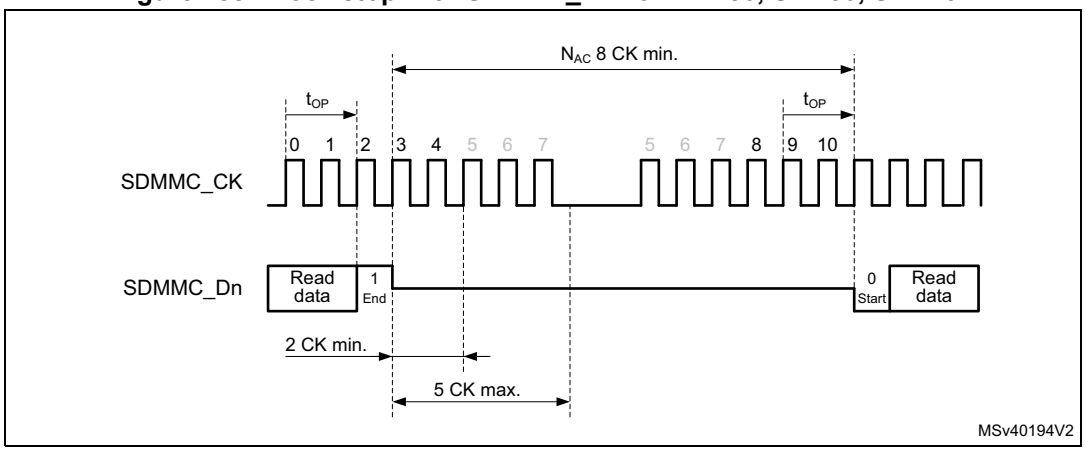
The SDMMC can perform a Read Wait with register settings according *Table 343*.

Read Wait is not available when block gap hardware flow control is enabled. (see *Section 40.7.2: Block gap hardware flow control*)

Depending the SDMMC operation mode (DS, HS, SDR12, SDR25) or (SDR50, SDR104, DDR) each method has a different characteristic.

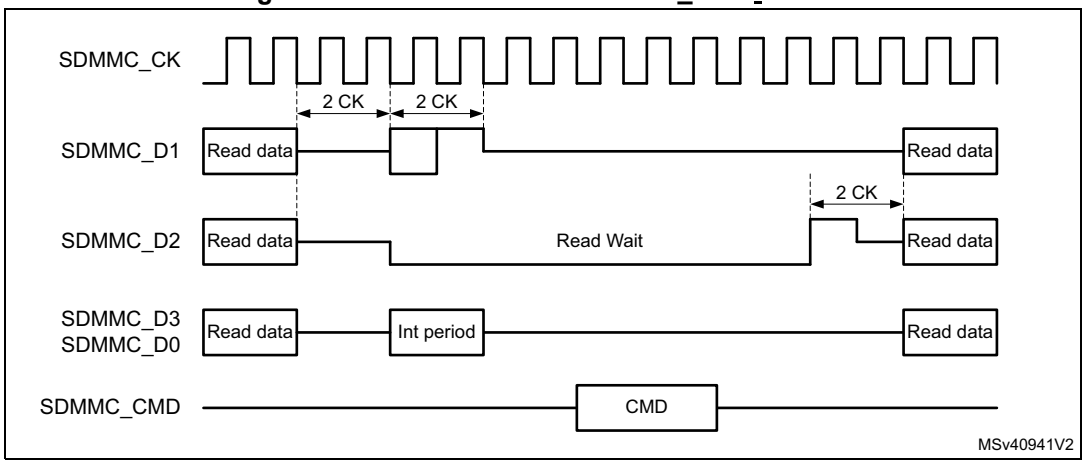


The timing for pause read operation by stopping the SDMMC_CK for DS, HS, SDR12, and SDR25, the SDMMC_CK may be stopped 2 SDMMC_CK cycles after the end bit. When ready the host resumes by restarting clock (see *Figure 287*).

Figure 287. Clock stop with SDMMC_CK for DS, HS, SDR12, SDR25

The timing for pause read operation by stopping the SDMMC_CK for SDR50, SDR104, and DDR50, the SDMMC_CK may be stopped minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, after the end bit. When ready the host resumes by restarting clock, see *Figure 288*. (In DDR50 mode the SDMMC_CK must only be stopped after the falling edge, when the clock line is low.)

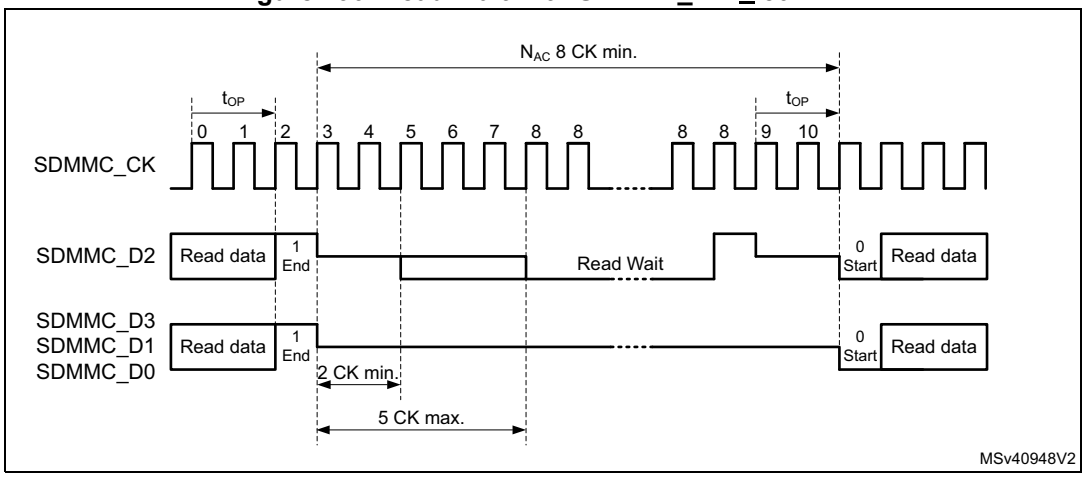
Figure 288. Clock stop with SDMMC_CK for DDR50, SDR50, SDR104



In Read Wait SDMMC_CK clock stopping, when RWSTART is set, the DSPM stops the clock after the end bit of the current received data block CRC. The clock start again after writing 1 to the RWSTOP bit, where after the DPSM waits for a start bit from the card.

As SDMMC_CK is stopped, no command can be issued to the card. During a Read Wait interval, the SDMMC can still detect SDIO interrupts on SDMMC_D1.

The optional Read Wait signaling on SDMMC_D2 (RW) operation is defined only for the SD 1-bit and 4-bit modes. The Read Wait operation enables the host to signal a card that is reading multiple registers (IO_RW_EXTENDED, CMD53) to temporarily stall the data transfer while allowing the host to send commands to any function within the SD I/O device. To determine when a card supports the Read Wait protocol, the host must test capability bits in the internal card registers.



The timing for Read Wait with a SDMMC_CK less then 50MