5:0] and FINE[6:0] of HSPI_CALFCR.

After auto-calibration, HSPI_CALSOR and HSPI_CALSIR are automatically loaded with the same value that corresponds to the delay for a quarter cycle.

When the memory is not supporting DQS (DQSE = 0), the automatic calibration is not used in reception. The DLL Master is used instead for delaying the feedback clock (HSPI_CALMR). This delay needs to be adjusted by the application itself, using a software sequence that determines which delay is optimal to guarantee the correct read operations.

When the clock is divided in DTR transmission mode, the quarter cycle delays on DQS/data are not inserted by the DLLs themselves, but by internal flops design scheme. In SDR transmission mode, the DLLs are not used and this, whatever the clock prescaler value.

In case of DTR mode and prescaler bypassed (PRESCALER[7:0] = 0), the kernel clock provided to interface must have a 50 % duty-cycle.

When using the high-speed-interface, the system clock (AHB clock) must be at least as fast as the SPI clock.
30.4.19 HSPI BUSY and ABORT

Once the HSPI starts an operation with the external device, BUSY is automatically set in HSPI_SR.

In indirect mode, BUSY is reset once the HSPI has completed the requested command sequence and the FIFO is empty.

In automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on an abort.

Any operation can be aborted by setting ABORT in HSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers. When DMA is enabled to handle the data read or write operations in HSPI_DR, it is recommended to disable the DMA channel before aborting the HSPI.

Note: Some devices may misbehave if a write operation to a status register is aborted.

30.4.20 HSPI reconfiguration or deactivation

Before any HSPI reconfiguration, the software must ensure that all the transactions are completed:

- After a memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a memory-mapped read, the software must perform a synchronization barrier then an abort.

30.4.21 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 (clock mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

![Figure 176. NCS when CKMODE = 0 (T = CLK period)](MSv44100V1)
When CKMODE = 1 (clock mode 3: CLK goes high when no operation is in progress) and when in SDR mode, NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

**Figure 177. NCS when CKMODE = 1 in SDR mode (T = CLK period)**

When the CKMODE = 1 (clock mode 3) and DDTR = 1 (data DTR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge (see the figure below). Because the DTR operations must finish with a falling edge, the CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

**Figure 178. NCS when CKMODE = 1 in DTR mode (T = CLK period)**

When the FIFO stays full during a read operation, or if the FIFO stays empty during a write operation, the operation stalls and CLK stays low until the software services the FIFO. If an abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later (see the figure below).

**Figure 179. NCS when CKMODE =1 with an abort (T = CLK period)**
### 30.5 Address alignment and data number

The following table summarizes the effect of the address alignment and programmed data number depending on the use case.

### 30.6 HSPI interrupts

An interrupt can be produced on the following events:

- timeout
- status match
- FIFO threshold
- transfer complete
- transfer error

Separate interrupt enable bits are available to provide more flexibility.

**Bits 31:30 MSEL[1:0]: Flash select**

These bits select the memory to be addressed in single-, dual-, quad-, or octal-SPI mode in single-memory configuration (when DMM = 0).

- when in quad-SPI mode:
  00: Data exchanged over IO[3:0]
  01: Data exchanged over IO[7:4]
  10: Data exchanged over IO[11:8]
  11: Data exchanged over IO[15:12]

- when in octal-SPI mode or dual-quad configuration:
  0x: Data exchanged over IO[7:0]
  1x: Data exchanged over IO[15:8]

These bits are ignored when in dual-octal configuration (data on 8 bits and DMM = 1) or 16-bit configuration (data exchanged over IO[15:0]).

*Note: Bit 30 is mirrored in bit 7. This bitfield can be modified only when BUSY = 0.*

**Bits 29:28 FMODE[1:0]: Functional mode**

This bitfield defines the HSPI functional mode of operation.

00: Indirect-write mode
01: Indirect-read mode
10: Automatic status-polling mode (relevant in regular-command protocol only)
11: Memory-mapped mode

If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value. If FMODE[1:0] and FTHRES[4:0] are wrongly updated while DMAEN = 1, the DMA request signal automatically goes to inactive state.

*Note: This bitfield can be modified only when BUSY = 0.*

**Bits 27:24 Reserved, must be kept at reset value.**

**Bit 23 PMM: Polling match mode**

This bit indicates which method must be used to determine a match during the automatic status-polling mode.

0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.
1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.

*Note: This bit can be modified only when BUSY = 0.*
Bit 22 **APMS**: Automatic status-polling mode stop
   This bit determines if the automatic status-polling mode is stopped after a match.
   0: Automatic status-polling mode is stopped only by abort or by disabling the HSPI.
   1: Automatic status-polling mode stops as soon as there is a match.
   *Note:* This bit can be modified only when BUSY = 0.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE**: Timeout interrupt enable
   This bit enables the timeout interrupt.
   0: Interrupt disabled
   1: Interrupt enabled

Bit 19 **SMIE**: Status match interrupt enable
   This bit enables the status match interrupt.
   0: Interrupt disabled
   1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable
   This bit enables the FIFO threshold interrupt.
   0: Interrupt disabled
   1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable
   This bit enables the transfer complete interrupt.
   0: Interrupt disabled
   1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable
   This bit enables the transfer error interrupt.
   0: Interrupt disabled
   1: Interrupt enabled

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **FTHRES[5:0]**: FIFO threshold level
   This bitfield defines, in indirect mode, the threshold number of bytes in the FIFO that causes
   the FIFO threshold flag FTF in HSPI_SR, to be set.
   000000: FTF is set if there are one or more free bytes available to be written to in the FIFO
   in indirect-write mode, or if there are one or more valid bytes can be read from the FIFO
   in indirect-read mode.
   000001: FTF is set if there are two or more free bytes available to be written to in the FIFO
   in indirect-write mode, or if there are two or more valid bytes can be read from the FIFO
   in indirect-read mode.
   ...
   111111: FTF is set if there are 64 free bytes available to be written to in the FIFO
   in indirect-write mode, or if there are 64 valid bytes can be read from the FIFO
   in indirect-read mode.
   *Note:* If DMAEN = 1, the DMA controller for the corresponding channel must be disabled
   before changing the FTHRES[5:0] value.

Bit 7 Reserved, must be kept at reset value.
Bit 6  **DMM**: Dual-memory configuration  
This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity.  
0: Dual-memory configuration disabled  
1: Dual-memory configuration enabled  
*Note: This bit can be modified only when BUSY = 0.*  
Bits 5:4 Reserved, must be kept at reset value.  

Bit 3  **TCEN**: Timeout counter enable  
This bit is valid only when the memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.  
0: The timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in memory-mapped mode.  
1: The timeout counter is enabled, and thus the chip-select is released in the memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.  
*Note: This bit can be modified only when BUSY = 0.*  

Bit 2  **DMAEN**: DMA enable  
In indirect mode, the DMA can be used to input or output data via HSPI_DR. DMA transfers are initiated when FTF is set.  
0: DMA disabled for indirect mode  
1: DMA enabled for indirect mode  
*Note: Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.*  

Bit 1  **ABORT**: Abort request  
This bit aborts the ongoing command sequence. It is automatically reset once the abort is completed. This bit stops the current transfer.  
0: No abort requested  
1: Abort requested  
*Note: This bit is always read as 0.*  

Bit 0  **EN**: Enable  
This bit enables the HSPI.  
0: HSPI disabled  
1: HSPI enabled  
*Note: The DMA request can be aborted without having received the ACK in case this EN bit is cleared during the operation. In case this bit is set to 0 during a DMA transfer, the REQ signal to DMA returns to inactive state without waiting for the ACK signal from DMA to be active.*
30.7.2  **HSPI device configuration register 1 (HSPI_DCR1)**

Address offset: 0x008  
Reset value: 0x0000 0000  
This register can be modified only when BUSY = 0.

</tbody>
</table>

Bits 31:27  Reserved, must be kept at reset value.

Bits 26:24  **MTYP[2:0]: Memory type**  
This bitfield indicates the type of memory to be supported.  
000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes. In this mode, DQS signal polarity is inverted with respect to the memory clock signal. This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron.  
010: Standard mode  
011: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes with dedicated address mapping.  
100: HyperBus memory mode, the protocol follows the HyperBus specification.  
101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be non-cacheable, or indirect read/write modes must be used.  
110: APmemory mode. If DMODE = 101, there is a special hardware operation on address word from the bit 10 and above to fit the provider requirement (shift operation on the left from the address bit 10, keeping this last at 0).  
Others: Reserved

Bits 23:21  Reserved, must be kept at reset value.

Bits 20:16  **DEVSIZE[4:0]: Device size**  
This bitfield defines the size of the external device using the following formula:  
Number of bytes in device = 2[^DEVSIZE+1].  
DEVSIZE + 1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 Gbytes (addressed using 32-bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes. In regular-command protocol, if DMM = 1, DEVSIZE[4:0] indicates the total capacity of the two devices together.

Bits 15:14  Reserved, must be kept at reset value.
Bits 13:8 **CSHT[5:0]: Chip-select high time**

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.

0x0: NCS stays high for at least 1 cycle between external device commands.
0x1: NCS stays high for at least 2 cycles between external device commands.
...
0x3F: NCS stays high for at least 64 cycles between external device commands.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **FRCK**: Free running clock

This bit configures the free running clock.
0: CLK is not free running.
1: CLK is free running (always provided).

Bit 0 **CKMODE**: Clock mode 0/mode 3

This bit indicates the level taken by the CLK between commands (when NCS = 1).
0: CLK must stay low while NCS is high (chip-select released), referred to as clock mode 0.
1: CLK must stay high while NCS is high (chip-select released), referred to as clock mode 3.

**30.7.3 HSPI device configuration register 2 (HSPI_DCR2)**

Address offset: 0x00C
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

</table>

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **WRAPSIZE[2:0]: Wrap size**

This bitfield indicates the wrap size to which the memory is configured. For memories, which have a separate command for wrapped instructions, this bitfield indicates the wrap-size associated with the command held in HSPI_WPIR.
000: Wrapped reads are not supported by the memory.
010: External memory supports wrap size of 16 bytes.
011: External memory supports wrap size of 32 bytes.
100: External memory supports wrap size of 64 bytes.
101: External memory supports wrap size of 128 bytes.
Others: Reserved

Bits 15:8 Reserved, must be kept at reset value.
Bits 7:0 **PRESCALER[7:0]**: Clock prescaler

This bitfield defines the scaler factor for generating the CLK based on the kernel clock (value + 1).

0: \( F_{CLK} = F_{KERNEL} \) - kernel clock used directly as HSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the HSPI a kernel clock that has 50% duty-cycle.

1: \( F_{CLK} = F_{KERNEL}/2 \)

2: \( F_{CLK} = F_{KERNEL}/3 \)

... 255: \( F_{CLK} = F_{KERNEL}/256 \)

For odd clock division factors, the CLK duty cycle is not 50%. The clock signal remains low one cycle longer than it stays high.

Writing this bitfield automatically starts a new calibration of high-speed interface DLL at the start of next transfer, except in case HSPI_CALOSR or HSPI_CALISR have been written in the meantime. BUSY stays high during the whole calibration execution.

30.7.4 **HSPI device configuration register 3 (HSPI_DCR3)**

Address offset: 0x010

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

</table>

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary

This bitfield enables the transaction boundary feature. When active, a minimum value of three is recommended.

The NCS is released on each boundary of \( 2^{CSBOUND} \) bytes.

0: NCS boundary disabled

Others: NCS boundary set to \( 2^{CSBOUND} \) bytes

Bits 15:0 Reserved, must be kept at reset value.
### 30.7.5 HSPI device configuration register 4 (HSPI_DCR4)

Address offset: 0x014  
Reset value: 0x0000 0000  
This register can be modified only when BUSY = 0.

<table>
<thead>
<tr>
<th>Address offset</th>
<th>Reset value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x014</td>
<td>0x0000 0000</td>
</tr>
</tbody>
</table>

### Bits 31:0 REFRESH[31:16]: Refresh rate

This bitfield enables the refresh rate feature. The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads. These two values can be extended with few clock cycles when refresh occurs during a byte transmission in single-, dual-, or quad-SPI mode, because the byte transmission must be completed.

- 0: Refresh disabled
- Others: Maximum communication length is set to REFRESH + 1 clock cycles.

### 30.7.6 HSPI status register (HSPI_SR)

Address offset: 0x020  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address offset</th>
<th>Reset value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x020</td>
<td>0x0000 0000</td>
</tr>
</tbody>
</table>

### Bits 31:15 Reserved, must be kept at reset value.

### Bits 14:8 FLEVEL[6:0]: FIFO level

This bitfield gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 64 when it is full. In automatic-status polling mode, FLEVEL is zero.

### Bits 7:6 Reserved, must be kept at reset value.

#### Bit 5 BUSY: Busy

This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

#### Bit 4 TOF: Timeout flag

This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

#### Bit 3 SMF: Status match flag

This bit is set in automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (HSPI_PSMAR). It is cleared by writing 1 to CSMF.
Bit 2  **FTF**: FIFO threshold flag
In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete.
It is cleared automatically as soon as the threshold condition is no longer true.
In automatic status-polling mode this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1  **TCF**: Transfer complete flag
This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted. It is cleared by writing 1 to CTCF.

Bit 0  **TEF**: Transfer error flag
This bit is set in indirect mode when an invalid address is being accessed in indirect mode.
It is cleared by writing 1 to CTEF.

### 30.7.7 HSPI flag clear register (HSPI_FCR)

Address offset: 0x024
Reset value: 0x0000 0000

<table>
<thead>
<tr>

<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

Bits 31:5  Reserved, must be kept at reset value.

Bit 4  **CTOF**: Clear timeout flag
Writing 1 clears the TOF flag in the HSPI_SR register.

Bit 3  **CSMF**: Clear status match flag
Writing 1 clears the SMF flag in the HSPI_SR register.

Bit 2  Reserved, must be kept at reset value.

Bit 1  **CTCF**: Clear transfer complete flag
Writing 1 clears the TCF flag in the HSPI_SR register.

Bit 0  **CTEF**: Clear transfer error flag
Writing 1 clears the TEF flag in the HSPI_SR register.
30.7.8 HSPI data length register (HSPI_DLR)

Address offset: 0x040
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.

<table>
<thead>
<tr>

<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:0 DL[31:0]: Data length
Number of data to be retrieved (value + 1) in indirect and automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for automatic status-polling mode. All 1’s in indirect mode means undefined length, where HSPI continues until the end of the memory, as defined by DEVSIZE. 0x0000_0000: 1 byte is to be transferred. 0x0000_0001: 2 bytes are to be transferred. 0x0000_0002: 3 bytes are to be transferred. 0x0000_0003: 4 bytes are to be transferred. ... 0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred. 0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred. 0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F. DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes. This bitfield has no effect when in memory-mapped mode.

30.7.9 HSPI address register (HSPI_AR)

Address offset: 0x048
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0 and FMODE ≠ 11.

</tbody>
</table>

ADDRESS[31:16]

ADDRESS[15:0]
Bits 31:0 **ADDRESS[31:0]: Address**
Address to be sent to the external device. In HyperBus protocol, this bitfield must be even as this protocol is 16-bit word oriented. In dual-memory configuration, AR[0] is forced to 0.

**Caution:** Some memory specifications consider that each address corresponds to a 16-bit value. HSPI considers that each address corresponds to an 8-bit value. So the software needs to multiple the address by two when accessing the memory registers.

### 30.7.10 HSPI data register (HSPI_DR)

Address offset: 0x050
Reset value: 0x0000 0000

<table>
<thead>
<tr>

<td></td>
</tr>
</tbody>
</table>

**Bits 31:0 DATA[31:0]: Data**

Data to be sent/received to/from the external SPI device

In indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.

In indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.

In automatic status-polling mode, this register contains the last data read from the external device (without masking).

Word, half-word, and byte accesses to this register are supported. In indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes. Similarly, in indirect-read mode, a byte read removes 1 byte from the FIFO, a half-word read 2 bytes, and a word read 4 bytes. Accesses in indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].
30.7.11  **HSPI polling status mask register (HSPI_PSMKR)**

Address offset: 0x080  
Reset value: 0x0000 0000  
This register can be modified only when BUSY = 0.

**MASK[15:0]**

Bits 31:0  **MASK[31:0]**: Status mask  
Mask to be applied to the status bytes received in automatic status-polling mode  
For bit n:  
0: Bit n of the data received in automatic status-polling mode is masked and its value is not considered in the matching logic.  
1: Bit n of the data received in automatic status-polling mode is unmasked and its value is considered in the matching logic.

30.7.12  **HSPI polling status match register (HSPI_PSMAR)**

Address offset: 0x088  
Reset value: 0x0000 0000  
This register can be modified only when BUSY = 0.

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 DQSE: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 DDTR: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for the data phase
1: DTR mode enabled for the data phase
Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
101: Data on 16 lines
Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.
30.7.15  HSPI timing configuration register (HSPI_TCR)

Address offset: 0x108

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bit 31  Reserved, must be kept at reset value.

Bit 30  SSHIFT: Sample shift
By default, the HSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bits 29:5  Reserved, must be kept at reset value.

Bits 4:0  DCYC[4:0]: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).
### 30.7.16 HSPI instruction register (HSPI_IR)

Address offset: 0x110  
Reset value: 0x0000 0000

**Bits 15:0  **TIMEOUT[15:0]: Timeout period

After each access in memory-mapped mode, the HSPI prefetches the subsequent bytes and hold them in the FIFO.

This bitfield indicates how many CLK cycles the HSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

**Bit 29  **DQSE: DQS enable

This bit enables the data strobe management.

0: DQS disabled

1: DQS enabled

**Bit 27  **DDTR: Data double transfer rate

This bit sets the DTR mode for the data phase.

0: DTR mode disabled for the data phase

1: DTR mode enabled for the data phase

**Bits 26:24  **DMODE[2:0]: Data mode

This bitfield defines the data phase mode of operation.

000: No data

001: Data on a single line

010: Data on two lines

011: Data on four lines

100: Data on eight lines

101: Data on 16 lines

Others: Reserved

**Bits 23:22  **Reserved, must be kept at reset value.

| Device Read-to-write/write-to-read minimum recovery time expressed in number of communication clock cycles |
| Bit 15:8 **TACC[7:0]**: Access time |
| Device access time according to the memory latency, expressed in number of communication clock cycles |
| Bit 7:2 Reserved, must be kept at reset value. |
| Bit 1 **WZL**: Write zero latency |
| This bit enables zero latency on write operations. |
| 0: Latency on write accesses |
| 1: No latency on write accesses |
| Bit 0 **LM**: Latency mode |
| This bit selects the latency mode. |
| 0: Variable initial latency |
| 1: Fixed latency |
| Note: This bit must be set when using the dual-octal HyperBus configuration. |

30.7.28 HSPI full-cycle calibration configuration (HSPI_CALFCR)

Address offset: 0x210
Reset value: 0x0000 0000

This read-only register gives the calibration code needed by the DLL master so that its delay is equivalent to a full memory-clock cycle. The value of this register is updated every time that auto-calibration finishes.
30.7.29 HSPI DLL master calibration configuration (HSPI_CALMR)

Address offset: 0x218
Reset value: 0x0000 0000

The DLL Master is used for delaying the feedback clock when reading without DQS.
The delay of the master DLL is determined by the value in this register.
This register can always be read by software and can be modified only when BUSY = 0.
This register never gets updated automatically by hardware.

| Bit 31 | CALMAX: Max value
|        | This bit gets set when the memory-clock period is outside the range of DLL master, in which case HSPI_CALFCR and HSPI_CALSR are updated with the values for the maximum delay.
| Bits 30:21 | Reserved, must be kept at reset value.
| Bits 20:16 | COARSE[4:0]: Coarse calibration
| | The delay unitary value for this bitfield depends on product technology (see the datasheet).
| Bits 15:7 | Reserved, must be kept at reset value.
| Bits 6:0 | FINE[6:0]: Fine calibration
| | The delay unitary value for this bitfield depends on product technology (see the datasheet).
30.7.30 HSPI DLL slave output calibration configuration (HSPI_CALSOR)

Address offset: 0x220
Reset value: 0x0000 0000

The DLL output slave is used to delay the output data in DDR mode for write operations. The delay of the output slave DLL is determined by the value in this register.

This register is updated automatically by hardware at the end of calibration (at the same moment that HSPI_CALFCR is updated).

If this register is written after the last write to HSPI_DCR2, then auto-calibration is not executed on the next transfer.

This register can always be read by software and can be modified only when BUSY = 0.

| Bit 31–21 | Reserved, must be kept at reset value. |
| Bit 20–16 | COARSE[4:0]: Coarse calibration. The delay unitary value for this bitfield depends on product technology (see the datasheet). |
| Bit 15–7  | Reserved, must be kept at reset value. |
| Bit 6–0   | FINE[6:0]: Fine calibration. The delay unitary value for this bitfield depends on product technology (see the datasheet). |
30.7.31  **HSPI DLL slave input calibration configuration (HSPI_CALSIR)**

Address offset: 0x228  
Reset value: 0x0000 0000  

The DLL input slave is used to delay the DQS input for sampling the data when DQS is enabled for read operations. The delay of the input slave DLL is determined by the value in this register.

This register is updated automatically by hardware at the end of calibration (at the same moment that HSPI_CALFCR is updated).

If this register is written after the last write to HSPI_DCR2, then auto-calibration is not executed on the next transfer.

This register can always be read by software and can be modified only when BUSY = 0.

Refer to Section 2.3 for the register boundary addresses.
31 Secure digital input/output MultiMediaCard interface (SDMMC)

31.1 SDMMC main features

The SD/SDIO, embedded MultiMediaCard (e•MMC) host interface (SDMMC) provides an interface between the AHB bus and SD memory cards, SDIO cards and e•MMC devices.

The MultiMediaCard system specifications are available through the MultiMediaCard Association website at www.jedec.org, published by the MMCA technical committee.

SD memory card and SD I/O card system specifications are available through the SD card Association website at www.sdcard.org.

The SDMMC features include the following:

  Card support for three different databus modes: 1-bit (default), 4-bit and 8-bit. (HS200 SDMMC_CK speed limited to maximum allowed I/O speed)(HS400 is not supported).
- Full compatibility with previous versions of MultiMediaCards (backward compatibility).
- Full compliance with SD memory card specifications version 6.0.
  (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Full compliance with SDIO card specification version 4.0.
  Card support for two different databus modes: 1-bit (default) and 4-bit.
  (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Data transfer up to 208 Mbyte/s for the 8-bit mode.
  (depending maximum allowed I/O speed).
- Data and command output enable signals to control external bidirectional drivers.
- IDMA linked list support

The MultiMediaCard/SD bus connects cards to the host.

The current version of the SDMMC supports only one SD/SDIO/e•MMC card at any one time and a stack of e•MMC.

1. X = supported.
2. Not available in STM32U535/545.
31.3 SDMMC bus topology

Communication over the bus is based on command/response and data transfers.

The basic transaction on the SD/SDIO/eMMC bus is the command/response transaction. These types of bus transaction transfer their information directly within the command or response structure. In addition, some operations have a data token.

Data transfers are done in the following ways:

- **Block mode**: data block(s) with block size $2^N$ bytes with $N$ in the range 0-14.
- **SDIO multibyte mode**: single data block with block size range 1-512 bytes
- **eMMC Stream mode**: continuous data stream

Data transfers to/from eMMC cards are done in data blocks or streams.

---

**Figure 180. SDMMC “no response” and “no data” operations**

- From host to card
- From card to host

---

**Figure 181. SDMMC (multiple) block read operation**

- From host to card
- From card to host

---

**Note:** The Stop Transmission command is not required at the end of a eMMC multiple block read with predefined block count.
Figure 182. SDMMC (multiple) block write operation

Note: The Stop Transmission command is not required at the end of an eMMC multiple block write with predefined block count.

Note: The SDMMC does not send any data as long as the Busy signal is asserted (SDMMC_D0 pulled low).

Figure 183. SDMMC (sequential) stream read operation

Figure 184. SDMMC (sequential) stream write operation

Stream data transfer operates only in a 1-bit wide bit bus configuration on SDMMC_D0 in single data rate modes (DS, HS, and SDR).

1. SDR single data rate signaling.
2. DDR double data rate signaling. (data is sampled on both SDMMC_CK clock edges).
3. e-MMC bus speed with 8bit bus width.
4. Maximum frequency depending on maximum allowed I/O speed.
5. Supported signal voltage level depends on I/O port characteristics, refer to device datasheet.

HS200 mode requires variable delay support using sampling point tuning.
31.5 SDMMC functional description

The SDMMC consists of four parts:
- The AHB slave interface accesses the SDMMC adapter registers, and generates interrupt signals and IDMA control signals.
- The SDMMC adapter block provides all functions specific to the eMMC/SD/SD I/O card such as the clock generation unit, command and data transfer.
- The internal DMA (IDMA) block with its AHB master interface.
- A delay block (DLYB) taking care of the receive data sample clock alignment. The delay block is NOT part of the SDMMC. A delay block is mandatory when supporting SDR104 or HS200.

31.5.1 SDMMC block diagram

*Figure 185* shows the SDMMC block diagram.

![SDMMC block diagram](image)

31.5.2 SDMMC pins and internal signals

### 31.5.3 General description

The **SDMMC_D[7:0]** lines have different operating modes:

- By default, SDMMC_D0 line is used for data transfer. After initialization, the host can change the databus width.
- For an eMMC, 1-bit (SDMMC_D0), 4-bit (SDMMC_D[3:0]) or 8-bit (SDMMC_D[7:0]) data bus widths can be used.
- For an SD or an SDIO card, 1-bit (SDMMC_D0) or 4-bit (SDMMC_D[3:0]) can be used. All data lines operate in push-pull mode.

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the data lines is indicated with I/O direction signals. The **SDMMC_D0DIR** signal indicates the I/O direction for the SDMMC_D0 data line, the **SDMMC_D123DIR** for the SDMMC_D[3:1] data lines.

**SDMMC_CMD** only operates in push-pull mode:

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the SDMMC_CMD line is indicated with the I/O direction signal **SDMMC_CDIR**.
Secure digital input/output MultiMediaCard interface (SDMMC)

SDMMC_CK clock to the card originates from sdmmc_ker_ck:

- When the sdmmc_ker_ck clock has 50 % duty cycle, it can be used even in bypass mode (CLKDIV = 0).
- When the sdmmc_ker_ck duty cycle is not 50 %, the CLKDIV must be used to divide it by 2 or more (CLKDIV > 0).
- The phase relation between the SDMMC_CMD / SDMMC_D[7:0] outputs and the SDMMC_CK can be selected through the NEGEDGE bit. The phase relation depends on the CLKDIV, NEGEDGE, and DDR settings. See Figure 186.

Table 272. SDMMC Command and data phase selection

By default, the sdmmc_io_in_ck feedback clock input is selected for sampling incoming data in the SDMMC receive path. It is derived from the SDMMC_CK pin.

For tuning the phase of the sampling clock to accommodate the receive data timing, the DLYB delay block available on the device can be connected between sdmmc_io_in_ck signal (DLYB input dlyb_in_ck) and sdmmc_fb_ck clock input of SDMMC (DLYB output dlyb_out_ck). Selecting the sdmmc_fb_ck clock input in the receive path then enables using the phase-tuned sampling clock for the incoming data. This is required for SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.
When using an external driver (a voltage switch transceiver), the SDMMC_CKIN feedback clock input can be selected to sample the receive data.

For an SD/SDIO/eMMC card, the clock frequency can vary between 0 and 208 MHz (limited by maximum I/O speed).

Depending on the selected bus mode (SDR or DDR), one bit or two bits are transferred on SDMMC_D[7:0] lines with each clock cycle. The SDMMC_CMD line transfers only one bit per clock cycle.

### 31.5.4 SDMMC adapter

The SDMMC adapter (see Figure 185: SDMMC block diagram) is a multimedia/secure digital memory card bus master that provides an interface to a MultiMediaCard stack or to a secure digital memory card. It consists of the following subunits:

- Control unit
- Data transmit path
- Command path
- Data receive path
- Response path
- Receive data path clock multiplexer
- Delay block (DLYB), external to the SDMMC
- Adapter register block
- Data FIFO
- Internal DMA (IDMA)

**Note:** The adapter registers and FIFO use the AHB clock domain (sdmmc_hclk). The control unit, command path and data transmit path use the SDMMC adapter clock domain (sdmmc_ker_ck). The response path and data receive path use the SDMMC adapter feedback clock domain from the sdmmc_io_in_ck, or SDMMC_CKIN, or from the sdmmc_fb_ck generated by DLYB.

The DLYB delay block on the device can be used in conjunction with the SDMMC adapter, to tune the phase of the sampling clock for incoming data in SDMMC receive mode. It is required for the SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.

**Adapter register block**

The adapter register block contains all system control registers, the SDMMC command and response registers and the data FIFO.

This block also generates the signals from the corresponding bit location in the SDMMC Clear register that clear the static flags in the SDMMC adapter.

**Control unit**

The control unit illustrated in Figure 187, contains the power management functions, the SDMMC_CK clock management with divider, and the I/O direction management.
The power management subunit disables the card bus output signals during the power-off and power-up phases.

There are three power phases:
- power-off
- power-up
- power-on

The clock management subunit uses the `sdmmc_ker_ck` to generate the `SDMMC_CK` and provides the division control. It also takes care of stopping the `SDMMC_CK` for i.e. flow control.

The clock outputs are inactive:
- after reset
- during the power-off or power-up phases
- if the power saving mode (register bit `PWRSAV`) is enabled and the card bus is in the Idle state for eight clock periods. The clock is stopped eight cycles after both the command/response CPSM and data path DPSM subunits have enter the Idle phase. The clock is restarted when the command/response CPSM or data path DPSM is activated (enabled).

The I/O management subunit takes care of the `SDMMC_Dn` and `SDMMC_CMD` I/O direction signals, which controls the external voltage transceiver.

**Command/response path**

The command/response path subunit transfers commands and responses on the `SDMMC_CMD` line. The command path is clocked on the `SDMMC_CK` and sends commands to the card. The response path is clocked on the `sdmmc_rx_ck` and receives responses from the card.
Command/response path state machine (CPSM)

- When the command register is written to and the enable bit is set, command transfer starts. When the command has been sent the CRC is appended and the command path state machine (CPSM) sets the status flags and:
  - if a response is not required enters the Idle state.
  - If a response is required, it waits for the response.
- When the response is received,
  - for a response with CRC, the received CRC code and the internally generated code are compared, and the appropriate status flag is set according the result.
  - for a response without CRC, no CRC is checked, and the appropriate status flag is not set.

When ever the CPSM is active, i.e. not in the Idle state, the CPSMACT bit is set.
• **Idle**: The command path is inactive. When the command control register is written and the enable bit (CPSMEN) is set, the CPSM activates the SDMMC_CK clock (when stopped due to power save PWRSAV bit) and moves
  – to the Send state when WAITPEND = 0 and BOOTEN = 0.
  – to the Pending state when WAITPEND = 1.
  – to the Boot state when BOOTEN = 1.

• **Send**: The command is sent and the CRC is appended.
  – When CMDTRANS bit is set or when BOOTEN bit is set and BOOTMODE is alternative boot, and the DTDIR = receive, the CPSM DataEnable signal is issued to the DPSM at the end of the command.
  – When the CMDTRANS bit is set and the CMDSUSPEND bit is 0 the interrupt period is terminated at the end of the command.
  – When CMDSTOP bit is set the CPSM Abort signal is issued to the DPSM at the end of the command.
  – If no response is expected (WAITRESP = 00) the CPSM moves to the Idle state and the CMDSENT flag is set. When BOOTMODE = 1 and BOOTEN = 0 the CMDSENT flag is delayed 56 cycles after the command end bit, otherwise the
CMDSENT flag is generated immediately after the command end bit. The RESPMDCR and RESPxR registers are not modified.

- If a command response is expected (WAITRESP ≠ not 00) the CPSM moves to the Wait state and start the response timeout.

**Wait:** The command path waits for a response.

- When WAITINT bit is 0 the command timer starts running and the CPSM waits for a start bit.
  a) If a start bit is detected before the timeout the CPSM moves to the Receive state.
  b) If the timeout is reached before the CPSM detect a response start bit, the timeout flag (CTIMEOUT) is set and the CPSM moves to the Idle state.

- When WAITINT bit is 1, the timer is disabled and the CPSM waits for an interrupt request (response start bit) from one of the cards.
  a) When a start bit is detected the CPSM moves to the Receive state.
  b) When writing WAITINT to 0 (interrupt mode abort), the host sends a response by itself and on detecting the start bit the CPSM move to the Receive state.

**Receive:** The command response is received. Depending the response mode bits WAITRESP in the command control register, the response can be either short or long, with CRC or without CRC. The received CRC code when present is verified against the internally generated CRC code.

- When the CMDUSUSPEND bit is set and the SDIO Response bit BS = 0 (response bit [39]), the interrupt period is started after the response.
  When the CMDUSUSPEND bit is cleared, or the CMDUSUSPEND bit is 1 and the SDIO Response bit BS = 1 (response bit [39]), there is no interrupt period started.
- When the CMDTRANS bit is set and the CMDUSUSPEND bit is set and the SDIO Response bit DF= 1 (response bit [32]) the interrupt period is terminated after the response.
- When the CRC status passes or no CRC is present the CMDREN flag is set, the CPSM moves to the Idle state.
  The RESPMDCR and RESPxR registers are updated with received response.
- When CMDTRANS bit is set and the DTDIR = transmit, the CPSM DataEnable signal is issued to the DPSM to start the data transfer.

- When CMDTRANS bit is set and the DTDIR = transmit, the CPSM DataEnable signal is issued to the DPSM to start the data transfer. The CPSM waits for a send CMD signal from the

**Pending:** According the pending WAITPEND bit in the command register, the CPSM enters the pending state.

- When DATALENGTH <= 5 bytes the CPSM moves to the Sent state and generates the DataEnable signal to start the data transfer aligned with the CMD12 Stop Transmission command.
- When DATALENGTH > 5 bytes, the CPSM DataEnable signal is issued to the DPSM to start the data transfer. The CPSM waits for a send CMD signal from the
DPSM before moving to the Send state. This enables i.e. the CMD12 Stop Transmission command to be sent aligned with the data.

- When writing WAITPEND to 0, the CPSM moves to the Send state.

**Boot:** If the BOOTEN bit is set in the command register, the CPSM enters the Boot state, and when:

- BOOTMODE = 0 the SDMMC_CMD line is driven low and when CMDTRANS bit is set and the DTDIR = receive, the CPSM DataEnable signal is issued to the DPSM. This enables normal boot operation. This state is left at the end of the boot procedure by clearing the register bit BOOTEN, which cause the SDMMC_CMD line to be driven high and the CPSM Abort signal is issued to the DPSM, before moving to the Idle state. The CMDSENT flag is generated 56 cycles after SDMMC_CMD line is high.

- BOOTMODE = 1, move to the Send state. This enables sending of the CMD0 (boot). Clearing BOOTEN has no effect.

**Note:** The CPSM remains in the Idle state for at least eight SDMMC_CK periods to meet the NCC and NRC timing constraints. NCC is the minimum delay between two host commands, and NRC is the minimum delay between the host command and the card response.

**Note:** The response timeout has a fixed value of 64 SDMMC_CK clock periods.

A command is a token that starts an operation. Commands are sent from the host to either a single card (addressed command) or all connected cards (broadcast command are available for eMMC V3.31 or previous). Commands are transferred serially on the SDMMC_CMD line. All commands have a fixed length of 48 bits. The general format for a command token for SD-Memory cards, SDIO cards, and eMMC cards is shown in Table 273.

The command token data is taken from 2 registers, one containing a 32-bits argument and the other containing the 6-bits command index (six bits sent to a card).

The command token format is shown in Table 273.

Next to the command data there are command type (WAITRESP) bits controlling the command path state machine (CPSM). These bits also determine whether the command requires a response, and whether the response is short (48 bit) or long (136 bits) long, and if a CRC is present or not.

A response is a token that is sent from an addressed card or synchronously from all connected cards to the host as an answer to a previous received command. All responses are sent via the command line SDMMC_CMD. The response transmission always starts with the left bit of the bit string corresponding to the response code word. The code length depends on the response type. Response tokens R1, R2, R3, R4, R5, and R6 have various
coding schemes, depending on their content. The general formats for the response tokens for SD-Memory cards, SDIO cards, and eMMC cards are shown in Table 274, Table 275 and Table 276.

A response always starts with a start bit (always 0), followed by the bit indicating the direction of transmission (card = 0). A value denoted by x in the tables below indicates a variable entry. Most responses, except some, are protected by a CRC. Every command code word is terminated by the end bit (always 1).

The response token data is stored in 5 registers, four containing the 32-bits card status, OCR register, argument or 127-bits CID or CSD register including internal CRC, and one register containing the 6-bits command index.

The command/response path operates in a half-duplex mode, so that either commands can be sent or responses can be received. If the CPSM is not in the Send state, the
SDMMC_CMD output is in the Hi-Z state. Data sent on SDMMC_CMD are synchronous with the SDMMC_CK according the NEGEDGE register bit see Figure 186.

The command and short response with CRC, the CRC generator calculates the CRC checksum for all 40 bits before the CRC code. This includes the start bit, transmission bit, command index, and command argument (or card status).

For the long response the CRC checksum is calculated only over the 120 bits of R2 CID or CSD. Note that the start bit, transmission bit and the six reserved bits are not used in the CRC calculation.

The CRC checksum is a 7-bit value:
\[
\text{CRC}[6:0] = \text{remainder } [(M(x) * x^7) / G(x)]
\]
\[
G(x) = x^7 + x^3 + 1
\]
\[
M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + ... + (\text{last bit before CRC}) * x^0
\]

Where \( n = 39 \) or 119.

The CPSM can send a number of specific commands to handle various operating modes when CPSMEN is set, see Table 277.

1. When CMDTRANS is set, also a stop_transmission command must be send to move the DPSM to Idle.

**Data path**

The data path subunit transfers data on the SDMMC_D[7:0] lines to and from cards. The data transmit path is clocked on the SDMMC_CK and sends data to the card. The data receive path is clocked on the sdmmc_rx_ck and receives data from the card. Figure 190 shows the data path block diagram.
The card data bus width can be programmed in the clock control register bits WIDBUS. The supported data bus width modes are:

- If the wide bus mode is not enabled, only one bit is transferred over SDMMC_D0.
- If the 4-bit wide bus mode is enabled, data is transferred at four bits over SDMMC_D[3:0].
- If the 8-bit wide bus mode is enabled, data is transferred at eight bits over SDMMC_D[7:0].

Next to the data bus width the data sampling mode can be programmed in the clock control register bit DDR. The supported data sampling modes are:

- Single data rate signaling (SDR), data is clocked on the rising edge of the clock.
- Double data rate signaling (DDR), data is clocked on the both edges of the clock. DDR mode is only supported in wide bus mode (4-bit wide and 8-bit wide).

Note: The data sampling mode only applies to the SDMMC_D[7:0] lines. (not applicable to the SDMMC_CMD line.)
In DDR mode, data is sampled on both edges of the SDMMC_CK according to the following rules, see also Figure 191 and Figure 192:

- On the rising edge of the clock odd bytes are sampled.
- On the falling edge of the clock even bytes are sampled.
- Data payload size is always a multiple of 2 Bytes.
- Two CRC16 are computed per data line
  - Odd bits CRC16 clocked on the falling edge of the clock.
  - Even bits CRC16 clocked on the rising edge of the clock.
- Start, end bits and idle conditions are full cycle.
- CRC status / boot acknowledgment and busy signaling are full cycle and are only sampled on the rising edge of the clock.

In DDR mode the SDMMC_CK clock division must be >= 2.

**Figure 191. DDR mode data packet clocking**

![Figure 191](image1)

**Figure 192. DDR mode CRC status / boot acknowledgment clocking**

![Figure 192](image2)

**Data path state machine (DPSM)**

Depending on the transfer direction (send or receive), the data path state machine (DPSM) moves to the Wait_S or Wait_R state when it is enabled:

- Send: the DPSM moves to the Wait_S state. If there is data in the transmit FIFO, the DPSM moves to the Send state, and the data path subunit starts sending data to a card.
- Receive: the DPSM moves to the Wait_R state and waits for a start bit. When it receives a start bit, the DPSM moves to the Receive state, and the data path subunit starts receiving data from a card.
For boot operation with acknowledgment the DPSM moves to the Wait_Ack state and waits for the boot acknowledgment before moving to the Wait_R state.

The DPSM operates at SDMMC_CK. The DPSM has the following states, as shown in Figure 193. When ever the DPSM is active, i.e. not in the Idle state, the DPSMACT bit is set.

**Figure 193. Data path state machine (DPSM)**

- **Idle state**: the data path is inactive, and the SDMMC_D[7:0] outputs are according the PWRCTRL setting. The DPSM is activated either by sending a command with CMDTRANS bit set or by setting the DTEN bit, or by detecting Busy on SDMMC_D0 (that is, after a command with R1b response).

When not busy, the DPSM activates the SDMMC_CK clock (when stopped due to power save PWRSAV bit), loads the data counter with a new (DATALENGTH) value and:
  - When the data direction bit (DTDIR) indicates send, moves to the Wait_S.
  - When the data direction bit (DTDIR) indicates receive, moves to the Receive state.

When busy the DPSM keeps the SDMMC_CK clock active and move to the Busy state.

- **Busy state**: the data path is busy, and the SDMMC_D[7:0] outputs are according the PWRCTRL setting. The DPSM operates at SDMMC_CK. The DPSM has the following states, as shown in Figure 193. When ever the DPSM is active, i.e. not in the Idle state, the DPSMACT bit is set.

When busy, the DPSM keeps the SDMMC_CK clock active and move to the Busy state.

- **Wait_Ack**: Ack status OK
  - End of data: DATACOUNT=0 or DTHOLD=1 or CPSM Abort & FIFO empty
  - End of packet: (End of packet) & DATACOUNT = not 0 & RWSTART=1

- **Wait_R**: Receive start bit detected
  - End of packet: (End of packet) & DATACOUNT = not 0 & RWSTART=1

- **Send**: Start bit detected
  - End of packet: (End of packet) & DATACOUNT = not 0 & RWSTART=1

- **Receive**: Receive start bit detected
  - End of packet: (End of packet) & DATACOUNT = not 0 & RWSTART=1
**Note:**  *DTEN must not be used to start data transfer with SD, SDIO and e•MMC cards.*

- **Wait_Ack** state: the data path waits for the boot acknowledgment token.
  - The DPSM moves to the Wait_R state if it receives an error free acknowledgment before a timeout.
  - When a pattern different from the acknowledgment is received an acknowledgment status error is generated, and the ack fail status flag (ACKFAIL) is set. The DPSM stays in Wait_Ack.
  - If it reaches a timeout (ACKTIME) before it detects a start bit, it sets the timeout status flag (ACKTIMEOUT). The DPSM stays in Wait_Ack.
  - When the CPSM Abort signal is set it moves to the Idle state and sets the DABORT flag.

- **Wait_R** state: the data path, if the data counter is not zero and data is not hold, waits for a start bit on SDMMC_D[n:0]. If the data counter is zero or data is hold, wait for the FIFO to be empty.
  - In block mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DBLOCKSIZE.
  - In SDIO multibyte mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DATALENGTH.
  - In stream mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data counter with DATALENGTH.
  - If the data counter (DATACOUNT) equals zero (end of data) the DPSM moves to the Idle state when the receive FIFO is empty and the DATAEND flag is set.
  - If it reaches a timeout (DATATIME) before it detects a start bit, it sets the timeout status flag (DATETIMEOUT) and the DPSM stays in the Wait_R state.
  - If the CPSM Abort signal is set:
    - If DATACOUNT > 0, the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFIRST, and sets the DABORT flag.
    - If DATACOUNT is zero normal operation is continued, there is no DABORT flag since the transfer has completed normally.
  - if the DTHOLD bit is set:
    - When DATACOUNT > 0, the DPSM moves to the Idle state when the receive FIFO is empty and when IDMAEN = 0 reset with FIFIRST, and issues the DHOLD flag. When holding the timeout is disabled. When an CPSM Abort signal is received during holding, the transfer is aborted.
- When DATACOUNT = 0, the transfer is completed normally and there is no DHOLD flag.
  – When DPSM has been started with DTEN, after an error (DTIMEOUT) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.

• **R_W** state: the data path Read Wait the bus.
  – The DPSM moves to the Wait_R state when the Read Wait stop bit (RWSTOP) is set, and start the receive timeout.
  – If the CPSM Abort signal is set, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then moves to the Idle state and sets the DABORT flag.

• **Receive** state: the data path receives serial data from a card. Pack the data in bytes and written it to the data FIFO. Depending on the transfer mode selected in the data control register (DTMODE), the data transfer mode can be either block or stream:
  – In block mode, when the data block size (DBLOCKSIZE) number of data bytes are received, the DPSM waits until it receives the CRC code.
  – In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are received, the DPSM waits until it receives the CRC code.

  a) If the received CRC code matches the internally generated CRC code, the DPSM moves to the
     - R_W state when RWSTART = 1 and DATACOUNT > zero, the DBCKEND flag is set.
     - Wait_R state otherwise.

  b) If the received CRC code fails the internally generated CRC code any further data reception is prevented.
     - When not all data has been received (DATACOUNT > 0), the CRC fail status flag (DCRCFAIL) is set and the DPSM stays in the Receive state.
     - When all data has been received (DATACOUNT = 0), wait for the FIFO to be empty after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.

  – In stream mode, the DPSM receives data while the data counter DATACOUNT > 0. When the counter is zero, the remaining data in the shift register is written to the data FIFO, and the DPSM moves to the Wait_R state.

  – When a FIFO overrun error occurs, the DPSM sets the FIFO overrun error flag (RXOVERR) and any further data reception is prevented. The DPSM stays in the Receive state.

  – When an CPSM Abort signal is received:
    - If the CPSM Abort signal is received before the 2 last bits of the data with DATACOUNT = 0, the transfer is aborted. The remaining data in the shift register is written to the data FIFO, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and the DABORT flag is set.
    - If the CPSM Abort signal is received during or after the 2 last bits of the transfer with DATACOUNT=0, the transfer is completed normally. The DPSM stays in the Receive state no DABORT flag is generated.

  – When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or RXOVERR) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.
- **Wait_S** state: the data path waits for data to be available from the FIFO.
  - If the data counter \( \text{DATACOUNT} > 0 \), waits until the data FIFO empty flag (TXFIFOE) is de-asserted and DTHOLD is not set, and moves to the Send state.
  - If the data counter \( \text{DATACOUNT} = 0 \) the DPSM moves to the Idle state.
  - When DTHOLD is disabled, the DATAEND flag is set.
  - When DTHOLD is enabled, the DHOLD flag is set.
  - When DTHOLD is set and the DATACOUNT > 0
    - When IDMA is enabled, the DBCKEND flag is set and subsequently the FIFO is flushed, furthermore the DPSM moves to the Idle state and the DHOLD flag is set.
    - When IDMA is disabled the DBCKEND flag is set. Wait for the FIFO to be reset by software with FIFORST, then DPSM moves to the Idle state and issues the DHOLD flag.
  - When DTHOLD is set and \( \text{DATACOUNT} = 0 \) the transfer is completed normally.
  - When receiving the CPSM Abort signal
    - If the CPSM Abort signal is received before the 2 last bits of the data with \( \text{DATACOUNT} = 0 \), the transfer is aborted, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and sets the DABORT flag.
    - If the CPSM Abort signal is received during or after the 2 last bits of the transfer with \( \text{DATACOUNT} = 0 \), normal operation is continued, there is no DABORT flag since the transfer has completed normally.

Note: The DPSM remains in the Wait_S state for at least two clock periods to meet the \( N_{WR} \) timing requirements, where \( N_{WR} \) is the number of clock cycles between the reception of the card response and the start of the data transfer from the host.

- **Send** state: the DPSM starts sending data to a card. Depending on the transfer mode bit in the data control register, the data transfer mode can be either block, SDIO multibyte or stream:
  - In block mode, when the data block size (DBLOCKSIZE) number of data bytes are send, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state and start the transmit timeout.
  - In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are send, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state and start the transmit timeout.
  - In stream mode, the DPSM sends data to a card while the data counter \( \text{DATACOUNT} > 0 \). When the data counter reaches zero moves to the Busy state and start the transmit timeout.
    Before sending the last stream Byte according to \( \text{DATACOUNT} \), the DPSM issues a trigger on the send CMD signal. This signal is used by the CPSM to sent any pending command. (i.e. CMD12 Stop Transmission command)
    - If a FIFO underrun error occurs, the DPSM sets the FIFO underrun error flag (TXUNDERR). The DPSM stays in the Send state.
    - When receiving the CPSM Abort signal
      - If the CPSM Abort signal is received before the 2 last bits of the transfer with \( \text{DATACOUNT} = 0 \), the transfer is aborted. The DPSM sends a last data bit followed by an end bit. The FIFO is disabled/flushed, and the DPSM moves to the Busy state to wait for not busy before setting the DABORT flag.
      - If the CPSM Abort signal is received during or after the 2 last bits of the transfer
with DATACOUNT=0, the transfer is completed normally, there is no DABORT flag.

- **Busy** state: the DPSM waits for the CRC status token when expected, and wait for a not busy signal:
  - If a CRC status token is expected and indicate “non-erroneous transmission” or when there is no CRC expected:
    - it moves to the Wait_S state when SDMMC_D0 is not low (the card is not busy).
    - When the card is busy SDMMC_D0 is low it remains in the Busy state.
  - If a CRC status token is expected and indicates “erroneous transmission”.
    - When not all data has been send (DATACOUNT > 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set. The FIFO is disabled/flushed and the DPSM stays in the Busy state.
    - When all data has been send (DATACOUNT = 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.
  - If a CRC status (Ncrc) timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag (DTIMEOUT) and stays in the Busy state.

- When receiving the CPSM Abort signal in the Busy state:
  - If the CPSM Abort signal is received before the 2 last bits of the CRC response with DATACOUNT > 0, the data transfer is aborted. The DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.
  - If the CPSM Abort signal is received during or after the 2 last bits of the CRC response when DATACOUNT=0 or when no CRC is expected and DATACOUNT = 0 and there has been no DTIMEOUT error, the DPSM stays in the Busy state no DABORT flag is generated, since the transfer may completed normally.
  - If the CPSM Abort signal is received when a DTIMEOUT error has occurred the DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.

- When entering the Busy state due to an abort in the Send state, the DPSM waits for not busy before moving to the Idle state and the DABORT flag is set.

- When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or DTIMEOUT) the DPSM moves to the Idle state when the FIFO is reset.

- When the DPSM has been started due to Busy on SDMMC_D0, waits for not busy after which the Busy end status flag (BUSYD0END) is set and the DPSM moves to the Idle state.
The data timer (DATATIME) is enabled when the DPSM is in the Wait_R or Busy state 2 cycles after the data block end bit, or data read command end bit, or R1b response, and generates the data timeout error (DTIMEOUT):

- When transmitting data, the timeout occurs
  - when a CRC status is expected and no start bit is received within 8 SDMMC_CK cycles, the DTIMEOUT flag is set.
  - when the Busy state takes longer than the programmed timeout period, the DTIMEOUT flag is set.
- When receiving data, the timeout occurs
  - when there is still data to be received DATACOUNT > 0 and no start bit is received before the programmed timeout period, the DTIMEOUT flag is set.
- After a R1b response, the timeout occurs
  - when the Busy state takes longer than the programmed timeout period, the DTIMEOUT flag is set.

When DATATIME = 0,
- In receive the start bit must be present 2 cycles after the data block end bit or data read command end bit.
- In transmit busy is timed out 2 cycles after the CRC token end bit or stream data end bit.
- After a R1b response busy is timed out 2 cycles after the response end bit.

Data can be transferred from the card to the host (transmit, send) or vice versa (receive). Data are transferred via the SDMMC_Dn data lines, they are stored in a FIFO.

Table 280. Data token format

**Data FIFO**

The data FIFO (first-in-first-out) subunit contains the transmit and receive data buffer. A single FIFO is used for either transmit or receive as selected by the DTDIR bit. The FIFO contains a 32-bit wide, 16-word deep data buffer and control logic. Because the data FIFO operates in the AHB clock domain (sdmmc_hclk), all signals from the subunits in the SDMMC clock domain (SDMMC_CK/sdmmc_rx_ck) are resynchronized.
The FIFO can be in one of the following states:

- The transmit FIFO refers to the transmit logic and data buffer when sending data out to the card. (DTDIR = 0)
- The receive FIFO refers to the receive logic and data buffer when receiving data in from the card. (DTDIR = 1)

The end of a correctly completed SDMMC data transfer from the FIFO is indicated by the DATAEND flags driven by the data path subunit. Any incorrect (aborted) SDMMC data transfer from the FIFO is indicated by one of the error flags (DCRCFAIL, DTIMEOUT, DABORT) driven by the data path subunit, or one of the FIFO error flags (TXUNDERR, RXOVERR) driven by the FIFO control.

The data FIFO can be accessed in the following ways, see Table 283.

Transmit FIFO:

Data can be written to the transmit FIFO when the DPSM has been activated (DPSMACT = 1).

When IDMAEN = 1 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by firmware via the AHB slave interface. The transmit FIFO is accessible via sequential addresses. The transmit FIFO contains a data output register that holds the data word pointed to by the read pointer. When the data path subunit has loaded its shift register, it increments the read pointer and drives new data out. The transmit FIFO is handled in the following way:

1. Write the data length into DATALENGTH and the block length in DBLOCKSIZE.
   - For block data transfer (DTMODE = 0), DATALENGTH must be an integer multiple of DBLOCKSIZE.
2. Set the SDMMC in transmit mode (DTDIR = 0).
   - Configures the FIFO in transmit mode.
3. Enable the data transfer
   - either by sending a command from the CPSM with the CMDTRANS bit set
   - or by setting DTEN bit
4. When (DPSMACT = 1) write data to the FIFO.
   - The DPSM stays in the Wait_S state until FIFO is full (TXFIFOF = 1), or the number indicated by DATALENGTH.
- The SDMMC keeps sending data as long as FIFO is not empty, hardware flow control during data transfer is used to prevent FIFO underrun.

5. Write data to the FIFO.
   - When the FIFO is handled by software, wait until the FIFO is half empty (TXFIFOHE flag), write data to the FIFO until FIFO is full (TXFIFOF = 1), or last data has been written.
   - When the FIFO is handled by the IDMA, the IDMA transfers the FIFO data.

6. When last data has been written wait for end of data (DATAEND flag)
   - SDMMC has completely sent all data and the DPSM is disabled (DPSMACT = 0).

In case of a data transfer error or transfer hold when IDMAEN = 0, firmware must stop writing to the FIFO and flush and reset the FIFO with the FIFORST register bit.

The transmit FIFO status flags are listed in Table 284.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TXFIFOF</td>
<td>Set to high when all transmit FIFO words contain valid data.</td>
</tr>
<tr>
<td>TXFIFOE</td>
<td>Set to high when the transmit FIFO does not contain valid data.</td>
</tr>
<tr>
<td>TXFIFOHE</td>
<td>Set to high when half or more transmit FIFO words are empty.</td>
</tr>
<tr>
<td>TXUNDERR</td>
<td>Set to high when an underrun error occurs. This flag is cleared by writing to the SDMMC Clear register.</td>
</tr>
</tbody>
</table>

Receive FIFO:

Data can be read from the receive FIFO when the DPSM is activated (DPSMACT = 1).

When IDMAEN = 1 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by firmware via the AHB slave interface. When the data path subunit receives a word of data, it drives the data on the write databus. The write pointer is incremented after the write operation completes. On the read side, the contents of the FIFO word pointed to by the current value of the read pointer is driven onto the read databus. The receive FIFO is accessible via sequential addresses.

The receive FIFO is handled in the following way:
1. Write the data length into DATALENGTH and the block length in DBLOCKSIZE.
   – For block data transfer (DTMODE = 0), DATALENGTH must be an integer multiple of DBLOCKSIZE.
2. Set the SDMMC in receive mode (DTDIR = 1).
   – Configures the FIFO in receive mode.
3. Enable the DPSM transfer
   – either by sending a command from the CPSM with the CMDTRANS bit set
   – or by setting DTEN bit.
4. When (DPSMACT = 1) the FIFO is ready to receive data.
   – The DPSM writes the received data to the FIFO.
     - The SDMMC keeps receiving data as long as FIFO is not full, hardware flow control during the data transfer is used to prevent FIFO overrun.
5. Read data from the FIFO.
   – When the FIFO is handled by software, wait until the FIFO is half full (RXFIFOHF flag), read data from the FIFO until FIFO is empty (RXFIFOE = 1).
     - When last data has been received, read data from the FIFO until FIFO is empty (DATAEND = 1).
     - When the FIFO is handled by the IDMA, the IDMA transfers the FIFO data.
6. SDMMC has completely received all data and the DPSM is disabled (DPSMACT = 0).

In case of a data transfer hold when IDMAEN = 0, the firmware must read the remaining data until the FIFO is empty and reset the FIFO with the FIFOSET register bit. This causes the DPSM to go to the Idle state (DPSMACT = 0).

In case of a data transfer error when IDMAEN = 0, the firmware must stop reading the FIFO and flush and reset the FIFO with the FIFOSET register bit. This causes the DPSM to go to the Idle state (DPSMACT = 0).

The receive FIFO status flags are listed in Table 285.

### Table 285. Receive FIFO status flags

### CLKMUX unit

The CLKMUX selects the source for clock sdmmc_rx_ck to be used with the received data and command response. The receive data clock source can be selected by the clock control register bit SELCLKR0X, between:

- sdmmc_io_in_ck bus master main feedback clock.
- SDMMC_CKIN external bus feedback clock.
- sdmmc_fb_ck bus tuned feedback clock.

The sdmmc_io_in_ck is selected when there is no external driver, with DS and HS.
The SDMMC_CKIN is selected when there is an external driver with SDR12, SDR25, SDR50 and DDR50.

The sdmmc_fb_ck clock input must be selected when the DLYB block on the device is used with SDR104, HS200 and optionally with SDR50 and DDR50 modes.

**31.5.5 SDMMC AHB slave interface**

The AHB slave interface generates the interrupt requests, and accesses the SDMMC adapter registers and the data FIFO. It consists of a data path, register decoder, and interrupt logic.

**SDMMC FIFO**

The FIFO access is restricted to word access only:

- In transmit FIFO mode
  - Data are written to the FIFO in words (32-bits) until all data according DATALENGTH has been transferred. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are written with a word transfer.

- In receive FIFO mode
  - Data are read from the FIFO in words (32-bits) until all data according DATALENGTH has been transferred. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are read with a word transfer padded with 0 value bytes.

When accessing the FIFO with half word or byte accesses an AHB bus fault is generated.

**SDMMC interrupts**

The interrupt logic generates an interrupt request signal that is asserted when at least one of the unmasked status flags is active. A mask register is provided to allow selection of the conditions that generate an interrupt. A status flag generates the interrupt request if a corresponding mask flag is set. Some status flags require an implicit clear in the clear register.

**31.5.6 SDMMC AHB master interface**

The AHB master interface is used to transfer the data between a memory and the FIFO using the SDMMC IDMA.
SDMMC IDMA

Direct memory access (DMA) is used to provide high-speed transfer between the SDMMC FIFO and the memory. The AHB master optimizes the bandwidth of the system bus. The SDMMC internal DMA (IDMA) provides one channel to be used either for transmit or receive.

The IDMA is enabled by the IDMAEN bit and supports burst transfers of 8 beats.

- In transmit burst transfer mode:
  - Data are fetched in burst from memory whenever the FIFO is empty for the number of burst transfers, until all data according DATALENGTH has been transferred. When the DATALENGTH is not an integer multiple of the burst size the remaining, smaller than burst size data is transferred using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are fetched with a word transfer.

- In receive burst transfer mode:
  - Data are stored in burst in to memory whenever the FIFO contains the number of burst transfers, until all data according DATALENGTH has been transferred. When the DATALENGTH is not an integer multiple of the burst transfer the remaining, smaller than burst size data, is transferred using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are stored with halfword and or byte transfers.

In addition the IDMA provides the following channel configurations selected by bit IDMABMODE:

- single buffered channel
- linked list channel

Single buffered channel

In single buffer configuration the data at the memory side is accessed in a linear matter starting from the base address IDMABASE. When the IDMA has finished transferring all data the and the DPSM has completed the transfer the DATAEND flag is set.

Linked list channel

In linked list configuration, IDMAMODE = 1, the data at the memory side is subsequently accessed from linked buffers, located at base address IDMABASE. The size of the memory buffers is defined by IDMABSIZE. The buffer size must be an integer multiple of the burst size. The bit ULA is used to indicate if a new linked list buffer configuration has to be loaded from the linked list table. A new linked list configuration is loaded when the ULA bit for the current linked list item is set.

The first linked list item configuration is programmed by firmware directly in the SDMMC registers.

When the IDMA has finished transferring all the data of one linked list buffer, according IDMABSIZE, and when the linked list item ULA bit is set, the IDMA loads the new linked list item from the linked list table, and continues transferring data from the next linked list buffer. When the IDMA has finished transferring all data, according IDMABSIZE and ULA, and the DPSM has completed the transfer, according DATALENGHT, the DATAEND flag is set.
In the following cases, the linked list provides more buffer space than the data to transfer which means the current linked list buffer data has not completely be transfered:

- the ULA bit is set, and all SDMMC data according DATALENGTH has been transfered (DATAEND flag)
- a transfer error (DCRCFAIL when DATACOUNT > 0, RXOVERR, TXUNDERR) occurs
- a transfer is hold (DTHOLD)

In all above cases, the IDMA linked list is stopped and the FIFO is flushed/reset. Before starting or restarting a new SDMMC transfer, the software must initialize a new linked list with correct IDMABASE and IDMABSIZE.

When a IDMA transfer error occurs (see Section : IDMA transfer error management) or when the linked list does not provide sufficient buffer space:

- the linked list ends with ULA = 0 and all last linked list buffer data has been transfered, and not all SDMMC data according DATALENGTH has been transfered. The SDMMC transfer is stopped and an IDMA transfer error is generated (see Section : IDMA transfer error management).

For a given linked list item, the base address is given by the linked list base IDMABA register value plus the linked list offset IDMALA register value.

The content of each linked list item can be specified by the ULS bit, which makes possible to optionally load the IDMABSIZE, resulting in a 3-word linked list structure. When the IDMABSIZE is not to be loaded (i.e. fixed size buffers) a compacted reduced 2-word linked list structure can be used containing only the IDMABASER and the IDMALAR values.

For a given linked list item, the base address is given by the linked list base IDMABA register value plus the linked list offset IDMALA register value.

The content of each linked list item can be specified by the ULS bit, which makes possible to optionally load the IDMABSIZE, resulting in a 3-word linked list structure. When the IDMABSIZE is not to be loaded (i.e. fixed size buffers) a compacted reduced 2-word linked list structure can be used containing only the IDMABASER and the IDMALAR values.

There is no restriction on mixing both linked list item structures in a single list, this enables the IDMABSIZE to be updated only when needed.

Whenever a linked list buffer has been transfered and the current buffer ULA = 1, an end-of-linked-list-buffer-transfer-complete interrupt (IDMABTC) may be generated (if interrupt is enabled).
Linked list acknowledgment

In the case where software dynamically updates the linked list, during the SDMMC transfer, the availability of a new linked list buffer can be acknowledged by the acknowledge buffer ready (ABR) bit.

When ABR acknowledges that the new linked list buffer is ready, the IDMA continues transferring data from the new linked list buffer.

When ABR indicates that the new linked list buffer is not ready, an IDMA transfer error is generated (see Section : IDMA transfer error management). Depending when the IDMA transfer error occurs, it normally causes the generation of an TXUNDERR or RXOVERR error. When a linked list buffer is not acknowledged in time the SDMMC transfer is stopped.

The ABR information is “don’t care” when starting the linked list from software programmed register information. The first linked list buffer must be ready to be used before starting the SDMMC transfer.

IDMA transfer error management

An IDMA transfer error can occur:

- When reading or writing a reserved address space (for data or linked list information).
- When there is no more linked list buffer space to store received SDMMC data.
- When all linked list buffer data has been transfered and still more SDMMC data needs to be sent.
- When the availability of a linked list buffer is not acknowledged.

On a IDMA transfer error subsequent IDMA transfers are disabled and an IDMATE flag is set and hardware flow control is disabled. Depending when the IDMA transfer error occurs, it normally causes the generation of a TXUNDERR or RXOVERR error.

The behavior of the IDMATE flag depend on when the IDMA transfer error occurs during the SDMMC transfer:

- An IDMA transfer error is detected before any SDMMC transfer error (TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT):
  - The IDMATE flag is set at the same time as the SDMMC transfer error flag.
  - The TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT interrupt is generated.
- An IDMA transfer error is detected during a STOP_TRANSNMISSION command:
  - The IDMATE flag is set at the same time as the DABORT flag.
  - The DABORT interrupt is generated.
- An IDMA transfer error is detected at the end of the SDMMC transfer (DHOLD, or DATAEND):
  - The IDMATE flag is set at the end of the SDMMC transfer.
  - A SDMMC transfer end interrupt is generated and a DHOLD or DATAEND flag is set.

The IDMATE is generated on an other SDMMC transfer interrupt (TXUNDERR, RXOVERR, DCRCFAIL, DTIMEOUT, DABORT, DHOLD, or DATAEND).
31.5.7 AHB and SDMMC_CK clock relation

The AHB must at least have 3x more bandwidth than the SDMMC bus bandwidth i.e. for SDR50 4-bit mode (50 Mbyte/s) the minimum sdmmc_hclk frequency is 37.5 MHz (150 Mbyte/s).

### Table 286. AHB and SDMMC_CK clock frequency relation

31.6 Card functional description

31.6.1 SD I/O mode

The following features are SDMMC specific operations:

- SDIO interrupts
- SDIO suspend/resume operation (write and read suspend)
- SDIO Read Wait operation by stopping the clock
- SDIO Read Wait operation by SDMMC_D2 signaling

### Table 287. SDIO special operation control

**SD I/O interrupts**

To allow the SD I/O card to interrupt the host, an interrupt function is available on pin 8 (shared with SDMMC_D1 in 4-bit mode) on the SD interface. The use of the interrupt is optional for each card or function within a card. The SD I/O interrupt is level-sensitive, which means that the interrupt line must be held active (low) until it is either recognized and acted upon by the host or deasserted due to the end of the interrupt period. After the host has serviced the interrupt, the interrupt status bit is cleared via an I/O write to the appropriate bit in the SD I/O card internal registers. The interrupt output of all SD I/O cards is active low and the application must provide external pull-up resistors on all data lines (SDMMC_D[3:0]).

In SD 1-bit mode pin 8 is dedicated to the interrupt function (IRQ), and there are no timing constraints on interrupts.

In SD 4-bit mode the host samples the level of pin 8 (SDMMC_D1/IRQ) into the interrupt detector only during the interrupt period. At all other times, the host interrupt ignores this value. The interrupt period begins when interrupts are enabled at the card and SDIOEN bit is set see register settings in *Table 287*.

In 4-bit mode the card can generate a synchronous or asynchronous interrupt as indicated by the card CCCR register SAI and EAI bits.

- **Synchronous interrupt**, require the SDMMC_CK to be active.
- **Asynchronous interrupt**, can be generated when the SDMMC_CK is stopped, 4 cycles after the start of the card interrupt period following the last data block.

![Figure 196. Asynchronous interrupt generation](image)

The timing of the interrupt period is depended on the bus speed mode:
In DS, HS, SDR12, and SDR25 mode, selected by register bit BUSSPEED, the interrupt period is synchronous to the SD clock.

- The interrupt period ends at the next clock from the end bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set.
- The interrupt period resumes 2 SDMMC_CK after the completion of the data block.
- At the data block gap the interrupt period is limited to 2 SDMMC_CK cycles.

**Note:** *DTEN must not be used to start data transfer with SD and eMMC cards.*
In SDR50, SDR104, and DDR50, selected by register bit BUSSPEED, due to propagation delay from the card to host, the interrupt period is asynchronous.

- The card interrupt period ends after 0 to 2 SDMMC_CK cycles after the end bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set. At the host the interrupt period ends after the end bit of a command that transfers data block(s). A card interrupt issued in the 1 to 2 cycles after the command end bit are not detected by the host during this interrupt period.

- The card interrupt period resumes 2 to 4 SDMMC_CK after the completion of the last data block. The host resumes the interrupt period always 2 cycles after the last data block.

- There is NO interrupt period at the data block gap.

**Note:** *DTEN must not be used to start data transfer with SD and eMMC cards.*

**Figure 199. Asynchronous interrupt period data read**
When transferring Open-ended multiple block data and using DTMODE “block data transfer ending with STOP_TRANSMISSION command”, the SDMMC masks the interrupt period after the last data block until the end of the CMD12 STOP_TRANSMISSION command.

The interrupt period is applicable for both memory and I/O operations.

In 4-bit mode interrupts can be differentiated from other signaling according Table 288.

SD I/O suspend and resume

This function is NOT supported in SDIO version 4.00 or later.

Within a multifunction SD I/O or a card with both I/O and memory functions, there are multiple devices (I/O and memory) that share access to the eMMC/SD bus. To share access to the host among multiple devices, SD I/O and combo cards optionally implement the concept of suspend/resume. When a card supports suspend/resume, the host can temporarily halt (suspend) a data transfer operation to one function or memory to free the bus for a higher-priority transfer to a different function or memory. After this higher-priority transfer is complete, the original transfer is restarted (resume) where it left off.

To perform the suspend/resume operation on the bus, the host performs the following steps:
1. Determines the function currently using the SDMMC_D[3:0] line(s)
2. Requests the lower-priority or slower transaction to suspend
3. Waits for the transaction suspension to complete
4. Begins the higher-priority transaction
5. Waits for the completion of the higher priority transaction
6. Restores the suspended transaction

The card receiving a suspend command responds with its current bus status. Only when the bus has been suspended by the card the bus status indicates suspension completed.

There are different suspend cases conditions:
- Suspend request accepted prior to the start of data transfer.
- Suspend request not accepted, (due to data being transferred at the same time), the host keeps checking the request until it is accepted. (data transfer has suspended)
- Suspend request during write busy.
- Suspend request with write multiple.
- Suspend request during Read Wait.

For the host to know if the bus has been released it must check the status of the suspend request, suspension completed.

When the bus status of the suspend request response indicates suspension completed, the card has released the bus. At this time the state of the suspended operation must be saved where after an other operation can start.

The suspend command must be sent with the CMD_SUSPEND bit set. This makes possible to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).

The hardware does not save the number of remaining data to be transferred when resuming the suspended operation. It is up to firmware to determine the data that has been transferred and resume with the correct remaining number of data bytes.

While receiving data from the card, the SDMMC can suspend the read operation after the read data block end (DPSM in Wait_R). After receiving the suspend acknowledgment response from the card the following steps must be taken by firmware:

1. The normal receive process must be stopped by setting DTHOLD bit.
   a) The remaining number of data bytes in the FIFO must be read until the receive FIFO is empty (RXFIFOE flag is set), and when IDMAEN = 0 the FIFO must be reset with FIFORST.

2. The confirmation that all data has been read from the FIFO, and that the suspend is completed is indicated by the DHOLD flag.
   a) The remaining number of data bytes (multiple of data blocks) still to be read when resuming the operation must be determined from the remaining number of bytes indicated by the DATACOUNT.

Note: When a DTIMEOUT flag occurs during the suspend procedure, this must be ignored.

To resume receiving data from the card, the following steps must be taken by firmware:
1. The remaining number of data bytes (multiple of data blocks) must be programmed in DATALENGTH.
2. The DPSM must be configured to receive data in the DTDIR bit.
3. The resume command must be sent from the CPSM, with the CMDTRANS bit set and the CMDSUSPEND bit set, which ends the interrupt period when data transfer is resumed (response bit DF = 1) and enabled the DPSM, after which the card resumes sending data.

While sending data to the card, the SDMMC can suspend the write operation after the write data block CRC status end (DPSM in Busy). Before sending the suspend command to the card the following steps must be taken by firmware:

1. Enable DHOLD flag (and DBCKEND flag when IDMAEN = 0)
2. The DPSM must be prevented from start sending a new data block by setting DTHOLD.
3. When IDMAEN = 0: When receiving the DBCKEND flag the data transfer is stopped. Firmware can stop filling the FIFO, after which the FIFO must be reset with FIFO_RST. Any bytes still in the FIFO need to be rewritten when resuming the operation.
4. When receiving the DHOLD flag the data transfer is stopped. The remaining number of data bytes still to be written when resuming must be determined from the remaining number of bytes indicated by the DATACOUNT.
5. To suspend the card the suspend command must be sent by the CPSM with the CMDSUSPEND bit set. This makes possible to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).

To resume sending data to the card, the following steps must be taken by firmware:

1. The remaining number of data bytes must be programmed in DATALENGTH.
2. The DPSM must be configured for transmission with DTDIR set and enabled by having the CPSM send the resume command with the CMDTRANS bit set and the CMDSUSPEND bit set. This ends the interrupt period and start the data transfer. The DPSM either goes to the Wait_S state when SDMMC_D0 does not signal busy, or goes to the Busy state when busy is signaled.
3. When IDMAEN = 1: The IDMA needs to be reprogrammed for the remaining bytes to be transfered.
4. When IDMAEN = 0: Firmware must start filling the FIFO with the remaining data.

**SD I/O Read Wait**

There are 2 methods to pause the data transfer during the Block gap:

1. Stopping the SDMMC_CK.
2. Using Read Wait signaling on SDMMC_D2.

The SDMMC can perform a Read Wait with register settings according Table 287. Depending the SDMMC operation mode (DS, HS, SDR12, SDR25) or (SDR50, SDR104, DDR) each method has a different characteristic.

The timing for pause read operation by stopping the SDMMC_CK for DS, HS, SDR12, and SDR25, the SDMMC_CK may be stopped 2 SDMMC_CK cycles after the end bit. When ready the host resumes by restarting clock, see Figure 201.
The timing for pause read operation by stopping the SDMMC_CK for SDR50, SDR104, and DDR50, the SDMMC_CK may be stopped minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, after the end bit. When ready the host resumes by restarting clock, see Figure 202. (In DDR50 mode the SDMMC_CK must only be stopped after the falling edge, when the clock line is low.)

In Read Wait SDMMC_CK clock stopping, when RWSTART is set, the DPSM stops the clock after the end bit of the current received data block CRC. The clock start again after writing 1 to the RWSTOP bit, where after the DPSM waits for a start bit from the card.

As SDMMC_CK is stopped, no command can be issued to the card. During a Read Wait interval, the SDMMC can still detect SDIO interrupts on SDMMC_D1.

The optional Read Wait signaling on SDMMC_D2 (RW) operation is defined only for the SD 1-bit and 4-bit modes. The Read Wait operation enables the host to signal a card that is reading multiple registers (IO_RW_EXTENDED, CMD53) to temporarily stall the data transfer while allowing the host to send commands to any function within the SD I/O device. To determine when a card supports the Read Wait protocol, the host must test capability bits in the internal card registers.

The timing for Read Wait with a SDMMC_CK less then 50MHz (DS, HS, SDR12, SDR25) is based on the interrupt period generated by the card on SDMMC_D1. The host by asserting SDMMC_D2 low during the interrupt period requests the card to enter Read Wait. To exit Read Wait the host must raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z, see Figure 203.
For SDR50, SDR104 with a SDMMC_CK more than 50MHz, and DDR50, the card treats the Read Wait request on SDMMC_D2 as an asynchronous event. The host by asserting SDMMC_D2 low after minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, request the card to enter Read Wait. To exit Read Wait the host must raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z. The host must raise SDMMC_D2 on the SDMMC_CK clock (see Figure 204).

In Read Wait SDMMC_D2 signaling, when RWSTART is set, the DPSM drives SDMMC_D2 after the end bit of the current received data block CRC. The Read Wait signaling on SDMMC_D2 is removed when writing 1 to the RWSTOP bit. The DPSM remains in R_W state for two more SDMMC_CK clock cycles to drive SDMMC_D2 to 1 for one clock cycle (in accordance with SDIO specification), where after the DPSM waits for a start bit from the card.

During the Read Wait signaling on SDMMC_D2 commands can be issued to the card. During the Read Wait interval, the SDMMC can detect SDIO interrupts on SDMMC_D1.

31.6.2 CMD12 send timing

CMD12 is used to stop/abort the data transfer, the card data transmission is terminated two clock cycles after the end bit of the Stop Transmission command.
All data write and read commands can be aborted any time by a Stop Transmission command CMD12. The following data abort procedure applies during an ongoing data transfer:

<table>
<thead>
<tr>
<th>Data operation</th>
<th>Stop Transmission command CMD12 Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SDMMC stream write</td>
<td>The data transfer is stopped/aborted by sending the Stop Transmission command.</td>
</tr>
<tr>
<td>SDMMC open ended multiple block write</td>
<td>The data transfer is stopped/aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.</td>
</tr>
<tr>
<td>SDMMC block write with predefined block count</td>
<td>The Stop Transmission command is not required at the end of this type of multiple block write. (sending the Stop Transmission command after the card has received the last block is regarded as an illegal command.) If the card detects an error, the host must abort the operation by sending the Stop Transmission command.</td>
</tr>
<tr>
<td>SDMMC stream read</td>
<td>The data transfer is stopped/aborted by sending the Stop Transmission command.</td>
</tr>
<tr>
<td>SDMMC open ended multiple block read</td>
<td>The data transfer is stopped/aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.</td>
</tr>
<tr>
<td>SDMMC block read with predefined block count</td>
<td>The Stop Transmission command is not required at the end of this type of multiple block read. (sending the Stop Transmission command after the card has transmitted the last block is regarded as an illegal command.) Transaction can be aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.</td>
</tr>
</tbody>
</table>
1. Load CMD12 Stop Transmission command in registers and set the CMDSTOP bit.
   a) This causes the CPSM Abort signal to be generated when the command is sent to
      the DPSM.

2. Configure the CPSM to send a command immediately (clear WAITPEND bit).
   a) The card, when sending data, stops data transfer 2 cycles after the Stop
      Transmission command end bit.
      The card when no data is being sent, does not start sending any new data.
   b) The host, when sending data, sends one last data bit followed by an end bit after
      the Stop Transmission command end bit.
      The host when not sending data, does not start sending any new data.

3. When IDMAEN = 0, the FIFO need to be reset with FIFORST.
   a) When writing data to the card. On the CMDREND flag, firmware must stop writing
      data to the FIFO. Subsequently the FIFO must be reset with FIFORST, this flushes
      the FIFO.
   b) When reading data from the card. On the CMDREND flag, firmware must read the
      remaining data from the FIFO. Subsequently the FIFO must be reset with
      FIFORST.

4. When IDMAEN = 1, hardware takes care of the FIFO.
   a) When writing data to the card. On the CPSM Abort signal, hardware stops the
      IDMA and subsequently the FIFO is flushed.
   b) When reading data from the card. On the CPSM Abort signal, hardware instructs
      the IDMA to transfer the remaining data from the FIFO to RAM.

5. When the FIFO is empty/reset the DABORT flag is generated.

**Stream operation and CMD12**

To stop the stream transfer after the last byte to be transfered, the CMD12 end bit timing
must be sent aligned with the data stream end of last byte. The following write stream data
procedure applies:

1. Initialize the stream data in the DPSM, DTMODE = MCC stream data transfer.
2. Send the WRITE_DATA_STREAM command from the CPSM with CMDTRANS = 1.
3. Preload CMD12 in command registers, with the CMDSTOP bit set.
4. Configure the CPSM to send a command only after a wait pending (WAITPEND = 1)
   end of last data (according DATALENGTH).
5. Enabling the CPSM to send the STOP_TRANSMISSION command, the stream data
   end bit and command end bit are aligned.
   a) When DATALENGTH > 5 bytes, Command CMD12 is waited in the CPSM to be
      aligned with the data transfer end bit.
   b) When DATALENGTH < 5 bytes, Command CMD12 is started before and the
      DPSM remains in the Wait_S state to align the data transfer end with the CMD12
      end bit.
6. The write stream data can be aborted any time by clearing the WAITPEND bit. This
   causes the Preloaded CMD12 to be sent immediately and stop the write data stream.
To stop the read stream transfer after the last byte, the CMD12 end bit timing must occur after the last data stream byte. The following read stream data procedure applies:

1. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   a) The DPSM does not receive more data than indicated by DATALENGTH, even if the card is sending more data.
2. Send CMD12 by the CPSM.
   a) CMD12 stops the card sending data.

*Note:* The SDMMC does not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

**Block operation and CMD12**

To stop block transfer at the end of the data, the CMD12 end bit must be sent after the last block end bit.

When writing data to the card the CMD12 end bit must be sent after the write data block CRC token end bit. This requires the CMD12 sending to be tied to the data block transmission timing. To stop an Open-ended Multiple block write, the following procedure applies:

1. Before starting the data transfer, set DTMODE to "block data transfer ending with STOP_TRANSMISSION command".
2. Wait for all data to be sent by the DPSM and the CRC token to be received, (DATAEND flag).
   a) The DPSM does not send more data than indicated by DATALENGTH.
3. Send CMD12 by the CPSM.
   a) CMD12 sets the card to Idle mode.

When reading data from the card the CMD12 end bit must be sent earliest at the same time as the card read data block last data bit. This requires the CMD12 sending to be tied to the data block reception timing. The following stop Open-ended Multiple block read data block procedure applies:
1. Before starting the data transfer, set DTMODE to "block data transfer ending with STOP_TRANSMISSION command".

2. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   a) The DPSM does not receive more data than indicated by DATALENGTH, even if the card is sending more data.

3. Send CMD12 with CMDSTOP bit set by the CPSM.
   a) CMD12 stops the Card sending more data and set the card to Idle mode. Any ongoing block transfer is aborted by the Card.

Note: The SDMMC does not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

31.6.3 Sleep (CMD5)

The eMMC card may be switched between a Sleep state and a Standby state by CMD5. In the Sleep state the power consumption of the card is minimized and the Vcc power supply may be switched off.

The CMD5 (SLEEP) is used to initiate the state transition from Standby state to Sleep state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Sleep state is reached when the card stops pulling down the SDMMC_DO line.

To set the card into Sleep state the following procedure applies:
1. Enable interrupt on BUSYD0END.
2. Send CMD5 (SLEEP).
3. On BUSYD0END interrupt, card is in Sleep state
4. Vcc power supply can be switched off

The CMD5 (AWAKE) is used to initiate the state transition from Sleep state to Standby state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Standby state is reached when the card stops pulling down the SDMMC_DO line.

To set the card into Sleep state the following procedure applies:
1. Switch on Vcc power supply and wait unit minimum operating level is reached.
2. Enable interrupt on BUSYD0END.
3. Send CMD5 (AWAKE).
4. On BUSYD0END interrupt card is in Standby state.

The Vcc power supply can be switched off only after the Sleep state has been reached. The Vcc supply must be reinstalled before CMD5 (AWAKE) is sent.
31.6.4 Interrupt mode (Wait-IRQ)

The host and card enter and exit interrupt mode (Wait-IRQ) simultaneously. In interrupt mode there is no data transfer. The only message allowed is an interrupt service request response from the card or the host. For the interrupt mode to work correctly the SDMMC_CK frequency must be set in accordance with the achievable SDMMC_CMD data rate in Open Drain mode, which depend on the capacitive load and pull-up resistor. The CLKDIV must be set >1, and the SETCLKRX must select either the sdmmc_io_in_ck or SDMMC_CLKin source.

The host must ensure that the card is in Standby state before issuing the CMD40 (GO_IRQ_STATE). While waiting for an interrupt response the SDMMC_CK clock signal must be kept active.

A card in interrupt mode (IRQ state):
- is waiting for an internal card interrupt event. Once the event occurs, the card starts to send the interrupt service request response. The response is sent in open-drain mode.
- while waiting for the internal card interrupt event, the card also monitors the SDMMC_CMD line for a start bit. Upon detection of a start bit the card aborts the interrupt mode and switch to Standby state.

The host in interrupt mode (CPSM Wait state waiting for interrupt):
- is waiting for a card interrupt service request response (start bit).
- while waiting for a card interrupt service request response the host may abort the interrupt mode (by clearing the WAITINT register bit), which causes the host to send a interrupt service request response R5 with RCA = 0x0000 in open-drain mode.

When sending the interrupt service request response, the sender bit-wise monitors the SDMMC_CMD bit stream. The sender whose interrupt service request response bit does not correspond to the bit on the SDMMC_CMD line stops sending. In the case of multiple senders only one successfully sends its full interrupt service request response. If the host sends simultaneously, it loses sending after the transmission bit.

To handle the interrupt mode, the following procedure applies:
1. Set the SDMMC_CK frequency in accordance with the achievable SDMMC_CMD data rate in Open-drain mode, CLKDIV must be set >1, and SETCLKRX must select the sdmmc_io_in_ck.

2. Load CMD40 (GO_IRQ_STATE) in the command registers.

3. Enable wait for interrupt by setting WAITINT register bit.

4. Configure the CPSM to send a command immediately.
   a) This causes the CMD40 to be sent and the CPSM to be halted in the Wait state, waiting for an interrupt service request response.

5. To exit the wait for interrupt state (CPSM Wait state):
   a) Upon the detection of an interrupt service request response start bit the CPSM moves to the Receive state where the response is received. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.
   b) To abort the interrupt mode the host clears the WAITINT register bit, which causes the host to send an interrupt service request response by itself. This moves the CPSM to the Receive state. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.

Note: On a simultaneous send interrupt service request response start bit collision the host loses the bus access after the transmission bit.

31.6.5 Boot operation

In boot operation mode the host can read boot data from the card by either one of the 2 boot operation functions:
1. Normal boot. (keeping CMD line low)
2. Alternative boot (sending CMD0 with argument 0xFFFFFFFA)

The boot data can be read according the following configuration options, depending on card register settings:
- The partition from which boot data is read (EXT_CSD Byte[179])
- The boot data size (EXT_CSD Byte[226])
- The bus configuration during boot (EXT_CSD Byte[177])
- Receiving boot acknowledgment from the card. (EXT_CSD Byte[179])

If boot acknowledgment is enabled the card send pattern 010 on SDMMC_D0 within 50ms after boot mode has been requested by either CMD line going low or after CMD0 with argument 0xFFFFFFFA. A boot acknowledgment timeout (ACKTIMEOUT) and acknowledgment status (ACKFAIL) is provided.

Normal boot operation

If the SDMMC_CMD line is held low for at least 74 clock cycles after card power-up or reset, before the first command is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD line goes low, the card starts to send the first boot code data on the SDMMC_Dn line(s). The host must keep the SDMMC_CMD line low until after all boot data has been read. The host can terminate boot mode by pulling the SDMMC_CMD line high.
To perform the normal boot procedure the following steps needed:

1. Reset the card.
2. If a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKFAIL and ACKTIMEOUT interrupt.
3. Enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data bytes to be received in DATALENGTH.
4. Enable the DTIMEOUT, DATAEND, and CMDSENT interrupts for end of boot command confirmation.
5. Select the normal boot operation mode in BOOTMODE, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN. This causes:
   - the SDMMC_CMD to be driven low. (BOOTMODE = normal boot).
   - the ACK timeout to start.
   - DPSM to be enabled.
6. The incorrect reception of the boot acknowledgment can be detected with ACKFAIL flag or ACKTIMEOUT flag when enabled.
   - when an incorrect boot acknowledgment is received the ACKFAIL flag occurs.
   - when the boot acknowledgment is not received in time the ACKTIMEOUT flag occurs.
7. When all boot data has been received the DATAEND flag occurs.
   - when data CRC fails the DCRCFAIL flag is also generated.
   - when the data timeout occurs the DTIMEOUT flag is also generated.
8. When last data has been received, read data from the FIFO until FIFO is empty after which end of data DATAEND flag is generated.
   - SDMMC has completely received all data and the DPSM is disabled.
9. The boot procedure is terminated by firmware clearing BOOTEN, which causes the SDMMC_CMD line to go high. The CMDSENT flag is generated 56 cycles later to indicate that a new command can be sent.
   a) If the boot procedure is aborted by firmware before all data has been received the CPSM Abort signal stops data reception and disables the DPSM which triggers an DABORT flag when enabled.
10. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command.
Alternative boot operation

After card power-up or reset, if the host send CMD0 with the argument 0xFFFFFFFA after 74 clock cycles before CMD0 is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD0 with argument 0xFFFFFFFA has been sent, the card starts to send the first boot code data on the SDMMC_Dn line(s). The master terminates boot operation by sending CMD0 (Reset).

Figure 208. Alternative boot mode operation

To perform the alternative boot procedure the following steps needed:
1. Move the SDMMC to power-off state, and reset the card
2. Move the SDMMC to power-on state. This guarantees the 74 SCDMMC_CK cycles to be clocked before any command.
3. if a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKTIMEOUT flag.
4. enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data to be received in DATALENGTH. Enable the DTIMEOUT and DATAEND flags.
5. Select the alternative boot operation mode in BOOTMODE, load the CMD0 with the 0xFFFFFFFA argument in the command registers. Enable CMDSENT flag for end of
boot command confirmation, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN. This causes:
– the loaded command and argument to be sent out. (BOOTMODE = alternative boot).
– the ACK timeout to start.
– DPSM to be enabled.
6. When the command has been sent the CMDSENT flag is generated, at which time the BOOTEN bit must be cleared.
7. the reception of the boot acknowledgment can be detected with ACKFAIL flag when enabled.
   – when the boot acknowledgment is not received in time the ACKTIMEOUT flag occurs.
8. when all boot data has been received the DATAEND flag occurs.
   – when data CRC fails the DCRCFAIL flag is also generated.
   – when the data timeout occurs the DTIMEOUT flag is also generated.
9. When last data has been received, read data from the FIFO until FIFO is empty after which end of data DATAEND flag is generated.
   – SDMMC has completely received all data and the DPSM is disabled.
10. The BOOTEN bit must be cleared, before terminating the boot procedure by sending CMD0 (Reset) with BOOTMODE = alternative boot. This causes the CMDSENT flag to occur 56 cycles after the Command.
   – if the boot procedure is aborted by firmware before all data has been received the CPSM Abort signal stops the data transfer and disable the DPSM which triggers an DABORT flag when enabled.
11. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command. When the RESET command has been sent successfully, the BOOTMODE control bit has to be cleared to terminate the boot operation.

31.6.6 Response R1b handling
When sending commands which have a R1b response the busy signaling is reflected in the BUSYD0 register bit and the release of busy with the BUSYD0END flag. The SDMMC_D0 line is sampled at the end of the R1b response and signaled in the BUSYD0 register bit. The BUSYD0 register bit is reset to not busy when the SDMMC_D0 line release busy, at the same time the BUSYD0END flag is generated.

Figure 209. Command response R1b busy signaling
The expected maximum busy time must be set in the DATATIME register before sending the command. When enabled, the DTIMEOUT flag is set when after the R1b response busy stays active longer than the programmed time.

To detect the SDMMC_D0 busy signaling when sending a Command with R1b response the following procedure applies:

- Enable CMDREND flag
- Send Command through CPSM.
- On the CMDREND flag check the BUSYD0 register bit.
  - If BUSYD0 signals not busy, signal busy release to the Firmware
  - If BUSYD0 signals busy, wait for BUSYD0END flag
- On BUSYD0END flag signal busy released to the firmware.
- On DTIMEOUT flag busy is active longer than programmed time.

### 31.6.7 Reset and card cycle power

**Reset**

Following reset the SDMMC is in the reset state. In this state the SDMMC is disabled and no command or data can be transferred. The SDMMC_D[7:0] and SDMMC_CMD are in HiZ and the SDMMC_CK is driven low.

Before moving to the power-on state the SDMMC must be configured.

In the power-on state the SDMMC_CK clock is running. First 74 SDMMC_CK cycles are clocked after which the SDMMC is enabled and command and data can be transferred.

The SDMMC states are controlled by Firmware with the PWRCTRL register bits according [Figure 210](#).

![Figure 210. SDMMC state control](MSV40947V1)

**Card cycle power**

To perform a card cycle power the following procedure applies:
1. Reset the SDMMC with the RCC.SDMMCxRST register bit. This resets the SDMMC to the reset state and the CPSM and DPSM to the Idle state.
2. Disable the Vcc power to the card.
3. Set the SDMMC in power-cycle state. This makes that the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low, to prevent the card from being supplied through the signal lines.
4. After minimum 1 ms enable the Vcc power to the card.
5. After the power ramp period set the SDMMC to the power-off state for minimum 1 ms. The SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are set to drive “1”.
6. After the 1 ms delay set the SDMMC to power-on state in which the SDMMC_CK clock is enabled.
7. After 74 SDMMC_CK cycles the first command can be sent to the card.

![Figure 211. Card cycle power / power up diagram](MSv39275V1)

### 31.7 Hardware flow control

The hardware flow control during data transfer functionality is used to avoid FIFO underrun (TX mode) and overrun (RX mode) errors.

The behavior is to stop SDMMC_CK during data transfer and freeze the SDMMC state machines. The data transfer is stalled when the FIFO is unable to transmit or receive data. The data transfer remains stalled until the transmit FIFO is half full or all data according DATALENGHT has been stored, or until the receive FIFO is half empty. Only state machines clocked by SDMMC_CK are frozen, the AHB interfaces are still alive. The FIFO can thus be filled or emptied even if flow control is activated.

On an IDMA linked list transfer error, the hardware flow control is disabled. As a consequence, depending on when the IDMA linked list transfer error occurs, an underrun or overrun error may also occur (see Section : IDMA transfer error management).
To enable hardware flow control during data transfer, the HWFC_EN register bit must be set to 1. After reset hardware flow control is disabled.

Hardware flow control must only be used when the SDMMC_Dn data is cycle-aligned with the SDMMC_CK. Whenever the sdmmc_fb_ck from the DLYB delay block is used, i.e in the case of SDR104 mode with a tOP and DtOP delay > 1 cycle, hardware flow control can not be used.

31.8 Ultra-high-speed phase I (UHS-I) voltage switch

UHS-I mode (SDR12, SDR25, SDR50, SDR104, and DDR50) requires the support for 1.8V signaling. After power up the card starts in 3.3V mode. CMD11 invokes the voltage switch sequence to the 1.8V mode. When the voltage sequence is completed successfully the card enters UHS-I mode with default SDR12 and card input and output timings are changed.

Figure 212. CMD11 signal voltage switch sequence

To perform the signal voltage switch sequence the following steps are needed:

1. Before starting the Voltage Switch procedure, the SDMMC_CK frequency must be set in the range 100 kHz - 400 kHz.

2. The host starts the Voltage Switch procedure by setting the VSWITCHEN bit before sending the CMD11.

3. The card returns an R1 response.
   - if the response CRC is pass, the Voltage Switch procedure continues the host does no longer drive the CMD and SDMMC_D[3:0] signals until completion of the voltage switch sequence. Some cycles after the response the SDMMC_CK is stopped and the CKSTOP flag is set.
   - if the response CRC is fail (CCRCFAIL flag) or no response is received before the timeout (CTIMEOUT flag), the Voltage Switch procedure is stopped.

4. The card drives CMD and SDMMC_D[3:0] to low at the next clock after the R1 response.

5. The host, after having received the R1 response, may monitor the SDMMC_D0 line using the BUSYD0 register bit. The SDMMC_D0 line is sampled two SDMMC_CK clock cycles after the Response. The Firmware may read the BUSYD0 register bit following the CKSTOP flag.
   - When the BUSYD0 is detected low the host firmware switches the Voltage regulator to 1.8V, after which it instructs the SDMMC to start the timing critical
section of the Voltage Switch sequence by setting register bit VSWITCH. The hardware continues to stop the SDMMC_CK by holding it low for at least 5 ms.

- When the BUSYD0 is detected high the host aborts the Voltage Switch sequence and cycle power the card.

6. The card after detecting SDMMC_CK low begins switching signaling voltage to 1.8 V.
7. The host SDMMC hardware after at least 5 ms restarts the SDMMC_CK.
8. The card within 1 ms from detecting SDMMC_CK transition drives CMD and DAT[3:0] high for at least 1 SDMMC_CK cycle and then stop driving CMD and DAT[3:0].
9. The host SDMMC hardware, 1 ms after the SDMMC_CK has been restarted, the SDMMC_D0 is sampled into BUSYD0 and the VSWEND flag is set.
10. The host, on the VSWEND flag, checks SDMMC_D0 line using the BUSYD0 register bit, to confirm completion of voltage switch sequence:
    - When BUSYD0 is detected high, Voltage Switch has been completed successfully.
    - When BUSYD0 is detected low, Voltage Switch has failed, the host cycles the card power.

The minimum 5 ms time to stop the SDMMC_CK is derived from the internal un-gated SDMMC_CK clock, which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The >5 ms time is counted by $2^{12}$ cycles (10.24 ms @ 400 kHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time for the SDMMC_CK clock to be stopped is longer.

The maximum 1 ms time for the card to drive the SDMMC_Dn and SDMMC_CMD lines high is derived from the internal ungated SDMMC_CK which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The SDMMC checks the lines after >1 ms time which is counted by $2^5$ cycles (1.28 ms @ 25 MHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time to check the lines is longer.

The signal voltage level is supported through an external voltage translation transceiver like STMicroelectronics ST6G3244ME.
To interface with an external driver (a voltage switch transceiver), next to the standard signals the SDMMC uses the following signals:

**SDMMC_CKIN** feedback input clock

**SDMMC_CDIR** I/O direction control for the CMD signal.

**SDMMC_D0DIR** I/O direction control for the SDMMC_D0 signal.

**SDMMC_D123DIR** I/O direction control for the SDMMC_D1, SDMMC_D2 and SDMMC_D3 signals.

The voltage transceiver signals **EN** and **SEL** are to be handled through general-purpose I/O.

The polarity of the SDMMC_CDIR, SDMMC_D0DIR and SDMMC_D123DIR signals can be selected through SDMMC_POWER.DIRPOL control bit.

31.10 SDMMC registers

The device communicates to the system via 32-bit control registers accessible via AHB slave interface.

The peripheral registers have to be accessed by words (32-bit). Byte (8-bit) and halfword (16-bit) accesses trigger an AHB bus error.

31.10.1 SDMMC power control register (SDMMC_POWER)

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 DIRPOL: Data and command direction signals polarity selection

This bit can only be written when the SDMMC is in the power-off state (PWRCTRL = 00).

0: Voltage transceiver IOs driven as output when direction signal is low.
1: Voltage transceiver IOs driven as output when direction signal is high.

Bit 3 VSWITCHEN: Voltage switch procedure enable

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

This bit is used to stop the SDMMC_CK after the voltage switch command response:
0: SDMMC_CK clock kept unchanged after successfully received command response.
1: SDMMC_CK clock stopped after successfully received command response.

Bit 2 VSWITCH: Voltage switch sequence start

This bit is used to start the timing critical section of the voltage switch sequence:
0: Voltage switch sequence not started and not active.
1: Voltage switch sequence started or active.

Bits 1:0 PWRCTRL[1:0]: SDMMC state control bits

These bits can only be written when the SDMMC is not in the power-on state (PWRCTRL ≠ 11).

These bits are used to define the functional state of the SDMMC signals:
00: After reset, Reset: the SDMMC is disabled and the clock to the Card is stopped, SDMMC_D[7:0], and SDMMC_CMD are HiZ and SDMMC_CK is driven low. When written 00, power-off: the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven high.
01: Reserved. (When written 01, PWRCTRL value does not change)
10: Power-cycle, the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low.
11: Power-on: the card is clocked, The first 74 SDMMC_CK cycles the SDMMC is still disabled. After the 74 cycles the SDMMC is enabled and the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are controlled according the SDMMC operation. Any further write is ignored, PWRCTRL value keeps 11.
31.10.2 SDMMC clock control register (SDMMC_CLKCR)

Address offset: 0x004  
Reset value: 0x0000 0000  

The SDMMC_CLKCR register controls the SDMMC_CK output clock, the sdmmc_rx_ck receive clock, and the bus width.

| Address offset: 0x004 | Reset value: 0x0000 0000 |

The SDMMC_CLKCR register controls the SDMMC_CK output clock, the sdmmc_rx_ck receive clock, and the bus width.

| Bits 31:22 | Reserved, must be kept at reset value. |
| Bits 21:20 | SELCLKRX[1:0]: Receive clock selection |
| | These bits can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0) |
| | 00: sdmmc_io_in_ck selected as receive clock |
| | 01: SDMMC_CKIN feedback clock selected as receive clock |
| | 10: sdmmc_fb_ck tuned feedback clock selected as receive clock |
| | 11: Reserved (select sdmmc_io_in_ck) |
| Bit 19 | BUSSPEED: Bus speed for selection of SDMMC operating modes |
| | This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0) |
| | 0: DS, HS, SDR12, SDR25, Legacy compatible, High speed SDR, High speed DDR bus speed mode selected |
| | 1: SDR50, DDR50, SDR104, HS200 bus speed mode selected |
| Bit 18 | DDR: Data rate signaling selection |
| | This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0) |
| | DDR rate must only be selected with 4-bit or 8-bit wide bus mode. (WIDBUS > 00). DDR = 1 has no effect when WIDBUS = 00 (1-bit wide bus). |
| | DDR rate must only be selected with clock division >1. (CLKDIV > 0) |
| | 0: SDR Single data rate signaling |
| | 1: DDR double data rate signaling |
| Bit 17 | HWFC_EN: Hardware flow control enable |
| | This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0) |
| | 0: Hardware flow control is disabled |
| | 1: Hardware flow control is enabled |
| | When Hardware flow control is enabled, the meaning of the TXFIFOE and RXFIFOF flags change, see SDMMC status register definition in Section 31.10.11. |
Bit 16 **NEGEDGE**: SDMMC_CK dephasing selection bit for data and command

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

When clock division = 1 (CLKDIV = 0), this bit has no effect. Data and Command change on SDMMC_CK falling edge.

0: When clock division >1 (CLKDIV > 0) and DDR = 0:
   - Command and data changed on the sdmmc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
   - SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

1: When clock division >1 (CLKDIV > 0) and DDR = 1:
   - Command changed on the sdmmc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
   - Data changed on the sdmmc_ker_ck falling edge succeeding a SDMMC_CK edge.
   - SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

Bits 15:14 **WIDBUS[1:0]**: Wide bus mode enable bit

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

00: Default 1-bit wide bus mode: SDMMC_D0 used (Does not support DDR)
01: 4-bit wide bus mode: SDMMC_D[3:0] used
10: 8-bit wide bus mode: SDMMC_D[7:0] used

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PWRSAV**: Power saving configuration bit

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

For power saving, the SDMMC_CK clock output can be disabled when the bus is idle by setting PWRSAV:

0: SDMMC_CK clock is always enabled
1: SDMMC_CK is only enabled when the bus is active

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:0 **CLKDIV[9:0]**: Clock divide factor

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

This field defines the divide factor between the input clock (sdmmc_ker_ck) and the output clock (SDMMC_CK): SDMMC_CK frequency = sdmmc_ker_ck / [2 * CLKDIV].

0x000: SDMMC_CK frequency = sdmmc_ker_ck / 1 (Does not support DDR)
0x001: SDMMC_CK frequency = sdmmc_ker_ck / 2
0x002: SDMMC_CK frequency = sdmmc_ker_ck / 4
0x0XX: etc..
0x080: SDMMC_CK frequency = sdmmc_ker_ck / 256
0xXXX: etc..
0x3FF: SDMMC_CK frequency = sdmmc_ker_ck / 2046
Note:  1 While the SD/SDIO card or eMMC is in identification mode, the SDMMC_CK frequency must be less than 400 kHz.
2 The clock frequency can be changed to the maximum card bus frequency when relative card addresses are assigned to all cards.
3 At least seven sdmcc_hclk clock periods are needed between two write accesses to this register. SDMMC_CK can also be stopped during the Read Wait interval for SD I/O cards: in this case the SDMMC_CLKCR register does not control SDMMC_CK.

31.10.3 SDMMC argument register (SDMMC_ARGR)

Address offset: 0x008
Reset value: 0x0000 0000

The SDMMC_ARGR register contains a 32-bit command argument, which is sent to a card as part of a command message.

<table>

Bits 31:0 CMDARG[31:0]: Command argument
These bits can only be written by firmware when CPSM is disabled (CPSMEN = 0). Command argument sent to a card as part of a command message. If a command contains an argument, it must be loaded into this register before writing a command to the command register.

31.10.4 SDMMC command register (SDMMC_CMDR)

Address offset: 0x00C
Reset value: 0x0000 0000

The SDMMC_CMDR register contains the command index and command type bits. The command index is sent to a card as part of a command message. The command type bits control the command path state machine (CPSM).

ST
Bits 31:17  Reserved, must be kept at reset value.

Bit 16  **CMD SUSPEND**: The CPSM treats the command as a Suspend or Resume command and signals interrupt period start/end
   This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
   CMD SUSPEND = 1 and CMDTRANS = 0 Suspend command, start interrupt period when response bit BS=0.
   CMD SUSPEND = 1 and CMDTRANS = 1 Resume command with data, end interrupt period when response bit DF=1.

Bit 15  **BOOTEN**: Enable boot mode procedure
   0: Boot mode procedure disabled
   1: Boot mode procedure enabled

Bit 14  **BOOT MODE**: Select the boot mode procedure to be used
   This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0)
   0: Normal boot mode procedure selected
   1: Alternative boot mode procedure selected.

Bit 13  **DTHOLD**: Hold new data block transmission and reception in the DPSM
   If this bit is set, the DPSM does not move from the Wait_S state to the Send state or from the Wait_R state to the Receive state.

Bit 12  **CPSM EN**: Command path state machine (CPSM) enable bit
   This bit is written 1 by firmware, and cleared by hardware when the CPSM enters the Idle state.
   If this bit is set, the CPSM is enabled.
   When DTEN = 1, no command is transferred nor boot procedure is started. CPSMEN is cleared to 0.
   During Read Wait with SDMMC_CK stopped no command is sent and CPSMEN is kept 0.

Bit 11  **WAIT PEND**: CPSM waits for end of data transfer (CmdPend internal signal) from DPSM
   This bit when set, the CPSM waits for the end of data transfer trigger before it starts sending a command.
   WAITPEND is only taken into account when DTMODE = eMMC stream data transfer, WIDBUS = 1-bit wide bus mode, DPSMACT = 1 and DTDIR = from host to card.

Bit 10  **WAIT INT**: CPSM waits for interrupt request
   If this bit is set, the CPSM disables command timeout and waits for an card interrupt request (Response).
   If this bit is cleared in the CPSM Wait state, it causes the abort of the interrupt mode.

Bits 9:8  **WAITRESP[1:0]**: Wait for response bits
   This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
   They are used to configure whether the CPSM is to wait for a response, and if yes, which kind of response.
   00: No response, expect CMDSENT flag
   01: Short response, expect CMDREND or CCRCFAIL flag
   10: Short response, expect CMDREND flag (No CRC)
   11: Long response, expect CMDREND or CCRCFAIL flag
31.10.5 SDMMC command response register (SDMMC_RESPCMDR)

Address offset: 0x010
Reset value: 0x0000 0000

The SDMMC_RESPCMDR register contains the command index field of the last command response received. If the command response transmission does not contain the command index field (long or OCR response), the RESPCMD field is unknown, although it must contain 111111b (the value of the reserved field from the response).

</tbody>
</table>

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **RESPCMD[5:0]**: Response command index
Read-only bit field. Contains the command index of the last command response received.

Note:

1. At least seven sdmmc_hclk clock periods are needed between two write accesses to this register.
2. MultiMediaCard can send two kinds of response: short responses, 48 bits, or long responses, 136 bits. SD card and SD I/O card can send only short responses, the argument can vary according to the type of response: the software distinguishes the type of response according to the send command.

Bit 7 **CMDSTOP**: The CPSM treats the command as a Stop Transmission command and signals abort to the DPSM
This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
If this bit is set, the CPSM issues the abort signal to the DPSM when the command is sent.

Bit 6 **CMDTRANS**: The CPSM treats the command as a data transfer command, stops the interrupt period, and signals DataEnable to the DPSM
This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
If this bit is set, the CPSM issues an end of interrupt period and issues DataEnable signal to the DPSM when the command is sent.
31.10.6 **SDMMC response x register (SDMMC_RESPxR)**

Address offset: 0x010 + 0x004 * x, (x = 1 to 4)
Reset value: 0x0000 0000

The SDMMC_RESP1/2/3/4R registers contain the status of a card, which is part of the received response.

<table>

</tr>
</tbody>
</table>

Bits 31:0 **CARDSTATUS[31:0]**: Card status according table below

See Table 291.

The card status size is 32 or 128 bits, depending on the response type.

**Table 291. Response type and SDMMC_RESPxR registers**

<table>
<thead>
<tr>
<th>Register</th>
<th>Short response</th>
<th>Long response</th>

<td>Card status [63:32]</td>
</tr>
<tr>
<td>SDMMC_RESP4R</td>
<td>all 0</td>
<td>Card status [31:0][2]</td>
</tr>
</tbody>
</table>

1. The most significant bit of the card status is received first.
2. The SDMMC_RESP4R register LSB is always 0.

31.10.7 **SDMMC data timer register (SDMMC_DTIMER)**

Address offset: 0x024
Reset value: 0x0000 0000

The SDMMC_DTIMER register contains the data timeout period, in card bus clock periods.

A counter loads the value from the SDMMC_DTIMER register, and starts decrementing when the data path state machine (DPSM) enters the Wait_R or Busy state. If the timer reaches 0 while the DPSM is in either of these states, the timeout status flag is set.

</tbody>
</table>

1230/3637  RM0456 Rev 5
Bits 31:0 **DATETIME[31:0]**: Data and R1b busy timeout period

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

Data and R1b busy timeout period expressed in card bus clock periods.

**Note:** A data transfer must be written to the data timer register and the data length register before being written to the data control register.

### 31.10.8 SDMMC data length register (SDMMC_DLENR)

Address offset: 0x028

Reset value: 0x0000 0000

The SDMMC_DLENR register contains the number of data bytes to be transferred. The value is loaded into the data counter when data transfer starts.

<table>
<thead>
<tr>

</tbody>
</table>

**DATALENGTH[24:16]**

bits 24:0 **DATALENGTH[24:0]**: Data length value

This register can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Number of data bytes to be transferred.

When DDR = 1 DATALENGTH is truncated to a multiple of 2. (The last odd byte is not transferred)

When DATALENGTH = 0 no data are transferred, when requested by a CPSMEN and CMDTRANS = 1 also no command is transferred. DTEN and CPSMEN are cleared to 0.

**Note:** For a block data transfer, the value in the data length register must be a multiple of the block size (see SDMMC_DCTRL). A data transfer must be written to the data timer register and the data length register before being written to the data control register.

For an SDMMC multibyte transfer the value in the data length register must be between 1 and 512.
### 31.10.9 SDMMC data control register (SDMMC_DCTRL)

Address offset: 0x02C  
Reset value: 0x0000 0000  
The SDMMC_DCTRL register control the data path state machine (DPSM).

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td>0: Read Wait control using SDMMC_D2</td>
</tr>
<tr>
<td></td>
<td>1: Read Wait control stopping SDMMC_CK</td>
</tr>
<tr>
<td>Bit 9</td>
<td>RWSTOP: Read Wait stop</td>
</tr>
<tr>
<td></td>
<td>This bit is written by firmware and auto cleared by hardware when the DPSM moves from the R_W state to the Wait_R or Idle state.</td>
</tr>
<tr>
<td></td>
<td>0: No Read Wait stop.</td>
</tr>
<tr>
<td></td>
<td>1: Enable for Read Wait stop when DPSM is in the R_W state.</td>
</tr>
<tr>
<td>Bit 8</td>
<td>RWSTART: Read Wait start</td>
</tr>
<tr>
<td></td>
<td>If this bit is set, Read Wait operation starts.</td>
</tr>
</tbody>
</table>
Bits 7:4  **DBLOCKSIZE[3:0]**: Data block size

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Define the data block length when the block data transfer mode is selected:
- 0000: Block length = $2^0 = 1$ byte
- 0001: Block length = $2^1 = 2$ bytes
- 0010: Block length = $2^2 = 4$ bytes
- 0011: Block length = $2^3 = 8$ bytes
- 0100: Block length = $2^4 = 16$ bytes
- 0101: Block length = $2^5 = 32$ bytes
- 0110: Block length = $2^6 = 64$ bytes
- 0111: Block length = $2^7 = 128$ bytes
- 1000: Block length = $2^8 = 256$ bytes
- 1001: Block length = $2^9 = 512$ bytes
- 1010: Block length = $2^{10} = 1024$ bytes
- 1011: Block length = $2^{11} = 2048$ bytes
- 1100: Block length = $2^{12} = 4096$ bytes
- 1101: Block length = $2^{13} = 8192$ bytes
- 1110: Block length = $2^{14} = 16384$ bytes
- 1111: Reserved

When DATALENGTH is not a multiple of DBLOCKSIZE, the transferred data is truncated at a multiple of DBLOCKSIZE. (None of the remaining data are transferred.)

When DDR = 1, DBLOCKSIZE = 0000 must not be used. (No data are transferred)

Bits 3:2  **DTMODE[1:0]**: Data transfer mode selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
- 00: Block data transfer ending on block count.
- 01: SDIO multibyte data transfer.
- 10: eMMC Stream data transfer. (WIDBUS must select 1-bit wide bus mode)
- 11: Block data transfer ending with STOP_TRANSMISSION command (not to be used with DTEN initiated data transfers).

Bit 1  **DTDIR**: Data transfer direction selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
- 0: From host to card.
- 1: From card to host.

Bit 0  **DTEN**: Data transfer enable bit

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0). This bit is cleared by Hardware when data transfer completes.

This bit must only be used to transfer data when no associated data transfer command is used, i.e. must not be used with SD or eMMC cards.
- 0: Do not start data transfer without CPSM data transfer command.
- 1: Start data transfer without CPSM data transfer command.

### 31.10.10 SDMMC data counter register (SDMMC_DCNTR)

Address offset: 0x030

Reset value: 0x0000 0000

The SDMMC_DCNTR register loads the value from the data length register (see SDMMC_DLENR) when the DPSM moves from the Idle state to the Wait_R or Wait_S state. As data is transferred, the counter decrements the value until it reaches 0. The DPSM then
moves to the Idle state and when there has been no error, and no transmit data transfer hold, the data status end flag (DATAEND) is set.

Bits 31:25  Reserved, must be kept at reset value.

Bits 24:0 **DATACOUNT[24:0]**: Data count value

When read, the number of remaining data bytes to be transferred is returned. Write has no effect.

**Note:** *This register must be read only after the data transfer is complete, or hold. When reading after an error event the read data count value may be different from the real number of data bytes transferred.*

### 31.10.11 SDMMC status register (SDMMC_STAR)

Address offset: 0x034

Reset value: 0x0000 0000

The SDMMC_STAR register is a read-only register. It contains two types of flag:

- **Static flags (bits [28, 21, 11:0]):** these bits remain asserted until they are cleared by writing to the SDMMC interrupt Clear register (see SDMMC_ICR)
- **Dynamic flags (bits [20:12]):** these bits change state depending on the state of the underlying logic (for example, FIFO full and empty flags are asserted and deasserted as data while written to the FIFO)

| 21   | **BUSYD0END**: end of SDMMC_D0 Busy following a CMD response detected | This indicates only end of busy following a CMD response. This bit does not signal busy due to data transfer. Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.  
0: card SDMMC_D0 signal does NOT signal change from busy to not busy.  
1: card SDMMC_D0 signal changed from busy to NOT busy. |
| 20   | **BUSYD0**: Inverted value of SDMMC_D0 line (Busy), sampled at the end of a CMD response and a second time 2 SDMMC_CK cycles after the CMD response | This bit is reset to not busy when the SDMMCD0 line changes from busy to not busy. This bit does not signal busy due to data transfer. This is a hardware status flag only, it does not generate an interrupt.  
0: card signals not busy on SDMMC_D0.  
1: card signals busy on SDMMC_D0. |
| 19   | **RXFIFOE**: Receive FIFO empty                           | This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes full. |
| 18   | **TXFIFOE**: Transmit FIFO empty                          | This bit is cleared when one FIFO location becomes full. |
| 17   | **RXFIFOF**: Receive FIFO full                            | This bit is cleared when one FIFO location becomes empty. |
| 16   | **TXFIFOF**: Transmit FIFO full                           | This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes empty. |
| 15   | **RXFIFOHF**: Receive FIFO half full                      | There are at least half the number of words in the FIFO. This bit is cleared when the FIFO becomes half+1 empty. |
| 14   | **TXFIFOHE**: Transmit FIFO half empty                    | At least half the number of words can be written into the FIFO. This bit is cleared when the FIFO becomes half+1 full. |
| 13   | **CPSMACT**: Command path state machine active, i.e. not in Idle state | This is a hardware status flag only, does not generate an interrupt. |
| 12   | **DPSMACT**: Data path state machine active, i.e. not in Idle state | This is a hardware status flag only, does not generate an interrupt. |
| 11   | **DABORT**: Data transfer aborted by CMD12               | Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR. |
Bit 10 **DBCKEND**: Data block sent/received
DBCKEND is set when:
- CRC check passed and DPSM moves to the R_W state
  or
- IDMAEN = 0 and transmit data transfer hold and DATACOUNT >0 and DPSM moves to Wait_S.
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 9 **DHOlD**: Data transfer Hold
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 8 **DATAEND**: Data transfer ended correctly
DATAEND is set if data counter DATACOUNT is zero and no errors occur, and no transmit data transfer hold.
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 7 **CMDSENT**: Command sent (no response required)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 6 **CMDREND**: Command response received (CRC check passed, or no CRC)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 5 **RXOVERR**: Received FIFO overrun error (masked by hardware when IDMA is enabled)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 4 **TXUNDERR**: Transmit FIFO underrun error (masked by hardware when IDMA is enabled)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 3 **DTIMEOUT**: Data timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 2 **CTIMEOUT**: Command response timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
The Command Timeout period has a fixed value of 64 SDMMC_CK clock periods.

Bit 1 **DCRCFAIL**: Data block sent/received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 0 **CCRCFAIL**: Command response received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

*Note*: FIFO interrupt flags must be masked in SDMMC_MASKR when using IDMA mode.
### 31.10.12 SDMMC interrupt clear register (SDMMC_ICR)

Address offset: 0x038  
Reset value: 0x0000 0000

The SDMMC_ICR register is a write-only register. Writing a bit with 1 clears the corresponding bit in the SDMMC_STAR status register.

### 31.10.13 SDMMC mask register (SDMMC_MASKR)

Address offset: 0x03C
Reset value: 0x0000 0000

The interrupt mask register determines which status flags generate an interrupt request by setting the corresponding bit to 1.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **IDMABTCIE**: IDMA buffer transfer complete interrupt enable
Set and cleared by software to enable/disable the interrupt generated when the IDMA has transferred all data belonging to a memory buffer.
0: IDMA buffer transfer complete interrupt disabled
1: IDMA buffer transfer complete interrupt enabled

Bit 27 Reserved, must be kept at reset value.

Bit 26 **CKSTOPIE**: Voltage Switch clock stopped interrupt enable
Set and cleared by software to enable/disable interrupt caused by Voltage Switch clock stopped.
0: Voltage Switch clock stopped interrupt disabled
1: Voltage Switch clock stopped interrupt enabled

Bit 25 **VSWENDIE**: Voltage switch critical timing section completion interrupt enable
Set and cleared by software to enable/disable the interrupt generated when voltage switch critical timing section completion.
0: Voltage switch critical timing section completion interrupt disabled
1: Voltage switch critical timing section completion interrupt enabled
Bit 24 **ACKTIMEOUTIE**: Acknowledgment timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment timeout.
0: Acknowledgment timeout interrupt disabled
1: Acknowledgment timeout interrupt enabled

Bit 23 **ACKFALLIE**: Acknowledgment Fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment Fail.
0: Acknowledgment Fail interrupt disabled
1: Acknowledgment Fail interrupt enabled

Bit 22 **SDIOITIE**: SDIO mode interrupt received interrupt enable
Set and cleared by software to enable/disable the interrupt generated when receiving the SDIO mode interrupt.
0: SDIO Mode interrupt received interrupt disabled
1: SDIO Mode interrupt received interrupt enabled

Bit 21 **BUSYD0ENDIE**: BUSYD0END interrupt enable
Set and cleared by software to enable/disable the interrupt generated when SDMMC_D0 signal changes from busy to NOT busy following a CMD response.
0: BUSYD0END interrupt disabled
1: BUSYD0END interrupt enabled

Bits 20:19 Reserved, must be kept at reset value.

Bit 18 **TXFIFOEIE**: Tx FIFO empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO empty.
0: Tx FIFO empty interrupt disabled
1: Tx FIFO empty interrupt enabled

Bit 17 **RXFIFOFIE**: Rx FIFO full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO full.
0: Rx FIFO full interrupt disabled
1: Rx FIFO full interrupt enabled

Bit 16 Reserved, must be kept at reset value.

Bit 15 **RXFIFOHFIE**: Rx FIFO half full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO half full.
0: Rx FIFO half full interrupt disabled
1: Rx FIFO half full interrupt enabled

Bit 14 **TXFIFOHEIE**: Tx FIFO half empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO half empty.
0: Tx FIFO half empty interrupt disabled
1: Tx FIFO half empty interrupt enabled

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **DABORTIE**: Data transfer aborted interrupt enable
Set and cleared by software to enable/disable interrupt caused by a data transfer being aborted.
0: Data transfer abort interrupt disabled
1: Data transfer abort interrupt enabled

Bit 10 **DBCKENDIE**: Data block end interrupt enable
Set and cleared by software to enable/disable interrupt caused by data block end.
0: Data block end interrupt disabled
1: Data block end interrupt enabled

### 31.10.14 SDMMC acknowledgment timer register (SDMMC_ACKTIMER)

Address offset: 0x040  
Reset value: 0x0000 0000

The SDMMC_ACKTIMER register contains the acknowledgment timeout period, in SDMMC_CK bus clock periods.

A counter loads the value from the SDMMC_ACKTIMER register, and starts decrementing when the data path state machine (DPSM) enters the Wait_Ack state. If the timer reaches 0 while the DPSM is in this states, the acknowledgment timeout status flag is set.

#### 31.10.15 SDMMC data FIFO registers x (SDMMC_FIFORx)

Address offset: 0x080 + 0x004 * x, (x =0 to 15)  
Reset value: 0x0000 0000

The receive and transmit FIFOs can be only read or written as word (32-bit) wide registers. The FIFOs contain 16 entries on sequential addresses. This enables the CPU to use its load and store multiple operands to read from/write to the FIFO. The FIFO register interface takes care of correct data alignment inside the FIFO, the FIFO register address used by the CPU does matter.

When accessing SDMMC_FIFOR with half word or byte access an AHB bus fault is generated.

---

Bits 31:2 Reserved, must be kept at reset value.

**Bit 1 IDMBMODE**: Buffer mode selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Single buffer mode.

1: Linked list mode.

**Bit 0 IDMAEN**: DMA enable

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: DMA disabled

1: DMA enabled

31.10.17 **SDMMC DMA buffer size register (SDMMC_IDMABSIZER)**

Address offset: 0x054

Reset value: 0x0000 0000

The SDMMC_IDMABSIZER register contains the buffer size when in linked list configuration.

Bits 31:2 Reserved, must be kept at reset value.

**IDMABNDT**: Buffer mode selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Single buffer mode.

1: Linked list mode.

**IDMAEN**: DMA enable

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: DMA disabled

1: DMA enabled
Bits 31:17  Reserved, must be kept at reset value.

Bits 16:5  IDMABNDT[11:0]: Number of bytes per buffer
This 12-bit value must be multiplied by 8 to get the size of the buffer in 32-bit words and by 32 to get the size of the buffer in bytes.
Example: IDMABNDT = 0x001: buffer size = 8 words = 32 bytes.
Example: IDMABNDT = 0x800: buffer size = 16384 words = 64 Kbyte.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 4:0  Reserved, must be kept at reset value.

31.10.18  SDMMC IDMA buffer base address register (SDMMC_IDMABASER)
Address offset: 0x058
Reset value: 0x0000 0000
The SDMMC_IDMABASER register contains the memory buffer base address in single buffer configuration and linked list configuration.

31.10.19  SDMMC IDMA linked list address register (SDMMC_IDMALAR)
Address offset: 0x064
Reset value: 0x0000 0000
Bit 31  **ULA**: Update SDMMC_IDMALAR from linked list when in linked list mode  
(SDMMC_IDMACONR.IDMABMODE select linked list mode)  
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).  
0: SDMMC_IDMALAR is not to be updated, last linked list item.  
1: SDMMC_IDMALAR is to be updated from linked list table.

Bit 30  **ULS**: Update SDMMC_IDMABSIZE from the next linked list when in linked list mode  
(SDMMC_IDMACONR.IDMABMODE select linked list mode and ULA = 1)  
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).  
0: SDMMC_IDMABSIZE is not to be updated from next linked list table.  
1: SDMMC_IDMABSIZE is to be updated from next linked list table.

Bit 29  **ABR**: Acknowledge linked list buffer ready  
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).  
This bit is not taken into account when starting the first linked list buffer from the software  
programmed register information. ABR is only taken into account on subsequent loaded  
linked list items.  
0: Loaded linked list buffer is not ready (this causes a linked list IDMA transfer error to be  
generated).  
1: Loaded linked list buffer ready acknowledge. Linked list buffer data are transferred by  
IDMA.

Bits 28:16  Reserved, must be kept at reset value.

Bits 15:2  **IDMALA[13:0]**: Word aligned linked list item address offset  
Linked list item offset pointer to the base of the next linked list item structure.  
Linked list item base address is IDMABA + IDMALA.  
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 1:0  Reserved, must be kept at reset value.

### 31.10.20 SDMMC IDMA linked list memory base register  
( SDMMC_IDMABAR )

Address offset: 0x068  
Reset value: 0x0000 0000

Refer to Section 2.3 on page 139 for the register boundary addresses.
32 Delay block (DLYB)

32.1 Introduction
The delay block (DLYB) is used to generate an output clock that is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an SDMMC or Octo-SPI interface.

The delay is voltage- and temperature-dependent, that may require the application to reconfigure and recenter the output clock phase with the receive data.

32.2 DLYB main features
The delay block has the following features:
- Input clock frequency ranging from 25 MHz to the maximum frequency supported by the communication interface (see datasheet)
- Up to 12 oversampling phases.

32.3 DLYB implementation

<table>

32.4 DLYB functional description

32.4.1 DLYB diagram
The delay block includes the following sub-blocks (shown in the figure below):
- register interface block providing AHB access to the DLYB registers
- delay line supporting the unit delays
- delay line length sampling
- output clock selection multiplexer
### 32.4.2 DLYB pins and internal signals

*Table 294* lists the DLYB internal signals.

**Table 294. DLYB internal input/output signals**

</tbody>
</table>

### 32.4.3 General description

The delay block is enabled by setting the DEN bit in the DLYB control register (DLYB_CR). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT[6:0] field in the DLYB configuration register (DLYB_CFG).

*Note:* **UNIT[6:0] can be programmed only when the output clock is disabled (SEN = 1).**

When the delay block is enabled, the output clock phase is selected through the SEL[3:0] field in DLYB_CFG register.

*Note:* **SEL can be programmed only when the output clock is disabled (SEN = 1).**

The output clock can be de-phased over one input clock period by configuring the delay line length to span one period. The delay line length can be configured by enabling the length sampler through the SEN bit, that gives access to the delay line length (LNG[11:0]) and length valid flag (LNGF) in DLYB_CFG.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced. This allows a smaller unit delay providing higher resolution.
Once the delay line length is configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL[3:0]. The output clock is only available on the selected phase when SEN is set to 0.

The table below gives a summary of the delay block control.

<table>
<thead>
<tr>
<th>DEN</th>
<th>SEN</th>
<th>UNIT</th>
<th>SEL</th>
<th>LNG</th>
<th>LNGF</th>
<th>Output clock</th>
</tr>
</thead>
<tbody>
<tr>

<td>0</td>
<td>Unit delay(^{(1)})</td>
<td>Output clock phase(^{(2)})</td>
<td>Don’t care</td>
<td>Don’t care</td>
<td>Enabled (= selected phase)</td>
</tr>
</tbody>
</table>

1. The unit delay can only be changed when SEN = 1.
2. The output clock phase can only be changed when SEN = 1.

### 32.4.4 Delay line length configuration procedure

LNG[11:0] is used to determine the delay line length with respect to the input clock period. The length must be configured so that one full input clock period is covered by the delay line length.

Note that despite the delay line has 12 unit delay elements, the following procedure description returns a length between 0 and 10, as the upper delay output value is used to ensure that the delay is calibrated over one full input clock cycle. Depending on the clock frequency and UNIT value, unit delay element 10 may also be truncated from the clock cycle length.

A clock input (free running clock) must be present during the whole tuning procedure.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to 1.
2. Enable the length sampling by setting SEN bit to 1.
3. Enable all delay cells by setting SEL[3:0] to 12.
4. For UNIT[6:0] = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT[6:0] value and wait till the length flag LNGF is set to 1.
   b) Read LNG[11:0].
   If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period: for N = 0 to 10, if LNG[N] = 1, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to 0.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced smaller than one input clock period. This allows a smaller unit delay, providing a higher resolution spanning a shorter time interval.
32.4.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:
1. Disable the output clock and enable the access to the phase selection SEL[3:0] bits by setting SEN bit to 1.
2. Program SEL[3:0] with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to 0.

32.5 DLYB registers

All registers can be accessed in word, half-word and byte access.

Refer to Section 2.3 on page 139 for the register boundary addresses.
STM32U535/545/575/585 devices embed one analog-to-digital converter (ADC1) while STM32U59x/5Ax/5Fx/5Gx devices embed two analog-to-digital converters (ADC1 and ADC2), controlled by a single interface ADC12.

### 33.1 Introduction

This section describes the implementation of the 14-bit ADC successive approximation analog-to-digital converter.

ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is a master).

The ADC features up to 20 multiplexed channels. Channel A/D conversion can be performed in single, continuous, scan, or discontinuous mode. The result of the ADC can be stored in a left-aligned or right-aligned 32-bit data register.

The ADC is mapped on the AHB bus to enable fast data handling.

In addition, the analog watchdog features enable the application to detect if the input voltage goes outside user-defined high or low thresholds.

The ADC features a built-in hardware oversampler that improves analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is also implemented to achieve very low consumption at low frequency.

### 33.2 ADC main features

- High-performance features
  - Dual mode operation (refer to Section 33.3: ADC implementation)
  - 14-, 12-, 10-, or 8-bit configurable resolution
  - ADC conversion time independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Management of single-ended or differential inputs (programmable per channels)
  - AHB slave bus interface for fast data handling
  - Self-calibration (both offset and linearity)
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Up to four injected channels (fully configurable analog input assignment to regular or injected channels)
  - Hardware assistant to prepare the injected channel context and enable fast context switching
  - Data alignment with in-built data coherency
  - Data management by general-purpose DMA for regular channel conversions with FIFO
  - Data routing to MDF for post processing
- Four dedicated data registers for injected channels
- **Oversampler**
  - 32-bit data register
  - Oversampling ratio adjustable from 2 to 1024
  - Programmable data right and left shift
- **Data preconditioning**
  - Gain compensation
  - Offset compensation
- **Low-power features**
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Support of slow bus frequency applications while keeping optimum ADC performance
  - Automatic control to avoid ADC overrun in AHB bus clock low-frequency application (auto-delayed mode)
- Up to 17 external analog input channels connected to dedicated GPIO pads
- 3 internal dedicated channels
  - One channel for internal reference voltage ($V_{REFINT}$)
  - One channel for internal temperature sensor ($V_{SENSE}$)
  - One channel for $V_{BAT}$ monitoring channel ($V_{BAT}/4$)
- Start-of-conversion can be initiated:
  - by software for both regular and injected conversions or
  - by hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions
- **Conversion modes**
  - Single mode: the ADC converts a single channel. The conversion is triggered by a special event.
  - Scan mode: the ADC scans and converts a sequence of channels.
  - Continuous mode: the ADC converts continuously selected inputs.
  - Discontinuous mode: the ADC converts a subset of the conversion sequence.
- Interrupt generation when the ADC is ready, at end of sampling, end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or when an overrun event occurs
- Three analog watchdogs
  The watchdogs can perform filtering to ignore out-of-range data.
- **ADC input range**: $V_{REF-} \leq V_{IN} \leq V_{REF+}$

*Figure 215* shows the block diagram of one ADC.
33.3 ADC implementation

The tables below describe the ADC implementation on STM32U5 Series devices. It also includes ADC4 for comparison.

33.4.3 ADC clocks

Dual clock domain architecture

Dual clock-domain architecture means that the ADC kernel clock is independent from the AHB bus clock that is used to access ADC registers.

The adc_ker_ck input clock can be selected between different clock sources (see Figure 216: ADC clock scheme). This selection is done in the RCC (refer to th RCC section for more information):
1. The ADC clock can be provided by an internal or external clock source, which is independent and asynchronous with the AHB clock.
2. The ADC clock can be derived from the AHB clock.

Option 1 has the advantage of achieving the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by a ratio of 1, 2, 4, 6, 8, 10, 12, 16, 32, 64, 128 or 256, using the prescaler configured through the PRESC[3:0] bits in the ADC12_CCR register.

Option 2 enables to bypass the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and the application requires that the ADC is accurately triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

The clock is configured through the RCC. It must be compliant with the operating frequency specified in the device datasheet.
1. Refer to the RCC section for information on adc_hclk and adc_ker_ck generation.

**Clock ratio constraint between ADC clock and AHB clock**

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock. However, the ratio must be carefully chosen to avoid any overrun especially if the clock AHB is much slower than the ADC clock.
33.4.4 ADC connectivity

Figure 217. ADC1 connectivity

1. $V_{IN}[i]$ signal can only be used when the corresponding ADC input channel is configured as differential mode.
Figure 218. ADC2 connectivity (STM32U59x/5Ax/5Fx/5Gx)
33.4.5 Slave AHB interface

The ADC implements an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests and never generates AHB errors.

33.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in Deep-power-down mode where its supply voltage is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADC_CR register).

To start ADC operations, follow the sequence below:

1. First exit Deep-power-down mode by clearing the DEEPPWD bit.
2. Then, enable the ADC internal voltage regulator by setting the ADVREGEN bit in the ADC_CR register. The software must wait for the startup time of the ADC voltage regulator ($T_{ACVREG\_STUP}$) before launching a calibration or enabling the ADC. This can be done by software by polling the LDORDY bit of the ADC_ISR register.

After ADC operations are complete, the ADC can be disabled (ADEN = 0). It is possible to save power by also disabling the ADC voltage regulator. This is done by clearing the ADVREGEN bit. Power consumption can be further reduced by reducing the leakage currents. In addition, it is possible to enter again in ADC Deep-power-down mode by setting DEEPPWD bit in ADC_CR register. This is particularly interesting before entering Stop mode.

Note: Setting DEEPPWD automatically disables the ADC voltage regulator and the ADVREGEN bit is automatically cleared.

When the internal voltage regulator is disabled (ADVREGEN = 0), the internal analog calibration factor is kept.

In ADC Deep-power-down mode (DEEPPWD = 1), the internal analog calibration is lost and it is necessary either to relaunch a calibration or apply again the calibration factor, which was previously saved (refer to Section 33.4.8: Calibration (ADCAL, ADCALLIN, ADC_CALFACT)).

33.4.7 Single-ended and differential input channels

ADC channels can be configured either as single-ended input or as differential input. This is done by writing DIFSEL[19:0] bits in the ADC_DIFSEL register. This configuration must be performed while the ADC is disabled (ADEN = 0).

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{INP}[i]$ (positive input) and $V_{REF}$ (negative input).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{INP}[i]$ (positive input) and $V_{INN}[i]$ (negative input).
The output data in differential mode is an unsigned data:

- When $V_{\text{INP}[i]} = V_{\text{REF}-}$, $V_{\text{INN}[i]} = V_{\text{REF}+}$ and output data = 0x0000 (14-bit resolution mode),
- When $V_{\text{INP}[i]} = V_{\text{REF}+}$, $V_{\text{INN}[i]} = V_{\text{REF}-}$ and output data = 0x3FFF.

For a complete description of how the input channels are connected, refer to Section 33.4.4: ADC connectivity.

**Caution:** When channel “i” is configured in differential input mode, its negative input voltage is connected to $V_{\text{INN}[i-1]}$.

### 33.4.8 Calibration (ADCAL, ADCALLIN, ADC_CALFACT)

The ADC provides an automatic calibration procedure that controls the whole calibration sequence including the ADC power-on/off. During the procedure, the ADC calculates an offset calibration factor for single-ended and differential mode. This factor includes the internal offset and the linearity that are applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until the calibration is complete.

The calibration is a prerequisite to any ADC operation. It removes the systematic errors that may vary from chip to chip and enables to compensate offset and linearity deviation.

The offset calibration is the same for single-ended or differential channels.

The linearity correction must be done only once, regardless of single / differential configuration:

- Set ADCALLIN in ADC_CR before launching a calibration that runs the linearity calibration simultaneously with the offset calibration or
- Clear ADCALLIN in ADC_CR before launching a calibration that does not run the linearity calibration but only the offset calibration.

The calibration is then initiated by software by setting the ADCAL bit. The calibration can only be initiated when the ADC is disabled (ADEN = 0). ADCAL bit remains at 1 during all the calibration sequence. It is cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC.

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). However, if the ADC is disabled for extended periods of time, the temperature changes, or the supply voltage is modified of more than 10%, it is recommended that a new offset calibration cycle is run before enabling the ADC again.

The internal analog calibration is lost each time the ADC power is switched off (for example, when the device enters Standby or VBAT mode). In this case, to avoid spending time recalibrating the ADC, the calibration factor can be written again to the ADC analog block without recalibrating, assuming that the software has previously saved the calibration factor generated during the previous calibration.

$$\text{Converted value} = \frac{\text{ADC\_Full\_Scale}}{2} \times \left[ 1 + \frac{V_{\text{INP}} - V_{\text{INN}}}{V_{\text{REF}+}} \right]$$

When ADC is configured as differential mode, both inputs must be biased at $V_{\text{REF}+} / 2$ voltage.
The calibration factor obtained during factory tests is programmed in a specific device option byte. To reduce the calibration time, this value can be copied to the analog ADC.

The calibration factor can be written if the ADC is enabled and no calibration is ongoing (ADEN = 1 and ADSTART = 0 and JADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This operation is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate the ADC offset when VREF+ changes of more than 10%.

Refer to the device datasheet for the offset and linearity calibration time requirements.

**Software procedure to calibrate the ADC**

1. Make sure DEEPPWD = 0, ADVREGEN = 1 and check that the ADC voltage regulator startup time has elapsed (LDORDY = 1).
2. Make sure ADEN = 0.
3. Either enable the linearity calibration (ADCALLIN = 1) or disable it (ADCALLIN = 0).
4. Make sure CAPTURE_COEF and LATCH_COEF in ADC_CALFACT are cleared.
5. Set ADCAL in the ADC_CR register and wait until ADCAL = 0.

*Figure 219* shows the ADC calibration timing diagram.

*Note:* The software can launch the calibration only when ADEN = 0, LDORDY = 1 (ADC disabled and LDO ready).

Single-ended and differential channels cannot be calibrated separately. The offset calibration must be performed within the same sequence.

*Figure 219. ADC calibration*
Reading calibration factor procedure

Once the calibration is complete (ADCAL bit cleared by hardware), the calibration factor can be read using the ADC_CALFACT2 register. Nine read accesses are required to perform this operation:

1. Make sure DEEPPWD = 0, ADVREGEN = 1, and check that the ADC voltage regulator startup time has elapsed (LDORDY = 1).
2. Make sure that ADEN = 1.
3. Set CAPTURE_COEF and clear LATCH_COEF in the ADC_CALFACT register.
4. Select the calibration factor by setting CALLINDEX[0:3] in ADC control register (ADC_CR).
5. Read the calibration factor from the ADC_CALFACT2 register.
6. Repeat steps 4 and 5 for each required calibration factor.
7. Clear the CAPTURE_COEF bit in the ADC_CALFACT register.

Note: The software can access the calibration factor only when ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).

Software procedure to reinject the calibration factor into the ADC

1. Make sure ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).
2. Clear the CAPTURE_COEF and LATCH_COEF bits in the ADC_CALFACT register.
3. Set CALINDEX[3:0] to the targeted calibration index to be updated, then write the calibration factor to CALFACT[31:0] in the ADC_CALFACT2 register.
4. Repeat step 3 for the necessary calibration index.
5. Set the LATCH_COEF bit in the ADC_CALFACT register.
6. Clear the LATCH_COEF bit in the ADC_CALFACT register.

Note: The software is allowed to update the calibration factor only when ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).

Calibration factor index

The calibration factors are stored in the analog block in an indexed way. Index 0b0000 and 0b1000 contain the offset calibration factor while index 0b0001 to 0b0110 contain the linearity factor. The lower two bytes of index 0b0111 contain the linearity calibration factor. The internal offset calibration factor must be programmed into the second byte of index 0b0111. However, it is read at byte 3 of index 0b1000. When programming or reinjecting the calibration factor, make sure to use the correct indexes for read and write operations.

Refer to Table 305 for a summary.

<table>
<thead>
<tr>
<th>CALINDEX[3:0] values</th>
<th>Calibration factor</th>
<th>Byte location</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Byte 3</td>
<td>Byte 2</td>
</tr>
<tr>
<td>0b0000</td>
<td>Differential offset</td>
<td>Single-end offset</td>
</tr>
<tr>
<td>0b0001</td>
<td>Linearity factor 1</td>
<td></td>
</tr>
</tbody>
</table>

Table 305. Calibration factor index
To run an offset calibration when the linearity calibration factor is programmed by software, first program the linearity calibration factor, then run the offset calibration. Running the offset calibration first would cause the offset calibration factor to be overwritten when the LATCH_COEF bit is programmed.

It is impossible to program the offset calibration alone since byte 1 and byte 0 (linearity factor 7) are overwritten when programming the offset calibration factor into byte 2 of index 0b0111. To avoid this, read the linearity calibration factor then program index 0b0111 with the read value.

**Extended calibration mode**

To enhance the ADC performance, the extended calibration mode is implemented on some product versions (see Section 33.3: ADC implementation).

Below the procedure to enable the extended calibration mode:

1. Make sure that DEEPPWD = 0 and ADVREGEN = 1, and check that the ADC voltage regulator startup time has elapsed (LDORDY = 1).
2. Set ADCCALLIN in the ADC_CR register.
3. Make sure CAPTURE_COEF and LATCH_COEF of ADC_CALFACT are cleared.
4. Set ADEN and wait until ADRDY is set.
5. Set CALINDEX[3:0] = 0b1001, then write CALFACT[31:0] = 0x0302 1100 in the ADC_CALFACT2 register.
6. Set the LATCH_COEF bit in the ADC_CALFACT register.
7. Set the ADDIS and wait until the ADEN bit is cleared.
8. Set the ADCAL in the ADC_CR register and wait until ADCAL bit is cleared.

**Note:** Once the calibration is complete, the value of CALFACT[31:0] at CALINDEX[3:0] = 0b1001 is reset.
33.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure described in Section 33.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).

Once the DEEPPWD bit is cleared and the ADVREGEN bit is set, the ADC can be enabled. It requires a stabilization time of $t_{STAB}$ before starting converting accurately (see Figure 220). Two control bits enable or disable the ADC:
- When $ADEN = 1$: the ADC is enabled. The ADRDY is set as soon as the ADC is ready for operation.
- When $ADDIS = 1$: the ADC is disabled.

ADEN and ADDIS bits are automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversions can then start either by setting ADSTART (refer to Section 33.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN[1:0], JEXTSEL, JEXTEN[1:0])) or when an external trigger event occurs if triggers are enabled.

Injected conversions start by setting JADSTART or when an external injected trigger event occurs if injected triggers are enabled.

Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by writing 1.
2. Set ADEN = 1.
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done by using the associated interrupt (ADRDYIE = 1).
4. Clear the ADRDY bit in the ADC_ISR register by writing 1 (optional).

Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to make sure that no conversion is ongoing. If required, stop any ongoing regular and injected conversion by setting ADSTP = 1 and JADSTP = 1 and then wait until ADSTP = 0 and JADSTP = 0.
2. Set ADDIS.
3. If required by the application, wait until ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).
33.4.10 Constraints when writing the ADC control bits

The software can program the RCC control bits to configure and enable the ADC clock (refer to the Reset and clock control section), the control DIFSEL bits in the ADC_DIFSEL register, the ADC12_CCR register and the ADCAL and ADEN control bits in the ADC_CR register, only if the ADC is disabled.

The software can program the ADCAL bit to launch the calibration when ADEN is cleared. It can read or update the calibration factor if ADEN is set and no conversion is ongoing (ADSTART and JADSTART both cleared).

The software is then allowed to write the ADSTART, JADSTART, and ADDIS control bits in the ADC_CR register only if the ADC is enabled and there is no pending request to disable it (ADEN must be equal to 1 and ADDIS to 0).

The following constraints apply to all the other control bits of the ADC_CFGRx, ADC_SMPRx, ADC_LTRy, ADC_HTRy, ADC_SQRy, ADC_OFRy and ADC_IER registers:

- Control bits related to configuration of regular conversions: the software is allowed to write them only if the ADC is enabled (ADEN = 1) and no regular conversion is ongoing (ADSTART must be equal to 0).
- Control bits related to configuration of injected conversions: the software is allowed to write them only if the ADC is enabled (ADEN = 1) and no injected conversion is ongoing (JADSTART must be equal to 0).
- ADC_LTRy, ADC_HTRy registers can be modified when an analog-to-digital conversion is ongoing (refer to Section 33.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy) for details).

The software can write ADSTP or JADSTP control bits in the ADC_CR register only if the ADC is enabled, a conversion is ongoing and there is no pending request to disable it (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).

Note: There is no hardware protection to prevent these forbidden write accesses that may cause the ADC to enter an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN as well as all the bits of the ADC_CR register).
33.4.11 Channel selection (SQRx, JSQRx)

The ADC features up to 20 multiplexed channels per ADC:

- Up to 17 analog inputs coming from GPIO pads
- Each ADC is connected to 3 internal analog inputs:
  - the internal temperature sensor (V\text{SENSE})
  - the internal reference voltage (V\text{REFINT})
  - the V\text{BAT} monitoring channel (V\text{BAT}/4)

Refer to Table ADC interconnection in Section 33.4.2: ADC pins and internal signals for the connection of the above internal analog inputs to external ADC pins or internal signals.

The conversions can be organized in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADC\_IN3, ADC\_IN8, ADC\_IN2, ADC\_IN2, ADC\_IN0, ADC\_IN2, ADC\_IN2, ADC\_IN15.

- A regular group is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC\_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC\_SQR1 register.
- An injected group is composed of up to four conversions. The injected channels and their order in the conversion sequence must be selected in the ADC\_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC\_JSQR register.

ADC\_SQRy registers must not be modified while regular conversions are ongoing. To modify ADC\_SQRy registers, the ADC regular conversions must first be stopped by setting ADSTP (refer to Section 33.4.18: Stopping an ongoing conversion (ADSTP, JADSTP)).

Note: To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming VBATEN, VSENSESEL, or VREFEN bits in the ADC12\_CCR registers.

33.4.12 Channel preselection register (ADC\_PCSEL)

For each channel selected through SQRx or JSQRx bits, the corresponding ADC\_PCSEL bit must be configured in advance.

This ADC\_PCSEL bit controls the analog switch integrated in the I/O level. The ADC input multiplexer selects the ADC input according to SQRx and JSQRx configuration with very high speed and the analog switch integrated in the I/O cannot react as fast as the ADC multiplexer does. To avoid the delay due to on analog switch control on the I/O, it is necessary to preselect the input channels that are selected through the SQRx and JSQRx. The selection is based on the V\text{INP}[i] of each ADC input. For example, if the ADC converts ADC\_IN1, the PCSEL1 bit must also be set in ADC\_PCSEL.

33.4.13 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.
Each channel can be sampled with a different sampling time that is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC_SMPR2 registers. It is therefore possible to select among the following sampling time values:

- \( \text{SMP} = 000 \): 5 ADC clock cycles
- \( \text{SMP} = 001 \): 6 ADC clock cycles
- \( \text{SMP} = 010 \): 12 ADC clock cycles
- \( \text{SMP} = 011 \): 20 ADC clock cycles
- \( \text{SMP} = 100 \): 36 ADC clock cycles
- \( \text{SMP} = 101 \): 68 ADC clock cycles
- \( \text{SMP} = 110 \): 391 ADC clock cycles
- \( \text{SMP} = 111 \): 814 ADC clock cycles

The total conversion time is calculated as follows:

\[
T_{\text{CONV}} = \text{Sampling time} + \text{Conversion time}
\]

**Example**

When converting a single data, the sampling time is five cycles and the conversion time is 17 cycles for 14-bit mode. With an \( F_{\text{adc, ker, ck}} \) of 55 MHz:

\[
T_{\text{CONV}} = (5 + 17) \text{ ADC clock cycles} = 22 \text{ ADC clock cycles} = 0.40 \mu\text{s}
\]

The above result assumes that \( R_{\text{AIN}} << 1 \, \Omega \) (refer to the datasheet for additional sampling time to be added depending on the external resistance).

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

**I/O analog switch voltage booster**

The resistance of the I/O analog switches increases when the \( V_{\text{DDA}} \) voltage is too low. The sampling time must consequently be adapted accordingly (refer to the device datasheet for the corresponding electrical characteristics). This resistance can be minimized at low \( V_{\text{DDA}} \) voltage by enabling an internal voltage booster (refer to the SYSCFG section for more details).

**Bulb sampling mode**

When the BULB bit is set in the ADC_CFGR2 register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in the ADC_SMPR1 register. The very first ADC conversion, after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The bulb mode is effective starting from the second conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

The bulb mode may not be used in continuous conversion mode or with injected channel conversion.

When the BULB bit is set, it is not allowed to set the SMPTRIG bit in ADC_CFGR2.

When conversions in bulb mode are stopped by setting ADSTP bit or when the DMA transfers are complete, the ADC must be disabled by setting ADDIS bit.
Sampling time control trigger mode

When the SMPTRIG bit is set, the sampling time programmed through SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected, each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion.

When a software trigger is selected, the software trigger is not the ADSTART bit in ADC_CR but the SWTRIG bit. SWTRIG bit has to be set to start the sampling period, and the SWTRIG bit has to be cleared to end the sampling period and start the conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is not compatible with the continuous conversion mode and injected channel conversion.

When the SMPTRIG bit is set, it is not allowed to set the BULB bit.

### 33.4.14 Single conversion mode (CONT = 0)

In single conversion mode, the ADC performs once the conversions of all channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel, with software trigger selected)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel, with software trigger selected)
- External hardware trigger event (for a regular or injected channel)
  ADSTART bit or JADSTART bit must be set before triggering an external event.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set
Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 32-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

Note: To convert a single channel, program a sequence with a length of 1.

33.4.15 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts each conversion of the sequence. This mode is started with the CONT bit at 1 either by an external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using the JAUTO bit), refer to Section : Auto-injection mode).
33.4.16 Starting conversions (ADSTART, JADSTART)

The software starts ADC regular conversions by setting ADSTART. When ADSTART is set, the conversion starts:

- immediately if EXTEN[1:0] = 0x0 (software trigger) or
- at the next active edge of the selected regular hardware trigger, if EXTEN[1:0] is not equal to 0x0

The software starts ADC injected conversions by setting JADSTART. When JADSTART is set, the conversion starts:

- immediately, if JEXTEN[1:0] = 0x0 (software trigger) or
- at the next active edge of the selected injected hardware trigger if JEXTEN[1:0] is not equal to 0x0

**Note:** In auto-injection mode (JAUTO = 1), use the ADSTART bit to start regular conversions followed by auto-injected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether any ADC operation is ongoing. The ADC can be reconfigured while ADSTART and JADSTART are both cleared (the ADC is idle).

ADSTART is cleared by hardware:

- In single mode with software trigger (CONT = 0, EXTEN[1:0] = 0x0): at any end of the conversion sequence (EOS = 1)
- In discontinuous mode with software trigger (CONT = 0, DISCEN = 1, EXTEN[1:0] = 0x0): at end of conversion (EOC = 1)
- In all other cases (CONT = x, EXTEN[1:0] = x): after executing the ADSTP assertion procedure by software.

**Note:** In continuous mode (CONT = 1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT = 0 and EXTEN[1:0] ≠ 0x0), ADSTART is not cleared by hardware with the assertion of EOS to help the software that does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

JADSTART is cleared by hardware:

- In single mode with software injected trigger (JEXTEN[1:0] = 0x0): at any end of the injected conversion sequence (JEOS assertion) or at any end of subgroup processing if JDISCEN = 1
- In all other cases (JEXTEN[1:0]=x): after executing the JADSTP assertion procedure by software.

**Note:** When the software trigger is selected, the ADSTART bit must not be set if the EOC flag is still high.
33.4.17 Timing

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution for single conversion and minus the overlap time between the sampling and the previous SAR for continuous conversion.

In single conversion mode:

\[
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = 5\text{ min} + 17\text{ bits} \times T_{\text{adc_ker_ck}}
\]

\[
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = 22 \times T_{\text{adc_ker_ck}} \text{ min for 14 bits} = 400.0 \text{ ns for } F_{\text{adc_ker_ck}} = 55 \text{ MHz}
\]

Figure 222. Analog to digital conversion time in single conversion

33.4.18 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP, and injected conversions ongoing by setting JADSTP.

Stopping conversions resets the ongoing ADC operation. The ADC can then be reconfigured (for example by changing the channel selection or the trigger). It is then ready for a new operation.

Injected conversions can be stopped while regular conversions are still ongoing and vice versa. This enables, for instance, to reconfigure the injected conversion sequence and triggers while regular conversions are still ongoing (and vice versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC would restart a new sequence).
Once this procedure is complete, ADSTP/ADSTART bits (in case of regular conversion), or JADSTP/JADSTART bits (in case of injected conversion) are cleared by hardware. The software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

**Note:** In auto-injection mode (JAUTO = 1), setting the ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).
33.4.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN[1:0], JEXTSEL, JEXTEN[1:0])

A conversion or a sequence of conversions can be triggered either by software or by an external event (for example, timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 00, then external events are able to trigger a conversion with the selected polarity.

The regular trigger selection is effective once software has set bit ADSTART = 1 and the injected trigger selection is effective once software has set bit JADSTART = 1.

Any hardware trigger which occurs while a conversion is ongoing are ignored.
- If ADSTART = 0, regular hardware triggers are ignored.
- If JADSTART = 0, injected hardware triggers are ignored.

Table 306 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

### Table 306. Configuring the trigger polarity for regular external triggers

<td>Hardware trigger with detection on both the rising and falling edges</td>
</tr>
</tbody>
</table>

The EXTSEL[4:0] and JEXTSEL[4:0] control bits select which events can trigger regular and injected groups conversion, out of 21 possibilities.

A regular group conversion can be interrupted by an injected trigger.

**Note:** The trigger selection cannot be changed on-the-fly.
33.4.20 Injected channel management

Triggered injection mode

To use triggered injection, the JAUTO bit must be cleared in the ADC_CFGR1 register:

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once).
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.
4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. Figure 226 shows the corresponding timing diagram.

**Note:** When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 44 ADC clock cycles (that is two conversions with a minimum sampling time), the minimum interval between triggers must be 45 ADC clock cycles.
**Auto-injection mode**

If the JAUTO bit is set in the ADC_CFPGR1 register, the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, the external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

*Note:* It is not possible to use both the auto-injected and discontinuous modes simultaneously.

When the DMA is used for exporting the regular sequencer’s data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in the DMA_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence is stopped upon a DMA Transfer Complete event.

**Figure 226. Injected conversion latency**

![Diagram](image)

1. The maximum latency value can be found in the electrical characteristics of the device datasheet.
33.4.21 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR1 register.

It is used to convert a short sequence (subgroup) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR1 register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQRx registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example

- DISCEN = 1, n=3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ...

- DISCEN = 0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10,11
  - First trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.

Note: When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR1 register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed at 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.
Example
- JDISCEN = 1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

33.4.22 Programmable resolution (RES) - fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 14, 12, 10, 8 bits by programming the control bits RES[1:0]. Figure 231, Figure 232, Figure 233 and Figure 234 show the conversion result format with respect to the resolution as well as to the data alignment (in continuous mode assuming no added extra sampling cycle for high input resistance).

Lower resolution enables faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to Table 308.

<table>
<thead>
<tr>

</tbody>
</table>

33.4.23 End of conversion and end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy registers. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.
The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

### 33.4.24 End of conversion sequence (EOS, JEOS)

The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.

### 33.4.25 Timing diagrams example (single/continuous modes, hardware/software triggers)

![Timing Diagram](MS33549V1.png)

**Figure 227. Single conversions of a sequence, software trigger**

1. EXTEN[1:0] = 0x0, CONT = 0
2. Channels selected = 1, 9, 10, 17; AUTDLY = 0.
1. **EXTEN[1:0] = 0x0, CONT = 1**

2. Channels selected = 1, 9, 10, 17; **AUTDLY = 0**.

---

**Figure 229. Single conversions of a sequence, hardware trigger**

1. **TRGx (over-frequency) is selected as trigger source, EXTEN[1:0] = 01, CONT = 0**

2. Channels selected = 1, 2, 3, 4; **AUTDLY = 0**.
1. TRGx is selected as trigger source, EXTEN[1:0] = 10, CONT = 1
2. Channels selected = 1, 2, 3, 4; AUTDLY = 0.

33.4.26 Low-frequency trigger mode (LFTRIG)

Once the ADC is enabled or when the last ADC conversion is complete, the ADC is ready to
start the next conversion. The ADC needs to be started at a defined time (T_idle) otherwise
the converted data can be corrupted due to transistor leakage (refer to the datasheet for the
maximum value of T_idle).

If the user application requires a time higher than T_idle maximum value between one trigger
to another for single conversion mode, or between ADC enable and the first conversion,
then the ADC converter input multiplexer must be re initialized. This operation is selected by
setting LFTRIG bit in ADC_CFGR2.

33.4.27 Data management

Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT)

Data and alignment

At the end of each regular conversion channel (when the EOC event occurs), the result of
the converted data is stored into the ADC_DR data register which is 32 bits wide.

At the end of each injected conversion channel (when the JEOC event occurs), the result of
the converted data is stored into the corresponding ADC_JDRy data register which is 32 bits
wide.

The OVSS[3:0] and LSHIFT[3:0] bitfields in the ADC_CFGR2 register selects the alignment
of the data stored after conversion. By default, data are right-aligned. Refer to Figure 231,
Figure 232, Figure 233 and Figure 234 for examples of data alignment.

Note: The data can be realigned in normal and in oversampling mode.

Offset

An offset y (y = 1,2,3,4) can be applied to a channel by programming a value different from
0 in the OFFSETy[23:0] bitfield of the ADC_OFRy register. The channel to which the offset
is applied is programmed into the bits OFFSETy_CH[4:0] of ADC_OFRy register. The offset
can be positive or negative depending on the value of the POSOFF bit. When POSOFF is cleared, the converted value is subtracted by the user-defined offset written in OFFSETy[23:0] bits. The result can be a negative value. The read data is consequently signed and the SEXT bit represents the extended sign value.

The offset value must be lower than the maximum conversion value (for example, in 14-bit mode, the maximum offset value is 0x3FFF).

The offset can be used to convert unsigned data to signed data (for example, in 14-bit mode, the offset value is equal to 0x2000).

The offset correction is also supported in oversampling mode. For the oversampling mode, offset is subtracted before OVSS right shift applied.

Table 309 describes how the comparison is performed for all the possible resolutions for analog watchdog 1, 2, 3.

**Table 309. Offset computation versus data resolution**

Management of signed and unsigned saturation format (SSAT, USAT)

The offset correction might result in the data width to be wider than the original data.

To limit the original width, the data saturation can be enabled through the SSAT and USAT bits of the ADC_OFRy register.
Unsigned 14-bit data can be extended to 15-bit signed data by using an offset value different from 0x2000.

The original data width can be preserved by setting the SSAT bit to limit the data width to 14 bits.

Unsigned data can be saturated to the original data width by setting the USAT bit.

*Table 310* shows the sign-extended data format corresponding to different resolutions.

**Caution:** SSAT must not be used in conjunction with USAT. No hardware check is performed to ensure that this recommendation is respected.
Gain compensation

When the GCOMP bit is set in the ADC_CFGR2 register, the gain compensation is activated on all converted data. After each conversion, data is calculated using the following formula.

\[
DATA = DATA(\text{adc result}) \times \frac{\text{GCOMPCOEFF}}{4096}
\]

As GCOMPCOEFF can be programmed from 0 to 16383, the actual gain compensation factor can range from 0 to 3.999756.

Before storing the resulting data in the RDATA or JDATAx registers, the LSB−1 value is evaluated to round up the data and minimize the error.

The gain compensation is also effective for the oversampling. When the gain compensation is used for the oversampling mode, the gain calculation is performed after the accumulation and right-shift operations to minimize the power consumption (the gain calculation is done only once instead of at each conversion). The internal multiplier width is 32 bits and the input data width for the gain compensation must be less than 18 bits. When using oversampling with injected and regular conversion mode the bit ADC_CFGR2.ROVSM bit must be set to resume the pending conversion with the correct value.

ADC overrun (OVRMOD)

The overrun flag (OVR) notifies of that a buffer overrun event occurred when the regular converted data has not been read (by the CPU or the DMA) before ADC_DR FIFO (eight stages) is overflowed.

The OVR flag is set when a new conversion completes while the ADC_CR register FIFO was full. An interrupt is generated if the OVRIE bit is set.

When an overrun event occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting the ADSTP bit.

OVR flag is cleared by software by writing 1 to it.

Data can be configured to be preserved or overwritten when an overrun event occurs by programming the OVRMOD control bit of the ADC_CFGR1 register:

- **OVRMOD = 0**
  The overrun event preserves the data register from being overwritten: the old data is maintained up to ADC_DR FIFO depth (eight data) and the new conversion is discarded and lost. If OVR remains at 1, further conversions occur but the result data are also discarded.

- **OVRMOD = 1**
  The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, further conversions operate normally and the ADC_DR register always contains the latest converted data.
Note: There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.
Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case, the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD must be configured to 0 to manage overrun events as an error.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (for example if the device features an analog watchdog). In this case, the OVRMOD bit must be configured to 1 and the OVR flag must be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored in a unique data register, it is useful to use DMA to convert more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMNGT[1:0] = 01 or 11 in the ADC_CFGR register in single ADC mode or DAMDF different from 00 in dual ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.

Despite this, if an overrun occurs (OVR = 1) because the DMA cannot serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. This means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of the OVRMOD bit, the data is either preserved or overwritten.

The DMA transfer requests are blocked until the software clears the OSV bit.

Two different DMA modes are proposed depending on the application. They can be configured through the DMNGT[1:0] bitfield of the ADC_CFGR1 register and the DAMDF bit of the ADC12_CCR register, in single ADC mode and in dual ADC mode, respectively:

- **DMA one shot mode (DMNGT[1:0] = 01).**
  This mode is suitable when the DMA is programmed to transfer a fixed number of data.

- **DMA circular mode (DMNGT[1:0] = 11)**
  This mode is suitable when programming the DMA in circular mode.

**DMA one shot mode (DMNGT[1:0] = 01)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when a transfer complete interrupt occurs - refer to DMA section) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
• No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions, which are started.
• Scan sequence is stopped and reset.
• The DMA is stopped.

**DMA circular mode (DMNGT[1:0] = 11)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

**DMA with FIFO**

The output data register features an eight-stage FIFO. Two different DMA requests are generated in parallel. When a data is available, an “SREQ single request” is generated. When four data are available, a “BREQ burst request” is generated. DMA can be programmed either single transfer mode or incremental burst mode (four beats), according to this mode, correct request line is selected by the DMA. Refer to the DMA chapter for further information.

### 33.4.28 Managing conversions using the MDF

The ADC conversion results can be transferred directly to the MDF.

In this case, the DMNGT[1:0] bits must be set to 10.

The ADC transfers the 16 least significant bits of the regular data register to the MDF through adcx_dat[15:0] bus, which in turn resets the EOC flag once the transfer is effective.

The data format must be in 16-bit signed format:

- ADC_DR[31:16] = don’t care
- ADC_DR[15] = sign
- ADC_DR[14:0] = data

Any value above 16-bit signed format is truncated.

### 33.4.29 Dynamic low-power features

**Auto-delayed conversion mode (AUTDLY)**

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

When AUTDLY = 1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADC_DR register has been read or if the EOC bit has been cleared (see *Figure 237*).
- For an injected conversion: when the JEOS bit has been cleared (see *Figure 238*).

The auto-delayed conversion mode enables to automatically adapt the speed of the ADC to the speed of the system which reads the data.
The delay is inserted after each regular conversion (whatever DISCEN = 0 or 1) and after each sequence of injected conversions (whatever JDISCEN = 0 or 1).

Note: There is no delay inserted between each conversion of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

Note: This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to restart a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see Figure 238).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see Figure 240).

The behavior is slightly different in auto-injected mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see Figure 241).

To stop a conversion in continuous auto-injection mode combined with auto-delay mode (JAUTO = 1, CONT = 1 and AUTDLY = 1), follow the following procedure:
1. Wait until JEOS = 1 (no more conversions are restarted).
2. Clear JEOS.
3. Set ADSTP = 1.
4. Read the regular data.

If this procedure is not respected, a new regular sequence can restart if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

33.4.30 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

**Figure 242. Analog watchdog guarded area**

![Diagram of guarded area with analog voltage, higher threshold (HTR), lower threshold (LTR), and guarded area]

**AWDx flag and interrupt**

An interrupt can be enabled for each of the three analog watchdogs by setting AWDyIE in the ADC_IER register (y = 1, 2, 3).

AWDy (y = 1, 2, 3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

**Description of analog watchdog 1**

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR1 register. This watchdog monitors whether either one selected channel or all enabled channels remain within a configured voltage range (window).

*Table 312* shows how the ADC_CFGR1 registers must be configured to enable the analog watchdog on one or more channels.

**Table 312. Analog watchdog channel selection**

1. Selected by the AWDyCH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.

These thresholds are programmed in the HTR1[24:0] bits of the ADC_HTR1 register and LTR1[24:0] of the ADC_LTR1 register for the analog watchdog 1.

The threshold can be up to 25-bits (14-bit resolution with oversampling, OSR=256).
When converting data with a resolution of less than 14 bits (according to bits RES[1:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 14-bit converted data (left aligned to the half-word boundary).

Table 313 describes how the comparison is performed for all the possible resolutions for analog watchdog 1,2,3.

</tbody>
</table>

1. The watchdog comparison is performed when the oversampling, the gain compensation and the offset compensation are complete (the data that are compared can be either signed or unsigned).

### Analog watchdog filter for watchdog 1

When the ADC is configured with only one input channel (selecting several channels in scan mode not allowed), a valid ADC conversion data range can be configured through the ADC_LTR1 and ADC_HTR1 register:

- When converted data belong to the range defined in ADC_LTR1 and ADC_HTR1, a DMA request is generated.
- Otherwise, no DMA request is issued. RDATA register is updated at each conversion. If data are out-of-range a number of times higher than the value specified in the AWDFILT bit of ADC_HTR1, the AWDX flag is set and the corresponding interrupt is issued.

### Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDC[19:y] (y=2,3).

The corresponding watchdog is enabled when any bit of AWDC[19:y] (y=2,3) is set.

The threshold can be up to 25 bits (14-bit resolution with oversampling, OSR = 1024, and offset conversion in signed format) and are programmed with the ADC_HTR2, ADC_LTR2, ADC_LTR3, and ADC_HTR3 registers.

When converting data with a resolution of less than 14 bits (according to bits RES[1:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 14-bit converted data (left aligned).
ADC_AWDy_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADC_AWDy_OUT (y being the watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADC_AWDy_OUT signal as ETR.

ADC_AWDy_OUT is activated when the associated analog watchdog is enabled:

- ADC_AWDy_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADC_AWDy_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (it remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADC_AWDy_OUT is also reset when disabling the ADC (when setting ADDIS = 1).

Note that stopping regular or injected conversions (setting ADSTP = 1 or JADSTP = 1) has no influence on the generation of ADCy_AWDx_OUT.

Note: AWDx flag is set by hardware and reset by software: AWDy flag has no influence on the generation of ADC_AWDy_OUT (ex: ADCy_AWDy_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

- Converting the injected channels 1, 2, 3, 4
- All injected channels 1, 2, 3, 4 are guarded
Analog watchdog threshold control

LTRx[24:0] and HTRx[24:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTRx[24:0] and HTRx[24:0] are updated during the ADC conversion of the ADC guarded channel, the watchdog function is masked for this conversion. This masking is removed at the next start of conversion, resulting in an analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new interval, no interrupt and AWDx_OUT signal are issued. The interrupt and the AWD generation only happen at the end of the conversion which started after the threshold update. If AWD_xOUT is already asserted, programming the new thresholds does not deassert the AWD_OUT signal.

Analog watchdog with gain and offset compensation

When gain and offset compensation are enabled, the analog watchdog compares the threshold after the compensated data.

33.4.31 Oversampler

The oversampling unit performs data preprocessing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 24-bit (14-bit values and OSR = 1024).

It provides a result with the following form, where N and M can be adjusted:

\[
\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n-N-1} \text{Conversion}(t_n)
\]

It enables the following functions to be performed by hardware: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OSR[9:0] bits in the ADC_CFGR2 register, and can range from 2x to 1024x. The division coefficient M consists of a right bit shift up to 10 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 24 bits (1024 x 14-bit results), which can be left or right shifted. When right shifting is selected, it is rounded to the nearest value using the least significant bits left apart by the shifting, before being transferred into the ADC_DR data register.

*Figure 247* gives a numerical example of the processing, from a raw 24-bit accumulated data to the final 14-bit result.
Figure 247. 14-bit result oversampling with 10-bits right shift and rounding

The conversion timings in oversampling mode do not change: the sample time is maintained during the whole oversampling sequence. A new data is provided every N conversions with an equivalent delay equal to $N \times T_{CONV} = N \times (t_{SMPL} + t_{SAR})$. The flags are set as follows:

- The end of the sampling phase (EOSMP) is set after each sampling phase.
- The end of conversion (EOC) occurs once every N conversions, when the oversampled result is available.
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (i.e. after $N \times$ sequence length conversions total).

Operating modes supported during oversampling

In oversampling mode, most of the ADC operating modes are maintained:

- Single or continuous mode conversions
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (configured through the RES[1:0] bits of the ADC_CFGR1 register) are accumulated, truncated, rounded, and shifted in the same way as 14-bit conversions.

Note: The alignment mode is not available when working with oversampled data. The ALIGN bit in ADC_CFGR is ignored and the data are always provided right-aligned.

Offset correction is not supported in oversampling mode. When the ROVSE and/or JOVSE bit is set, the value of the OFFSETy_EN bit in the ADC_OFRy register is ignored (considered as reset).
Analog watchdog

The analog watchdog functionality is maintained, with the following differences:

- The RES[1:0] bits are ignored. The comparison is always done using the full 25-bit values, HTRx[24:0] and LTRx[24:0].
- The comparison is performed on the oversampled accumulated value before shifting.

**Note:** Care must be taken when using high shifting values, since this reduces the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding an 8-bit right-aligned data, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HT[7:0]/LT[7:0]. HT[11:8]/LT[11:8] must be kept reset.

Triggered mode

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with the TROVS bit of the DC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

The Figure 248 below shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

**Figure 248. Triggered regular oversampling mode (TROVS bit = 1)**

Injected and regular sequencer management when oversampling

In oversampling mode, injected and regular sequencers can have different behaviors. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

Oversampling regular channels only

The regular oversampling mode bit, ROVSM, defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- In continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is
complete whatever the injection frequency (providing at least one regular conversion can be completed between triggers);

- In resumed mode, the accumulation restarts from 0 (previous conversions results are ignored). This mode guarantees that all data used for oversampling were converted back-to-back within a single time-slot. Care must be taken to have an injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be completed and the regular sequencer is blocked.

*Figure 249* gives examples for an oversampling ratio of 4x.

**Figure 249. Regular oversampling modes (4x ratio)**

**Oversampling injected channels only**

The injected oversampling mode bit, JOVSE, enables oversampling solely for conversions in the injected sequencer.
Oversampling regular and injected channels

Both ROVSE and JOVSE bits can be set simultaneously. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as shown in Figure 250.

**Figure 250. Regular and injected oversampling modes used simultaneously**

![Diagram showing regular and injected oversampling modes used simultaneously](MS34455V2)

**Triggered regular oversampling with injected conversions**

Injected conversions can be performed in triggered regular mode. In this case, the injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (resumed mode forced). The JOVSE bit must be reset. The behavior is shown in Figure 251.

**Figure 251. Triggered regular oversampling with injection**

![Diagram showing triggered regular oversampling with injection](MS34456V4)
Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers. This enables to save a DMA resource. This mode is available only when both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1. Other combinations are not supported. The ROVSM bit is ignored in auto-injected mode.

Figure 252 shows how the conversions are sequenced.

**Figure 252. Oversampling in auto-injected mode**

It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as follows: JAUTO = 1, DISCEN = 0, JDISCEN = 0, ROVSE = 1, JOVSE = 1 and TROVSE = 1.

Dual ADC modes support when oversampling

It is possible to have oversampling enabled when working in dual ADC configuration, for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).

Summary of combined modes

Table 314 summarizes all mode combinations, including non-supported modes.

33.4.32 Dual ADC modes

In devices with two ADCs or more, dual ADC modes can be used (see Figure 33.4.33):

- ADC1 and ADC2 can be used together in dual mode (ADC1 is master)

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADCx master to the ADC slave, depending on the mode selected by the DUAL[4:0] bits of the ADC12_CCR register.

Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + regular simultaneous mode
- Regular simultaneous mode + alternate trigger mode
- Injected simultaneous mode + interleaved mode

In dual ADC mode (when bits DUAL[4:0] in the ADC12_CCR register are not equal to zero), the bits CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JAUTO of the ADC_CFGR register are shared between the master and slave ADC: the bits in the slave ADC are always equal to the corresponding bits of the master ADC.

To start a conversion in dual mode, the user must program the bits EXTEN[1:0], EXTSEL, JEXTEN[1:0], JEXTSEL of the master ADC only, to configure a software or hardware trigger, and a regular or injected trigger. (the bits EXTEN[1:0] and JEXTEN[1:0] of the slave ADC are don’t care).

In regular simultaneous or interleaved modes: once the user sets bit ADSTART or bit ADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit ADSTART or bit ADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes: once the user sets bit JADSTART or bit JADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit JADSTART or bit JADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADC12_CDR). The status bits can be also read in parallel by reading the dual-mode status register (ADC12_CSR).
1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.

2. The ADC common data register (ADC12_CDR) contains both the master and slave ADC regular converted data.
**Injected simultaneous mode**

This mode is selected by programming bits DUAL[4:0] = 00101

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL[4:0] bits in the ADC_JSQR register).

*Note:* Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In simultaneous mode, one must convert sequences with the same length and inside a sequence, the N-th conversion in master and slave must be configured with the same sampling time. Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- As the duration of the master injected sequence is equal to the duration of the slave injected one (like in Figure 254), it is possible for the software to enable only one of the two JEOS interrupts (for example master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

**Figure 254. Injected simultaneous mode on four channels: dual ADC mode**

If JDISCEN = 1, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the ongoing regular sequence and the associated delay phases are ignored. There is the same behavior for regular sequences occurring on the slave ADC.
Regular simultaneous mode with independent injected

This mode is selected by programming bits DUAL[4:0] = 00110.

This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL[4:0] bits in the ADC_CFGR register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on master or on the slave) aborts the current simultaneous conversions, which are restarted once the injected conversion is completed.

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, one must convert sequences with the same length and inside a sequence, the N-th conversion in master and slave must be configured with the same sampling time.

Software is notified by interrupts when it can read the data:

- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the slave ADC.
- As the duration of the master regular sequence is equal to the duration of the slave one (like in Figure 255), it is possible for the software to enable only one of the two EOC interrupt (ex: master EOC) and read both converted data from the Common Data register (ADC12_CDR).

It is also possible to read the regular data using the DMA. Two methods are possible:

- Using two DMA channels (one for the master and one for the slave). In this case bits DAMDF[1:0] must be kept cleared:
  - Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  - Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.
- Configuring dual ADC mode data format DAMDF[1:0] bits, which leaves one DMA channel free for other uses:
  - Configure DAMDF[1:0] = 10 or 11 (depending on resolution).
  - A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADC12_CDR)
  - A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADC12_CDR 32-bit register and the master ADC converted data is available in the lower half-word of the ADC12_CDR register.
  - both EOC flags are cleared when the DMA reads the ADC12_CDR register.

Note: When DAMDF[1:0] = 10 or 11, the user must program the same number of conversions in the master’s sequence as in the slave’s sequence. Otherwise, the remaining conversions do not generate a DMA request.
If DISCEN = 1 then each “n” simultaneous conversions of the regular sequence require a regular trigger event to occur (“n” is defined by DISCNUM).

This mode can be combined with AUTDLY mode:

- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence is started only if the common data register, ADC12_CDR (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADC12_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

It is possible to use the DMA to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multi-DMA mode is used: DAMDF[1:0] bits must be set to 10 or 11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:

- The number of conversions in the master’s sequence is equal to the number of conversions in the slave sequence.
- For each simultaneous conversion of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert and the sampling time and the resolution of each channel.

*Note:* This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

### Interleaved mode with independent injected

This mode is selected by programming bits DUAL[4:0] = 00111.

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately.
- The slave ADC starts after a delay of several-ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay which separates two conversions in interleaved mode is configured in the DELAY bits in the ADC12_CCR register. This delay starts to count after the end of the sampling phase of the master conversion. This way, an ADC cannot start a conversion if the
complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.

- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However, the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

Note: In 16-bit data format, enable only the slave EOC interrupt and read the common data register (ADC12_CDR). For 32-bit data format, enable both the slave and master EOC interrupts and read ADC12_CDR2 register. But in this case, the user must ensure that the duration of the conversions are compatible to ensure that inside the sequence, a master conversion is always followed by a slave conversion before a new master conversion restarts. It is recommended to use the MDMA mode.

It is also possible to have the regular data transferred by DMA. In this case, individual DMA requests on each ADC cannot be used and it is mandatory to use the DAMDF mode, as following:

- Configure DAMDF[1:0] = 10 or 11 (depending on resolution).
- A single DMA channel is used (the one of the masters). Configure the DMA master ADC channel to read the common ADC register (ADC12_CDR).
- A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADC12_CDR 32-bit register and the master ADC converted data is available in the lower half-word of the ADC12_CCR register.
- Both EOC flags are cleared when the DMA reads the ADC12_CCR register.
If DISCEN = 1, each "n" simultaneous conversions ("n" is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In this mode, injected conversions are supported. When injection is done (either on master or on slave), both the master and the slave regular conversions are aborted and the sequence is restarted from the master (see Figure 258 below).
**Alternate trigger mode**

This mode is selected by programming bits DUAL[4:0] = 01001.

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN[1:0] must not be 0x0.

**Injected discontinuous mode disabled (JDISCEN = 0 for both ADC)**

1. When the 1st trigger occurs, all injected master ADC channels in the group are converted.
2. When the 2nd trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.
Figure 259. Alternate trigger: injected group of each ADC

Note: Regular conversions can be enabled on one or all ADCs. In this case, the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between two trigger events must be greater than or equal to one ADC clock period. The minimum time interval between two trigger events that start conversions on the same ADC is the same as in the single ADC mode.

Injected discontinuous mode enabled (JDISCEN = 1 for both ADC)

If the injected discontinuous mode is enabled for both master and slave ADCs:
- When the 1st trigger occurs, the first injected channel of the master ADC is converted.
- When the 2nd trigger occurs, the first injected channel of the slave ADC is converted.
- And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversions.

If another external trigger occurs after all injected channels in the group have been converted, then the alternate trigger process restarts.
Combined regular/injected simultaneous mode

This mode is selected by programming bits DUAL[4:0] = 00001.

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

Note: The sequences must be converted with the same length, the N-th conversion in master and slave mode must be configured with the same sampling time inside a given sequence, or the interval between triggers has to be longer than the long conversion time of the two sequences. If the above conditions are not respected, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Combined regular simultaneous + alternate trigger mode

This mode is selected by programming bits DUAL[4:0] = 00010.

It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. Figure 261 shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.

Note: The sequences must be converted with the same length, the N-th conversion in master and slave mode must be configured with the same sampling time inside a given sequence, or the interval between triggers has to be longer than the long conversion time of the two sequences. If the above conditions are not respected, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.
If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. Figure 262 shows the behavior in this case (note that the 6th trigger is ignored because the associated alternate conversion is not complete).

**Figure 262. Case of trigger occurring during injected conversion**

Combined injected simultaneous plus interleaved

This mode is selected by programming bits DUAL[4:0] = 00011.

It is possible to interrupt an interleaved conversion with a simultaneous injected event. In this case the interleaved conversion is interrupted immediately and the simultaneous injected conversion starts. At the end of the injected sequence the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master’s one. Figure 263, Figure 264 and Figure 265 show the behavior using an example.

**Caution:** In this mode, it is mandatory to use the Common Data Register to read the regular data with a single read access. On the contrary, master-slave data coherency is not guaranteed.
Figure 263. Interleaved single channel CH0 with injected sequence CH11, CH12

Figure 264. Two interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 1: Master interrupted first

Figure 265. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 2: Slave interrupted first
DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to Figure 266: DMA Requests in regular simultaneous mode when DAMDF[1:0] = 00).

**Figure 266. DMA Requests in regular simultaneous mode when DAMDF[1:0] = 00**

In simultaneous regular and interleaved modes, it is also possible to save one DMA channel and transfer both data using a single DMA channel. For this the DAMDF[1:0] bits must be configured in the ADC12_CCR register:

- **DAMDF[1:0] = 10, 32-bit format**: A single DMA request is generated alternatively when either the master or slave EOC events have occurred. At that time, the data items are alternatively available in the ADC12_CDR2 32-bit register. This mode is used in interleaved mode and in regular simultaneous mode when resolution is above 16-bit.
  
  **Example:**
  
  Interleaved dual mode: a DMA request is generated each time a new 32-bit data is available:
  
  1st DMA request: ADC12_CDR2[31:0] = MST_ADC_DR[31:0]
  
  2nd DMA request: ADC12_CDR2[31:0] = SLV_ADC_DR[31:0]

- **DAMDF[1:0] = 10, 16-bit format**: A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADC12_CDR contains the two half-words representing two
ADC-converted data items. The slave ADC data take the upper half-word and the master ADC data take the lower half-word.

This mode is used in interleaved mode and in regular simultaneous mode when resolution is ranging from 10 to 16-bit. Any value above 16-bit in the master or the slave converter is truncated to the least 16 significant bits.

**Example:**

Interleaved dual mode: a DMA request is generated each time 2 data items are available:

1st DMA request: \( \text{ADC12}_{-}\text{CDR}[31:0] = \text{SLV}_{-}\text{ADC}_{-}\text{DR}[15:0] | \text{MST}_{-}\text{ADC}_{-}\text{DR}[15:0] \)

2nd DMA request: \( \text{ADC12}_{-}\text{CDR}[31:0] = \text{SLV}_{-}\text{ADC}_{-}\text{DR}[15:0] | \text{MST}_{-}\text{ADC}_{-}\text{DR}[15:0] \)

**Figure 267. DMA requests in regular simultaneous mode when DAMDF[1:0] = 10**

Configuration where each sequence contains only one conversion

</tbody>
</table>

Configuration where each sequence contains only one conversion

**Note:** When using multiple-ADC mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion is available.

- **DAMDF[1:0] = 11**: This mode is similar to the DAMDF[1:0] = 10. The only differences are that on each DMA request (two data items are available), two bytes representing two ADC converted data items are transferred as a half-word.

  This mode is used in interleaved and regular simultaneous mode when the result is 8-bit. A new DMA request is issued when four new 8-bit values are available.

**Example:**

Interleaved dual mode: a DMA request is generated each time 2 data items are available

DMA request:

- ADC12_CDR[7:0] = MST_ADC_DR[7:0]
- ADC12_CDR[15:8] = SLV_ADC_DR[7:0]
- ADC12_CDR[31:16] = 0x0

**Overrun detection**

In dual ADC mode (when DUAL[4:0] is not equal to 0b00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the DAMDF configuration). It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

**DMA one shot mode/ DMA circular mode when multiple-ADC mode is selected**

When DAMDF mode is selected (10 or 11), bit DMNGT[1:0] = 10 in the master ADC ADC12_CCR register must also be configured to select between DMA one shot mode and circular mode, as explained in section *Section : Managing conversions using the DMA.*
Stopping the conversions in dual ADC modes

The user must set the control bits ADSTP/JADSTP of the master ADC to stop the conversions of both ADC in dual ADC mode. The other ADSTP control bit of the slave ADC has no effect in dual ADC mode.

Once both ADCs are effectively stopped, the bits ADSTART/JADSTART of the master and slave ADCs are both cleared by hardware.

MDF mode in dual ADC mode interleaved mode

In dual ADC interleaved modes, the ADC conversion results can be transferred directly to the multifunction digital filter (MDF).

This mode is enabled by setting the bits DMNGT[1:0] = 10 in the master ADC ADC_CFGR register.

The ADC transfers alternatively the 16 least significant bits of the regular data register from the master and the slave converter to a single channel of the MDF.

The data format must be 16-bit signed:

\[
\text{ADC\_DR}[31:16] = 0x0000 \\
\text{ADC\_DR}[15] = \text{sign} \\
\text{ADC\_DR}[14:0] = \text{data}
\]

Any value above 16-bit signed format in any converter is truncated.

MDF mode in dual ADC simultaneous mode

The dual mode is not required to use MDF in dual ADC simultaneous mode since conversion data are treated by each individual channel. Single mode with same trigger source results in simultaneous conversion with MDF interface.

33.4.33 Temperature sensor

The temperature sensor can measure the device junction temperature (TJ) in the –40 to 125 °C temperature range.

The temperature sensor is internally connected ADC input channels that are used to convert the sensor output voltage to a digital value (see Section 33.4.4: ADC connectivity for more details). The sampling time for the temperature sensor analog pin must be greater than the stabilization time specified in the device datasheet.

When it is not in use, the sensor can be placed in power-down mode.

Figure 269 shows the block diagram of the temperature sensor.
Reading the temperature

To use the sensor:
1. Select the input channels to which the temperature sensor is connected (with the appropriate sampling time).
2. Program with the appropriate sampling time (refer to electrical characteristics section of the device datasheet).
3. Set the VSENSESEL bit in the ADC12_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting data in the ADC data register.
6. Calculate the actual temperature using the following formula:

\[
\text{Temperature (in } ^\circ\text{C}) = \frac{\text{TS\_CAL2\_TEMP} - \text{TS\_CAL1\_TEMP}}{\text{TS\_CAL2} - \text{TS\_CAL1}} \times (\text{TS\_DATA} - \text{TS\_CAL1}) + \text{TS\_CAL1\_TEMP}
\]

Where:
- \( \text{TS\_CAL2} \) is the temperature sensor calibration value acquired at \( \text{TS\_CAL2\_TEMP} \).
- \( \text{TS\_CAL1} \) is the temperature sensor calibration value acquired at \( \text{TS\_CAL1\_TEMP} \).
- \( \text{TS\_DATA} \) is the actual temperature sensor output value converted by ADC.

Refer to Section 33.3: ADC implementation for more information on TS\_CAL1 and TS\_CAL2 calibration points.

Note: The sensor has a startup time after waking from power-down mode and before it can output at the correct level. The ADC also has a startup time after power-on. As a result, to minimize the delay, the ADEN and VSENSESEL bits must be set simultaneously.
33.4.34 V_{BAT} supply monitoring

The V_{BAT}EN bit in the ADC12_CCR register is used to switch to the battery voltage. As the V_{BAT} voltage can be higher than V_{DDA}, the V_{BAT} pin is internally connected to a bridge divider by 4 to ensure the correct operation of the ADC. This bridge is automatically enabled when V_{BATEN} is set, to connect V_{BAT}/4 to the corresponding ADC input channels (see Section 33.4.4: ADC connectivity for more details). As a consequence, the converted digital value is one fourth of the V_{BAT} voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the V_{BAT}/4 voltage.

*Figure 270* shows the block diagram of the V_{BAT} sensing feature.

---

**Note:** The V_{BATEN} bit of the ADC12_CCR register must be set to enable the conversion of the ADC internal channels to which V_{BAT} is connected (see Section 33.4.4: ADC connectivity for more details).

33.4.35 Monitoring the internal voltage reference

The internal voltage reference can be monitored to have a reference point for evaluating the ADC V_{REF+} voltage level.

Refer to Section 33.4.4: ADC connectivity for details on the ADC input channels to which the internal voltage reference is internally connected.

The sampling time for this channel must be greater than the stabilization time specified in the device datasheet.

*Figure 270* shows the block diagram of the V_{REFINT} sensing feature.
Calculating the actual $V_{REF+}$ voltage using the internal reference voltage

The $V_{DDA}$ power supply voltage applied to the microcontroller may be subject to variation or not precisely known. The embedded internal voltage reference ($V_{REFINT}$) and its calibration data acquired by the ADC during the manufacturing process at $V_{REF+} = 3.0 \, V$ can be used to evaluate the actual $V_{REF+}$ voltage level, if $V_{REF+}$ pin is connected to a variable $V_{DDA}$ power supply.

The following formula gives the actual $V_{REF+}$ voltage supplying the device:

$$V_{REF+} = 3.0 \, V \times \frac{V_{REFINT\_CAL}}{V_{REFINT\_DATA}}$$

Where:
- $V_{REFINT\_CAL}$ is the VREFINT calibration value (refer to Section 33.3: ADC implementation for the value of $V_{REFINT\_CAL}$).
- $V_{REFINT\_DATA}$ is the actual VREFINT output value converted by ADC.

Note: The VREFEN bit of the ADC12_CCR register must be set to enable the conversion of the ADC internal channels to which VREFINT is connected (see Section 33.4.4: ADC connectivity for more details).
Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between the voltage reference $V_{REF+}$ and the voltage applied on the converted channel. For most application use cases, it is necessary to convert this ratio into a voltage independent of $V_{DDA}$. For applications where $V_{DDA}$ is known and ADC converted values are right-aligned, the following formula can be used to calculate this absolute value:

$$V_{CHANNELx} = \frac{V_{REF+}}{NUM\_CODES} \times ADC\_DATA$$

For applications where $V_{DDA}$ value is not known, the internal voltage reference and $V_{DDA}$ can be replaced by the expression provided in Section : Calculating the actual $V_{REF+}$ voltage using the internal reference voltage, resulting in the following formula:

$$V_{CHANNELx} = \frac{3.0 \times V_{REFINT\_CAL} \times ADC\_DATA}{V_{REFINT\_DATA} \times NUM\_CODES}$$

Where:
- $V_{REFINT\_CAL}$ is the $V_{REFINT}$ calibration value (refer to Section 33.3: ADC implementation for the value of $V_{REFINT\_CAL}$).
- $ADC\_DATA$ is the value measured by the ADC on channel x (right-aligned).
- $V_{REFINT\_DATA}$ is the actual $V_{REFINT}$ output value converted by the ADC.
- $NUM\_CODES$ is the number of ADC output codes. For example with 14-bit resolution, it is $2^{14} = 16384$ or with 8-bit resolution, $2^8 = 256$.

Note: If ADC measurements are done using an output format other than 14-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

33.5 ADC interrupts

For each ADC, an interrupt can be generated:
- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (OVR flag)

Separate interrupt enable bits are available for flexibility.
33.6 ADC registers (for each ADC)

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

33.6.1 ADC interrupt and status register (ADC_ISR)

Table 315. ADC interrupts

Bits 31:13  Reserved, must be kept at reset value.
Bit 12 **LDORDY**: ADC voltage regulator ready
- This bit is set by hardware. It indicates that the ADC internal supply is ready. The ADC is available after $t_{ADCVREG\_SETUP}$ time.
  0: ADC voltage regulator disabled
  1: ADC voltage regulator enabled

Bits 11:10 **Reserved, must be kept at reset value.**

Bit 9 **AWD3**: Analog watchdog 3 flag
- This bit is set by hardware when the converted voltage crosses the values programmed in the fields $LT3[7:0]$ and $HT3[7:0]$ of ADC_LTR3 & ADC_HTR3 register. It is cleared by software writing 1 to it.
  0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)
  1: Analog watchdog 3 event occurred

Bit 8 **AWD2**: Analog watchdog 2 flag
- This bit is set by hardware when the converted voltage crosses the values programmed in the fields $LT2[7:0]$ and $HT2[7:0]$ of ADC_LTR2 & ADC_HTR2 register. It is cleared by software writing 1 to it.
  0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)
  1: Analog watchdog 2 event occurred

Bit 7 **AWD1**: Analog watchdog 1 flag
- This bit is set by hardware when the converted voltage crosses the values programmed in the fields $LT1[11:0]$ and $HT1[11:0]$ of ADC_LTR1, & ADC_HTR1 register. It is cleared by software writing 1 to it.
  0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)
  1: Analog watchdog 1 event occurred

Bit 6 **JEOS**: Injected channel end of sequence flag
- This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.
  0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)
  1: Injected conversions complete

Bit 5 **JEOC**: Injected channel end of conversion flag
- This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register
  0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)
  1: Injected channel conversion complete

Bit 4 **OVR**: ADC overrun
- This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.
  0: No overrun occurred (or the flag event was already acknowledged and cleared by software)
  1: Overrun has occurred
Bit 3 **EOS**: End of regular sequence flag  
This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.  
0: Regular conversions sequence not complete (or the flag event was already acknowledged and cleared by software)  
1: Regular conversions sequence complete

Bit 2 **EOC**: End of conversion flag  
This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register  
0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)  
1: Regular channel conversion complete

Bit 1 **EOSMP**: End of sampling flag  
This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.  
0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)  
1: End of sampling phase reached

Bit 0 **ADRDY**: ADC ready  
This bit is set by hardware after the ADC has been enabled (bit ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.  
It is cleared by software writing 1 to it.  
0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)  
1: ADC is ready to start conversion

### 33.6.2 ADC interrupt enable register (ADC_IER)

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **AWD3IE**: Analog watchdog 3 interrupt enable  
This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.  
0: Analog watchdog 3 interrupt disabled  
1: Analog watchdog 3 interrupt enabled  

*Note: Software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*
Bit 8  **AWD2IE**: Analog watchdog 2 interrupt enable
This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.
0: Analog watchdog 2 interrupt disabled
1: Analog watchdog 2 interrupt enabled
*Note: Software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 7  **AWD1IE**: Analog watchdog 1 interrupt enable
This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.
0: Analog watchdog 1 interrupt disabled
1: Analog watchdog 1 interrupt enabled
*Note: Software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 6  **JEOSIE**: End of injected sequence of conversions interrupt enable
This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.
0: JEOS interrupt disabled
1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.
*Note: Software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

Bit 5  **JEOCIE**: End of injected conversion interrupt enable
This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.
0: JEOC interrupt disabled.
1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.
*Note: Software is allowed to write this bit only when JADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 4  **OVRIE**: Overrun interrupt enable
This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.
0: Overrun interrupt disabled
1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.
*Note: Software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 3  **EOSIE**: End of regular sequence of conversions interrupt enable
This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.
0: EOS interrupt disabled
1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.
*Note: Software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 2  **EOCIE**: End of regular conversion interrupt enable
This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.
0: EOC interrupt disabled.
1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.
*Note: Software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*
Bit 1 **EOSMPIE**: End of sampling flag interrupt enable for regular conversions
This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.
0: EOSMP interrupt disabled.
1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.
*Note: Software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 0 **ADRDYIE**: ADC ready interrupt enable
This bit is set and cleared by software to enable/disable the ADC Ready interrupt.
0: ADRDY interrupt disabled
1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.
*Note: Software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 31 **ADCAL**: ADC calibration
This bit is set by software to start the ADC calibration.
It is cleared by hardware after calibration is complete.
0: Calibration complete
1: Write 1 to calibrate the ADC. Read at 1 means that a calibration in progress.
*Note: The software is allowed to launch a calibration by setting ADCAL only when ADEN = 0.*

Bit 30 Reserved, must be kept at reset value.

Bit 29 **DEEPPWD**: Deep-power-down enable
This bit is set and cleared by software to put the ADC in Deep-power-down mode.
0: ADC not in deep-power down
1: ADC in Deep-power-down (default reset state)
*Note: The software is allowed to write this bit only when the ADC is disabled (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).*
Bit 28  **ADVREGEN**: ADC voltage regulator enable
This bit is set by software to enable the ADC voltage regulator. Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.

0: ADC Voltage regulator disabled
1: ADC Voltage regulator enabled.

For more details about the ADC voltage regulator enable and disable sequences, refer to Section 33.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).
The software can program this bitfield only when the ADC is disabled (ADCAL = 0, JADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 27:24  **CALINDEX[3:0]**: Calibration factor
This bitfield controls the calibration factor to be read or written. Calibration index 0 is dedicated to single-ended and differential offsets, calibration index 1 to 7 to the linearity calibration factors, and index 8 to the internal offset:

0000: Offset calibration factor
0001: Linearity calibration factor 1
0010: Linearity calibration factor 2
0011: Linearity calibration factor 3
0100: Linearity calibration factor 4
0101: Linearity calibration factor 5
0110: Linearity calibration factor 6
0111: Linearity calibration factor 7 and internal offset (write access only)
1000: Internal offset (read access only)
1001: Calibration mode selection
Others: Reserved, must not be used

Note: ADC_CALFACT2[31:0] correspond to the location of CALINDEX[3:0] calibration factor data (see Section 33.4.8: Calibration (ADCAL, ADCALLIN, ADC_CALFACT) for details).

Bits 23:17  Reserved, must be kept at reset value.

Bit 16  **ADCALLIN**: Linearity calibration
This bit is set and cleared by software to enable the linearity calibration.

0: Writing ADCAL launches a calibration without the linearity calibration.
1: Writing ADCAL launches a calibration with the linearity calibration.

Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 15:6  Reserved, must be kept at reset value.

Bit 5  **JADSTP**: ADC stop of injected conversion command
This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command).
It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

0: No ADC stop injected conversion command ongoing
1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: The software is allowed to set JADSTP only when JADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC).
In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)
Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command). It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

0: No ADC stop regular conversion command ongoing
1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

*Note:* The software is allowed to set ADSTP only when ADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

Bit 3 **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN[1:0], a conversion starts immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

– in single conversion mode when software trigger is selected (JEXTSEL = 0x0): at the assertion of the end of injected conversion sequence (JEOS) flag.
– in all cases: after the execution of the JADSTP command, at the same time as JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.
1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

*Note:* The software is allowed to set JADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared).

Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN[1:0], a conversion starts immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

– In single conversion mode (CONT = 0, DISCEN = 0) when software trigger is selected (EXTEN[1:0] = 0x0): at the assertion of the end of regular conversion sequence (EOS) flag.
– In discontinuous conversion mode (CONT = 0, DISCEN = 1), when the software trigger is selected (EXTEN[1:0] = 0x0): at the end of conversion (EOC) flag.
– in all other cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.
1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

*Note:* The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)
Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).
It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).
0: no ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

**Note**: The software is allowed to set ADDIS only when ADEN = 1 and both ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the flag ADRDY has been set.
It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.
0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

**Note**: The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)

Bit 31 Reserved, must be kept at reset value.

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog 1 channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.
00000: ADC analog input channel-0 monitored by AWD1
00001: ADC analog input channel-1 monitored by AWD1
.....
10011: ADC analog input channel-19 monitored by AWD1

Others: Reserved, must not be used

**Note**: The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers. Software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
Bit 25 **JAUTO**: Automatic injected group conversion
   This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.
   0: Automatic injected group conversion disabled
   1: Automatic injected group conversion enabled
   *Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no regular nor injected conversion is ongoing).*

Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels
   This bit is set and cleared by software
   0: Analog watchdog 1 disabled on injected channels
   1: Analog watchdog 1 enabled on injected channels
   *Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels
   This bit is set and cleared by software
   0: Analog watchdog 1 disabled on regular channels
   1: Analog watchdog 1 enabled on regular channels
   *Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels
   This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels
   0: Analog watchdog 1 enabled on all channels
   1: Analog watchdog 1 enabled on a single channel
   *Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 21 Reserved, must be kept at reset value.

Bit 20 **JDISCEN**: Discontinuous mode on injected channels
   This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.
   0: Discontinuous mode on injected channels disabled
   1: Discontinuous mode on injected channels enabled
   *Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing). It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.*

Bits 19:17 **DISCNUM[2:0]**: Discontinuous mode channel count
   These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.
   000: 1 channel
   001: 2 channels
   ...
   111: 8 channels
   *Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*
Bit 16 **DISCEN**: Discontinuous mode for regular channels
This bit is set and cleared by software to enable/disable discontinuous mode for regular channels.
0: Discontinuous mode for regular channels disabled
1: Discontinuous mode for regular channels enabled

*Note:* It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode
This bit is set and cleared by software to enable/disable the auto-delayed conversion mode.
0: Auto-delayed conversion mode off
1: Auto-delayed conversion mode on

*Note:* The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions
This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.
0: Single conversion mode
1: Continuous conversion mode

*Note:* It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 12 **OVRMOD**: Overrun Mode
This bit is set and cleared by software and configure the way data overrun is managed.
0: ADC_DR register is preserved with the old data when an overrun is detected.
1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

*Note:* The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels
These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.
00: Hardware trigger detection disabled (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).
Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group
These bits select the external event used to trigger the start of conversion of a regular group:
- 00000: adc_ext_trg0
- 00001: adc_ext_trg1
...  
Refer to the ADC external trigger for regular channels in Section 33.4.2: ADC pins and internal signals for details on trigger mapping.

*Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **RES[1:0]**: Data resolution
These bits are written by software to select the resolution of the conversion.
- 00: 14 bits
- 01: 12 bits
- 10: 10 bits
- 11: 8 bits

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 1:0 **DMNGT[1:0]**: Data management configuration
This bit is set and cleared by software to select how the ADC interface output data are managed.
- 00: Regular conversion data stored in DR only
- 01: DMA One-shot mode selected
- 10: MDF mode selected
- 11: DMA circular mode selected

*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

RM0456 Rev 5 1339/3637
Bits 31:28 **LSHIFT[3:0]**: Left shift factor
   - This bitfield is set and cleared by software to define the left shifting applied to the final result with or without oversampling.
   - 0000: No left shift
   - 0001: 1-bit left shift
   - 0010: 2-bit left shift
   - 0011: 3-bit left shift
   - 0100: 4-bit left shift
   - 0101: 5-bit left shift
   - 0110: 6-bit left shift
   - 0111: 7-bit left shift
   - 1000: 8-bit left shift
   - 1001: 9-bit left shift
   - 1010: 10-bit left shift
   - 1011: 11-bit left shift
   - 1100: 12-bit left shift
   - 1101: 13-bit left shift
   - 1110: 14-bit left shift
   - 1111: 15-bit left shift
   - **Note:** The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 27 **LFTRIG**: Low-frequency trigger
   - This bit is set and cleared by software
   - 0: Low-frequency trigger mode disabled
   - 1: Low-frequency trigger mode enabled
   - **Note:** The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 26 Reserved, must be kept at reset value.

Bits 25:16 **OSR[9:0]**: Oversampling ratio
   - This bitfield is set and cleared by software to define the oversampling ratio.
   - 0: 1x (no oversampling)
   - 1: 2x
   - 2: 3x
   - ...
   - 1023: 1024x
   - **Note:** The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 15 **SMPTRIG**: Sampling time control trigger mode
   - This bit is set and cleared by software to enable the sampling time control trigger mode.
   - 0: Sampling time control trigger mode disabled
   - 1: Sampling time control trigger mode enabled
   - The sampling time starts on the trigger rising edge, and the conversion on the trigger falling edge.
   - EXTEN[1:0] bits must be set to 01. BULB bit must not be set when the SMPTRIG bit is set.
   - When EXTEN[1:0] bits is set to 00, set SWTRIG to start the sampling and clear SWTRIG bit to start the conversion.
   - **Note:** The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).
Bit 14  **SWTRIG**: Software trigger bit for sampling time control trigger mode

This bit is set and cleared by software to enable the bulb sampling mode.

0: Software trigger starts the conversion for sampling time control trigger mode
1: Software trigger starts the sampling for sampling time control trigger mode.

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 13  **BULB**: Bulb sampling mode

This bit is set and cleared by software to select the bulb sampling mode.

0: Bulb sampling mode disabled
1: Bulb sampling mode enabled. The sampling period starts just after the previous end of the conversion.

**SMPTRIG** bit must not be set when the **BULB** bit is set.

The very first ADC conversion is performed with the sampling time specified in SMPx bits.

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 12:11 Reserved, must be kept at reset value.

Bit 10  **ROVSM**: Regular oversampling mode

This bit is set and cleared by software to select the regular oversampling mode.

0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)
1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 9  **TROVS**: Triggered regular oversampling

This bit is set and cleared by software to enable triggered oversampling

0: All oversampled conversions for a channel are done consecutively following a trigger
1: Each oversampled conversion for a channel needs a new trigger

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 8:5  **OVSS[3:0]**: Oversampling right shift

This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.

0000: No right shift
0001: 1-bit right shift
0010: 2-bit right shift
0011: 3-bit right shift
0100: 4-bit right shift
0101: 5-bit right shift
0110: 6-bit right shift
0111: 7-bit right shift
1000: 8-bit right shift
1001: 9-bit right shift
1010: 10-bit right shift
1011: 11-bit right shift
Others: Reserved, must not be used.

*Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).*
Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **JOVSE**: Injected oversampling enable
This bit is set and cleared by software to enable injected oversampling.
0: Injected oversampling disabled
1: Injected oversampling enabled

*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)*

Bit 0 **ROVSE**: Regular oversampling enable
This bit is set and cleared by software to enable regular oversampling.
0: Regular oversampling disabled
1: Regular oversampling enabled

*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)*

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]**: Channel x sampling time selection (x = 9 to 0)
These bits are written by software to select the sampling time individually for each channel.
During sample cycles, the channel selection bits must remain unchanged.
000: 5 ADC clock cycles
001: 6 ADC clock cycles
010: 12 ADC clock cycles
011: 20 ADC clock cycles
100: 36 ADC clock cycles
101: 68 ADC clock cycles
110: 391 ADC clock cycles
111: 814 ADC clock cycles

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 3:0 **L[3:0]:** Regular channel sequence length

These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

0000: 1 conversion
0001: 2 conversions
...
1111: 16 conversions

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]:** 9th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 9th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]:** 8th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 8th in the regular conversion sequence

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]:** 7th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 7th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]:** 6th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 6th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.
Bits 4:0 **SQ5[4:0]**: 5th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 5th in the regular conversion sequence.

*Note*: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

### 33.6.11 ADC regular sequence register 3 (ADC_SQR3)

Address offset: 0x38
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ14[4:0]**: 14th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 14th in the regular conversion sequence.

*Note*: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ13[4:0]**: 13th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 13th in the regular conversion sequence.

*Note*: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ12[4:0]**: 12th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 12th in the regular conversion sequence.

*Note*: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ11[4:0]**: 11th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 11th in the regular conversion sequence.

*Note*: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.
Bits 4:0 **SQ10[4:0]**: 10th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 10th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

### 33.6.12 ADC regular sequence register 4 (ADC_SQR4)

**Bits 31:11** Reserved, must be kept at reset value.

**Bits 10:6** **SQ16[4:0]**: 16th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 16th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

**Bits 4:0** **SQ15[4:0]**: 15th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 15th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

</tbody>
</table>

Bits 31:27 JSQ4[4:0]: 4th conversion in the injected sequence
These bits are written by software with the channel number (0..19) assigned as the 4th in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 JSQ3[4:0]: 3rd conversion in the injected sequence
These bits are written by software with the channel number (0..19) assigned as the 3rd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 JSQ2[4:0]: 2nd conversion in the injected sequence
These bits are written by software with the channel number (0..19) assigned as the 2nd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 JSQ1[4:0]: 1st conversion in the injected sequence
These bits are written by software with the channel number (0..19) assigned as the 1st in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 8:7 JEXTEN[1:0]: External trigger enable and polarity selection for injected channels
These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.
00: Hardware trigger detection disabled (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).
Bits 6:2 **JEXTSEL[4:0]**: External trigger selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

00000: adc_jext_trg0
00001: adc_jext_trg1
...

Refer to the ADC external trigger for injected channels in Section 33.4.2: ADC pins and internal signals for details on trigger mapping.

*Note*: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 1:0 **JL[1:0]**: Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion
01: 2 conversions
10: 3 conversions
11: 4 conversions

*Note*: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

### 33.6.15 ADC offset y register (ADC_OFRy)

Address offset: 0x60 + 0x04 * (y - 1), (y = 1 to 4)

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:27 <strong>OFFSET_CH[4:0]</strong>: Channel selection for the data offset y</th>
</tr>
</thead>
<tbody>
<tr>
<td>These bits are written by software to define the channel to which the offset programmed into OFFSETy[25:0] bits applies.</td>
</tr>
</tbody>
</table>

*Note*: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

If OFFSETy_EN bit is set, it is not allowed to select the same channel in different ADC_OFRy registers.

Bit 26 **SSAT**: Signed saturation enable

This bit is written by software to enable or disable the Signed saturation feature.

(see Section: Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT) for details).

0: Offset is subtracted maintaining data integrity and extending converted data size (9-bit and 15-bit signed format).
1: Offset is subtracted and result is saturated to maintain converted data size.

*Note*: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
Bit 25 **USAT**: Unsigned saturation enable

This bit is written by software to enable or disable the unsigned saturation feature.

0: Offset is subtracted maintaining data integrity and keeping converted data size
1: Offset is subtracted and result is saturated to maintain converted data size.

**Note:** The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 24 **POSOFF**: offset sign

This bit is set and cleared by software to enable the positive offset.

0: Negative offset
1: Positive offset

**Note:** The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 23:0 **OFFSET[23:0]**: Data offset y for the channel programmed into OFFSETy.CH[4:0] bits

These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (regular or injected). The channel to which the data offset y applies must be programmed to the OFFSETy.CH[4:0] bits. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

When OFFSETy[21:0] bitfield is reset, the offset compensation is disabled.

**Note:** The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

If several offsets (OFFSETy) point to the same channel, only the offset with the lowest y value is considered for the subtraction.

For example, if OFFSET1.CH[4:0] = 4 and OFFSET2.CH[4:0] = 4, this is OFFSET1[25:0] that is subtracted when converting channel 4.

### 33.6.16 ADC gain compensation register (ADC_GCOMP)

**Address offset:** 0x70

**Reset value:** 0x0000 0000

<p>| | | | | | | | | | | | | | | | |</p>
<table>
<thead>

<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

**Bits 30:14** Reserved, must be kept at reset value.

Bit 31 **GCOMP**: Gain compensation mode

This bit is set and cleared by software to enable the gain compensation mode.

0: Regular ADC operating mode
1: Gain compensation enabled and applied on all channels

**Note:** The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).
Bits 13:0 **GCOMPCOEFF[13:0]**: Gain compensation coefficient
These bits are set and cleared by software to program the gain compensation coefficient.

- 00 1000 0000 0000: gain factor of 0.5
- ... 
- 01 0000 0000 0000: gain factor of 1
- 10 0000 0000 0000: gain factor of 2
- 11 0000 0000 0000: gain factor of 3
- ...

The coefficient is divided by 4096 to get the gain factor ranging from 0 to 3.999756.

**Note:** This gain compensation is only applied when GCOMP bit of ADCx_CFGR2 register is 1.

### 33.6.17 ADC injected data register (ADC_JDRy)

Address offset: 0x80 + 0x04 * (y - 1), (y = 1 to 4)
Reset value: 0x0000 0000

![ADC Injected Data Register](image)

<table>
<thead>
<tr>
<th>Bits 31:0</th>
<th><strong>JDATA[31:16]</strong></th>
<th><strong>JDATA[15:0]</strong></th>

<td>r w r w r w</td>
</tr>
</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.
Bits 19:0 **AWD2CH[19:0]**: Analog watchdog 2 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

- AWD2CH[i] = 0: ADC analog input channel-i is not monitored by AWD2
- AWD2CH[i] = 1: ADC analog input channel-i is monitored by AWD2

> When AWD2CH[19:0] = 000..0, the analog Watchdog 2 is disabled

**Note:** The channels selected by AWD2CH must be also selected into the SQRi or JSQRi registers.

Software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

### 33.6.19 ADC analog watchdog 3 configuration register (ADC_AWD3CR)

**Address offset:** 0xA4

**Reset value:** 0x0000 0000

**AWD3CH[15:0]**

Bits 31:20 **Reserved, must be kept at reset value.**

**Bits 19:0** **AWD3CH[19:0]**: Analog watchdog 3 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.

- AWD3CH[i] = 0: ADC analog input channel-i is not monitored by AWD3
- AWD3CH[i] = 1: ADC analog input channel-i is monitored by AWD3

> When AWD3CH[19:0] = 000..0, the analog Watchdog 3 is disabled

**Note:** The channels selected by AWD3CH must be also selected into the SQRi or JSQRi registers.

The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 24:0 **HTR3[24:0]**: Analog watchdog 3 higher threshold  
These bits are written by software to define the higher threshold for the analog watchdog 3.  
Refer to Section 33.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH,  
AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy).

### 33.6.26 ADC differential mode selection register (ADC_DIFSEL)

Address offset: 0xC0  
Reset value: 0x0000 0000

</tr>
</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **DIFSEL[19:0]**: Differential mode for channels 19 to 0  
These bits are set and cleared by software. They allow selecting if a channel is configured as single-ended or differential mode.  
DIFSEL[i] = 0: ADC analog input channel-i is configured in single-ended mode  
DIFSEL[i] = 1: ADC analog input channel-i is configured in differential mode  
*Note:* The software is allowed to write these bits only when the ADC is disabled (ADCAL = 0,  
JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).
33.6.27  ADC user control register (ADC_CALFACT)

Address offset: 0xC4
Reset value: 0x0000 0000

| Bit 31-26 | Reserved, must be kept at reset value. |
| Bit 25   | CAPTURE_COEF: Calibration factor capture enable bit |
|          | This bit enables the internal calibration factor capture. |
|          | 0: Calibration factor not captured |
|          | 1: Calibration factor available in CALFACT[31:0] bits, the calibration factor index being defined by CALINDEX[3:0] bits |
| Bit 24   | LATCH_COEF: Calibration factor latch enable bit |
|          | This bit latches the calibration factor in the CALFACT[31:0] bits. |
|          | 0: No effect |
|          | 1: Calibration factor latched in the analog block on LATCH_COEF bit transition from 0 to 1. Prior to latching the calibration factor, CALFACT[31:0] bits must be programmed with the content of CALINDEX[3:0] bits |
| Bit 16   | VALIDITY: Delayed write access status bit |
|          | This bit indicates the communication status between the ADC digital and analog blocks. |
|          | 0: Operation still in progress |
|          | 1: Operation complete |
| Bits 15-8| I_APB_DATA[7:0]: Delayed write access data |
|          | This bitfield contains the data that are being written during delayed write accesses. |
| Bits 7-0 | I_APB_ADDR[7:0]: Delayed write access address |
|          | This bitfield contains the address that is being written during delayed write accesses. |

33.6.28  ADC calibration factor register (ADC_CALFACT2)

Address offset: 0xC8
Reset value: 0x0000 0000

| Bit 31-16 | CALFACT[31:16] |
| Bit 15-0  | CALFACT[15:0]  |

1356/3637  RM0456 Rev 5
33.7  ADC common registers

These registers define the control and status registers common to master and slave ADCs.

33.7.1  ADC common status register (ADC12_CSR)

Address offset: 0x00
Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

This register provides an image of the status bits of the different ADCs. Nevertheless, it is read-only and does not clear the different status bits. Instead, each status bit must be cleared by writing 1 to it in the corresponding ADC_ISR register.

ADC1 and ADC2 are controlled by the same interface.

This register is available only the devices that support dual mode (see Section 33.3: ADC implementation).

Bits 31:29  Reserved, must be kept at reset value.

Bit 28  **LDORDY_SLV**: ADC voltage regulator ready flag of the slave ADC
This bit is a copy of the LDORDY bit of the corresponding ADCx+1_ISR register.

Bits 27:26  Reserved, must be kept at reset value.

Bit 25  **AWD3_SLV**: Analog watchdog 3 flag of the slave ADC
This bit is a copy of the AWD3 bit in the corresponding ADCx+1_ISR register.

Bit 24  **AWD2_SLV**: Analog watchdog 2 flag of the slave ADC
This bit is a copy of the AWD2 bit in the corresponding ADCx+1_ISR register.
Bit 23  AWD1_SLV: Analog watchdog 1 flag of the slave ADC
This bit is a copy of the AWD1 bit in the corresponding ADCx+1_ISR register.

Bit 22  JEOS_SLV: End of injected sequence flag of the slave ADC
This bit is a copy of the JEOS bit in the corresponding ADCx+1_ISR register.

Bit 21  JEOC_SLV: End of injected conversion flag of the slave ADC
This bit is a copy of the JEOC bit in the corresponding ADCx+1_ISR register.

Bit 20  OVR_SLV: Overrun flag of the slave ADC
This bit is a copy of the OVR bit in the corresponding ADCx+1_ISR register.

Bit 19  EOS_SLV: End of regular sequence flag of the slave ADC
This bit is a copy of the EOS bit in the corresponding ADCx+1_ISR register.

Bit 18  EOC_SLV: End of regular conversion of the slave ADC
This bit is a copy of the EOC bit in the corresponding ADCx+1_ISR register.

Bit 17  EOSMP_SLV: End of sampling phase flag of the slave ADC
This bit is a copy of the EOSMP2 bit in the corresponding ADCx+1_ISR register.

Bit 16  ADRDY_SLV: Slave ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADCx+1_ISR register.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12  LDORDY_MST: ADC voltage regulator ready flag of the master ADC
This bit is a copy of the LDORDY bit of the corresponding ADC_ISR register.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9   AWD3_MST: Analog watchdog 3 flag of the master ADC
This bit is a copy of the AWD3 bit in the corresponding ADCx_ISR register.

Bit 8   AWD2_MST: Analog watchdog 2 flag of the master ADC
This bit is a copy of the AWD2 bit in the corresponding ADCx_ISR register.

Bit 7   AWD1_MST: Analog watchdog 1 flag of the master ADC
This bit is a copy of the AWD1 bit in the corresponding ADCx_ISR register.

Bit 6   JEOS_MST: End of injected sequence flag of the master ADC
This bit is a copy of the JEOS bit in the corresponding ADCx_ISR register.

Bit 5   JEOC_MST: End of injected conversion flag of the master ADC
This bit is a copy of the JEOC bit in the corresponding ADCx_ISR register.

Bit 4   OVR_MST: Overrun flag of the master ADC
This bit is a copy of the OVR bit in the corresponding ADCx_ISR register.

Bit 3   EOS_MST: End of regular sequence flag of the master ADC
This bit is a copy of the EOS bit in the corresponding ADCx_ISR register.

Bit 2   EOC_MST: End of regular conversion of the master ADC
This bit is a copy of the EOC bit in the corresponding ADCx_ISR register.

Bit 1   EOSMP_MST: End of Sampling phase flag of the master ADC
This bit is a copy of the EOSMP bit in the corresponding ADCx_ISR register.

Bit 0   ADRDY_MST: Master ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADCx_ISR register.
33.7.2 ADC system control register (ADC12_CCR)

Address offset: 0x08
Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

ADC12_CCR is common to ADC1 and ADC2. ADC2 is not available on all devices (refer to Section 33.3: ADC implementation).

</table>

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **VBATEN**: VBAT enable
This bit is set and cleared by software to control the $V_{BAT}$ channel.
0: $V_{BAT}$ channel disabled
1: $V_{BAT}$ channel enabled

*Note: The software is allowed to write this bit only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).*

Bit 23 **VSENSESEL**: Temperature sensor voltage selection
This bit is set and cleared by software to control the temperature sensor channel.
0: Temperature sensor channel disabled
1: Temperature sensor channel enabled

*Note: The software is allowed to write this bit only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).*

Bit 22 **VREFEN**: VREFINT enable
This bit is set and cleared by software to enable/disable the $V_{REFINT}$ buffer.
0: $V_{REFINT}$ channel disabled
1: $V_{REFINT}$ channel enabled

*Note: The software is allowed to write this bit only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).*
Bits 21:18 **PRESC[3:0]: ADC prescaler**
These bits are set and cleared by software to select the frequency of the ADC clock. The clock is common to all ADCs.
- 0000: input ADC clock not divided
- 0001: input ADC clock divided by 2
- 0010: input ADC clock divided by 4
- 0011: input ADC clock divided by 6
- 0100: input ADC clock divided by 8
- 0101: input ADC clock divided by 10
- 0110: input ADC clock divided by 12
- 0111: input ADC clock divided by 16
- 1000: input ADC clock divided by 32
- 1001: input ADC clock divided by 64
- 1010: input ADC clock divided by 128
- 1011: input ADC clock divided by 256
Others: Reserved, must not be used

*Note: The software is allowed to write this bit only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).*

Bits 17:16 Reserved, must be kept at reset value.

Bits 15:14 **DAMDF[1:0]: Dual ADC mode data format**
This bit-field is set and cleared by software. It specifies the data format in the common data register ADC12_CDR.
- 00: Dual ADC mode without data packing (ADC12_CDR and ADC12_CDR2 registers not used).
- 01: Reserved.
- 10: Data formatting mode for 32 down to 10-bit resolution
- 11: Data formatting mode for 8-bit resolution

*Note: This register is available only the devices that support dual mode (see Section 33.3: ADC implementation).*

The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:8 **DELAY[3:0]: Delay between the end of the master ADC sampling phase and the beginning of the slave ADC sampling phase.**
These bits are set and cleared by software. These bits are used in dual interleaved modes. Refer to Table 316 for the value of ADC resolution versus DELAY bits values.

*Note: This register is available only the devices that support dual mode (see Section 33.3: ADC implementation).*

The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 7:5 Reserved, must be kept at reset value.
Bits 4:0 **DUAL[4:0]**: Dual ADC mode selection

These bits are written by software to select the operating mode. All the ADCs are independent:

- **00000**: Independent mode

The configurations 00001 to 01001 correspond to the following operating modes: dual mode, master and slave ADCs working together:

- **00001**: Combined regular simultaneous + injected simultaneous mode
- **00010**: Combined regular simultaneous + alternate trigger mode
- **00011**: Combined interleaved mode + injected simultaneous mode
- **00100**: Reserved.
- **00101**: Injected simultaneous mode only
- **00110**: Regular simultaneous mode only
- **00111**: Interleaved mode only
- **01001**: Alternate trigger mode only

All other combinations are reserved and must not be programmed

**Note:** This register is available only on the devices that support dual mode (see Section 33.3: ADC implementation).

The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

**RDATA_SLV[15:0]**

Bits 31:16 **RDATA_SLV[15:0]**: Regular data of the slave ADC
In dual mode, these bits contain the regular data of the slave ADC. Refer to Section 33.4.32: Dual ADC modes.

The data alignment is applied as described in Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT)

Bits 15:0 **RDATA_MST[15:0]**: Regular data of the master ADC.
In dual mode, these bits contain the regular data of the master ADC. Refer to Section 33.4.32: Dual ADC modes.

The data alignment is applied as described in Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT)

In DAMDF[1:0] = 11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

33.7.4 **ADC common regular data register for 32-bit dual mode (ADC12_CDR2)**

Address offset: 0x10
Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

ADC1 and ADC2 are controlled by the same interface.

This register is available only the devices that support dual mode (see Section 33.3: ADC implementation).

Bits 31:0 **RDATA_ALT[31:0]**: Regular data of the master/slave alternated ADCs
In dual mode, these bits alternatively contains the regular 32-bit data of the master and the slave ADC. Refer to Section 33.4.32: Dual ADC modes.
The data alignment is applied as described in Section: Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT).

34 Analog-to-digital converter (ADC4)

34.1 Introduction

The 12-bit ADC is a successive approximation analog-to-digital converter. It has up to 25 multiplexed channels enabling it to measure signals from up to 19 external sources and 6 internal sources. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 16-bit data register.

The analog watchdog feature enables the application to detect if the input voltage goes outside the user-defined higher or lower thresholds.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

A built-in hardware oversampler allows improving analog performances while off-loading the related computational burden from the CPU.

34.2 ADC main features

- **High performance**
  - 12-bit, 10-bit, 8-bit or 6-bit configurable resolution
  - ADC conversion time: 0.4 µs for 12-bit resolution (2.5 Msps), faster conversion times can be obtained by lowering resolution.
  - Self-calibration
  - Programmable sampling time
  - Data alignment with built-in data coherency
  - DMA support
- **Low-power**
  - The application can reduce the bus clock frequency for low-power operation while still keeping optimum ADC performance. For example, 0.4 µs conversion time is kept, whatever the bus clock frequency
  - Wait mode: prevents ADC overrun in applications with low bus clock frequency
  - Auto-off mode: ADC is automatically powered off except during the active conversion phase. This dramatically reduces the power consumption of the ADC.
- **Autonomous mode**
  - Conversion and DMA transfers supported in Stop mode
  - Wake-up from Stop on ADC interrupts
  - Enter and exit from Deep-power-down mode managed automatically
- **Analog input channels**
  - up to 19 external analog inputs
  - 1 channel for the internal temperature sensor \(V_{\text{SENSE}}\)
  - 1 channel for the internal reference voltage \(V_{\text{REFINT}}\)
  - 1 channel for the internal digital core voltage \(V_{\text{CORE}}\)
  - 1 channel for monitoring the external VBAT power supply pin
• Connection to DAC internal channels
• Start-of-conversion can be initiated:
  – By software
  – By hardware triggers with configurable polarity (timer events or GPIO input events)
• Conversion modes
  – Can convert a single channel or can scan a sequence of channels.
  – Single mode converts selected inputs once per trigger
  – Continuous mode converts selected inputs continuously
  – Discontinuous mode
• Interrupt generation at the end of sampling, end of conversion, end of sequence conversion, and in case of analog watchdog or overrun events
• Analog watchdog
• Oversampler
  – 16-bit data register
  – Oversampling ratio adjustable from 2 to 256x
  – Programmable data shift up to 8 bits
• ADC input range: $V_{SSA} \leq V_{IN} \leq V_{REF+}$

34.4.3 ADC voltage regulator (ADVREGEN)

The ADC has a specific internal voltage regulator which must be enabled and stable before using the ADC.

The ADC internal voltage regulator can be enabled by setting ADVREGEN bit to 1 in the ADC_CR register. The software must wait for the ADC voltage regulator startup time \(t_{ADCVREG\_SETUP}\) before launching a calibration or enabling the ADC. The LDO status can be verified by checking the LDORDY bit in ADC_ISR register.

After ADC operations are complete, the ADC can be disabled (ADEN = 0). It is then possible to save additional power by disabling the ADC voltage regulator (refer to Section: ADC voltage regulator disable sequence).

Note: When the internal voltage regulator is disabled, the internal analog calibration factor is reset, and a new calibration must be performed.

ADC voltage regulator enable sequence

To enable the ADC voltage regulator, follow the sequence below:
1. Clear the LDORDY bit in ADC_ISR register by programming this bit to 1.
2. Set the ADVREGEN bit to 1 in ADC_CR register.
3. Wait until LDORDY = 1 in the ADC_ISR register (LDORDY is set after the ADC voltage regulator startup time). This can be handled by interrupt if the interrupt is enabled by setting the LDORDYIE bit in the ADC_IER register.

ADC voltage regulator disable sequence

To disable the ADC voltage regulator, follow the sequence below:
1. Make sure that the ADC is disabled (ADEN = 0).
2. Clear ADVREGEN bit in ADC_CR register.
3. Clear the LDORDY bit in ADC_ISR register by programming this bit to 1 (optional).

34.4.4 Calibration (ADCAL)

The ADC has a calibration feature. During the procedure, the ADC calculates a calibration factor which is internally applied to the ADC until the next ADC power-off. The application must not use the ADC during calibration and must wait until it is complete.

The calibration must be performed before starting analog-to-digital conversion. It removes the offset error which may vary from chip to chip due to process variation, supply voltage and temperature.

The calibration is initiated by software by setting bit ADCAL to 1. It can be initiated only when all the following conditions are met:
- the ADC voltage regulator is enabled (ADVREGEN = 1 and LDORDY = 1),
- the ADC is disabled (ADEN = 0), and
- the auto-off mode is disabled (AUTOFF = 0).

ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. After this, the calibration factor can be read from the ADC_DR register (from bits 6 to 0).
The internal analog calibration is kept if the ADC is disabled (ADEN = 0). When the ADC operating conditions change (VDDA changes are the main contributor to ADC offset variations and temperature change to a lesser extent), it is recommended to re-run a calibration cycle. It is recommended to recalculate when VREF+ voltage changed more than 10%.

The calibration factor is lost in the following cases:

- The power supply is removed from the ADC (for example when the product enters Standby or VBAT mode).
- The ADC peripheral is reset.

The calibration factor is lost each time power is removed from the ADC (for example when the product enters Standby or VBAT mode). Still, it is possible to save and restore the calibration factor by software to save time when re-starting the ADC (as long as temperature and voltage are stable during the ADC power-down).

The calibration factor can be written if the ADC is enabled but not converting (ADEN = 1 and ADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion.

**Software calibration procedure**

1. Ensure that ADEN = 0, ADVREGEN = 1, AUTOFF = 0, DPD = 0, and DMAEN = 0.
2. Set ADCAL = 1.
3. Wait until ADCAL = 0 (or until EOCAL = 1). This can be handled by interrupt if the interrupt is enabled by setting the EOCALIE bit in the ADC_IER register.
4. The calibration factor can be read from bits 6:0 of ADC_DR or ADC_CALFACT registers.

---

**Figure 273. ADC calibration**

---

1. Refer to the device datasheet for the value of tCAB.
Calibration factor forcing software procedure

1. Ensure that ADEN = 1 and ADSTART = 0 (ADC started with no conversion ongoing).
2. Write ADC_CALFACT with the saved calibration factor.
3. The calibration factor is used as soon as a new conversion is launched.

34.4.5 ADC on-off control (ADEN, ADDIS, ADRDY)

At power-up, the ADC is disabled and put in power-down mode (ADEN = 0).

As shown in Figure 275, the ADC needs a stabilization time of $t_{STAB}$ before it starts converting accurately.

Two control bits are used to enable or disable the ADC:

- Set ADEN = 1 to enable the ADC. The ADRDY flag is set as soon as the ADC is ready for operation.
- Set ADDIS = 1 to disable the ADC and put the ADC in Power-down. The ADEN and ADDIS bits are then automatically cleared by hardware as soon as the ADC is fully disabled.

Conversion can then start either by setting ADSTART to 1 (refer to Section 34.4.16: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN) on page 1383) or when an external trigger event occurs if triggers are enabled.

Follow the procedure below to enable the ADC:
1. Clear the ADRDY bit in ADC_ISR register by programming this bit to 1.
2. Set ADEN = 1 in the ADC_CR register.
3. Wait until ADRDY = 1 in the ADC_ISR register (ADRDY is set after the ADC startup time). This can be handled by interrupt if the interrupt is enabled by setting the ADRDYIE bit in the ADC_IER register.

Follow the procedure below to disable the ADC:
1. Check that ADSTART = 0 in the ADC_CR register to ensure that no conversion is ongoing. If the software trigger mode was used, stop the software trigger mode by writing 1 to the ADSTP bit of the ADC_CR register and waiting until this bit is read at 0.
2. Set ADDIS = 1 in the ADC_CR register.
3. If required by the application, wait until ADEN = 0 in the ADC_CR register, indicating that the ADC is fully disabled (ADDIS is automatically reset once ADEN = 0).
4. Clear the ADRDY bit in ADC_ISR register by programming this bit to 1 (optional).
Note: In auto-off mode (AUTOFF = 1) the power-on/off phases are performed automatically, by hardware and the ADRDY flag is not set.

34.4.6 ADC clock (PRESC[3:0])

The ADC has a dual clock-domain architecture, so that the ADC can be fed with a clock (ADC asynchronous clock) independent from the bus clock.

1. Refer to Section Reset and clock control (RCC) for how the bus clock and ADC asynchronous clock are enabled.

The adc_ker_ck input clock can be selected between different clock sources (see Figure 276: ADC clock scheme). This selection is done in the RCC (refer to th RCC section for more information):

- The ADC clock can be provided by an internal or external clock source, which is independent and asynchronous with the bus clock.
- The ADC clock can be derived from the bus clock by selecting the adc_ker_ck as bus clock.
Option a) has the advantage of reaching the maximum ADC clock frequency whatever the clock scheme selected. The ADC clock can eventually be divided by a programmable ratio of 1, 2, 4, 6, 8, 10, 12, 16, 32, 64, 128 or 256, configured through PRESC[3:0] bits in the ADCx_CCR register.

Option b) has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

Table 326. Latency between trigger and start of conversion(1)

</table>

1. Refer to the device datasheet for the maximum $F_{ADC}$ frequency.
34.4.7 ADC connectivity

ADC inputs are connected to the external channels as well as internal sources as described in Figure 277.

Figure 277. ADC4 connectivity

1. $V_{IN}[5]$ to $V_{IN}[8]$ are reserved on STM32U535/545 devices.
34.4.8 Configuring the ADC

The software can write to the ADCAL and ADEN bits in the ADC_CR and ADC_PWRR register if the ADC is disabled (ADEN must be 0).

The software must only write to the ADSTART and ADDIS bits in the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN = 1 and ADDIS = 0).

For all the other control bits in the ADC_IER, ADC_CFGRI, ADC_SMPR, ADC_CHSELR and ADC_CCR registers, refer to the description of the corresponding control bit in Section 34.7: ADC registers. If the ADC operates in software trigger mode, set the ADSTP bit in ADC_CR register, then wait until ADSTP bit become 0 before reconfiguring the above registers.

ADC_AWDTRi registers can be modified when a conversion is ongoing.

The software must only write to the ADSTP bit in the ADC_CR register if the ADC is enabled (and possibly converting) and there is no pending request to disable the ADC (ADSTART = 1 and ADDIS = 0).

Note: There is no hardware protection preventing software from making write operations forbidden by the above rules. If such a forbidden write access occurs, the ADC may enter an undefined state. To recover correct operation in this case, the ADC must be disabled (clear ADEN = 0 and all the bits in the ADC_CR register).

34.4.9 Channel selection (CHSEL, SCANDIR, CHSELMOD)

There are up to 25 multiplexed channels:

- up to 19 analog inputs from GPIO pins (ADC_INx)
- 6 internal analog inputs: temperature Sensor, internal reference voltage, V_CORE, V_BAT channel, DAC internal channels

It is possible to convert a single channel or a sequence of channels.

The sequence of the channels to be converted can be programmed in the ADC_CHSELR channel selection register: each analog input channel has a dedicated selection bit (CHSELx).

The ADC scan sequencer can be used in two different modes:

- Sequencer not fully configurable:
  - The order in which the channels are scanned is defined by the channel number (CHSELMOD bit must be cleared in ADC_CFGRI1 register):
    - Sequence length configured through CHSELx bits in ADC_CHSELR register
    - Sequence direction: the channels are scanned in a forward direction (from the lowest to the highest channel number) or backward direction (from the highest to the lowest channel number) depending on the value of SCANDIR bit (SCANDIR = 0: forward scan, SCANDIR = 1: backward scan)
– Any channel can belong to in these sequences

• Fully-configurable sequencer
  The CHSELRMOD bit is set in ADC_CFGR1 register.
  – Sequencer length is up to eight channels
  – The order in which the channels are scanned is independent from the channel number. Any order can be configured through SQ1[3:0] to SQ8[3:0] bits in ADC_CHSELR register.
  – Only 15 channels can be selected in this sequence (refer to Section 34.7.10: ADC channel selection register [alternate] (ADC_CHSEL).
  – If the sequencer detects SQx[3:0] = 0b1111, the following SQx[3:0] registers are ignored.
  – If no 0b1111 is programmed in SQx[3:0], the sequencer scans full eight channels.

The software is allowed to program the CHSEL, SCANDIR and CHSELRMOD bit only when ADSTART bit is cleared in ADC_CR register. This ensures that no conversion is ongoing. If the ADC operated in software trigger mode, set ADSTP bit then wait until ADSTP bit become 0 before reconfiguring these registers. This sequence must be respected even if ADSTART bit is cleared to 0 after the conversion,

**Temperature sensor, DAC output, VREFINT, VBAT, and VCORE internal channels**

The temperature sensor, the internal DAC channels, the internal reference voltage (VREFINT), VBAT, and VCORE are connected to ADC internal channels. Refer to **Table ADC interconnection** in Section 34.4.2: ADC pins and internal signals for details.

### 34.4.10 Programmable sampling time (SMPx[2:0])

Before starting a conversion, the ADC needs to establish a direct connection between the voltage source to be measured and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the sample and hold capacitor to the input voltage level.

Having a programmable sampling time allows the conversion speed to be trimmed according to the input resistance of the input voltage source.

The ADC samples the input voltage for a number of ADC clock cycles that can be modified using the SMP1[2:0] and SMP2[2:0] bits in the ADC_SMPR register.

Each channel can choose one out of two sampling times configured in SMP1[2:0] and SMP2[2:0] bitfields, through SMPSELx bits in ADC_SMPR register.

The total conversion time is calculated as follows:

\[ t_{CONV} = \text{Sampling time} + 12.5 \times \text{ADC clock cycles} \]

Example:

With ADC_CLK = 16 MHz and a sampling time of 1.5 ADC clock cycles:

\[ t_{CONV} = 1.5 + 12.5 = 14 \text{ ADC clock cycles} = 0.875 \mu s \]

The ADC indicates the end of the sampling phase by setting the EOSMP flag.

**I/O analog switch voltage booster**

The resistance of the I/O analog switch increases when the VDDA voltage is too low. The sampling time must consequently be adapted accordingly (refer to the device datasheet for
analog-to-digital converter (ADC4) RM0456

the corresponding electrical characteristics). This resistance can be minimized at low VDDA voltage by enabling an internal voltage booster through the BOOSTEN bit of the SYSCFG_CFGR1 register or by selecting a VDD booster voltage through the ANASWVDD bit of the SYSCFG_CFGR1 register.

34.4.11 Single conversion mode (CONT = 0)

In single conversion mode, the ADC performs a single sequence of conversions, converting all the channels once. This mode is selected when CONT is cleared in the ADC_CFGR1 register. Conversion is started by either:

- Setting the ADSTART bit in the ADC_CR register
- Hardware trigger event

Inside the sequence, after each conversion is complete:

- The converted data are stored in the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then the ADC stops until a new external trigger event occurs or the ADSTART bit is set again.

Note: To convert a single channel, program a sequence with a length of 1.

34.4.12 Continuous conversion mode (CONT = 1)

In continuous conversion mode, when a software or hardware trigger event occurs, the ADC performs a sequence of conversions, converting all the channels once and then automatically re-starts and continuously performs the same sequence of conversions. This mode is selected when CONT is set to 1 in the ADC_CFGR1 register. Conversion is started by either:

- Setting the ADSTART bit in the ADC_CR register
- Hardware trigger event

Inside the sequence, after each conversion is complete:

- The converted data are stored in the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.
### 34.4.13 Starting conversions (ADSTART)

Software starts ADC conversions by setting ADSTART to 1.

When ADSTART is set, the conversion:
- Starts immediately if EXTEN = 00 (software trigger)
- At the next active edge of the selected hardware trigger if EXTEN ≠ 00

The ADSTART bit is also used to indicate whether an ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART remains at 0, indicating that the ADC is idle.

The ADSTART bit is cleared by hardware:
- In single mode with software trigger (CONT = 0, EXTEN = 00)
  - At any end of conversion sequence (EOS = 1)
- In discontinuous mode with software trigger (CONT = 0, DISCEN = 1, EXTEN = 00)
  - At end of conversion (EOC = 1)
- In all cases (CONT = x, EXTEN = XX)
  - After execution of the ADSTP procedure invoked by software (see Section 34.4.15: Stopping an ongoing conversion (ADSTP) on page 1383).

When the ADC operates in autonomous mode (DPD bit transition from 1 to 0, see Section: Autonomous mode (AUTOFF, DPD)), the ADSTART bit can be set only when the ADC is powered on. (both LDORDY = 1 and ADRDY = 1). In continuous mode (CONT = 1), the ADSTART bit is not cleared by hardware when the EOS flag is set because the sequence is automatically relaunched.

**Note:** When hardware trigger is selected in single mode (CONT = 0 and EXTEN = 01), ADSTART is not cleared by hardware when the EOS flag is set. This avoids the need for software having to set the ADSTART bit again and ensures the next trigger event is not missed.

It is necessary to set ADSTP to 1 and wait until ADSTP is cleared before reconfiguring or disabling the ADC, even if ADSTART bit is cleared to after the software triggered ADC conversion mode.
34.4.14 Timings

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

\[
t_{\text{CONV}} = t_{\text{SMPL}} + t_{\text{SAR}} = [1.5 \text{ min} + 12.5 \times t_{\text{ADC_CLK}}]
\]

\[
t_{\text{CONV}} = t_{\text{SMPL}} + t_{\text{SAR}} = 42.9 \text{ ns min} + 357.1 \text{ ns} \times [12\text{bit}] = 0.400 \mu\text{s min (for } f_{\text{ADC_CLK}} = 35 \text{ MHz)}
\]

**Figure 278. Analog to digital conversion time**

**Figure 279. ADC conversion timings**

1. EXTEN = 00 or EXTEN ≠ 00.
2. Trigger latency (refer to datasheet for more details).
3. ADC_DR register write latency (refer to datasheet for more details).
34.4.15 Stopping an ongoing conversion (ADSTP)

The software can decide to stop any ongoing conversions by setting ADSTP to 1 in the ADC_CR register.

This resets the ADC operation and the ADC is idle, ready for a new operation.

When the ADSTP bit is set by software, any ongoing conversion is aborted and the result is discarded (ADC_DR register is not updated with the current conversion).

The scan sequence is also aborted and reset (meaning that restarting the ADC would restart a new sequence).

Once this procedure is complete, the ADSTP and ADSTART bits are both cleared by hardware and the software must wait until ADSTART is cleared to 0 before starting new conversions.

![Figure 280. Stopping an ongoing conversion](image)

34.4.16 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN)

A conversion or a sequence of conversion can be triggered either by software or by an external event (for example timer capture). If the EXTEN[1:0] control bits are not equal to “0b00”, then external events are able to trigger a conversion with the selected polarity. The trigger selection is effective once software has set bit ADSTART to 1.

Any hardware triggers which occur while a conversion is ongoing are ignored.

If bit ADSTART is cleared, any hardware triggers which occur are ignored.

Table 327 provides the correspondence between the EXTEN[1:0] values and the trigger polarity.

![Table 327. Configuring the trigger polarity](image)

<table>
<thead>
<tr>
<th>Source</th>
<th>EXTEN[1:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trigger detection disabled</td>
<td>00</td>
</tr>
<tr>
<td>Detection on rising edge</td>
<td>01</td>
</tr>
<tr>
<td>Detection on falling edge</td>
<td>10</td>
</tr>
<tr>
<td>Detection on both rising and falling edges</td>
<td>11</td>
</tr>
</tbody>
</table>

**Note:** The polarity of the external trigger can be changed only when the ADC is not converting (ADSTART = 0).

The EXTSEL[2:0] control bits are used to select which of 8 possible events can trigger conversions.
Refer to Table ADC interconnection in Section 34.4.2: ADC pins and internal signals for the list of all the external triggers that can be used for regular conversion.

The software source trigger events can be generated by setting the ADSTART bit in the ADC_CR register.

**Note:** The trigger selection can be changed only when the ADC is not converting (ADSTART = 0).

### 34.4.17 Discontinuous mode (DISCEN)

This mode is enabled by setting the DISCEN bit in the ADC_CFGR1 register.

In this mode (DISCEN = 1), a hardware or software trigger event is required to start each conversion defined in the sequence. On the contrary, if DISCEN is cleared, a single hardware or software trigger event successively starts all the conversions defined in the sequence.

**Example:**

- DISCEN = 1, channels to be converted are channels 0, 3, 7 and 10
  - 1st trigger: channel 0 is converted and an EOC event is generated
  - 2nd trigger: channel 3 is converted and an EOC event is generated
  - 3rd trigger: channel 7 is converted and an EOC event is generated
  - 4th trigger: channel 10 is converted and both EOC and EOS events are generated.
  - 5th trigger: channel 0 is converted an EOC event is generated
  - 6th trigger: channel 3 is converted and an EOC event is generated
  - ...
- DISCEN = 0, channels to be converted are channels 0, 3, 7 and 10
  - 1st trigger: the complete sequence is converted: channel 0, then 3, 7 and 10. Each conversion generates an EOC event and the last one also generates an EOS event.
  - Any subsequent trigger events restarts the complete sequence.

**Note:** It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.

### 34.4.18 Programmable resolution (RES) - fast conversion mode

It is possible to obtain faster conversion times (tSAR) by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the RES[1:0] bits in the ADC_CFGR1 register. Lower resolution allows faster conversion times for applications where high data precision is not required.

**Note:** The RES[1:0] bit must only be changed when the ADEN bit is reset.

The result of the conversion is always 12 bits wide and any unused LSB bits are read as zeros.

Lower resolution reduces the conversion time needed for the successive approximation steps as shown in Table 328.
The ADC indicates each end of conversion (EOC) event. The ADC sets the EOC flag in the ADC_ISR register as soon as a new conversion data result is available in the ADC_DR register. An interrupt can be generated if the EOCIE bit is set in the ADC_IER register. The EOC flag is cleared by software either by writing 1 to it, or by reading the ADC_DR register.

The ADC also indicates the end of sampling phase by setting the EOSMP flag in the ADC_ISR register. The EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if the EOSMPIE bit is set in the ADC_IER register.

The aim of this interrupt is to allow the processing to be synchronized with the conversions. Typically, an analog multiplexer can be accessed in hidden time during the conversion phase, so that the multiplexer is positioned when the next sampling starts.

**Note:** As there is only a very short time left between the end of the sampling and the end of the conversion, it is recommended to use polling or a WFE instruction rather than an interrupt and a WFI instruction.

### End of conversion, end of sampling phase (EOC, EOSMP flags)

34.4.20 End of conversion sequence (EOS flag)

The ADC notifies the application of each end of sequence (EOS) event. The ADC sets the EOS flag in the ADC_ISR register as soon as the last data result of a conversion sequence is available in the ADC_DR register. An interrupt can be generated if the EOSIE bit is set in the ADC_IER register. The EOS flag is cleared by software by writing 1 to it.

34.4.21 Example timing diagrams (single/continuous modes hardware/software triggers)

Figure 281. Single conversions of a sequence, software trigger

1. EXTEN = 00, CONT = 0.
2. CHSEL = 0x20601, WAIT = 0, AUTOFF = 0.
Figure 282. Continuous conversion of a sequence, software trigger

1. EXTEN = 00, CONT = 1.
2. CHSEL = 0x20601, WAIT = 0, AUTOFF = 0.

Figure 283. Single conversions of a sequence, hardware trigger

1. EXTSEL = TRGx (over-frequency), EXTEN = 01 (rising edge), CONT = 0.
2. CHSEL = 0xF, SCANDIR = 0, WAIT = 0, AUTOFF = 0.
34.4.22 Low-frequency trigger mode

If the application has to support a time longer than the maximum $t_{IDLE}$ value (between one trigger to another for single conversion mode or between the ADC enable and the first ADC conversion), then the ADC internal state needs to be rearmed. This mechanism can be enabled by setting LFTRIG bit to 1 in ADC_CFGR2 register. By setting this bit, any trigger (software or hardware) sends a rearm command to ADC. The conversion is started after a two ADC clock cycle delay compared to LFTRIG set to 0.

It is not necessary to use this mode when AUTOFF bit is set to 1. For wait mode, only the first trigger generates an internal rearm command.

34.4.23 Data management

**Data register and data alignment (ADC_DR, ALIGN)**

At the end of each conversion (when an EOC event occurs), the result of the converted data is stored in the ADC_DR data register which is 16-bit wide.

The format of the ADC_DR depends on the configured data alignment and resolution.

The ALIGN bit in the ADC_CFGR1 register selects the alignment of the data stored after conversion. Data can be right-aligned (ALIGN = 0) or left-aligned (ALIGN = 1) as shown in Figure 285.
Figure 285. Data alignment and resolution (oversampling disabled: OVSE = 0)

ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) indicates a data overrun event, when the converted data was not read in time by the CPU or the DMA, before the data from a new conversion is available.

The OVR flag is set in the ADC_ISR register if the EOC flag is still at 1 at the time when a new conversion completes. An interrupt can be generated if the OVRIE bit is set in the ADC_IER register.

When an overrun condition occurs, the ADC keeps operating and can continue to convert unless the software decides to stop and reset the sequence by setting the ADSTP bit in the ADC_CR register.

The OVR flag is cleared by software by writing 1 to it.

It is possible to configure if the data is preserved or overwritten when an overrun event occurs by programming the OVRMOD bit in the ADC_CFGR1 register:

- **OVRMOD = 0**
  - An overrun event preserves the data register from being overwritten: the old data is maintained and the new conversion is discarded. If OVR remains at 1, further conversions can be performed but the resulting data is discarded.

- **OVRMOD = 1**
  - The data register is overwritten with the last conversion result and the previous unread data is lost. If OVR remains at 1, further conversions can be performed and the ADC_DR register always contains the data from the latest conversion.
Managing a sequence of data converted without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by software. In this case the software must use the EOC flag and its associated interrupt to handle each data result. Each time a conversion is complete, the EOC bit is set in the ADC_ISR register and the ADC_DR register can be read. The OVRMOD bit in the ADC_CFGR1 register must be configured to 0 to manage overrun events as an error.

Managing converted data without using the DMA without overrun

It may be useful to let the ADC convert one or more channels without reading the data after each conversion. In this case, the OVRMOD bit must be configured at 1 and the OVR flag must be ignored by the software. When OVRMOD is set to 1, an overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion data.

Managing converted data using the DMA

Since all converted channel values are stored in a single data register, it is efficient to use DMA when converting more than one channel. This avoids losing the conversion data results stored in the ADC_DR register.

When DMA mode is enabled (DMAEN bit set to 1 in the ADC_CFGR1 register), a DMA request is generated after the conversion of each channel. This allows the transfer of the
converted data from the ADC_DR register to the destination location selected by the software.

*Note:* The DMAEN bit in the ADC_CFRG1 register must be set after the ADC calibration phase.

Despite this, if an overrun occurs (OVR = 1) because the DMA did not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to *Section: ADC overrun (OVR, OVRMOD)* on page 1389).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMACFG in the ADC_CFRG1 register:

- DMA one-shot mode (DMACFG = 0).
  - This mode must be selected when the DMA is programmed to transfer a fixed number of data words.
- DMA circular mode (DMACFG = 1)
  - This mode must be selected when programming the DMA in circular mode or double buffer mode.

**DMA one-shot mode (DMACFG = 0)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data word is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when a transfer complete interrupt occurs - refer to DMA section), even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted and its partial result discarded
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- The scan sequence is stopped and reset
- The DMA is stopped

**DMA circular mode (DMACFG = 1)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data word is available in the data register, even if the DMA has reached the last DMA transfer. This allows the DMA configuration in circular mode in order to handle a continuous analog input data stream.
34.4.24 Low-power features

Wait conversion mode (WAIT)

Wait conversion mode can be used to simplify the software as well as optimizing the performance of applications clocked at low frequency where there might be a risk of ADC overrun occurring.

When the WAIT bit is set to 1 in the ADC_CFGR1 register, a new conversion can start only if the previous data has been treated, once the ADC_DR register has been read or if the EOC bit has been cleared.

This is a way to automatically adapt the speed of the ADC to the speed of the system that reads the data.

Note: Any hardware triggers which occur while a conversion is ongoing or during the wait time preceding the read access are ignored.

Figure 287. Wait conversion mode (continuous mode, software trigger)

1. EXTEN = 00, CONT = 1.
2. CHSEL = 0x3, SCANDIR = 0, WAIT = 1, AUTOFF = 0.
ADC power-saving modes

The ADC embeds two power-saving modes, the auto-off and the autonomous modes.

Auto-off mode (AUTOFF)

The auto-off mode is enabled by setting the AUTOFF bit to 1 in the ADC_PWRR register. Below the auto-off mode operating sequence:

1. When AUTOFF is set to 1, the ADC is always powered off when no conversion is ongoing.
2. It then automatically wakes up when a conversion is triggered by software or by hardware, and a startup time is inserted between the trigger event and the ADC sampling time.
3. The ADC is then automatically disabled once the conversion or sequence of conversions is complete.
4. When consecutive hardware or software triggers occur, the ADC is automatically enabled and the conversion is processed.

Refer to Figure 288 for a description of auto-off mode state diagram.

The auto-off mode dramatically reduces power consumption in applications requiring a limited number of conversions or conversion requests far between enough (for example with a low-frequency hardware trigger) to justify the extra power and time used for switching the ADC on and off.

Auto-off mode can be combined with wait mode (WAIT = 1) for applications clocked at low frequency. This combination can achieve significant power saving if the ADC is automatically powered off during the wait phase and restarted as soon as the ADC_DR register is read by the application (see Figure 289: ADC behavior with WAIT = 0 and AUTOFF = 1 and Figure 290: ADC behavior with WAIT = 1 and AUTOFF = 1).

The auto-off mode is compatible with the low-power background autonomous mode (LPBAM).

Note: Refer to the Section Reset and clock control (RCC) for the description of how to manage the dedicated internal oscillators. The ADC interface can automatically switch on/off these internal oscillators to save power.
Figure 288. Auto-off mode state diagram

Figure 289. ADC behavior with WAIT = 0 and AUTOFF = 1

1. EXTSEL = TRGx, EXTEN = 01 (rising edge), CONT = x, ADSTART = 1, CHSEL = 0xF, SCANDIR = 0, WAIT = 0, AUTOFF = 1.
Autonomous mode (AUTOFF, DPD)

The autonomous mode is enabled by setting both AUTOFF and DPD bits to 1 in ADC_PWRR register. In addition, the autonomous mode must be enabled in the RCC.

Below the autonomous mode operating sequence:

1. When AUTOFF and DPD are both set to 1, the ADC is powered off when no conversion is ongoing.
2. Upon hardware trigger reception, the ADC requests the adc_ker_ck and adc_hclk clocks to the RCC, the ADC voltage regulator is enabled, the calibration factor is loaded, the ADC is enabled and the conversion starts.
3. Once the ADC conversion is complete, the ADC can either generate an AWDx interrupt or a DMA request, depending on peripheral configuration:
   - When DMA mode is enabled, the ADC generates a DMA request to transfer data to memory or to another peripherals.
   - When an analog watchdog is enabled, ADC data do not need to be transferred. The analog watchdog compares the data to the threshold value and generates an AWDx interrupt to wake up the device if the data is under or over the programmed threshold.
4. When the ADC conversion/sequence or conversion is complete, the ADC and the ADC voltage regulator are automatically disabled as well as VREFINT buffer and the temperature sensor, and further clock requests are deasserted. This allows the minimization of current consumption.
5. When consecutive hardware triggers occur, the ADC is automatically enabled and the conversion is processed.

Refer to Figure 291 for a description of autonomous mode state diagram.

The autonomous mode enables the ADC peripheral to operate when the device is in Stop mode. However it can also be used in Run or Sleep mode.
It is compatible with the low-power background autonomous mode (LPBAM).

**Figure 291. Autonomous mode state diagram**

### 34.4.25 Analog window watchdog

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

**Description of analog watchdog 1**

AWD1 analog watchdog is enabled by setting the AWD1EN bit in the ADC_CFGR1 register. It is used to monitor that either one selected channel or all enabled channels (see Table 330: Analog watchdog 1 channel selection) remain within a configured voltage range (window) as shown in Figure 292.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold. These thresholds are programmed in HT1[11:0] and LT1[11:0] bits of ADC_AWD1TR register. An interrupt can be enabled by setting the AWD1IE bit in the ADC_IER register.

The AWD1 flag is cleared by software by programing it to 1.

When converting data with a resolution of less than 12-bit (according to bits DRES[1:0]), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned).

*Table 329* describes how the comparison is performed for all the possible resolutions.
Table 329. Analog watchdog comparison

1. Selected by the AWD1CH[4:0] bits

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the AWDxCHy in ADC_AWDxCR (x = 2, 3).

The corresponding watchdog is enabled when any AWDxCHy bit (x = 2,3) is set in ADC_AWDxCR register.

When converting data with a resolution of less than 12 bits (configured through DRES[1:0] bits), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned).

Table 329 describes how the comparison is performed for all the possible resolutions.

The AWD2/3 analog watchdog status bit is set if the analog voltage converted by the ADC is below a low threshold or above a high threshold. These thresholds are programmed in
HTx[11:0] and LTx[11:0] of ADC_AWDxTR registers (x = 2 or 3). An interrupt can be enabled by setting the AWDxIE bit in the ADC_IER register.

The AWD2 and AWD3 flags are cleared by software by programming them to 1.

**ADC_AWDx_OUT signal output generation**

Each analog watchdog is associated to an internal hardware signal, ADC_AWDx_OUT (x being the watchdog number) that is directly connected to the ETR input (external trigger) of some on-chip timers (refer to the timers section for details on how to select the ADC_AWDx_OUT signal as ETR).

ADC_AWDx_OUT is activated when the associated analog watchdog is enabled:

- ADC_AWDx_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADC_AWDx_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds. It remains at 1 if the next guarded conversions are still outside the programmed thresholds.
- ADC_AWDx_OUT is also reset when disabling the ADC (when setting ADDIS to 1). Note that stopping conversions (ADSTP set to 1), might clear the ADC_AWDx_OUT state.
- ADC_AWDx_OUT state does not change when the ADC converts the none-guarded channel (see Figure 295)

AWDx flag is set by hardware and reset by software: AWDx flag has no influence on the generation of ADC_AWDx_OUT (as an example, ADC_AWDx_OUT can toggle while AWDx flag remains at 1 if the software has not cleared the flag).

The ADC_AWDx_OUT signal is generated by the ADC_CLK domain. This signal can be generated even the bus clock is stopped.

The AWD comparison is performed at the end of each ADC conversion. The ADC_AWDx_OUT rising edge and falling edge occurs two ADC_CLK clock cycles after the comparison.

As ADC_AWDx_OUT is generated by the ADC_CLK domain and AWD flag is generated by the bus clock domain, the rising edges of these signals are not synchronized.

Converted channels: 1,2,3,4,5,6,7
Guarded converted channels: 1,2,3,4,5,6,7
Analog watchdog threshold control

LTx[11:0] and HTx[11:0] can be changed during an analog-to-digital conversion (that is between the start of the conversion and the end of conversion of the ADC internal state). If HTx and LTx bits are programmed during the ADC guarded channel conversion, the watchdog function is masked for this conversion. This mask is cleared when starting a new conversion, and the resulting new AWD threshold is applied starting the next ADC conversion result. AWD comparison is performed at each end of conversion. If the current ADC data are out of the new threshold interval, this does not generated any interrupt or an ADC_AWDx_OUT signal. The Interrupt and the ADC_AWDx_OUT generation only occurs at the end of the ADC conversion that started after the threshold update. If ADC_AWDx_OUT is already asserted, programming the new threshold does not deassert the ADC_AWDx_OUT signal.
34.4.26 Oversampler

The oversampling unit performs data preprocessing to offload the CPU. It can handle multiple conversions and average them into a single data with increased data width, up to 16-bit.

It provides a result with the following form, where N and M can be adjusted:

\[
\text{Result} = \frac{1}{M} \times \sum_{n=0}^{N-1} \text{Conversion}(t_n)
\]

It allows the following functions to be performed by hardware: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OVSR[2:0] bits in the ADC_CFGR2 register. It can range from 2x to 256x. The division coefficient M consists of a right bit shift up to 8 bits. It is configured through the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 20 bits (256 x 12-bit), which is first shifted right. The lower bits of the result are then truncated, keeping only the 16 least significant bits rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred into the ADC_DR data register.

Note: If the intermediate result after the shifting exceeds 16 bits, the upper bits of the result are simply truncated.
The Figure 298 gives a numerical example of the processing, from a raw 20-bit accumulated data to the final 16-bit result.

**Figure 298. Numerical example with 5-bits shift and rounding**

![Figure 298](image)

The Table 331 below gives the data format for the various N and M combination, for a raw conversion data equal to 0xFFF.

</tbody>
</table>

The conversion timings in oversampler mode do not change compared to standard conversion mode: the sample time is maintained equal during the whole oversampling sequence. New data are provided every N conversion, with an equivalent delay equal to N x t\(_{\text{CONV}}\) = N x (t\(_{\text{SMPL}}\) + t\(_{\text{SAR}}\)). The flags features are raised as following:

- the end of the sampling phase (EOSMP) is set after each sampling phase
- the end of conversion (EOC) occurs once every N conversions, when the oversampled result is available
- the end of sequence (EOCSEQ) occurs once the sequence of oversampled data is completed (i.e. after N x sequence length conversions total)
ADC operating modes supported when oversampling

In oversampling mode, most of the ADC operating modes are available:

- Single or continuous mode conversions, forward or backward scanned sequences and up to 8 channels programmed sequence
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (WAIT, AUTOFF)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits in ADC_CFGR1 register) are accumulated, truncated, rounded and shifted in the same way as 12-bit conversions are

**Note:** The alignment mode is not available when working with oversampled data. The ALIGN bit in ADC_CFGR1 is ignored and the data are always provided right-aligned.

Analog watchdog

The analog watchdog functionality is available, with the following differences:

- the RES[1:0] bits are ignored, comparison is always done on using the full 12-bits values HTx[11:0] and LTx[11:0]
- the comparison is performed on the most significant 12 bits of the 16 bits oversampled results ADC_DR[15:4]

**Note:** Care must be taken when using high shifting values. This reduces the comparison range. For instance, if the oversampled result is shifted by 4 bits thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HTx[7:0] / LTx[7:0], and HTx[11:8] / LTx[11:8] must be kept reset.

Triggered mode

The averager can also be used for basic filtering purposes. Although not a very efficient filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TOVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

**Figure 299** below shows how conversions are started in response to triggers in discontinuous mode.

If the TOVS bit is set, the content of the DISCEN bit is ignored and considered as 1.
34.4.27 Temperature sensor and internal reference voltage

The temperature sensor can be used to measure the junction temperature (T_J) of the device. The temperature sensor is internally connected an ADC internal input channel which is used to convert the sensor’s output voltage to a digital value. The sampling time for the temperature sensor analog pin must be greater than the minimum T_S_temp value specified in the datasheet. When not in use, the sensor can be put in Power-down mode.

The internal voltage reference (VREFINT) provides a stable (bandgap) voltage output for the ADC and the comparators.

Refer to Table ADC interconnection in Section 34.4.2: ADC pins and internal signals for details on the ADC internal input channel to which the above voltages are connected.

Figure 300 shows the block diagram of connections between the temperature sensor, the internal voltage reference and the ADC.

The VSENSESEL bit must be set to enable the conversion of VSENSE while VREFEN bit must be set to enable the conversion of VREFINT.

When the ADC operates in autonomous mode, these signals are controlled automatically to reduce power consumption (VSENSESEL and VREFEN must be set to measure the voltage in autonomous mode).

The temperature sensor output voltage linearly changes with the temperature. The offset of this line varies from chip to chip due to process variation (up to 45 °C from one chip to another).

The uncalibrated internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. To improve the accuracy of the temperature sensor measurement, calibration values are stored in system memory for each device by STMicroelectronics during production.

During the manufacturing process, the calibration data of the temperature sensor and the internal voltage reference are stored in the system memory area. The user application can then read them and use them to improve the accuracy of the temperature sensor or the internal reference. Refer to the datasheet for additional information.

During the manufacturing process, the calibration data of the internal voltage reference are stored in the system memory area. The user application can then read them and use them...
to improve the accuracy of the internal reference. Refer to the electrical characteristics section of the device datasheet for additional information.

**Main features**

- Linearity: ±2 °C max., precision depending on calibration

**Figure 300. Temperature sensor and VREFINT channel block diagram**

**Reading the temperature**

1. Select the input channel connected to VSENSE (refer to Table *ADC interconnection* in Section 34.4.2: ADC pins and internal signals).
2. Select an appropriate sampling time specified in the device datasheet (T$_{S_{temp}}$).
3. Set the VSENSESEL bit in the ADC_CCR register to wake up the temperature sensor from power-down mode and wait for its stabilization time (t$_{START}$).
4. Start the ADC conversion by setting the ADSTART bit in the ADC_CR register (or by external trigger)
5. Read the resulting VSENSE data in the ADC_DR register
6. Calculate the temperature using the following formula

\[
\text{Temperature (in °C)} = \frac{\text{TS\_CAL2\_TEMP} - \text{TS\_CAL1\_TEMP}}{\text{TS\_CAL2} - \text{TS\_CAL1}} \times (\text{TS\_DATA} - \text{TS\_CAL1}) + \text{TS\_CAL1\_TEMP}
\]

Where:
- TS\_CAL2 is the temperature sensor calibration value acquired at TS\_CAL2\_TEMP.
- TS\_CAL1 is the temperature sensor calibration value acquired at TS\_CAL1\_TEMP.
- TS\_DATA is the actual temperature sensor output value converted by the ADC.

Refer to *Section 34.3: ADC implementation* for more information on TS\_CAL1 and TS\_CAL2 calibration points.
The sensor has a startup time after waking up from power-down mode before it can output VSENSE at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and VSENSESEL bits must be set at the same time.

Calculating the actual VREF+ voltage using the internal reference voltage

The \( V_{\text{DDA}} \) power supply voltage applied to the microcontroller may be subject to variation or not precisely known. The embedded internal voltage reference (VREFINT) and its calibration data acquired by the ADC during the manufacturing process at \( V_{\text{REF+}} = 3.0 \text{ V} \) can be used to evaluate the actual VREF+ voltage level, if VREF+ pin is connected to a variable \( V_{\text{DDA}} \) power supply.

The following formula gives the actual VREF+ voltage supplying the device:

\[
V_{\text{REF+}} = 3.0 \, \text{V} \times \frac{\text{VREFINT}_\text{CAL}}{\text{VREFINT}_\text{DATA}}
\]

Where:
- \( \text{VREFINT}_\text{CAL} \) is the VREFINT calibration value
- \( \text{VREFINT}_\text{DATA} \) is the actual VREFINT output value converted by ADC

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between the voltage reference \( V_{\text{REF+}} \) and the voltage applied on the converted channel. For most application use cases, it is necessary to convert this ratio into a voltage independent from \( V_{\text{REF+}} \). For applications where \( V_{\text{REF+}} \) is known and ADC converted values are right-aligned, the following formula can be used to calculate this absolute value:

\[
V_{\text{CHANNEL}x} = \frac{V_{\text{REF+}} \times \text{ADC}_\text{DATA}_x}{\text{FULL}_\text{SCALE}}
\]

For applications where \( V_{\text{REF+}} \) value is not known, the internal voltage reference and \( V_{\text{REF+}} \) can be replaced by the expression provided in Section: Calculating the actual VREF+ voltage using the internal reference voltage, resulting in the following formula:

\[
V_{\text{CHANNEL}x} = \frac{3.0 \times \text{VREFINT}_\text{CAL} \times \text{ADC}_\text{DATA}_x}{\text{VREFINT}_\text{DATA} \times \text{FULL}_\text{SCALE}}
\]

Where:
- \( \text{VREFINT}_\text{CAL} \) is the VREFINT calibration value (refer to Section 34.3: ADC implementation for the value of \( \text{VREFINT}_\text{CAL} \)).
- \( \text{ADC}_\text{DATA}_x \) is the value measured by the ADC on channelx (right-aligned).
- \( \text{VREFINT}_\text{DATA} \) is the actual VREFINT output value converted by the ADC.
- \( \text{FULL}_\text{SCALE} \) is the maximum digital value of the ADC output. For example with 12-bit resolution, it is \( 2^{12} - 1 = 4095 \) or with 8-bit resolution, \( 2^8 - 1 = 255 \).

Note: If ADC measurements are done using an output format other than 12 bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

34.4.28 Battery voltage monitoring

The VBATEN bit in the ADC_CCR register allows the application to measure the battery voltage on the VBAT pin. As the VBAT voltage may be higher than \( V_{\text{DDA}} \), to ensure the correct operation of the ADC, the VBAT pin is internally connected to a bridge divider by 4.
This bridge is automatically enabled when VBATEN is set, to connect V\textsubscript{BAT}/4 to the corresponding ADC input channel (refer to Table ADC interconnection in Section 34.4.2: ADC pins and internal signals). As a consequence, the converted digital value is half the V\textsubscript{BAT} voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only during ADC conversion.

Figure 301. V\textsubscript{BAT} channel block diagram

34.4.29 Concurrent operation with another ADC

When ADC\textsubscript{4} is used simultaneously with another ADC (let us call it ADC\textsubscript{x}, x being different from 4), ADC\textsubscript{x} operation might generate noise on V\textsubscript{REF+} voltage. Since V\textsubscript{REF+} is also ADC\textsubscript{4} reference voltage, this might cause conversion errors. To prevent this issue from happening, set VREFPROTEN bit in ADC\_PWRR register. As soon as ADC\textsubscript{x} sampling phase starts, ADC\textsubscript{4} is put on hold during one ADC\textsubscript{4} clock cycle, thus resulting in ADC\textsubscript{4} conversion time to be longer of one clock cycle.

In addition, ADC\textsubscript{x} might have two sampling phases during ADC\textsubscript{4} conversion. This is due to the injected conversion function of ADC\textsubscript{x}. By setting VREFSECSMP to 1 in ADC\_PWRR, ADC\textsubscript{4} operation can be held twice during the conversion phase. When VREFSECSMP bit is set, ADC\textsubscript{4} conversion time is longer of two clock cycles.

VREFSECSMP and VREFPROTEN bits must be set simultaneously.

ADC\textsubscript{x} and ADC\textsubscript{4} must use the same clock source to be able to use the concurrent operation feature.
34.5 ADC low-power modes

Table 332. Effect of low-power modes on the ADC

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect, DMA requests are functional. ADC interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The content of the ADC register is kept. ADC can be functional. DMA request are functional, and the interrupt cause the device to exit Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The ADC peripheral is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

34.6 ADC interrupts

An interrupt can be generated by any of the following events:

- End of calibration (EOCAL flag)
- ADC power-up, when the ADC is ready (ADRDY flag)
- End of any conversion (EOC flag)
- End of a sequence of conversions (EOS flag)
- When an analog watchdog detection occurs (AWD1, AWD2, AWD3 flags)
- When the end of sampling phase occurs (EOSMP flag)
- When a data overrun occurs (OVR flag)
- LDO ready, when LDO output is stabilized (LDORDY flag)

Separate interrupt enable bits are available for flexibility.

Bits 31:13 Reserved, must be kept at reset value.

- **Bit 12 LDORDY:** LDO ready  
  This bit is set by hardware. It indicates that the ADC internal LDO output is ready.  
  It is cleared by software by writing 1 to it.  
  0: ADC voltage regulator disabled  
  1: ADC voltage regulator enabled and stabilized

- **Bit 11 EOCAL:** End of calibration flag  
  This bit is set by hardware when calibration is complete. It is cleared by software writing 1 to it.  
  0: Calibration is not complete  
  1: Calibration is complete

- **Bit 10 Reserved, must be kept at reset value.**

- **Bit 9 AWD3:** Analog watchdog 3 flag  
  This bit is set by hardware when the converted voltage crosses the values programmed in ADC_AWD3TR and ADC_AWD3TR registers. It is cleared by software by writing 1 to it.  
  0: No analog watchdog event occurred (or the flag event was already acknowledged and cleared by software)  
  1: Analog watchdog event occurred

- **Bit 8 AWD2:** Analog watchdog 2 flag  
  This bit is set by hardware when the converted voltage crosses the values programmed in ADC_AWD2TR and ADC_AWD2TR registers. It is cleared by software writing 1 to it.  
  0: No analog watchdog event occurred (or the flag event was already acknowledged and cleared by software)  
  1: Analog watchdog event occurred

- **Bit 7 AWD1:** Analog watchdog 1 flag  
  This bit is set by hardware when the converted voltage crosses the values programmed in ADC_TR1 and ADC_HR1 registers. It is cleared by software by writing 1 to it.  
  0: No analog watchdog event occurred (or the flag event was already acknowledged and cleared by software)  
  1: Analog watchdog event occurred

Bits 6:5 Reserved, must be kept at reset value.
34.7.2 ADC interrupt enable register (ADC_IER)

Address offset: 0x04  
Reset value: 0x0000 0000

Bit 4 **OVR**: ADC overrun
   This bit is set by hardware when an overrun occurs, meaning that a new conversion has complete while the EOC flag was already set. It is cleared by software writing 1 to it.
   0: No overrun occurred (or the flag event was already acknowledged and cleared by software)
   1: Overrun has occurred

Bit 3 **EOS**: End of sequence flag
   This bit is set by hardware at the end of the conversion of a sequence of channels selected by the CHSEL bits. It is cleared by software writing 1 to it.
   0: Conversion sequence not complete (or the flag event was already acknowledged and cleared by software)
   1: Conversion sequence complete

Bit 2 **EOC**: End of conversion flag
   This bit is set by hardware at the end of each conversion of a channel when a new data result is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.
   0: Channel conversion not complete (or the flag event was already acknowledged and cleared by software)
   1: Channel conversion complete

Bit 1 **EOSMP**: End of sampling flag
   This bit is set by hardware during the conversion, at the end of the sampling phase. It is cleared by software by writing 1 to it.
   0: Not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)
   1: End of sampling phase reached

Bit 0 **ADRDY**: ADC ready
   This bit is set by hardware after the ADC has been enabled (ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.
   It is cleared by software writing 1 to it.
   0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)
   1: ADC is ready to start conversion
Bits 31:13  Reserved, must be kept at reset value.

Bit 12  **LDORDYIE**: LDO ready interrupt enable

This bit is set and cleared by software. It is used to enable/disable the LDORDY interrupt.
0: LDO ready interrupt disabled
1: LDO ready interrupt enabled. An interrupt is generated when the LDO output is ready.

*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensure that no conversion is ongoing).*

Bit 11  **EOCALIE**: End of calibration interrupt enable

This bit is set and cleared by software to enable/disable the end of calibration interrupt.
0: End of calibration interrupt disabled
1: End of calibration interrupt enabled

*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 10  Reserved, must be kept at reset value.

Bit 9  **AWD3IE**: Analog watchdog 3 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog interrupt.
0: Analog watchdog interrupt disabled
1: Analog watchdog interrupt enabled

*Note: The Software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 8  **AWD2IE**: Analog watchdog 2 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog interrupt.
0: Analog watchdog interrupt disabled
1: Analog watchdog interrupt enabled

*Note: The Software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 7  **AWD1IE**: Analog watchdog 1 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog interrupt.
0: Analog watchdog interrupt disabled
1: Analog watchdog interrupt enabled

*Note: The Software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bits 6:5  Reserved, must be kept at reset value.

Bit 4  **OVRIE**: Overrun interrupt enable

This bit is set and cleared by software to enable/disable the overrun interrupt.
0: Overrun interrupt disabled
1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 3  **EOSIE**: End of conversion sequence interrupt enable

This bit is set and cleared by software to enable/disable the end of sequence of conversions interrupt.
0: EOS interrupt disabled
1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.

*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*
Bit 2 **EOCIE**: End of conversion interrupt enable
This bit is set and cleared by software to enable/disble the end of conversion interrupt.
- 0: EOC interrupt disabled
- 1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.
*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 1 **EOSMPIE**: End of sampling flag interrupt enable
This bit is set and cleared by software to enable/disble the end of the sampling phase interrupt.
- 0: EOSMP interrupt disabled.
- 1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.
*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 0 **ADRDYIE**: ADC ready interrupt enable
This bit is set and cleared by software to enable/disble the ADC Ready interrupt.
- 0: ADRDY interrupt disabled.
- 1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.
*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

#### Bit 31 ADCAL: ADC calibration
- This bit is set by software to start the calibration of the ADC.
- It is cleared by hardware after calibration is complete.
- **0**: Calibration complete
- **1**: Write 1 to calibrate the ADC. Read at 1 means that a calibration is in progress.

**Note:** The software is allowed to set ADCAL only when the ADC is disabled (ADCAL = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0, AUTOFF = 0, and ADEN = 0).

The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN is set to 1 and ADSTART is cleared to 0 by writing ADSTP to 1 (ADC enabled and no conversion is ongoing).

#### Bits 30:29 Reserved, must be kept at reset value.

#### Bit 28 ADVREGEN: ADC voltage regulator enable
- This bit is set by software, to enable the ADC internal voltage regulator. The voltage regulator output is available after $t_{ADCVREG\_SETUP}$.
- It is cleared by software to disable the voltage regulator. It can be cleared only if ADEN is set to 0.
- **0**: ADC voltage regulator disabled
- **1**: ADC voltage regulator enabled

**Note:** The software is allowed to program this bit field only when the ADC is disabled (ADCAL = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

#### Bits 27:5 Reserved, must be kept at reset value.

#### Bit 4 ADSTP: ADC stop conversion command
- This bit is set by software to stop and discard an ongoing conversion (ADSTP Command).
- It is cleared by hardware when the conversion is effectively discarded and the ADC is ready to accept a new start conversion command.
- **0**: No ADC stop conversion command ongoing
- **1**: Write 1 to stop the ADC. Read 1 means that an ADSTP command is in progress.

**Note:** To clear the A/D converter state, ADSTP must be set to 1 even if ADSTART is cleared to 0 after the software trigger A/D conversion. It is recommended to set ADSTP to 1 whenever the configuration needs to be modified.

#### Bit 3 Reserved, must be kept at reset value.
Bit 2 **ADSTART**: ADC start conversion command

This bit is set by software to start ADC conversion. Depending on the EXTEN [1:0] configuration bits, a conversion either starts immediately (software trigger configuration) or once a hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- In single conversion mode (CONT = 0, DISCEN = 0), when software trigger is selected (EXTEN = 00): at the assertion of the end of Conversion Sequence (EOS) flag.
- In discontinuous conversion mode (CONT=0, DISCEN = 1), when the software trigger is selected (EXTEN = 00): at the assertion of the end of Conversion (EOC) flag.
- In all other cases: after the execution of the ADSTP command, at the same time as the ADSTP bit is cleared by hardware.

0: No ADC conversion is ongoing.
1: Write 1 to start the ADC. Read 1 means that the ADC is operating and may be converting.

*Note: The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).*

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: No ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

*Note: Setting ADDIS to 1 is only effective when ADEN = 1 and ADSTART = 0 (which ensures that no conversion is ongoing)*

Bit 0 **ADEN**: ADC enable command

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the ADRDY flag has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

*Note: The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL = 0, ADSTP = 0, ADSTART = 0, ADDIS = 0 and ADEN = 0)*

Bit 31  Reserved, must be kept at reset value.

Bits 30:26  **AWD1CH[4:0]:** Analog watchdog channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

- 00000: ADC analog input Channel 0 monitored by AWD
- 00001: ADC analog input Channel 1 monitored by AWD
- ....
- 10001: ADC analog input Channel 17 monitored by AWD
- 10110: ADC analog input Channel 22 monitored by AWD
- 10111: ADC analog input Channel 23 monitored by AWD
- Others: Reserved

*Note:* The channel selected by the AWDCH[4:0] bits must be also set into the CHSELR register. The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bits 25:24  Reserved, must be kept at reset value.

Bit 23  **AWD1EN:** Analog watchdog enable

This bit is set and cleared by software.

- 0: Analog watchdog disabled
- 1: Analog watchdog enabled

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 22  **AWD1SGL:** Enable the watchdog on a single channel or on all channels

This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWDCH[4:0] bits or on all the channels.

- 0: Analog watchdog enabled on all channels
- 1: Analog watchdog enabled on a single channel

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 21  **CHSELMOD:** Mode selection of the ADC_CHSELR register

This bit is set and cleared by software to control the ADC_CHSELR feature:

- 0: Each bit of the ADC_CHSELR register enables an input
- 1: ADC_CHSELR register is able to sequence up to 8 channels

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bits 20:17  Reserved, must be kept at reset value.
Bit 16 **DISCEN**: Discontinuous mode
This bit is set and cleared by software to enable/disable discontinuous mode.
- 0: Discontinuous mode disabled
- 1: Discontinuous mode enabled

*Note:* It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.

*The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 15 Reserved, must be kept at reset value.

Bit 14 **WAIT**: Wait conversion mode
This bit is set and cleared by software to enable/disable wait conversion mode.
- 0: Wait conversion mode off
- 1: Wait conversion mode on

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 13 **CONT**: Single/continuous conversion mode
This bit is set and cleared by software. If it is set, conversion takes place continuously until it is cleared.
- 0: Single conversion mode
- 1: Continuous conversion mode

*Note:* It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.

*The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 12 **OVRMOD**: Overrun management mode
This bit is set and cleared by software and configure the way data overruns are managed.
- 0: ADC_DR register is preserved with the old data when an overrun is detected.
- 1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection
These bits are set and cleared by software to select the external trigger polarity and enable the trigger.
- 00: Hardware trigger detection disabled (conversions can be started by software)
- 01: Hardware trigger detection on the rising edge
- 10: Hardware trigger detection on the falling edge
- 11: Hardware trigger detection on both the rising and falling edges

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 9 Reserved, must be kept at reset value.
Bits 8:6 **EXTSEL[2:0]:** External trigger selection
These bits select the external event used to trigger the start of conversion (refer to table ADC interconnection in Section 34.4.2: ADC pins and internal signals for details):

- 000: adc_trg0
- 001: adc_trg1
- 010: adc_trg2
- 011: adc_trg3
- 100: adc_trg4
- 101: adc_trg5
- 110: adc_trg6
- 111: adc_trg7

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 5 **ALIGN:** Data alignment
This bit is set and cleared by software to select right or left alignment. Refer to Figure 285: Data alignment and resolution (oversampling disabled: OVSE = 0) on page 1389

- 0: Right alignment
- 1: Left alignment

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 4 **SCANDIR:** Scan sequence direction
This bit is set and cleared by software to select the direction in which the channels are scanned in the sequence. It is effective only if CHSELROMD bit is cleared to 0.

- 0: Upward scan (from CHSEL0 to CHSEL23)
- 1: Backward scan (from CHSEL23 to CHSEL0)

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bits 3:2 **RES[1:0]:** Data resolution
These bits are written by software to select the resolution of the conversion.

- 00: 12 bits
- 01: 10 bits
- 10: 8 bits
- 11: 6 bits

*Note:* The software is allowed to write these bits only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).
Bit 1 **DMACFG**: Direct memory access configuration
This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN = 1.
0: DMA one-shot mode selected
1: DMA circular mode selected
For more details, refer to Section : Managing converted data using the DMA on page 1390
Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 0 **DMAEN**: Direct memory access enable
This bit is set and cleared by software to enable the generation of DMA requests. This allows the automatic management of the converted data by the DMA controller. For more details, refer to Section : Managing converted data using the DMA on page 1390.
0: DMA disabled
1: DMA enabled
Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **LFTRIG**: Low-frequency trigger mode enable
This bit must be set by software.
0: Reserved
1: Low-frequency trigger mode enabled.
Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bits 28:10 Reserved, must be kept at reset value.

Bit 9 **TOVS**: Triggered Oversampling
This bit is set and cleared by software.
0: All oversampled conversions for a channel are done consecutively after a trigger
1: Each oversampled conversion for a channel needs a trigger
Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).
Bits 8:5 **OVSS[3:0]: Oversampling shift**
This bit is set and cleared by software.
- 0000: No shift
- 0001: Shift 1-bit
- 0010: Shift 2-bits
- 0011: Shift 3-bits
- 0100: Shift 4-bits
- 0101: Shift 5-bits
- 0110: Shift 6-bits
- 0111: Shift 7-bits
- 1000: Shift 8-bits
Others: Reserved

*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*

Bits 4:2 **OVSR[2:0]: Oversampling ratio**
This bit filed defines the number of oversampling ratio.
- 000: 2x
- 001: 4x
- 010: 8x
- 011: 16x
- 100: 32x
- 101: 64x
- 110: 128x
- 111: 256x

*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*

Bit 1 Reserved, must be kept at reset value.

Bit 0 **OVSE: Oversampler Enable**
This bit is set and cleared by software.
- 0: Oversampler disabled
- 1: Oversampler enabled

*Note: Software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*

### 34.7.6 ADC sampling time register (ADC_SMPR)

34.7.8 ADC watchdog threshold register (ADC_AWD2TR)

Address offset: 0x24

Reset value: 0xFFFF 0000

| Bits 31:28 | Reserved, must be kept at reset value. |
| Bits 27:16 | HT2[11:0]: Analog watchdog 2 higher threshold |
|           | These bits are written by software to define the higher threshold for the analog watchdog. |
|           | Refer to Section 34.4.25: Analog window watchdog on page 1396. |
| Bits 15:12 | Reserved, must be kept at reset value. |
| Bits 11:0  | LT2[11:0]: Analog watchdog 2 lower threshold |
|           | These bits are written by software to define the lower threshold for the analog watchdog. |
|           | Refer to Section 34.4.25: Analog window watchdog on page 1396. |
34.7.9 ADC channel selection register [alternate] (ADC_CHSELR)

Address offset: 0x28
Reset value: 0x0000 0000

The same register can be used in two different modes:
– Each ADC_CHSELR bit enables an input (CHSELRMOD = 0 in ADC_CFGR1). Refer to the current section.
– ADC_CHSELR is able to sequence up to 8 channels (CHSELRMOD = 1 in ADC_CFGR1). Refer to next section.

CHSELRMOD = 0 in ADC_CFGR1

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 CHSELx: Channel x selection (x = 23 to 0)
These bits are written by software and define which channels are part of the sequence of channels to be converted.
0: Input Channel-x is not selected for conversion
1: Input Channel-x is selected for conversion

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

34.7.10 ADC channel selection register [alternate] (ADC_CHSELR)

Address offset: 0x28
Reset value: 0x0000 0000

The same register can be used in two different modes:
– Each ADC_CHSELR bit enables an input (CHSELRMOD = 0 in ADC_CFGR1). Refer to the current previous section.
– ADC_CHSELR is able to sequence up to 8 channels (CHSELRMOD = 1 in ADC_CFGR1). Refer to this section.

CHSELRMOD = 1 in ADC_CFGR1

1010: CH10
1011: CH11
1100: CH12
1101: CH13
1110: CH14
1111: No channel selected (End of sequence)

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bits 27:24 **SQ7[3:0]**: 7th conversion of the sequence
These bits are programmed by software with the channel number assigned to the 7th conversion of the sequence. 0b1111 indicates end of the sequence. When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.
Refer to **SQ8[3:0]** for a definition of channel selection.

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bits 23:20 **SQ6[3:0]**: 6th conversion of the sequence
These bits are programmed by software with the channel number assigned to the 6th conversion of the sequence. 0b1111 indicates end of the sequence. When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.
Refer to **SQ8[3:0]** for a definition of channel selection.

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bits 19:16 **SQ5[3:0]**: 5th conversion of the sequence
These bits are programmed by software with the channel number assigned to the 5th conversion of the sequence. 0b1111 indicates end of the sequence. When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.
Refer to **SQ8[3:0]** for a definition of channel selection.

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bits 15:12 **SQ4[3:0]**: 4th conversion of the sequence
These bits are programmed by software with the channel number assigned to the 4th conversion of the sequence. 0b1111 indicates end of the sequence. When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.
Refer to **SQ8[3:0]** for a definition of channel selection.

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).
### 34.7.11 ADC watchdog threshold register (ADC_AWD3TR)

Address offset: 0x2C

Reset value: 0x0FFF 0000

#### Bits 11:8 SQ3[3:0]: 3rd conversion of the sequence

These bits are programmed by software with the channel number assigned to the 3rd conversion of the sequence. 0b1111 indicates end of the sequence.

When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.

Refer to SQ8[3:0] for a definition of channel selection.

*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*

#### Bits 7:4 SQ2[3:0]: 2nd conversion of the sequence

These bits are programmed by software with the channel number assigned to the 2nd conversion of the sequence. 0b1111 indicates end of the sequence.

When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.

Refer to SQ8[3:0] for a definition of channel selection.

*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*

#### Bits 3:0 SQ1[3:0]: 1st conversion of the sequence

These bits are programmed by software with the channel number assigned to the 1st conversion of the sequence. 0b1111 indicates end of the sequence.

When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.

Refer to SQ8[3:0] for a definition of channel selection.

*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **VREFSECSMP**: VREF+ second sample bit
This bit is set and cleared by software. It is used to enable/disable the second VREF+ protection when multiple ADCs are working simultaneously and a clock divider of 1 is used.

0: VREF+ second sample disabled
1: VREF+ second sample enabled

*Note: The software is allowed to write this bit only when ADEN bit is cleared to 0 (this ensures that no conversion is ongoing).*

Bit 2 **VREFPROT**: VREF+ protection bit
This bit is set and cleared by software. It is used to enable/disable VREF+ protection when multiple ADCs are working simultaneously and a clock divider is used.

0: VREF+ protection disabled
1: VREF+ protection enabled

*Note: The software is allowed to write this bit only when ADEN bit is cleared to 0 (this ensures that no conversion is ongoing).*

Bit 1 **DPD**: Deep-power-down mode bit
This bit is set and cleared by software. It is used to enable/disable Deep-power-down mode in autonomous mode when the ADC is not used.

0: Deep-power-down mode disabled
1: Deep-power-down mode enabled

*Note: The software is allowed to write this bit only when ADEN bit is cleared to 0 (this ensures that no conversion is ongoing).*

Setting DPD in auto-off mode automatically disables the LDO.

Bit 0 **AUTOFF**: Auto-off mode bit
This bit is set and cleared by software. It is used to enable/disable the auto-off mode.

0: Auto-off mode disabled
1: Auto-off mode enabled

*Note: The software is allowed to write this bit only when ADEN bit is cleared to 0 (this ensures that no conversion is ongoing).*

Bits 31:24 Reserved, must be kept at reset value.

Note: The channels selected through ADC_AWD3CR must be also configured into the ADC_CHSELR registers. Refer to SQ8[3:0] for a definition of channel selection. The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).
Bits 31:7 Reserved, must be kept at reset value.

Bits 6:0 CALFACT[6:0]: Calibration factor
These bits are written by hardware or by software.
– Once a calibration is complete, they are updated by hardware with the calibration factors.
– Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new calibration is launched.
– Just after a calibration is complete, DATA[6:0] contains the calibration factor.

Note: Software can write these bits only when ADEN = 1 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

Reset value

Refer to Section 2.3 on page 139 for the register boundary addresses.
35 Digital-to-analog converter (DAC)

35.1 Introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data can be left- or right-aligned. The DAC features two output channels, each with its own converter. In dual DAC channel mode, conversions can be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, VREF+ (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to voltage reference buffer (VREFBUF) section.

The DACx_OUTy pin can be used as general purpose input/output (GPIO) when the DAC output is disconnected from output pad and connected to on-chip peripheral. The DAC output buffer can be optionally enabled to obtain a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the Sample and hold mode.

35.2 DAC main features

The DAC main features are the following (see Figure 302: Dual-channel DAC block diagram)

- One DAC interface, maximum two output channels
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- Double data DMA capability to reduce the bus activity
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Each DAC output can be disconnected from the DACx_OUTy output pin
- DAC output connection to on-chip peripherals
- Sample and hold mode for low power operation in Stop mode
- Autonomous mode to reduce the power consumption for the system
- Input voltage reference from VREF+ pin or internal VREFBUF reference

Figure 302 shows the block diagram of a DAC channel and Table 336 gives the pin description.
35.3 DAC implementation

35.4 DAC functional description

35.4.1 DAC block diagram

Figure 302. Dual-channel DAC block diagram

1. MODEx bits in the DAC_MCR control the output mode and allow switching between the Normal mode in buffer/unbuffered configuration and the Sample and hold mode.

2. Refer to Section 35.3: DAC implementation for channel2 availability.
35.4.2 DAC pins and internal signals

The DAC includes:

- Up to two output channels
- The DACx_OUTy can be disconnected from the output pin and used as an ordinary GPIO
- The dac_outx can use an internal pin connection to on-chip peripherals such as comparator, operational amplifier and ADC (if available).
- DAC output channel buffered or non buffered
- Sample and hold block and registers operational in Stop mode, using the LSI/LSE clock source (dac_hold_ck) for static conversion.

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DACx_OUTy output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The Sample and hold block and its associated registers can run in Stop mode using the LSI/LSE clock source (dac_hold_ck).

</table>
35.4.3 DAC clocks

Two clock sources can be used to update the DAC:
- dac_hclk: DAC peripheral clock (AHB clock)
- dac_ker_ck: DAC kernel clock: this clock can be used to synchronize DAC and ADC.
- dac_hold_ck: low-power clock used in Sample and hold mode

The DAC clock is selected in the RCC.

35.4.4 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC_CR register. The DAC channel is then enabled after a tWAKEUP startup time.

DACxRDY bit is set in the DAC_SR register when the DAC interface is ready to accept data. Writing new data or asserting the trigger is not allowed when ENx bit is set while DACxRDY signal is reset.

**Note:** The ENx bit enables the analog DAC channel x only. The DAC channel x digital interface is enabled even if the ENx bit is reset.
35.4.5 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channel
  
  There are three possibilities:
  - 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)
  - 12-bit left alignment: the software has to load data into the DAC_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)
  - 12-bit right alignment: the software has to load data into the DAC_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding registers, which are internal non-memory-mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.

- Dual DAC channels (when available)
  
  There are three possibilities:
  - 8-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)
  - 12-bit left alignment: data for DAC channel1 to be loaded into the DAC_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)
  - 12-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC_DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.
Signed/unsigned data

DAC input data are unsigned: 0x000 corresponds to the minimum value and 0xFFF to the maximum value for 12-bit mode.

The DAC can also handle signed input data in 2’s complement format. This is done by setting SINFORMATx bit in the DAC_MCR register.

When SINFORMATx bit is set, the MSB bit of the data written to DHRx registers is inverted when it is copied to the DAC_DORx register, and the DAC interface can accept signed data (Q1.15, Q1.11 or Q1.7 format). DAC_DHR12Lx register can be used to store 16-bit signed data in the data holding registers. The 12 MSBs of 16-bit data are used for the DAC output data and the MSB bit is inverted. The four LSBs are simply ignored.

<table>

35.4.6 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channel must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one dac_hclk clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three dac_hclk clock cycles after the trigger signal.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time \( t_{\text{SETTLING}} \) that depends on the power supply voltage and the analog output load.
To synchronize DAC and ADC, the same clock source can be used for both peripherals. This is done by selecting the dac_ker_ck clock instead of the dac_hclk clock (AHB clock) in the RCC.

HFSEL bits of DAC_MCR must be set when dac_hclk or dac_ker_ck clock speed is faster than 80 MHz. It adds an extra delay to the transfer from DAC_DHRx register to DAC_DORx register.

Refer to Table HFSEL description below for the limitation of the DAC_DORx update rate depending on HFSEL bits and dac_hclk clock frequency.

If the data is updated or a software/hardware trigger event occurs during the non-allowed period, the peripheral behavior is unpredictable.

The above timing is only related to the limitation of the DAC interface. Refer also to the tSETTLING parameter value in the product datasheet.

Table 340. HFSEL description

1. Refer to the device datasheet for the value of the maximum AHB frequency.

Figure 305. Timing diagram for conversion with trigger disabled TEN = 0

![Timing diagram](image-url)
35.4.7 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and $V_{REF+}$. The analog output voltages on each DAC channel pin are determined by the following equation:

$$\text{DAC output} = V_{REF} \times \frac{D\text{OR}}{4096}$$

35.4.8 DAC trigger selection

If the TEN control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events triggers the conversion as shown in TSELx[3:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers. Refer to the interconnection table in Section 35.4.2: DAC pins and internal signals.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the DAC_DORx register. The DAC_DORx register is updated three dac_hclk cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

**Note:**

TSELx[3:0] bit cannot be changed when the ENx bit is set.

When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one dac_hclk clock cycle.

35.4.9 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit must be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

**DMA underrun**

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

The software must clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA...
workload to avoid a new DMA underrun. Finally, the DAC conversion can be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channel, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

**DMA Double data mode**

When the DMA controller is used in Normal mode, only 12-bit (or 8-bit) data are transferred by a DMA request. As the AHB width is 32 bits, two 12-bit data may be transferred simultaneously. To use this mode, set the DMADOUBLEEx bit of DAC_MCR register.

A DAC DMA request is generated every two external triggers (except for software triggers) when the DMAENx bit is set:

1. When the first trigger is detected, the value of the DAC_DHRx and DAC_DHRBx registers are transferred into the DAC_DORx and DAC_DORBx registers. The actual DAC data is loaded into the DAC_DORx register. A DMA request is then generated. The DMA writes the new data to the DAC_DHRx and DAC_DHRBx data registers.

2. When the next trigger is detected, the actual DAC data is loaded into the DAC_DHRBx register. This second trigger does not generate any DMA request. The DORSTATx bit indicates which DOR data is actually loaded into the analog DAC input.

DMA underrun function is also supported in DMA Double data mode.

In DMA Double mode, DMA requests can only handle one DAC channel. To use two channel outputs in DMA Double mode, each DMA channel has to be configured separately.

The following conditions must be met to change from Double data to single data mode or vice versa:

- The DAC must be disabled.
- DMAEN bit must be cleared (ENx = 0 and DMAEN = 0).

### 35.4.10 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01. The preloaded value in LFSR is 0xAAA. This register is updated three dac_hclk clock cycles after each trigger event, following a specific calculation algorithm.
The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then transferred into the DAC_DORx register.

If LFSR is 0x0000, a ‘1’ is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

**Note:** The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.
35.4.11 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEX[1:0] to 10. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three dac_hclk clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

![Figure 308. DAC triangle wave generation](image1)

![Figure 309. DAC conversion (SW trigger enabled) with triangle wave generation](image2)

Note: The DAC trigger must be enabled for triangle wave generation by setting the TENx bit in the DAC_CR register. The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.
35.4.12 DAC channel modes

Each DAC channel can be configured in Normal mode or Sample and hold mode. The output buffer can be enabled to obtain a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In Normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUTy pin interconnections.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:
- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:
- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals

Sample and hold mode

In Sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI/LSE low-speed clock (dac_hold_ck) in addition to the dac_hclk clock, allowing using the DAC channels in deep low power modes such as Stop mode.

The LSI/LSE low-speed clock (dac_hold_ck) must not be stopped when the Sample and hold mode is enabled.

The sample/hold mode operations can be divided into 3 phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEEx[9:0] bits, the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clocks domains (AHB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation

2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC_SHHR register

3. Refresh phase: the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register
The timings for the three phases above are in units of LSI/LSE clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI/LSE ~32 KHz is selected:

12 cycles are required for sample phase: TSAMPLEx[9:0] = 11,
62 cycles are required for hold phase: THOLDx[9:0] = 62,
and 4 cycles are required for refresh period: TREFRESHx[7:0] = 4.

In this example, the power consumption is reduced by almost a factor of 15 versus Normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

### Table 341. Sample and refresh timings

<table>
<thead>
<tr>
<th>Buffer State</th>
<th>( t_{\text{SAMP}}^{(1)(2)} )</th>
<th>( t_{\text{REFRESH}}^{(2)(3)} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable</td>
<td>( 7 \mu s + (10*R_{\text{BON}}*C_{\text{SH}}) )</td>
<td>( 7 \mu s + (R_{\text{BON}}<em>C_{\text{SH}})</em>\ln(2*N_{\text{LSB}}) )</td>
</tr>
<tr>
<td>Disable</td>
<td>( 3 \mu s + (10*R_{\text{BOFF}}*C_{\text{SH}}) )</td>
<td>( 3 \mu s + (R_{\text{BOFF}}<em>C_{\text{SH}})</em>\ln(2*N_{\text{LSB}}) )</td>
</tr>
</tbody>
</table>

1. In the above formula the settling to the desired code value with ½ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8 bits resolution, the settling time is 7 constant time.

2. \( C_{\text{SH}} \) is the capacitor in Sample and hold mode.

3. The tolerated voltage drop during the hold phase “Vd” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with ½ LSB error accuracy requires \( \ln(2*N_{\text{LSB}}) \) constant time of the DAC.

### Example of the sample and refresh time calculation with output buffer on

The values used in the example below are provided as indication only. Refer to the product datasheet for product data.

\( C_{\text{SH}} = 100 \text{ nF} \)

\( V_{\text{REF+}} = 3.0 \text{ V} \)

**Sampling phase:**

\( t_{\text{SAMP}} = 7 \mu s + (10 * 2000 * 100 * 10^{-9}) = 2.007 \text{ ms} \)
(where \( R_{\text{BON}} = 2 \text{ k}\Omega \))

**Refresh phase:**

\( t_{\text{REFRESH}} = 7 \mu s + (2000 * 100 * 10^{-9}) \cdot \ln(2*10) = 606.1 \mu s \)
(where \( N_{\text{LSB}} = 10 \) (10 LSB drop during the hold phase)

**Hold phase:**

\( D_{\text{V}} = i_{\text{leak}} \cdot t_{\text{hold}} / C_{\text{SH}} = 0.0073 \text{ V} \) (10 LSB of 12bit at 3 V)

\( i_{\text{leak}} = 150 \text{ nA} \) (worst case on the IO leakage on all the temperature range)

\( t_{\text{hold}} = 0.0073 \times 100 \times 10^{-9} / (150 \times 10^{-9}) = 4.867 \text{ ms} \)
Like in Normal mode, the Sample and hold mode has different configurations.

To enable the output buffer, MODEX[2:0] bits in DAC_MCR register must be set to:
- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals

To disable the output buffer, MODEX[2:0] bits in DAC_MCR register must be set to:
- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

When MODEX[2:0] bits are equal to 111, an internal capacitor, $C_{\text{int}}$, holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All Sample and hold phases are interruptible, and any change in DAC_DHRx immediately triggers a new sample phase.

35.4.13 DAC channel buffer calibration

The transfer function for an N-bit digital-to-analog converter (DAC) is:

\[ V_{\text{out}} = \left( \frac{D}{2^N} \right) \times G \times V_{\text{ref}} + V_{\text{OS}} \]

Where \( V_{\text{OUT}} \) is the analog output, \( D \) is the digital input, \( G \) is the gain, \( V_{\text{ref}} \) is the nominal full-scale voltage, and \( V_{\text{OS}} \) is the offset voltage. For an ideal DAC channel, \( G = 1 \) and \( V_{\text{OS}} = 0 \).

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the \( V_{\text{OS}} \), a calibration is required by a trimming technique.

The calibration is only valid when the DAC channel is operating with buffer enabled (MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101). If applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to \( V_{\text{REF+2}} \) signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAGx bit).

Two calibration techniques are provided:

- Factory trimming (default setting)
  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.
- User trimming
  The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when \( V_{\text{DDA}} \) voltage, temperature, \( V_{\text{REF+}} \) values change and can be done at any point during application by software.

Note: Refer to the datasheet for more details of the Nominal factory trimming conditions

In addition, when \( V_{\text{DD}} \) is removed (example the device enters in STANDBY or VBAT modes) the calibration is required.

The steps to perform a user trimming calibration are as below:

<table>
<thead>
<tr>
<th>MODEx[2:0]</th>
<th>Mode</th>
<th>Buffer</th>
<th>Output connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0 0</td>
<td>Sample and hold mode</td>
<td>Enabled</td>
<td>Connected to external pin</td>
</tr>
<tr>
<td>1 0 1</td>
<td>Sample and hold mode</td>
<td>Enabled</td>
<td>Connected to external pin and to on chip peripherals (such as comparators)</td>
</tr>
<tr>
<td>1 1 0</td>
<td>Sample and hold mode</td>
<td>Disabled</td>
<td>Connected to external pin and to on chip peripherals (such as comparators)</td>
</tr>
<tr>
<td>1 1 1</td>
<td>Sample and hold mode</td>
<td>Disabled</td>
<td>Connected to on chip peripherals (such as comparators)</td>
</tr>
</tbody>
</table>
1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101.
3. Start the DAC channelx calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIMx[4:0] bits, starting by 0b00000.
   b) Wait for tTRIM delay.
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   d) If CAL_FLAGx is set to 1, the OTRIMx[4:0] trimming code is found and can be used during device operation to compensate the output value, else increment OTRIMx[4:0] and repeat sub-steps from (a) to (d) again.

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way.

The commutation/toggle of CAL_FLAGx bit indicates that the offset is correctly compensated and the corresponding trim code must be kept in the OTRIMx[4:0] bits in DAC_CCR register.

**Note:**

A tTRIM delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL_FLAGx bit in DAC_SR register in order to get a correct value. This parameter is specified into datasheet electrical characteristics section.

If VDDA, VREF+ and temperature conditions do not change during device operation while it enters more often in standby and VBAT mode, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers. Then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time.

When CENx bit is set, it is not allowed to set ENx bit.

### 35.4.14 Dual DAC channel conversion modes (if dual channels are available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time. For the wave generation, no accesses to DHRxxxD registers are required. As a result, two output channels can be used either independently or simultaneously.

15 conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHRx registers if needed.

All modes are described in the paragraphs below.

**Independent trigger without wave generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).
When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three dac_hclk clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three dac_hclk clock cycles later).

**Independent trigger with single LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.

**Independent trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.
Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Independent trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bits.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Simultaneous software start

To configure the DAC in this conversion mode, the following sequence is required:

- Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

In this configuration, one dac_hclk clock cycle later, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively.

Simultaneous trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three dac_hclk clock cycles).

**Simultaneous trigger with single LFSR generation**

1. To configure the DAC in this conversion mode, the following sequence is required:
2. Set the two DAC channel trigger enable bits TEN1 and TEN2.
3. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
4. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
5. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD).

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with single triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value using the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Simultaneous trigger with different triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0]  bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three AHB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the DAC channel2 triangle counter is updated.

### 35.4.15 DAC Autonomous mode

The Autonomous mode can be used to update the DAC output voltage in Stop mode. This allows DMA transfers to be performed when the device operates in Run, Sleep or Stop mode. The Autonomous mode is supported AUTOMODE only when the DAC is in Sample and hold mode. It is enabled by setting the bit in the DAC_AUTOCR register. DMA requests must also be enabled (DMAEN = 1).

When the AUTOMODE bit is set, each hardware trigger signal generates an AHB clock request to the RCC. Once the peripheral receives the AHB clock, the content of the DHRx register is loaded into DAC_DOR register and a DMA request is generated. When the DMA transaction is complete, the DAC deasserts the AHB clock request and waits for a new trigger event.

When the Sample and hold mode is selected, the dac_ker_ck low-power clock must be enabled by the RCC.
DMA transfers in Autonomous mode are performed following the sequence described below:
1. The DAC outputs the voltage on a GPIO or on an on-chip peripheral (dac_ker_ck and dac_hclk are not required).
2. The DAC receives a hardware trigger from another peripheral.
3. The DAC asserts the clock request.
4. The DAC loads DHRx register into DAC_DOR register.
5. The DAC generates a DMA request.
6. The DMA transfers the new data from memory to DHRx registers.
7. The DAC deasserts the clock request.

To initialize the DAC to operate autonomously in Stop mode, follow the sequence below:
1. Enable the DAC clock Autonomous mode in the RCC.
2. Select the DAC kernel clock in the RCC.
3. Enable dac_hold_ck clock for the DAC in the RCC.
4. Select a Sample and hold mode through MODEEx bit.
5. Configure the Sample and hold mode by setting TSAMPLEEx[9:0], THOLDx[9:0], TREFRESHx[7:0] bits.
6. Load the target value into DHRx register.
7. Set TENx bit to output the DAC value.
8. Configure the trigger setting through TSEL[3:0] bits.
9. Set DMAENx bit and configure the DMA interface.
10. Set the AUTOMODE bit.

**Timing uncertainty of DHRx to DAC_DOR transfer**

After each trigger event, the data contained in DHRx register is transferred to the DAC_DOR register. Since this transfer is based on AHB clock, the transfer timing depends on the clock availability.

When the AHB clock is stopped, a minimum time is required to restart it. This time depends on the clock source.

### 35.5 DAC in low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect, DAC used with DMA.</td>
</tr>
<tr>
<td>Stop(^{(1)})</td>
<td>The DAC remains functional and can perform DMA transfers in Sample and hold mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The DAC peripheral is powered down and must be reinitialized after exiting Standby or Shutdown mode.</td>
</tr>
<tr>
<td>Shutdown</td>
<td></td>
</tr>
</tbody>
</table>

1. Refer to [Section 35.3: DAC implementation](#) for information on the Stop modes supported by the DAC peripheral.
### 35.6 DAC interrupts

Table 344. DAC interrupts

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
<th>Exit Sleep mode</th>
<th>Exit Stop mode</th>
<th>Exit Standby mode</th>

</tbody>
</table>
Bits 27:24 **MAMP2[3:0]**: DAC channel2 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.
0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

*Note:* These bits are available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.

Bits 23:22 **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable

These bits are set/reset by software.
00: wave generation disabled
01: Noise wave generation enabled
1x: Triangle wave generation enabled

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)

These bits are available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.

Bits 21:18 **TSEL2[3:0]**: DAC channel2 trigger selection

These bits select the external event used to trigger DAC channel2
0000: SWTRIG2
0001: dac_ch2_trg1
0010: dac_ch2_trg2
...
1111: dac_ch2_trg15

Refer to the trigger selection tables in Section 35.4.2: DAC pins and internal signals for details on trigger configuration and mapping.

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)

These bits are available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.

Bit 17 **TEN2**: DAC channel2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel2 trigger
0: DAC channel2 trigger disabled and data written into the DAC_DHR2 register are transferred one dac_hclk clock cycle later to the DAC_DOR2 register
1: DAC channel2 trigger enabled and data from the DAC_DHR2 register are transferred three dac_hclk clock cycles later to the DAC_DOR2 register

*Note:* When software trigger is selected, the transfer from the DAC_DHR2 register to the DAC_DOR2 register takes only one dac_hclk clock cycle.

These bits are available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.
Bit 16  **EN2**: DAC channel2 enable
This bit is set and cleared by software to enable/disable DAC channel2.
0: DAC channel2 disabled
1: DAC channel2 enabled

*Note:* These bits are available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.

Bit 15  Reserved, must be kept at reset value.

Bit 14  **CEN1**: DAC channel1 calibration enable
This bit is set and cleared by software to enable/disable DAC channel1 calibration, it can be written only if bit EN1 = 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.
0: DAC channel1 in Normal operating mode
1: DAC channel1 in calibration mode

Bit 13  **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable
This bit is set and cleared by software.
0: DAC channel1 DMA Underrun Interrupt disabled
1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12  **DMAEN1**: DAC channel1 DMA enable
This bit is set and cleared by software.
0: DAC channel1 DMA mode disabled
1: DAC channel1 DMA mode enabled

Bits 11:8  **MAMP1[3:0]**: DAC channel1 mask/amplitude selector
These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.
0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6  **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable
These bits are set and cleared by software.
00: wave generation disabled
01: Noise wave generation enabled
1x: Triangle wave generation enabled
Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).
### 35.7.2 DAC software trigger register (DAC_SWTRGR)

**Address offset:** 0x04  
**Reset value:** 0x0000 0000

**Bits 5-2**  **TSEL[3:0]:** DAC channel1 trigger selection  
These bits select the external event used to trigger DAC channel1  
0000: SWTRIG1  
0001: dac_ch1_trg1  
0010: dac_ch1_trg2  
...  
1111: dac_ch1_trg15  
Refer to the trigger selection tables in *Section 35.4.2: DAC pins and internal signals* for details on trigger configuration and mapping.  
*Note:* Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

**Bit 1**  **TEN1:** DAC channel1 trigger enable  
This bit is set and cleared by software to enable/disable DAC channel1 trigger.  
0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one dac_hclk clock cycle later to the DAC_DOR1 register  
1: DAC channel1 trigger enabled and data from the DAC_DHR1 register are transferred three dac_hclk clock cycles later to the DAC_DOR1 register  
*Note:* When software trigger is selected, the transfer from the DAC_DHR1 register to the DAC_DOR1 register takes only one dac_hclk clock cycle.

**Bit 0**  **EN1:** DAC channel1 enable  
This bit is set and cleared by software to enable/disable DAC channel1.  
0: DAC channel1 disabled  
1: DAC channel1 enabled
Bits 31:2  Reserved, must be kept at reset value.

Bit 1  **SWTRIG2**: DAC channel2 software trigger
This bit is set by software to trigger the DAC in software trigger mode.
0: No trigger
1: Trigger

*Note:* This bit is cleared by hardware (one dac_hclk clock cycle later) once the DAC_DHR2 register value has been loaded into the DAC_DOR2 register.

This bit is available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.

Bit 0  **SWTRIG1**: DAC channel1 software trigger
This bit is set by software to trigger the DAC in software trigger mode.
0: No trigger
1: Trigger

*Note:* This bit is cleared by hardware (one dac_hclk clock cycle later) once the DAC_DHR1 register value has been loaded into the DAC_DOR1 register.

</table>

**Bit 31 BWST2:** DAC channel2 busy writing sample time flag

This bit is systematically set just after Sample and hold mode enable. It is set each time the software writes the register DAC_SHSR2. It is cleared by hardware when the write operation of DAC_SHSR2 is complete. (It takes about 3 LSI/LSE periods of synchronization).

0: There is no write operation of DAC_SHSR2 ongoing; DAC_SHSR2 can be written
1: There is a write operation of DAC_SHSR2 ongoing; DAC_SHSR2 cannot be written

**Note:** This bit is available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.

**Bit 30 CAL_FLAG2:** DAC channel2 calibration offset status

This bit is set and cleared by hardware

0: calibration trimming value is lower than the offset correction value
1: calibration trimming value is equal or greater than the offset correction value

**Note:** This bit is available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.

**Bit 29 DMAU:** DAC channel2 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel2
1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate).

**Note:** This bit is available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.

**Bit 28 DORST2:** DAC channel2 output register status bit

This bit is set and cleared by hardware. It is applicable only when the DAC operates in Double data mode.

0: DOR[11:0] is used actual DAC output
1: DORB[11:0] is used actual DAC output

**Note:** This bit is available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.

**Bit 27 DAC2RDY:** DAC channel2 ready status bit

This bit is set and cleared by hardware.

0: DAC channel2 is not yet ready to accept the trigger nor output data
1: DAC channel2 is ready to accept the trigger or output data

**Note:** This bit is available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.
35.7.15 DAC calibration control register (DAC_CCR)

Address offset: 0x38

Reset value: 0x00XX 00XX

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 OTRIM2[4:0]: DAC channel2 offset trimming value

   These bits are available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.

Bits 15:5 Reserved, must be kept at reset value.

Bits 4:0 OTRIM1[4:0]: DAC channel1 offset trimming value

This bit is systematically set just after Sample and hold mode enable and is set each time the software writes the register DAC_SHSR1. It is cleared by hardware when the write operation of DAC_SHSR1 is complete. (It takes about 3 LSI/LSE periods of synchronization).

0: There is no write operation of DAC_SHSR1 ongoing: DAC_SHSR1 can be written
1: There is a write operation of DAC_SHSR1 ongoing: DAC_SHSR1 cannot be written

This bit is systematically set just after Sample and hold mode enable and is set each time the software writes the register DAC_SHSR1. It is cleared by hardware when the write operation of DAC_SHSR1 is complete. (It takes about 3 LSI/LSE periods of synchronization).

0: There is no write operation of DAC_SHSR1 ongoing: DAC_SHSR1 can be written
1: There is a write operation of DAC_SHSR1 ongoing: DAC_SHSR1 cannot be written

This bit is set and cleared by hardware. It is applicable only when the DAC operates in Double data mode.
0: DOR[11:0] is used actual DAC output
1: DORB[11:0] is used actual DAC output

This bit is set and cleared by hardware. This bit is set by hardware and cleared by software (by writing it to 1).
0: No DMA underrun error condition occurred for DAC channel1
1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

This bit is set and cleared by hardware. This bit is set and cleared by hardware.
0: DAC channel1 is not yet ready to accept the trigger nor output data
1: DAC channel1 is ready to accept the trigger or output data

Bits 10:0 Reserved, must be kept at reset value.
### 35.7.16 DAC mode control register (DAC_MCR)

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **SINFO2**: Enable signed format for DAC channel2

This bit is set and cleared by software.

0: Input data is in unsigned format  
1: Input data is in signed format (2’s complement). The MSB bit represents the sign.

**Note:** This bit is available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.

Bit 24 **DMADouble2**: DAC channel2 DMA double data mode

This bit is set and cleared by software.

0: DMA Normal mode selected  
1: DMA Double data mode selected

**Note:** This bit is available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.

Bits 23:19 Reserved, must be kept at reset value.

Bits 18:16 **MODE2[2:0]**: DAC channel2 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN2 = 0 and bit CEN2 = 0 in the DAC_CR register). If EN2 = 1 or CEN2 = 1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel2 mode:

- **DAC channel2 in Normal mode**
  - 000: DAC channel2 is connected to external pin with Buffer enabled
  - 001: DAC channel2 is connected to external pin and to on chip peripherals with buffer enabled
  - 010: DAC channel2 is connected to external pin with buffer disabled
  - 011: DAC channel2 is connected to on chip peripherals with Buffer disabled

- **DAC channel2 in Sample and hold mode**
  - 100: DAC channel2 is connected to external pin with Buffer enabled
  - 101: DAC channel2 is connected to external pin and to on chip peripherals with Buffer enabled
  - 110: DAC channel2 is connected to external pin and to on chip peripherals with Buffer disabled
  - 111: DAC channel2 is connected to on chip peripherals with Buffer disabled

**Note:** This register can be modified only when EN2 = 0.  
Refer to Section 35.3: DAC implementation for the availability of DAC channel2.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 TREFRESH2[7:0]: DAC channel2 refresh time (only valid in Sample and hold mode)

Refresh time = (TREFRESH[7:0]) x LSI/LSE clock period

Note: This register can be modified only when EN2 = 0.

These bits are available only on dual-channel DACs. Refer to Section 35.3: DAC implementation.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 TREFRESH1[7:0]: DAC channel1 refresh time (only valid in Sample and hold mode)

Refresh time = (TREFRESH[7:0]) x LSI/LSE clock period

Note: This register can be modified only when EN1 = 0.

Note: These bits can be written only when the DAC channel is disabled and in Normal operating mode (when bit ENx = 0 and bit CENx = 0 in the DAC_CR register). If ENx = 1 or CENx = 1 the write operation is ignored.
35.7.21  DAC Autonomous mode control register (DAC_AUTOCR)

Address offset: 0x54
Reset value: 0x0000 0000

36 Voltage reference buffer (VREFBUF)

36.1 Introduction

The devices embed a voltage reference buffer which can be used as voltage reference for ADCs, DACs and also as voltage reference for external components through the VREF+ pin.

36.2 VREFBUF implementation

The table below describes the VREFBUF voltages typical values:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>VREFBUF0</td>
<td>1.5 V</td>
</tr>
<tr>
<td>VREFBUF1</td>
<td>1.8 V</td>
</tr>
<tr>
<td>VREFBUF2</td>
<td>2.048 V</td>
</tr>
<tr>
<td>VREFBUF3</td>
<td>2.5 V</td>
</tr>
</tbody>
</table>

*Note: Refer to the product datasheet for more details.*

36.3 VREFBUF functional description

![Figure 311. VREFBUF block diagram](image)
The internal voltage reference buffer is an operational amplifier, with programmable gain. The amplifier input is connected to the internal voltage reference \( V_{\text{REFINT}} \). The VREFBUF supports four voltages\(^{[a]}\), which are configured with VRS bits in the VREFBUF_CSR register:

- \( \text{VRS} = 000 \): VREFBUF0 voltage selected.
- \( \text{VRS} = 001 \): VREFBUF1 voltage selected.
- \( \text{VRS} = 010 \): VREFBUF2 voltage selected.
- \( \text{VRS} = 011 \): VREFBUF3 voltage selected.

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

<table>
<thead>
<tr>
<th>ENVR</th>
<th>HIZ</th>
<th>VREF buffer configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>VREFBUF buffer off mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– ( V_{\text{REF+}} ) pin pulled-down to ( V_{\text{SSA}} )</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>External voltage reference mode (default value):</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– ( V_{\text{REF+}} ) pin input mode</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Internal voltage reference mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer on</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– ( V_{\text{REF+}} ) pin connected to VREFBUF buffer output</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Hold mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF is enable without output buffer, ( V_{\text{REF+}} ) pin voltage is hold with the external capacitor</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VRR detection disabled and VRR bit keeps last state</td>
</tr>
</tbody>
</table>

After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

### 36.4 VREFBUF trimming

The VREFBUF output voltage is factory-calibrated by ST. At reset, and each time the VRS setting is changed, the calibration data is automatically loaded to the TRIM register.

Optionally user can trim the output voltage by changing the TRIM register bits directly. In this case, the VRS setting has no more effect on the TRIM register until the device is reset.

\(^{[a]}\) The minimum \( V_{\text{DDA}} \) voltage depends on VRS setting, refer to the product datasheet.
36.5 VREFBUF registers

36.5.1 VREFBUF control and status register (VREFBUF_CSR)

Address offset: 0x00
Reset value: 0x0000 0002

<table>
<thead>
<tr>
<th>Address Offset</th>
<th>Bits 31:7</th>
<th>Bits 6:4</th>
<th>Bits 3</th>
<th>Bit 2</th>
<th>Bit 1</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Reserved</td>
<td>VRS[2:0]</td>
<td>VRR</td>
<td>Reserved</td>
<td>HIZ</td>
<td>ENVR</td>
</tr>
<tr>
<td></td>
<td>Reserved</td>
<td>Bitfield</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **VRS[2:0]**: Voltage reference scale

These bits select the value generated by the voltage reference buffer.

- VRS = 000: VREFBUF0 voltage selected.
- VRS = 001: VREFBUF1 voltage selected.
- VRS = 010: VREFBUF2 voltage selected.
- VRS = 011: VREFBUF3 voltage selected.
- Others: Reserved

*Note: Refer to the product datasheet for each VREFBUFx voltage setting value. The software can program this bitfield only when the VREFBUF is disabled (ENVR=0).*

Bit 3 **VRR**: Voltage reference buffer ready

- 0: the voltage reference buffer output is not ready.
- 1: the voltage reference buffer output reached the requested level.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **HIZ**: High impedance mode

This bit controls the analog switch to connect or not the VREF+ pin.

- 0: VREF+ pin is internally connected to the voltage reference buffer output.
- 1: VREF+ pin is high impedance.

Refer to **Table 347: VREF buffer modes** for the mode descriptions depending on ENVR bit configuration.

Bit 0 **ENVR**: Voltage reference buffer mode enable

This bit is used to enable the voltage reference buffer mode.

- 0: Internal voltage reference mode disable (external voltage reference mode).
- 1: Internal voltage reference mode (reference buffer enable or hold mode) enable.
36.5.2 VREFBUF calibration control register (VREFBUF_CCR)

Address offset: 0x04
Reset value: 0x0000 00XX

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>14</td>
<td>13</td>
<td>12</td>
<td>11</td>
<td>10</td>
<td>9</td>
<td>8</td>
<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 TRIM[5:0]: Trimming code

The TRIM code is a 6-bit unsigned data (minimum 000000, maximum 111111) that is set and updated according the mechanism described below.

Reset:
TRIM[5:0] is automatically initialized with the VRS = 0 trimming value stored in the flash memory during the production test.

VRS change:
TRIM[5:0] is automatically initialized with the trimming value (corresponding to VRS setting) stored in the flash memory during the production test.

Write in TRIM[5:0]:
User can modify the TRIM[5:0] with an arbitrary value. This is permanently disabling the control of the trimming value with VRS (until the device is reset).

Note: If the user application performs the trimming, the trimming code must start from 000000 to 111111 in ascending order.

36.5.3 VREFBUF register map

The following table gives the VREFBUF register map and the reset values.

Refer to Section 2.3 for the register boundary addresses.
37 Comparator (COMP)

37.1 Introduction

The device embeds two ultra-low-power comparators COMP1 and COMP2. These comparators can be used for a variety of functions including:

- Wake-up from low-power mode triggered by an analog signal
- Analog signal conditioning
- Cycle-by-cycle current control loop when combined with a PWM output from a timer

37.2 COMP main features

- Each comparator has configurable plus and minus inputs used for flexible voltage selection:
  - Multiplexed I/O pins
  - DAC channel1 and channel2
  - Internal reference voltage and three submultiple values (1/4, 1/2, 3/4) provided by a scaler (buffered voltage divider)
- Programmable hysteresis
- Programmable speed/consumption
- Outputs that can be redirected to an I/O or to timer inputs for triggering break events for fast PWM shutdows
- Comparator outputs with blanking source
- Comparators that can be combined as a window comparator
- Interrupt generation capability for each comparator with wake-up from Sleep and Stop modes (through the EXTI controller)

37.3 COMP implementation

The following table describes COMP features on the STM32U5 Series devices.

<table>
<thead>
<tr>
<th>COMP modes/features</th>
<th>STM32U535/545</th>
<th>Other devices</th>

2. '-' = non supported
37.4 COMP functional description

37.4.1 COMP block diagram

The block diagram of the comparators is shown in the figure below.

![Comparator block diagrams](image)

37.4.2 COMP pins and internal signals

The I/Os used as comparators inputs must be configured in analog mode in the GPIOs registers.

The comparator output can be connected to the I/Os using the alternate function channel given in “Alternate function mapping” table in the datasheet.

The output can also be internally redirected to a variety of timer input for the following purposes:

- Emergency shut-down of PWM signals, using BKin and BKin2 inputs
- Cycle-by-cycle current control, using OCRef_CLR inputs
- Input capture for timing measures

The comparator output can be simultaneously redirected internally and externally.

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications having specific functional safety requirements, the comparator programming must not be altered in case of spurious register access or program counter corruption. For this purpose, the comparator control and status registers can be write-protected (read-only).

Once the programming is completed, the COMPxLOCK bit can be set to 1. This causes the whole COMPx_CSR register to become read-only, including the COMPxLOCK bit. The write protection can only be reset by an MCU reset.

### Comparator LOCK mechanism

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications having specific functional safety requirements, the comparator programming must not be altered in case of spurious register access or program counter corruption. For this purpose, the comparator control and status registers can be write-protected (read-only).

Once the programming is completed, the COMPxLOCK bit can be set to 1. This causes the whole COMPx_CSR register to become read-only, including the COMPxLOCK bit. The write protection can only be reset by an MCU reset.

### Window comparator

The purpose of the window comparator is to monitor the analog voltage if it is within the voltage range defined by the lower and upper threshold.

The two embedded comparators can be used to create a window comparator. The monitored analog voltage is connected to the non-inverting (plus) inputs of comparators connected together. The upper and lower threshold voltages are connected to the inverting (minus) inputs of the comparators.

Two non-inverting inputs can be connected internally together by enabling the WINMODE bit to save one IO for other purposes.

37.4.3 Comparator LOCK mechanism

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications having specific functional safety requirements, the comparator programming must not be altered in case of spurious register access or program counter corruption. For this purpose, the comparator control and status registers can be write-protected (read-only).

Once the programming is completed, the COMPxLOCK bit can be set to 1. This causes the whole COMPx_CSR register to become read-only, including the COMPxLOCK bit. The write protection can only be reset by an MCU reset.

37.4.4 Window comparator

The purpose of the window comparator is to monitor the analog voltage if it is within the voltage range defined by the lower and upper threshold.

The two embedded comparators can be used to create a window comparator. The monitored analog voltage is connected to the non-inverting (plus) inputs of comparators connected together. The upper and lower threshold voltages are connected to the inverting (minus) inputs of the comparators.

Two non-inverting inputs can be connected internally together by enabling the WINMODE bit to save one IO for other purposes.
The comparator includes a programmable hysteresis to avoid spurious output transitions in case of noisy signals. The hysteresis can be disabled if it is not needed (for instance when exiting a low-power mode) to be able to force the hysteresis value using external components.

The blanking function prevents the current regulation to trip upon short current spikes at the beginning of the PWM period (typically the recovery current in power switches anti parallel diodes). This blanking function consists of a selection of a blanking window that is a timer output compare signal. The selection is done by the software (refer to the comparator register description for possible blanking signals).

The complementary of the blanking signal is ANDed with the comparator output to provide the wanted comparator output (see the example in the figure below).
37.4.7 **COMP power and speed modes**

COMP1 and COMP2 power consumption versus propagation delay can be adjusted to have the optimum trade-off for a given application.

37.4.8 **Scaler function**

The scaler block provides the different voltage reference levels to the comparator inputs. This block is based on an amplifier driving a resistor bridge. The amplifier input is connected to the internal voltage reference. The amplifier and the resistor bridge are enabled by setting the INMSEL value in the COMP_CFRGx registers, to connect the corresponding inverting input to the scaler output.

When the resistor divided voltage is not used, the resistor bridge and the amplifier are disabled to reduce the consumption. When the resistor bridge is disconnected, the 1/4 VREF_COMP, 1/2 VREF_COMP, and 3/4 VREF_COMP levels are equal to VREF_COMP.
### 37.5 COMP low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect on the comparators. Comparator interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>No effect on the comparators. Comparator interrupts cause the device to exit Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The COMP registers are powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

### 37.6 COMP interrupts

The comparator outputs are internally connected to the extended interrupts and events controller (EXTI). Each comparator has its own EXTI line and can generate either interrupts or events. The same mechanism is used to exit the low-power modes.

Refer to *Section 23: Extended interrupts and event controller (EXTI)* for more details.

To enable the COMPx interrupt, follow this sequence:

1. Configure and enable the EXTI line corresponding to the COMPx output event in interrupt mode and select the rising, falling or both edges sensitivity.
2. Configure and enable the NVIC IRQ channel mapped to the corresponding EXTI lines.
3. Enable the COMPx.

Bit 15 **POLARITY**: COMP1 polarity selector  
This bit is controlled by the software (if not locked). It selects the COMP1 output polarity.  
0: Non-inverted  
1: Inverted

Bit 14 **WINOUT**: COMP1 output selector  
This bit is controlled by the software (if not locked). It selects the COMP1 output.  
This bit must be kept at zero when window comparator feature is not supported.  
0: COMP1_VALUE  
1: COMP1_VALUE XOR COMP2_VALUE (required for window mode, see Figure 313)

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WINMODE**: COMP1 non-inverting input selector for window mode  
This bit is controlled by the software (if not locked). It selects the signal for the COMP1_INP input of the COMP1.  
This bit must be kept at zero when window comparator feature is not supported.  
0: Signal selected with INPSEL[1:0]  
1: COMP2_INP signal of COMP2 (required for window mode, see Figure 313)

Bits 10:8 **INPSEL[2:0]**: COMP1 signal selector for non-inverting input  
This field is controlled by the software (if not locked). It selects the signal for the non-inverting input COMP1_INP (see Table 350 for the assignment).

Bits 7:4 **INMSEL[3:0]**: COMP1 signal selector for inverting input INM  
This field is controlled by the software (if not locked). It selects the signal for the inverting input COMP1_INM (see Table 351 for the assignment).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **EN**: COMP1 enable  
This bit is controlled by the software (if not locked). It enables COMP1.  
0: COMP1 disabled  
1: COMP1 enabled

### 37.7.2 COMP2 control and status register (COMP2_CSR)

**1486/3637**  
**RM0456 Rev 5**
Bit 31 **LOCK**: COMP2_CSR register lock
This bit is set by the software and cleared by reset. It locks the whole content of COMP2_CSR.
0: COMP2_CSR read/write bits can be written by the software.
1: COMP2_CSR bits can be read but not written by the software.

Bit 30 **VALUE**: COMP2 output status
This bit is read-only. It reflects the level of the COMP2 output after the polarity selector and blanking (see Figure 315).

Bits 29:25 Reserved, must be kept at reset value.

Bits 24:20 **BLANKSEL[4:0]**: COMP2 blanking source selector
This field is controlled by the software (if not locked) and selects the PWM signal for comparator output-blanking (see Table 355 for the assignment).

Bits 19:18 **PWRMODE[1:0]**: COMP2 power mode selector
This bitfield is controlled by the software (if not locked). It selects the power consumption and, as a consequence, the speed of the COMP2.
00: High speed
01-10: Medium speed and power
11: Ultra-low-power

Bits 17:16 **HYST[1:0]**: COMP2 hysteresis selector
This bitfield is controlled by the software (if not locked). It selects the COMP2 hysteresis.
00: None
01: Low hysteresis
10: Medium hysteresis
11: High hysteresis

Bit 15 **POLARITY**: COMP2 polarity selector
This bit is controlled by the software (if not locked). It selects the COMP2 output polarity.
0: Non-inverted
1: Inverted

Bit 14 **WINOUT**: COMP2 output selector
This bit is controlled by the software (if not locked). It selects the COMP2 output.
0: COMP2_VALUE
1: COMP1_VALUE XOR COMP2_VALUE (required for window mode, see Figure 313)

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WINMODE**: COMP2 non-inverting input selector for window mode
This bit is controlled by the software (if not locked). It selects the signal for the COMP2_INP input of the COMP2.
0: Signal selected with INPSEL[1:0]
1: COMP1_INP signal of COMP1 (required for window mode, see Figure 313)

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **INPSEL[1:0]**: COMP2 signal selector for non-inverting input
This field is controlled by the software (if not locked). It selects the signal for the non-inverting input COMP2_INP (see Table 352 for the assignment).
Bits 7:4  **INMSEL[3:0]**: COMP2 signal selector for inverting input INM
This field is controlled by the software (if not locked). It selects the signal for the inverting input COMP2_INM (see Table 353 for the assignment).

Bits 3:1  Reserved, must be kept at reset value.

Bit 0  **EN**: COMP2 enable
This bit is controlled by the software (if not locked). It enables COMP2.
0: COMP2 disabled
1: COMP2 enabled

### 37.7.3 COMP register map

Refer to **Section 2.3** for the register boundary addresses.
38 Operational amplifier (OPAMP)

38.1 OPAMP introduction

STM32U535/545 devices embed one operational amplifier and STM32U575/585/59x/5Ax/5Fx/5Gx devices embed two operational amplifiers with two inputs and one output each. The three I/Os can be connected to the external pins, this enables any type of external interconnections. The operational amplifier can be configured internally as a follower or as an amplifier with a non-inverting gain ranging from 2 to 16.

The positive input can be connected to the internal DAC. The output can be connected to the internal ADC.

38.2 OPAMP main features

- Rail-to-rail input voltage range
- Low input bias current
- Low input offset voltage
- Low-power mode
- High-speed mode to achieve a better slew rate
- Fast wake-up time
- Gain bandwidth of 1.6 MHz

38.3 OPAMP functional description

The OPAMP has several modes.

Each OPAMP can be individually enabled, when disabled the output is high-impedance.

When enabled, it can be in calibration mode, all input and output of the OPAMP are then disconnected, or in functional mode.

There are three functional modes: the low-power mode, the high-speed mode and the normal mode. In functional mode the inputs and output of the OPAMP are connected as described in the Section 38.3.3.

38.3.1 OPAMP reset and clocks

The operational amplifier clock is necessary for accessing the registers. When the application does not need read or write access to those registers, the clock can be switched off using the peripheral clock enable register (see OPAMPEN bit in RCC_APB3ENR).

The OPAEN bit in OPAMPx_CSR enables and disables the OPAMP operation. The OPAMP registers configurations can be changed when the OPAEN bit is set in OPAMPx_CSR. However it can create spurious effects (noise, glitch, overshoot or saturation). If the configuration is changed, the application firmware must take care of these spurious effects (such as ignore the ADC result on the OPAMP output).
When the OPAMP output is no more needed, the OPAMP can be disabled to save power. All the configurations previously set (including the calibration) are maintained while the OPAMP is disabled.

### 38.3.2 Initial configuration

The OPAMP default configuration is a functional mode where the three IOs are connected to external pins. In the default mode, the OPAMP uses the factory trimming values (see “electrical characteristics” section of the datasheet for factory trimming conditions. Usually the temperature is 30 °C and the voltage is 3 V). The trimming values can be adjusted (see Section 38.3.5). The default configuration uses the normal mode, that provides the standard performance. The OPALPM bit in OPAMPx_CSR can be set in order to switch the OPAMP to low-power mode and reduced performance. Normal, low-power, and high-speed modes characteristics are defined in the “electrical characteristics” section of the datasheet. Before utilization, the OPA_RANGE bit in OPAMP1_CSR must be set to 1.

As soon as the OPAEN bit in OPAMPx_CSR is set, the OPAMP is functional. The two input pins and the output pin are connected as defined in Section 38.3.3 and the default connection settings can be changed.

*Note:* The inputs and output pins must be configured in analog mode (default state) in the corresponding GPIOx_MODER register.

### 38.3.3 Signal routing

The routing for the OPAMP pins is determined by the OPAMPx_CSR register.

The connections of the operational amplifiers (OPAMP1 and OPAMP2) are described in the table below.

#### Table 359. Operational amplifier possible connections (1)

<table>
<thead>
<tr>
<th>Signal</th>
<th>Pin</th>
<th>Internal</th>
<th>comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPAMP1_VINM</td>
<td>PA1 or dedicated pin(2)</td>
<td>OPAMP1_OUT or PGA</td>
<td>Controlled by OPAMODE and VM_SEL</td>
</tr>
<tr>
<td>OPAMP1_VINP</td>
<td>PA0</td>
<td>dac1_out1</td>
<td>Controlled by bit VP_SEL</td>
</tr>
<tr>
<td>OPAMP1_VOUT</td>
<td>PA3</td>
<td>ADC1_IN8, ADC2_IN8</td>
<td>The pin is connected when the OPAMP is enabled. The ADC input is controlled by the ADC.</td>
</tr>
<tr>
<td>OPAMP2_VINM</td>
<td>PA7 or dedicated pin(2)</td>
<td>OPAMP2_OUT or PGA</td>
<td>Controlled by bits OPAMODE and VM_SEL</td>
</tr>
<tr>
<td>OPAMP2_VINP</td>
<td>PA6</td>
<td>dac1_out2</td>
<td>Controlled by bit VP_SEL</td>
</tr>
<tr>
<td>OPAMP2_VOUT</td>
<td>PB0</td>
<td>ADC1_IN15, ADC2_IN15, ADC4_IN18</td>
<td>The pin is connected when the OPAMP is enabled. The ADC input is controlled by the ADC.</td>
</tr>
</tbody>
</table>

1. STM32U535/545 devices only embed OPAMP1.
2. The dedicated pin is only available on BGA132/169/216 packages. This configuration provides the lowest input bias current (see datasheet).
38.3.4 OPAMP modes

The OPAMP inputs and outputs are all accessible on terminals. The amplifiers can be used in the following configuration environments:

- standalone mode (external gain setting mode)
- follower configuration mode
- PGA modes

The amplifier output pin is directly connected to the output pad to minimize the output impedance. It cannot be used as a general purpose I/O, even if the amplifier is configured as a PGA and only connected to the ADC channel.

The impedance of the signal must be maintained below a level that avoids the input leakage to create significant artifacts (due to a resistive drop in the source). Refer to the “electrical characteristics” section in the datasheet for further details.

Standalone mode (external gain setting mode)

The procedure to use the OPAMP in standalone mode is detailed below:

1. Keep default value of OPAMPx_CSR and the default state of GPIOx_MODER.
2. As soon as OPAEN is set in OPAMPx_CSR, the two input pins and the output pin are connected to the operational amplifier.

This default configuration uses the factory trimming values and operates in normal mode (standard performance). The OPAMP behavior can be changed with the following bits in OPAMPx_CSR:

- If OPALPM is set to 1, the OPAMP switches in low-power mode in order to save power.
- If OPAHSM is set to 1, the OPAMP switches in high-speed mode in order to have high slew rate.
- If USERTRIM is set to 1, the input offset values can be trimmed.

Figure 317. Standalone mode: external gain setting mode
**Follower configuration mode**

The procedure to use the OPAMP in follower mode is detailed below (all bits in OPAMPx_CSR):

2. Clear VP_SEL to 0 (GPIO connected to OPAMPx_VINP, named VINP in this document).
3. As soon as OPAEN is set to 1, the signal on the VINP pin is copied to the OPAMP_VOUT pin.

*Note:* The pin corresponding to OPAMP_VINM is free for another usage.

The signal on the OPAMP output is also seen as an ADC input. As a consequence, the OPAMP configured in follower mode can be used to perform impedance adaptation on input signals before feeding them to the ADC input, assuming the input signal frequency is compatible with the operational amplifier gain bandwidth specification.

**Programmable gain amplifier mode**

The procedure to use the OPAMP to amplify the amplitude of an input signal is presented hereafter (all bits in OPAMPx_CSR):

1. Set OPAMODE[1:0] to 10 (internal PGA enabled).
2. Set PGA_GAIN[1:0] to the selected PGA gain (2, 4, 8 or 16) in OPAMPx_CSR.
3. Set VM_SEL[1:0] to 1x in OPAMPx_CSR (inverting input not externally connected).
4. Clear VP_SEL to 0 in OPAMPx_CSR (GPIO connected to VINP).
5. As soon as OPAEN is set in OPAMPx_CSR, the signal on the OPAMP_VINP pin is amplified by the selected gain and visible on the OPAMP_VOUT pin.

*Note:* To avoid saturation, the input voltage must stay below \( V_{DDA} \) divided by the selected gain.
Programmable gain amplifier mode with external filtering

The procedure to use the OPAMP to amplify the amplitude of an input signal, with an external Set, is detailed below (all bits in OPAMPx_CSR):

1. Configure OPAMODE[1:0] to 10 (internal PGA enabled).
2. Set PGA_GAIN[1:0] to the selected PGA gain (2, 4, 8 or 16).
3. Clear VM_SEL[1:0] to 00 or 01 (GPIO connected to VINM).
4. Clear VP_SEL to 0 (GPIO connected to VINP).

Any external connection on VINP can be used in parallel with the internal PGA. For example, a capacitor can be connected between VOUT and VINM for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).
38.3.5 Calibration

At startup, the trimming values are initialized with the preset ‘factory’ trimming value.

Each OPAMP offset can be trimmed by the user. Specific registers allow different trimming values for normal and low-power modes.

The calibration purpose is to cancel as much as possible the OPAMP inputs offset voltage. The calibration circuitry allows the inputs offset voltage to be reduced to less than +/- 1.5 mV within stable voltage and temperature conditions.

For each OPAMP and each mode, two trimming values can be trimmed: one for N differential pair and one for P differential pair.

The registers used to trim the offsets for each operational amplifiers are:

- OPAMPx_OTR for normal mode
- OPAMPx_LPOTR for low-power mode

Each register is composed of five bits for P differential pair trimming and five bits for N differential pair trimming. These are the ‘user’ values.

The user is able to switch from ‘factory’ values to ‘user’ trimmed values, with the USERTRIM bit in OPAMPx_CSR. This bit is reset at startup and the ‘factory’ value are applied by default to the OPAMP trimming registers.

The trimming values can be changed in calibration or in functional mode.

The offset trimming registers are typically configured after the initialization of the calibration operation (CALON set to 1 in OPAMPx_CSR). When CALON = 1, the OPAMP inputs are disconnected from the functional environment.

Setting CALSEL to 1 in OPAMPx_CSR initializes the offset calibration for the P differential pair (low-voltage reference used).
Clearing CALSEL to 0 initializes the offset calibration for the N differential pair (high voltage reference used).

When CALON = 1, the CALOUT bit in OPAMPx_CSR reflects the influence of the trimming value selected by CALSEL and OPALPM. When the value of CALOUT switches between two consecutive trimming values, this means that those two values are the best trimming values. The CALOUT flag needs up to 1 ms after the trimming value is changed to become steady (see tOFFTRIM max delay specification in the “electrical characteristics” section of the datasheet).

**Note:** The closer the trimming value is to the optimum trimming value, the longer it takes to stabilize (with a maximum stabilization time remaining below 1 ms in any case).

When the calibration operation is done, OPAHSM must be cleared to 0 in OPAMPx_CSR.

**Table 360. Operating modes and calibration**

<table>
<thead>
<tr>
<th>Mode</th>

<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Offset cal low for low-power mode</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

**Calibration procedure**

Here are the steps to perform a full calibration of either one of the operational amplifiers:

1. Set OPAEN to 1 in OPAMPx_CSR to enable the OPAMP and set OPA_RANGE = 1 in OPAMP1_CSR.
2. Clear OPAHSM to 0 in OPAMPx_CSR.
3. Set CALON and USERTRIM to 1 in OPAMPx_CSR.
4. Choose a calibration mode (refer to Table 360). Steps 4 to 5 must be repeated four times. For the first iteration, select normal mode, offset cal high (N differential pair), with OPALPM = 0 and CALSEL = 0 in OPAMPx_CSR.
5. Increment TRIMOFFSETN[4:0] in OPAMPx_OTR starting from 0, until CALOUT changes to 1 in OPAMPx_CSR.

Between the write to OPAMPx_OTR and the read of the CALOUT value, make sure to wait for the tOFFTRIM max delay specified in the “electrical characteristics” section of the datasheet, to get the correct CALOUT value.

The commutation means that the offset is correctly compensated and that the corresponding trim code must be saved in OPAMPx_OTR.
6. Repeat steps 4 to 5 for:
   - normal mode and offset cal low
   - low-power mode and offset cal high
   - low-power mode and offset cal low
   If a mode is not used, the corresponding calibration can be skipped.

All OPAMPs can be calibrated at the same time.

**Note:** During the whole calibration phase:
- the external connection of the OPAMP output must not pull up or down currents higher than 500 µA.
- OPAMODE[1:0] must be set to 00 or 01 (PGA disable) or 11 (internal follower).

### 38.4 OPAMP low-power modes

1496/3637  RM0456 Rev 5
Bit 30 **OPAHSM**: OPAMP high-speed mode
   This bit is effective for both normal and low-power modes.
   0: normal mode (standard slew rate)
   1: increased consumption to improve the slew rate

Bits 29:16 Reserved, must be kept at reset value.

Bit 15 **CALOUT**: OPAMP calibration output
   During the calibration mode, the offset is trimmed when this signal toggles.

Bit 14 **USERTRIM**: ‘factory’ or ‘user’ offset trimmed values selection
   This bit is active for normal and low-power modes.
   0: ‘factory’ trim code used
   1: ‘user’ trim code used

Bit 13 **CALSEL**: Calibration selection
   0: NMOS calibration (200 mV applied on OPAMP inputs)
   1: PMOS calibration (VDDA - 200 mV applied on OPAMP inputs)

Bit 12 **CALON**: Calibration mode enable
   0: normal mode
   1: calibration mode (all switches opened by hardware)

Bit 11 Reserved, must be kept at reset value.

Bit 10 **VP_SEL**: Non-inverted input selection
   0: GPIO connected to VINP
   1: DAC connected to VINP

Bits 9:8 **VM_SEL[1:0]**: Inverting input selection
   These bits are used only when OPAMODE = 00, 01 or 10.
   00: GPIO connected to VINM (valid also in PGA mode for filtering)
   01: dedicated low-leakage input connected to VINM (valid also in PGA mode for filtering)
   1x: inverting input not externally connected

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **PGA_GAIN[1:0]**: OPAMP programmable amplifier gain value
   00: internal PGA gain 2
   01: internal PGA gain 4
   10: internal PGA gain 8
   11: internal PGA gain 16

Bits 3:2 **OPAMODE[1:0]**: OPAMP PGA mode
   00 and 01: internal PGA disabled
   10: internal PGA enabled, gain programmed in PGA_GAIN
   11: internal follower

Bit 1 **OPALPM**: OPAMP low-power mode
   The OPAMP must be disabled to change this configuration.
   0: normal mode
   1: low-power mode

Bit 0 **OPAEN**: OPAMP enable
   0: OPAMP disabled
   1: OPAMP enabled
### 38.5.2 OPAMP1 offset trimming register in normal mode (OPAMP1_OTR)

39 Multi-function digital filter (MDF)

39.1 Introduction

The multi-function digital filter (MDF) is a high-performance module dedicated to the connection of external sigma-delta (ΣΔ) modulators. It is mainly targeted for the following applications:
- audio capture signals
- motor control
- metering

The MDF features up to 6 digital serial interfaces (SITFx) and digital filters (DFLTx) with flexible digital processing options to offer up to 24-bit final resolution.

The DFLTx of the MDF also include the filters of the audio digital filter (ADF).

The MDF can receive, via its serial interfaces, streams coming from various digital sensors.

The MDF supports the following standards allowing the connection of various ΣΔ modulator sensors:
- SPI interface
- Manchester coded 1-wire interface
- PDM interface

A flexible bitstream matrix (BSMX) allows the connection of any incoming bitstream to any filter.

The MDF converts an input data stream into clean decimated digital data words. This conversion is done thanks to low-pass digital filters and decimation blocks. In addition it is possible to insert a high-pass filter or a DC offset correction block.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter type, filter order, decimation ratio, integrator length. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion and continuous modes. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A flexible trigger interface can be used to control the conversion start. This timing control can trigger simultaneous conversions or insert a programmable delay between conversions.

The MDF features an out-of-limit detectors (OLD) function. There is one OLD for each digital filter chain. Independent programmable thresholds are available for each OLD, making it very suitable for over-current detection.

A short circuit detector (SCD) is also available for every selected bitstream. The SCD is able to detect a short-circuit condition with a very short latency. Independent programmable thresholds are offered in order to define the short circuit condition.

The digital processing is performed using only the kernel clock. The MDF requests the bus interface clock (AHB clock) only when data must be transferred or when a specific event requests the attention of the system processor.
39.2 MDF main features

- AHB interface
- up to 6 serial digital inputs:
  - configurable SPI interface to connect various digital sensors
  - configurable Manchester coded interface support
  - compatible with PDM interface to support digital microphones
- 2 common clocks input/output for ΣΔ modulators
- Flexible matrix (BSMX) for connection between filters and digital inputs
- 2 inputs to connect the internal ADCs
- up to 6 flexible digital filter paths, including:
  - A configurable CIC filter:
    - Can be split into 2 CIC filters: high-resolution filter and out-of-limit detector
    - Can be configured in Sinc⁴ filter
    - Can be configured in Sinc⁵ filter
    - Adjustable decimation ratio
  - A reshape filter to improve the out-of-band rejection and in-band ripple
  - A high-pass filter to cancel the DC offset
  - An offset error cancellation
  - Gain control
  - Saturation blocks
  - An out-of-limit detector
- Short-circuit detector
- Clock absence detector
- 16- or 24-bit signed output data resolution
- Continuous or single conversion
- Possibility to delay independently each bitstream
- Various trigger possibilities
- Break generation on out-of-limit or short-circuit detector events
- Autonomous functionality in Stop modes
- DMA can be used to read the conversion data
- Interrupts services

39.3 MDF implementation

The devices embed one MDF instance and one ADF instance, both being digital filters with common features.

### 39.4.3 Serial input interfaces (SITF)

The SITFx input interfaces allow the connection of the external sensors to the digital filters, via the bitstream matrix (BSMX). The SITFx serial interface can be configured in the following modes:

- LF_MASTER SPI mode (low-frequency)
- normal SPI mode
- Manchester mode

The amount of SITFx instances is equal to the amount of filters.

The data from each serial interface can be routed to any filter in order to perform:

- the PDM to PCM conversion
- the out-of-limit detection
- the short detection

The serial interfaces are enabled by setting the corresponding SITFEN bit to 1. Once the interface is enabled, it receives serial data from the external \(\Sigma\Delta\) modulator.

**Note:** Before enabling the serial interface, the user must insure that the mdf_proc_ck is already enabled (see Section 39.4.5 for details).

The SITFx are controlled via the MDF serial interface control register x (MDF_SITFxCR).

As shown in Figure 322, for each SITF, there is a large choice of clocking possibilities:

- If the serial interface is programmed in SPI mode, the selected clock source is a copy of the clock present on MDF_CCK0 or MDF_CCK1 or MDF_CKlx pin (see 2 in Figure 322).
- If the serial interface is programmed in LF_MASTER SPI mode, the selected clock source must be the clock directly provided by the CCKDIV to the MDF_CCK0 or MDF_CCK1 pin (see 1 in Figure 322). In this case MDF_CKlx must not be selected.
See Table 369 for additional information.

Note: Using the common clock (MDF_CCK0 or MDF_CK1) can be helpful to share the same clock between several SITFx.

LF_MASTER and normal SPI modes

The LF_MASTER SPI mode is a special mode allowing the usage of a mdf_proc_ck clock frequency, only two times higher than the sensor clock. This mode is dedicated to low-power use-cases, using low-speed sensors.

In LF_MASTER SPI mode, the MDF must provide the bitstream clock to the external sensors via MDF_CCK0 and MDF_CCK1 pins, and receives the bitstream data via the serial data input MDF_SDIx.
For each SITFx, the application must select the same clock than the one provided to the external sensor (MDF_CCK0 or MDF_CCK1), in order to guarantee optimal timing performances. This selection is done via SCKSRC[1:0].

**Warning:** The MDF_CKIx pin cannot be used in LF_MASTER SPI mode.

The normal SPI interface is a more flexible interface than the LF_MASTER SPI, but the mdf_proc_ck frequency must be at least four times higher than the sensor clock.

The application can select MDF_CCK0, MDF_CCK1 or MDF_CKIx clock for the capture of the data received via the MDF_SDIx pin.

The MDF can generate a clock to the sensors via MDF_CCK0 or MDF_CCK1 if needed.

For all SPI modes, all SITFs can share the same clock input (MDF_CCK0 or MDF_CCK1), in order to optimize the amount of requested I/Os.

For all SPI modes, the serial data is captured using the rising and the falling edge of the selected clock. The SITFx always provides the following bitstreams:

- bitstream received using the bitstream clock falling edge (bsx_f)
- bitstream received using the bitstream clock rising edge (bsx_r)

According to the sensors connected, one of the two bitstreams may not be available.

The application can select the wanted stream via the BSMX matrix.

**Figure 323. SPI timing example**

To properly synchronize/receive the data stream, the frequency of the mdf_proc_ck clock must be adjusted according to the constraints listed in Table 370.

**Clock absence detection**

A no-clock-transition period may be detected when the serial interface works in normal SPI mode. This feature can be used to detect a clock failure in the SPI link.

The application can program a timeout value via the STH[4:0] bitfield of the corresponding SITFx. If the MDF does not detect clock transitions for a duration of STH[4:0] x T_mdf_proc_ck, then the CKABF flag is set.
An interrupt can be generated if CKABIE is set to 1. The STH[4:0] bitfield is in the MDF serial interface control register x (MDF_SITFxCR).

When the serial interface is enabled, the CKABF flag remains to 1 until a first clock transition is detected.

To avoid spurious clock absence detection, the following sequence must be respected:
1. Configure the serial interface in normal SPI mode and enable it.
2. Clear the CKABF flag by writing CKABF bit to 1.
   - If no clock transition is detected on the serial interface, the hardware immediately sets the CKABF flag to 1.
3. Read the CKABF flag:
   - If CKABF = 1, go back to step 2.
   - If CKABF = 0, a clock has been detected. The CKABIE bit can be set to 1 if the application wants an interrupt on detection of a clock absence.

**Note:** The clock absence detection feature is not available in the LF_MASTER SPI mode.

**Manchester mode**

In Manchester coded format, the MDF receives data stream from the external sensor via the MDF_SDIx pin only.

The MDF_CKIX pins are not needed in this mode.

Decoded data and clock signals are recovered from serial stream after Manchester decoding. They are available on bsi_x_r. There are two possible settings of Manchester codings:
- signal rising edge decoded as 0 and signal falling edge decoded as 1
- signal rising edge decoded as 1 and signal falling edge decoded as 0
To decode the incoming Manchester stream, the user must program the STH[4:0] bitfield in the MDF serial interface control register x (MDF_SITFxCR). The STH[4:0] bitfield is used by the SITFx to estimate the Manchester symbol length and to detect a clock absence. An internal counter (MCNT) is restarted every time a transition is detected in the MDF_SDIx input. It is used to detect short transitions, long transitions or clock absence. A long transition indicates that the data value changed. Figure 324 shows a case where the OVR is around height and STH[4:0] = 5.

The estimated Manchester symbol rate ($T_{SYMB}$) must respect the following formula:

$$(STH + 1) \times T_{mdf\_proc\_ck} < T_{SYMB} < (2 \times STH \times T_{mdf\_proc\_ck})$$

It is recommended to compute STH as follows:

$$STH[4:0] = \text{round}\left(\frac{(2 \times OVR) - 1}{3}\right)$$

where OVR represents the ratio between the mdf_proc_ck frequency and the expected Manchester symbol frequency. OVR must be higher than five, and the mdf_proc_ck clock must be adjusted according to the constraints listed in Table 370.

The clock absence flag CKABF is set to 1 when no transition is detected during more than $2 \times STH[4:0] \times T_{mdf\_proc\_ck}$, or when the SITFx is not yet synchronized to the incoming Manchester stream. In addition, an interrupt can be generated if the bit CKABIE is set to 1.
When the serial interface is enabled, the MDF must first be synchronized to the incoming Manchester stream. The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (pink circle in the Figure 324) is detected.

The end of the synchronization phase can be checked by following the software sequence:
1. Clear the CKABF flag in the MDF DFLTx interrupt status register x (MDF_DFLTxISR) by writing CKABF bit to 1. If the serial interface is not yet synchronized, the hardware immediately sets the CKABF flag to 1.
2. Read the CKABF flag.
   - If CKABF = 1, go back to step 1.
   - If CKABF = 0, the Manchester interface is synchronized and provides valid data.

**Programming example**

In the following example, the MDF kernel clock frequency (F_{mdf_ker_ck}) is 100 MHz and the received Manchester stream is at about 6 MHz (F_{SYMB}).

1. Provide a valid mdf_proc_ck to the SITFx.
   - The mdf_proc_ck frequency must be at least six times higher than the Manchester symbol frequency (means at least 36 MHz).
   - PROCDIV is programmed to 1 to perform a division by two of the kernel clock. In that case, F_{mdf_proc_ck} = 50 MHz (8.33 times higher than the Manchester symbol frequency).

2. Compute STH.
   - OVR is given by: \( OVR = \frac{F_{mdf_proc_ck}}{F_{SYMB}} = \frac{50 \text{ MHz}}{6 \text{ MHz}} = 8.33 \).
   - Then \( STH[4:0] = \text{round} \left( \frac{2 \times 8.33 - 1}{3} \right) = 5 \).

   The minimum allowed frequency for the Manchester stream is then:
   \( 1 / (2 \times STH \times T_{mdf_proc_ck}) = 1 / (10 \times 20 \text{ ns}) = 5 \text{ MHz} \)

   The maximum allowed frequency for the Manchester stream is then:
   \( 1 / ((STH+1) \times T_{mdf_proc_ck}) = 1 / (6 \times 20 \text{ ns}) = 8.33 \text{ MHz} \)

**39.4.4 ADC slave interface (ADCITF)**

The ADCs are not always connected to the MDF. Refer to Section 39.3 to check the situation for this product.

The MDF allows the connection of up to two ADCs to the filter path. For each filter, the DATSRC[1:0] bitfield in the MDF digital filter configuration register x (MDF_DFLTxCICR) allows the application to select either data from the ADCs.

---

**Warning:** The MDF does not support receiving interleaved data from one of the ADCITF input.
39.4.5 Clock generator (CKGEN)

The RCC (reset and clock controller) provides the following clocks to the MDF:

- AHB clock (mdf_hclk) used for the register interface
- Kernel clock (mdf_ker_ck) mainly used by all other parts of the circuit via the CKGEN

Those clocks are not supposed to be phase locked, so all signals crossing those clock domains are re-synchronized.

The clock generator (CKGEN) is responsible of the generation of the processing clock, and the clock provided to the MDF_CCK0 and MDF_CCK1 pins. All those clocks are generated from the mdf_ker_ck.

The processing clock (mdf_proc_ck) is used to run all the signals processing and to re-sample the incoming serial or parallel stream.

Note: The reshape filter (RSFLT) needs up to 24 cycles of mdf_proc_ck clock to process a sample.

To adapt the kernel clock frequency provided by the RCC, the following dividers are available:

- PROCDIV[6:0] used to adapt the kernel clock frequency to the constraints of the parallel and serial interfaces, and to the processing blocks
- CCKDIV[3:0] used to adapt the frequency of the MDF_CCK0 and MDF_CCK1 clocks

PROCDIV[6:0] and CCKDIV[3:0] must be programmed when no clock is provided to the dividers (CKGDEN = 0).

The mdf_proc_ck generation is controlled by CKGDEN.

In addition, the CKGMOD bit allows the application to define the way to trigger the CCKDIV divider:

- When CKGMOD = 0, the CCKDIV divider is started as soon as CKGDEN is set to 1.
- When CKGMOD = 1, the CCKDIV divider is started when CKGDEN is set to 1 and the programmed trigger condition occurred.

All bits and fields controlling the CKGEN are in MDF_CKGCR.
The trigger logic for CKGEN is handled by the TRG_CK block. As shown in Figure 334, the CCKDIV divider can be triggered on the rising or falling edge of one of the 16 trigger sources. When the proper trigger condition occurs, the cck_trg signal goes to high, allowing the CCKDIV divider to start. The TRG_CK logic is reset when CKGDEN is set to 0.

This feature can be helpful to synchronize the MDF_CCK0 (y = 0) or MDF_CCK1 (y = 1) clock of several MDF instances, or to synchronize the clock generation to a timer event.

The application can control the activation of the MDF_CCK0 or MDF_CCK1 pin CCK0EN/CCK1EN and CCK0DIR/CCK1DIR bits:

- **CCKyEN** is used to enable the CCKDIV, and thus generates a clock for the external sensors.
- **CCKyDIR** is used to control the direction of the ADF_CCKy pin (input or output)

### Table 369. Control of the common clock generation

<table>
<thead>
<tr>
<th>CCKyEN</th>
<th>CCKyDIR</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>The MDF_CCKy pin is in input. An external clock can be connected to the MDF_CCKy pin and used by the SITFx in order to decode the serial stream</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>The MDF_CCKy pin is in output. No clock is generated, thus the MDF_CCKy pin is driven low.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>The MDF_CCKy pin is in output. A clock is generated on the MDF_CCKy pin. The SITFx can use this pin as clock source in order to decode the serial stream</td>
</tr>
</tbody>
</table>

1. The configuration with CCKyEN = 1 and CCKyDIR = 0 must be avoided (no interest).

When CCKyDIR = 1, as soon as the CCKyEN bit is set to 1, a clock is generated to the corresponding output without any spurs.

**Note:** The mdf_proc_ck must be enabled (by CKGDEN = 1) before enabling other blocks (such as SITFx or DFLTx).
CKGEN activation sequence example

1. Set CKGDEN to 0.
2. Wait for CKGACTIVE = 0. If CKGDEN was previously enabled, this phase can take two periods of mdf_hclk and two periods of mdf_proc_ck.
3. Program PROCDIV[6:0], CKGMOD, CCKDIV[3:0], TRGSRCSRC[3:0] and TRGSENS.
4. Set CKGDEN to 1.
5. Set CCKxDIR to 1 (optional).
6. Set CCKxEN to 1 (optional).

When needed, at any moment, the CCK0EN or CCK1EN value can be changed without disabling the clock generator.

Clock frequency constraints

The table below shows the frequency constraints to receive and process properly the samples.

### Table 370. Clock constraints with respect to the incoming stream(1)

<table>
<thead>
<tr>

<td>$F_{mdf, hclk} \geq F_{mdf, proc, ck}$</td>
</tr>
</tbody>
</table>

1. $F_{MDM, CCKy}$ represents the frequency of the clock received via MDF_CKlx and MDF_CCKy, or generated via MDF_CCKy. $F_{SYMB}$ represents the frequency of the received symbol rate for Manchester mode.

39.4.6 Bitstream matrix (BSMX)

The BSMX receives the bitstreams from all serial interfaces (SITFx) and provides the selected input to the digital filters (DFLTx) and to the short-circuit detectors (SCDx). For each filter path, any of the bitstream input can be selected.

As shown in the Figure 322, each SITFx block provides two bitstreams (bsx_r and bsx_f) to the BSMX.
The application to select the wanted stream via the *MDF bitstream matrix control register x (MDF_BSMXxCR)*. This selection is intended to be static.

**Figure 326. BSMX overview**

**BSMX programming sequence example**

The BSSEL[4:0] bitfield cannot be changed if the corresponding SCDx, OLDx or DFLTx is enabled. The following steps are needed to change the value of BSMX, for filter path x:

1. Set SCDEN of SCDx to 0.
2. Set DFLTEN of DFLTx to 0.
3. Set OLDEN of OLDx to 0.
4. Wait for BSMXACTIVE = 0.
5. Program BSSEL[4:0] of filter path x.
6. Set SCDEN of SCDx to 1 (optional).
7. Set DFLTEN of DFLTx to 1 (optional).
8. Set OLDEN of OLDx block to 1 (optional).

**39.4.7 Short-circuit detectors (SCD)**

The SCDx detects, with a very fast response time, if an analog signal reached saturated values (out-of-full scale ranges) and remained on this value for a given time.
This behavior can detect short-circuit or open-circuit errors (such as over current or over voltage). An interrupt event or/and a break signal can be generated.

**Figure 327. SCD functional view**

The SCDx is counting consecutive zeros or consecutive ones received from the serial interface (SITFx). A counter is restarted if there is a change in the data stream received. If this counter reaches a short-circuit threshold value (SCDT[7:0] in the MDF short circuit detector control register x (MDF_SCDxCR)), then a short-circuit event is invoked. Each BSMX output has its own short-circuit detector. Any BSMX output can be continuously monitored by setting the corresponding SCDEN bit to 1 in MDF_SCDxCR. Each SCD has its own threshold settings (SCDT) and its own status bit (SCDF).

The figure below shows an example where SCDT[7:0] is set to six. The break signal remains high as long as the short circuit condition is present.

No overrun event is generated when the interrupt event is pending while a new short-circuit condition is detected.

**Figure 328. SCD timing example**

Writing 1 to SCDF...
The SCDx event generated by the SCDx block can be assigned to break output signals mdf_break[3:0]. The break signal assignment to a given short-circuit detector event is done by BKSCD[3:0] in MDF_SCDxCR. The break outputs are shared with the over-current function.

Note: SCDs cannot be used to monitor the ADC data interface (ADCITF).

SCD activation sequence example
1. Enable and configure CKGEN to generate the mdf_proc_ck.
2. Set SCDEN to 0.
3. Wait for SCDACTIVE = 0. If SCDEN was previously enabled, this phase can take two periods of mdf_hclk, and two periods of mdf_proc_ck.
4. Program BKSCD[3:0] and SCDT[7:0].
5. Set SCDEN to 1.

Note: BKSCD[3:0] and SCDT[7:0] must not be changed when SCDACTIVE = 1.

39.4.8 Digital filter processing (DFLT)

The digital filter processing includes the following sub-blocks:
- symbol remap (SBR)
- source selector
- clock skipper delay (DLY)
- CIC decimation filter that can be configured:
  - in single Sinc4 or Sinc5 order CIC (MCIC)
  - in two CIC filters:
    - a main filter (MCIC), high resolution
    - an auxiliary filter (ACIC), low-latency, for the out-of-limit detector (OLD)
    - both MCIC and ACIC can be configured as Sinc1, Sinc2, Sinc3 or FastSinc
- gain control (SCALE)
- signal saturation (SAT)
- reshape filter (RSFLT)
- high-pass filter (HPF)
- integrator (INT)
- receive RXFIFO

Figure 329 shows the filter-path configuration according to CICMOD[2:0]. Several configuration bits are available to configure the digital filter to the application needs.
Symbol remap and source selection

The symbol remap (SBR) converts the bitstream selected by the BSMX into data usable by the filter path. More especially:

- The high levels are converted into a 16-bit signed number + 1.
- The low levels are converted into a 16-bit signed number - 1.

The signal source of the digital filter can be selected via DATSRC[1:0] between the two following:

- data coming from the BSMX
- data coming from one of the ADC interfaces (ADCITF2 or 1)

Programmable micro-delay control (DLY)

The digital filter has a delay line that allows the timing adjustment of each stream with the resolution of the bitstream clock.

This feature is particularly helpful in the case of microphone beam forming applications where delays smaller than the final sampling rate, must be applied to the incoming stream. This feature is helpful when the MDF is synchronized with other ADF or MDF blocks for a beam forming application for example.

The delay is performed by discarding a given number of samples from the selected input stream, before samples enter into the CIC filter. This data discarding is performed by skipping a given number of data strobe, preventing the CIC filter to take into account those data.

When the wanted amount of data strobe has been skipped, the next incoming samples are strobed normally.

*Figure 330* shows an example of how to apply dynamically small delay to an incoming stream. For simplification, the CIC filter performs a decimation by height in this example. CIC1 represents the CIC included in the ADF and CIC0 represents a filter from another ADF or MDF instance.
The CIC of filter 1 (CIC1) receives a command in order to skip three incoming samples. So the input samples named b10, b11 and b12 are not processed by CIC1. As a consequence, the output sample N+1 generated by CIC0 is build from input samples a[23:16] while the sample N+1 of CIC1 is build from input samples b[26:19].

Finally, the non-skipped data stream looks delayed by three bitstream periods.

**Note:** When the input data strobes are skipped, the decimation counter remains frozen. As a consequence, the samples delivered by the CIC1 are a bit delayed.

**Warning:** It is not recommended to apply a delay bigger than the programmed decimation ratio (CIC + RSFLT decimation), especially if the MDF is programmed in interleaved acquisition mode. There is a strong risk of data misalignment inside the FIFOs.

The following steps are needed to program the amount of bitstream clock periods to be skipped:

1. Wait for SKPBF equal to 0.
2. Write SKPDLY[6:0] to the wanted number of bitstream clock periods to be skipped. The SKPBF flag goes immediately to 1, indicating that the delay value entered into SKPDLY[6:0] is under process.
   - If the corresponding DFLTn is not yet enabled (DFLTEN = 0), then the DLY logic waits for DFLTEN = 1. When the application sets DFLTEN to 1, the DLY logic starts to skip the amount of wanted data strobes.
   - If the corresponding digital filter is already enabled (DFLTEN = 1), then the DLY logic immediately starts to skip the amount of wanted data strobes.

When the MDF skipped the amount of wanted data strobes, then SKPBF goes back to 0.
3. If the application needs to skip more data strobes, then the operation must be restarted from step 1.
The effect of the delay performed with this mechanism is cumulative as long as the MDF is enabled. In a given filter, if the application performs a D1 delay, followed by a D2 delay, then all other active filters are delayed by D1 + D2.

Data coming from ADCs can also benefit from this feature.

In interleaved acquisition mode, it is up to the application to ensure that the delay applied on the different microphones is in line with the depth of the RXFIFO buffers. If the relative delay between each activated filter is less than the decimation ratio, then it costs one FIFO location.

If the interleaved acquisition mode is not used, then the delay value has no impact on the RXFIFO buffering.

**Note:** If SKPDLY[6:0] is written when SKPBF = 1, the write operation is ignored.

### Cascaded-integrator-comb (CIC) filter

The CIC digital filters are an efficient implementation of low-pass filters, often used for decimation and interpolation. The CIC frequency response is equal to a SincN function, this is why they are often called Sinc filters.

The SincN digital filter embedded into the MDF is configurable according to the application targeted.

- For audio applications, such as speech capture from digital microphones, the application can select a high-resolution low-pass decimation filter by setting CICMOD to 100 or 101.
- If the targeted application is motor control or any other sensor capture, then the application can configure the CIC in order to offer a main filter path for acquisition (MCIC) and an auxiliary filter for fast-event generation (ACIC). This auxiliary filter can be used for example, to detect over-current conditions. This mode is selected by setting CICMOD[2:0] = 0xx.

When CICMOD[2:0] = 0xx, the following CIC filters are available:

- main filter (MCIC)
- auxiliary CIC filter (ACIC)

Both of them are configurable in FastSinc, Sinc1 to Sinc3.

When CICMOD[2:0] = 100, the CIC is configured into a single Sinc4 and when CICMOD[2:0] = 101, the CIC is configured into a single Sinc5 filter.

The filters have the following transfer function (impulse response in z domain):

- SincN filter type: 
  \[ H(z) = \left( \frac{1 - z^{-D}}{1 - z^{-1}} \right)^N \]

- FastSinc filter type: 
  \[ H(z) = \left( \frac{1 - z^{-D}}{1 - z^{-1}} \right)^2 \cdot \left( 1 + z^{-2D} \cdot z^{-D} \right) \]

where N can be 1, 2, 3, 4 or 5, and D is the decimation ratio.

D is equal to MCICD+1 or ACICD+1.
CIC output data size

The size of samples delivered by the CIC (DS\textsubscript{CIC}) depends on the following parameters:

- CIC order (N)
- CIC decimation ratio (D)
- data size of the input stream (DS\textsubscript{IN})

The CIC order and decimation ratio must be programmed in order to insure that the data size does not exceed the 26-bit CIC capability.

The following formula gives the output data size (DS\textsubscript{CIC}) according to the parameters above.

\[
DS_{CIC} = \left( \frac{N \times \ln(D)}{\ln(2)} \right) + DS_{IN}
\]

and the CIC gain is given by this formula:

\[
G_{CIC} = (D)^N
\]

The decimation ratio can be adjusted from 2 to 512 for the main CIC filter and from 1 to 32 for the auxiliary CIC filter.

The table below gives some data output size in bits for some decimation values, when the data source is a full-scale signal coming from the serial interface or from a 12-bit ADC.

**Note:** DS\textsubscript{IN} = 1 bit for a serial bitstream but can be up to 16 bits when coming from the ADCITF.

**Table 371. Data size according to CIC order and CIC decimation values**

The LSB part of the data provided by the CIC is not necessarily significant: it depends on the sensor performances and the ability of the CIC to reject the out-of-band noise. The sample size at CIC output can be adjusted thanks to the SCALE block.

The table below shows the maximum allowed decimation ratio for the CIC filter, depending on the input data size. Bigger decimation ratio causes a wrap-around of the signal at CIC output, for strong input signals.

**Note:** The MDF cannot detect or prevent a CIC wrap-around.

**Scaling (SCALE) and saturation (SAT)**

The SCALE block allows the application to adjust the amplitude of the signal provided by the CIC, by steps of 3 dB ± 0.5 dB).

The signal amplitude can be decreased by up to 8 bits (-48.2 dB) and can be increased by up to 12 bits (+72.2 dB).

The gain is adjusted by the SCALE[5:0] bitfield in the **MDF digital filter configuration register x (MDM_DFLTxCICR)**.

SCALE[5:0] can be changed even if the corresponding DLFTx is enabled. During the gain transition, the signal provided by the filter is disturbed.

Due to internal resynchronization, there is a delay of some cycles of mdf_proc_ck clock between the moment where the application writes the new gain, and the moment where the gain is effectively applied to the samples. If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back SCALE[5:0] informs the application on the current gain value.
The table below shows the possible gain values.

</table>

The SAT blocks avoid having a wrap-around of the binary code when the code exceeds its maximal or minimal value.

The MDF performs saturation operations at the following levels:
- after the SCALE block (performed by the SAT block). The signal is saturated at 24 bits.
- inside the RSFLT, to insure a good filter behavior
- at the output of the HPF, to insure that the output signal does not exceed 24 bits

The SATF bit informs the application that a saturation occurred either after the SCALE, inside the RSFLT or after the HPF. In addition, an interrupt can be generated if SATIE is set to 1. As soon as a saturation is detected, the SATF flag is set to 1. It is up to the application to clear this flag in order to be able to detect a new saturation.

Those bits are in the MDF DFLTx interrupt enable register x (MDF_DFLTxIER) and MDF DFLTx interrupt status register x (MDF_DFLTxISR).

**Gain adjustment policy**

To get the best MDF performances, it is important to properly adjust the gain value via SCALE[5:0].

A usual way to adjust the gain is to select the SCALE[5:0] value that gives a final signal amplitude as close as possible to the 24-bit full scale, for the maximum input signal.
A way to select the optimal gain is detailed below:

1. Check that, for the expected input signal, the data size into the CIC filter does not exceed 26 bits. This can be checked using this formula:

\[
\frac{\ln(SIN_{pp} \cdot D^N)}{\ln(2)} < 26
\]

where \(N\) represents the CIC order, \(D\) the decimation ratio and \(SIN_{pp}\) the maximum peak-to-peak amplitude of the input signal. \(SIN_{pp}\) can take:

- a maximum peak-to-peak amplitude of 2 (± 1), for samples coming from SITF
- a maximum peak-to-peak amplitude of 4095 (+ 2047, - 2048) for samples coming from a 12-bit ADC

**Example:** a Sinc\(^4\) can be used with a decimation ratio of 96, if the maximum input signal does not exceed ± 0.35. Indeed:

\[
\frac{\ln(0.7 \cdot 96^4)}{\ln(2)} - 25.82 \text{ bits} < 26 \text{ bits}
\]

2. Adjust the SCALE value.

To select the most appropriate SCALE value, the user must check if the RSFLT is used or not. If the RSFLT is used, the data size at SCALE output must not exceed 22 bits, otherwise the data size can be up to 24 bits.

The SCALE value in dB is selected using this formula:

\[
\text{SCALE}_{db} < 20 \cdot \log_{10} \left( \frac{2^{NB}}{\text{SIN}_{pp} \cdot D^N} \right)
\]

where \(NB\) is equal to 22 if RSFLT is enabled, or 24 if RSFLT is bypassed. \(\text{SCALE}_{db}\) represents the gain value selected by SCALE[5:0].

**Example:** for a Sinc\(^4\) with a decimation ratio of 96 and a \(\text{SIN}_{pp}\) of 0.7:

- If the RSFLT is bypassed:

  \[
  20 \cdot \log_{10} \left( \frac{2^{24}}{0.7 \cdot 96^4} \right) = -11 \text{ dB}
  \]

  \(\text{SCALE}_{db}\) value must be lower than -11 dB. The closest lower value is -12 dB (SCALE[5:0] = 0x2C).

- If the RSFLT is enabled:

  \[
  20 \cdot \log_{10} \left( \frac{2^{22}}{0.7 \cdot 96^4} \right) = -23 \text{ dB}
  \]

  \(\text{SCALE}_{db}\) value must be lower than -23 dB, the closest lower value is -24.1 dB (SCALE[5:0] = 0x28).

If SCALE[5:0] is set to a higher value, then a saturation may occur. An event flag informs the user if a saturation occurred.

The table below proposes gain values for different filter configurations, when the data comes from the SITFx, according to the CIC order, and the CIC decimation ratio. This table is not exhaustive, and considers a full-scale input signal (see Section 39.7.5 for details).
Reshaping filter (RSFLT)

In addition to the CIC, the MDF offers a reshaping IIR filter mainly dedicated to the audio application but also usable in other applications.

When the RSFLT is used, the sample size at its input must not exceed 22 bits.

The samples at the RSFLT output can be decimated by four or not according to the RSFLTD bit in the MDF reshape filter configuration register x (MDF_DFLTxRSFR).

The RSFLT can be bypassed by setting RSFBYP to 1 in MDF_DFLTxRSFR.

The table below shows which sampling rate must be provided to the RSFLT in order to process the most common audio streams.

The RSFLT cutoff frequency ($F_C$) depends on the sample rates at its input ($F_{RS}$), and is given by the following formula:

$$F_C = 0.111 \times F_{RS}$$

</table>
The figure below shows the frequency response of the reshape filter.

Figure 332. Reshape filter frequency response normalized \( F_{RS} / 2 = 1 \)

The RSFLT gain is about 9.3 dB, so the output data size is a little bit lower than 24 bits for a 22-bit wide input signal.

The RSFLT takes 24 clock cycles of mdf_proc_ck clock to process one sample at \( F_{RS} \). When the RSFLT is enabled, the application must insure that the mdf_proc_ck is at least 24 times faster \( F_{RS} \).

The RSFLT generates an event (rfovr_evt) and sets the RFOVRF flag, if the RSFLT receives a new sample while the previous one is still under processing.

When RFOVRF is set, the samples provided by the RSFLT are invalid. The application must then stop the data acquisition and provide a faster mdf_proc_ck clock to the RSFLT.

High-pass filter (HPF)

The high-pass filter suppresses the low-frequency content from the final output data stream in case of continuous conversion mode. The high-pass filter can be enabled or disabled via HPFBYP in the MDF reshape filter configuration register x (MDF_DFLTxRSFR).

The HPF is useful when there is parasitic low-frequency noise (or DC signal) in the input data source and it must be removed from the final data.
The HPF is a first order IIR filter and the cut-off frequency can be selected via HPFC[1:0] in the MDF reshape filter configuration register x (MDF_DFLTxRSFR), among the following values:

- $0.000625 \times F_{PCM}$
- $0.00125 \times F_{PCM}$
- $0.00250 \times F_{PCM}$
- $0.00950 \times F_{PCM}$

The HPF output is saturated at 24 bits. The SATF flag is set if a sample is saturated.

### Offset error compensation (OEC)

Each digital filter has its own OEC. The offset correction is performed by subtracting to the signal provided by the CIC, the OFFSET[25:0] in the MDF offset error compensation control register x (MDF_OECxCR).

Due to the internal resynchronization, there is a delay of some cycles of mdf_proc_ck clock between the moment where the application writes the new offset, and the moment where the new offset value is effectively applied to the samples. If the application attempts to write a new offset value while the previous one is not yet applied, this new offset value is ignored. Reading back OFFSET[25:0] informs the application on the current offset value.

### Integrator (INT)

The INT performs additional decimation and a resolution increase of data coming from the digital filter. The INT simply performs the sum of data from a digital filter for a given number of data samples from a filter.

The INT is enabled by setting INTVAL[6:0] to a value different from 0.

The amount of integrated values can be defined by INTVAL[6:0] in the range of 2 to 128.

In order to control the data width at the integrator output, the resulting data can be divided by 1, 4, 32 or 128. This feature is controlled by INTDIV[1:0].

### 39.4.9 Out-of-limit detector (OLD)

The OLD triggers an event when a signal reaches or crosses given maximum and minimum threshold values. The generated event can drive an interrupt or break signals (mdf_break[3:0]) when conditions are met.

The OLD can be used only if the CIC filter is configured in motor and sensing mode (CICMOD[2:0] = 0xx).

---

<td>76</td>
</tr>
</tbody>
</table>
The OLD takes the input signal selected by the main filter, process it using a Sinc\textsuperscript{N} or FastSinc filter (ACIC), and compares the resulting signal to programmed thresholds.

The OLD is enabled via the OLDEN bit in MDF_OLD0CR. Once enabled, the input data are continuously monitored. There is no need to have the DFLTx enabled for using the OLD function.

The MDF offers a high- and low-threshold register that are compared with given data values. The application can generate an event if the signal is inside or outside the boundary defined by those two thresholds. This behavior is controlled via THINB in the MDF_OLD0CR.

If the application only wants to generate an event when the input signal is higher than OLDTHH, then THINB and OLDTHL must both be cleared to 0.

If the application only wants to generate an event when the input signal is lower than OLDTHH, then THINB must be set to 1 and OLDTHL must be cleared to 0.

\textit{Note:} \textit{It is not recommended to set a OLDTHL to a value bigger than OLDTHH.}

The response time of the OLD depends on several parameters, the most important are listed hereafter:

- sampling rate frequency used by the external sensor
- ACIC decimation ratio
- ACIC order

The OLD can be used for over-current detection but also as current limiter if the PWM signal is generated by a timer receiving a old_brk signal. Generally, to get a fast response time for over-current detection, it is recommended to use the ACIC with lowest order as possible and the minimum decimation ratio. FastSinc is also a good choice for over-current detection. The application must perform a trade-off between the filter resolution and the response time.
Status flags are available in order to inform the application that an OLD event is detected. Latched events are cleared by writing 1 into the OLDF bit.

As shown in Figure 333, when THINB = 0, the interrupt signal remains active as long as the signal is outside the gray area. At position A, the application clears the interrupt, but the interrupt is re-asserted because the signal is still outside the gray area. When the application clears OLDF, THHF and THLF are cleared as well.

An OLD event can be assigned to one or several break output signals (mdf_break[3:0]). The break signal assignment to a given OLD event is done by BKOLD[3:0] in the MDF out-of limit detector control register x (MDF_OLDxCRR).

Note: The generation of break signals is independent from the interrupts generation.

OLD activation sequence example

1. Enable and configure CKGEN.
2. Set OLDEN to 0.
3. Wait for OLDACTIVE = 0. If OLDEN was previously enabled, this phase can take two periods of mdf_hclk and two periods of mdf_proc_clk.

4. Program BKOLD[3:0], ACICN[1:0], ACICD[4:0], THIN, OLDTHL[25:0] and OLDTHH[25:0].

5. Set OLDEN to 1.

### 39.4.10 Digital filter acquisition modes

The MDF offers the following modes to perform a data capture:

- asynchronous continuous acquisition mode
- asynchronous single-shot acquisition mode
- synchronous continuous acquisition mode
- synchronous single-shot acquisition mode
- window continuous acquisition mode
- synchronous snapshot acquisition mode

For each filter, one of these modes can be selected independently.

**Note:** To perform a data capture, the filters, the interfaces providing the data (SITFx or ADCITF) and the CKGEN must be enabled. If needed, MDF_CCK0 or MDF_CCK1 must be enabled as well.

The filter can be stopped immediately when DFLTEN is set to 0. This resets the filters and flushes the RXFIFO of the corresponding filter path. The DFLTACTIVE flag also goes back to 0 when the RXFIFO and the filters are reset.
The figure below shows a simplified view of the trigger logic available for each filter and for the clock generator.

**Figure 3.34. Trigger logic for DFLT and CKGEN**

A block common to all TRIG blocks performs the rising and falling edges detection and the resynchronization of the input triggers to the mdf_ker_ck clock domain. This implementation allows the application to use triggers with pulse width smaller than the mdf_ker_ck period.

In synchronous modes, the TRIG block offers the possibility to select one of the following trigger sources:
- mdf_trgli[13:0] signals (refer to Table 3.66 for the triggers connections)
- TRGO bit in MDF_GCR
- OLD event of each filter path

The edge sensitivity can also be selected, except for TRGO and OLD events.

**Asynchronous continuous acquisition mode**

This mode allows the application to start a continuous acquisition on one or several filters by simply writing their DFLTEN bits to 1.
The Asynchronous continuous acquisition mode is selected when ACQMOD[2:0] = 0.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN) so that the mdf_proc_ck frequency is compatible with the targeted application (see examples in Table 380).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 0.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1 for the filters to enable, the acquisition sequence starts immediately.

The figure below shows a simplified example of the samples generated by the DFLTx.

![Figure 335. Asynchronous continuous mode (ACQMOD[2:0] = 0)](image)

**Note:** The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Asynchronous single-shot acquisition mode

This mode allows the application to start the acquisition of one sample on one or several filters by simply writing their DFLTEN bits to 1.

The Asynchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 001.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are cleared to 0):

1. Configure and enable the clock generator (CKGEN), so that the mdf_proc_ck frequency is compatible with the targeted application (see examples in Table 376).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 001.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.

6. When DFLTEN is set to 1 for the filters to enable, each selected filter provides one data to the RXFIFO and stops the acquisition.

To trigger a new acquisition, for each filter, the application must:
1. Check that the previous acquisition is completed, by waiting that DFLTRUN = 0.
2. Set again DFLTEN to 1.

This sequence can be repeated every time a new data must be converted.

As shown in the Figure 336, every time DFLTEN is set to 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset, and the filter is ready to start a new conversion.

If the DFLTEN is set to 0 while an acquisition is ongoing, the ongoing conversion is stopped (in the example, S3 is lost). This situation can be avoided with the following steps:
1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Set DFLTEN to 0.

**Figure 336. Asynchronous single-shot mode (ACQMOD[2:0] = 001)**

![Diagram](image)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

**Synchronous continuous acquisition mode**

This mode allows the application to start a continuous acquisition on one or several filters by using the following trigger sources:
- one of the mdf_trg[13:0] signals
- OLD event of the corresponding filter
- TRGO bit

The Synchronous continuous acquisition mode is selected when ACQMOD[2:0] = 010.
The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in Table 376).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 010.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1 for the filters to enable.
8. When the trigger condition is met, the filters start the acquisition.

The TRGSENS bit allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). The first rising edge of the trigger signal is ignored because DFLTEN = 0. The next rising edge is taken into account and starts the acquisition. All other rising edges are ignored. The trigger logic is re-initialized when DFLTRUN goes back to 0.

**Figure 337. Synchronous continuous mode (ACQMOD[2:0] = 010)**

**Note:** The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

**Synchronous single-shot acquisition mode**

This mode allows the application to start a single acquisition on one or several filters by using the following trigger sources:

- one of the mdf_trg[13:0] signals
- OLD event of the corresponding filter
- TRGO bit
The Synchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 011.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in Table 376).
2. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the wanted filter configuration and set the ACQMOD[2:0] to 011.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence has been properly terminated.
7. Set DFLTEN to 1 for the filters to enable.
8. Then when the trigger condition is met, the filters start the acquisition and provide one data to the RXFIFO, then the filters are ready to accept a new trigger.

TRGSENS allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). Every time a trigger rising edge is detected with DFLTEN = 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset. DFLTRUN is set to 0 and the filter is ready to start a new conversion.

Figure 338. Synchronous single-shot mode (ACQMOD[2:0] = 011)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Figure 338 shows a case where DFLTEN is cleared to 0 while an acquisition is ongoing: thus the sample S2 is lost. This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Clear DFLTEN to 0.
Note: The ongoing DMA transfer is properly terminated.

Window continuous acquisition mode

This mode allows the application to start or stop a continuous acquisition on one or several filters controlled by consecutive edges of one of the following trigger sources:

- one of the mdf_trg[13:0] signals
- TRGO bit

The window continuous acquisition mode is selected when ACQMOD[2:0] = 100.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in Table 376).
2. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the wanted filter settings and set the ACQMOD[2:0] to 100.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence has been properly terminated.
7. Set DFLTEN to 1 for the filters to enable.
8. If TRGSENS = 0, the acquisition starts on trigger rising edge and stops on trigger falling edge. If TRGSENS = 1, the acquisition starts on trigger falling edge and stops on trigger rising edge.

Note: The acquisition may restart if the trigger condition becomes again active.

Figure 339 shows a simplified example of window continuous acquisition mode, with TRGSENS = 1. Once DFLTEN is set to 1, the MDF waits for a falling edge on the selected trigger input. When the trigger condition is met, DFLTRUN goes to 1 and the acquisition starts. The acquisition stops if the MDF detects a rising edge on the selected trigger input. If DFLTEN is still set to 1, the MDF waits again for a falling edge on the selected trigger input.

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA
transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous snapshot acquisition mode

In the acquisition modes described on previous sections, the application must wait for filters settling time or the end of conversion before getting a new valid sample. For applications very critical in latency, the last valid sample can be get immediately, with an information on the age of this sample by using the snapshot acquisition mode.

In snapshot mode, the DFLTx is continuously acquiring the samples, but the processed samples are not stored into the RXFIFO. When a trigger occurs, the last valid sample, the current decimation value of MCIC and the sample counter of the INT are stored in MDF_SNPS0DR.

The possible trigger sources are the following:
- one of the mdf_trg[13:0] signals
- OLD event of the corresponding filter
- TRGO bit

The Synchronous snapshot acquisition mode is selected when ACQMOD[2:0] = 101.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):
1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in Table 376).
2. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the wanted filter settings and set the ACQMOD[2:0] to 101. FTH is usually cleared to 0 to receive an interrupt as soon as the RXFIFO is not empty.
4. Set the SITFEN bit of the requested data interfaces to 1.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence has been properly terminated,
7. Set DFLTEN to 1 for the filters to enable.

When the trigger condition is met,
1. The MDF stores the last valid data provided by the corresponding filter, the value of the MCIC decimation counter, and the counter value of INT if selected by SNPSFMT into a shadow register.
2. The snps_evt is activated, indicating that a data is ready. If SSDRIE is set to 1, the MDF requests the AHB clock.
3. When the AHB clock is available the shadow register is stored in MDF snapshot data register x (MDF_SNPSxDR) and an interrupt is generated.
4. In the interrupt sub-routine, the application must do the following:
   a) Read the data located in MDF_SNPSxDR.
   b) Clear the SSDRF flag by writing it to 1.

As shown in the Figure 340, in snapshot mode, when the trigger event occurs, it is resynchronized with the processing clock (mdf_proc_ck), the decimation counter of the MCIC (MCIC_CNTR), the integrator counter (INT_CNTR) and the last valid sample (S_{N-2}), are stored into a shadow register, and the snps_evt event is generated. When the AHB
clock is available, an interrupt is generated and the shadow register is copied in MDF_SNPSxDR. The application can read immediately the sample and the timing information.

The SSOVRF overrun flag is also available, allowing the application to check if an overrun condition occurs. A snapshot overrun condition is detected when the SSDRF flag is set to 1 while a new trigger event occurs.

In that case, the new trigger event is not taken into account. The application must clear the SSOVRF flag.

Figure 340. Snapshot mode example

Note: When an activated filter did not receive a data strobe, the filter is frozen. If the interface providing the stream is not enabled (SITF or ADCITF), the filter is frozen. Once a DFLT x is activated, CIC, HPF, IIR and INT are reinitialized. For each filter a status bit indicates if the filter is currently running or not.

Starting several filters synchronously

To start the acquisition of several filters synchronously, the following sequence must be performed (assuming that DFLTEN is set to 0):

1. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
2. Set the SITFEN bit of the requested data interfaces to 1.
3. For each filter, set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. For each filter, set TRGSRC[3:0] to 0 (TRGO is selected).
5. For each filter, set TRGSENS to 0 (rising edge).
6. For each filter, set DFLTEN to 1.
7. Read TRGO bit until it is read to 0.
8. Set TRGO to 1. Then the acquisition sequence for all selected filters starts immediately.
To trigger a new acquisition (in case of single-shot), the application must do the following:
1. Check that the previous acquisition is completed, by waiting DFLTRUN = 0.
2. Read TRGO until it is read to 0.
3. Set again TRGO to 1.

**Discarded samples**

The MDF offers the possibility to program the amount of samples to be discarded after each restart:
- to avoid capturing samples affected by the impulse response of the filter
- to delay the acquisition of filters by a specific amount of samples

The discard function is controlled via NBDIS[7:0] as follows:
- When NBDIS[7:0] = 0, the discard function is disabled.
- When NBDIS[7:0] ≠ 0, the discard function is activated in one of the following condition:
  - when the DFLTEN bit goes to 1
  - every time an acquisition is started in (A)synchronous single-shot modes

Refer to Figure 335 to Figure 339, Figure 342 and Figure 343.

In the example shown in the figure below, the discard function is used to drop the first five samples provided by the digital filter (S1 to S5). The first sample transferred to the RXFIFO (or INT block if enabled) is S6.

**Figure 341. Discard function example**

---

**Warning:** All filters working in interleaved DMA mode must have the same NBDIS[7:0] value.

---

**Data interface activation**

The data interfaces are enabled by setting the corresponding SITFEN or ADCITFEN bit to 1. Once the digital filter is enabled, it receives the serial data from the external $\Sigma\Delta$ modulator or parallel internal data sources (ADC).

**39.4.11 Start-up sequence examples**
**Figure 342** details an acquisition sequence start of a digital filter triggered by DFLTEN (ACQMOD[2:0] = 0), with NBDIS[7:0] = 3 (three samples to discard before acquisition).

The DFLTx is configured for audio application: MCIC, RSFLT and HPF activated. The data interface (SITF or ADCITF) is assumed to be already activated.

Note: NBDIS[7:0] is set on purpose to a low value to simplify the drawing.

**Figure 342. Start sequence with DFLTEN, in continuous mode, audio configuration**

The DFLTEN bit is re-sampled into the MDF processing clock domain. When DFLTEN is detected high, the filter chain is enabled and the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

When the MCIC decimation counter reaches its programmed value N, a sample is available for the RSFLT.

The RSFLT processes all the samples provided by the MCIC and delivers a sample to the HPF every time it processes four samples (decimation by 4). The RSFLT needs up to 24 cycles of mdf_proc_ck clock before delivering a sample (P1).

The HPF processes all the samples provided by the RSFLT, but the NBDIS function prevents the data writing in the RXFIFO as long as NBDIS_CNTR does not reach 0. This counter is decremented every time the HPF delivers a sample.

When NBDIS_CNTR reaches 0, the samples provided by the HPF are stored into the RXFIFO.
The example shown in Figure 343 is based in a motor-control filter configuration:
• MCIC and INT are enabled.
• SFLT and HPF are disabled.
• ACQMOD[2:0] is set to 1 and uses a mdf_trgiy input as trigger.
• NBDIS[7:0] is set to 3.
• INTVAL[6:0] is set to 2.

The mdf_trgiy input signal is re-sampled into the MDF processing clock domain to avoid any metastability issues. When the trigger condition is met (rising edge), the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

When the MCIC decimation counter reaches its programmed value N, a sample is available. The NBDIS function prevents the samples writing in the INT as long as NBDIS_CNTR does not reach 0. This counter is decremented every time the MCIC delivers a sample.

When NBDIS_CNTR reaches 0, the new samples are provided to the INT, that performs the integration of three consecutive samples and stores them into the RXFIFO.

Figure 343. Start sequence with trigger input, in continuous mode, motor configuration

39.4.12 Break interface

The break interface merges the break events coming from the OLDx and SDCx blocks into four break signals connected to various peripherals of the product (see Table 366 for details).

As shown in Figure 344, several blocks can share the same break line. A same block can also drive several break lines. The break interface is controlled via MDF_OLDxCR and MDF_SCDxCR.
39.4.13 Data transfer to memory

Data format

The samples processed by DFLTx are stored into a RXFIFO. The application can read the samples stored into the FIFOs via the MDF digital filter data register x (MDF_DFLTxDR). The samples inside this register are signed and left aligned. The bit 31 always represents the sign.

The MDF provides 24-bit left-aligned data. Performing a 16-bit access to MDF_DFLTxDR allows the application to get the 16 most significant bits. Performing a 32-bit access to MDF_DFLTxDR allows the application to get a 24-bit data size.

Data re-synchronization

The samples stored into the RXFIFOs can be transferred into the memory by using either DMA requests or interrupt signaling.

Note: The same logic is implemented for each mdf_breaky output (y can be 0, 1, 2 or 3).
The sample transfer from the RXFIFO to MDF_DFLTxDR takes two periods of the AHB clock (mdf_hclk) and two periods of the mdf_ker_ck clock. The MDF inserts automatically wait-states if the application performs a read operation of MDF_DFLTxDR while the transfer of the new sample from the RXFIFO to MDF_DFLTxDR is not yet completed.

**Independent-transfer mode**

In this mode, each RXFIFO has its own DMA channel and its own FTHF flag event. Both single and burst DMA transfers are supported in this mode, but the application must care about the following points:

- The RXFIFO must contain at least the same amount of samples than the burst size.
- The burst mode efficiency may be reduced due to the data re-synchronization explained in the previous section.

In addition, the application can select the RXFIFO threshold (FTH bit) to trigger the data transfer: a data transfer can be triggered as soon as the RXFIFO is not empty, or when the RXFIFO is half-full (containing depth / 2 samples).

For the DMA transfer, as soon as one of the RXFIFO reaches the threshold level, the corresponding DMA request is asserted in order to ask for data transfer. Successive DMA requests are performed as long as the corresponding RXFIFO is not empty.

The DMA mode of the RXFIFOx is enabled via the corresponding DMAEN bit in the MDF digital filter control register x (MDF_DFLTxCR).

For the interrupt signaling, the following cases must be considered:

- If FTH = 0, as soon as a data is available in MDF_DFLTxDR, the corresponding FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as MDF_DFLTxDR is read.
- If FTH = 1, as soon as one of the RXFIFO reaches the threshold level and a data is available into MDF_DFLTxDR, the corresponding FTHF is set, allowing the generation of an interrupt. The FTHF flag is released as soon as one data is read. FTHF is set again if the threshold condition is met again. In this mode, every time an interrupt occurs, the application is supposed to read FIFO_SIZE / 2 data.

The independent-transfer mode must be used when the sample rates provided by each filter paths are not perfectly synchronous, or when the streams are independent. This situation may occur for example:

- when SITF is in SLAVE mode and each external sensor provides its own sampling clock
• when the decimation ratios of the DFLTx are not the same
• when all the streams are not starting at the same time

Interleaved-transfer mode

This mode optimizes the DMA request resources by sharing a single DMA request with several RXFIFOs.

Only single DMA transfers are supported in this mode.

In interleaved-transfer mode, FTH cannot be used and only the FTHF of RXFIFO0 is available for the interrupt signaling.

For the DMA transfer, when all the RXFIFOs working in interleaved-transfer mode are not empty, some DMA requests are generated in order to read sequentially one sample of each RXFIFOs, via MDF_DFLT0DR.

For the RXFIFOs working in interleaved-transfer mode, the DMA channel is enabled by setting to 1 DMAEN in MDF_DFLT0DR and by defining the amount of RXFIFOs working in interleaved mode via ILVNB[3:0]. DMAEN for the other RXFIFOs working in interleaved-transfer mode (RXFIFO 1 to ILVNB[3:0]) are not taken into account.

Figure 347 shows four RXFIFOs working in interleaved-transfer mode. Each RXFIFO has a delay due to the programming of the DLY block.

When all the RXFIFOs have at least one sample available (in this example the last FIFO receiving a sample is RXFIFO1), the MDF requests the data transfer to the memory (see 1 in Figure 347). In this figure, the DMA is assumed to be used for the data transfer to memory.

The acquisition can be simply stopped by setting DFTLEN to 0 for one of the filter configured in interleaved-transfer mode. In the example, when a DFLTEN is set to 0 (see 2 in Figure 347), the transfer to memory is immediately stopped. Samples M2S(N), M3S(N) and M4S(N) may be lost.

Figure 347. Data transfer in interleaved-transfer mode
In interrupt mode, when all the RXFIFOs working in interleaved-transfer mode have a data ready, the FTHF flag of RXFIFO0 is asserted to allow the interrupt generation. The application is then supposed to read sequentially one sample of each RXFIFOs, via MDF_DFLT0DR. The FTHF event is released when the first data is read.

For the RXFIFOs working in interleaved-transfer mode, the interrupt mode is enabled by setting FTHIE to 1 in MDF_DFLT0DR and by defining the amount of RXFIFOs working in interleaved-transfer mode via ILVNB[3:0]. FTHIE of the other RXFIFOs working in interleaved-transfer mode (RXFIFO1 to ILVNB[3:0]) are not taken into account.

The interleaved-transfer mode can only be applied starting at RXFIFO0 up to RXFIFOk. The number of RXFIFOs working in interleaved-transfer mode are defined by ILVNB[3:0].

When ILVNB[3:0] = 0, all RXFIFOs work in independent-transfer mode.

The interleaved-transfer mode can be used only for digital filters delivering samples perfectly synchronous each other. This is typically the case of sound capture with an array of digital microphones sharing the same bitstream clock.

**Caution:** To make the MDF working properly in interleaved-transfer mode, the following rules must be respected:

- All filters working in interleaved-transfer mode must be all synchronized together, meaning that all filters must select the same ACQM[2:0] (must be equal to 010 or 011), the same trigger source and the same trigger sensitivity.
- All filters working in interleaved-transfer mode must have the same configuration.
- All sensors providing the data for the filters working in interleaved-transfer mode must use the same bitstream clock frequency.
- The maximum delay difference applied with SPK[6:0] for the filters working in interleaved-transfer mode must remain strictly lower than the RXFIFO depth. Normally this delay does not need to exceed one TPCM period.

**Note:** Both independent- and interleaved-transfer modes can work in parallel: for example, the first RXFIFOs (RXFIFO0 to RXFIFOk) may work in interleaved-transfer mode when the others (RXFIFO(k+1) to RXFIFO(N)) works in independent-transfer mode.

If the AHB clock is not present when a data transfer must be performed, the MDF first requests the AHB clock (refer to Section 39.4.5: Clock generator (CKGEN) for details).
The figure below shows the data path for a configuration in independent-transfer mode (left-hand figure) and a configuration mixing both independent- and interleaved-transfer modes (right-hand figure).

**Figure 348. Data path for interleaved- and independent-transfer modes**

In the right-hand figure, the DFLT0 and DFLT1 filters are configured in interleaved-transfer mode. For those filters, FTH is no longer taken into account by the hardware. The samples provided by DFLT0 and DFLT1 are read from MDF_DFLT0DR. When both RXFIFOs are no longer empty, the MDF generates two DMA requests to read the sample from DFLT0 and the sample from DFLT1. If both RXFIFOs are not empty again, the same sequence is triggered.

**Note:** When one of the filter working in interleaved-transfer mode is disabled, the data transfer to memory of all filters in interleaved-transfer mode is stopped immediately as well.

**RXFIFO overrun**

A RXFIFO overrun condition is detected when the RXFIFO is full and a new sample from the DFLTx must be written.

In this case, DOVRF is set and the new sample is dropped. When the RXFIFO has at least one location available, the new incoming sample is written into the RXFIFO.

**Figure 349** shows an example based on a RXFIFO depth of four words and FTH set to 1, so that FTHF goes to 1 when the RXFIFO is half-full.

The S7 sample is lost due to an overrun: the RXFIFO is full while S7 must be written into the RXFIFO. The S7 write operation is not performed. DOVRF is set to 1 at the moment where the write operation was expected. The overflow event remains to 1 as long as it is not cleared by the application.

In this example, DOVRIE is set to 1 to have an interrupt if an overrun condition is detected.

After the S7 sample, the application manages to read data from the RXFIFO and the MDF can write the S8 sample and consecutive. Later, the application clears DOVR, allowing the detection of a new overrun situation.
In the mdf_hclk line, the gray boxes indicate that the MDF requested the AHB clock. The figure below shows the AHB clock available only when the MDF requests it. In real applications, the AHB clock may also be present if the MDF does not request it.

**Figure 349. Example of overflow and transfer to memory**

![Diagram showing overflow and transfer to memory](image)

Note: If the MDF works in interleaved-transfer mode, the application must check the overrun status of all RXFIFOs that works in interleaved-transfer mode.

### 39.4.14 Autonomous mode

The MDF can work even if the AHB bus clock is not available (Stop modes). The MDF uses the AHB clock only for the register interface. All the processing part is clocked with the kernel clock.

In Stop mode, the MDF receives a kernel clock if the following conditions are met:
- The MDF autonomous mode is enabled in the RCC.
- The selected kernel clock source is taken from an oscillator available in Stop mode.

In Stop mode, the MDF receives the AHB clock if the following conditions are met:
- The MDF autonomous mode is enabled in the RCC.
- The MDF requests the AHB clock, in the following situations:
  - when the MDF must transfer data into the memory via the DMA
    The data are directly transferred to the SRAM thanks to the DMA while the product remains in Stop mode. The AHB clock request is maintained until the DMA transfer is completed.
  - when the MDF must generate an interrupt
    An interrupt generally wakes up the device from Stop mode, as an action from the application is needed. Once the AHB clock is available, the interrupt is
generated. The AHB clock request is maintained as long as an enabled interrupt flag is active. More precisely, when an interrupt must be generated, the MDF requests the AHB clock.

### 39.4.15 Register protection

The MDF embeds some hardware protection to prevent invalid situations. The table below shows the list of write-protected and unprotected fields.

#### Table 377. Register protection summary

<table>

</tbody>
</table>
All the MDF processing is performed in the mdf_proc_ck clock domain. For that reason, enabling or disabling a MDF sub-block may take some time due to the re-synchronization between the AHB clock domain and the mdf_proc_ck clock domain. XXXACTIVE flags are available to allow the application to check that the synchronization between the two clock domains is completed.

To change a write-protected bitfield, the application must follow this sequence:
1. Set the enable bit of the sub-block to 0.
2. Wait for corresponding flag XXXACTIVE = 0.
3. Modify the wanted fields.
4. Set the enable bit of the sub-block to 1.

Refer to the description of each sub-block for more details.

### 39.5 MDF low-power modes

#### Table 378. Effect of low-power modes on MDF

<table>
<thead>

</tr>
<tr>
<td>Standby</td>
<td>The MDF is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

1. Refer to Section 39.3: MDF implementation for details about Stop modes supported by the MDF.

### 39.6 MDF interrupts

To increase the CPU performance, the MDF offers the following interrupt lines per digital filter:
- receive interrupt MDF_FLTx_RX (mdf_fltx_rx_it)
- event interrupt MDF_FLTx_EVT (mdf_fltx_evt_it)
- a combination of both interrupts MDF_FLTx (mdf_fltx_it)

**Note:**

Interrupts are not always connected to the device (see Section 39.3: MDF implementation for more details).

The status flags are available even if the corresponding interrupt enable flag is not enabled.
The interrupt interface is controlled via the MDF DFLTx interrupt enable register x (MDF_DFLTxIER) and the MDF DFLTx interrupt status register x (MDF_DFLTxISR).

Figure 350. MDF interrupt interface

(1) Not always implemented. Refer to the vector table of the product for details.
The table below shows which interrupt line is affected by which event, and how to clear and activate each interrupt/event.

### Table 379. MDF interrupt requests

1. Refer to Section 39.3: MDF implementation for details.
2. MDF_FLTx vector corresponds to the assertion of mdf_fltx_it signal
3. MDF_FLTx_RX vector corresponds to the assertion of mdf_fltx_rx signal.
4. MDF_FLTx_EVT vector corresponds to the assertion of mdf_fltx_evt signal.

### 39.7 MDF application informations

#### 39.7.1 MDF configuration examples for audio capture

*Table 380* gives some examples of the MDF settings for the digital microphones, focusing on 16 and 48 kHz output data rate. In these examples, the following is expected:

- The INT block is bypassed (INTVAL = 0).
- The offset error compensation is disabled (OFFSET = 0).

Configurations #1 and #2 are for very low-power use-cases and have a reduced signal-to-noise ratio. The user must also insure that the selected digital microphone can work properly at 512 kHz. These configurations can be used for sound detection. The RSFLT is not used to reduce as much as possible the frequency of the kernel clock (mdf_ker_ck).

Configurations #3, #4, #9, #10, #11 give signal-to-noise ratios around 115 dB, with an ideal microphone model, with a sinus signal of 997 Hz. Using the RSFLT allows a good control on the in-band ripple and a good image rejection.
Configurations #7, #8, #10 give signal-to-noise ratio around 120 dB, with an ideal microphone model, using a sinus signal of 997 Hz.

1. CICMOD = 100 for CIC order equal to 4. CICMOD = 101 for CIC order equal to 5.

### 39.7.2 Programming examples

This example describes how to capture sound from four microphones, assuming that each microphone pair shares the same data line. The MDF_SD0 and MDF_SD2 data lines are used. The microphone clock is provided by the MDF via MDF_CCK0 pin.

#### 39.7.3 Connection examples

*Figure 351* shows simple connection examples of the MDF to external sensors:

- Picture on the left: four digital microphones connected to the MDF

In this connection, DMIC1 is intended to be used alone. This is why it uses a dedicated clock (MDF_CCK0). DMIC1 is also connected to a dedicated data line in case the application intends to power-down DMIC2/3/4, when only DMIC1 is used. If the application keeps DMIC2/3/4 powered, DMIC2 and DMIC1 can share the same data line, reducing the connection to four I/Os.

If the power consumption is not an issue, when a single microphone is used, all the microphones can be connected to the same common clock (MDF_CCK0) and each
microphone pair can share the same data line. In this case, only three I/Os are required.
In this example, the data transfer to memory can be performed either using the interleaved- or the independent-transfer mode.

- Picture in the center: sensor providing several data lines with a common clock
  Each data line can represent different parameters (such as current or voltage). The common clock can be provided either by the sensor or by the MDF. The data line can be shared or not by two sensors if the sensor allows it. In the figure below, the sensor does not allow the sharing of the data lines.
  In this example, the data transfer to memory can be performed either using the interleaved- or independent-transfer mode.

- Picture on the right: two independent sensors connected to the MDF
  Each of them has its dedicated clock and data lines. In this case, the data transfer to memory must use the independent-transfer mode.

**Figure 351. Sensor connection examples**

39.7.4 Global frequency response

*Figure 352* shows the global frequency response for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enable with a cut-off frequency of 40 Hz
The figure below shows the theoretical frequency response using a CIC4 and a CIC5.

**Figure 352. Global frequency response**

![Global frequency response](image)

*Figure 353* shows the in-band ripple for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:
- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enable with a cut-off frequency of 20 Hz

The resulting in-band ripple is ± 0.41 dB for CIC5, and ± 0.45 for CIC4.

The -3 dB cut-off frequency is 7061 Hz.

**Figure 353. Detailed frequency response**

![Detailed frequency response](image)

### 39.7.5 Total MDF gain

This section details how to compute the signal level provided by the MDF according to the filter settings. The formula does not take into account the filters transfer function.

A signal level may be expressed in dBFS (decibel full scale). A 0 dBFS level is assigned to the maximum possible digital level. For example, a signal that reaches 50 % of the maximum level, has a - 6 dBFS level (6 dB below full scale).

For example, for the MDF offering a final data width of 24 bits, a signal having an amplitude of $2 \times 10^6$ LSB has a level of:

$$20 \times \log_{10} \left( \frac{2 \times 10^6}{2^{(24-1)}} \right) = -12.45 \text{ dBFS}$$
In addition, the data size of a signal having an amplitude (Amp) expressed in LSB is given by:

$$DS = \left( \frac{\ln(Amp)}{\ln(2)} + 1 \right) \text{bits}$$

One bit need to be added for negative values. So a signal having an amplitude of $2 \times 10^6$ LSB, has a data size of 21.9 bits.

**CIC gain**

The CIC gain ($G_{CIC}$ and $GdB_{CIC}$) can be deduced from the following formula giving data size in bits ($DS_{CIC}$).

$$DS_{CIC} = (N \times \log_2(D1)) + DS_{IN}$$

And the bit growth is:

$$BG_{CIC} = (N \times \log_2(D1))$$

where $N$ represents the CIC order (selected by CICMOD[2:0]), and $D1$ is the decimation ratio (given by MCICD).

$DS_{IN}$ represents the data size (in bits) of the input signal.

---

**Warning:** $DS_{CIC}$ is very important for CIC filters. In order to work fine, $DS_{CIC}$ must not exceed 26 bits.

$$G_{CIC} = 2^{BG_{CIC}} = (D1)^N$$

which gives, in decibels:

$$GdB_{CIC} = 20 \times \log_{10}((D1)^N)$$

**Note:** The same formulas are valid for the ACIC.

**Data size at SCALE output**

The data size at SCALE output (including the CIC gain) is a key information as the RSFLT starts to have some saturations if the peak-to-peak signal amplitude at SCALE output is higher than 22 bits.
If the RSFLT is bypassed, then a peak-to-peak signal amplitude of 24 bits is accepted. The resulting data size is given by:

\[
DS_{\text{SCALE}} = N \times \log_2(D1) + \log_2\left(\frac{GDB_{\text{SCALE}}}{10^{\frac{20}{20}}}\right) + DS_{\text{IN}}
\]

The data size at SCALE output (DS_{\text{SCALE}}) is expressed in bits and GDB_{\text{SCALE}} represents the gain selected by SCALE[5:0], in dB.

**RSFLT gain**

The RSFLT gain in the useful bandwidth is typically 9.5 dB, but due to ripple a margin of about ± 0.5 dB must be considered. Typically, the RSFLT increases the bit size by \(BG_{\text{RSFLT}}\):

\[
BG_{\text{RSFLT}} = 10^{\frac{9.5\ \text{dB}}{20}} = 2.98 = 1.6 \text{ bits}
\]

**INT gain**

The INT block can also introduce a gain if the rescaling value is different from the integration value.

\[
G_{\text{INT}} = \frac{\text{IVAL}}{\text{IDIV}}
\]

and:

\[
GdB_{\text{INT}} = 20 \times \log_{10}\left(\frac{\text{IVAL}}{\text{IDIV}}\right)
\]

The bit growth of the INT is then given by the following formula:

\[
BG_{\text{INT}} = \log_2\left(\frac{\text{IVAL}}{\text{IDIV}}\right)
\]

IVAL represents the integration value selected by INTVAL[6:0], and IDIV represents the integrator output division selected by INTDIV[1:0].

**Note:** The HPF filter has a gain of 0 dB.
The figure below shows a simplified view of the filter path, and gives for each significant component the expression of the bit growth and the gain.

Figure 354. Simplified DFLT view with gain information

The table below summarizes the final data size for different filter configurations.

</table>

Example using the main filter chain

If the MDF filter is programmed as follows:

- The input signal is coming from a serial interface ($DS_{IN} = 1$ bit).
- CIC order = 5 (N), with a decimation value of 24 (D1).
- $SCALE[5:0]$ is set to -12 dB.
- RSFLT is enabled and the decimation by four is enabled.
- HPF is enabled.
- INT is disabled.

Check first the data size at CIC output:

$DS_{CIC} = (5 \times \log_{2}(24)) + 1$ bit = 23.92 bits

The size is lower than 26 bits, so the CIC works in good conditions.
The data size at CIC output is very close to 24 bits, so the SCALE must be adjusted in order to provide a signal 22 bits max to the RSFLT. An attenuation of 12 dB is needed.

Then the signal level provided to the RSFLT is:

$$DS_{SCALE} = DS_{CIC} + \log_2 \left( \frac{10^{-12}}{2^{20}} \right) = 23.92 - 1.99 = 21.93 \text{ bits}$$

At the end, the final signal amplitude is:

$$DS_{OUT} = DS_{SCALE} + 1.6 \text{ bits} = (21.93 + 1.6) = 23.52 \text{ bits}$$

or

$$SDB_{OUT} = 20 \times \log_{10} \left( \frac{2^{23.52}}{2^{24}} \right) = -2.84 \text{ dBFS}$$

The RSFLT ripple a margin of about ±0.41 dB (in this configuration) must be considered.

**Example using the OLD filter chain**

In the following example, the application wants to trigger an OLD event when the voltage coming from a shunt resistor reaches ±200 mV.

Hypothesis:
- The $\Sigma$Δ sensor is specified to support a full-scale signal of ±350 mV.
- The ACIC decimation ratio (D2) is fixed to 32.
- The ACIC order (N) is fixed to 3.

The $\Sigma$Δ sensor provides a full-scale digital signal (amplitude of one bit) for a signal higher or equal to ±350 mV. If the input signal is equal 200 mV, then the digital signal amplitude provided by the sensor is $200 / 350 = 0.571$.

The gain of the ACIC filter is:

$$G_{CIC} = (D2)^N = 32^3 = 32768$$

A signal having an amplitude of 200 mV at sensor input has then an amplitude of about $32768 \times 0.571 = 18725$ LSB at ACIC output.

OLDTHH must be set to 18725 and OLDTHL must be set to -18725.

### 39.8 MDF registers

All the MDF registers must be accessed either in word (32-bit) or half-word (16-bit) formats.

The registers are described for the MDF instance having the biggest number of filters. For registers related to filters, the number of registers is equal to the amount of filters. Refer to **Section 39.3** for details.
39.8.1 **MDF global control register (MDF_GCR)**

Address offset: 0x000

Reset value: 0x0000 0000

This register is used for controls common to all digital filters.

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **ILVNB[3:0]**: Interleaved number

This bitfield is set and reset by software. It enables or disables the interleaved-transfer mode and defines how many digital filters work in this mode.

This bitfield cannot be changed when DFLTEN = 1 in MDF_DFLT0CR.

0000: Interleaved-transfer mode disabled
0001: Data from DFLT0 and DFLT1 are interleaved.
0010: Data from DFLT0, DFLT1 and DFLT2 are interleaved.
...
1111: Data from DFLT0 to DFLT15 are interleaved.

*Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).*

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **TRGO**: Trigger output control

This bit is set by software and reset by hardware. It is used to start the acquisition of several filters synchronously. It is also able to synchronize several MDF together by controlling the mdf_trgo signal.

0: Write 0 has no effect. Read 0 means that the trigger can be set again to 1.
1: Write 1 generates a positive pulse on mdf_trgo signal and triggers the acquisition on the enabled filters having ACQMOD[2:0] = 0x1 and selecting TRGO as trigger. Read 1 means that the trigger pulse is still active.

39.8.2 **MDF clock generator control register (MDF_CKGCR)**

Address offset: 0x004

Reset value: 0x0000 0000

This register is used to control the clock generator. The mdf_proc_ck clock must be enabled before enabling other MDF parts.

RM0456 Rev 5 1563/3637
Bit 31 **CKGACTIVE**: Clock generator active flag

This bit is set and cleared by hardware. This flag must be used by the application to check if the clock generator is effectively enabled (active) or not. The protected fields of this function can only be updated when CKGACTIVE = 0 (refer to Section 39.4.15 for details). The delay between a transition on CKGDEN and a transition on CKGACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.

0: The clock generator is not active and can be configured if needed.
1: The clock generator is active and protected fields cannot be configured.

Bits 30:24 **PROCDIV[6:0]**: Divider to control the serial interface clock

This bitfield is set and reset by software. It is used to adjust the frequency of the clock provided to the SITF.

\[ F_{\text{mdf_ker_ck}} = \frac{F_{\text{mdf_ker_ck}}}{(\text{PROCDIV} + 1)} \]

This bitfield must not be changed if one of the filters is enabled (DFTEN = 1).

0: mdf_ker_ck provided to the SITF
1: mdf_ker_ck/2 provided to the SITF
2: mdf_ker_ck/3 provided to the SITF
...
127: mdf_ker_ck/128 provided to the SITF

*Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).*

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **CCKDIV[3:0]**: Divider to control the MDF_CCK clock

This bitfield is set and reset by software. It is used to adjust the frequency of the MDF_CCK clock. The input clock of this divider is the clock provided to the SITF. More globally, the frequency of the MDF_CCK is given by the following formula:

\[ F_{\text{MDF_CCK}} = \frac{F_{\text{mdf_ker_ck}}}{(\text{PROCDIV} + 1) \times (\text{CCKDIV} + 1)} \]

This bitfield must not be changed if one of the filters is enabled (DFTEN = 1).

0000: The MDF_CCK clock is mdf_proc_ck.
0001: The MDF_CCK clock is mdf_proc_ck / 2.
0010: The MDF_CCK clock is mdf_proc_ck / 3.
...
1111: The MDF_CCK clock is mdf_proc_ck / 16.

*Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).*

Bits 15:12 **TRGSRC[3:0]**: Digital filter trigger signal selection

This bitfield is set and cleared by software. It is used to select which external signals trigger for the corresponding filter. This bitfield is not significant if CKGMOD = 0.

000x: TRGO selected
0010: mdf_trg[0] selected
0011: mdf_trg[1] selected
...
1111: mdf_trg[13] selected

*Note: This bitfield can be write-protected (refer to Section 39.4.15 for details.)*

Bits 11:9 Reserved, must be kept at reset value.
Bit 8  **TRGSENS**: CKGEN trigger sensitivity selection

This bit is set and cleared by software. It is used to select the trigger sensitivity of the trigger signals. This bit is not significant if the CKGMOD = 0.

0: A rising edge event triggers the activation of CKGEN dividers.
1: A falling edge even triggers the activation of CKGEN dividers.

**Note:** When the trigger source is TRGO, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge. This bit can be write-protected (refer to Section 39.4.15 for details).

Bit 7  Reserved, must be kept at reset value.

Bit 6  **CCK1DIR**: MDF_CCK1 direction

This bit is set and reset by software. It is used to control the direction of the MDF_CCK1 pin.

0: MDF_CCK1 pin direction is in input.
1: MDF_CCK1 pin direction is in output.

**Note:** This bit can be write-protected (refer to Section 39.4.15 for details).

Bit 5  **CCK0DIR**: MDF_CCK0 direction

This bit is set and reset by software. It is used to control the direction of the MDF_CCK0.

0: MDF_CCK0 pin direction is in input.
1: MDF_CCK0 pin direction is in output.

**Note:** This bit can be write-protected (refer to Section 39.4.15 for details).

Bit 4  **CKGMOD**: Clock generator mode

This bit is set and reset by software. It is used to define the way the clock generator is enabled. This bit must not be changed if one of the filters is enabled (DFTEN = 1).

0: The kernel clock is provided to the dividers as soon as CKGDEN is set to 1.
1: The kernel clock is provided to the dividers when CKGDEN is set to 1 and the trigger condition met.

**Note:** This bit can be write-protected (refer to Section 39.4.15 for details).

Bit 3  Reserved, must be kept at reset value.

Bit 2  **CCK1EN**: MDF_CCK1 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the MDF_CCK1 pin.

0: Bitstream clock not generated
1: Bitstream clock generated on the MDF_CCK1 pad

Bit 1  **CCK0EN**: MDF_CCK0 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the MDF_CCK0 pin.

0: Bitstream clock not generated
1: Bitstream clock generated on the MDF_CCK0 pad

Bit 0  **CKGDEN**: CKGEN dividers enable

This bit is set and reset by software. It is used to enable/disable the clock dividers of the CKGEN: PROCDIV and CCKDIV.

0: CKGEN dividers disabled
1: CKGEN dividers enabled
39.8.3 MDF serial interface control register x (MDF_SITFxCR)

Address offset: 0x080 + 0x80 \* x, (x = 0 to 5)

Reset value: 0x0000 1F00

This register is used to control the serial interfaces (SITFx). The number of registers is equal to the amount of filters. Refer to Section 39.3 for details.

Bit 31 SITFACTIVE: Serial interface active flag
This bit is set and cleared by hardware. It is used by the application to check if the serial interface is effectively enabled (active) or not. The protected fields of this function can only be updated when the SITFACTIVE is set to 0 (refer to Section 39.4.15 for details).

The delay between a transition on SITFEN and a transition on SITFACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.

0: The serial interface is not active and can be configured if needed.
1: The serial interface is active and protected fields cannot be configured.

Bits 30:13 Reserved, must be kept at reset value.

Bits 12:8 STH[4:0]: Manchester symbol threshold/SPI threshold
This bitfield is set and cleared by software. It is used for Manchester mode to define the expected symbol threshold levels (refer to Manchester mode for details on computation).
In addition this bitfield is used to define the timeout value for the clock absence detection in Normal SPI mode. STH[4:0] values lower than four are invalid.

Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 SITFMOD[1:0]: Serial interface type
This bitfield is set and cleared by software. It is used to define the serial interface type.
00: LF_MASTER SPI mode
01: Normal SPI mode
10: Manchester mode: rising edge = logic 0, falling edge = logic 1
11: Manchester mode: rising edge = logic 1, falling edge = logic 0

Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 SCKSRC[1:0]: Serial clock source
This bitfield is set and cleared by software. It is used to select the clock source of the serial interface.
00: Serial clock source is MDF_CCK0.
01: Serial clock source is MDF_CCK1.
1x: Serial clock source is MDF_CKlx (not allowed in LF_MASTER SPI mode).

Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).
39.8.4  MDF bitstream matrix control register x (MDF_BSMXxCR)

Address offset: 0x084 + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 0000

This register is used to select the bitstream to be provided to the corresponding digital filter and to the SCD. The number of registers is equal to the amount of filters. Refer to Section 39.3 for details.

#### Bit 31  DFLTA<\text{CTIVE}>: Digital filter active flag

- This bit is set and cleared by hardware. It indicates if the digital filter is active: can be running or waiting for events.
  - 0: Digital filter not active (can be re-enabled again, via DFLTEN, if needed)
  - 1: Digital filter active

#### Bit 30  DFLTRUN: Digital filter run status flag

- This bit is set and cleared by hardware. It indicates if the digital filter is running or not.
  - 0: Digital filter not running and ready to accept a new trigger event
  - 1: Digital filter running

#### Bits 29:28  Reserved, must be kept at reset value.

#### Bits 27:20  NBDIS[7:0]: Number of samples to be discarded

- This bitfield is set and cleared by software. It is used to define the number of samples to be discarded every time the DFLTx is re-started.
  - 0: No sample discarded
  - 1: 1 sample discarded
  - 2: 2 samples discarded
  - ...  
  - 255: 255 samples discarded

*Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).*

#### Bits 19:17  Reserved, must be kept at reset value.

#### Bit 16  SNPSFMT: Snapshot data format

- This bit is set and cleared by software. It is used to select the data format for the snapshot mode.
  - 0: Integrator counter (INT_CNT) not inserted into MDF_SNPSxDR, leaving a data resolution of 23 bits
  - 1: Integrator counter (INT_CNT) inserted at position [15:9] of MDF_SNPSxDR, leaving a data resolution of 16 bits.

*Note: This bit can be write-protected (refer to Section 39.4.15 for details).*
Bits 15:12 TRGSRC[3:0]: Digital filter trigger signal selection
   This bitfield is set and cleared by software. It is used to select which external signals trigger the corresponding filter.
   0000: TRGO selected
   0001: OLDx event selected
   0010: mdf_trg[0] selected
   ... 
   1111: mdf_trg[13] selected
   Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 TRGSENS: Digital filter trigger sensitivity selection
   this bit is set and cleared by software. It is used to select the trigger sensitivity of the external signals
   0: A rising edge event triggers the acquisition.
   1: A falling edge even triggers the acquisition.
   Note: When the trigger source is TRGO or OLDx event, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge, when OLDx event is selected, the sensitivity is forced to rising edge.
   This bit can be write-protected (refer to Section 39.4.15 for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 ACQMOD[2:0]: Digital filter trigger mode
   This bitfield is set and cleared by software. It is used to select the filter trigger mode.
   000: Asynchronous continuous acquisition mode
   001: Asynchronous single-shot acquisition mode
   010: Synchronous continuous acquisition mode
   011: Synchronous, single-shot acquisition mode
   100: Window continuous acquisition mode
   101: Synchronous snapshot mode
   Others: same a 000
   Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 FTH: RXFIFO threshold selection
   This bit is set and cleared by software. It is used to select the RXFIFO threshold. This bit is not significant for RXFIFOS working in interleaved-transfer mode (see Interleaved-transfer mode for details).
   0: RXFIFO threshold event generated when the RXFIFO is not empty
   1: RXFIFO threshold event generated when the RXFIFO is half-full
   Note: This bit can be write-protected (refer to Section 39.4.15 for details).

Bit 1 DMAEN: DMA requests enable
   This bit is set and cleared by software. It is used to control the generation of DMA request to transfer the processed samples into the memory.
   0: DMA interface for the corresponding digital filter disabled
   1: DMA interface for the corresponding digital filter enabled
   Note: This bit can be write-protected (refer to Section 39.4.15 for details).
Bit 0 **DFLTEN**: Digital filter enable

This bit is set and cleared by software. It is used to control the start of acquisition of the corresponding digital filter path. This bit behavior depends on ACQMOD[2:0] and external events. The serial or parallel interface delivering the samples must be enabled as well.

0: Acquisition immediately stopped
1: Acquisition immediately started if ACQMOD[2:0] = 00x or 101, or acquisition started when the proper trigger event occurs if ACQMOD[2:0] = 01x or 100.

### 39.8.6 MDF digital filter configuration register x (MDF_DFLTxCICR)

Address offset: 0x08C + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used to control the main CIC filter. The number of registers is equal to the amount of filters. Refer to [Section 39.3](#) for details.

| Bit 31:26 | Reserved, must be kept at reset value. |
| Bit 25:20 | **SCALE[5:0]**: Scaling factor selection |
| Bit 19:17 | Reserved, must be kept at reset value. |

Bits 31:26: Reserved, must be kept at reset value.

**Bits 25:20**: **SCALE[5:0]**: Scaling factor selection

This bitfield is set and cleared by software. It is used to select the gain to be applied at CIC output (refer to Table 373 for details). If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back this bitfield informs the application on the current gain value.

- 000000: 0 dB
- 000001: + 3.5 dB
- 000010: + 6 dB or shift left by 1 bit
  ...
- 011000: + 72 dB or shift left by 12 bits
- 100000: - 48.2 dB or shift right by 8 bits (default value)
- 100001: - 44.6 dB
- 100010: - 42.1 dB or shift right by 7 bits
- 100011: - 38.6 dB
  ...
- 101110: - 6 dB or shift right by 1 bit
- 101111: - 2.5 dB

 Others: Reserved

Bits 19:17: Reserved, must be kept at reset value.
Bits 16:8 **MCICD[8:0]**: CIC decimation ratio selection
This bitfield is set and cleared by software. It is used to select the CIC decimation ratio. A decimation ratio smaller than two is not allowed. The decimation ratio is given by (CICDEC+1).
0: Decimation ratio is 2.
1: Decimation ratio is 2.
2: Decimation ratio is 3.
3: Decimation ratio is 4
...
511: Decimation ratio is 512.
*Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).*

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **CICMOD[2:0]**: Select the CIC mode
This bitfield is set and cleared by software. It is used to select the configuration and the order of the MCIC. When CICMOD[2:0] = 0xx, the CIC is split into two filters: the main CIC (MCIC) and the auxiliary CIC (ACIC, used for the out-of-limit detector).
000: CIC split in two filters and MCIC configured in FastSinc filter
001: CIC split in two filters and MCIC configured in Sinc\(^1\) filter
010: CIC split in two filters and MCIC configured in Sinc\(^2\) filter
011: CIC split in two filters and MCIC configured in Sinc\(^3\) filter
100: CIC configured in single Sinc\(^4\) filter
others: CIC configured in single Sinc\(^5\) filter

*Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).*

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **DATSRC[1:0]**: Source data for the digital filter
This bitfield is set and cleared by software.
0x: Stream coming from the BSMX selected
10: Stream coming from the ADCITF1 selected
11: Stream coming from the ADCITF2 selected

*Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).*

### 39.8.7 MDF reshape filter configuration register x (MDF_DFLTxRSFR)

Address offset: 0x090 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used to control the reshape and HPF filters. The number of registers is equal to the amount of filters. Refer to Section 39.3 for details.

</table>
Bits 31:10  Reserved, must be kept at reset value.

Bits 9:8  HPFC[1:0]: High-pass filter cut-off frequency
This bitfield is set and cleared by software. It is used to select the cut-off frequency of the
high-pass filter. \( F_{\text{PCM}} \) represents the sampling frequency at HPF input.
00: Cut-off frequency = 0.000625 \( \times F_{\text{PCM}} \)
01: Cut-off frequency = 0.00125 \( \times F_{\text{PCM}} \)
10: Cut-off frequency = 0.00250 \( \times F_{\text{PCM}} \)
11: Cut-off frequency = 0.00950 \( \times F_{\text{PCM}} \)

*Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).*

Bit 7  HPFBYP: High-pass filter bypass
This bit is set and cleared by software. It is used to bypass the high-pass filter.
0: HPF not bypassed (default value)
1: HPF bypassed

*Note: This bit can be write-protected (refer to Section 39.4.15 for details).*

Bits 6:5  Reserved, must be kept at reset value.

Bit 4  RSFLTD: Reshaper filter decimation ratio
This bit is set and cleared by software. It is used to select the decimation ratio for the reshape
filter.
0: Decimation ratio is 4 (default value).
1: Decimation ratio is 1.

*Note: This bit can be write-protected (refer to Section 39.4.15 for details).*

Bits 3:1  Reserved, must be kept at reset value.

Bit 0  RSFLTBYP: Reshaper filter bypass
This bit is set and cleared by software. It is used to bypass the reshape filter and its
decimation block.
0: Reshape filter not bypassed (default value)
1: Reshape filter bypassed

*Note: This bit can be write-protected (refer to Section 39.4.15 for details).*

### 39.8.8  MDF integrator configuration register x (MDF_DFLTxINTR)

Address offset: 0x094 + 0x80 \( \times x \), \( x = 0 \) to 5

Reset value: 0x0000 0000

This register is used to the integrator (INT) settings. The number of registers is equal to the
amount of filters. Refer to Section 39.3 for details.

### 39.8.9 MDF out-of limit detector control register x (MDF_OLDxCB)

Address offset: 0x098 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used to configure the OLDx. The number of registers is equal to the amount of filters. Refer to Section 39.3 for details.

Bits 21:17  **ACICD[4:0]**: OLDx CIC decimation ratio selection

This bitfield is set and cleared by software. It is used to select the decimation ratio of the ACIC. It is only taken into account by the MDF when CICMOD[2:0] = 0xx. The decimation ratio is given by (ACICD + 1).

0: Decimation ratio is 1.
1: Decimation ratio is 2.
2: Decimation ratio is 3.
3: Decimation ratio is 4.
...
31: Decimation ratio is 32.

*Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).*

Bits 16:14  Reserved, must be kept at reset value.

Bits 13:12  **ACICN[1:0]**: OLDx CIC order selection

This bitfield is set and cleared by software. It is used to select the ACIC type and order. It is only taken into account by the MDF when CICMOD[2:0] = 0xx.

00: FastSinc filter type
01: Sinc1 filter type
10: Sinc2 filter type
11: Sinc3 filter type

*Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).*

Bits 11:8  Reserved, must be kept at reset value.

Bits 7:4  **BKOLD[3:0]**: Break signal assignment for out-of limit detector

This bitfield is set and cleared by software.

BKOLD[i] = 0: Break signal (mdf_break[i]) not assigned to threshold event
BKOLD[i] = 1: Break signal (mdf_break[i]) assigned to threshold event

*Note: This bitfield can be write-protected (refer to Section 39.4.15 for details).*

Bits 3:2  Reserved, must be kept at reset value.

Bit 1  **THINB**: Threshold In band

This bit is set and cleared by software.

0: The OLDx generates an event if the signal is lower than OLDTHL or higher than OLDTHH (default value).
1: The OLDx generates an event if the signal is lower than OLDTHH and higher than OLDTHL.

*Note: This bit can be write-protected (refer to Section 39.4.15 for details).*

Bit 0  **OLDEN**: OLDx enable

This bit is set and cleared by software.

0: OLDx disabled (default value)
1: OLDx enabled, including the ACIC filter working in continuous mode
39.8.10 MDF OLDx low threshold register x (MDF_OLDxTHLR)

Address offset: 0x09C + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 0000

This register is used for the adjustment of the out-of-limit low threshold. The number of registers is equal to the amount of filters. Refer to Section 39.3 for details.

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **OLDTHL[25:0]:** OLD low threshold value

This bitfield is set and cleared by software. OLDTHL represents a 26-bit signed value. The real threshold compared to the signal provided by the filter is OLDTHL.

*Note:* This bitfield can be write-protected (refer to Section 39.4.15 for details).

39.8.11 MDF OLDx high threshold register x (MDF_OLDxTHHR)

Address offset: 0x0A0 + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 0000

This register is used for the adjustment of the OLDx high threshold. The number of registers is equal to the amount of filters. Refer to Section 39.3 for details.

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **OLDTHH[25:0]:** OLDx high threshold value

This bitfield is set and cleared by software. OLDTHH represents a 26-bit signed value. The real threshold compared to the signal provided by the filter is OLDTHH.

*Note:* This bitfield can be write-protected (refer to Section 39.4.15 for details).
### 39.8.12 MDF delay control register x (MDF_DLYxCR)

Address offset: 0x0A4 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used for the adjustment stream delays. The number of registers is equal to the amount of filters. Refer to Section 39.3 for details.

#### Bit 31 SKPBF: Skip busy flag
- This bit is set and cleared by hardware. It is used to control if the delay sequence is completed.
  - 0: MDF ready to accept a new value into SKPDLY[6:0]
  - 1: Last valid SKPDLY[6:0] still under processing

#### Bits 30:7 Reserved, must be kept at reset value.

#### Bits 6:0 SKPDLY[6:0]: Delay to apply to a bitstream
- This bitfield is set and cleared by software. It defines the number of input samples that are skipped. Skipping is applied immediately after writing to this bitfield, if SKPBF = 0 and the corresponding DFLTEN = 1. If SKPBF = 1, the value written into the register is ignored by the delay state machine.
  - 0: No input sample skipped
  - 1: 1 input sample skipped
  - ... 127: 127 input samples skipped

### 39.8.13 MDF short circuit detector control register x (MDF_SCDxCR)

Address offset: 0x0A8 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used for the adjustment stream delays. The number of registers is equal to the amount of filters. Refer to Section 39.3 for details.

</tbody>
</table>

Bits 31:12 Reserved, must be kept at reset value.

- **Bit 11 RFOVRF**: Reshape filter overrun detection flag
  - This bit is set by hardware and cleared by software by writing this bit to 1.
  - 0: Read 0 means that no reshape filter overrun is detected. Write 0 has no effect.
  - 1: Read 1 means that reshape filter overrun is detected. Write 1 clears this flag.

- **Bit 10 CKABF**: Clock absence detection flag
  - This bit is set by hardware and cleared by software by writing this bit to 1.
  - 0: Read 0 means that no clock absence is detected. Write 0 has no effect.
  - 1: Read 1 means that a clock absence is detected. Write 1 clears this flag.

- **Bit 9 SATF**: Saturation detection flag
  - This bit is set by hardware and cleared by software by writing this bit to 1.
  - 0: Read 0 means that no saturation is detected. Write 0 has no effect.
  - 1: Read 1 means that a saturation is detected. Write 1 clears this flag.

- **Bit 8 SCDF**: Short-circuit detector flag
  - This bit is set by hardware and cleared by software by writing this bit to 1.
  - 0: Read 0 means that no SCD0 event is detected. Write 0 has no effect.
  - 1: Read 1 means that a SCD0 event is detected. Write 1 clears this flag.

- **Bit 7 SSIVRF**: Snapshot overrun flag
  - This bit is set by hardware and cleared by software by writing this bit to 1.
  - 0: Read 0 means that no snapshot overrun event is detected. Write 0 has no effect.
  - 1: Read 1 means that a snapshot overrun event is detected. Write 1 clears this flag.
Bit 6 **THHF**: High-threshold status flag
This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the high-threshold comparator when the last OLD0 event occurred. This bit gives additional information on the conditions triggering the last OLD0 event. It can be cleared by writing OLDF flag to 1.
0: The signal was lower than OLDTHH when the last OLD0 event occurred.
1: The signal was higher than OLDTHH when the last OLD0 event occurred.

Bit 5 **THLF**: Low-threshold status flag
This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the low-threshold comparator when the last OLD0 event occurred. This bit gives additional information on the conditions triggering the last OLD0 event. It can be cleared by writing OLDF flag to 1.
0: The signal was higher than OLDTHL when the last OLD0 event occurred.
1: The signal was lower than OLDTHL when the last OLD0 event occurred.

Bit 4 **OLDF**: OLD0 flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no OLD0 event is detected. Write 0 has no effect.
1: Read 1 means that an OLD0 event is detected Write 1 clears THHF, THLF and OLDF.

Bit 3 **RXNEF**: RXFIFO not-empty flag
this bit is set and cleared by hardware according to the RXFIFO level.
0: RXFIFO empty
1: RXFIFO not empty

Bit 2 **SSDRF**: Snapshot data ready flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no data is available. Write 0 has no effect.
1: Read 1 means that a new data is available. Write 1 clears this flag.

Bit 1 **DOVRF**: Data overflow flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no overflow is detected. Write 0 has no effect.
1: Read 1 means that an overflow is detected; Write 1 clears this flag.

Bit 0 **FTHF**: RXFIFO threshold flag
This bit is set by hardware and cleared by hardware when the RXFIFO level is lower than the threshold.
0: RXFIFO threshold not reached
1: RXFIFO threshold reached
39.8.17  MDF DFLTx interrupt status register x (MDF_DFLTxISR)

Address offset: 0x130 + 0x80 * (x - 1), (x = 1 to 5)
Reset value: 0x0000 0000

This register contains the status flags for each digital filter path. The number of registers is
equal to the amount of filters. Refer to Section 39.3 for details.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
1 5 1 4 1 3 1 2 1 1 1 0 9 8 7 6 5 4 3 2 1 0
RFOVR F CKABF SATF SCDF SSOVR F THHF THLF OLDF RXNEF SSDRF DOVRF FTHF
rc_w1 rc_w1 rc_w1 rc_w1 rc_w1 r r rc_w1 r rc_w1 rc_w1 r
```

Bits 31:12  Reserved, must be kept at reset value.

Bit 11  **RFOVR F**: Reshape filter overrun detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no reshape filter overrun is detected. Write 0 has no effect.
1: Read 1 means that reshape filter overrun is detected. Write 1 clears this flag.

Bit 10  **CKABF**: Clock absence detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no clock absence is detected. Write 0 has no effect.
1: Read 1 means that a clock absence is detected. Write 1 clears this flag.

Bit 9  **SATF**: Saturation detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no saturation is detected. Write 0 has no effect.
1: Read 1 means that a saturation is detected. Write 1 clears this flag.

Bit 8  **SCDF**: Short-circuit detector flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no SCD event is detected. Write 0 has no effect.
1: Read 1 means that a SCD event is detected. Write 1 clears this flag.

Bit 7  **SSOVR F**: Snapshot overrun flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no snapshot overrun event is detected. Write 0 has no effect.
1: Read 1 means that a snapshot overrun event is detected. Write 1 clears this flag.

Bit 6  **THHF**: High-threshold status flag
This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the
status of the high-threshold comparator when the last OLDx event occurred. This bit gives
additional information on the conditions triggering the last OLDx event. It can be cleared by
writing OLDF flag to 1.
0: The signal was lower than OLDTTH when the last OLDx event occurred.
1: The signal was higher than OLDTTH when the last OLDx event occurred.
Bit 5  **THLF**: Low-threshold status flag

This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the low-threshold comparator when the last OLDx event occurred. This bit gives additional information on the conditions triggering the last OLDx event. It can be cleared by writing OLDF flag to 1.

0: The signal was higher than OLDTHL when the last OLDx event occurred.
1: The signal was lower than OLDTHL when the last OLDx event occurred.

Bit 4  **OLDF**: OLDx flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no OLDx event is detected. Write 0 has no effect.
1: Read 1 means that an OLDx event is detected. Write 1 clears THHF, THLF and OLDF.

Bit 3  **RXNEF**: RXFIFO not-empty flag

This bit is set and cleared by hardware according to the RXFIFO level.

0: RXFIFO empty
1: RXFIFO not empty

Bit 2  **SSDRF**: Snapshot data ready flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no data is available. Write 0 has no effect.
1: Read 1 means that a new data is available. Write 1 clears this flag.

Bit 1  **DOVRF**: Data overflow flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no overflow is detected. Write 0 has no effect.
1: Read 1 means that an overflow is detected. Write 1 clears this flag.

Bit 0  **FTHF**: RXFIFO threshold flag

This bit is set by hardware and cleared by hardware when the RXFIFO level is lower than the threshold.

0: RXFIFO threshold not reached
1: RXFIFO threshold reached

### 39.8.18  MDF offset error compensation control register x (MDF_OECxCR)

Address offset: 0x0B4 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register contains the offset compensation value. The number of registers is equal to the amount of filters. Refer to Section 39.3 for details.

Bits 25:0 **OFFSET[25:0]:** Offset error compensation

This bitfield is set and cleared by software. If the application attempts to write a new offset value while the previous one is not yet applied, this new offset value is ignored. Reading back this bitfield informs the application on the current offset value.

This bitfield represents the value to be subtracted to the signal before going to the SCALE.

### 39.8.19 MDF snapshot data register x (MDF_SNPSxDR)

Address offset: 0x00EC + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used to read the data processed by each digital filter in snapshot mode.

The number of registers is equal to the amount of filters. Refer to [Section 39.3](#) for details.

#### Bits 31:16 SDR[15:0]: Contains the 16 MSB of the last valid data processed by the digital filter.

#### Bits 15:9 EXTSDR[6:0]: Extended data size

If SNPSFMT = 0, this bitfield contains the bits 7 to 1 of the last valid data processed by the digital filter.

If SNPSFMT = 1, this bitfield contains the INT accumulator counter value when the last trigger event occurs (INT_CNT).

#### Bits 8:0 MCICDC[8:0]: Contains the MCIC decimation counter value when the last trigger event occurs (MCIC_CNT)

### 39.8.20 MDF digital filter data register x (MDF_DFLTxDR)

Address offset: 0x00F0 + 0x80 * x, (x = 0 to 5)

Reset value: 0x0000 0000

This register is used to read the data processed by each digital filter. The number of registers is equal to the amount of filters. Refer to [Section 39.3](#) for details.

#### Bits 31:8 DR[23:0]: Data processed by digital filter

#### Bits 7:0 Reserved, must be kept at reset value.

40  Audio digital filter (ADF)

40.1  Introduction

The audio digital filter (ADF) is a high-performance module dedicated to the connection of external sigma-delta (ΣΔ) modulators. It is mainly targeted for the following applications:

- audio capture signals
- metering

The ADF features one digital serial interface (SITF0) and one digital filter (DFLT0) with flexible digital processing options in order to offer up to 24-bit final resolution.

The ADF serial interface supports several standards allowing the connection of various ΣΔ modulator sensors:

- SPI interface
- Manchester coded 1-wire interface
- PDM interface

The ADF converts an input data stream into clean decimated digital data words. This conversion is done thanks to low-pass digital filters and decimation blocks. In addition, it is possible to insert a high-pass filter.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter bypass, filter order, decimation ratio. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion and continuous modes. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A sound activity detector (SAD) is available for the detection of sounds or voice signals. The SAD is connected at the output of the DFLT0. Several parameters can be programmed in order to adjust properly the SAD to the sound environment. The SAD strongly reduces the power consumption by preventing the storage of samples into the system memory, as long as the observed signal does not match the programmed criteria.

The digital processing is performed using only the kernel clock. The ADF requests the bus interface clock (AHB clock) only when data must be transferred or when a specific event requests the attention of the system processor.

40.2  ADF main features

- AHB Interface
- 1 serial digital input:
  - configurable SPI interface to connect various digital sensors
  - configurable Manchester coded interface support
  - compatible with PDM interface to support digital microphones
- 2 common clocks input/output for ΣΔ modulators
- 1 flexible digital filter path including:
  - A MCIC filter configurable in Sinc\(^4\) or Sinc\(^5\) filter with an adjustable decimation ratio
  - A reshape filter to improve the out-of-band rejection and in-band ripple
– A high-pass filter to cancel the DC offset
– Gain control
– Saturation blocks
• Clock absence detector
• Sound activity detector
• 24-bit signed output data resolution
• Continuous or single conversion
• Possibility to delay the selected bitstream
• One trigger input
• Autonomous functionality in Stop modes
• DMA can be used to read the conversion data
• Interrupts services

40.3 **ADF implementation**

The devices embed one MDF instance and one ADF instance, both being digital filters with common features

40.4.3 Serial input interface (SITF)

The SITF0 input interface allows the connection of the external sensor to the digital filter via the bitstream matrix (BSMX). The SITF0 can be configured in the following modes:

- LF_MASTER SPI mode (low-frequency)
- normal SPI mode
- Manchester mode

The data from the serial interface is routed to the filter in order to perform the PDM to PCM conversion and the sound activity detection.

The serial interface is enabled by setting the SITFEN bit to 1. Once the interface is enabled, it receives serial data from the external \(\Sigma\Delta\) modulator.

Note: Before enabling the serial interface, the user must insure that the adf_proc_ck is already enabled (see Section 40.4.5: Clock generator (CKGEN) for details).

The SITF0 is controlled via the ADF serial interface control register 0 (ADF_SITF0CR).

As shown in the Figure 355, ADF_CCK0 or ADF_CCK1 can be selected as clock source, in order to sample the incoming bitstream:

- If the serial interface is programmed in SPI mode, the selected clock source is a copy of the clock present on the ADF_CCK0 or ADF_CCK1 pin.
- If the serial interface is programmed in LF_MASTER SPI mode, the selected clock source is the clock directly provided by the CCKDIV to the ADF_CCK0 or ADF_CCK1 pin.

See Table 386 for additional information.
**LF_MASTER and normal SPI modes**

The LF_MASTER SPI mode is a special mode allowing the use of an adf_proc_ck clock frequency, only two times bigger than the sensor clock. This mode is dedicated to low-power use-cases, using low-speed sensors.

In LF_MASTER SPI mode, the ADF must provide the bitstream clock to the external sensors via ADF_CCK0 and ADF_CCK1 pins. The ADF receives the bitstream data via the serial data input ADF_SDI0.

For the SITF0, the application must select the same clock than the one provided to the external sensor (ADF_CCK0 or ADF_CCK1), in order to guarantee optimal timing performances. This selection is done via SCKSRC[1:0].

The normal SPI interface is a more flexible interface than the LF_MASTER SPI, but the adf_proc_ck frequency must be at least four times higher than the sensor clock.

The application can select ADF_CCK0 or ADF_CCK1 clock for the capture of the data received via the ADF_SDI0 pin.

The ADF can generate a clock to the sensors via ADF_CCK0 or ADF_CCK1 if needed.

For all SPI modes, the serial data is captured using the rising and the falling edge of the selected clock. The SITF0 always provides the following bitstreams:

- bitstream received using the bitstream clock falling edge (bs0_f)
- bitstream received using the bitstream clock rising edge (bs0_r)

According to the sensors connected, one of the two bitstreams may not be available.

The application can select the wanted stream via the BSMX matrix.
To properly synchronize/receive the data stream, the adf_proc_ck frequency must be adjusted according to the constraints listed in Table 387.

Clock absence detection

A no-clock-transition period may be detected when the serial interface works in normal SPI mode. This feature can be used to detect a clock failure in the SPI link.

The application can program a timeout value via the STH[4:0] bitfield of the SITF0. If the ADF does not detect clock transitions for a duration of STH[4:0] x Tadf_proc_ck, then the CKABF flag is set.

An interrupt can be generated if CKABIE is set to 1. The STH[4:0] bitfield is in the ADF serial interface control register 0 (ADF_SITF0CR).

When the serial interface is enabled, the CKABF flag remains to 1 until a first clock transition is detected.

To avoid spurious clock absence detection, the following sequence must be respected:

1. Configure the serial interface in normal SPI mode and enable it.
2. Clear the CKABF flag by writing CKABF bit to 1.
   - If no clock transition is detected on the serial interface, the hardware immediately sets the CKABF flag to 1.
3. Read the CKABF flag:
   - If CKABF = 1, go back to step 2.
   - If CKABF = 0, a clock has been detected. The CKABIE bit can be set to 1 if the application wants an interrupt on detection of a clock absence.

Note: The clock absence detection feature is not available in the LF_MASTER SPI mode.

Manchester mode

In Manchester coded format, the ADF receives data stream from the external sensor via the ADF_SDI0 pin only.

The ADF_CCK0 and ADF_CCK1 pins are not needed in this mode.
Decoded data and clock signals are recovered from serial stream after Manchester decoding. They are available on bs0_r. There are two possible settings of Manchester codings:

- signal rising edge decoded as 0 and signal falling edge decoded as 1
- signal rising edge decoded as 1 and signal falling edge decoded as 0

**Figure 358. Manchester timing example (SITFMOD = 11)**

To decode the incoming Manchester stream, the user must program STH[4:0] in the ADF serial interface control register 0 (ADF_SITF0CR). The STH[4:0] bitfield is used by the SITF0 to estimate the Manchester symbol length and to detect a clock absence. An internal counter (MCNT) is restarted every time a transition is detected in the ADF_SDI0 input. It is used to detect short transitions, long transitions or clock absence. A long transition indicates that the data value changed. **Figure 357** shows a case where the OVR is around height and STH[4:0] = 5.

The estimated Manchester symbol rate ($T_{SYMB}$) must respect the following formula:

$$(STH + 1) \times T_{adf\_proc\_ck} < T_{SYMB} < (2 \times STH \times T_{adf\_proc\_ck})$$

It is recommended to compute STH as follows:

$$STH[4:0] = \text{round}\left(\frac{2 \times OVR}{3} - 1\right)$$
where OVR represents the ratio between the adf_proc_ck frequency and the expected Manchester symbol frequency. OVR must be higher than five, and the adf_proc_ck clock must be adjusted according to the constraints listed in Table 387.

The clock absence flag CKABF is set to 1 when no transition is detected during more than 2 x STH[4:0] x Tadf_proc_ck, or when the SITF0 is not yet synchronized to the incoming Manchester stream. In addition, an interrupt can be generated if the bit CKABIE is set to 1.

When the serial interface is enabled, the ADF must first be synchronized to the incoming Manchester stream. The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (pink circle in the Figure 357) is detected.

The end of the synchronization phase can be checked by following the software sequence:
1. Clear the CKABF flag in the ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR) by writing CKABF bit to 1. If the serial interface is not yet synchronized the hardware immediately set the CKABF flag to 1.
2. Read the CKABF flag:
   - If CKABF= 1, go back to step 1.
   - If CKABF = 0, the Manchester interface is synchronized and provides valid data.

Programming example

In the following example, the ADF kernel clock frequency (Fadf_ker_ck) is 100 MHz and the received Manchester stream is at about 6 MHz (FSYMB):
1. Provide a valid adf_proc_ck to the SITF0.
   The adf_proc_ck frequency must be at least six times higher than the Manchester symbol frequency (means at least 36 MHz).
   PROCDIV is programmed to 1 to perform a division by two of the kernel clock. In that case, Fadf_proc_ck = 50 MHz (8.33 times higher than the Manchester symbol frequency).
2. Compute STH.
   OVR is given by: OVR = Fadf_proc_ck / FSYMB = 50 MHz / 6 MHz = 8.33.

   Then STH[4:0] = \( \lfloor \frac{2 \times 8.33 - 1}{3} \rfloor \) = 5

   The minimum allowed frequency for the Manchester stream is then:
   \( \frac{1}{2 \times STH \times T_{adf\_proc\_ck}} = \frac{1}{(10 \times 20 \, \text{ns})} = 5 \, \text{MHz} \)

   The maximum allowed frequency for the Manchester stream is then:
   \( \frac{1}{(STH+1) \times T_{adf\_proc\_ck}} = \frac{1}{(6 \times 20 \, \text{ns})} = 8.33 \, \text{MHz} \)

40.4.4 ADC slave interface (ADCITF)

The ADCs are not always connected to the ADF. Refer to Section 40.3 to check the situation for this product.

The ADF allows the connection of up to two ADCs to the filter path. For the filter, the DATSRC[1:0] bitfield in the ADF digital filter configuration register 0 (ADF_DFLT0CIRC) allows the application to select data from the ADCs.
Warning: The ADF does not support receiving interleaved data from one of the ADCITF input.

40.4.5 Clock generator (CKGEN)

The RCC (reset and clock controller) provides the following clocks to the ADF:

- AHB clock (adf_hclk) used for the register interface
- Kernel clock (adf_ker_ck) mainly used by all other parts of the circuit via the CKGEN

Those clocks are not supposed to be phase locked, so all signals crossing those clock domains are re-synchronized.

The clock generator (CKGEN) is responsible for the generation of the processing clock, and the clock provided to the ADF_CCK0 and ADF_CCK1 pins. All those clocks are generated from the adf_ker_ck.

The processing clock (adf_proc_ck) is used to run all the signal processing and to re-sample the incoming serial or parallel stream.

To adapt the kernel clock frequency provided by the RCC, the following dividers are available:

- PROCDIV[6:0] used to adapt the kernel clock frequency to the constraints of the parallel and serial interfaces, and to the processing blocks
- CCKDIV[3:0] used to adapt the frequency of the ADF_CCK0 and ADF_CCK1 clocks

PROCDIV[6:0] and CCKDIV[3:0] must be programmed when no clock is provided to the dividers (CKGDEN = 0).

The adf_proc_ck generation is controlled by CKGDEN.

In addition, the CKGMOD bit allows the application to define the way to trigger the CCKDIV divider:

- When CKGMOD = 0, the CCKDIV divider is started as soon as CKGDEN is set to 1.
- When CKGMOD = 1, the CCKDIV divider is started when CKGDEN is set to 1 and the programmed trigger condition occurred.

All the bits and fields controlling the CKGEN are in the ADF clock generator control register (ADF_CKGCR).
The trigger logic for CKGEN is handled by the block TRG_CK. As shown in Figure 364, the CCKDIV divider can be triggered on the rising or falling edge of an external trigger source. When the proper trigger condition occurs, the cck_trg signal goes to high, allowing the CCKDIV divider to start. The TRG_CK logic is reset when CKGDEN is set to 0.

This feature can be helpful to synchronize the ADF_CCKy (y = 0,1) clock of several ADF instances, or to synchronize the clock generation to a timer event.

The application can control the activation of the ADF_CCK0 or ADF_CCK1 pin thanks to CCK0EN/CCK1EN and CCK0DIR/CCK1DIR bits:
- CCKyEN is used to enable the CCKDIV, and thus generates a clock for the external sensors.
- CCKyDIR is used to control the direction of the ADF_CCKy pin (input or output)

### Table 388. Control of the common clock generation

<table>
<thead>
<tr>
<th>CCKyEN</th>
<th>CCKyDIR</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>The ADF_CCKy pin is in input. An external clock can be connected to the ADF_CCKy pin and used by the SITF0 in order to decode the serial stream</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>The ADF_CCKy pin is in output. No clock is generated. The ADF_CCKy pin is driven low.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>The ADF_CCKy pin is in output. A clock is generated on the ADF_CCKy pin. The SITF0 can use this pin as clock source in order to decode the serial stream</td>
</tr>
</tbody>
</table>

Note: The adf_proc_ck must be enabled (by CKGDEN = 1) before enabling other blocks (such as SITF0 or DFLT0).

### CKEN activation sequence example

- Set CKGDEN to 0.
- Wait for CKGACTIVE = 0. If CKGDEN was previously enabled, this phase can take two periods of adf_hclk, and two periods of adf_proc_ck.
- Program PROCIDIV[6:0], CKGMOD, CCKDIV[3:0], TRGSRC[3:0], TRGSENS, CCK1EN and CCK0EN.
- Set CKGDEN to 1.

When needed, at any moment, CCK[1:0]EN bitfield value can be changed without disabling the clock generator.

**Clock frequency constraints**

The table below shows the frequency constraints to receive and process properly the samples.

*Note:* The reshape filter (RSFLT) needs up to 24 cycles of adf_proc_ck clock to process one sample.

1. $F_{ADF\_CCKy}$ represents the frequency of clock received via ADF_CCKy, or generated via ADF_CCKy. $F_{SYMB}$ represents the frequency of the received symbol rate for Manchester mode.

### 40.4.6 Bitstream matrix (BSMX)

The BSMX receives the bitstreams from the serial interface SITF0 and provides the selected stream to the digital filter DFLT0.

As shown in the Figure 355, the SITF0 provides two bitstreams (bs0_r and bs0_f) to the BSMX.

The application to select the wanted stream via the ADF bitstream matrix control register 0 (ADF_BSMX0CR). This selection is intended to be static.
BSMX programming sequence example

The BSSEL[4:0] bitfield cannot be changed if the DFLT0 is enabled. The following steps are needed to change the value of BSMX:

- Set DFLTEN of DFLT0 to 0.
- Wait for BSMXACTIVE = 0.
- Program BSSEL[4:0].
- Set DFLTEN of DFLT0 to 1.

40.4.7 Digital filter processing (DFLT)

The digital filter processing includes the following sub-blocks:

- symbol remap (SBR)
- clock skipper delay (DLY)
- MCIC decimation filter that can be configured in Sinc⁴ or Sinc⁵
- gain control (SCALE)
- signal saturation (SAT)
- reshape filter (RSFLT)
- high-pass filter (HPF)
- receive RXFIFO
The figure below shows the filter path configuration according to CICMOD[2:0]. Several configuration bits are available to configure the digital filter to the application needs.

Figure 361. DFLT overview

Symbol remap and source selection

The symbol remap (SBR) converts the bitstream selected by the BSMX into data usable by the filter path. More especially:

- The high levels are converted into a 16-bit signed number + 1.
- The low levels are converted into a 16-bit signed number - 1.

The signal source of the digital filter can be selected via DATSRC[1:0] between the two following:

- data coming from the BSMX
- data coming from one of the ADC interfaces (ADCITF2 or 1)

Programmable micro-delay control (DLY)

The digital filter has a delay line that allows the timing adjustment of each stream with the resolution of the bitstream clock.

This feature is particularly helpful in the case of microphone beam forming applications where delays smaller than the final sampling rate must be applied to the incoming stream. This feature can be used when the ADF is synchronized with another MDF instance (if present in the product) for a beam forming application for example.

The delay is performed by discarding a given number of samples from the selected input stream, before samples enter into the CIC filter. This data discarding is done by skipping a given number of data strobe, preventing the CIC filter to take into account those data.

When the wanted amount of data strobe has been skipped, the next incoming samples are strobed normally.

The figure below shows an example on how to apply dynamically small delay to an incoming stream. For simplification, the CIC filter performs a decimation by height in this example. CIC1 represents the CIC included in the ADF and CIC0 represents a filter from another MDF instance (if present in the product).
The CIC of the ADF (CIC1) receives a command in order to skip three incoming samples. So the input samples named b10, b11 and b12 are not processed by CIC1. As a consequence, the output sample \(N+1\) generated by CIC0 is built from input samples \([a_{23:16}]\) while the sample \(N+1\) of CIC1 is built from input samples \([b_{26:19}]\).

Finally, the non-skipped data stream looks delayed by three bitstream periods.

**Note:** *When the input data strobes are skipped, the decimation counter remains frozen. As a consequence, the samples delivered by the CIC1 are a bit delayed.*

The following steps are needed to program the amount of bitstream clock periods to be skipped:

1. Wait for SKPBF equal to 0.
2. Write SKPDLY[6:0] to the wanted number of bitstream clock periods to be skipped. The SKPBF flag goes immediately to 1, indicating that the delay value entered into SKPDLY[6:0] is under process.
   - If the DFLT0 is not yet enabled (DFLTEN = 0), then the DLY logic waits for DFLTEN = 1. When the application sets DFLTEN to 1, the DLY logic starts to skip the amount of wanted data strobes.
   - If the DFLT0 is already enabled (DFLTEN = 1), then the DLY logic immediately starts to skip the amount of wanted data strobes.

When the ADF skipped the amount of wanted data strobes, then SKPBF goes back to 0.

3. If the application needs to skip more data strobes, then the operation must be restarted from step 1.

The effect of the delay performed with this mechanism is cumulative as long as the ADF is enabled. If the application performs a D1 delay followed by a D2 delay, then all other active filters are delayed by \(D1 + D2\).

**Note:** *If SKPDLY[6:0] is written when SKPBF = 1, the write operation is ignored.*

**Cascaded-integrator-comb (CIC) filter**

The CIC digital filters are an efficient implementation of low-pass filters, often used for decimation and interpolation. The CIC frequency response is equal to a \(\text{Sinc}^N\) function, this is why they are often called Sinc filters.
The Sinc\textsuperscript{N} digital filter embedded into the ADF can be configurable in Sinc\textsuperscript{4} or Sinc\textsuperscript{5}, according to CICMOD:

- If CICMOD\[2:0\] = 4, Sinc\textsuperscript{4} is selected.
- If CICMOD\[2:0\] = 5, Sinc\textsuperscript{5} is selected.

The filters have the following transfer function:

\[
H(z) = \left(\frac{1 - z^{-D}}{1 - z^{-1}}\right)^N
\]

where \(N\) can be 4 or 5, and \(D\) is the decimation ratio. \(D\) is equal to MCICD+1.

**Figure 363. CIC4 and CIC5 frequency response with decimation ratio = 32 or 16**

### CIC output data size

The size of samples delivered by the CIC (DS\textsubscript{CIC}), depends on the following parameters:

- CIC order (\(N\))
- CIC decimation ratio (\(D\))
- data size of the input stream (DS\textsubscript{IN})

The CIC order and decimation ratio must be programmed in order to insure that the data size does not exceed the 26-bit CIC capability.

The following formula gives the output data size (DS\textsubscript{CIC}) according to the parameters above.
and the CIC gain is given by this formula:

\[ G_{\text{CIC}} = (D)^N \]

The decimation ratio can be adjusted from 2 to 512 for the CIC filter.

The table below gives some data output size in bits for some decimation values, when the data source is a full-scale signal coming from the serial interface or from a 12-bit ADC.

**Note:** \( DS_{\text{IN}} = 1 \text{ bit for a serial bitstream, but can be up to 16 bits when coming from the ADCITF.} \)

**Table 390. Data size according to CIC order and CIC decimation values**

<table>
<thead>
<tr>
<th>Decimation</th>
<th>Data size (bits) when ( DS_{\text{IN}} = 1 \text{ bit} ) (data from SITF0)</th>

</tr>
<tr>
<td>64</td>
<td>25</td>
<td>-</td>
</tr>
<tr>
<td>76</td>
<td>26</td>
<td>-</td>
</tr>
</tbody>
</table>

**Note:** For a full-scale input signal, the decimation ratio must not exceed 76 for a \( Sinc^4 \) and 32 for a \( Sinc^5 \).

The LSB parts of the data provided by the CIC is not necessarily significant: it depends on the sensor performances and the ability of the CIC to reject the out-of-band noise.

The sample size at CIC output can be adjusted thanks to the SCALE block.

**Scaling (SCALE) and saturation (SAT)**

The SCALE block allows the application to adjust the amplitude of the signal provided by the CIC, by steps of 3 dB (± 0.5 dB).

The signal amplitude can be decreased by up to 8 bits (- 48.2 dB), and can be increased by up to 12 bits (+ 72.2 dB).
The gain is adjusted by the SCALE[5:0] bitfield in the *ADF digital filter configuration register 0 (ADF_DFLT0CFR)*.

SCALE[5:0] can be changed even if the DFLT0 is enabled. During the gain transition, the signal provided by the filter is disturbed.

Due to internal resynchronization, there is a delay of some cycles of adf_proc_ck clock between the moment where the application writes the new gain, and the moment where the gain is effectively applied to the samples. If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back SCALE[5:0] informs the application on the current gain value.

The table below shows the possible gain values.

Table 391. Possible gain values

The SAT blocks avoid having a wrap-around of the binary code when the code exceeds its maximal or minimal value.

The ADF performs saturation operations at the following levels:
- after the SCALE block (performed by the SAT block): The signal is saturated at 24 bits.
- inside the RSFLT, to insure a good filter behavior
- at the output of the HPF, to insure that the output signal does not exceed 24 bits

The SATF bit informs the application that a saturation occurred either after the SCALE, inside the RSFLT or after the HPF. In addition, an interrupt can be generated if SATIE is set to 1. As soon as a saturation is detected, the SATF flag is set to 1. It is up to the application to clear this flag in order to be able to detect a new saturation.

Those bits are in the *ADF DFLT0 interrupt enable register (ADF_DFLT0IER)* and *ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)*.

**Gain adjustment policy**

To get the best ADF performances, it is important to properly adjust the gain value via SCALE[5:0].
A usual way to adjust the gain is to select the SCALE[5:0] value that gives a final signal amplitude as close as possible to the 24-bit full-scale, for the maximum input signal.

A way to select the optimal gain is detailed below:
1. Check that, for the expected input signal, the data size into the CIC filter does not exceed 26 bits. This can be checked using this formula:

\[
\ln\left(\frac{\text{SIN}_{pp} \cdot D^N}{\ln(2)}\right) < 26
\]

where \(N\) represents the CIC order, \(D\) the decimation ratio and \(\text{SIN}_{pp}\) the maximum peak-to-peak amplitude of the input signal.

\(\text{SIN}_{pp}\) can take:
- a maximum peak-to-peak amplitude of 2 (± 1), for samples coming from SITF0
- A maximum peak-to-peak amplitude of 4095 (+ 2047, - 2048), for samples coming from a 12-bit ADC

**Example:** a Sinc\(^4\) can be used with a decimation ratio of 96, if the maximum input signal does not exceed ± 0.35. Indeed:

\[
\frac{\ln(0.7 \cdot 96^4)}{\ln(2)} \approx 25.82 \text{ bits} < 26 \text{ bits}
\]
2. Adjust the SCALE value.

To select the most appropriate SCALE value, the user must check if the RSFLT is used or not. If the RSFLT is used, the data size at SCALE output must not exceed 22 bits, otherwise the data size can be up to 24 bits. The SCALE value in dB must be selected using this formula:

$$\text{SCALE}_{\text{dB}} < 20 \cdot \log_{10} \left( \frac{2^{\text{NB}}}{\text{SIN}_{\text{pp}} \cdot (2^{\text{Dn}})} \right)$$

where NB is equal to 22 if RSFLT is enabled, or 24 if RSFLT is bypassed. SCALE_{dB} represents the gain value selected by SCALE[5:0].

**Example:** For a Sinc\(^4\) with a decimation ratio of 96 and a SIN\(_{pp}\) of 0.7.

- If the RSFLT is bypassed:

  $$20 \cdot \log_{10} \left( \frac{2^{24}}{0.7 \cdot 96^4} \right) = -11 \text{ dB}$$

  SCALE\(_{dB}\) value must be lower than -11 dB, the closest lower value is -12 dB (SCALE[5:0] = 0x2C).

- If the RSFLT is enabled:

  $$20 \cdot \log_{10} \left( \frac{2^{22}}{0.7 \cdot 96^4} \right) = -23 \text{ dB}$$

  SCALE\(_{dB}\) value must be lower than -23 dB, the closest lower value is -24.1 dB (SCALE[5:0] = 0x28).

If SCALE[5:0] is set to a higher value, then a saturation may occur. An event flag informs the user if a saturation occurred.

The table below proposes gain values for different filter configurations, when the data comes from the SITF0, according to the MCIC order, and the MCIC decimation ratio. This table is not exhaustive and considers a full-scale input signal (see Section 40.7.5: Total ADF gain for details).

Reshaping filter (RSFLT)

In addition to the CIC, the ADF offers a reshaping IIR filter mainly dedicated to the audio application, but also usable in other applications.

When the RSFLT is used, the sample size at its input must not exceed 22 bits.

The samples at the RSFLT output can be decimated by four or not according to the RSFLT bit in the ADF reshape filter configuration register 0 (ADF_DFLT0RSFR).

The RSFLT can be bypassed by setting RSFBYP to 1 in the ADF reshape filter configuration register 0 (ADF_DFLT0RSFR).

The table below shows which sampling rate must be provided to the RSFLT in order to process the most common audio streams.

The RSFLT cutoff frequency \( F_C \) depends on the sample rates at its input \( F_{RS} \), and is given by the following formula:

\[
F_C = 0.111 \times F_{RS}
\]

### Table 393. Most common microphone settings

</tr>
</tbody>
</table>
The figure below shows the frequency response of the reshape filter.

**Figure 364. Reshape filter frequency response normalized \( F_{RS} / 2 = 1 \)**

The RSFLT gain is close to 9.3 dB, so the output data size is a little bit lower than 24 bits for a 22-bit wide input signal.

The RSFLT takes 24 clock cycles of adf_proc_ck clock to process one sample at \( F_{RS} \). When the RSFLT is enabled, the application must insure that the adf_proc_ck is at least 24 times faster than \( F_{RS} \).

The RSFLT generates an event (rfovr_evt) and sets the RFOVRF flag, if the RSFLT receives a new samples while the previous one is still under processing.

When RFOVRF is set, the samples provided by the RSFLT are invalid. The application must then stop the data acquisition and provides a faster adf_proc_ck clock to the RSFLT.

**High-pass filter (HPF)**

The high-pass filter suppresses the low-frequency content from the final output data stream in case of continuous conversion mode. The high-pass filter can be enabled or disabled via HPFBYP in the ADF reshape filter configuration register 0 (ADF_DFLT0RSFR).

The HPF is useful when there is parasitic low-frequency noise (or DC signal) in the input data source that must be removed from the final data.
The HPF is a first order IIR filter and the cut-off frequency can be selected via HPFC[1:0] in the ADF reshape filter configuration register 0 (ADF_DFLT0RSFR), among the following values:

- 0.000625 x FPCM
- 0.00125 x FPCM
- 0.00250 x FPCM
- 0.00950 x FPCM

The HPF output is saturated at 24 bits. The SATF flag is set if a sample is saturated.

40.4.8 Digital filter acquisition modes

The ADF offers the following modes to perform a data capture:

- asynchronous continuous acquisition mode
- asynchronous single-shot acquisition mode
- synchronous continuous acquisition mode
- synchronous single-shot acquisition mode
- window continuous acquisition mode

**Note:** To perform a data capture, the filter, the interface providing the data (SITF0 or ADCITF) and the CKGEN must be enabled. If needed, the ADF_CCK0 or ADF_CCK1 must be enabled as well.

The filter can be stopped immediately when DFLTEN is set to 0. This action resets the filter and flushes the RXFIFO. The DFLTACTIVE flag also goes back to 0 when the RXFIFO and the filter is reset.

The figure below shows a simplified view of the trigger logic available for each filter and for the clock generator.

**Figure 365. Trigger logic for DFLT and CKGEN**

A block common to all TRIG blocks performs the rising and falling edges detection and the re-synchronization of the input trigger to the adf_ker_ck clock domain. This implementation allows the application to use triggers with pulse width smaller than the adf_ker_ck period.

In synchronous modes, the TRIG block offers the possibility to select adf_trgi or TRGO bit as trigger sources. The TRGO bit is in the **ADF global control register (ADF_GCR)**.

The edge sensitivity can also be selected.

**Asynchronous continuous acquisition mode**

This mode allows the application to start a continuous acquisition by simply writing the DFLTEN bit to 1.

The asynchronous continuous acquisition mode is selected when ACQMOD[2:0] = 0.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN) so that the adf_proc_ck frequency is compatible with the targeted application (see examples in **Table 398**).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 0.
4. Set to 1 the SITFEN bit of the serial data interface.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1, the acquisition sequence starts immediately.
The figure below shows a simplified example of the samples generated by the DFLT0.

**Figure 366. Asynchronous continuous mode (ACQMOD[2:0] = 0)**

<table>
<thead>
<tr>
<th>DFLTEN</th>
<th>DFLT0 output</th>
<th>DFLTRUN</th>
<th>ADFACTIVE</th>
<th>ADF_CCK0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

**Asynchronous single-shot acquisition mode**

This mode allows the application to start the acquisition of one sample by simply writing the DFLTEN bit to 1.

The asynchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 001.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the adf_proc_ck frequency is compatible with the targeted application (see examples in Table 398).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 001.
4. Set to 1 the SITFEN bit.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1, the filter provides one data to the RXFIFO and stops the acquisition.

To trigger a new acquisition, the application must:

1. Check that the previous acquisition is completed, by waiting that DFLTRUN = 0.
2. Set again DFLTEN to 1.

This sequence can be repeated every time a new data must be converted.

As shown in the Figure 366, every time DFLTEN is set to 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset, and the filter is ready to start a new conversion.
If DFLTEN is set to 0 while an acquisition is ongoing, the ongoing conversion is stopped (in the example, S3 is lost). This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Set DFLTEN to 0.

Figure 367. Asynchronous single-shot mode (ACQMOD[2:0] = 001)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous continuous acquisition mode

This mode allows the application to start a continuous acquisition by using one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The Synchronous continuous acquisition mode is selected when ACQMOD[2:0] = 010.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in Table 398).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 010.
4. Set to 1 the bit SITFEN.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. When the trigger condition is met, the filter starts the acquisition.
The TRGSENS bit allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). The first rising edge of the trigger signal is ignored because DFLTEN = 0. Then the next rising edge is taken into account and starts the acquisition. All other rising edges are ignored. The trigger logic is re-initialized when DFLTRUN goes back to 0.

**Figure 368. Synchronous continuous mode (ACQMOD[2:0] = 010)**

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

**Synchronous single-shot acquisition mode**

This mode allows the application to start a single acquisition by using one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The Synchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 011.
The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in Table 398).
2. Enable the CKGEN and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 011.
4. Set to 1 the SITFEN bit.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. When the trigger condition is met, the filter starts the acquisition and provides one data to the RXFIFO, then the filter is ready to accept a new trigger.

TRGSENS allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing, or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). Every-time a trigger rising edge is detected with DFLTEN = 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset. DFLTRUN is set to 0 and the filter is ready to start a new conversion.

![Figure 369. Synchronous single-shot mode (ACQMOD[2:0] = 011)](image)

**Note:** The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

*Figure 368* shows a case where the DFLTEN is set to 0 while an acquisition is ongoing (the sample S2 is lost). This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Clear DFLTEN to 0.
Window continuous acquisition mode

This mode allows the application to start or stop a continuous acquisition controlled by consecutive edges of one of the following trigger sources:
- adf_trgi signal
- TRGO bit

The window continuous acquisition mode is selected when ACQMOD[2:0] = 100.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):
1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in Table 398).
2. Enable the CKGEN and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter settings and set the ACQMOD[2:0] to 100.
4. Set to 1 the SITFEN bit.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. If TRGSENS = 0, the acquisition starts on trigger rising edge and stops on trigger falling edge. If TRGSENS = 1, the acquisition starts on trigger falling edge and stops on trigger rising edge.

Note: The acquisition may restart if the trigger condition becomes again active.

Figure 369 shows a simplified example of window continuous acquisition mode, with TRGSENS = 1. Once DFLTEN is set to 1, the ADF waits for a falling edge on the selected trigger input. When the trigger condition is met, DFLTRUN goes to 1 and the acquisition starts. The acquisition stops if the ADF detects a rising edge on the selected trigger input. If DFLTEN is still set to 1, the ADF waits again for a falling edge on the selected trigger input.

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.
Starting several filters synchronously

If the ADF is used with MDF instances (if present in the product), it is possible to start simultaneously the acquisition of all the filters. This synchronization capability depends on the way the triggers are connected in the product. Generally, an ADF is able to trigger MDF instances, if its adf_trgo signal is connected as trigger input to those blocks (see Section 40.4.2: ADF pins and internal signals to check trigger capabilities).

In the following programming example, one ADF has its adf_trgo signal connected to some MDFs. To start the acquisition of several filters synchronously, the following sequence must be performed (assuming that DFLTEN bits of the filters are set to 0):

On MDFs receiving the adf_trgo trigger:
1. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
2. Set to 1 the SITFEN bit of the requested data interfaces.
3. For each filter, set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. For each filter, set TRGSRC[3:0] in order to select the adf_trgo trigger input.
5. For each filter, set TRGSENS to 0 (rising edge).
6. For each filter, set DFLTEN to 1.

On the ADF generating the adf_trgo trigger:
1. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK[1:0] clocks.
2. Set to 1 the SITFEN bit of the requested data interfaces.
3. Set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. Set TRGSRC[3:0] to 0 (TRGO selected).
5. Set TRGSENS to 0 (rising edge).
6. Set DFLTEN to 1.
7. Read TRGO bit until it is read to 0.
8. Set TRGO to 1. Then the acquisition sequence for all selected filters starts immediately.

To trigger a new acquisition (in case of single-shot) the application must do the following:
- Check that the previous acquisition is completed, by waiting DFLTRUN = 0.
- Read TRGO until it is read to 0.
- Set again the bit TRGO to 1.

Discarded samples

The ADF offers the possibility to program the amount of samples to be discarded after each restart:
- to avoid capturing samples affected by the impulse response of the filter
- to delay the acquisition of filters by a specific amount of samples

The discard function is controlled via NBDIS[7:0] as follows:
- When NBDIS[7:0] = 0, the discard function is disabled.
- When NBDIS[7:0] ≠ 0, the discard function is activated in one of the following condition:
  - when the DFLTEN bit goes to 1
  - every time an acquisition is started in (A)synchronous single-shot modes

Refer to Figure 365 to Figure 369, and Figure 371.
In the example shown in the figure below, the discard function is used to drop the first five samples provided by the digital filter (S1 to S5). The first sample transferred to the RXFIFO is S6.

**Figure 371. Discard function example**

40.4.9 **Start-up sequence examples**

The figure below details a start of acquisition sequence of a digital filter triggered by DFLTEN (ACQMOD[2:0] = 0), with NBDIS[7:0] = 3 (three samples to discard before acquisition).

The DFLT0 is configured for audio application: MCIC, RSFLT and HPF activated. The data interface (SITF0 or ADCITF) is assumed to be already activated.

Note: NBDIS[7:0] is set on purpose to a small value to simplify the drawing.

**Figure 372. Start sequence with DFLTEN, in continuous mode, audio configuration**
The DFLTEN bit is re-sampled into the ADF processing clock domain. When DFLTEN is detected high, the filter chain is enabled, and the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

When the MCIC decimation counter reached its programmed value N, a sample is available for the RSFLT.

The RSFLT processes all the samples provided by the MCIC, and delivers a sample to the HPF every-time it processes four samples (decimation by 4). The RSFLT needs up to 24 cycles of adf_proc_ck clock before delivering a sample (P1).

The HPF processes all the samples provided by the RSFLT, but the NBDIS function prevents the data writing in the RXFIFO as long as NBDIS_CNTR does not reach 0.

When NBDIS_CNTR reaches 0, the samples provided by the HPF are stored into the RXFIFO.

### 40.4.10 Sound activity detection (SAD)

The SAD is based on the computation of the ambient noise level (ANLVL) and of the short-term sound level (SDLVL). The SAD offers the following ways to detect a sound:
- when the SDLVL reaches a threshold referenced to the ambient noise level
- when the SDLVL reaches a fixed threshold
- when the ANLVL reaches a fixed threshold

As shown in the figure below, the SAD takes the 16 MSB samples from the DFLT0 output.

#### Figure 373. SAD block diagram

The SAD is highly configurable, and the application can adjust several parameters:
- SAD detection behavior (SADMOD)
- number of samples used to compute the sound level (FRSIZE)
- number of frames used to compute the ambient noise level during the learning phase (LFRNB)
- slope of the ambient noise estimator (ANSLP)
- minimum expected ambient noise level (ANMIN)
- threshold level (SNTHR)
- threshold hysteresis (HYSTEN)
• hangover window in order to filter spurious transitions between DETECT and MONITOR states (HGOVR)
• data capture mode (DATCAP)

SAD detection behavior

The SAD can use the following ways to detect a sound, selected by SADMOD[1:0]:

• When SADMOD[1:0] = 0, the SAD works like a voice-activity detection. In this mode, the SAD estimates the ambient noise level according to the computed sound level values. The threshold of the trigger is elaborated from the estimated ambient noise. Finally the current sound level is compared to this threshold. In a first approximation, the SAD triggers if the peak-to-average value of the input signal reaches a level defined by SNTHR[3:0].

• When SADMOD[1:0] = 01, the SAD compares the current sound level (SDLVL) to a fixed trigger value defined by the application via SNTHR[3:0] and ANMIN[12:0]. This mode allows a fast SAD reaction as the amount of samples used to compute the sound level can be configured via FRSIZE[2:0].

• When SADMOD[1:0] = 1x, the SAD compares the estimated ambient noise level (ANLVL) to a fixed trigger value defined by the application via SNTHR[3:0] and ANMIN[12:0]. This mode avoids unwanted triggers, due to peak levels, but the SAD reacts more slowly to an input signal variation. It is nevertheless possible to adjust the reaction time via FRSIZE[2:0] and ANSLP[2:0].

SAD states

As shown in Figure 373, the SAD works as follows:

1. When enabled (SADEN = 1), the SAD is first in LEARN state to perform a first estimation of the ambient noise level.

2. The SAD continuously computes the short-term sound level (SDLVL) using the samples provided by the DFLT0. The amount of samples used to compute the sound level is given by FRSIZE[2:0]. The samples processed by the DFLT0 can be transferred into the memory or not depending on DATCAP[1:0] value.

3. The initial ambient noise level (ANLVL) is computed using the consecutive sound level values. The application can define how much sound level values are used to perform the computation of this initial ambient noise estimation (LFRNB).

4. When the initial ambient noise level (ANLVL) is computed, the SAD switches to the MONITOR state.

5. Every time a new short-term sound level value is available, the SAD updates the ambient noise level and the thresholds according to the selected detection mode.

6. If the SAD triggers, then the following happens:
   – The SAD switches to DETECT state.
   – The sddet_evt event is asserted.
   – The adf_sad_det signal is set to high.

7. The hangover function insures that the DETECT state is maintained even if the sound level goes below the threshold level for a time given by HGOVR.
Sound level computation (SDLVL)

Once enabled, the SAD computes continuously the sound level value. The sound level represents the average of the absolute value of an amount of PCM samples given by FRSIZE[2:0].

\[
SDLVL = \frac{1}{N_{FRSIZEx}} \sum_{n=1}^{N_{FRSIZEx}} |\text{PCM}(n)|
\]

where \(N_{FRSIZEx}\) is the amount of PCM samples given by FRSIZE[2:0].
Ambient noise estimation (ANLVL)

The ambient noise level (ANLVL) is computed when SADMOD[1:0] is 00 or 10.

The ambient noise level is computed differently according to the state of the SAD as detailed below:

- **ANLVL computation during the LEARN state**
  
  Every time the SAD is enabled, a learning phase is initiated in order to estimate a first value of the ambient noise level. During this phase, the SAD cannot trigger.

  During the LEARN phase, the ambient noise level is computed as follows:

  \[
  ANLVL = \frac{1}{NLFRNB} \times \sum_{n=1}^{NLFRNB} |S|DLVL(n)|
  \]

  where \( NLFRNB \) is the amount of frames given by LFRNB[2:0] bitfield.

- **ANLVL computation during the MONITOR or DETECT state**
  
  When the learning phase is completed, the SAD updates the ambient noise level in the following way:

  a) The SAD computes the new possible values for the ambient noise level:

  \[
  ANLVL\_UP = ANLVL \times (1+2^{(ANSLP-12)})
  \]

  \[
  ANLVL\_DN = ANLVL \times (1-2^{(ANSLP-10)})
  \]

  b) The ANLVL takes the ANLVL\_DN value if the current sound level is lower than ANLVL\_DN, otherwise ANLVL takes the value of ANLVL\_UP.

  The ANLVL is not updated if the current sound level is higher than the threshold level, except if SADMOD[1:0] = 10.

  c) When SADMOD[1:0] = 0, if the new ANLVL value is lower than ANMIN[12:0], ANLVL is replaced by ANMIN.

  The slope of the noise estimator can be adjusted to optimize the detection of the wanted signal. This slope is adjusted via ANSLP[2:0] in the ADF SAD configuration register (ADF_SADCFG).
The table below shows the allowed values according to the frame size and the sampling rate of the data observed by the SAD. The recommended values when the SADMOD[1:0] = 0 are the ones into the gray shaded cells.

**Table 395. ANSLP values versus FRSIZE and sampling rates**

<table>
<thead>
<tr>
<th>FRSIZE</th>
<th>ANSLP values for Fs = 8 kHz</th>
<th>ANSLP values for Fs = 16 kHz</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Slow(1)</td>
<td>typical(2)</td>

</tr>
<tr>
<td>6 (512 samples)</td>
<td>6</td>
<td>7</td>
</tr>
</tbody>
</table>

1. The slow slope is equal to -8.5 dB/s for the negative slope and +2.1 dB/s for the positive slope.
2. The typical slope is equal to -17.1 dB/s for the negative slope and +4.2 dB/s for the positive slope.
3. The fast slope is equal to -34.2 dB/s for the negative slope and +8.5 dB/s for the positive slope.

The slopes can also be computed using the following formulas:

\[
SLC_{UP} = 20 \times \frac{F_s}{FSIZE} \times \log_{10}(1 + 2^{(ANSLP_{-12})})
\]

\[
SLC_{DN} = 20 \times \frac{F_s}{FSIZE} \times \log_{10}(1 - 2^{(ANSLP_{-10})})
\]

where \(F_s\) is the sampling rate of the stream observed by the SAD and \(FSIZE\) is the frame size defined by FRSIZE[2:0].

**Threshold computation**

The way the threshold value is computed depends on SADMOD[1:0]:

- If SADMOD[1:0] = 0, THRH is obtained by multiplying the current ANLVL value with the gain defined in SNTHR[3:0].
  \[
  THR_H = ANLVL \times \frac{GdB_{SNTHR}}{20}
  \]
  This threshold value is then compared to the current sound level (SDLVL).

- If SADMOD[1:0] = 01, THRH is obtained by multiplying the current ANMIN[12:0] with the gain defined by SNTHR[3:0].
  \[
  THR_H = ANMIN \times \frac{GdB_{SNTHR}}{20}
  \]
  This threshold value is then compared to the current sound level (SDLVL).
- If SADMOD[1:0] = 1x, THRH is obtained by multiplying the current ANMIN[12:0] by 4.

\[
\text{THR}_H = \text{ANMIN} \times 4
\]

This threshold value is then compared to:

\[
\frac{\text{ANLVL}}{10} \times 10^{\frac{\text{SNTHR}[1:0]}{20}}
\]

The hysteresis mode can be enabled to reduce the spurious transitions between MONITOR and DETECT states. In hysteresis mode (HYSTEN = 1), the following threshold values are used:
- THRH when the SAD is in MONITOR state.
- THRL when the SAD is in DETECT state.

The table below shows the thresholds values according to SNTHR.

<table>

</tr>
</tbody>
</table>

1. LVL must be replaced by ANLVL when SADMOD[1:0] = 0 and by ANMIN for other SADMOD[1:0] values.

When the hysteresis function is disabled, the SAD always use THRH.

Note: The hysteresis mode must not be used when SADMOD[1:0] = 1x.

Trigger logic
The signal compared to this threshold depends also on SADMOD[1:0].

The trigger condition is reached when the selected signal (SELSIG) is bigger than the threshold level.

If the trigger condition is met, the following happens:
- The SAD switches to DETECT state.
- The SAD refreshes the hangover counter with HGOVR.
- The sddet_evt event is asserted if the SAD transits from MONITOR to DETECT.
The adf_sad_det signal is set to high. The SAD remains in DETECT state as long as the trigger condition is met or the hangover down-counter is different from 0.

The sddet_evt event indicates when the SAD enters and/or exits the DETECT state. This event is used to generate an interrupt when a sound is detected or when a sound is no longer detected:
- When DETCFG = 0, the application receives an event only when the SAD enters the DETECT state.
- When DETCFG = 1, the application receives an event when the SAD enters or exits the DETECT state.

The adf_sad_det signal remains high as long as the SAD is in DETECT state.

The SAD also provides a flag indicating that a new sound level value is available (SDLVLF). The last computed sound level (SDLVL[14:0]) is available in the **ADF SAD sound level register (ADF_SADSDLVR)**, and the last computed ambient noise level (ANLVL[14:0]), in the **ADF SAD ambient noise level register (ADF_SADANLVR)**.

**Note:** The SAD can work even when the AHB clock is not present. In that case, the SAD does not update SDLVL[14:0] and ANLVL[14:0].

To get the latest valid SDLVL[14:0] and ANLVL[14:0] values, the application must read the ADF_SADSDLVR, and ADF_SADANLVR registers, when the SDLVLF flag goes high. This can be done in the following ways:
- by polling the SDLVLF flag:
  a) Clear the SDLVLF flag by writing SDLVLF to 1.
  b) Wait for SDLVLF = 1, by reading ADF_DFLTxISR.
  c) Read ADF_SADSDLVR and ADF_SADANLVR.
  d) Clear SDLVLF by writing it to 1.
  e) Go to step 2 if other values must to be read.
- by generating an interrupt:
  a) Read ADF_DFLTxISR.
  b) If SDLVLF = 1, read ADF_SADSDLVR and ADF_SADANLVR, and clear SDLVLF by writing it to 1.
  c) Handle other status flags and exit from ISR.

**Sample transfer to memory**

The SAD offers the following options to control the samples transfer from DFLT0 to the system memory:
- If DATCAP[1:0] = 1x, the samples are transferred into the system memory as soon as DFLT0 and SAD are enabled. The transfer does not depend on the SAD state.
- If DATCAP[1:0] = 01, the samples are transferred into the system memory when the SAD detects a sound (when the SAD is in DETECT state), assuming that DFLT0 and SAD are enabled.
- If DATCAP[1:0] = 0, the samples are not transferred into the memory. This mode can be used if the application only wants to observe but does not need samples for other processing.
Note: DATCAP[1:0] is taken into account only when the SADEN = 1. For example, if the SAD configuration is DATCAP[1:0] = 0, SADEN = DFLTEN = 1, and if the application sets now SADEN to 0, the samples provided by the DFLT0 are transferred to the RXFIFO.

Programming recommendations

To make the SAD function working properly, the ADF must be programmed as follows:

1. Provide the proper kernel clock (adf_ker_ck) to the ADF.
2. Configure the CKGEN and enable it.
3. Configure the SITF and enable it (note that microphones have a settling time of several milliseconds).
4. Configure the DFLT0. A typical setting is the following:
   - CIC5 with a decimation ratio of 12, 16 or 24
   - RSFLT with a decimation ratio of 4
   - HPF with HPFC = 2 or 3
   For a very-low power implementation, the RSFLT can be bypassed.
5. Set SADEN to 0.
6. Wait for SADACTIVE = 0. If SADEN was previously enabled, this phase can take two periods of adf_hclk, and two periods of adf_proc_ck.
7. Configure the SAD as follows:
   - Set DATCAP[1:0] to 0, if the application does not want to store the samples into the system memory.
   - Set DATCAP[1:0] to 01, if the application wants to store the samples into the system memory only when the SAD detects a sound.
   - Set DATCAP[1:0] to 11, if the application wants to store the samples into the system memory continuously.
8. Configure the DMA (optional).
9. Enable the SAD.
10. Enable the DFLT0.

Figure 374 shows a simplified timing diagram when the SAD works with DATCAP[1:0] = 01.

Thanks to the kernel clock (adf_ker_ck), the SAD continuously monitors the audio signal provided by the DFLT0. The threshold is also continuously updated according to the ambient noise level estimation.

- When the SAD detects a sound higher than the programmed threshold (1), the ADF requests the bus clock (adf_bus_ckreq asserted).
- When the bus clock is available (see 2 in Figure 374) then:
  - The data transfer to the memory is triggered.
  - The event interrupt (adf_evt_it) can be generated.
- In this example, the event interrupt (adf_evt_it) is used to wake up the application. The interrupt line is released by clearing SDDETF by writing 1 to it.
- As long as the SAD remains in DETECT state, the application waits to get enough samples and calls, for example the keyword recognition algorithm (see 3 in Figure 374).
- In the case shown in the figure below, the SAD state (SADST) goes back to MONITOR before the keyword is recognized. If DETCFG is set to 1, an event signals when the SAD goes back to MONITOR state. The SAD stops the transfer of samples into the
memory and the application can clean up the receive buffer for the next detection (see 4 in Figure 374).

Figure 375. SAD timing diagram example

40.4.11 Data transfer to memory

Data format

The samples processed by DFLT0 are stored into a RXFIFO. The application can read the samples stored into these FIFOs via the ADF digital filter data register 0 (ADF_DFLT0DR). The samples inside this register are signed and left aligned. The bit 31 always represents the sign.

The ADF provides 24-bit left-aligned data. Performing a 16-bit access to ADF_DFLT0DR allows the application to get the 16 most significant bits. Performing a 32-bit access to ADF_DFLT0DR allows the application to get a 24-bit data size.

Figure 376. ADF_DFLTxDR data format
Data re-synchronization

The samples stored into the RXFIFO can be transferred into the memory by using either DMA requests or interrupt signaling.

Note: The RXFIFO is located into the adf_ker_ck clock domain, while ADF_DFLT0DR is located into the adf_hclk (AHB) clock domain.

When the AHB clock is available, if ADF_DFLT0DR is empty and if a sample is available into the RXFIFO, this sample is transferred into ADF_DFLT0DR.

The sample transfer from the RXFIFO to ADF_DFLT0DR takes two periods of the AHB clock (adf_hclk) and two periods of the adf_ker_ck clock. The ADF inserts automatically wait-states if the application performs a read operation of ADF_DFLT0DR while the transfer of the new sample from the RXFIFO to ADF_DFLT0DR is not yet completed.

Figure 377. Data re-synchronization

Data transfer

The content of the RXFIFO can be transferred to the memory either by using a DMA channel or interrupt services.

Both single and burst, DMA transfers are supported by the ADF, but the application has to care about the following points:

- The RXFIFO must contain at least the same amount of samples than the burst size.
- The burst mode efficiency may be reduced due to the data re-synchronization explained in the previous section.

Note: The burst mode is not available in all products (see the DMA section to check if the product supports it).

In addition, the application can select the RXFIFO threshold (FTH bit) in order to trigger the data transfer: a data transfer can be triggered as soon as the RXFIFO is not empty, or when the RXFIFO is half-full (containing depth/2 samples).

For the DMA transfer, as soon as one of the RXFIFO reaches the threshold level, the DMA request is asserted in order to ask for data transfer. Successive DMA requests are performed as long as the RXFIFO is not empty.

The DMA mode of the RXFIFO is enabled via the DMAEN bit in ADF_DFLT0DR.

For the interrupt signaling, the following cases must be considered:

- If FTH = 0, as soon as a data is available in ADF_DFLT0DR, the FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as ADF_DFLT0DR is read.
- If FTH = 1, as soon as the RXFIFO reaches the threshold level and a data is available in ADF_DFLT0DR, the FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as one data is read. FTHF is set again if the threshold condition is
met again. In this mode, every time an interrupt occurs, the application is supposed to read FIFO_SIZE/2 data.

**RXFIFO overrun**

A RXFIFO overrun condition is detected when the RXFIFO is full, and a new sample from the DFLT0 must be written.

In this case, DOVRF is set and the new sample is dropped. When the RXFIFO has at least one location available, the new incoming sample is written into the RXFIFO.

*Figure 377* shows an example based on a RXFIFO depth of four words and FTH set to 1, so that FTHF goes to 1 when the RXFIFO is half-full.

The S7 sample is lost due to an overrun: the RXFIFO is full while S7 must be written into the RXFIFO. The S7 write operation is not performed. DOVRF is set to 1 at the moment where the write operation was expected. The overflow event remains to 1 as long as it is not cleared by the application.

In this example, DOVRIE is set to 1 to have an interrupt if an overrun condition is detected.

After the S7 sample, the application manages to read data from the RXFIFO, and the ADF can write the S8 sample and consecutive. Later, the application clears DOVR, allowing the detection of a new overrun situation.

In the adf_hclk line, the gray boxes indicate that the ADF requested the AHB clock. The figure below shows the AHB clock available only when the ADF requests it. In real applications, the AHB clock may also be present if the ADF does not request it.

*Figure 378. Example of overflow and transfer to memory*
40.4.12 Autonomous mode

The ADF can work even if the AHB bus clock is not available (Stop modes). The ADF uses the AHB clock only for the register interface. All the processing part is clocked with the kernel clock.

In Stop mode, the ADF receives a kernel clock if the following conditions are met:
- The ADF autonomous mode is enabled in the RCC.
- The selected kernel clock source is taken from an oscillator available in Stop mode.

In Stop mode, the ADF receives the AHB clock if the following conditions are met:
- The ADF autonomous mode is enabled in the RCC.
- The ADF requests the AHB clock in the following situations:
  - when the ADF must transfer data into memory via the DMA
    The data is directly transferred to the SRAM thanks to the DMA while the product remains in Stop mode. The AHB clock request is maintained until the DMA transfer is completed.
  - when the ADF needs to generate an interrupt
    An interrupt generally wakes up the device from Stop mode, as an action from the application is needed. Once the AHB clock is available, the interrupt is generated. The AHB clock request is maintained as long as an enabled interrupt flag is still active.

40.4.13 Register protection

The ADF embeds some hardware protection to prevent invalid situations. The table below shows the list of write-protected and unprotected fields.

<table>
<thead>
<tr>
<th>Registers</th>
<th>Unprotected fields</th>
<th>Write-protected fields</th>
<th>Write-protection condition</th>

<td>-</td>
<td>SKPDLY[6:0]</td>
<td>SKPBF = 1</td>
</tr>
</tbody>
</table>
All the ADF processing is performed in the adf_proc_ck clock domain. For that reason, enabling or disabling an ADF sub-block may take some time due to the re-synchronization between the AHB clock domain and the adf_proc_ck clock domain. XXXACTIVE flags are available to allow the application to check that the synchronization between the two clock domains is completed.

To change a write-protected bitfield, the application must follow this sequence:
1. Set the enable bit of the sub-block to 0.
2. Wait for corresponding flag XXXACTIVE = 0.
3. Modify the wanted fields.
4. Set the enable bit of the sub-block to 1.

Refer to the description of each sub-block for details.

### 40.5 ADF low-power modes

#### Table 398. Effect of low-power modes on ADF

<tr>
<td>Stop(1)</td>
<td>The ADF registers content is kept. If the autonomous mode is enabled in the RCC and the ADF is clocked by an internal oscillator available in Stop mode, the ADF remains active. The DMA requests are functional and the interrupts in these modes cause the device to exit Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The ADF is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

1. Refer to Section 40.3: ADF implementation for details about Stop modes supported by the ADF.

### 40.6 ADF interrupts

To increase the CPU performance, the ADF offers an interrupt line (adf_flt0_it), sensitive to several events.

**Note:** The status flags are available even if the corresponding interrupt enable flag is not enabled.
The interrupt interface is controlled via the **ADF DFLT0 interrupt enable register (ADF_DFLT0IER)** and the **ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)**.

**Figure 379. ADF interrupt interface**

(1) Only present if the SAD is implemented, refer to section ADF implementation for details.

The table below shows which interrupt line is affected by which event, and how to clear and activate each interrupt/event.

**Table 399. ADF interrupt requests**

40.7 ADF application information

40.7.1 ADF configuration examples for audio capture

Table 398 gives some examples of the ADF settings for the digital microphones, focusing on 16 and 48 kHz output data rate.

Configurations #1 and #2 are for very low-power use-cases and have a reduced signal-to-noise ratio. The user must also insure that the selected digital microphone can work properly at 512 kHz. These configurations can be used for sound detection. The RSFLT is not used to reduce as much as possible the frequency of the kernel clock (adf_ker_ck).

Configurations #3, #4, #9, #10, #11 give signal-to-noise ratios around 115 dB, with an ideal microphone model, with a sinus signal of 997 Hz. Using the RSFLT allows a good control on the in-band ripple, and a good image rejection.

Configurations #7, #8, #10 give signal-to-noise ratio around 120 dB, with an ideal microphone model, using a sinus signal of 997 Hz.

40.7.3 Connection examples

*Figure 379* shows simple connection examples of the ADF to external sensors.

- **Picture on the left:** two digital microphones connected to the ADF
  
  In this connection, the amount of connections is optimized; DMIC1 and DMIC2 are sharing the same data line, and the same clock line. BSMX allows the application to connect the digital filter either to DMIC1 or to DMIC2. In this configuration when one of the microphone is used, the other is activated as well, as they share the same clock.

- **Picture in the center:** two digital microphones connected to the ADF
  
  In this connection, DMIC1 and DMIC2 are sharing the same data line, but have a dedicated clock line. BSMX allows the application to connect the filter either to DMIC1 or to DMIC2. When the application wants to use a microphone, it is possible to keep the other in low-power mode by forcing its clock line to 0 (CCKyEN = 0, CCKyDIR = 1).
Picture on the right: single sensor connected to the ADF. It is also possible to configure the CCK0 and CCK1 pins to input in order to connect sensors providing the clock.

### 40.7.4 Global frequency response

*Figure 380* shows the global frequency response for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:
- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enabled with a cut-off frequency of 40 Hz

The figure below shows the theoretical frequency response using a CIC4 and a CIC5.

**Figure 381. Global frequency response**

*Figure 381* shows the in-band ripple for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:
- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enabled with a cut-off frequency of 20 Hz

The resulting in-band ripple is ± 0.41 dB for CIC5, and ± 0.45 dB for CIC4.

The - 3 dB cut-off frequency is 7061 Hz.
40.7.5 Total ADF gain

This section details how to compute the signal level provided by the ADF according to the filter settings.

A signal level may be expressed in dBFS (decibel full scale). A 0 dBFS level is assigned to the maximum possible digital level. For example, a signal that reaches 50% of the maximum level, has a −6 dBFS level (6 dB below full scale).

For example, for the ADF offering a final data width of 24 bits, a signal having an amplitude of $2 \times 10^6$ LSB has a level of:

$$20 \times \log_{10} \left( \frac{2 \times 10^6}{2^{24-1}} \right) = -12.45 \text{ dBFS}$$

In addition, the data size of a signal having an amplitude (Amp) expressed in LSB is given by:

$$DS = \left( \frac{\ln(Amp)}{\ln(2)} + 1 \right) \text{ bits}$$

One bit need to be added for negative values.
So a signal having an amplitude of $2 \times 10^6$ LSB, has a data size of 21.9 bits.

CIC gain

The CIC gain ($G_{CIC}$ and $Gd_{CIC}$) can be deduced from the following formula giving data size in bits ($DS_{CIC}$).

$$DS_{CIC} = (N \times \log_2(D1)) + DS_{in}$$

where $N$ represents the CIC order (selected by CICMOD[2:0]), and $D1$ is the decimation ratio (given by MCICD[8:0]).
$DS_{in}$ represents the data size (in bits) of the signal at CIC input.
Warning: DS\textsubscript{CIC} is very important for CIC filter. In order to work fine, DS\textsubscript{CIC} must not exceed 26 bits.

The CIC gain $G_{\text{CIC}}$ is given by:

$$G_{\text{CIC}} = (D1)^N$$

which gives in decibels:

$$G_{\text{dB,CIC}} = 20 \times \log_{10}((D1)^N)$$

Data size at SCALE output

The data size at SCALE output (including the CIC gain), is a key information as the RSFLT starts to have some saturations, if the peak-to-peak signal amplitude at SCALE output is higher than 22 bits.

If the RSFLT is bypassed, then a peak-to-peak signal amplitude of 24 bits is accepted.

The signal amplitude at SCALE output is:

$$A_{\text{out,SCALE}} = D1^N \times 10^{\frac{G_{\text{dB,SCALE}}}{20}} \times A_{\text{in,DFLT}}$$

$G_{\text{dB,SCALE}}$ represents the gain selected by SCALE[5:0], in dB.

$A_{\text{out,SCALE}}$ is the signal amplitude at SCALE output (in LSB), and $A_{\text{in,DFLT}}$ is the signal amplitude at CIC input (LSB).

$$D_{\text{SCALE}} = \frac{\ln(A_{\text{out,SCALE}})}{\ln(2)} + 1$$

The data size at SCALE output ($D_{\text{SCALE}}$) is expressed in bits.

RSFLT gain

The RSFLT gain in the useful bandwidth is typically 9.5 dB, but due to ripple a margin of about ± 0.41 dB must be considered.

$$G_{\text{RSFLT}} = 10^{\frac{9.5 \text{ dB}}{20}} = 2.98 \text{ typical}$$

Note: The HPF filter has a gain of 0 dB.

SAD gain

The SAD is using only the 16 MSB on the signal, as a consequence, from the SAD point of view, the truncation from 24 to 16 bits can be seen as an attenuation.
The figure below shows a simplified view of the filter path and gives, for each significant component, the expression of the bit growth and the gain.

**Table 403. Output signal levels**

<table>
<thead>
<tr>

<td>( A_{\text{out}}<em>{\text{HPF}} = D_1^N \times \frac{G</em>{\text{DBSCALE}}}{20} \times 10^{\frac{9.5}{20}} \times A_{\text{sinDFLT}} )</td>
</tr>
<tr>
<td></td>
<td>DS_{\text{SCALE}} must be lower than 24 bits</td>
</tr>
</tbody>
</table>

(1) The SAD is not always implemented (see the ADF implementation section for details).
Example using the main filter chain

If the ADF filter is programmed as follows:
- The input signal is coming from a serial interface \( \text{DsinRSFLT} = 1 \) bit.
- CIC order = 5 (N), with a decimation value of 24 (D1).
- SCALE[5:0] is set to -12 dB.
- RSFLT enabled, and the decimation by four is enabled.
- HPF is enabled.

Check first the data size at CIC output:
\[
\text{DS}_{\text{CIC}} = (5 \times \log_2(24)) + 1 \text{ bit} = 23.92 \text{ bits}
\]

The size is lower than 26 bits, so the CIC works in good conditions.

The data size at CIC output is very close to 24 bits, so the SCALE must be adjusted in order
to provide a 22-bit max signal to the RSFLT. An attenuation of 12 dB is needed.

Then the signal level provided to the RSFLT is:

\[
\text{As}_{\text{out SCALE}} = 24^5 \times 10^{-12/20} \times 1 = 2.10^6
\]

\[
\text{DS}_{\text{SCALE}} = \frac{\ln(2.10^6)}{\ln(2)} + 1 = 21.93 \text{ bits}
\]

If a higher gain is used, the RSFLT may saturate the output signal for strong input signals.

At the end, the final signal amplitude is:

\[
\text{As}_{\text{out HPF}} = 24^5 \times 10^{-12/20} \times 10^{-9.5/20} \times 1 = 5.9711 \times 10^6
\]

\[
\text{DS}_{\text{out HPF}} = \left( \frac{\ln(5.9711 \times 10^6)}{\ln(2)} + 1 \right) = 23.51 \text{ bits}
\]

or:

\[
\text{SDB}_{\text{OUT}} = 20 \times \log_{10} \left( \frac{2^{23.51}}{2^{24}} \right) = -2.84 \text{ dBFS}
\]

40.7.6 How to compute SAD thresholds

The SAD does not compute the RMS value of the converted signal, but the average of the absolute values. As a consequence, the estimated level differs from the RMS value of the signal:
- For a sine signal having an RMS value of 1, the SAD computes a level of 0.9.
- For a white or pink noise signal having an RMS value of 1, the SAD computes a level of about 0.8.
Audio digital filter (ADF) RM0456

Note: FRSIZE[2:0] has a big influence on the accuracy of the level estimation: big FRSIZE[2:0] values give better results.

Threshold programming with SADMOD = 01

Consider the case of a sound capture where the application wants to wake up the system when the captured sound is bigger than 63 dBSPL.

The sound capture can be performed with a digital microphone such as the MP45DT02.

The sensitivity of this microphone is typically -26 dBFS for an input signal of 94 dBSPL.

An acoustic signal at 63 dBSPL produces a digital signal of about:
- 26 dBFS - (94 - 63) = - 57 dBFS.

• SCALE value adjustment
  For this example, the filter configuration is the following:
  – CIC5 with a decimation by 16
  – RSFLT enabled with a decimation by 4
  – HPF enabled
  A SCALE value of 3.5 dB is recommended for this configuration. As DFTL0 provides samples only used for a sound detection (samples not provided to the application), a bigger gain value can be applied: it increases the SAD accuracy and a saturation does not affect the SAD behavior (for example, a SCALE value of 15.6 dB).

• Input signal amplitude
  The input signal is - 57 dBFS, corresponding to an amplitude
  \[ A_{\text{in}} = 10^{(-57/20)} = 0.00141 \text{ LSB} \]

• Signal level at SAD input
  The total filter gain for the SAD is:
  \[ G_{\text{SAD}} = 16^5 \times 10^{15.6/20} \times 10^{9.5/20} \times \frac{1}{256} = 73.68 \times 10^3 \text{ or } 97.3 \text{ dB} \]
  The signal amplitude received by the SAD is:
  \[ A_{\text{in, SAD}} = 0.00141 \times G_{\text{SAD}} \times 104 \text{ LSB} \]
  The gain can be increased if the expected amplitude is too small. For the targeted application, 104 LSB is fine.
  If the input signal is expected to be a sine, the sound level for a signal amplitude of 104 LSB is:
  \[ \text{SDLVL} = \frac{A_{\text{in, SAD}} \times \sqrt{2}}{2} \times 0.9 \times 66 \text{ LSB} \]
  where 0.9 is the correction factor to apply with respect to the RMS value.
• Program the trigger value

ANMIN and SNTHR must be programmed to trigger the SAD when the input signal level reaches 66 LSB.

For SADMOD[1:0] = 01, the threshold value is given by:

\[ \text{THRH} = \text{ANMIN} \times 10^{\frac{\text{GdB}_{\text{SNTHR}}}{20}} \]

where GdB_{SNTHR} represents the decibel value selected by SNTHR[3:0].

When SNTHR[3:0] = 6 dB for example, this formula becomes:

\[ \text{THRH} = 2 \times \text{ANMIN} \]

So ANMIN = THRH/2 = 66 /2 = 33 LSB.

In Figure 383, the trigger value (THRH in red) is fixed to 66 LSB. The input signal is at -65dBFS during 256 samples, then its value goes to -55 dB for 256 samples, and finally it is reduced to -60 dBFS.

The blue curve is showing the sound level estimation (SDLVL) versus time. Fluctuation on the estimated value can be observed due to windowing effect of FRSIZE samples.

The SAD DETECT state (when green signal is high) is maintained during four additional frames due to hangover function value.

In this example ANSLP = FRSIZE = 3 (64 samples), LFRNB = 0 (2 frames), HGOVR = 0 (4 frames), SNTHR = 1 (6 dB) and ANMIN = 33.

Figure 384. SAD example working with SADMOD = 01

Threshold programming with SADMOD = 1x

Consider the case of a sound capture where the application wants to wake up the system when the captured sound is bigger than 57 dBSPL.

The sound capture can be performed with a digital microphone such as the MP45DT02. The sensitivity of this microphone is typically -26 dBFS for an input signal of 94 dBSPL.
An acoustic signal at 57 dBSPL produces a digital signal of about:
- 26 dBFS - (94-63) = - 63 dBFS.

- Adjust SCALE value
  For this example, the filter configuration is the following:
  - CIC4 with a decimation by 48
  - RSFLT bypassed
  - HPF enabled

A SCALE value of 3.5 dB is recommended for this configuration. The samples provided by DFTL0 are only used for a sound detection, without providing the samples to the application, a bigger gain value can be provided: it increases the SAD accuracy and a saturation does not affect the SAD behavior (for example, a SCALE value of 24 dB).

- Input signal amplitude
  The input signal is - 63 dBFS, corresponding to an amplitude:
  \[ A_{\text{in}} = 10^{-63/20} = 0.000708 \text{ LSB}. \]
• Signal level at SAD input
  The total filter gain for the SAD is:

  \[ G_{\text{SAD}} = 48^4 \times 10^{24} \times 0.003906 = 328.6 \times 10^3 \text{ or } 110.3 \, \text{dB} \]

  The signal amplitude received by the SAD is:

  \[ A_{\text{in SAD}} = 0.000708 \times G_{\text{SAD}} \sim 232 \, \text{LSB} \]

  The gain can be increased if the expected amplitude is too small.
  If the input signal is expected to be a sine, the sound level for a signal amplitude of 232 LSB is:

  \[ \text{SDLVL} = \frac{A_{\text{in SAD}} \times \sqrt{2}}{2} \times 0.9 \sim 148 \, \text{LSB} \]

  where 0.9 is the correction factor to apply with respect to the RMS value.

  Note: **ANLVL converges to average of SDLVL values, with a long constant time.**
  So SDLVL \sim ANLVL = 148 LSB for a constant input signal at 57 dB SPL.

• Programming trigger value
  For SADMOD = 1', the SAD compares the estimated ambient noise multiplied by the gain selected by SNTHR[3:0] to ANMIN[12:0] \times 4.
  For simplification, SNTHR[3:0] is set to 1 (6 dB), meaning that ANLVL is multiplied by two.
  The SAD triggers if \(2 \times \text{ANLVL} > \text{THRH}\).
  In this mode,

  \[ \text{THRH} = 4 \times \text{ANMIN} \]

  So the SAD triggers if:

  \[ \text{ANLVL} > 2 \times \text{ANMIN} \]

  So \( \text{ANMIN} = 148 / 2 = 74 \, \text{LSB} \)

In *Figure 384*, the trigger value (THRH in red) is fixed to 148 LSB. The input signal is at -75 dBFS during 512 samples, then its value goes to -62 dB for 11000 samples, and finally it is reduced to -70 dBFS.

The blue curve shows the sound level estimation (SDLVL) versus time. The black curve shows the ambient noise estimation versus time, increasing or decreasing logarithmically. During the learning phase, it reaches the SDLVL value.

In this example ANSLP = 6, FRSIZE = 3 (64 samples), LFRNB = 0 (2 frames),
HGOVR = 0 (4 frames), SNTHR = 1 (6 dB) and ANMIN = 74.

Figure 385. SAD example working with SADMOD = 1x

40.8 ADF registers

All the ADF registers must be accessed either in word (32-bit) or half-word (16-bit) formats.

40.8.1 ADF global control register (ADF_GCR)

Address offset: 0x000
Reset value: 0x0000 0000

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 TRGO: Trigger output control

This bit is set by software and reset by hardware. It is used to start the acquisition of several filters synchronously. It is also used to synchronize several ADF together by controlling the adf_trgo signal.

0: Write 0 has no effect. Read 0 means that the trigger can be set again to 1.
1: Write 1 generates a positive pulse on the adf_trgo signal and triggers the acquisition on enabled filter having their ACQMOD[2:0] = 01x and selecting TRGO as trigger. Read 1 means that the trigger pulse is still active.
40.8.2 ADF clock generator control register (ADF_CKGCR)

Address offset: 0x004
Reset value: 0x0000 0000

This register is used to control the clock generator. The clock adf_proc_ck must be enabled before enabling other ADF parts.

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>CKGACTIVE: Clock generator active flag</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
</tr>
</tbody>
</table>

| Bits 23:20 | Reserved, must be kept at reset value. |
Bits 19:16 **CCKDIV[3:0]**: Divider to control the ADF_CCK clock

This bitfield is set and reset by software. It is used to adjust the frequency of the ADF_CCK clock. The input clock of this divider is the clock provided to the SITF. More globally, the frequency of the ADF_CCK is given by the following formula:

\[
F_{ADF \_CCK} = \frac{F_{\text{adf\_ker\_ck}}}{(\text{PROCDIV} + 1) \times (\text{CCKDIV} + 1)}
\]

This bitfield must not be changed if the filter is enabled (DFTEN = 1).

- 0000: The ADF_CCK clock is adf_proc_ck.
- 0001: The ADF_CCK clock is adf_proc_ck / 2.
- 0010: The ADF_CCK clock is adf_proc_ck / 3.
- ...
- 1111: The ADF_CCK clock is adf_proc_ck / 16.

*Note: This bitfield can be write-protected (see Section 40.4.13 for details)*.

Bits 15:12 **TRGSRC[3:0]**: Digital filter trigger signal selection

This bitfield is set and cleared by software. It is used to select which external signals trigger the corresponding filter. This bitfield is not significant if the CKGMOD = 0.

- 000x: TRGO selected
- 0010: adf_trg1 selected
- Others: Reserved

*Note: This bitfield can be write-protected (see Section 40.4.13 for details)*.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: CKGEN trigger sensitivity selection

This bit is set and cleared by software. It is used to select the trigger sensitivity of the trigger signals. This bit is not significant if the CKGMOD = 0.

- 0: A rising edge event triggers the activation of CKGEN dividers.
- 1: A falling edge even triggers the activation of CKGEN dividers.

*Note: When the trigger source is TRGO, the sensitivity is forced to falling edge, thus TRGSENS value is not taken into account. This bit can be write-protected (see Section 40.4.13 for details)*.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CCK1DIR**: ADF_CCK1 direction

This bit is set and reset by software. It is used to control the direction of the ADF_CCK1 pin.

- 0: The ADF_CCK1 pin direction is in input.
- 1: The ADF_CCK1 pin direction is in output.

*Note: This bit can be write-protected (see Section 40.4.13 for details)*.

Bit 5 **CCK0DIR**: ADF_CCK0 direction

This bit is set and reset by software. It is used to control the direction of the ADF_CCK0 pin.

- 0: The ADF_CCK0 pin direction is in input.
- 1: The ADF_CCK0 pin direction is in output.

*Note: This bit can be write-protected (see Section 40.4.13 for details)*.

Bit 4 **CKGMOD**: Clock generator mode

This bit is set and reset by software. It is used to define the way the clock generator is enabled. This bit must not be changed if the filter is enabled (DFTEN = 1).

- 0: The kernel clock is provided to the dividers as soon as CKGDEN is set to 1.
- 1: The kernel clock is provided to the dividers when CKGDEN is set to 1 and the trigger condition met.

*Note: This bit can be write-protected (see Section 40.4.13 for details)*.
Bit 3 Reserved, must be kept at reset value.

Bit 2 **CCK1EN**: ADF_CCK1 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the ADF_CCK1 pin.

0: Bitstream clock not generated
1: Bitstream clock generated on the ADF_CCK1 pin.

Bit 1 **CCK0EN**: ADF_CCK0 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the ADF_CCK0 pin.

0: Bitstream clock not generated
1: Bitstream clock generated on the ADF_CCK0 pin

Bit 0 **CKG DEN**: CKGEN dividers enable

This bit is set and reset by software. It is used to enable/disable the clock dividers of the CKGEN: PROCDIV and CCKDIV.

0: CKGEN dividers disabled
1: CKGEN dividers enabled

### 40.8.3 ADF serial interface control register 0 (ADF_SITF0CR)

<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
Bit 8 **TRGSENS**: DFLT0 trigger sensitivity selection
This bitfield is set and cleared by software. It is used to select the trigger sensitivity of the external signals.

0: A rising edge event triggers the acquisition.
1: A falling edge even triggers the acquisition.

*Note:* When the trigger source is TRGO, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge.

This bit can be write-protected (see Section 40.4.13 for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ACQMOD[2:0]**: DFLT0 trigger mode
This bitfield is set and cleared by software. It is used to select the filter trigger mode.

000: Asynchronous continuous acquisition mode
001: Asynchronous single-shot acquisition mode
010: Synchronous continuous acquisition mode
011: Synchronous single-shot acquisition mode
100: Window continuous acquisition mode
Others: Same as 000

*Note:* This bitfield can be write-protected (see Section 40.4.13 for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FTH**: RXFIFO threshold selection
This bit is set and cleared by software. It is used to select the RXFIFO threshold.

0: RXFIFO threshold event generated when the RXFIFO is not empty
1: RXFIFO threshold event generated when the RXFIFO is half-full

*Note:* This bit can be write-protected (see Section 40.4.13 for details).

Bit 1 **DMAEN**: DMA requests enable
This bit is set and cleared by software. It is used to control the generation of DMA request to transfer the processed samples into the memory.

0: DMA interface for the corresponding digital filter disabled
1: DMA interface for the corresponding digital filter enabled

*Note:* This bit can be write-protected (see Section 40.4.13 for details).

Bit 0 **DFLTEN**: DFLT0 enable
This bit is set and cleared by software. It is used to control the start of acquisition of the DFLT0 path. This bit behavior depends on ACQMOD[2:0] and external events. The serial or parallel interface delivering the samples must be enabled as well.

0: Acquisition immediately stopped
1: Acquisition immediately started if ACQMOD[2:0] = 00x or 101, or acquisition started when the proper trigger event occurs if ACQMOD[2:0] = 01x.
40.8.6 ADF digital filter configuration register 0 (ADF_DFLT0CICR)

Address offset: 0x08C
Reset value: 0x0000 0000

This register is used to control the main CIC filter.

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:20 **SCALE[5:0]**: Scaling factor selection

This bitfield is set and cleared by software. It is used to select the gain to be applied at CIC output (see Table 389 for details). If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back this bitfield informs the application on the current gain value.

Bit 7 Reserved, must be kept at reset value.
Bits 6:4 **CICMOD[2:0]**: Select the CIC order
This bitfield is set and cleared by software. It is used to select the order of the MCIC.
- 100: MCIC configured in single Sinc⁴ filter
- 101: MCIC configured in single Sinc⁵ filter
- Others: Reserved

*Note: This bitfield can be write-protected (see Section 40.4.13 for details).*

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **DATSRC[1:0]**: Source data for the digital filter
This bitfield is set and cleared by software.
- 00: Stream coming from the BSMX selected
- 10: Stream coming from the ADCITF1 selected
- 11: Stream coming from the ADCITF2 selected

*Note: This bitfield can be write-protected (see Section 40.4.13 for details).*

## 40.8.7 ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:8 **HPFC[1:0]**: High-pass filter cut-off frequency
This bitfield is set and cleared by software. It is used to select the cut-off frequency of the high-pass filter. \( F_{PCM} \) represents the sampling frequency at HPF input.
- 00: Cut-off frequency = \( 0.000625 \times F_{PCM} \)
- 01: Cut-off frequency = \( 0.00125 \times F_{PCM} \)
- 10: Cut-off frequency = \( 0.00250 \times F_{PCM} \)
- 11: Cut-off frequency = \( 0.00950 \times F_{PCM} \)

*Note: This bitfield can be write-protected (see Section 40.4.13 for details).*

Bit 7 **HPFBYP**: High-pass filter bypass
This bit is set and cleared by software. It is used to bypass the high-pass filter.
- 0: HPF not bypassed (default value)
- 1: HPF bypassed

*Note: This bit can be write-protected (see Section 40.4.13 for details).*

Bits 6:5 Reserved, must be kept at reset value.
Bit 4 **RSFLTD**: Reshaper filter decimation ratio
   This bit is set and cleared by software. It is used to select the decimation ratio for the reshape filter.
   0: Decimation ratio is 4 (default value).
   1: Decimation ratio is 1.
   Note: This bit can be write-protected (see Section 40.4.13 for details).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **RSFLTBYP**: Reshaper filter bypass
   This bit is set and cleared by software. It is used to bypass the reshape filter and its decimation block.
   0: Reshape filter not bypassed (default value)
   1: Reshape filter bypassed
   Note: This bit can be write-protected (see Section 40.4.13 for details).

### 40.8.8 ADF delay control register 0 (ADF_DLY0CR)

Address offset: 0x0A4
Reset value: 0x0000 0000

Bit 31 **SKPBF**: Skip busy flag
   This bit is set and cleared by hardware. It is used to control if the delay sequence is completed.
   0: ADF ready to accept a new value into SKPDLY[6:0]
   1: Last valid SKPDLY[6:0] still under precessing

Bits 30:7 Reserved, must be kept at reset value.

Bits 6:0 **SKPDLY[6:0]**: Delay to apply to a bitstream
   This bitfield is set and cleared by software. It defines the number of input samples that are skipped. Skipping is applied immediately after writing to this bitfield, if SKPBF = 0 and DFLTEN = 1. If SKPBF = 1, the value written into the register is ignored by the delay state machine.
   0: No input sample skipped
   1: 1 input sample skipped
   ...
   127: 127 input samples skipped
40.8.9  **ADF DFLT0 interrupt enable register (ADF_DFLT0IER)**

Address offset: 0x0AC

Reset value: 0x0000 0000

This register is used for allowing or not the events to generate an interrupt.

Bits 31:14  Reserved, must be kept at reset value.

Bit 13  **SDLVLIE**: SAD sound-level value ready enable
- This bit is set and cleared by software.
  - 0: Sound-level-ready interrupt disabled
  - 1: Sound-level-ready interrupt enabled

Bit 12  **SDDETIE**: Sound activity detection interrupt enable
- This bit is set and cleared by software.
  - 0: Sound-trigger interrupt disabled
  - 1: Sound-trigger interrupt enabled

Bit 11  **RFOVRIE**: Reshape filter overrun interrupt enable
- This bit is set and cleared by software.
  - 0: Reshape filter overrun interrupt disabled
  - 1: Reshape filter overrun interrupt enabled

Bit 10  **CKABIE**: Clock absence detection interrupt enable
- This bit is set and cleared by software.
  - 0: Clock absence interrupt disabled
  - 1: Clock absence interrupt enabled

Bit 9  **SATIE**: Saturation detection interrupt enable
- This bit is set and cleared by software.
  - 0: Saturation interrupt disabled
  - 1: Saturation interrupt enabled

Bits 8:2  Reserved, must be kept at reset value.

Bit 1  **DOVRIE**: Data overflow interrupt enable
- This bit is set and cleared by software.
  - 0: Data overflow interrupt disabled
  - 1: Data overflow interrupt enabled

Bit 0  **FTHIE**: RXFIFO threshold interrupt enable
- This bit is set and cleared by software.
  - 0: RXFIFO threshold interrupt disabled
  - 1: RXFIFO threshold interrupt enabled
40.8.10 ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)

Address offset: 0x0B0
Reset value: 0x0000 0000

This register contains the status flags for the digital filter path.

</tbody>
</table>

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **SDLVLF**: Sound level value ready flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that new sound level value is not ready. Write 0 has no effect.
1: Read 1 means that new sound level value is ready. Write 1 clears this flag.

Bit 12 **SDDETF**: Sound activity detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no sound activity is detected. Write 0 has no effect.
1: Read 1 means that sound activity is detected. Write 1 clears this flag.

Bit 11 **RFOVRF**: Reshape filter overrun detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no reshape filter overrun is detected. Write 0 has no effect.
1: Read 1 means that reshape filter overrun is detected. Write 1 clears this flag.

Bit 10 **CKABF**: Clock absence detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no clock absence is detected. Write 0 has no effect.
1: Read 1 means that a clock absence is detected. Write 1 clears this flag.

Bit 9 **SATF**: Saturation detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no saturation is detected. Write 0 has no effect.
1: Read 1 means that a saturation is detected. Write 1 clears this flag.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **RXNEF**: RXFIFO not empty flag
This bit is set and cleared by hardware according to the RXFIFO level.
0: RXFIFO empty
1: RXFIFO not empty

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DOVRF**: Data overflow flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no overflow is detected. Write 0 has no effect.
1: Read 1 means that an overflow is detected; Write 1 clears this flag.
40.8.11 ADF SAD control register (ADF_SADCR)

Address offset: 0x0B8
Reset value: 0x0000 0000

This register is used for the configuration and the control of the sound activity detection.

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>30:14</th>
<th>13:12</th>
<th>11:0</th>
<th>9:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SADACTIVE</td>
<td>Reserved</td>
<td>SADMOD[1:0]</td>
<td>FRSIZE[2:0]</td>
<td>HYSTE</td>
</tr>
</tbody>
</table>

Bit 0 FTHF: RXFIFO threshold flag
This bit is set by hardware, and cleared by the hardware when the RXFIFO level is lower than the threshold.
0: RXFIFO threshold not reached
1: RXFIFO threshold reached

Bits 30:14 Reserved, must be kept at reset value.

Bits 13:12 SADMOD[1:0]: SAD working mode
This bitfield is set and cleared by software. It is used to define the way the SAD works.
00: Threshold value computed according to the estimated ambient noise
The SAD triggers when the sound level (SDLVL) is bigger than the defined threshold. In this mode, the SAD works like a voice activity detector.
01: Threshold value equal to ANMIN[12:0], multiplied by the gain selected by SNTHR[3:0]
The SAD triggers when the sound level (SDLVL) is bigger than the defined threshold. In this mode, the SAD works like a sound detector.
1x: Threshold value given by 4 x ANMIN[12:0]
The SAD triggers when the estimated ambient noise (ANLVL), multiplied by the gain selected by SNTHR[3:0] is bigger than the defined threshold. In this mode, the SAD is working like an ambient noise estimator. Hysteresis function cannot be used in this mode.

Note: This bitfield can be write-protected (see Section 40.4.13 for details).

Bit 11 Reserved, must be kept at reset value.
Bits 10:8 **FRSIZE[2:0]**: Frame size

This bitfield is set and cleared by software. It is used to define the size of one frame and also to define how many samples are taken into account to compute the short-term signal level.

- 000: 8 PCM samples used to compute the short-term signal level
- 001: 16 PCM samples used to compute the short-term signal level
- 010: 32 PCM samples used to compute the short-term signal level
- 011: 64 PCM samples used to compute the short-term signal level
- 100: 128 PCM samples used to compute the short-term signal level
- 101: 256 PCM samples used to compute the short-term signal level
- 11x: 512 PCM samples used to compute the short-term signal level

*Note: This bitfield can be write-protected (see Section 40.4.13 for details).*

Bit 7 **HYSTEN**: Hysteresis enable

This bit is set and cleared by software. It is used to enable/disable the hysteresis function (see Table 389 for details). This bit must be kept to 0 when SADMOD[1:0] = 1x.

- 0: Hysteresis function disabled. THR↓ is always used.
- 1: Hysteresis function enabled. THR↑ is used for MONITOR to DETECT transition and THR↓ is used for DETECT to MONITOR transition.

*Note: This bit can be write-protected (see Section 40.4.13 for details).*

Bit 6 Reserved, must be kept at reset value.

Bits 5:4 **SADST[1:0]**: SAD state

This bitfield is set and cleared by hardware. It indicates the SAD state and is meaningful only when SADEN = 1. The SAD state can be:
- LEARN when the SAD is in learning phase or in SDLVL computation mode
- MONITOR when the SAD is in monitoring phase
- DETECT when the SAD detects a sound

- 00: SAD in LEARN state
- 01: SAD in MONITOR state
- 11: SAD in DETECT state

Bit 3 **DETCFG**: Sound trigger event configuration

This bit is set and cleared by software. It is used to define if the sddet_evt event is generated only when the SAD enters to MONITOR state or when the SAD enters or exits the DETECT state.

- 0: sddet_evt generated when SAD enters the MONITOR state
- 1: sddet_evt generated when SAD enters or exits the DETECT state

*Note: This bit can be write-protected (see Section 40.4.13 for details).*

Bits 2:1 **DATCAP[1:0]**: Data capture mode

This bitfield is set and cleared by software. It is used to define in which conditions, the samples provided by DLFT0 are stored into the memory.

- 00: Samples from DFLT0 not transferred into the memory
- 01: Samples from DFLT0 transferred into the memory when SAD is in DETECT state
- 1x: Samples from DFLT0 transferred into memory when SAD and DFLT0 are enabled

*Note: This bitfield can be write-protected (see Section 40.4.13 for details).*

Bit 0 **SADEN**: Sound activity detector enable

This bit is set and cleared by software. It is used to enable/disable the SAD.

- 0: SAD disabled and SAD state reset
- 1: SAD enabled
40.8.12 ADF SAD configuration register (ADF_SADCFGR)

Address offset: 0x0BC
Reset value: 0x0000 0000

This register is used for the configuration of the sound activity detection.

</tbody>
</table>
Bits 6:4 **ANSLP[2:0]**: Ambient noise slope control

This bitfield is set and cleared by software. It is used to define the positive and negative slope of the noise estimator, in charge of updating the ANLVL (see Ambient noise estimation (ANLVL) for information about programming this bitfield).

*Note:* This bitfield can be write-protected (see Section 40.4.13 for details).

Bits 3:0 **SNTHR[3:0]**: Signal to noise threshold

This bitfield is set and cleared by software. It is used to define THR_H (and THR_L if hysteresis is enabled). See Table 389 for details.

- 0000: THR_H is 3.5 dB higher than ANLVL
- 0001: THR_H is 6.0 dB higher than ANLVL
- 0010: THR_H is 9.5 dB higher than ANLVL
- 0011: THR_H is 12 dB higher than ANLVL
- 0100: THR_H is 15.6 dB higher than ANLVL
- 0101: THR_H is 18 dB higher than ANLVL
- 0110: THR_H is 21.6 dB higher than ANLVL
- 0111: THR_H is 24.1 dB higher than ANLVL
- 1000: THR_H is 27.6 dB higher than ANLVL
- 1001: THR_H is 30.1 dB higher than ANLVL
- Others: Reserved

*Note:* This bitfield can be write-protected (see Section 40.4.13 for details).

### 40.8.13 ADF SAD sound level register (ADF_SADSDLVR)

Address offset: 0x0C0

Reset value: 0x0000 0000

This register contains the short-term sound-level computed by the SAD.

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **SDLVL[14:0]**: Short term sound level

This bitfield is set by hardware. It contains the latest sound level computed by the SAD. To refresh this value, SDLVLF must be cleared.
40.8.14  ADF SAD ambient noise level register (ADF_SADANLVR)

Address offset: 0x0C4
Reset value: 0x0000 0000

This register contains the ambient noise level computed by the SAD.

| Bit 31:15 | Reserved, must be kept at reset value. |
| Bit 14:0  | ANLVL[14:0]: Ambient noise level estimation |
| This bitfield is set by hardware. It contains the latest ambient noise level computed by the SAD. To refresh this bitfield, the SDLVLF flag must be cleared. |

40.8.15  ADF digital filter data register 0 (ADF_DFLT0DR)

Address offset: 0x0F0
Reset value: 0x0000 0000

This register is used to read the data processed by the digital filter.

| Bit 31:8  | DR[23:0]: Data processed by DFT0 |
| Bit 7:0   | Reserved, must be kept at reset value. |

| Bit 31:15 | Reserved, must be kept at reset value. |
| Bit 14:0  | DR[23:0]: Data processed by DFT0 |

Refer to Section 2.3 for the register boundary addresses.
41    Digital camera interface (DCMI)

41.1    Introduction
The digital camera is a synchronous parallel interface able to receive a high-speed data flow from an external 8-, 10-, 12- or 14-bit CMOS camera module. It supports different data formats: YCbCr4:2:2/RGB565 progressive video and compressed data (JPEG).

41.2    DCMI main features
- 8-, 10-, 12- or 14-bit parallel interface
- Embedded/external line and frame synchronization
- Continuous or snapshot mode
- Crop feature
- Supports the following data formats:
  - 8/10/12/14-bit progressive video: either monochrome or raw Bayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG

41.3    DCMI functional description
The digital camera interface is a synchronous parallel interface that can receive high-speed data flows. It consists of up to 14 data lines (DCMI_D[13:0]) and a pixel clock line (DCMI_PIXCLK). The pixel clock has a programmable polarity, so that data can be captured on either the rising or the falling edge of the pixel clock.

The data are packed into a 32-bit data register (DCMI_DR) and then transferred through a general-purpose DMA channel. The image buffer is managed by the DMA, not by the camera interface.

The data received from the camera can be organized in lines/frames (raw YUB/RGB/Bayer modes) or can be a sequence of JPEG images. To enable JPEG image reception, the JPEG bit (bit 3 of DCMI_CR register) must be set.

The data flow is synchronized either by hardware using the optional DCMI_HSYNC (horizontal synchronization) and DCMI_VSYNC (vertical synchronization) signals or by synchronization codes embedded in the data flow.
### 41.3.1 DCMI block diagram

*Figure 386* shows the DCMI block diagram.

<td>DCMI interface clock</td>
</tr>
</tbody>
</table>
41.3.3 DCMI clocks

The digital camera interface uses two clock domains, DCMI_PIXCLK and HCLK. The signals generated with DCMI_PIXCLK are sampled on the rising edge of HCLK once they are stable. An enable signal is generated in the HCLK domain, to indicate that data coming from the camera are stable and can be sampled. The maximum DCMI_PIXCLK period must be higher than 2.5 HCLK periods.

41.3.4 DCMI DMA interface

The DMA interface is active when the CAPTURE bit of the DCMI_CR register is set. A DMA request is generated each time the camera interface receives a complete 32-bit data block in its register.

41.3.5 DCMI physical interface

The interface is composed of 11/13/15/17 inputs. Only the Slave mode is supported.

The camera interface can capture 8-bit, 10-bit, 12-bit or 14-bit data depending on the EDM[1:0] bits of the DCMI_CR register. If less than 14 bits are used, the unused input pins must be connected to ground.

DCMI pins are shown in Table 405.

The data are synchronous with DCMI_PIXCLK and change on the rising/falling edge of the pixel clock depending on the polarity.

The DCMI_HSYNC signal indicates the start/end of a line.

The DCMI_VSYNC signal indicates the start/end of a frame.

![Figure 387. DCMI signal waveforms](image)

1. The capture edge of DCMI_PIXCLK is the falling edge, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.

2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

8-bit data

When EDM[1:0] = 00 in DCMI_CR the interface captures 8 LSBs at its input (DCMI_D[7:0]) and stores them as 8-bit data. The DCMI_D[13:8] inputs are ignored. In this case, to capture a 32-bit word, the camera interface takes four pixel clock cycles.

The first captured data byte is placed in the LSB position in the 32-bit word and the 4th captured data byte is placed in the MSB position in the 32-bit word. The table below gives an example of the positioning of captured data bytes in two 32-bit words.
10-bit data
When EDM[1:0] = 01 in DCMI_CR, the camera interface captures 10-bit data at its input DCMI_D[9:0] and stores them as the 10 least significant bits of a 16-bit word. The remaining most significant bits of the DCMI_DR register (bits 11 to 15) are cleared to zero. So, in this case, a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

Table 407. Positioning of captured data bytes in 32-bit words (8-bit width)

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>D_{n+3}[7:0]</td>
<td>D_{n+2}[7:0]</td>
<td>D_{n+1}[7:0]</td>
<td>D_{n}[7:0]</td>
</tr>
<tr>
<td>4</td>
<td>D_{n+7}[7:0]</td>
<td>D_{n+6}[7:0]</td>
<td>D_{n+5}[7:0]</td>
<td>D_{n+4}[7:0]</td>
</tr>
</tbody>
</table>

12-bit data
When EDM[1:0] = 10 in DCMI_CR, the camera interface captures the 12-bit data at its input DCMI_D[11:0] and stores them as the 12 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

Table 408. Positioning of captured data bytes in 32-bit words (10-bit width)

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:26</th>
<th>25:16</th>
<th>15:10</th>
<th>9:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>D_{n+1}[9:0]</td>
<td>0</td>
<td>D_{n}[9:0]</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>D_{n+3}[9:0]</td>
<td>0</td>
<td>D_{n+2}[9:0]</td>
</tr>
</tbody>
</table>

14-bit data
When EDM[1:0] = 11 in DCMI_CR, the camera interface captures the 14-bit data at its input DCMI_D[13:0] and stores them as the 14 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

Table 409. Positioning of captured data bytes in 32-bit words (12-bit width)

41.3.6 DCMI synchronization

The digital camera interface supports embedded or hardware (DCMI_HSYNC and DCMI_VSYNC) synchronization. When embedded synchronization is used, it is up to the digital camera module to make sure that the 0x00 and 0xFF values are used ONLY for synchronization (not in data). Embedded synchronization codes are supported only for the 8-bit parallel data interface width (that is, in the DCMI_CR register, the EDM[1:0] bits must be cleared).

For compressed data, the DCMI supports only the hardware synchronization mode. In this case, DCMI_VSYNC is used as a start/end of the image, and DCMI_HSYNC is used as a Data Valid signal. Figure 388 shows the corresponding timing diagram.

**Figure 388. Timing diagram**

![Timing diagram](image)

**Hardware synchronization mode**

In hardware synchronization mode, the two synchronization signals (DCMI_HSYNC/DCMI_VSYNC) are used.

Depending on the camera module/mode, data may be transmitted during horizontal/vertical synchronization periods. The DCMI_HSYNC/DCMI_VSYNC signals act like blanking signals since all the data received during DCMI_HSYNC/DCMI_VSYNC active periods are ignored.

In order to correctly transfer images into the DMA/RAM buffer, data transfer is synchronized with the DCMI_VSYNC signal. When the hardware synchronization mode is selected, and
capture is enabled (CAPTURE bit set in DCMI_CR), data transfer is synchronized with the
deactivation of the DCMI_VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by DMA to successive
buffers or the same/circular buffer. To allow the DMA management of successive frames, a
VSIF (Vertical synchronization interrupt flag) is activated at the end of each frame.

**Embedded data synchronization mode**

In this synchronization mode, the data flow is synchronized using 32-bit codes embedded in
the data flow. These codes use the 0x00/0xFF values that are not used in data anymore.
There are 4 types of codes, all with a 0xFF0000XY format. The embedded synchronization
codes are supported only in 8-bit parallel data width capture (in the DCMI_CR register, the
EDM[1:0] bits must be cleared). For other data widths, this mode generates unpredictable
results and must not be used.

**Note:** Camera modules can have 8 such codes (in interleaved mode). For this reason, the
interleaved mode is not supported by the camera interface (otherwise, every other
half-frame would be discarded).

- **Mode 2**
  - Four embedded codes signal the following events
    - Frame start (FS)
    - Frame end (FE)
    - Line start (LS)
    - Line end (LE)
  
  The XY values in the 0xFF0000XY format of the four codes are programmable (see
  Section 41.5.7: DCMI embedded synchronization code register (DCMI_ESCR)).
  A 0xFF value programmed as a “frame end” means that all the unused codes are
  interpreted as valid frame end codes.
  In this mode, once the camera interface has been enabled, the frame capture starts
  after the first occurrence of the frame end (FE) code followed by a frame start (FS)
  code.

- **Mode 1**
  - An alternative coding is the camera mode 1. This mode is ITU656 compatible.
  The codes signal another set of events:
    - SAV (active line) - line start
    - EAV (active line) - line end
    - SAV (blanking) - end of line during interframe blanking period
    - EAV (blanking) - end of line during interframe blanking period
  
  This mode can be supported by programming the following codes:
  - FS ≤ 0xFF
  - FE ≤ 0xFF
  - LS ≤ SAV (active)
  - LE ≤ EAV (active)

An embedded unmask code is also implemented for frame/line start and frame/line end
codes. Using it, it is possible to compare only the selected unmasked bits with the
programmed code. A bit can therefore be selected to compare in the embedded code and
detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

**Example**

FS = 0xA5

Unmask code for FS = 0x10

In this case the frame start code is embedded in the bit 4 of the frame start code.

### 41.3.7 DCMI capture modes

This interface supports two types of capture: snapshot (single frame) and continuous grab.

#### Snapshot mode (single frame)

In this mode, a single frame is captured (CM = 1 of the DCMI_CR register). After the CAPTURE bit is set in DCMI_CR, the interface waits for the detection of a start of frame before sampling the data. The camera interface is automatically disabled (CAPTURE bit cleared in DCMI_CR) after receiving the first complete frame. An interrupt is generated (IT_FRAME) if it is enabled.

In case of an overrun, the frame is lost and the CAPTURE bit is cleared.

**Figure 389. Frame capture waveforms in snapshot mode**

1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

#### Continuous grab mode

In this mode (CM bit = 0 in DCMI_CR), once the CAPTURE bit has been set in DCMI_CR, the grabbing process starts on the next DCMI_VSYNC or embedded frame start depending on the mode. The process continues until the CAPTURE bit is cleared in DCMI_CR. Once the CAPTURE bit has been cleared, the grabbing process continues until the end of the current frame.
1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

In continuous grab mode, the FCRC[1:0] bits in DCMI_CR can be configured to grab all pictures, every second picture or one out of four pictures to decrease the frame capture rate.

**Note:** In the hardware synchronization mode (ESS = 0 in DCMI_CR), the IT_VSYNC interrupt is generated (if enabled) even when CAPTURE = 0 in DCMI_CR so, to reduce the frame capture rate even further, the IT_VSYNC interrupt can be used to count the number of frames between 2 captures in conjunction with the Snapshot mode. This is not allowed by embedded data synchronization mode.

### 41.3.8 DCMI crop feature

With the crop feature, the camera interface can select a rectangular window from the received image. The start (upper left corner) coordinates and size (horizontal dimension in number of pixel clocks and vertical dimension in number of lines) are specified using two 32-bit registers (DCMI_CWSTRT and DCMI_CWSIZE). The size of the window is specified in number of pixel clocks (horizontal dimension) and in number of lines (vertical dimension).

**Figure 391. Coordinates and size of the window after cropping**

These registers specify the coordinates of the starting point of the capture window as a line number (in the frame, starting from 0) and a number of pixel clocks (on the line, starting from 0), and the size of the window as a line number and a number of pixel clocks. The CAPCNT value can only be a multiple of 4 (two least significant bits are forced to 0) to allow the correct transfer of data through the DMA.
If the DCMI_VSYNC signal goes active before the number of lines is specified in the DCMI_CWSIZE register, then the capture stops and an IT_FRAME interrupt is generated when enabled.

Figure 392. Data capture waveforms

1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

41.3.9 DCMI JPEG format

To allow JPEG image reception, it is necessary to set the JPEG bit of the DCMI_CR register. JPEG images are not stored as lines and frames, so the DCMI_VSYNC signal is used to start the capture while DCMI_HSYNC serves as a data enable signal. The number of bytes in a line may not be a multiple of 4. This case must be carefully handled since a DMA request is generated each time a complete 32-bit word has been constructed from the captured data. When an end of frame is detected and the 32-bit word to be transferred has not been completely received, the remaining data are padded with zeros and a DMA request is generated.

The crop feature and embedded synchronization codes cannot be used in JPEG format.

41.3.10 DCMI FIFO

A 8-word FIFO is implemented to manage data rate transfers on the AHB. The DCMI features a simple FIFO controller with a read pointer incremented each time the camera interface reads from the AHB, and a write pointer incremented each time the camera interface writes to the FIFO. There is no overrun protection to prevent the data from being overwritten if the AHB interface does not sustain the data transfer rate.

In case of overrun or errors in the synchronization signals, the FIFO is reset and the DCMI interface waits for a new start of frame.
41.3.11 DCMI data format description

Data formats

Three types of data are supported:

- 8/10/12/14-bit progressive video: either monochrome or raw Bayer format
- YCbCr 4:2:2 progressive video
- RGB565 progressive video. A pixel coded in 16 bits (5 bits for blue, 5 bits for red, 6 bits for green) takes two clock cycles to be transferred.

Compressed data: JPEG

For B&W (black and white), YCbCr or RGB data, the maximum input size is 2048 × 2048 pixels. No limit in JPEG compressed mode.

For monochrome, RGB and YCbCr, the frame buffer is stored in raster mode. 32-bit words are used. Only the little-endian format is supported.

Figure 393. Pixel raster scan order

Monochrome format

Characteristics:

- Raster format
- 8 bits per pixel

The table below shows how the data are stored.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>

<td>n</td>
</tr>
<tr>
<td>4</td>
<td>n + 7</td>
<td>n + 6</td>
<td>n + 5</td>
<td>n + 4</td>
</tr>
</tbody>
</table>

RGB format

Characteristics:

- Raster format
- RGB
- Interleaved: one buffer: R, G and B interleaved (such as BRGBRGBRG)
- Optimized for display output
The RGB planar format is compatible with standard OS frame buffer display formats. Only 16 BPP (bits per pixel): RGB565 (2 pixels per 32-bit word) is supported.

The 24 BPP (palletized format) and gray-scale formats are not supported. Pixels are stored in a raster scan order, that is from top to bottom for pixel rows, and from left to right within a pixel row. Pixel components are R (red), G (green) and B (blue). All components have the same spatial resolution (4:4:4 format). A frame is stored in a single part, with the components interleaved on a pixel basis.

The table below shows how the data are stored.

### Table 412. Data storage in RGB progressive video format

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:27</th>
<th>26:21</th>
<th>20:16</th>
<th>15:11</th>
<th>10:5</th>
<th>4:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Red ( n + 1 )</td>
<td>Green ( n + 1 )</td>
<td>Blue ( n + 1 )</td>
<td>Red ( n )</td>
<td>Green ( n )</td>
<td>Blue ( n )</td>
</tr>
<tr>
<td>4</td>
<td>Red ( n + 4 )</td>
<td>Green ( n + 3 )</td>
<td>Blue ( n + 3 )</td>
<td>Red ( n + 2 )</td>
<td>Green ( n + 2 )</td>
<td>Blue ( n + 2 )</td>
</tr>
</tbody>
</table>

**YCbCr format**

Characteristics:
- Raster format
- YCbCr 4:2:2
- Interleaved: one buffer: Y, Cb and Cr interleaved (such as CbYCrYCbYCr)

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). Each component is encoded in 8 bits. Luma and chroma are stored together (interleaved) as shown in the table below.

### Table 413. Data storage in YCbCr progressive video format

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Y ( n + 1 )</td>
<td>Cr ( n )</td>
<td>Y ( n )</td>
<td>Cb ( n )</td>
</tr>
<tr>
<td>4</td>
<td>Y ( n + 3 )</td>
<td>Cr ( n + 2 )</td>
<td>Y ( n + 2 )</td>
<td>Cb ( n + 2 )</td>
</tr>
</tbody>
</table>

**YCbCr format - Y only**

Characteristics:
- Raster format
- YCbCr 4:2:2
- The buffer only contains Y information - monochrome image

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). In this mode, the chroma information is dropped. Only the luma component of each pixel, encoded in 8 bits, is stored as shown in Table 414.

The result is a monochrome image having the same resolution as the original YCbCr data.
Half resolution image extraction

This is a modification of the previous reception modes, being applicable to monochrome, RGB or Y extraction modes.

This mode is used to only store a half resolution image. It is selected through OELS and LSM control bits.

### 41.4 DCMI interrupts

Five interrupts are generated. All interrupts are maskable by software. The global interrupt (dcmi_it) is the OR of all the individual interrupts. The table below gives the list of all interrupts.

#### Table 414. Data storage in YCbCr progressive video format - Y extraction mode

<td><em>This mode only works for EDM[1:0] = 00. For all other EDM values, this field must be programmed to the reset value.</em></td>
</tr>
<tr>
<td>Bit 15</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>Bit 14</td>
<td><strong>ENABLE</strong>: DCMI enable</td>
</tr>
<tr>
<td></td>
<td>0: DCMI disabled</td>
</tr>
<tr>
<td></td>
<td>1: DCMI enabled</td>
</tr>
<tr>
<td><strong>Note</strong>:</td>
<td><em>The DCMI configuration registers must be programmed correctly before enabling this bit.</em></td>
</tr>
<tr>
<td>Bits 13:12</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
Bits 11:10 **EDM[1:0]:** Extended data mode
   00: Interface captures 8-bit data on every pixel clock.
   01: Interface captures 10-bit data on every pixel clock.
   10: Interface captures 12-bit data on every pixel clock.
   11: Interface captures 14-bit data on every pixel clock.

Bits 9:8 **FCRC[1:0]:** Frame capture rate control
   These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode. They are ignored in snapshot mode.
   00: All frames are captured.
   01: Every alternate frame captured (50% bandwidth reduction)
   10: One frame out of four captured (75% bandwidth reduction)
   11: reserved

Bit 7 **VSPOL:** Vertical synchronization polarity
   This bit indicates the level on the DCMI_VSYNC pin when the data are not valid on the parallel interface.
   0: DCMI_VSYNC active low
   1: DCMI_VSYNC active high

Bit 6 **HSPOL:** Horizontal synchronization polarity
   This bit indicates the level on the DCMI_HSYNC pin when the data are not valid on the parallel interface.
   0: DCMI_HSYNC active low
   1: DCMI_HSYNC active high

Bit 5 **PCKPOL:** Pixel clock polarity
   This bit configures the capture edge of the pixel clock.
   0: Falling edge active
   1: Rising edge active

Bit 4 **ESS:** Embedded synchronization select
   0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the DCMI_HSYNC/DCMI_VSYNC signals.
   1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.
   *Note:* Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when the ESS bit is set.
   This bit is disabled in JPEG mode.

Bit 3 **JPEG:** JPEG format
   0: Uncompressed video format
   1: This bit is used for JPEG data transfers. The DCMI_HSYNC signal is used as data enable. The crop and embedded synchronization features (ESS bit) cannot be used in this mode.

Bit 2 **CROP:** Crop feature
   0: The full image is captured. In this case the total number of bytes in an image frame must be a multiple of four.
   1: Only the data inside the window specified by the crop register is captured. If the size of the crop window exceeds the picture size, then only the picture size is captured.

Bit 1 **CM:** Capture mode
   0: Continuous grab mode - The received data are transferred into the destination memory through the DMA. The buffer location and mode (linear or circular buffer) is controlled through the system DMA.
   1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame and then transfers a single frame through the DMA. At the end of the frame, the CAPTURE bit is automatically reset.
Bit 0 **CAPTURE**: Capture enable
- 0: Capture disabled
- 1: Capture enabled

The camera interface waits for the first start of frame, then a DMA request is generated to transfer the received data into the destination memory.

In snapshot mode, the CAPTURE bit is automatically cleared at the end of the first frame received.

In continuous grab mode, if the software clears this bit while a capture is ongoing, the bit is effectively cleared after the frame end.

*Note: The DMA controller and all DCMI configuration registers must be programmed correctly before enabling this bit.*

### 41.5.2 DCMI status register (DCMI_SR)

**Address offset**: 0x04  
**Reset value**: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-3</td>
<td>Reserved, must be kept at reset value.</td>
<td></td>
</tr>
<tr>

<td>FNE: FIFO not empty</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>VSYNC: Vertical synchronization</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>HSYNC: Horizontal synchronization</td>
<td>0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>15-1</td>
<td>Reserved</td>
<td>r</td>
</tr>
</tbody>
</table>

**Bits 31:3**: Reserved, must be kept at reset value.

**Bit 2** FNE: FIFO not empty
- 1: FIFO contains valid data.
- 0: FIFO empty

**Bit 1** VSYNC: Vertical synchronization
- 0: active frame
- 1: synchronization between frames

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.

**Bit 0** HSYNC: Horizontal synchronization
- 0: active line
- 1: synchronization between lines

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.
41.5.3  DCMI raw interrupt status register (DCMI_RIS)

DCMI_RIS gives the raw interrupt status and is accessible in read only. When read, this register returns the status of the corresponding interrupt before masking with the DCMI_IER register value.

Address offset: 0x08
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| r  | r  | r  | r  | r  | r  | r  |

Bits 31:5  Reserved, must be kept at reset value.

- **Bit 4  **LINE_RIS: Line raw interrupt status
  This bit gets set when the DCMI_HSYNC signal changes from the inactive state to the active state. It goes high even if the line is not valid.
  In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMI_CR is set.
  It is cleared by setting the LINE_ISC bit of the DCMI_ICR register.

- **Bit 3  **VSYNC_RIS: DCMI_VSYNC raw interrupt status
  This bit is set when the DCMI_VSYNC signal changes from the inactive state to the active state.
  In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMI_CR.
  It is cleared by setting the VSYNC_ISC bit of the DCMI_ICR register.

- **Bit 2  **ERR_RIS: Synchronization error raw interrupt status
  0: No synchronization error detected
  1: Embedded synchronization characters are not received in the correct order.
  This bit is valid only in the embedded synchronization mode. It is cleared by setting the ERR_ISC bit of the DCMI_ICR register.

  *Note:*  This bit is available only in embedded synchronization mode.

- **Bit 1  **OVR_RIS: Overrun raw interrupt status
  0: No data buffer overrun occurred
  1: A data buffer overrun occurred and the data FIFO is corrupted.
  The bit is cleared by setting the OVR_ISC bit of the DCMI_ICR register.

- **Bit 0  **FRAME_RIS: Capture complete raw interrupt status
  0: No new capture
  1: A frame has been captured.
  This bit is set when a frame or window has been captured.
  In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (for example window cropped outside the frame).
  The bit is cleared by setting the FRAME_ISC bit of the DCMI_ICR register.
### 41.5.4 DCMI interrupt enable register (DCMI_IER)

The DCMI_IER register is used to enable interrupts. When one of the DCMI_IER bits is set, the corresponding interrupt is enabled. This register is accessible in both read and write.

*Address offset: 0x0C*

*Reset value: 0x0000 0000*

### 41.5.5 DCMI masked interrupt status register (DCMI_MIS)

This DCMI_MIS register is a read-only register. When read, it returns the current masked status value (depending on the value in DCMI_IER) of the corresponding interrupt. A bit in this register is set if the corresponding enable bit in DCMI_IER is set and the corresponding bit in DCMI_RIS is set.

Address offset: 0x10

Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:5 Reserved, must be kept at reset value.

- **Bit 4 LINE_MIS**: Line masked interrupt status
  This bit gives the status of the masked line interrupt.
  0: No interrupt generation when the line is received
  1: An interrupt is generated when a line has been completely received and the LINE_IE bit is set in DCMI_IER.

- **Bit 3 VSYNC_MIS**: VSYNC masked interrupt status
  This bit gives the status of the masked VSYNC interrupt.
  0: No interrupt is generated on DCMI_VSYNC transitions.
  1: An interrupt is generated on each DCMI_VSYNC transition from the inactive to the active state and the VSYNC_IE bit is set in DCMI_IER.
  The active state of the DCMI_VSYNC signal is defined by the VSPOL bit.

- **Bit 2 ERR_MIS**: Synchronization error masked interrupt status
  This bit gives the status of the masked synchronization error interrupt.
  0: No interrupt is generated on a synchronization error.
  1: An interrupt is generated if the embedded synchronization codes are not received in the correct order and the ERR_IE bit in DCMI_IER is set.
  *Note*: This bit is available only in embedded synchronization mode.

- **Bit 1 OVR_MIS**: Overrun masked interrupt status
  This bit gives the status of the masked overflow interrupt.
  0: No interrupt is generated on overrun.
  1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received and the OVR_IE bit is set in DCMI_IER.

- **Bit 0 FRAME_MIS**: Capture complete masked interrupt status
  This bit gives the status of the masked capture complete interrupt
  0: No interrupt is generated after a complete capture.
  1: An interrupt is generated at the end of each received frame/crop window (in crop mode) and the FRAME_IE bit is set in DCMI_IER.
41.5.6 DCMI interrupt clear register (DCMI_ICR)

The DCMI_ICR register is write-only. Setting a bit of this register clears the corresponding flag in the DCMI_RIS and DCMI_MIS registers. Writing 0 has no effect.

Address offset: 0x14

Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 LINE_ISC: line interrupt status clear
Setting this bit clears the LINE_RIS flag in the DCMI_RIS register.

Bit 3 VSYNC_ISC: Vertical Synchronization interrupt status clear
Setting this bit clears the VSYNC_RIS flag in the DCMI_RIS register.

Bit 2 ERR_ISC: Synchronization error interrupt status clear
Setting this bit clears the ERR_RIS flag in the DCMI_RIS register.

Note: This bit is available only in embedded synchronization mode.

Bit 1 OVR_ISC: Overrun interrupt status clear
Setting this bit clears the OVR_RIS flag in the DCMI_RIS register.

Bit 0 FRAME_ISC: Capture complete interrupt status clear
Setting this bit clears the FRAME_RIS flag in the DCMI_RIS register.

41.5.7 DCMI embedded synchronization code register (DCMI_ESCR)

Address offset: 0x18

Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 LINE_ISC: line interrupt status clear
Setting this bit clears the LINE_RIS flag in the DCMI_RIS register.

Bit 3 VSYNC_ISC: Vertical Synchronization interrupt status clear
Setting this bit clears the VSYNC_RIS flag in the DCMI_RIS register.

Bit 2 ERR_ISC: Synchronization error interrupt status clear
Setting this bit clears the ERR_RIS flag in the DCMI_RIS register.

Note: This bit is available only in embedded synchronization mode.

Bit 1 OVR_ISC: Overrun interrupt status clear
Setting this bit clears the OVR_RIS flag in the DCMI_RIS register.

Bit 0 FRAME_ISC: Capture complete interrupt status clear
Setting this bit clears the FRAME_RIS flag in the DCMI_RIS register.
Bits 31:24 **FEC[7:0]:** Frame end delimiter code
This byte specifies the code of the frame end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FEC.
If FEC is programmed to 0xFF, all the unused codes (0xFF0000XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]:** Line end delimiter code
This byte specifies the code of the line end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]:** Line start delimiter code
This byte specifies the code of the line start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]:** Frame start delimiter code
This byte specifies the code of the frame start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FSC.
If FSC is programmed to 0xFF, no frame start delimiter is detected. But, the first occurrence of LSC after an FEC code is interpreted as a start of frame delimiter.

### 41.5.8 DCMI embedded synchronization unmask register (DCMI_ESUR)

**Address offset:** 0x1C

**Reset value:** 0x0000 0000

Bits 31:24 **FEU[7:0]:** Frame end delimiter unmask
This byte specifies the mask to be applied to the code of the frame end delimiter.
0: The corresponding bit in the FEC byte in DCMI_ESCR is masked while comparing the frame end delimiter with the received data.
1: The corresponding bit in the FEC byte in DCMI_ESCR is compared while comparing the frame end delimiter with the received data.

Bits 23:16 **LEU[7:0]:** Line end delimiter unmask
This byte specifies the mask to be applied to the code of the line end delimiter.
0: The corresponding bit in the LEC byte in DCMI_ESCR is masked while comparing the line end delimiter with the received data.
1: The corresponding bit in the LEC byte in DCMI_ESCR is compared while comparing the line end delimiter with the received data.

Bits 15:8 **LSU[7:0]:** Line start delimiter unmask
This byte specifies the mask to be applied to the code of the line start delimiter.
0: The corresponding bit in the LSC byte in DCMI_ESCR is masked while comparing the line start delimiter with the received data.
1: The corresponding bit in the LSC byte in DCMI_ESCR is compared while comparing the line start delimiter with the received data.
Bits 7:0 **FSU[7:0]**: Frame start delimiter unmask

This byte specifies the mask to be applied to the code of the frame start delimiter.

0: The corresponding bit in the FSC byte in DCMI_ESCR is masked while comparing the frame start delimiter with the received data.

1: The corresponding bit in the FSC byte in DCMI_ESCR is compared while comparing the frame start delimiter with the received data.

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **VST[12:0]**: Vertical start line count

The image capture starts with this line number. Previous line data are ignored.

0x0000: line 1
0x0001: line 2
0x0002: line 3

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **HOFFCNT[13:0]**: Horizontal offset count

This value gives the number of pixel clocks to count before starting a capture.

### 41.5.10 DCMI crop window size (DCMI_CWSIZE)

</table>

Bits 31:30 Reserved, must be kept at reset value.
Bits 29:16  **VLINE[13:0]**: Vertical line count
   This value gives the number of lines to be captured from the starting point.
   0x0000: 1 line
   0x0001: 2 lines
   0x0002: 3 lines
   ....

Bits 15:14  Reserved, must be kept at reset value.

Bits 13:0  **CAPCNT[13:0]**: Capture count
   This value gives the number of pixel clocks to be captured from the starting point on the
   same line. It value must corresponds to word-aligned data for different widths of parallel
   interfaces.
   0x0000: 1 pixel
   0x0001: 2 pixels
   0x0002: 3 pixels
   ....

### 41.5.11 DCMI data register (DCMI_DR)

Address offset: 0x28

Reset value: 0x0000 0000

The digital camera Interface packages all the received data in 32-bit format before
requesting a DMA transfer. A 8-word deep FIFO is available to leave enough time for DMA
transfers and avoid DMA overrun conditions.

Refer to Section 2.3 for the register boundary addresses.
42 Parallel synchronous slave interface (PSSI)

The PSSI peripheral and the DCMI (digital camera interface) use the same circuitry. As a result, these two peripherals cannot be used at the same time: when using the PSSI, the DCMI registers cannot be accessed, and vice-versa.

In addition, the PSSI and the DCMI share the same alternate functions and interrupt vector (see Section 42.3.2: PSSI pins and internal signals).

42.1 Introduction

The PSSI is a generic synchronous 8/16-bit parallel data input/output slave interface. It enables the transmitter to send a data valid signal that indicates when the data is valid, and the receiver to output a flow control signal that indicates when it is ready to sample the data.

42.2 PSSI main features

The PSSI peripheral main features are the following:

- Slave mode operation
- 8-bit or 16-bit parallel data input or output
- 8-word (32-byte) FIFO
- Data enable (PSSI_DE) alternate function input and Ready (PSSI_RDY) alternate function output
  When selected, these signals can either enable the transmitter to indicate when the data is valid, allow the receiver to indicate when it is ready to sample the data, or both.

42.3 PSSI functional description

The PSSI is a synchronous parallel slave interface that can send or receive high-speed data flows. It consists of up to 16 data lines (PSSI_D[15:0]) plus a clock line (PSSI_PDCK). The clock polarity can be configured so that data can be captured or transmitted on either the clock rising or falling edge.

Usually, a general-purpose DMA channel is used to pass 32-bit packed data via the data register (PSSI_DR).

The data flow can either be continuous or synchronized by hardware using the optional PSSI_DE (Data enable), and PSSI_RDY (Ready) signals. 

*Figure 394* shows the PSSI block diagram.
42.3.1 PSSI block diagram

Figure 394. PSSI block diagram

Figure 395. Top-level block diagram

42.3.2 PSSI pins and internal signals

The PSSI interface is composed of 19 pins, though nine signals are enough to transfer parallel data. Table 417 shows the PSSI pins.

When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, the alternate functions and the interrupt vector are associated with the PSSI. Otherwise, they are associated with the DCMI. The DCMI ENABLE bit (bit 15 of DCMI_CR) and the PSSI ENABLE bit (bit 14 of PSSI_CR) must not be set to 1 at the same time. As an example, if a GPIO is configured to use the alternate function PSSI_PDCK/DCMI_PIXCK, it is the PSSI_PDCK function which becomes active if PSSI_CR/ENABLE is set to 1.
Table 418 shows the PSSI internal input/output signals.

</tr>
</tbody>
</table>

#### 42.3.3 PSSI clock

The AHB clock frequency must be at least 2.5 times higher than the PSSI_PDCK frequency. At frequency ratios lower than 2.5, data might be corrupted or lost during transfers.

Data transfers are synchronous with PSSI_PDCK. The PSSI_PDCK polarity can be configured as follows, through CKPOL bit (bit 5 of PSSI_CR):

- When CKPOL = 0
  - Input pins are sampled on PSSI_PDCK falling edge
  - Output pins are driven on PSSI_PDCK rising edge
- When CKPOL = 1
  - Input pins are sampled on PSSI_PDCK rising edge
  - Output pins are driven on PSSI_PDCK falling edge

#### 42.3.4 PSSI data management

**Data direction**

The direction of data transfers is configured through the OUTEN control bit (bit 31 of PSSI_CR):

- When OUTEN is cleared to 0 (default setting), the PSSI operates in receive mode and the data is input on the data pins.
- When OUTEN is set to 1, the peripheral operates in transmit mode and the data is output on the data pins.

OUTEN can be modified only when the ENABLE bit is cleared to 0.
Data register and DMA

Data are transferred from/to the FIFO using the PSSI_DR data register:
- In receive mode, data must be read from the FIFO by reading PSSI_DR.
- In transmit mode, data must be written to the FIFO by writing into PSSI_DR.

Word (32-bit) accesses to PSSI_DR and half-word (16-bit) accesses to PSSI_DR[15:0] are permitted in all modes. Byte (8-bit) accesses to PSSI_DR[7:0] are permitted only when the PSSI is configured to transfer 8 bits at a time (EDM=00 in the PSSI_CR register).

To reduce the load on the CPU, it is recommended to use the DMA to transfer data from/to the PSSI FIFO. When it is used, the DMA must be configured to transfer data via the PSSI_DR register. Using 32-bit transfers optimizes bandwidth and reduces the bus load. However, 8-bit and 16-bit transfers are also permitted.

To use the DMA, set the PSSI DMA enable bit (DMAEN in PSSI_CR) to 1 (default setting). When DMAEN is set to 1, a DMA transfer is initiated when the FIFO is ready for a 32-bit transfer (four valid bytes in receive mode or four empty bytes in transmit mode). As a result, in receive mode, no DMA transfers are initiated if there are three bytes or fewer in the FIFO, even if the DMA is configured to perform 8-bit transfers.

The RTT4B and RTT1B status bits (PSSI_SR) are useful when the CPU directly perform transfers to and from the FIFO. RTT4B set to 1 indicates that the FIFO is ready to transfer four bytes: at least four valid bytes in the FIFO in receive mode or at least four free bytes in transmit mode. RTT1B set to 1 indicates that the FIFO is ready to transfer one byte: at least one valid byte in the FIFO in receive mode or at least one free byte in transmit mode.

8-bit data

The PSSI parallel interface can transfer either 8-bit (using D[7:0]) or 16-bit data (using D[15:0]) depending on the EDM[1:0] control bits (bits 11:10 of PSSI_CR). If the 8-bit configuration is selected (EDM[1:0] set to 00), the unused D[15:0] pins can be used for GPIO or other functions.

When EDM[1:0] in PSSI_CR are programmed to 00, the interface transfers 8 bits using the D[7:0] pins. In this case, D[15:8] are not used and four PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant byte (bits 7:0) correspond to the first byte transferred, and the most-significant byte (bits 31:28) corresponds to the forth byte transferred. Table 419 illustrates the positioning of the data bytes in two 32-bit words.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
16-bit data

When EDM[1:0] in PSSI_CR are programmed to 11, the interface transfers 16 bits using the D[15:0] pins. In this case, two PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant half word (bits 15:0) correspond to the first half word transferred, and the most-significant half-word (bits 31:16) corresponds to the second half word transferred. Table 420 illustrates the positioning of the data in two 32-bit words.

FIFO data buffer and error conditions

An eight-word FIFO helps improving performance and avoids overruns and underruns.

If the ready signal (PSSI_RDY) is disabled in receive mode, an overrun error is generated when a clock active edge occurs when the FIFO is full. In this case, the input data is lost.

If the data enable signal (PSSI_DE) is disabled in transmit mode, an underrun error is generated when a clock active edge occurs when the FIFO is empty. In this case, unpredictable data are output.

The OVR_RIS status bit indicates that either an overrun or an underrun occurred. An interrupt can be generated when these events occur.

42.3.5 PSSI optional control signals

Data Enable (PSSI_DE) alternate function input

The data enable signal, PSSI_DE, is an optional signal. It is driven by the data source/transmitter in order to indicate that the data is valid to be transferred during the current cycle. When PSSI_DE is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG (bits 20:18 of PSSI_CR) control bits. PSSI_DE polarity is configured through DEPOL control bit (bit 6 of PSSI_CR). PSSI_DE is active low when DEPOL is cleared to 0, and high when DEPOL is set to 1.

The direction of the PSSI_DE signal is defined by the OUTEN value. It is the same as the data direction.

If the PSSI_DE alternate function input is enabled (through DERDYCFG) in receive mode (OUTEN cleared to 0), the PSSI samples PSSI_DE on the same PSSI_PDCK edge as the one used for sampling the data (D[15:0]). If PSSI_DE is active, the sampled data is saved in the FIFO. Otherwise, the sampled data is considered invalid and discarded. The transmitting device can use PSSI_DE as a data valid signal, driving it inactive when the data in the current cycle is not valid. This flow control function allows avoiding underrun errors.
If the PSSI_DE alternate output function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI drives PSSI_DE on the same PSSI_PDCK edge that the one used to drive the data (D[15:0]). If a new 8 or 16-bit data (as programmed in the EDM[1:0] control bits in PSSI_CR) is available for transmission in the internal FIFO, this data is output on the data outputs (D[15:0]) and the PSSI_DE output becomes active on the current PSSI_PDCK edge. Otherwise (if the TX FIFO is empty), the D[15:0] outputs remains unchanged on the next clock edge and the PSSI_DE output becomes inactive.

Ready (PSSI_RDY) alternate function output

The ready signal, PSSI_RDY, is an optional signal. It is driven by the receiving device and indicates whether data is being accepted in the current cycle. When PSSI_RDY is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG control bits (bits 20:18 of PSSI_CR). PSSI_RDY polarity is configured through the RDYPOL control bit (bit 6 of PSSI_CR). PSSI_RDY is active low when RDYPOL is cleared to 0, and high when RDYPOL set to 1.

The direction of the PSSI_RDY signal is defined by the OUTEN (bit 31 of PSSI_CR). It is set in the opposite direction compared to the PSSI_DE and data signals.

If the PSSI_RDY alternate output function is enabled (through DERDYCFG) in receive mode (OUTEN=0), the PSSI drives PSSI_RDY one PSSI_PDCK half cycle after it samples...
the data (D[15:0]). If the FIFO has enough free space to receive more data, the PSSI drives the PSSI_RDY signal active. Otherwise, if the FIFO is full and cannot accept more data, the PSSI drives the PSSI_RDY signal inactive. The transmitting device must repeat the current data in the next cycle when it detects that PSSI_RDY is inactive. This flow control function allows the PSSI to avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

**Figure 398. Ready in receive mode waveform diagram (CKPOL=0)**

If the PSSI_RDY alternate input function is enabled (through DERDYMCFG) in transmit mode (OUTEN=1), the PSSI samples the PSSI_RDY signal on the opposite PSSI_PDCK edge to the one at which D[15:0] are driven. If the PSSI_RDY signal is inactive, the PSSI keeps the same data (D[15:0]) and PSSI_DE signals that valid data are available during the next PSSI_PDCK clock cycle. Otherwise, if PSSI_RDY signal is sampled as active, the next data from the TX FIFO (if available) is output on the data outputs (D[15:0]). If no new data are available in the TX FIFO, the PSSI keeps the data output values and outputs the PSSI_DE signal as inactive (if enabled).

The receiving device uses the PSSI_RDY to control the data flow and avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

**Bidirectional PSSI_DE/PSSI_RDY signal**

A single pin can be used for both data enable (PSSI_DE) and ready (PSSI_RDY) functions if DEPOL and RDYPOL are both set to 1 and DERDYMCFG is set to 111 or 100 in the PSSI_CR register. In this case, the GPIO corresponding to selected alternate function (PSSI_DE when DERDYMCFG=111 or PSSI_RDY when DERDYMCFG=100) must be configured as open-drain. The other device must also be configured to drive the line as open-drain, and a weak pull-up must be applied to the line.

The signal thus becomes bidirectional. If either the sender drives the line low (to indicate that the data is not valid) or the receiver drives the line low (to indicate that it is not sampling the current data), then both devices know that the data is not being transferred in the current cycle.
42.4 PSSI interrupts

The PSSI generates only one interrupt (IT_OVR). It is consequently equivalent to the global interrupt (pssi_it). Refer to Table 421 for the list of interrupts.

The PSSI and the DCMI share the same interrupt vector. When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, these interrupts are triggered by the PSSI. Otherwise, they are controlled by the DCMI.

The DCMI ENABLE bit (bit 14 of DCMI_CR) and PSSI ENABLE bit must not be set to 1 at the same time.

42.5 PSSI registers

An 8-bit write or a 16-bit write operation to any PSSI register besides PSSI_DR, results in a bus error. 32-bit read and write operations are permitted.

<td>111</td>
<td>Both PSSI_RDY and PSSI_DE features enabled - bidirectional on PSSI_DE pin (see Bidirectional PSSI_DE/PSSI_RDY signal on page 1692)</td>
</tr>
</tbody>
</table>

When the PSSI_RDY function is mapped to the PSSI_DE pin (settings 101 or 111), it is still the RDYPOL bit which determines its polarity. Similarly, when the PSSI_DE function is mapped to the PSSI_RDY pin (settings 110 or 111), it is still the DEPOL bit which determines its polarity.

| Bits 17:15 | Reserved, must be kept at reset value. |
Bit 14 **ENABLE**: PSSI enable

0: PSSI disabled
1: PSSI enabled

The contents of the FIFO are flushed when ENABLE is cleared to 0.

*Note:* When ENABLE=1, the content of PSSI_CR must not be changed, except for the ENABLE bit itself. All configuration bits can change as soon as ENABLE changes from 0 to 1.

The DMA controller and all PSSI configuration registers must be programmed correctly before setting the ENABLE bit to 1.

The ENABLE bit and the DCMI ENABLE bit (bit 15 of DCMI_CR) must not be set to 1 at the same time.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 **EDM[1:0]**: Extended data mode

00: Interface captures 8-bit data on every parallel data clock
01: Reserved, must not be selected
10: Reserved, must not be selected
11: The interface captures 16-bit data on every parallel data clock

Bit 9 Reserved, must be kept at reset value.

Bit 8 **RDYPOL**: Ready (PSSI_RDY) polarity

This bit indicates the level on the PSSI_RDY pin when the data are not valid on the parallel interface.

0: PSSI_RDY active low (0 indicates that the receiver is ready to receive)
1: PSSI_RDY active high (1 indicates that the receiver is ready to receive)

Bit 7 Reserved, must be kept at reset value.

Bit 6 **DEPOL**: Data enable (PSSI_DE) polarity

This bit indicates the level on the PSSI_DE pin when the data are not valid on the parallel interface.

0: PSSI_DE active low (0 indicates that data is valid)
1: PSSI_DE active high (1 indicates that data is valid)

Bit 5 **CKPOL**: Parallel data clock polarity

This bit configures the capture edge of the parallel clock or the edge used for driving outputs, depending on OUTEN.

0: Falling edge active for inputs or rising edge active for outputs
1: Rising edge active for inputs or falling edge active for outputs

Bits 4:0 Reserved, must be kept at reset value.

### 42.5.2 PSSI status register (PSSI_SR)

Address offset: 0x04

Reset value: 0x0000 0000

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**r** **r**
42.5.3 PSSI raw interrupt status register (PSSI_RIS)

Address offset: 0x08
Reset value: 0x0000 0000

PSSI_RIS gives the raw interrupt status. This register is read-only. When read, it returns the status of the corresponding interrupt before masking with the PSSI_IER register value.

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 OVR_RIS: Data buffer overrun/underrun raw interrupt status
0: No overrun/underrun occurred
1: An overrun/underrun occurred: overrun in receive mode, underrun in transmit mode.
This bit is cleared by writing a 1 to the OVR_ISC bit in PSSI_ICR.

Bit 0 Reserved, must be kept at reset value.
42.5.4 PSSI interrupt enable register (PSSI_IER)

Address offset: 0x0C
Reset value: 0x0000 0000

The PSSI_IER register is used to enable interrupts. When one of the PSSI_IER bits is set, the corresponding interrupt is enabled. This register is accessible both in read and write modes.

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_IE**: Data buffer overrun/underrun interrupt enable
- 0: No interrupt generation
- 1: An interrupt is generated if either an overrun or an underrun error occurred.

Bit 0 Reserved, must be kept at reset value.

42.5.5 PSSI masked interrupt status register (PSSI_MIS)

This PSSI_MIS register is read-only. When read, it returns the current masked status value of the corresponding interrupt (depending on the value in PSSI_IER). A bit in this register is set if the corresponding enable bit in PSSI_IER is set and the corresponding bit in PSSI_RIS is set.

Address offset: 0x10
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>

<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_MIS**: Data buffer overrun/underrun masked interrupt status
- This bit is set to 1 only when PSSI_IER/OVR_IE and PSSI_RIS/OVR_RIS are both set to 1.
- 0: No interrupt is generated when an overrun/underrun error occurs
- 1: An interrupt is generated if there is either an overrun or an underrun error and the OVR_IE bit is set in PSSI_IER.

Bit 0 Reserved, must be kept at reset value.
42.5.6 PSSI interrupt clear register (PSSI_ICR)

Address offset: 0x14
Reset value: 0x0000 0000

The PSSI_ICR register is write-only. Writing a 1 into a bit of this register clears the corresponding bit in the PSSI_RIS and PSSI_MIS registers. Writing a 0 has no effect. Reading this register always gives zeros.

<table>
<thead>
<tr>
<th>Bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
</tr>
<tr>
<td>30</td>
</tr>
<tr>
<td>29</td>
</tr>
<tr>

</tr>
<tr>
<td>19</td>
</tr>
<tr>
<td>18</td>
</tr>
<tr>
<td>17</td>
</tr>
<tr>
<td>16</td>
</tr>
</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR ISC**: Data buffer overrun/underrun interrupt status clear
Writing this bit to 1 clears the OVR_RIS bit in PSSI_RIS.

Bit 0 Reserved, must be kept at reset value.

42.5.7 PSSI data register (PSSI_DR)

Address offset: 0x28
Reset value: 0x0000 0000

In receive mode (OUTEN = 0), the DMA controller must read the received data from this register. Write operations to PSSI_DR result in an error response. When more bytes than the number of valid bytes are read in the FIFO, the invalid bytes return zeros.

In transmit mode (OUTEN = 1), the DMA controller must write the data to be transmitted into this register. Read operations to PSSI_DR result in an error response.

32-bit, 16-bit, and 8-bit accesses are all supported for PSSI_DR. For instance, 16-bit read/write operations remove/add two bytes from/to the FIFO. However, 8-bit accesses are permitted only when the PSSI is configured to transfer 8 data bits at a time (EDM=00 in PSSI_CR). 8-bit accesses to PSSI_DR when EDM is not set to 0 result in an error response.

All accesses must include byte 0: 8-bit accesses must be performed to bytes 7 to 0 and 16-bit accesses from bytes 15 to 0. Accesses that do not include byte 0 results in an error response.

Accessing PSSI_DR when ENABLE bit in PSSI_CR is set to 0 results in an error response.
Bits 31:24  **BYTE3[7:0]**: Data byte 3
Bits 23:16  **BYTE2[7:0]**: Data byte 2
Bits 15:8  **BYTE1[7:0]**: Data byte 1
Bits 7:0  **BYTE0[7:0]**: Data byte 0

### 42.5.8 PSSI register map

Refer to Section 2.3 for the register boundary addresses.
43 LCD-TFT display controller (LTDC)

This section only applies to the STM32U599/5A9/5Fx/5Gx devices.

43.1 Introduction

The LCD-TFT (liquid crystal display - thin film transistor) display controller provides a parallel digital RGB (red, green, blue) and signals for horizontal, vertical synchronization, pixel clock and data enable as output to interface directly to a variety of LCD and TFT panels.

43.2 LTDC main features

- 24-bit RGB parallel pixel output; 8 bits-per-pixel (RGB888)
- 2 display layers with dedicated FIFO (64x32-bit)
- Color look-up table (CLUT) up to 256 color (256x24-bit) per layer
- Programmable timings for different display panels
- Programmable background color
- Programmable polarity for HSYNC, VSYNC and data enable
- Up to 8 input color formats selectable per layer:
  - ARGB8888
  - RGB888
  - RGB565
  - ARGB1555
  - ARGB4444
  - L8 (8-bit luminance or CLUT)
  - AL44 (4-bit alpha + 4-bit luminance)
  - AL88 (8-bit alpha + 8-bit luminance)
- Pseudo-random dithering output for low bits per channel
  - Dither width 2 bits for red, green, blue
- Flexible blending between two layers using alpha value (per pixel or constant)
- Color keying (transparency color)
- Programmable window position and size
- Supports thin film transistor (TFT) color displays
- AHB master interface with burst of 16 words
- Up to 4 programmable interrupt events
43.3 LTDC functional description

43.3.1 LTDC block diagram

Figure 401. LTDC block diagram

43.3.2 LTDC pins and internal signals

The table below summarizes the LTDC signal interface.

<table>
<thead>
<tr>
<th>LCD-TFT signals</th>
<th>Signal type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LCD_CLK</td>
<td>Output</td>
<td>Clock output</td>
</tr>
<tr>
<td>LCD_HSYNC</td>
<td>Output</td>
<td>Horizontal synchronization</td>
</tr>
<tr>
<td>LCD_VSYNC</td>
<td>Output</td>
<td>Vertical synchronization</td>
</tr>
<tr>

<td>Output</td>
<td>8-bit Green data</td>
</tr>
<tr>
<td>LCD_B[7:0]</td>
<td>Output</td>
<td>8-bit Blue data</td>
</tr>
</tbody>
</table>

The LTDC pins must be configured by the user application. The unused pins can be used for other purposes.

For LTDC outputs up to 24 bits (RGB888), if less than 8 bpp are used to output for example RGB565 or RGB666 to interface on 16- or 18-bit displays, the RGB display data lines must be connected to the MSB of the LTDC RGB data lines.

As an example, in the case of an LTDC interfacing with a RGB565 16-bit display, the LTDC display R[4:0], G[5:0] and B[4:0] data lines pins must be connected to the LCD_R[7:3], LCD_G[7:2] and LCD_B[7:3] pins.
The internal signals of the LTDC are given in the table below.

**Table 424. LTDC internal signals**

<table>
<thead>

<td>ltdc_li</td>
<td>Output</td>
<td>gpdma_trigsel[47]</td>
</tr>
</tbody>
</table>

**43.3.3 LTDC reset and clocks**

The LTDC controller peripheral uses the following clock domains:

- **AHB clock domain (ltdc_aclk)**
  This domain contains the LTDC AHB master interface for data transfer from the memories to the layer FIFO and the frame-buffer configuration register.

- **APB clock domain (ltdc_pclk)**
  This domain contains the global configuration registers and the interrupt register.

- **Pixel clock domain (LCD_CLK)**
  This domain contains the pixel data generation, the layer configuration register as well as the LTDC interface signal generator. The LCD_CLK output must be configured following the panel requirements. The LCD_CLK is generated from a specific PLL output (refer to the reset and clock control section).

The table below summarizes the clock domain for each register.

**Table 426. Clock domain for each register**

<table>
<thead>
<tr>
<th>LTDC register</th>
<th>Clock domain</th>
</tr>
</thead>
<tbody>
<tr>
<td>LTDC_LxCR</td>
<td>ltdc_hclk</td>
</tr>
<tr>
<td>LTDC_LxCFBAR</td>
<td></td>
</tr>
<tr>
<td>LTDC_LxCFBLR</td>
<td></td>
</tr>
<tr>
<td>LTDC_LxCFBLNR</td>
<td></td>
</tr>
</tbody>
</table>
Care must be taken while accessing the LTDC registers, the APB bus is stalled during:

- six ldtc_pclk periods + five LCD_CLK periods (five ldtc_hclk periods for register on AHB clock domain) for register write access and update
- seven ldtc_pclk periods + five LCD_CLK periods (five ldtc_hclk periods for register on AHB clock domain) for register read access

For registers on ldtc_pclk clock domain, APB bus is stalled for six ldtc_pclk periods during the register write accesses, and for seven ldtc_pclk periods during read accesses.

The LTDC controller can be reset by setting the corresponding bit in the RCC. It resets the three clock domains.

43.4  **LTDC programmable parameters**

The LTDC controller provides flexible configurable parameters. It can be enabled or disabled through the LTDC_GCR register.

43.4.1  **LTDC global configuration parameters**

**Synchronous timings**

The figure below presents the configurable timing parameters generated by the synchronous timings generator block presented in the block diagram *Figure 401*. It generates the horizontal and vertical synchronization timings panel signals, the pixel clock and the data enable signals.

![Figure 402. LTDC synchronous timings](image)

The LTDC programmable synchronous timings are the following:

- **HSYNC and VSYNC width**: horizontal and vertical synchronization width, configured by programming a value of HSYNC width - 1 and VSYNC width - 1 in the LTDC_SSCR register.

- **HBP and VBP**: horizontal and vertical synchronization back porch width, configured by programming the accumulated value HSYNC width + HBP - 1 and the accumulated value VSYNC width + VBP - 1 in the LTDC_BPCR register.

- **Active width and active height**: the active width and active height are configured by programming the accumulated value HSYNC width + HBP + active width - 1 and the
accumulated value VSYNC width + VBP + active height - 1 in the LTDC_AWCR register.

• Total width: the total width is configured by programming the accumulated value HSYNC width + HBP + active width + HFP - 1 in the LTDC_TWCR register. The HFP is the horizontal front porch period.

• Total height: the total height is configured by programming the accumulated value VSYNC height + VBP + active height + VFP - 1 in the LTDC_TWCR register. The VFP is the vertical front porch period.

Note: When the LTDC is enabled, the timings generated start with X/Y = 0/0 position as the first horizontal synchronization pixel in the vertical synchronization area and following the back porch, active data display area and the front porch.

When the LTDC is disabled, the timing generator block is reset to X = total width - 1, Y = total height - 1 and held the last pixel before the vertical synchronization phase and the FIFO are flushed. Therefore only blanking data is output continuously.

Example of synchronous timings configuration

LTDC timings (must be extracted from panel datasheet):

• horizontal and vertical synchronization width: 0xA pixels and 0x2 lines
• horizontal and vertical back porch: 0x14 pixels and 0x2 lines
• active width and active height: 0x140 pixels, 0xF0 lines (320x240)
• horizontal front porch: 0xA pixels
• vertical front porch: 0x4 lines

The programmed values in the LTDC timings registers are:

• LTDC_SSCR register to be programmed to 0x00090001 (HSW[11:0] is 0x9 and VSH[10:0] is 0x1)
• LTDC_BPCR register to be programmed to 0x001D0003 (AHBP[11:0] is 0x1D (0xA + 0x13) and AVBP[10:0]A is 0x3 (0x2 + 0x1))
• LTDC_AWCR register to be programmed to 0x015D00F3 (AAW[11:0] is 0x15D (0xA + 0x14 +0x13F) and AAH[10:0] is 0xF3 (0x2 + 0x2 + 0xEF))
• LTDC_TWCR register to be programmed to 0x00000167 (TOTALW[11:0] is 0x167 (0xA +0x14 +0x140 + 0x9))
• LTDC_THCR register to be programmed to 0x000000F7 (TOTALH[10:0]is 0xF7 (0x2 +0x2 + 0xF0 + 3))

Programmable polarity

The horizontal and vertical synchronization, data enable and pixel clock output signals polarity can be programmed to active high or active low through the LTDC_GCR register.

Background color

A constant background color (RGB888) can programmed through the LTDC_BCCR register. It is used for blending with the bottom layer.

Dithering

The dithering pseudo-random technique using an LFSR is used to add a small random value (threshold) to each pixel color channel (R, G or B) value, thus rounding up the MSB in
some cases when displaying a 24-bit data on 18-bit display. Thus the dithering technique is used to round data which is different from one frame to the other.

The dithering pseudo-random technique is the same as comparing LSBs against a threshold value and adding a 1 to the MSB part only, if the LSB part is ≥ the threshold. The LSBs are typically dropped once dithering was applied.

The width of the added pseudo-random value is two bits for each color channel: two bits for red, two bits for green and two bits for blue.

Once the LTDC is enabled, the LFSR starts running with the first active pixel and it is kept running even during blanking periods and when dithering is switched off. If the LTDC is disabled, the LFSR is reset.

The dithering can be switched on and off on the fly through the LTDC_GCR register.

**Reload shadow registers**

Some configuration registers are shadowed. The shadow registers values can be reloaded immediately to the active registers when writing to these registers or at the beginning of the vertical blanking period following the configuration in the LTDC_SRCR register. If the immediate reload configuration is selected, the reload must be activated only when all new registers have been written.

The shadow registers must not be modified again before the reload is done. Reading from the shadow registers returns the actual active value. The new written value can only be read after the reload has taken place.

A register reload interrupt can be generated if enabled in the LTDC_IER register.

The shadowed registers are all Layer1 and Layer2 registers except LTDC_LxCLUTWR.

**Interrupt generation event**

Refer to **Section 43.5: LTDC interrupts** for the interrupt configuration.

### 43.4.2 Layer programmable parameters

Up to two layers can be enabled, disabled and configured separately. The layer display order is fixed and it is bottom up. If two layers are enabled, the layer2 is the top displayed window.

**Windowing**

Every layer can be positioned and resized and it must be inside the active display area.

The window position and size are configured through the top-left and bottom-right X/Y positions and the internal timing generator that includes the synchronous, back porch size and the active data area. Refer to LTDC_LxWHPCR and LTDC_WVPCR registers.

The programmable layer position and size defines the first/last visible pixel of a line and the first/last visible line in the window. It allows to display either the full image frame or only a part of the image frame (see Figure 403):

- The first and the last visible pixel in the layer are set by configuring the WHSTPOS[11:0] and WHSPPOS[11:0] in the LTDC_LxWHPCR register.
- The first and the last visible lines in the layer are set by configuring the WVSTPOS[10:0] and WVSPPOS[10:0] in the LTDC_LxWVPCR register.
Pixel input format

The programmable pixel format is used for the data stored in the frame buffer of a layer. Up to eight input pixel formats can be configured for every layer through the LTDC_LxPFCR register.

The pixel data is read from the frame buffer and then transformed to the internal 8888 (ARGB) format as follows: components having a width of less than 8 bits get expanded to 8 bits by bit replication. The selected bit range is concatenated multiple times until it is longer than 8 bits. Of the resulting vector, the 8 MSB bits are chosen. Example: 5 bits of an RGB565 red channel become (bit positions) 43210432 (the three LSBs are filled with the three MSBs of the five bits).

The table below describes the pixel data mapping depending on the selected format.

RM0456 Rev 5 1707/3637
Color look-up table (CLUT)

The CLUT can be enabled at run-time for every layer through the LTDC_LxCR register and it is only useful in case of indexed color when using the L8, AL44 and AL88 input pixel format.

First, the CLUT must be loaded with the R, G and B values that replace the original R, G, B values of that pixel (indexed color). Each color (RGB value) has its own address that is the position within the CLUT.

The R, G and B values and their own respective address are programmed through the LTDC_LxCLUTWR register:

- In case of L8 and AL88 input pixel format, the CLUT must be loaded by 256 colors. The address of each color is configured in the CLUTADD bits in the LTDC_LxCLUTWR register.

</tbody>
</table>
In case of AL44 input pixel format, the CLUT must be loaded by only 16 colors. The address of each color must be filled by replicating the 4-bit L channel to 8-bit as follows:
- L0 (indexed color 0), at address 0x00
- L1, at address 0x11
- L2, at address 0x22
- ....
- L15, at address 0xFF

Color frame buffer address

Every layer has a start address for the color frame buffer configured through the LTDC_LxCFBAR register.

When a layer is enabled, the data is fetched from the color frame buffer.

Color frame buffer length

Every layer has a total line length setting for the color frame buffer in bytes and a number of lines in the frame buffer configurable in the LTDC_LxCFBLR and LTDC_LxCFBLNR register respectively.

The line length and the number of lines settings are used to stop the prefetching of data to the layer FIFO at the end of the frame buffer:
- If it is set to less bytes than required, a FIFO underrun interrupt is generated if it has been previously enabled.
- If it is set to more bytes than actually required, the useless data read from the FIFO is discarded. The useless data is not displayed.

Color frame buffer pitch

Every layer has a configurable pitch for the color frame buffer, that is the distance between the start of one line and the beginning of the next line in bytes. It is configured through the LTDC_LxCFBLR register.

Layer blending

The blending is always active and the two layers can be blended following the blending factors configured through the LTDC_LxBFCR register.

The blending order is fixed and it is bottom up. If two layers are enabled, first the Layer1 is blended with the Background color, then the layer2 is blended with the result of blended color of layer1 and the background. Refer to the figure below.

![Figure 404. Blending two layers with background](MSv48123V1)
Default color

Every layer can have a default color in the format ARGB which is used outside the defined layer window or when a layer is disabled.

The default color is configured through the LTDC_LxDCCR register.

The blending is always performed between the two layers even when a layer is disabled. To avoid displaying the default color when a layer is disabled, keep the blending factors of this layer in the LTDC_LxBFCR register to their reset value.

Color keying

A color key (RGB) can be configured to be representative for a transparent pixel.

If the color keying is enabled, the current pixels (after format conversion and before CLUT respectively blending) are compared to the color key. If they match for the programmed RGB value, all channels (ARGB) of that pixel are set to 0.

The color key value can be configured and used at run-time to replace the pixel RGB value.

The color keying is enabled through the LTDC_LxCKCR register.

The color keying is configured through the LTDC_LxCKCR register. The programmed value depends on the pixel format as it is compared to current pixel after pixel format conversion to ARGB888.

Example: if the a mid-yellow color (50 % red + 50 % green) is used as the transparent color key:

- In RGB565, the mid-yellow color is 0x8400. Set the LTDC_LxCKCR to 0x848200.
- In ARGB8888, the mid-yellow color is 0x808000. Set LTDC_LxCKCR to 0x808000.
- In all CLUT-based color modes (L8, AL88, AL44), set one of the palette entry to the mid-yellow color 0x808000 and set the LTDC_LxCKCR to 0x808000.

43.5 LTDC interrupts

The LTDC provides four maskable interrupts logically ORed to two interrupt vectors.

The interrupt sources can be enabled or disabled separately through the LTDC_IER register. Setting the appropriate mask bit to 1 enables the corresponding interrupt.

The two interrupts are generated on the following events:

- Line interrupt: generated when a programmed line is reached. The line interrupt position is programmed in the LTDC_LIPCR register
- Register reload interrupt: generated when the shadow registers reload is performed during the vertical blanking period
- FIFO underrun interrupt: generated when a pixel is requested from an empty layer FIFO
- Transfer error interrupt: generated when an AHB bus error occurs during data transfer
These interrupt events are connected to the NVIC controller as described in the figure below.

**Figure 405. Interrupt events**

**LTDC programming procedure**

43.6

The steps listed below are needed to program the LTDC:
1. Enable the LTDC clock in the RCC register.
2. Configure the required pixel clock following the panel datasheet.
3. Configure the synchronous timings: VSYNC, HSYNC, vertical and horizontal back porch, active data area and the front porch timings following the panel datasheet as described in the Section 43.4.1.
4. Configure the synchronous signals and clock polarity in the LTDC_GCR register.
5. If needed, configure the background color in the LTDC_BCCR register.
6. Configure the needed interrupts in the LTDC_IER and LTDC_LIPCR register.
7. Configure the layer1/2 parameters by:
   - programming the layer window horizontal and vertical position in the LTDC_LxWHPCR and LTDC_WVPCR registers. The layer window must be in the active data area.
   - programming the pixel input format in the LTDC_LxFPCR register
   - programming the color frame buffer start address in the LTDC_LxCFBAR register
   - programming the line length and pitch of the color frame buffer in the LTDC_LxCFBLR register
   - programming the number of lines of the color frame buffer in the LTDC_LxCFBLNR register
   - if needed, loading the CLUT with the RGB values and its address in the LTDC_LxCLUTWR register
   - If needed, configuring the default color and the blending factors respectively in the LTDC_LxDCCR and LTDC_LxBFCR registers
8. Enable layer1/2 and if needed the CLUT in the LTDC_LxCR register.
9. If needed, enable dithering and color keying respectively in the LTDC_GCR and LTDC_LxCKCR registers. They can be also enabled on the fly.
10. Reload the shadow registers to active register through the LTDC_SRCR register.
11. Enable the LTDC controller in the LTDC_GCR register.
12. All layer parameters can be modified on the fly except the CLUT. The new configuration must be either reloaded immediately or during vertical blanking period by configuring the LTDC_SRCR register.

Note: All layer's registers are shadowed. Once a register is written, it must not be modified again before the reload has been done. Thus, a new write to the same register overrides the previous configuration if not yet reloaded.

43.7 LTDC registers

43.7.1 LTDC synchronization size configuration register (LTDC_SSCR)
Address offset: 0x008
Reset value: 0x0000 0000
This register defines the number of horizontal synchronization pixels minus 1 and the number of vertical synchronization lines minus 1. Refer to Figure 402 and Section 43.4 for an example of configuration.

43.7.2 LTDC back porch configuration register (LTDC_BPCR)
Address offset: 0x00C
Reset value: 0x0000 0000
This register defines the accumulated number of horizontal synchronization and back porch pixels minus 1 (HSYNC width + HBP - 1) and the accumulated number of vertical synchronization lines.
synchronization and back porch lines minus 1 (VSYNC height + VBP - 1).
Refer to Figure 402 and Section 43.4 for an example of configuration.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **AHBP[11:0]**: Accumulated horizontal back porch (in units of pixel clock period)
These bits defines the accumulated horizontal back porch width that includes the horizontal synchronization and horizontal back porch pixels minus 1.
The horizontal back porch is the period between horizontal synchronization going inactive and the start of the active display part of the next scan line.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **AVBP[10:0]**: Accumulated Vertical back porch (in units of horizontal scan line)
These bits define the accumulated vertical back porch width that includes the vertical synchronization and vertical back porch lines minus 1.
The vertical back porch is the number of horizontal scan lines at a start of frame to the start of the first active scan line of the next frame.

### 43.7.3 LTDC active width configuration register (LTDC_AWCR)

Address offset: 0x010
Reset value: 0x0000 0000

This register defines the accumulated number of horizontal synchronization, back porch and active pixels minus 1 (HSYNC width + HBP + active width - 1) and the accumulated number of vertical synchronization, back porch lines and active lines minus 1 (VSYNC height + VBP + active height - 1). Refer to Figure 402 and Section 43.4 for an example of configuration.

</table>

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **AAW[11:0]**: Accumulated active width (in units of pixel clock period)
These bits define the accumulated active width which includes the horizontal synchronization, horizontal back porch and active pixels minus 1.
The active width is the number of pixels in active display area of the panel scan line.
Refer to device datasheet for maximum active width supported following maximum pixel clock.
43.7.4 LTDC total width configuration register (LTDC_TWCR)

Address offset: 0x014
Reset value: 0x0000 0000

This register defines the accumulated number of horizontal synchronization, back porch, active and front porch pixels minus 1 (HSYNC width + HBP + active width + HFP - 1) and the accumulated number of vertical synchronization, back porch lines, active and front lines minus 1 (VSYNC height + VBP + active height + VFP - 1). Refer to Figure 402 and Section 43.4 for an example of configuration.

| Bits 31:28 | Reserved, must be kept at reset value. |
| Bits 27:16 | TOTALW[11:0]: Total width (in units of pixel clock period) |
| Bits 15:11 | Reserved, must be kept at reset value. |
| Bits 10:0  | TOTALH[10:0]: Total height (in units of horizontal scan line) |

43.7.5 LTDC global control register (LTDC_GCR)

Address offset: 0x018
Reset value: 0x0000 2220

This register defines the global configuration of the LCD-TFT controller.

| Bits 31:28 | Reserved, must be kept at reset value. |
| Bits 27:16 | TOTALW[11:0]: Total width (in units of pixel clock period) |
| Bits 15:11 | Reserved, must be kept at reset value. |
| Bits 10:0  | TOTALH[10:0]: Total height (in units of horizontal scan line) |
Bit 31  **HSPOL**: Horizontal synchronization polarity  
This bit is set and cleared by software.  
0: Horizontal synchronization polarity is active low.  
1: Horizontal synchronization polarity is active high.

Bit 30  **VSPOL**: Vertical synchronization polarity  
This bit is set and cleared by software.  
0: Vertical synchronization is active low.  
1: Vertical synchronization is active high.

Bit 29  **DEPOL**: Not data enable polarity  
This bit is set and cleared by software.  
0: Not data enable polarity is active low.  
1: Not data enable polarity is active high.

Bit 28  **PCPOL**: Pixel clock polarity  
This bit is set and cleared by software.  
0: Pixel clock polarity is active low.  
1: Pixel clock is active high.

Bits 27:17  Reserved, must be kept at reset value.

Bit 16  **DEN**: Dither enable  
This bit is set and cleared by software.  
0: Dither disabled  
1: Dither enabled

Bit 15  Reserved, must be kept at reset value.

Bits 14:12  **DRW[2:0]**: Dither red width  
These bits return the dither red bits.

Bit 11  Reserved, must be kept at reset value.

Bits 10:8  **DGW[2:0]**: Dither green width  
These bits return the dither green bits.

Bit 7  Reserved, must be kept at reset value.

Bits 6:4  **DBW[2:0]**: Dither blue width  
These bits return the dither blue bits.

Bits 3:1  Reserved, must be kept at reset value.

Bit 0  **LTDCEN**: LCD-TFT controller enable  
This bit is set and cleared by software.  
0: LTDC disabled  
1: LTDC enabled
43.7.6 LTDC shadow reload configuration register (LTDC_SRCR)

Address offset: 0x024
Reset value: 0x0000 0000

This register allows to reload either immediately or during the vertical blanking period, the shadow registers values to the active registers. The shadow registers are all Layer1 and Layer2 registers except the LTDC_L1CLUTWR and the LTDC_L2CLUTWR.

The shadow registers read back the active values. Until the reload has been done, the 'old' value is read.

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 VBR: Vertical blanking reload
This bit is set by software and cleared only by hardware after reload (it cannot be cleared through register write once it is set).
0: No effect
1: The shadow registers are reloaded during the vertical blanking period (at the beginning of the first line after the active display area).

Bit 0 IMR: Immediate reload
This bit is set by software and cleared only by hardware after reload.
0: No effect
1: The shadow registers are reloaded immediately.

43.7.7 LTDC background color configuration register (LTDC_BCCR)

Address offset: 0x02C
Reset value: 0x0000 0000

This register defines the background color (RGB888).

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 BCRED[7:0]: Background color red value
These bits configure the background red value.
Bits 15:8 **BCGREEN[7:0]**: Background color green value
These bits configure the background green value.

Bits 7:0 **BCBLUE[7:0]**: Background color blue value
These bits configure the background blue value.

### 43.7.8 LTDC interrupt enable register (LTDC_IER)

Address offset: 0x034
Reset value: 0x0000 0000

This register determines which status flags generate an interrupt request by setting the corresponding bit to 1.

Bits 31:4  Reserved, must be kept at reset value.

Bit 3  RRIF: Register reload interrupt flag
0: No register reload interrupt generated  
1: Register reload interrupt generated when a vertical blanking reload occurs (and the first line after the active area is reached)

Bit 2  TERRIF: Transfer error interrupt flag  
0: No transfer error interrupt generated  
1: Transfer error interrupt generated when a bus error occurs

Bit 1  FUIF: FIFO underrun interrupt flag  
0: No FIFO underrun interrupt generated  
1: FIFO underrun interrupt generated, if one of the layer FIFOs is empty and pixel data is read from the FIFO

Bit 0  LIF: Line interrupt flag  
0: No line interrupt generated  
1: Line interrupt generated when a programmed line is reached

43.7.10  LTDC interrupt clear register (LTDC_ICR)

Address offset: 0x03C  
Reset value: 0x0000 0000

<table>

Bits 31:4  Reserved, must be kept at reset value.

Bit 3  CRRIF: Clear register reload interrupt flag  
0: No effect  
1: Clear the RRIF flag in the LTDC_ISR register
43.7.11 LTDC line interrupt position configuration register (LTDC_LIPCR)

Address offset: 0x040
Reset value: 0x0000 0000

This register defines the position of the line interrupt. The line value to be programmed depends on the timings parameters. Refer to Figure 402.

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0 LIPOS[10:0]: Line interrupt position
These bits configure the line interrupt position.

43.7.12 LTDC current position status register (LTDC_CPSR)

Address offset: 0x044
Reset value: 0x0000 0000

Bits 31:16 CXPOS[15:0]: Current X position
These bits return the current X position.

Bits 15:0 CYPOS[15:0]: Current Y position
These bits return the current Y position.
43.7.13 LTDC current display status register (LTDC_CDSR)

Address offset: 0x048
Reset value: 0x0000 000F

This register returns the status of the current display phase which is controlled by the HSYNC, VSYNC, and horizontal/vertical DE signals.

Example: if the current display phase is the vertical synchronization, the VSYNCS bit is set (active high). If the current display phase is the horizontal synchronization, the HSYNCs bit is active high.

The returned status does not depend on the configured polarity in the LTDC_GCR register, instead it returns the current active display phase.

Bits 31:4 Reserved, must be kept at reset value.
43.7.15 LTDC layer x window horizontal position configuration register (LTDC_LxWHPCR)

Address offset: 0x0088 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the horizontal position (first and last pixel) of the layer 1 or 2 window.

The first visible pixel of a line is the programmed value of AHBP[11:0] bits + 1 in the LTDC_BPCR register.

The last visible pixel of a line is the programmed value of AAW[11:0] bits in the LTDC_AWCR register.

**Example:** The LTDC_BPCR register is configured to 0x0000E0005 (AHBP[11:0] is 0xE) and the LTDC_AWCR register is configured to 0x028E01E5 (AAW[11:0] is 0x28E). To configure the horizontal position of a window size of 630x460, with horizontal start offset of 5 pixels in the active data area:
- layer window first pixel, WHSTPOS[11:0], must be programmed to 0x14 (0xE+1+0x5).
- layer window last pixel, WHSPPOS[11:0], must be programmed to 0x28A.

<th>16</th>
</tr>
</thead>
</table>

Bits 31:28  Reserved, must be kept at reset value.

Bits 27:16  **WHSPPOS[11:0]:** Window horizontal stop position
These bits configure the last visible pixel of a line of the layer window. WHSPPOS[11:0] must be ≥ AHBP[11:0] bits + 1 (programmed in LTDC_BPCR register).
43.7.16  LTDC layer x window vertical position configuration register (LTDC_LxWVPCR)

Address offset: 0x08C + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the vertical position (first and last line) of the layer1 or 2 window.
The first visible line of a frame is the programmed value of AVBP[10:0] bits + 1 in the register LTDC_BPCR register.
The last visible line of a frame is the programmed value of AAH[10:0] bits in the LTDC_AWCR register.

Example:
The LTDC_BPCR register is configured to 0x000E0005 (AVBP[10:0] is 0x5) and the LTDC_AWCR register is configured to 0x028E01E5 (AAH[10:0] is 0x1E5).
To configure the vertical position of a window size of 630x460, with vertical start offset of eight lines in the active data area:
- layer window first line, WVSTPOS[10:0], must be programmed to 0xE (0x5 + 1 + 0x8).
- layer window last line, WVSPPOS[10:0] must be programmed to 0x1DA.

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:0 **WVSTPOS[11:0]**: Window vertical start position
These bits configure the first visible pixel of a line of the layer window.

Bits 10:0 **WVSPPOS[10:0]**: Window vertical stop position
These bits configure the last visible line of the layer window.

Bits 9:0 Reserved, must be kept at reset value.

Bits 8:0 **WVSTPOS[8:0]**: Window vertical start position
These bits configure the first visible pixel of a line of the layer window.
WVSTPOS[8:0] must be ≥ AVBP[8:0] bits + 1 (programmed in LTDC_BPCR register).

Bits 7:0 Reserved, must be kept at reset value.

Bits 6:0 **WVSPPOS[6:0]**: Window vertical stop position
These bits configure the last visible line of the layer window.

Bits 5:0 Reserved, must be kept at reset value.

Bits 4:0 **WVSTPOS[4:0]**: Window vertical start position
These bits configure the first visible pixel of a line of the layer window.

Bits 3:0 Reserved, must be kept at reset value.

Bits 2:0 **WVSPPOS[2:0]**: Window vertical stop position
These bits configure the last visible line of the layer window.

Bits 1:0 Reserved, must be kept at reset value.

Bits 0:0 **WVSTPOS[0:0]**: Window vertical start position
These bits configure the first visible pixel of a line of the layer window.
WVSTPOS[0:0] must be ≥ AVBP[0:0] bits + 1 (programmed in LTDC_BPCR register).
43.7.17 LTDC layer x color keying configuration register (LTDC_LxCKCR)

Address offset: 0x090 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the color key value (RGB), that is used by the color keying.

Bits 7:0 **CKBLUE[7:0]**: Color key blue value

43.7.18 LTDC layer x pixel format configuration register (LTDC_LxPFCR)

Address offset: 0x094 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the pixel format that is used for the stored data in the frame buffer of a layer. The pixel data is read from the frame buffer and then transformed to the internal format 8888 (ARGB).

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **PF[2:0]**: Pixel format

These bits configure the pixel format
000: ARGB8888
001: RGB888
010: RGB565
011: ARGB1555
100: ARGB4444
101: L8 (8-bit luminance)
110: AL44 (4-bit alpha, 4-bit luminance)
111: AL88 (8-bit alpha, 8-bit luminance)
43.7.19  **LTDC layer x constant alpha configuration register (LTDC_LxCACR)**

Address offset: 0x098 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 00FF

This register defines the constant alpha value (divided by 255 by hardware), that is used in the alpha blending. Refer to LTDC_LxBFCR register.

<table>
<thead>
<tr>
<th>Bits 31:8</th>
<th>Reserved, must be kept at reset value.</th>

</tr>
<tr>
<td></td>
<td>These bits configure the constant alpha used for blending. The constant alpha is divided by 255 by hardware.</td>
</tr>
<tr>
<td></td>
<td>Example: if the programmed constant alpha is 0xFF, the constant alpha value is 255 / 255 = 1.</td>
</tr>
</tbody>
</table>

43.7.20  **LTDC layer x default color configuration register (LTDC_LxDCCR)**

Address offset: 0x09C + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the default color of a layer in the format ARGB. The default color is used outside the defined layer window or when a layer is disabled. The reset value of 0x00000000 defines a transparent black color.

| Bits 31:24 | **DCALPHA[7:0]**: Default color alpha |
|           | These bits configure the default alpha value. |
| Bits 23:16 | **DCRED[7:0]**: Default color red |
|           | These bits configure the default red value. |
| Bits 15:8  | **DCGREEN[7:0]**: Default color green |
|           | These bits configure the default green value. |
| Bits 7:0   | **DCBLUE[7:0]**: Default color blue |
|           | These bits configure the default blue value. |
43.7.21  LTDC layer x blending factors configuration register (LTDC_LxBFCR)

Address offset: 0x0A0 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0607

This register defines the blending factors F1 and F2.

The general blending formula is: BC = BF1 x C + BF2 x Cs

- BC = blended color
- BF1 = blend factor 1
- C = current layer color
- BF2 = blend factor 2
- Cs = subjacent layers blended color

The constant alpha value, is the programmed value in LTDC_LxCACR divided by 255 by hardware.

Example: Only layer1 is enabled, BF1 configured to constant alpha. BF2 configured to 1 - constant alpha. The constant alpha programmed in LTDC_LxCACR is 240 (0xF0). Thus, the constant alpha value is 240 / 255 = 0.94. C: current layer color is 128.

CS: background color is 48. Layer1 is blended with the background color.

BC = constant alpha x C + (1 - Constant Alpha) x Cs = 0.94 x 128 + (1- 0.94) x 48 = 123.

Bits 31:11  Reserved, must be kept at reset value.

Bits 10:8  BF1[2:0]: Blending factor 1
These bits select the blending factor F1.
100: constant alpha
110: pixel alpha x constant alpha
Others: Reserved

Bits 7:3  Reserved, must be kept at reset value.

Bits 2:0  BF2[2:0]: blending factor 2
These bits select the blending factor F2
101: 1 - constant alpha
111: 1 - (pixel alpha x constant alpha)
Others: Reserved
43.7.22  **LTDC layer x color frame buffer address register (LTDC_LxCFBAR)**

Address offset: 0x0AC + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the color frame buffer start address which has to point to the address where the pixel data of the top left pixel of a layer is stored in the frame buffer.

Bits 31:0  **CFBADD[31:0]**: Color frame buffer start address
These bits define the color frame buffer start address.

43.7.23  **LTDC layer x color frame buffer length register (LTDC_LxCFBLR)**

Address offset: 0x0B0 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the color frame buffer line length and pitch.

Example:
- A frame buffer having the format RGB565 (2 bytes per pixel) and a width of 256 pixels (total number of bytes per line is 256 * 2 = 512), where pitch = line length requires a value of 0x02000203 to be written into this register.
- A frame buffer having the format RGB888 (3 bytes per pixel) and a width of 320 pixels (total number of bytes per line is 320 * 3 = 960), where pitch = line length requires a value of 0x03C003C3 to be written into this register.

<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:29  Reserved, must be kept at reset value.
Bits 28:16  **CFBP[12:0]**: Color frame buffer pitch in bytes
These bits define the pitch that is the increment from the start of one line of pixels to the start of the next line in bytes.

Bits 15:13  Reserved, must be kept at reset value.
43.7.24 LTDC layer x color frame buffer line number register (LTDC_LxCFBLNR)

Address offset: 0x0B4 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the number of lines in the color frame buffer.

The number of lines and line length settings define how much data is fetched per frame for every layer. If it is configured to less bytes than required, a FIFO underrun interrupt is generated if enabled.

The start address and pitch settings on the other hand define the correct start of every line in memory.

<table>
<thead>
<tr>
<th>Bits 12:0 CFBL[12:0]</th>
<th>Color frame buffer line length</th>
</tr>
</thead>
<tbody>
<tr>
<td>These bits define the length of one line of pixels in bytes + 3. The line length is computed as follows: active high width * number of bytes per pixel + 3.</td>
<td></td>
</tr>
</tbody>
</table>

43.7.25 LTDC layer x CLUT write register (LTDC_LxCLUTWR)

Address offset: 0x0C4 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the CLUT address and the RGB value.

The CLUT write register must be configured only during blanking period or if the layer is disabled. The CLUT can be enabled or disabled in the LTDC_LxCR register.

The CLUT is only meaningful for L8, AL44 and AL88 pixel format.
Bits 31:24 **CLUTADD[7:0]**: CLUT address
These bits configure the CLUT address (color position within the CLUT) of each RGB value.

Bits 23:16 **RED[7:0]**: Red value
These bits configure the red value.

Bits 15:8 **GREEN[7:0]**: Green value
These bits configure the green value.

Bits 7:0 **BLUE[7:0]**: Blue value
These bits configure the blue value.

44 DSI Host (DSI)

This section applies to STM32U599/5A9/5F9/5G9 devices only.

44.1 Introduction

Portions Copyright (c) Synopsys, Inc. All rights reserved. Used with permission.

The display serial interface (DSI) is part of a group of communication protocols defined by the MIPI® Alliance.

The MIPI® DSI Host controller is a digital core that implements all protocol functions defined in the MIPI® DSI specification. It provides an interface between the system and the MIPI® D-PHY, allowing the user to communicate with a DSI-compliant display.

44.2 Standard and references

- MIPI® Alliance Specification for Display Serial interface (DSI) v1.1 - 22 November 2011
- MIPI® Alliance Specification for Display Bus interface (DBI-2) v2.00 - 16 November 2005
- MIPI® Alliance Specification for Display Command set (DCS) v1.1 - 22 November 2011
- MIPI® Alliance Specification for Display Pixel interface (DPI-2) v2.00 - 15 September 2005
- MIPI® Alliance Specification for Stereoscopic Display Formats (SDF) v1.0 - 22 November 2011
- MIPI® Alliance Specification for D-PHY v1.1 - 7 November 2011
44.3 DSI Host main features

- Compliant with MIPI® Alliance standards (see Section 44.2: Standard and references)
- Interface with MIPI® D-PHY
- Supports all commands defined in the MIPI® Alliance specification for DCS:
  - Transmission of all command mode packets through the APB interface
  - Transmission of commands in low-power and high-speed during video mode
- Supports up to two D-PHY data lanes
- Bidirectional communication and escape mode support through data lane 0
- Supports non-continuous clock in D-PHY clock lane for additional power saving
- Supports ultra low-power mode with PLL disabled
- ECC and checksum capabilities
- Support for end of transmission packet (EoTp)
- Fault recovery schemes
- Configurable selection of system interfaces:
  - AMBA APB for control and optional support for generic and DCS commands
  - Video mode interface through LTDC
  - Adapted command mode interface through LTDC
  - Independently programmable virtual channel ID in video mode, adapted command mode and APB slave
- Video mode interfaces features:
  - LTDC interface color coding mappings into 24-bit interface:
    - 16-bit RGB, configurations 1, 2, and 3
    - 18-bit RGB, configurations 1 and 2
    - 24-bit RGB
  - Programmable polarity of all LTDC interface signals
  - Extended resolutions beyond the DPI standard maximum resolution of 800x480 pixels
  - Maximum resolution is limited by available DSI physical link bandwidth:
    - Number of lanes: 2
    - Maximum speed per lane: 500 Mbit/s
    - See examples in Section 44.4.3: Supported resolutions and frame rates
- Adapted interface features:
  - Support for sending large amounts of data through the memory_write_start (WMS) and memory_write_continue (WMC) DCS commands
  - LTDC interface color coding mappings into 24-bit interface:
    - 16-bit RGB, configurations 1, 2, and 3
    - 18-bit RGB, configurations 1 and 2
    - 24-bit RGB
- Video mode pattern generator:
  - Vertical and horizontal color bar generation without LTDC stimuli
  - BER pattern without LTDC stimuli
44.4 DSI Host functional description

44.4.1 General description

The MIPI® DSI Host includes dedicated video interfaces internally connected to the LTDC and a generic APB interface that can be used to transmit information to the display. More in detail:

- LTDC interface:
  - Used to transmit information in video mode, in which the transfers from the host processor to the peripheral take the form of a real-time pixel stream (DPI).
  - Through a customized mode, this interface can be used to transmit information in full bandwidth in the adapted command mode (DBI).
- APB slave interface: allows the transmission of generic information in command mode, and follows a proprietary register interface. This interface can operate concurrently with either LTDC interface in either video mode or adapted command mode.
- Video mode pattern generator: allows the transmission of horizontal/vertical color bar and D-PHY BER testing pattern without any kind of stimuli.

The block diagram is shown in Figure 406.

44.4.3 Supported resolutions and frame rates

The DSI specification does not define supported standard resolutions or frame rates. Display resolution, blanking periods, synchronization events duration, frame rates, and pixel color depth play a fundamental role in the required bandwidth. In addition, other link related attributes can influence the ability of the link to support a DSI-specific device, namely display input buffering capabilities, video transmission mode (burst or non-burst), bus turn-around (BTA) time, concurrent command mode traffic in a video mode transmission, or display device specifics. All these variables make it difficult to define a standard procedure to estimate the minimum lane rate and the minimum number of lanes that support a specific display device.

The basic assumptions for estimates are:

- clock lane frequency is 250 MHz, resulting in a bandwidth of 500 Mbit/s for each data lane
- the display must be capable of buffering the pixel data at the speed at which it is delivered in the DSI link
- no significant control traffic is present on the link when the pixel data is being transmitted.

44.4.4 System level architecture

*Figure 407* shows the architecture of the DSI Host
The different parts have the following functions:

- The DSI Wrapper ensures the interfacing between the LTDC and the DSI Host kernel. It can adapt the color mode, the signal polarity and manages the tearing effect (TE) management for automatic frame buffer update in adapted command mode. The DSI Wrapper also control the DSI bias, the DSI PLL and specific functions of the MIPI® D-PHY.

- The LTDC interface captures the data and control signals from the LTDC and conveys them to a FIFO for video control signals and another one for the pixel data. This data is then used to build one of the following:
  - Video packets, when in video mode (see Section 44.5)
  - The `memory_write_start` and `memory_write_continue` DCS commands, when in adapted command mode (see Section 44.6)

- The register bank is accessible through a standard AMBA-APB slave interface, providing access to the DSI Host registers for configuration and control. There is also a fully programmable interrupt generator to inform the system about certain events.

- The PHY interface control is responsible for managing the D-PHY interface. It acknowledges the current operation and enables low-power transmission/reception or a high-speed transmission. It also performs data splitting between available D-PHY lanes for high-speed transmission.

- The packet handler schedules the activities inside the link. It performs several functions based on the interfaces that are currently operational and the video transmission mode that is used (burst mode or non-burst mode with sync pulses or sync events). It builds
long or short packet generating correspondent ECC and CRC codes. This block also performs the following functions:
- packet reception
- validation of packet header by checking the ECC
- header correction and notification for single-bit errors
- termination of reception
- multiple header error notification
- depending on the virtual channel of the incoming packet, the handler routes the output data to the respective port.

- The APB-to-generic block bridges the APB operations into FIFOs holding the generic commands. The block interfaces with the following FIFOs:
  - Command FIFO
  - Write payload FIFO
  - Read payload FIFO

- The error management notifies and monitors the error conditions on the DSI link. It controls the timers used to determine if a timeout condition occurred, performing an internal soft reset and triggering an interruption notification.
44.5 **Functional description: video mode on LTDC interface**

The LTDC interface captures the data and control signals and conveys them to the FIFO interfaces that transmit them to the DSI link.

Two different streams of data are present at the interface, namely video control signals and pixel data. Depending on the interface color coding, the pixel data is disposed differently throughout the LTDC bus.

Interface pixel color coding is summarized in Table 432.

<table>

</tbody>
</table>
The LTDC interface can be configured to increase flexibility and promote correct use of this interface for several systems. The following configuration options are available:

- **Polarity control**: all the control signals are programmable to change the polarity depending on the LTDC configuration.

- After the core reset, DSI Host waits for the first VSYNC active transition to start signal sampling, including pixel data, thus avoiding starting the transmission of the image data in the middle of a frame.

- If interface pixel color coding is 18 bits and the 18-bit loosely packed stream is disabled, the number of pixels programmed in the VPSIZE field must be a multiple of four. This means that in this mode, the two LSBs in the configuration are always inferred as zero. The specification states that in this mode, the pixel line size must be a multiple of four.

- To avoid FIFO underflows and overflows, the configured number of pixels is assumed to be received from the LTDC at all times.

- To keep the memory organized with respect to the packet scheduling, the number of pixels per packet parameter is used to separate the memory space of different video packets.

For SHTDN and COLM sampling and transmission, the video streaming from the LTDC must be active. This means that if the LTDC is not actively generating the video signals like VSYNC and HSYNC, these signals are not transmitted through the DSI link. Because of such constraints and for commands to be correctly transmitted, the first VSYNC active pulse must occur for the command sampling and transmission. When shutting down the display, it is necessary for the LTDC to be kept active for one frame after the command being issued. This ensures that the commands are correctly transmitted before actually disabling the video generation at the LTDC interface.

The SHTDN and COLM values can be programmed in the DSI Wrapper control register (DSI_WCR).

For all of the data types, one entire pixel is received per each clock cycle. The number of pixels of payload is restricted to a multiple of a value, as shown in Table 433.

### 44.5.1 Video transmission mode

There are different video transmission modes, namely:

- **Burst mode**
- **Non-burst mode**
  - Non-burst mode with sync pulse
  - Non-burst mode with sync event
Burst mode
In this mode, the entire active pixel line is buffered into a FIFO and transmitted in a single packet with no interruptions. This transmission mode requires that the DPI pixel FIFO has the capacity to store a full line of active pixel data inside it. This mode is optimally used when the difference between the pixel required bandwidth and DSI link bandwidth is significant, it enables the DSI Host to quickly dispatch the entire active video line in a single burst of data and then return to low-power mode.

Non-burst mode
In this mode, the processor uses the partitioning properties of the DSI Host to divide the video line transmission into several DSI packets. This is done to match the pixel required bandwidth with the DSI link bandwidth. With this mode, the controller configuration does not require a full line of pixel data to be stored inside the LTDC interface pixel FIFO. It requires only the content of one video packet.

Guidelines for selecting the burst or non-burst mode
Selecting the burst and non-burst mode is mainly dependent on the system configuration and the device requirements. Choose the video transmission mode that suits the application scenario. The burst mode is more beneficial because it increases the probability of the link spending more time in the low-power mode, decreasing power consumption. The following conditions must be met to get the maximum benefits from the burst mode of operation:

• The DSI Host core must have sufficient pixel memory to store an entire pixel line to avoid the overflow of the internal FIFOs.
• The display device must support receiving a full pixel line in a single packet burst to avoid the overflow on the reception buffer.
• The DSI output bandwidth must be higher than the LTDC interface input bandwidth in a relation that enables the link to go to low-power once per line.

If the system cannot meet these requirements, it is likely that the pixel data is lost causing the malfunctioning of the display device while using the burst mode. These errors are related to the capabilities of the system to store the temporary pixel data.

If all the conditions for using the burst mode cannot be met, use the non-burst mode to avoid errors. The non-burst mode provides a better matching of rates for pixel transmission, enabling:

• Only a certain amount of pixels to be stored in the memory and not requiring a full pixel line (lesser LTDC interface RAM requirements in the DSI Host).
• Operation with devices that support only a small amount of pixel buffering (less than a full pixel line).

The DSI non-burst mode must be configured so that the DSI output pixel ratio matches with the LTDC interface input pixel ratio, reducing the memory requirements on both host and/or device side. This is achieved by dividing a pixel line into several chunks of pixels and optionally interleaving them with null packets.

The following equations show how the DSI Host core transmission parameters must be programmed in non-burst mode to match the DSI link pixel output ratio (left hand side of the “=” sign) and LTDC interface pixel input (right hand side of the “=” sign).
When the null packets are enabled:
\[
\text{lanebyteclkperiod} \times \text{NUMC} \times (\text{VPSIZE} \times \text{bytes_per_pixel} + 12 + \text{NPSIZE}) / \text{number_of_lanes} = \text{pixels_per_line} \times \text{LTDC\_Clock\_period}
\]
When the null packets are disabled:
\[
\text{lanebyteclkperiod} \times \text{NUMC} \times (\text{VPSIZE} \times \text{bytes_per_pixel} + 6) / \text{number_of_lanes} = \text{pixels_per_line} \times \text{LTDC\_Clock\_period}
\]

44.5.2 Updating the LTDC interface configuration in video mode

It is possible to update the LTDC interface configuration on the fly without impacting the current frame. It is done with the help of shadow registers. This feature is controlled by the DSI Host video shadow control register (DSI_VSCR).

The new configuration is only used when the system requests for it. To update the video configuration during the transmission of a video frame, the configuration of that frame needs to be stored in the auxiliary registers. This way, the new frame configurations can be set through the APB interface without corrupting the current frame.

By default, this feature is disabled. To enable this feature, set the enable (EN) bit of the DSI Host video shadow control register (DSI_VSCR) to 1.

When this feature is enabled, the system supplies the configuration stored in the auxiliary registers.

*Figure 408* shows the necessary steps to update the LTDC interface configuration.

**Figure 408. Flow to update the LTDC interface configuration using shadow registers**

Immediate update

When the shadow register feature is active, the auxiliary registers require the LTDC configuration before the video engine starts. This means that, after a reset, update register (UR) bit is immediately granted.
When it is required to immediately update the active registers without the reset (as in Figure 409), ensure that the enable (EN) and update register (UR) bits of the DSI Host video shadow control register (DSI_VSCR) are set to 0.

**Figure 409. Immediate update procedure**

Updating the configuration during the transmission of a frame using APB

To update the LTDC interface configuration, follow the steps shown in Figure 410:

1. Ensure that the enable (EN) bit of the DSI Host video shadow control register (DSI_VSCR) register is set to 1.
2. Set the update register (UR) bit of DSI Host video shadow control register (DSI_VSCR) to 1.
3. Monitor the update register (UR) bit. This bit is set to 0 when the update is complete.

**Figure 410. Configuration update during the transmission of a frame**

Requesting a configuration update

It is possible to request for the LTDC interface configuration update at any part of the frame. DSI Host waits until the end of the frame to change the configuration. However, avoid sending the update request during the first line of the frame because the data must propagate between clock domains.
44.6 **Functional description: adapted command mode on LTDC interface**

The adapted command mode, enables the system to input a stream of pixel from the LTDC that is conveyed by DSI Host using the command mode transmission (using the DCS packets). The adapted command mode also supports pixel input control rate signaling and tearing effect report mechanism.

The adapted command mode makes it possible to send large amounts of data through the `memory_write_start` (WMS) and `memory_write_continue` (WMC) DCS commands. It helps in delivering a wider data bandwidth for the memory write operations sent in command mode to MIPI® displays and to refresh large areas of pixels in high resolution displays. If additional commands such as display configuration commands, read back commands, and tearing effect initialization are to be transferred, then the APB slave generic interface must be used to complement the adapted command mode functionality.

Adapted command mode of operation supports 16 bpp, 18 bpp, and 24 bpp RGB.

To transmit the image data in adapted command mode:

- Set command mode (CMDM) bit of the DSI Host mode configuration register (DSI_MCR) to 1.
- Set DSI mode (DSIM) bit in the DSI Wrapper configuration register (DSI_WCFGR) to 1.

To transmit the image data, follow these steps:

- Define the image area to be refreshed, by using the `set_column_address` and `set_page_address` DCS commands. The image area needs to be defined only once and remains effective until different values are defined.
- Define the pixel color coding to be used by using the color coding (COLC) field in the DSI Host LTDC color coding register (DSI_LCOLCR).
- Define the virtual channel ID of the LTDC interface generated packets using the virtual channel ID (VCID) field in the DSI Host LTDC VCID register (DSI_LVCIDR). These also need to be defined only once.
- Start transmitting the data from the LTDC setting the LTDC enable (LTDCEN) bit of the DSI_WCR register.

*Figure 411* shows the adapted command mode usage flow.
When the command mode (CMDM) bit of the DSI Host mode configuration register (DSI_CFRGR) is set to 1, the LTDC interface assume the behavior corresponding to the adapted command mode.

In this mode, the host processor can use the LTDC interface to transmit a continuous stream of pixels to be written in the local frame buffer of the peripheral. It uses a pixel input bus to receive the pixels and controls the flow automatically to limit the stream of continuous pixels. When the first pixel is received, the current value of the command size (CMDSIZE) field of the DSI Host LTDC command configuration register (DSI_LCCR), is shadowed to the internal interface function. The interface increments a counter on every valid pixel that is input through the interface. When this pixel counter reaches command size (CMDSIZE), a command is written into the command FIFO and the packet is ready to be transmitted through the DSI link.

If the last pixel arrives before the counter reaches the value of shadowed command size (CMDSIZE), a WMS command is issued to the command FIFO with word count (WC) set to the amount of bytes corresponding to the value of the counter. If more than CMDSIZE pixels are received (shadowed value), a WMS command is sent to the command FIFO with WC set to the number of bytes corresponding to the command size (CMDSIZE) and the counter is restarted.

After the first WMS command has been written to the FIFO, the circuit behaves in a similar way, but issues WMC commands instead of WMS commands. The process is repeated until the last pixel of the image is received. The core automatically starts sending a new packet.
when the last pixel of the image is received, falls or command size (CMDSIZE) limit is reached.

**Synchronization with the LTDC**

The DSI Wrapper performs the synchronization of the transfer process by:

- controlling the start/halt of the LTDC
- making the data flow control between LTDC and DSI Host.

The transfer to refresh the display frame buffer can be triggered

- manually, setting the LTDC enable (LTDCEN) bit of the DSI Wrapper control register (DSI_WCR)
- automatically when a tearing effect (TEIF) event occurs and automatic refresh (AR) is enabled.

The selection between manual and automatic mode is done through the automatic refresh (AR) bit of the DSI Wrapper configuration register (DSI_WCFGR).

Once the transfer of one frame is done whatever in manual or automatic refresh mode, the DSI Wrapper is halting the TFT display controller (LTDC) resetting the LTDC enable (LTDCEN) bit of the DSI Wrapper control register (DSI_WCR) and set the end of refresh interrupt flag (ERIF) flag of the DSI Wrapper status register (DSI_WSR). If the end of refresh interrupt enable (ERIE) bit of the DSI Wrapper configuration register (DSI_WCFGR) is set, an interrupt is generated.

The end of refresh interrupt flag (ERIF) flag of the DSI Wrapper status register (DSI_WSR) can be reset setting the clear end of refresh interrupt flag (CERIF) bit of the DSI Wrapper clear interrupt flag register (DSI_WCIFR).

The halting of the TFT display controller (LTDC) by the DSI Wrapper is done synchronously on a rising edge or a falling edge of VSync according to the VSync polarity (VSPOL) bit of the DSI Wrapper configuration register (DSI_WCFGR).

**Support of tearing effect**

The DSI specification supports tearing effect function in command mode displays. It enables the Host processor to receive timing accurate information about where the display peripheral is in the process of reading the content of its frame buffer.

The tearing effect can be managed through

- a separate pin, which is not covered in the DSI specification
- the DSI tearing effect functionality: a `set_tear_on DCS` command must be issued through the APB interface using the generic interface registers.

**Tearing effect through a GPIO**

When the tearing effect source (TESRC) bit of the DSI Wrapper configuration register (DSI_WCFGR) is set, the tearing effect is signaled through a GPIO.

The polarity of the input signal can be configured by the tearing effect polarity (TEPOL) bit of the DSI Wrapper configuration register (DSI_WCFGR).

When the programmed edge is detected, the tearing effect interrupt flag (TEIF) bit of the DSI Wrapper interrupt and status register (DSI_WISR) is set.

If the tearing effect interrupt enable (TEIE) bit of the DSI Wrapper interrupt enable register (DSI_WIER) is set, an interrupt is generated.
Tearing effect through DSI link

When the TESRC bit of the DSI Wrapper configuration register (DSI_WCFGR) is reset, the tearing effect is managed through the DSI link:

The DSI Host performs a double bus turn-around (BTA) after sending the set_tear_on command granting the ownership of the link to the DSI display. The display holds the ownership of the bus until the tear event occurs, which is indicated to the DSI Host by a D-PHY trigger event. The DSI Host then decodes the trigger and reports the event setting the tearing effect interrupt flag (TEIF) bit of the DSI Wrapper interrupt and status register (DSI_WISR).

If the tearing effect interrupt enable (TEIE) bit of the DSI Wrapper interrupt enable register (DSI_WIER) is set, an interrupt is generated.

To use this function, it is necessary to issue a set_tear_on command after the update of the display using the WMS and WMC DCS commands. This procedure halts the DSI link until the display is ready to receive a new frame update.

The DSI Host does not automatically generate the tearing effect request (double BTA) after a WMS/WMC sequence for flexibility purposes, so several regions of the display can be updated improving DSI bandwidth usage. Tearing effect request must always be triggered by a set_tear_on command in the DSI Host implementation.

Configure the following registers to activate the tearing effect:

- DSI Host command mode configuration register (DSI_CMCR): TEARE
- DSI Host protocol configuration register (DSI_PCR): BTAE.
44.7 **Functional description: APB slave generic interface**

The APB slave interface allows the transmission of generic information in command mode, and follows a proprietary register interface. Commands sent through this interface are not constrained to comply with the DCS specification, and can include generic commands described in the DSI specification as manufacturer-specific.

The DSI Host supports the transmission of write and read command mode packets as described in the DSI specification. These packets are built using the APB register access. The DSI Host generic payload data register (DSI_GPDR) has two distinct functions based on the operation. Writing to this register sends the data as payload when sending a command mode packet. Reading this register returns the payload of a read back operation. The DSI Host generic header configuration register (DSI_GHCR) contains the command mode packet header type and header data. Writing to this register triggers the transmission of the packet implying that for a long command mode packet, the packet payload needs to be written in advance in the DSI Host generic payload data register (DSI_GPDR).

The valid packets that can be transmitted through the generic interface are the following:

- Generic write short packet 0 parameters
- Generic write short packet 1 parameters
- Generic write short packet 2 parameters
- Generic read short packet 0 parameters
- Generic read short packet 1 parameters
- Generic read short packet 2 parameters
- Maximum read packet configuration
- Generic long write packet
- DCS write short packet 0 parameters
- DCS write short packet 1 parameters
- DCS read short packet 0 parameters
- DCS write long packet.

A set of bits in the DSI Host generic packet status register (DSI_GPSR) reports the status of the FIFO associated with APB interface support.

Generic interface packets are always transported using one of the DSI transmission modes, i.e. video mode or command mode. If neither of these modes is selected, the packets are not transmitted through the link and the related FIFO eventually becomes overflown.

### 44.7.1 Packet transmission using the generic interface

The transfer of packets through the APB bus is based on the following conditions:

- The APB protocol defines that the write and read procedure takes two clock cycles each to be executed. This means that the maximum input data rate through the APB interface is always half the speed of the APB clock.
- The data input bus has a maximum width of 32 bits. This allows for a relation to be defined between the input APB clock frequency and the maximum bit rate achievable by the APB interface.
- The DSI link pixel bit rate when using solely APB is (APB clock frequency) * 16 Mbit/s.
- When using only the APB interface, the theoretical DSI link maximum bit rate can be expressed as DSI link maximum bit rate = APB clock frequency (in MHz) * 32 / 2 Mbit/s.
In this formula, the number 32 represents the APB data bus width, and the division by two is present because each APB write procedure takes two clock cycles to be executed.

- The bandwidth is dependent on the APB clock frequency; the available bandwidth increases with the clock frequency.

To drive the APB interface to achieve high bandwidth command mode traffic transported by the DSI link, the DSI Host must operate in the command mode only and the APB interface must be the only data source that is currently in use. Thus, the APB interface has the entire bandwidth of the DSI link and does not share it with any another input interface source.

The memory write commands require maximum throughput from the APB interface, because they contain the most amount of data conveyed by the DSI link. While writing the packet information, first write the payload of a given packet into the payload FIFO using the DSI Host generic payload data register (DSI_GPDR). When the payload data is for the command parameters, place the first byte to be transmitted in the least significant byte position of the APB data bus.

After writing the payload, write the packet header into the command FIFO. For more information about the packet header organization on the 32-bit APB data bus, so that it is correctly stored inside the command FIFO.

When the payload data is for a memory write command, it contains pixel information and it must follow the pixel to byte conversion organization referred in the Annexe A of the DCS specification.

Figures 412 to 416 show how the pixel data must be organized in the APB data write bus.

The memory write commands are conveyed in DCS long packets, encapsulated in a DSI packet. The DSI specifies that the DCS command must be present in the first payload byte of the packet. This is also included in the diagrams. In figures 412 to 416, the write memory command can be replaced by the DCS command write memory Start and write memory Continue.

44.8 Functional description: timeout counters

The DSI Host includes counters to manage timeout during the various communication phases. The duration of each timeout can be configured by the six timeout counter configuration registers (DSI_TCCR0...5).

There are two types of counters:
- contention error detection timeout counters (Section 44.8.1)
- peripheral response timeout counters (Section 44.8.2).

44.8.1 Contention error detection timeout counters

The DSI Host implements a set of counters and conditions to notify the errors. It features a set of registers to control the timers used to determine if a timeout has occurred, and also contains a set of interruption status registers that are cleared upon a read operation (detailed in Table 434). Optionally, these registers also trigger an interrupt signal that can be used by the system to be activated when an error occurs within the DSI connection.

<table>
<thead>
<tr>
<th>Timeout counter</th>
<th>Value register</th>

<td>TOHSTX</td>
</tr>
<tr>
<td>Low-power reception</td>
<td>DSI_TCCR1</td>
<td>TOLPRX</td>
<td>DSI_ISR1</td>
<td>TOLPRX</td>
</tr>
</tbody>
</table>

Time units for these 16-bit counters are configured in cycles defined in the timeout clock division (TOCKDIV) field in the DSI Host clock control register (DSI_CCR).

The value written to the timeout clock division (TOCKDIV) field in the DSI Host clock control register (DSI_CCR) defines the time unit for the timeout limits using the lane byte clock as input.

This mechanism increases the range to define these limits.

High-speed transmission contention detection

The timeout duration is configured in the high-speed transmission timeout count (HSTX_TOCNT) field of the DSI Host timeout counter configuration register 1 (DSI_TCCR0). A 16-bit counter measures the time during which the high-speed mode is active.

If that counter reaches the value defined by the high-speed transmission timeout count (HSTX_TOCNT) field of the DSI Host timeout counter configuration register 1 (DSI_TCCR0), the timeout high-speed transmission (TOHSTX) bit in the DSI Host interrupt and status register 1 (DSI_ISR1) is asserted and an internal soft reset is generated to the DSI Host.

If the timeout high-speed transmission interrupt enable (TOHSTXIE) bit of the DSI Host interrupt enable register 1 (DSI_IER1) is set, an interrupt is generated.

Low-power reception contention detection

The timeout is configured in the low-power reception timeout counter (LPRX_TOCNT) field of the DSI Host timeout counter configuration register 1 (DSI_TCCR1). A 16-bit counter measures the time during which the low-power reception is active.
If that counter reaches the value defined by the low-power reception timeout counter (LPRX_TOCNT) field of the DSI Host timeout counter configuration register 1 (DSI_TCCR0), the timeout low-power reception (TOLPRX) bit in the DSI Host interrupt and status register 1 (DSI_ISR1) is asserted and an internal soft reset is generated to the DSI Host.

If the timeout low-power reception interrupt enable (TOLPRXIE) bit of the DSI Host interrupt enable register 1 (DSI_IER1) is set, an interrupt is generated. Once the software gets notified by the interrupt, it must reset the D-PHY by de-asserting and asserting the Digital enable (DEN) bit of the DSI Host PHY control register (DSI_PCTLR).

### 44.8.2 Peripheral response timeout counters

A peripheral may not immediately respond correctly to some received packets. For example, a peripheral receives a read request, but due to its architecture cannot access the RAM for a while (e.g. the panel is being refreshed and takes some time to respond). In this case, set a timeout to ensure that the host waits long enough so that the device is able to process the previous data before receiving the new data or responding correctly to new requests.

*Table 435* lists the events belonging to various categories having an associated timeout for peripheral response.

The DSI Host ensures that, on sending an event that triggers a timeout, the D-PHY switches to the Stop state and a counter starts running until it reaches the value of that timeout. The link remains in the LP-11 state and unused until the timeout ends, even if there are other events ready to be transmitted.

Figures 417 to 419 illustrate the flow of counting in the PRESP_TO counter for the three categories listed in *Table 435*.

The values in these registers are measured in number of cycles of the lane byte clock. These registers are only used in command mode because in video mode, there is a rigid timing schedule to be met to keep the display properly refreshed and it must not be broken by these or any other timeouts. Setting a given timeout to 0 disables going into LP-11 state and timeout for events of that category.

The read and the write requests in high-speed mode are distinct from the read and the write requests in low-power mode. For example, if HSRD_TOCNT is set to zero and LPRD_TOCNT is set to a non-zero value, a generic read with no parameters does not activate the PRESP_TO counter in high-speed, but it activates the PRESP_TO in low-power.

The DSI Host timeout counter configuration register 4 (DSI_TCCR3) includes a special Presp mode (PM) bit to change the normal behavior of PRESP_TO in Adaptive command mode.
mode for high-speed write operation timeout. When set to 1, this bit allows the PRESP_TO
from HSWR_TOCNT to be used only once, when both of the following conditions are met:
- the LTDC VSYNC signal rises and falls
- the packets originated from the LTDC interface in adapted command mode are
  transmitted and its FIFO is empty again.

In this scenario, non-adapted command mode requests are not sent to the D-PHY, even if
there is traffic from the generic interface ready to be sent, returning them to the Stop state.
When it happens, the PRESP_TO counter is activated and only when it is completed, the
DSI Host sends any other traffic that is ready, as illustrated in Figure 420.

*Figure 420. Effect of prep mode at 1*
### 44.9 Functional description: transmission of commands

#### 44.9.1 Transmission of commands in video mode

The DSI Host supports the transmission of commands, both in high-speed and low-power, while in video mode. The DSI Host uses blanking or low-power (BLLP) periods to transmit commands inserted through the APB generic interface. Those periods correspond to the gray areas of Figure 421.

**Figure 421. Command transmission periods within the image area**

Commands are transmitted in the blanking periods after the following packets/states:

- Vertical Sync Start (VSS) packets, if the video sync pulses are not enabled
- Horizontal sync end (HSE) packets, in the VSA, VBP, and VFP regions
- Horizontal sync Start (HSS) packets, if the video sync pulses are not enabled in the VSA, VBP, and VFP regions
- Horizontal active (HACT) state

Besides the areas corresponding to BLLP, large commands can also be sent during the last line of a frame. In that case, the line time for the video mode is violated and the edpihalt signal is set to request the DPI video timing signals to remain inactive. Only if a command does not fit into any BLLP area, it is postponed to the last line, causing the violation of the line time for the video mode, as illustrated in Figure 422.
Only one command is transmitted per line, even in the case of the last line of a frame but one command is possible for each line.

There can be only one command sent in low-power per line. However, one low-power command is possible for each line. In high-speed, the DSI Host can send more than one command, as many as it determines to fit in the available time.

The DSI Host avoids sending commands in the last line because it is possible that the last line is shorter than the other ones. For instance, the line time (tL) can be half a cycle longer than the tL on the LTDC interface, that is, each line in the frame taking half a cycle from time for the last line. This results in the last line being (½ cycle) x (number of lines -1) shorter than tL.

The COLM and SHTDN bits of the DSI Wrapper control register (DSI_WCR) are also able to trigger the sending of command packets. The commands are:

- Color mode ON
- Color mode OFF
- Shut down peripheral
- Turn on peripheral

These commands are not sent in the VACT region. If the low-power command enable (LPCE) bit of the DSI Host video mode configuration register (DSI_VMCR) is set, these commands are sent in low-power mode.

In low-power mode, the largest packet size (LPSIZE) field of the DSI Host low-power mode configuration register (DSI_LPMCR) is used to determine if these commands can be transmitted. It is assumed that largest packet size (LPSIZE) is greater than or equal to four bytes (number of bytes in a short packet), because the DSI Host does not transmit these commands on the last line.

If the frame bus-turn-around acknowledge enable (FBTAAE) bit is set in the DSI Host low-power mode configuration register (DSI_LPMCR), a BTA is generated by DSI Host after the last line of a frame. This may coincide with a write command or a read command. In either case, the LTDC interface is halted until an acknowledge is received (control of the DSI bus is returned to the host).
44.9.2 Transmission of commands in low-power mode

DSI Host can be configured to send the low-power commands during the high-speed video mode transmission.

To enable this feature, set the Low Power command enable (LPCE) bit of the DSI Host video mode configuration register (DSI_VMCR) to 1. In this case, it is necessary to calculate the time available, in bytes, to transmit a command in low-power mode to horizontal front-porch (HFP), vertical sync active (VSA), vertical back-porch (VBP), and vertical front-porch (VFP) regions.

Bits 8 to 13 of the video mode configuration register (DSI_VMCR) register indicate if DSI Host can go to LP when in idle. If the low-power command enable (LPCE) bit is set and non-video packets are in queue, DSI Host ignores the low-power configuration and transmits low-power commands, even if it is not allowed to enter low-power mode in a specific region. After the low-power commands transmission, DSI Host remains in low-power until a sync event occurs.

For example, consider that the VFP is selected as high-speed region (LPVFPE = 1'b0) with LPCE set as a command to transmit in low-power in the VPF region. This command is transmitted in low-power, and the line stays in low-power mode until a new HSS arrives.

Calculating the time to transmit commands in LP mode in the VSA, VBP, and VFP Regions

The largest packet size (LPSIZE) field of the DSI Host low-power mode configuration register (DSI_LPMCR) indicates the time available (in bytes) to transmit a command in low-power mode (based on the escape clock) on a line during the VSA, VBP, and the VFP regions.

Calculation of largest packet size (LPSIZE) depends on the used video mode. 

*Figure 423* illustrates the timing intervals for the video mode in non-burst with sync pulses, while *Figure 424* refers to video mode in burst and non-burst with sync events.
This time is calculated as follows:

$$LPSIZE = \left( t_L - (t_{H1} + t_{HS->LP} + t_{LPDT} + 2 \times t_{ESCCLK}) \right) / (2 \times 8 \times t_{ESCCLK})$$

- $t_L$ = line time
- $t_{H1}$ = time of the HSA pulse for sync pulses mode (Figure 423) or time to send the HSS packet, including EoTp (Figure 424)
- $t_{HS->LP}$ = time to enter the low-power mode
- $t_{LP->HS}$ = time to leave the low-power mode
- $t_{LPDT}$ = D-PHY timing related with escape mode entry, LPDT command, and escape exit. According to the D-PHY specification, this value is always 11 bits in LP (or 22 TX escape clock cycles)
- $t_{ESCCLK}$ = escape clock period as programmed in the TXECKDIV field of the DSI_CCR register
- $t_{ESCCLK}$ = delay imposed by the DSI Host implementation.

In the above equation, division by eight is done to convert the available time to bytes. Division by two is done because one bit is transmitted every two escape clock cycles. The largest packet size (LPSIZE) field can be compared directly with the size of the command to be transmitted to determine if there is enough time to transmit the command. The maximum size of a command that can be transmitted in low-power mode is limited to 255 bytes by this field. You must program this register to a value greater than or equal to 4 bytes for the transmission of the DCTRL commands, such as shutdown and color in low-power mode.

Consider an example of a frame with 12.4 $\mu$s per line and assume an escape clock frequency of 20 MHz and a lane bit rate of 800 Mbits. In this case, it is possible to send 124 bits in escape mode (that is, 124 bit = 12.4 $\mu$s * 20 MHz / 2). Still, you need to take into consideration the D-PHY protocol and PHY timings.

The following assumptions are made:

- lane byte clock period is 10 ns (800 Mbits per lane)
- escape clock period is 50 ns (DSI_CCR.TXECKDIV = 5)
- video is transmitted in non-burst mode with sync pulses bounded by HSS and HSE packets
- DSI is configured for two lanes
- D-PHY takes 180 ns to transit from low-power to high-speed mode (DSI_DLTCR.LS2HS_TIME = 18)
- D-PHY takes 200 ns to transit from high-speed to low-power mode (DSI_DLTCR.HS2LP_TIME = 20)
- $t_{HSA} = 420$ ns.

In this example, a 13-byte command can be transmitted as follows:

$$LPSIZE = \left( 12.4 \mu s - (420 \text{ ns} + 180 \text{ ns} + 200 \text{ ns} + (22 \times 50 \text{ ns} + 2 \times 50 \text{ ns})) \right) / (2 \times 8 \times 50 \text{ ns}) = 13 \text{ bytes.}$$

### Calculating the time to transmit commands in low-power mode in HFP region

The VACT largest packet size (VLPSIZE) field of the DSI Host low-power mode configuration register (DSI_LPMCR) indicates the time available (in bytes) to transmit a command in low-power mode (based on the escape clock) in the vertical active (VACT) region.
To calculate the value of VACT largest packet size (VLPSIZE), consider the video mode being used. Figure 425 shows the timing intervals for video mode in non-burst with sync pulses, Figure 426 those for video mode in non-burst with sync events, and Figure 427 refers to the burst video mode.

**Figure 425. VLPSIZE for non-burst with sync pulses**

![Diagram for non-burst with sync pulses]

**Figure 426. VLPSIZE for non-burst with sync events**

![Diagram for non-burst with sync events]

**Figure 427. VLPSIZE for burst mode**

![Diagram for burst mode]

This time is calculated as follows:

\[
VLPSIZE = \frac{t_L - (t_{HSA} + t_{HBP} + t_{HACT} + t_{HS->LP} + t_{LP->HS} + t_{LPDT} + 2 \times t_{ESCCLK})}{2 \times 8 \times t_{ESCCLK}}
\]

where

- \( t_L \) = line time
- \( t_{HSA} \) = time of the HSA pulse (DSI_VHSACR.HSA)
- \( t_{HBP} \) = time of horizontal back-porch (DSI_VHBPCR.HBP)
- \( t_{HACT} \) = time of video active. For burst mode, the video active is time compressed and is calculated as 
  \( t_{HACT} = VPSIZE \times \text{Bytes per Pixel} / \text{Number Lanes} \times \text{Lane_byte_clk} \)
- \( t_{ESCCLK} \) = escape clock period as programmed in TXECKDIV field of the DSI_CCR register.
The VLPSIZE field can be compared directly with the size of the command to be transmitted to determine if there is time to transmit the command.

Consider an example of a frame with 16.4 μs per line and assume an escape clock frequency of 20 MHz and a lane bit rate of 800 Mbits/s. In this case, it is possible to send 420 bits in escape mode (that is, 164 bits = 16.4 μs * 20 MHz / 2). Still, since it is the vertical active region of the frame, take into consideration the HSA, HBP, and HACT timings apart from the D-PHY protocol and PHY timings. The following assumptions are made:

- number of active lanes is four
- Lane byte clock period (lanebyteclkperiod) is 10 ns (800 Mbits per lane)
- escape clock period is 50 ns (DSI_CCR.TXECCKDIV = 5)
- D-PHY takes 180 ns to pass from low-power to high-speed mode (DSI_DLTCR.LP2HS_TIME = 18)
- D-PHY takes 200 ns to pass from high-speed to low-power mode (DSI_DLTCR.HS2LP_TIME = 20)
- \( t_{\text{HSA}} = 420 \text{ ns} \)
- \( t_{\text{HBP}} = 800 \text{ ns} \)
- \( t_{\text{HACT}} = 12800 \text{ ns to send 1280 pixel at 24 bpp} \)
- video is transmitted in non-burst mode
- DSI is configured for four lanes.

In this example, consider that video is sent in non-burst mode. The VLPSIZE is calculated as follows:

\[
\text{VLPSIZE} = \frac{(16.4 \mu s - (420 \text{ ns} + 800 \text{ ns} + 12.8 \mu s + 180 \text{ ns} + 200 \text{ ns} + (22 \times 50 \text{ ns} + 2 \times 50 \text{ ns}))}{2 \times 8 \times 50 \text{ ns}} = 1 \text{ byte}
\]

Only one byte can be transmitted in this period. A short packet (for example, generic short write) requires a minimum of four bytes. Therefore, in this example, commands are not sent in the VACT region.

If burst mode is enabled, more time is available to transmit the commands in the VACT region, because HACT is time compressed.

\[
\text{VLPSIZE} = \frac{(16.4 \mu s - (420 \text{ ns} + 800 \text{ ns} + (1280 \times 3 / 4 \times 10 \text{ ns}) + 180 \text{ ns} + 200 \text{ ns} + (22 \times 50 \text{ ns} + 2 \times 50 \text{ ns}))}{2 \times 8 \times 50 \text{ ns}} = 5 \text{ bytes}
\]

For burst mode, the VLPSIZE is 5 bytes and then a 4-byte short packet can be sent.

**Transmission of commands in different periods**

The LPSIZE and VLPSIZE fields allow a simple comparison to determine if a command can be transmitted in any of the BLLP periods.

*Figure 428* illustrates the meaning of VLPSIZE and LPSIZE, matching them with the shaded areas and the VACT region.
44.9.3 Transmission of commands in high-speed

If the LPCE bit of the DSI_VMCR register is 0, the commands are sent in high-speed in video mode. In this case, the DSI Host automatically determines the area where each command can be sent and no programming or calculation is required.

44.9.4 Read command transmission

The MRD_TIME field of the register configures the maximum amount of time required to perform a read command in lane byte clock cycles, it is calculated as:

\[
\text{MRD\_TIME} = \frac{t_{\text{HS->LP}} + t_{\text{LP->HS}} + t_{\text{read}} + 2 \times t_{\text{BTA}}}{\text{lanebyteclkperiod}}
\]

The time to return the read data packet from the peripheral depends on the number of bytes read and the escape clock frequency of the peripheral, not the escape clock of the host. The MRD_TIME field is used in both high-speed and low-power mode to determine if there is time to complete a read command in a BLLP period.

In high-speed mode (LPCE = 0), MRD_TIME is calculated as follows:

\[
\text{MRD\_TIME} = \frac{t_{\text{HS->LP}} + t_{\text{LP->HS}} + t_{\text{read}} + 2 \times t_{\text{BTA}}}{\text{lanebyteclkperiod}}
\]

In low-power mode (LPCE = 1), MRD_TIME is calculated as follows:

\[
\text{MRD\_TIME} = \frac{t_{\text{HS->LP}} + t_{\text{LP->HS}} + t_{\text{LPDT}} + t_{\text{lpred}} + t_{\text{read}} + 2 \times t_{\text{BTA}}}{\text{lanebyteclkperiod}}, \text{ where:}
\]

- \( t_{\text{HS->LP}} \) = time to enter the low-power mode
- \( t_{\text{LP->HS}} \) = time to leave the low-power mode
- \( t_{\text{LPDT}} \) = D-PHY timing related to escape mode entry, LPDT command, and escape mode exit (according to the D-PHY specification, this value is always 11 bits in LP, or 22 TX escape clock cycles)
- \( t_{\text{lpred}} \) = read command time in low-power mode (64 * TX esc clock)
- \( t_{\text{read}} \) = time to return the read data packet from the peripheral
- \( t_{\text{BTA}} \) = time to perform a bus-turn-around (D-PHY dependent).
It is recommended to keep the maximum number of bytes read from the peripheral to a minimum to have sufficient time available to issue the read commands in a line time. Ensure that MRD_TIME x lane byte clock period is less than LPSIZE x 16 x escape clock period of the host, otherwise, the read commands are dispatched on the last line of a frame. If it is necessary to read a large number of parameters (> 16), increase the MRD_TIME while the read command is being executed. When the read has completed, decrease the MRD_TIME to a lower value.

If a read command is issued on the last line of a frame, the LTDC interface is halted and stays halted until the read command is in progress. The video transmission must be stopped during this period.

44.9.5 Clock lane in low-power mode

To reduce the power consumption of the D-PHY, the DSI Host, when not transmitting in the high-speed mode, allows the clock lane to enter into the low-power mode. The controller automatically handles the transition of the clock lane from HS (clock lane active sending clock) to LP state without direct intervention by the software. This feature can be enabled by configuring the DPCC and the ACR bits of the DSI_CLCR register.

In the command mode, the DSI Host can place the clock lane in the low-power mode when it does not have any HS packets to transmit.

In the video mode (LTDC interface), the DSI Host controller uses its internal video and PHY timing configurations to determine if there is time available for the clock line to enter the low-power mode and not compromise the video data transmission of pixel data and sync events.

Along with a correct configuration of the video mode (see Section 44.5: Functional description: video mode on LTDC interface), the DSI Host needs to know the time required by the clock lane to go from high-speed to low-power mode and vice-versa. The values required can be obtained from the D-PHY specification: program the DSI_CLTCR register with the following values:

- **HS2LP_TIME =** time from HS to LP in clock lane / byte clock period in HS (lanebyteclk)
- **LP2HS_TIME =** time from LP to HS in clock lane / byte clock period in HS (lanebyteclk)

Based on the programmed values, the DSI Host calculates if there is enough time for the clock lane to enter the low-power mode during inactive regions of the video frame.

The DSI Host decides the best approach to follow regarding power saving out of the three possible scenarios:

- there is no enough time to go to the low-power mode. Therefore, blanking period is added as shown in Figure 429
- there is enough time for the data lanes to go to the low-power mode but not enough time for the clock lane to enter the low-power mode, see Figure 430.
- there is enough time for both data lanes and clock lane to go to the low-power mode, as in Figure 431.

**Figure 429. Clock lane and data lane in HS**
Figure 430. Clock lane in HS and data lanes in LP

Figure 431. Clock lane and data lane in LP
44.10 **Functional description: virtual channels**

The DSI Host supports choosing the virtual channel (VC) for use for each interface. Using multiple virtual channels, the system can address multiple displays at the same time, when each display has a different virtual channel identifier.

When the LTDC interface is configured for a particular virtual channel, it is possible to use the APB slave generic interface to issue the commands while the video stream is being transmitted. With this, it is possible to send the commands through the ongoing video stream, addressing different virtual channels and thus enable the interface with multiple displays. During the video mode, the video stream transmission has the maximum priority. Therefore, the transmission of sideband packets such as the ones from the generic interface are only transported when there is time available within the video stream transmission. The DSI Host identifies the available time periods and uses them to transport the generic interface packets. *Figure 432* illustrates where the DSI Host inserts the packets from the APB generic interface within the video stream transmitted by the LTDC interface.

*Figure 432. Command transmission by the generic interface*

It is also possible to address the multiple displays with only the generic interface using different virtual channels. Because the generic interface is not restricted to any particular virtual channel through configuration, it is possible to issue the packets with different virtual channels. This enables the interface to time multiplex the packets to be provided to the displays with different virtual channels.

You can use the following configuration registers to select the virtual channel ID associated with transmissions over the LTDC and APB slave generic interfaces:

- DSI_LVCIDR.VCID field configures the virtual channel ID that is indexed to the video mode packets using the LTDC interface.
- DSI_GHCR register configures the packet header (which includes the virtual channel ID to be used) for transmissions using APB slave generic interface.
- DSI_GVCIDR register configures the virtual channel ID of the read responses to store and return to the generic interface.
44.11 Functional description: video mode pattern generator

The video mode pattern generator allows the transmission of horizontal/vertical color bar and D-PHY BER testing pattern without any stimuli.

The frame requirements must be defined in video registers that are listed in Table 437.

44.11.1 Color bar pattern

The color bar pattern comprises eight bars for white, yellow, cyan, green, magenta, red, blue, and black colors.

Each color width is calculated by dividing the line pixel size (vertical pattern) or the number of lines (horizontal pattern) by eight. In the vertical color bar mode (Figure 433), each single color bar has a width of the number of pixels in a line divided by eight. In case the number of pixels in a line is not divisible by eight, the last color (black) contains the remaining.

In the horizontal color bar mode (Figure 434), each color line has a color width of the number of lines in a frame divided by eight. In case the number of lines in a frame is not divisible by eight, the last color (black) contains the remaining lines.

44.11.3 BER testing pattern

The BER testing pattern simplifies conformance testing. This pattern tests the RX D-PHY capability to receive the data correctly. The following data patterns are required:

- X bytes of 0xAA (high-frequency pattern, inverted)
- X bytes of 0x33 (mid-frequency pattern)
- X bytes of 0xF0 (low-frequency pattern, inverted)
- X bytes of 0x7F (lone 0 pattern)
- X bytes of 0x55 (high-frequency pattern)
- X bytes of 0xCC (mid-frequency pattern, inverted)
- X bytes of 0x0F (low-frequency pattern)
- Y bytes of 0x80 (lone 1 pattern).

In most cases, Y is equal to X. However, depending on line length and the color coding used, Y may be different from X. With RGB888 color coding and horizontal resolution in multiples of eight, the pattern shown in Figure 435 appears on the DSI display.
44.11.4 **Video mode pattern generator resolution**

Depending on the orientation, BER mode, and color coding, the smallest resolutions accepted by the video mode pattern generator are:

- BER mode: 8x8
- horizontal color bar mode: 8x8
- vertical color bar mode: 8x8.

**Vertical pattern**

The width of each color bar is determined by the division of horizontal resolution (pixels) for eight test pattern colors. If the horizontal resolution is not divisible by eight, the last color (black) is extended to fill the resolution.

In the example in *Figure 436*, the horizontal resolution is 103.

*Figure 436. Vertical pattern (103x15)*

![Vertical pattern](image)

**Horizontal pattern**

The width of each color bar is determined by the division of the number of vertical resolution (lines) for eight test pattern colors. If the vertical resolution is not divisible by eight, the last color (black) is extended to fill the resolution, as shown in *Figure 437*.

*Figure 437. Horizontal pattern (103x15)*

![Horizontal pattern](image)
44.12 Functional description: D-PHY management

The embedded MIPI® D-PHY is control directly by the DSI Host and is configured through the DSI Wrapper.

A dedicated PLL and a dedicated bias are also embedded to supply the clock and the power supply to the DSI and D-PHY.

44.12.1 D-PHY configuration

The D-PHY configuration is carried out through the DSI Wrapper thanks to the DSI_WPCRx registers.

Slew-rate tuning on pins

To fine tune DSI communication, slew-rates can be adjusted:

- clock slew rate for HS-TX speed through the DSI_DPCSRCR
- data slew rate for HS-TX speed through the DSI_DPDLOSRCR and DSI_DPDLO1SRCR

Band setting

The frequency band of the D-PHY is controlled by the DSI_DPCBCR register for the clock lane and by the DSI_DPDLOBCR and DSI_DPDLO1BCR for the data lanes, it must be adjusted for clock and data lanes.

Custom lane configuration

To ease DSI integration, lane pins can be swapped on a lane as described in Table 440.

44.12.2 D-PHY HS2LP and LP2HS durations

The DSI system is able to switch to LP mode during blanking period if there is enough time between two HS transmission.

To be able to make the scheduling and estimate if it is possible or not to make the switch, the duration of the transitions from HS to LP and from LP to HS must be programmed in the DSI Host in the DSI_CLTCR register for the clock lane and in the DSI_DLTCR register for the data lanes.

Table 441 gives an estimation of the values to be programmed for these timings, expressed in lane byte clock cycles.
44.12.3 Special D-PHY operations

The DSI Wrapper features some control bits to force the D-PHY in some particular state and/or behavior.

Forcing lane state

It is possible to force the data lane and/or the clock lane in TX Stop mode through the bits FTXSMDL and FTXSMCL of the DSI_WPCR0 register.

Setting this bits causes the respective lane module to immediately jump in transmit control mode and to begin transmitting a stop state (LP-11).

This feature can be used to go back in TX mode after a wrong BTA sequence.

44.12.4 DSI PLL control

The dedicated DSI PLL is controlled through the DSI Wrapper, as shown in Figure 438.

![Figure 438. PLL block diagram](image)

The PLL output frequency is configured through the DSI_WRPCR register fields. The VCO frequency and the PLL output frequency are calculated as follows:

\[ F_{VCO} = (CLK_{IN} / IDF) \times 2 \times NDIV, \]

\[ PHI = F_{VCO} / ODF \]
where:
- \( \text{CLKIN} \) is in the 4 to 100 MHz range
- \( \text{DSI\_WRPCR\_NDIV} \) is in the 1 to 511 range
- \( \text{DSI\_WRPCR\_IDF} \) is in the 1 to 511 range
- \( F_{\text{PFD}} \) is in the 2 to 100 MHz range
- \( F_{\text{VCO}} \) is in the 500 MHz to 1 GHz range
- \( \text{DSI\_WRPCR\_ODF} \) can be 1 to 511
- \( \text{PHI} \) is in the 31.25 to 500 MHz range

The PLL is enabled by setting the PLLEN bit in the DSI\_WRPCR register.

Once the PLL is locked, the PLLLIF bit is set in the DSI\_WISR. If the PLLLIE bit is set in the DSI\_WIER, an interrupt is generated.

The PLL status (lock or unlock) can be monitored with the PLLLS flag in the DSI\_WISR register.

If the PLL gets unlocked, the PLLUIF bit of the DSI\_WISR is set. If the PLLUIE bit of the DSI\_WIER register is set, an interrupt is generated.

The DSI PLL settings can be changed only when the PLL is disabled.

### 44.12.5 D-PHY bias control

The bias providing the reference to the D-PHY is enabled setting the PWRUP bit of the DSI\_BCFGR register.

### 44.13 Functional description: interrupts and errors

The interrupts can be generated either by the DSI Host or by the DSI Wrapper.

All the interrupts are merged in one interrupt lane going to the interrupt controller.

#### 44.13.1 DSI Wrapper interrupts

An interrupt can be produced on the following events:
- tearing effect event
- end of refresh
- PLL locked
- PLL unlocked

Separate interrupt enable bits are available for flexibility.

Table 442. DSI Wrapper interrupt requests
44.13.2 DSI Host interrupts and errors

The DSI_ISR0 and DSI_ISR1 registers are associated with error condition reporting. These registers can trigger an interrupt to inform the system about the occurrence of errors.

The DSI Host has one interrupt line that is set high when an error occurs in either the DSI_ISR0 or the DSI_ISR1 register.

The triggering of the interrupt can be masked by programming the mask registers DSI_IER0 and DSI_IER1. By default all errors are masked. When any bit of these registers is set to 1, it enables the interrupt for a specific error. The error bit is always set in the respective DSI_ISR register. The DSI_ISR0 and DSI_ISR1 registers are always cleared after a read operation. The interrupt line is cleared if all registers that caused the interrupt are read.

The interrupt force registers (DSI_FIR0 and DSI_FIR1) are used for test purposes: they allow triggering the interrupt events individually without the need to activate the conditions that trigger the interrupt sources (it is extremely complex to generate the stimuli for that purpose). This feature also facilitates the development and testing of the software associated with the interrupt events. Setting any bit of these registers to 1 triggers the corresponding interrupt.
The light yellow boxes in Figure 439 illustrate the location of some of the errors.

**Figure 439. Error sources**

Table 443 explains the reasons that set off these interrupts and also explains how to recover from these interrupts.

44.14 Programing procedure

To operate the DSI Host the user must be familiar with the MIPI® DSI specification. Every software programmable register is accessible through the APB interface.

44.14.1 Programing procedure overview

The programming procedure for video mode or adapted command mode must respect the following order:

1. Configure the RCC (refer to the RCC chapter)
   - Enable clock for DSI and LTDC
   - Configure LTDC PLL, turn it ON and wait for its lock
2. Optionally configure the GPIO (if tearing effect requires GPIO usage for example)
3. Optionally valid the ISR
4. Configure the LTDC (refer to the LTDC chapter)
   - Program the panel timings
   - Enable the relevant layers
5. Turn on the DSI bias
6. Configure the DSI PLL, turn it ON and wait for its lock as described in Section 44.12.4
7. Configure the D-PHY parameters in the DSI Host, DSI D_PHY and the DSI Wrapper to define D-PHY configuration and timing as detailed in Section 44.14.2
8. Configure the DSI Host timings as detailed in Section 44.14.3
9. Configure the DSI Host flow control and DBI interface as detailed in Section 44.14.4
10. Configure the DSI Host LTDC interface as detailed in Section 44.14.5
11. Configure the DSI Host for video mode as detailed in Section 44.14.6 or adapted command mode as detailed in Section 44.14.7
12. Enable the D-PHY setting the DEN bit of the DSI_PCTRL
13. Enable the D-PHY clock lane setting the CKEN bit of the DSI_PCTRL
14. Enable the DSI Host setting the EN bit of the DSI_CR
15. Enable the DSI Wrapper setting the DSIEN bit of the DSI_WCR
16. Optionally send DCS commands through the APB generic interface to configure the display
17. Enable the LTDC in the LTDC
18. Start the LTDC flow through the DSI Wrapper (CR.LTDCEN = 1)

In video mode, the data streaming starts as soon as the LTDC is enabled.

In adapted command mode, the frame buffer update is launched as soon as the CR.LTDCEN bit is set.

44.14.2 Configuring the D-PHY parameters

The D-PHY requires a specific configuration prior starting any communications. The configuration parameters are stored either in the DSI Host or the DSI Wrapper.
Configuring the D-PHY parameters

The D-PHY must be configured to adjust:

- the slew rate for the clock lane through register DSI_DPCSRC
- the slew rate for the data lanes through DSI_DPDL0SRC and DSIDPDL1SRC
- the frequency band for the clock lane through DSI_DPCLBCR
- the frequency band for the data lanes through DSI_DPDL0BCR and DSI_DPBL1BCR

Configuring the D-PHY parameters in the DSI Host

The DSI Host stores the configuration of D-PHY timing parameters and number of lanes.

The following fields must be configured prior to any startup:

- Number of data lanes in the DSI_PCONFR register
- Automatic clock lane control (ACR) in the DSI_CLCR register
- Clock control (DPCC) in the DSI_CLCR register
- Time for LP/HS and HS/LP transitions for both clock lane and data lanes in DSI_CLTCR and DSI_DLTCR registers
- Stop wait time in the DSI_PCONFR register

44.14.3 Configuring the DSI Host timing

All the protocol timing must be configured in the DSI Host.

Clock divider configuration

Two clocks are generated internally

- Timeout clock
- TX escape clock.

The timeout clock is used as the timing unit in the configuration of HS to LP and LP to HS transition error. Its division factor is configured by the timeout clock division (TOCKDIV) field of the DSI Host clock control register (DSI_CCR).

The TX escape clock is used in low-power transmission. Its division factor is configured by the TX escape clock division (TXECKDIV) field of the DSI Host clock control register (DSI_CCR) relatively to the lanebyteclock. Its typical value must be around 20 MHz.

Timeout configuration

The timings for timeout management as described in Section 44.8 are configured in the DSI Host timeout counter configuration registers (DSI_TCCR0 to DSI_TCCR5).

44.14.4 Configuring flow control and DBI interface

The flow control is configured thanks to the DSI Host protocol configuration register (DSI_PCR). The configuration parameters are the following

- CRC reception enable (CRCRXE bit)
- ECC reception enable (ECCRXE bit)
- BTA enable (BTAE bit)
- EoTp reception enable (ETRXE bit)
- EoTp transmission enable (ETTXE bit)
Their values depend on the protocol to be used for the communication with the DSI display.

The virtual channel ID used for the generic DBI interface must be configured by the virtual channel ID (VCID) field of the DSI Host generic VCID register (DSI_GVCIDR).

All the DCS command, depending on their type, can be transmitted or received either in high-speed or low-power. For each of them, a dedicated configuration bit must be programmed in the DSI Host command mode configuration register (DSI_CMCR).

Acknowledge request for packet or tearing effect event must also be configured in the DSI Host command mode configuration register (DSI_CMCR).

44.14.5 Configuring the DSI Host LTDC interface

As the DSI Host is interface to the system through the LTDC for video mode or adapted command mode, the DSI Wrapper perform a low level interfacing in between.

The parameter programmed into the DSI Wrapper must be aligned with the parameters programmed into the LTDC and the DSI Host.

The following fields must be configured:

- Virtual channel ID in the virtual channel ID (VCID) field of the DSI Host LTDC VCID register (DSI_LVCIDR).
- Color coding (COLC) field of the DSI Host LTDC color coding register (DSI_LCOLCR) and the color multiplexing (COLMUX) in the DSI Wrapper configuration register (DSI_WCFGR).
- If loose packets are used for 18-bit mode, the loosely packet enable (LPE) bit of the DSI Host LTDC color coding register (DSI_LCOLCR) must be set.
- The HSYNC polarity in the HSync polarity (HSP) bit of the DSI Host LTDC polarity configuration register (DSI_LPCR).
- The VSYNC polarity in the VSync polarity (VSP) bit of the DSI Host LTDC polarity configuration register (DSI_LPCR) and in the VSync polarity (VSPOL) bit of the DSI Wrapper configuration register (DSI_WCFGR).
- The DATA ENABLE polarity data enable polarity (DEP) bit of the DSI Host LTDC polarity configuration register (DSI_LPCR).
44.14.6 Configuring the video mode

The video mode configuration defines the behavior of the controller in low-power for command transmission, the type of video transmission (burst or non-burst mode) and the panel horizontal and vertical timing:

- Select the video transmission mode to define how the processor requires the video line to be transported through the DSI link.
  - Configure the low-power transitions in the DSI_VMCR to define the video periods which are permitted to go to low-power if there is time available to do so.
  - Configure if the controller must request the peripheral acknowledge message at the end of frames (DSI_VMCR.FBTAAE).
  - Configure if commands are to be transmitted in low-power (DSI_VMCR.LPE).
- Select the video mode type
  - Burst mode:
    Configure the video mode type (DSI_VMCR.VMT) with value 2'b1x.
    Configure the video packet size (DSI_VPCR.VPSIZE) with the size of the active line period, measured in pixels.
    The registers DSI_VCCR and DSI_VNPCR are ignored by the DSI Host.
  - Non-burst mode:
    Configure the video mode type (DSI_VMCR.VMT) with 2'b00 to enable the transmission of sync pulses or with 2'b01 to enable the transmission of sync events.
    Configure the video packet size (DSI_VPCR.VPSIZE) with the number of pixels to be transmitted in a single packet. Selecting this value depends on the available memory of the attached peripheral, if the data is first stored, or on the memory you want to select for the FIFO in DSI Host.
    Configure the number of chunks (DSI_VCCR.NUMC) with the number of packets to be transmitted per video line. The value of VPSIZE * NUMC is the number of pixels per line of video, except if NUMC is 0, which disables the multi-packets. If you set it to 1, there is still only one packet per line, but it can be part of a chunk, followed by a null packet.
    Configure the null packet size (DSI_VNPCR.NPSIZE) with the size of null packets to be inserted as part of the chunks. Setting it to 0 disables null packets.
- Define the video horizontal timing configuration as follows:
  - Configure the horizontal line time (DSI_VLCR.HLINE) with the time taken by a LTDC video line measured in cycles of lane byte clock (for a clock lane at 500 MHz the lane byte clock period is 8 ns). When the periods of LTDC clock and lane byte clock are not multiples, the value to program the DSI_VLCR.HLINE needs to be rounded. A timing mismatch is introduced between the lines due to the rounding of configuration values. If the DSI Host is configured not to go to low-power, this timing divergence accumulates on every line, introducing a significant amount of mismatch towards the end of the frame. The reason for this is that the DSI Host cannot re-synchronize on every new line because it transmits the blanking packets when the horizontal sync event occurs on the LTDC interface. However, the accumulated mismatch must become extinct on the last line of a frame, where, according to the DSI specification, the link must always return to low-power regaining synchronization, when a new frame starts on a vertical sync event. If the accumulated timing mismatch is greater than the time in low-power on the last
line, a malfunction occurs. This phenomenon can be avoided by configuring the DSI Host to go to low-power once per line.

- Configure the horizontal sync duration (DSI_VHSACR.HSA) with the time taken by a LTDC horizontal sync active period measured in cycles of lane byte clock (normally a period of 8 ns).
- Configure the horizontal back-porch duration (DSI_VHBPCR.HBP) with the time taken by the LTDC horizontal back-porch period measured in cycles of lane byte clock (normally a period of 8 ns). Special attention must be given to the calculation of this parameter.

Define the vertical line configuration:

- Configure the vertical sync duration (DSI_VVSACR.VSA) with the number of lines existing in the LTDC vertical sync active period.
- Configure the vertical back-porch duration (DSI_VVBPCR.VBP) with the number of lines existing in the LTDC vertical back-porch period.
- Configure the vertical front-porch duration (DSI_VVFPCR.VFP) with the number of lines existing in the LTDC vertical front-porch period.
- Configure the vertical active duration (DSI_VVACR.VA) with the number of lines existing in the LTDC vertical active period.
Figure 440 illustrates the steps for configuring the DPI packet transmission.

**Figure 440. Video packet transmission configuration flow diagram**

1. **Global configuration**
   - Configure the DPI I/F

2. **Burst Mode**
   - YES
     - Configure video_packet_size
   - NO
     - Determine the DSI link to pixel ratio

3. **Enable multiple packets**
   - YES
     - If the DSI link to pixel ratio is >1
     - Determine number of pixel per packet
     - Calculate the number of chunks
     - Determine the chunk overhead (needs to be ≥ 12 or = 6)
     - Enable null packets
   - NO
     - Determine number of pixel per packet

4. **If the DSI chunk overhead is ≥ 12**
   - Calculate:
     - Hline_time - Hsa_time - Hbp_time
   - Configure:
     - VSA lines - VBP lines - Vact lines - VFP lines

5. **If the DSI link to pixel ratio is >1**
   - Determine number of pixel per packet
   - Calculate:
     - Hline_time - Hsa_time - Hbp_time
   - Configure:
     - VSA lines - VBP lines - Vact lines - VFP lines

6. **Null packet size**

7. **Enable null packets**
   - YES
   - NO
Example of video configuration

The following is an example of video packet transmission configuration:

Video resolution:
- PCLK period = 50 ns
- HSA = 8 PCLK
- HBP = 8 PCLK
- HACT = 480 PCLK
- HFP = 24 PCLK
- VSA = 2 lines
- VBP = 2 lines
- VACT = 640 lines
- VFP = 4 lines

Configuration steps:
- Video transmission mode configuration:
  a) Configure the low-power transitions:
     DSI_VMCR[13:8] = 6'b111111, to enable LP in all video period.
  b) DSI_VMCR.FBTAAE = 1, for the DSI Host to request an acknowledge response message from the peripheral at the end of each frame.
- To use the burst mode, follow these steps:
  DSI_VMCR.VMT = 2'b1x
  DSI_VPCR.VPSIZE = 480
- Horizontal timing configuration:
  - DSI_VLCR.HLINE = (HSA + HBP + HACT + HFP) * (PCLK period / Clk lane byte period) = (8 + 8 + 480 + 24) * (50 / 8) = 3250
  - DSI_VHSACR.HSA = HSA * (PCLK period/Clk lane byte period) = 8 * (50 / 8) = 50
  - DSI_VHBPCR.HBP = HBP * (PCLK period / Clk lane byte period) = 8 * (50 / 8) = 50
- Vertical line configuration:
  - DSI_VVSACR.VSA = 2
  - DSI_VVBPCR.VBP = 2
  - DSI_VVFPCR.VFP = 4
  - DSI_VVACR.VA = 640
44.14.7 Configuring the adapted command mode

The adapted command mode requires the following parameters to be configured:

- Command size (CMDSIZE) field of the DSI Host LTDC command configuration register (DSI_LCCR) to define the maximum allowed size for a write memory command.
- The tearing effect source (TESRC) and optionally tearing effect polarity (TEPOL) bits of the DSI Wrapper configuration register (DSI_WCFGR).
- The automatic refresh (AR) bit of the DSI Wrapper configuration register (DSI_WCFGR) if the display needs to be updated automatically each time a tearing effect event is received.

44.14.8 Configuring the video mode pattern generator

DSI Host can transmit a color bar pattern without horizontal/vertical color bar and D-PHY BER testing pattern without any kind of stimuli.

*Figure 441* shows the programming sequence to send a test pattern:

1. Configure the DSI_MCR register to enable video mode. Configure the video mode type using DSI_VMCR.VMT.
2. Configure the DSI_LCOLCR register.
3. Configure the frame using registers shown in *Figure 442* (where the gray area indicates the transferred pixels).
4. Configure the pattern generation mode (DSI_VMCR.PGM) and the pattern orientation (DSI_VMCR.PGO), and enable them (DSI_VMCR.PGE).

*Figure 441. Programming sequence to send a test pattern*
44.14.9 Managing ULPM

There are two ways to configure the software to enter and exit the ULPM:

- enter and exit the ULPM with the D-PHY PLL running (a faster process)
- enter and exit the ULPM with the D-PHY PLL turned off (a more efficient process in terms of power consumption).

Clock management for ULPM sequence

The ULPM management state machine is working on the lanebyteclock provided by the D-PHY.

Because the D-PHY is providing the lanebyteclock only when the clock lane is not in ULPM state, it is mandatory to switch the lanebyteclock source of the DSI Host before starting the ULPM mode entry sequence.

The lanebyteclock source is controlled by the RCC. It can be

- the lanebyteclock provided by the D-PHY (for all modes except ULPM)
- a clock generated by the system PLL (for ULPM)

Note: The number of pixels of payload is restricted to a multiple of a value provided in Table 433.
Process flow to enter the ULPM:

Implement the process described in detail in the following procedure to enter the ULPM on both clock lane and data lanes:

1. Verify the initial status of the DSI Host:
   - DSI_PCTLR[2:1] = 2'h3
   - DSI_WRPCR.PLLLEN = 1'h1 and DSI_WRPCR.REGEN = 1'h1
   - DSI_PUCR[3:0] = 4'h0
   - DSI_PTTCR[3:0] = 4'h0
   - Verify that all active lanes are in Stop state and the D-PHY PLL is locked:
     One-lane configuration: DSI_PS[6:4] = 3'h3 and DSI_PS[1] = 1'h0 and
     DSI_WISR.PLLS = 1'h1
     Two-lanes configuration: DSI_PS[8:4] = 5'h1B and DSI_PS[1] = 1'h0 and
     DSI_WISR.PLLS = 1'h1

2. Switch the lanebyteclock source in the RCC from D-PHY to system PLL

3. Set DSI_PUCR[3:0] = 4'h5 to enter ULPM in the data and the clock lanes.

4. Wait until the D-PHY active lanes enter into ULPM:
   - One-lane configuration: DSI_PS[6:1] = 6'h00
   - Two-lanes configuration: DSI_PS[8:1] = 8'h00
   The DSI Host is now in ULPM.

5. Turn off the D-PHY PLL by setting DSI_WRPCR.PLLLEN = 1'b0
**Process flow to exit the ULPM**

Implement the process flow described in the following procedure to exit the ULPM on both clock lane and data lanes:

1. Verify that all active lanes are in ULPM:
   - One-lane configuration: DSI_PSR[6:1] = 6'h00
   - Two-lanes configuration: DSI_PSR[8:1] = 8'h00

2. Turn on the D-PHY PLL by setting DSI_WRPCR.PLLEN = 1'b1.

3. Wait until D-PHY PLL locked
   - DSI_WISR.PLLS = 1'b1

4. Without de-asserting the ULPM request bits, assert the exit ULPM bits by setting DSI_PUCR[3:0] = 4'hF.

5. Wait until all active lanes exit ULPM:
   - One-lane configuration:
     - DSI_PSR[5] = 1'b1
     - DSI_PSR[3] = 1'b1
   - Two-lanes configuration:
     - DSI_PSR[8] = 1'b1
     - DSI_PSR[5] = 1'b1
     - DSI_PSR[3] = 1'b1

6. Wait for 1 ms.

7. De-assert the ULPM requests and the ULPM exit bits by setting DSI_PUCR[3:0] = 4'h0.

8. Switch the lanbyteclock source in the RCC from system PLL to D-PHY

9. The DSI Host is now in Stop state and the D-PHY PLL is locked:
   - One-lane configuration:
     - DSI_PSR[6:4] = 3'h3
     - DSI_PSR[1] = 1'h0
     - DSI_WRPCR.PLLEN = 1'b1
   - Two-lanes configuration:
     - DSI_PSR[8:4] = 5'h1B
     - DSI_PSR[1] = 1'h0
     - DSI_WRPCR.PLLEN = 1'b1
### 44.15 DSI Host registers

44.15.8  DSI Host protocol configuration register (DSI_PCR)

Address offset: 0x002C
Reset value: 0x0000 0000

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **LPISODE[7:0]: Largest packet size**
This field is used for the transmission of commands in low-power mode. It defines the size, in bytes, of the largest packet that can fit in a line during VSA, VBP and VFP regions.

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **VLPSIZE[7:0]: VACT largest packet size**
This field is used for the transmission of commands in low-power mode. It defines the size, in bytes, of the largest packet that can fit in a line during VACT regions.

Bits 31:6  Reserved, must be kept at reset value.

Bit 5  **ETTXLPE:** EoTp transmission in low-power enable
This bit enables the EoTP transmission in low-power.
0: EoTp transmission in low-power is disabled.
1: EoTp transmission in low-power is enabled.

Bit 4  **CRCRXE:** CRC reception enable
This bit enables the CRC reception and error reporting.
0: CRC reception is disabled.
1: CRC reception is enabled.

Bit 3  **ECCRXE:** ECC reception enable
This bit enables the ECC reception, error correction and reporting.
0: ECC reception is disabled.
1: ECC reception is enabled.

Bit 2  **BTAE:** Bus-turn-around enable
This bit enables the bus-turn-around (BTA) request.
0: Bus-turn-around request is disabled.
1: Bus-turn-around request is enabled.

Bit 1  **ETRXE:** EoTp reception enable
This bit enables the EoTp reception.
0: EoTp reception is disabled.
1: EoTp reception is enabled.

Bit 0  **ETTXE:** EoTp transmission enable
This bit enables the EoTP transmission.
0: EoTp transmission is disabled.
1: EoTp transmission is enabled.

|     | This bit enables the return to low-power inside the horizontal front-porch (HFP) period when timing allows. |         | 0: Return to low-power inside the HFP period is disabled.          |
|     | 1: Return to low-power inside the HFP period is enabled. |         |                                                           |
| 12  | LPHBPE                             | RW      | Low-power horizontal back-porch enable  
|     | This bit enables the return to low-power inside the horizontal back-porch (HBP) period when timing allows. |         | 0: Return to low-power inside the HBP period is disabled.          |
|     | 1: Return to low-power inside the HBP period is enabled. |         |                                                           |
Bit 11 **LPVAE**: Low-power vertical active enable  
This bit enables to return to low-power inside the vertical active (VACT) period when timing allows.  
0: Return to low-power inside the VACT is disabled.  
1: Return to low-power inside the VACT is enabled.

Bit 10 **LPVFPE**: Low-power vertical front-porch enable  
This bit enables to return to low-power inside the vertical front-porch (VFP) period when timing allows.  
0: Return to low-power inside the VFP is disabled.  
1: Return to low-power inside the VFP is enabled.

Bit 9 **LPVBPE**: Low-power vertical back-porch enable  
This bit enables to return to low-power inside the vertical back-porch (VBP) period when timing allows.  
0: Return to low-power inside the VBP is disabled.  
1: Return to low-power inside the VBP is enabled.

Bit 8 **LPVSAE**: Low-power vertical sync active enable  
This bit enables to return to low-power inside the vertical sync time (VSA) period when timing allows.  
0: Return to low-power inside the VSA is disabled.  
1: Return to low-power inside the VSA is enabled.

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **VMT[1:0]**: Video mode type  
This field configures the video mode transmission type:  
00: Non-burst with sync pulses.  
01: Non-burst with sync events.  
1x: Burst mode

### 44.15.12 DSI Host video packet configuration register (DSI_VPCR)

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:0 **VPSIZE[13:0]**: Video packet size  
This field configures the number of pixels in a single video packet.  
For 18-bit not loosely packed data types, this number must be a multiple of 4.  
For YCbCr data types, it must be a multiple of 2 as described in the DSI specification.
44.15.13  DSI Host video chunks configuration register (DSI_VCCR)

Address offset: 0x0040
Reset value: 0x0000 0000

Bits 31:13  Reserved, must be kept at reset value.

Bits 12:0  **NUMC[12:0]**: Number of chunks
           This register configures the number of chunks to be transmitted during a line period (a chunk consists of a video packet and a null packet).
           If set to 0 or 1, the video line is transmitted in a single packet.
           If set to 1, the packet is part of a chunk, so a null packet follows it if NPSIZE > 0. Otherwise, multiple chunks are used to transmit each video line.

44.15.14  DSI Host video null packet configuration register (DSI_VNPCR)

Address offset: 0x0044
Reset value: 0x0000 0000

Bits 31:13  Reserved, must be kept at reset value.

Bits 12:0  **NPSIZE[12:0]**: Null packet size
           This field configures the number of bytes inside a null packet.
           Setting to 0 disables the null packets.

44.15.15  DSI Host video HSA configuration register (DSI_VHSACR)

Address offset: 0x0048
Reset value: 0x0000 0000

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  **HSA[11:0]**: Horizontal synchronism active duration
This field configures the horizontal synchronism active period in lane byte clock cycles.

### 44.15.16  DSI Host video HBP configuration register (DSI_VHBPCR)

Address offset: 0x004C
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  **HBP[11:0]**: Horizontal back-porch duration
This field configures the horizontal back-porch period in lane byte clock cycles.

### 44.15.17  DSI Host video line configuration register (DSI_VLCR)

Address offset: 0x0050
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bit 13 **GSR2TX**: Generic short read two parameters transmission
   This bit configures the generic short read packet with two parameters command transmission type:
   0: High-speed
   1: Low-power

Bit 12 **GSR1TX**: Generic short read one parameters transmission
   This bit configures the generic short read packet with one parameters command transmission type:
   0: High-speed
   1: Low-power

Bit 11 **GSR0TX**: Generic short read zero parameters transmission
   This bit configures the generic short read packet with zero parameters command transmission type:
   0: High-speed
   1: Low-power

Bit 10 **GSW2TX**: Generic short write two parameters transmission
   This bit configures the generic short write packet with two parameters command transmission type:
   0: High-speed
   1: Low-power

Bit 9 **GSW1TX**: Generic short write one parameters transmission
   This bit configures the generic short write packet with one parameters command transmission type:
   0: High-speed
   1: Low-power

Bit 8 **GSW0TX**: Generic short write zero parameters transmission
   This bit configures the generic short write packet with zero parameters command transmission type:
   0: High-speed
   1: Low-power

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **ARE**: Acknowledge request enable
   This bit enables the acknowledge request after each packet transmission:
   0: Acknowledge request is disabled.
   1: Acknowledge request is enabled.

Bit 0 **TEARE**: Tearing effect acknowledge request enable
   This bit enables the tearing effect acknowledge request:
   0: Tearing effect acknowledge request is disabled.
   1: Tearing effect acknowledge request is enabled.

| Bit 15:8  | **DATA2[7:0]**      | Payload byte 2                           |
|           | This field indicates the byte 2 of the packet payload. |
| Bit 7:0   | **DATA1[7:0]**      | Payload byte 1                           |
|           | This field indicates the byte 1 of the packet payload. |
44.15.26 DSI Host generic packet status register (DSI_GPSR)

Address offset: 0x0074
Reset value: 0x0005 0015

| Bit 31:20 Reserved, must be kept at reset value. |
| Bit 19 PBF: Payload buffer full |
| This bit indicates the full status of the generic payload internal buffer: |
| 0: Payload internal buffer not full |
| 1: Payload internal buffer full |
| Bit 18 PBE: Payload buffer empty |
| This bit indicates the empty status of the generic payload internal buffer: |
| 0: Payload internal buffer not empty |
| 1: Payload internal buffer empty |
| Bit 17 CMDBF: Command buffer full |
| This bit indicates the full status of the generic command internal buffer: |
| 0: Command internal buffer not full |
| 1: Command internal buffer full |
| Bit 16 CMDBE: Command buffer empty |
| This bit indicates the empty status of the generic payload internal buffer: |
| 0: Payload internal buffer not full |
| 1: Payload internal buffer full |
| Bits 15:7 Reserved, must be kept at reset value. |
| Bit 6 RCB: Read command busy |
| This bit is set when a read command is issued and cleared when the entire response is stored in the FIFO: |
| 0: No read command on going |
| 1: Read command on going |
| Bit 5 PRDFF: Payload read FIFO full |
| This bit indicates the full status of the generic read payload FIFO: |
| 0: Read payload FIFO not full |
| 1: Read payload FIFO full. |
| Bit 4 PRDFE: Payload read FIFO empty |
| This bit indicates the empty status of the generic read payload FIFO: |
| 0: Read payload FIFO not empty |
| 1: Read payload FIFO empty |
| Bit 3 PWRFF: Payload write FIFO full |
| This bit indicates the full status of the generic write payload FIFO: |
| 0: Write payload FIFO not full |
| 1: Write payload FIFO full |
Bit 2 **PWRFE**: Payload write FIFO empty
This bit indicates the empty status of the generic write payload FIFO:
0: Write payload FIFO not empty
1: Write payload FIFO empty

Bit 1 **CMDFF**: Command FIFO full
This bit indicates the full status of the generic command FIFO:
0: Write payload FIFO not full
1: Write payload FIFO full

Bit 0 **CMDFE**: Command FIFO empty
This bit indicates the empty status of the generic command FIFO:
0: Write payload FIFO not empty
1: Write payload FIFO empty

### 44.15.27 DSI Host timeout counter configuration register 0 (DSI_TCCR0)

44.15.28  DSI Host timeout counter configuration register 1 (DSI_TCCR1)

Address offset: 0x007C
Reset value: 0x0000 0000

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **HSRD_TOCNT[15:0]**: High-speed read timeout counter

This field sets a period for which the DSI Host keeps the link still, after sending a high-speed read operation. This period is measured in cycles of lanebyteclk. The counting starts when the D-PHY enters the Stop state and causes no interrupts.

44.15.29  DSI Host timeout counter configuration register 2 (DSI_TCCR2)

Address offset: 0x0080
Reset value: 0x0000 0000

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **LPRD_TOCNT[15:0]**: Low-power read timeout counter

This field sets a period for which the DSI Host keeps the link still, after sending a low-power read operation. This period is measured in cycles of lanebyteclk. The counting starts when the D-PHY enters the Stop state and causes no interrupts.

44.15.30  DSI Host timeout counter configuration register 3 (DSI_TCCR3)

Address offset: 0x0084
Reset value: 0x0000 0000

Bits 31:15  Reserved, must be kept at reset value.

Bits 14:0  **HSWR_TOCNT[15:0]**: High-speed write timeout counter

This field sets a period for which the DSI Host keeps the link still, after sending a high-speed write operation. This period is measured in cycles of lanebyteclk. The counting starts when the D-PHY enters the Stop state and causes no interrupts.
Bits 31:25  Reserved, must be kept at reset value.

Bit 24  **PM**: Presp mode

When set to 1, this bit ensures that the peripheral response timeout caused by HSWR_TOCNT is used only once per LTDC frame in command mode, when both the following conditions are met:
- dpivsync_edpiwms has risen and fallen.
- Packets originated from LTDC in command mode have been transmitted and its FIFO is empty again.

In this scenario no non-LTDC command requests are sent to the D-PHY, even if there is traffic from generic interface ready to be sent, making it return to stop state. When it does so, PRESP_TO counter is activated and only when it finishes does the controller send any other traffic that is ready.

Bits 23:16  Reserved, must be kept at reset value.

Bits 15:0  **HSWR_TOCNT[15:0]**: High-speed write timeout counter

This field sets a period for which the DSI Host keeps the link inactive after sending a high-speed write operation. This period is measured in cycles of lanebyteclk. The counting starts when the D-PHY enters the Stop state and causes no interrupts.

**44.15.31**  **DSI Host timeout counter configuration register 4 (DSI_TCCR4)**

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **ACR**: Automatic clock lane control
This bit enables the automatic mechanism to stop providing clock in the clock lane when time allows.
0: Automatic clock lane control disabled
1: Automatic clock lane control enabled

Bit 0 **DPCC**: D-PHY clock control
This bit controls the D-PHY clock state:
0: Clock lane is in low-power mode.
1: Clock lane runs in high-speed mode.

Bits 31:21  Reserved, must be kept at reset value.

Bit 20  **PE4**: PHY error 4
This bit indicates the LP1 contention error ErrContentionLP1 from lane 0.

Bit 19  **PE3**: PHY error 3
This bit indicates the LP0 contention error ErrContentionLP0 from lane 0.

Bit 18  **PE2**: PHY error 2
This bit indicates the ErrControl error from lane 0.

Bit 17  **PE1**: PHY error 1
This bit indicates the ErrSyncEsc low-power transmission synchronization error from lane 0.

Bit 16  **PE0**: PHY error 0
This bit indicates the ErrEsc escape entry error from lane 0.

### 44.15.42 DSI Host interrupt and status register 1 (DSI_ISR1)

Address offset: 0x00C0  
Reset value: 0x0000 0000

| Bit 31:20 Reserved, must be kept at reset value. |
| Bit 19 | **PBUE**: Payload buffer underflow error  
This bit indicates that underflow has occurred when reading payload to build DSI packet for video mode. |
| Bit 18:13 Reserved, must be kept at reset value. |
| Bit 12 | **GPRXE**: Generic payload receive error  
This bit indicates that during a generic interface packet read back, the payload FIFO becomes full and the received data is corrupted. |
| Bit 11 | **GPRDE**: Generic payload read error  
This bit indicates that during a DCS read data, the payload FIFO becomes empty and the data sent to the interface is corrupted. |
| Bit 10 | **GPTXE**: Generic payload transmit error  
This bit indicates that during a generic interface packet build, the payload FIFO becomes empty and corrupt data is sent. |
| Bit 9 | **GPWRE**: Generic payload write error  
This bit indicates that the system tried to write a payload data through the generic interface and the FIFO is full. Therefore, the payload is not written. |
| Bit 8 | **GCWRE**: Generic command write error  
This bit indicates that the system tried to write a command through the generic interface and the FIFO is full. Therefore, the command is not written. |
| Bit 7 | **LPWRE**: LTDC payload write error  
This bit indicates that during a DPI pixel line storage, the payload FIFO becomes full and the data stored is corrupted. |
| Bit 6 | **EOTPE**: EoTp error  
This bit indicates that the EoTp packet is not received at the end of the incoming peripheral transmission. |
| Bit 5 | **PSE**: Packet size error  
This bit indicates that the packet size error is detected during the packet reception. |
| Bit 4 | **CRCE**: CRC error  
This bit indicates that the CRC error is detected in the received packet payload. |
| Bit 3 | **ECCME**: ECC multi-bit error  
This bit indicates that the ECC multiple error is detected in a received packet. |
Bit 2 **ECCSE**: ECC single-bit error  
This bit indicates that the ECC single error is detected and corrected in a received packet.

Bit 1 **TOLPRX**: Timeout low-power reception  
This bit indicates that the low-power reception timeout counter reached the end and contention is detected.

Bit 0 **TOHSTX**: Timeout high-speed transmission  
This bit indicates that the high-speed transmission timeout counter reached the end and contention is detected.

  0: Interrupt on acknowledge error 15 disabled  
  1: Interrupt on acknowledge error 15 enabled
Bit 14 **AE14IE**: Acknowledge error 14 interrupt enable
This bit enables the interrupt generation on acknowledge error 14.
0: Interrupt on acknowledge error 14 disabled
1: Interrupt on acknowledge error 14 enabled

Bit 13 **AE13IE**: Acknowledge error 13 interrupt enable
This bit enables the interrupt generation on acknowledge error 13.
0: Interrupt on acknowledge error 13 disabled
1: Interrupt on acknowledge error 13 enabled

Bit 12 **AE12IE**: Acknowledge error 12 interrupt enable
This bit enables the interrupt generation on acknowledge error 12.
0: Interrupt on acknowledge error 12 disabled
1: Interrupt on acknowledge error 12 enabled

Bit 11 **AE11IE**: Acknowledge error 11 interrupt enable
This bit enables the interrupt generation on acknowledge error 11.
0: Interrupt on acknowledge error 11 disabled
1: Interrupt on acknowledge error 11 enabled

Bit 10 **AE10IE**: Acknowledge error 10 interrupt enable
This bit enables the interrupt generation on acknowledge error 10.
0: Interrupt on acknowledge error 10 disabled
1: Interrupt on acknowledge error 10 enabled

Bit 9 **AE9IE**: Acknowledge error 9 interrupt enable
This bit enables the interrupt generation on acknowledge error 9.
0: Interrupt on acknowledge error 9 disabled
1: Interrupt on acknowledge error 9 enabled

Bit 8 **AE8IE**: Acknowledge error 8 interrupt enable
This bit enables the interrupt generation on acknowledge error 8.
0: Interrupt on acknowledge error 8 disabled
1: Interrupt on acknowledge error 8 enabled

Bit 7 **AE7IE**: Acknowledge error 7 interrupt enable
This bit enables the interrupt generation on acknowledge error 7.
0: Interrupt on acknowledge error 7 disabled
1: Interrupt on acknowledge error 7 enabled

Bit 6 **AE6IE**: Acknowledge error 6 interrupt enable
This bit enables the interrupt generation on acknowledge error 6.
0: Interrupt on acknowledge error 6 disabled
1: Interrupt on acknowledge error 6 enabled

Bit 5 **AE5IE**: Acknowledge error 5 interrupt enable
This bit enables the interrupt generation on acknowledge error 5.
0: Interrupt on acknowledge error 5 disabled
1: Interrupt on acknowledge error 5 enabled

Bit 4 **AE4IE**: Acknowledge error 4 interrupt enable
This bit enables the interrupt generation on acknowledge error 4.
0: Interrupt on acknowledge error 4 disabled
1: Interrupt on acknowledge error 4 enabled
Bit 3  **AE3IE**: Acknowledge error 3 interrupt enable  
This bit enables the interrupt generation on acknowledge error 3.  
0: Interrupt on acknowledge error 3 disabled  
1: Interrupt on acknowledge error 3 enabled

Bit 2  **AE2IE**: Acknowledge error 2 interrupt enable  
This bit enables the interrupt generation on acknowledge error 2.  
0: Interrupt on acknowledge error 2 disabled  
1: Interrupt on acknowledge error 2 enabled

Bit 1  **AE1IE**: Acknowledge error 1 interrupt enable  
This bit enables the interrupt generation on acknowledge error 1.  
0: Interrupt on acknowledge error 1 disabled  
1: Interrupt on acknowledge error 1 enabled

Bit 0  **AE0IE**: Acknowledge error 0 interrupt enable  
This bit enables the interrupt generation on acknowledge error 0.  
0: Interrupt on acknowledge error 0 disabled  
1: Interrupt on acknowledge error 0 enabled
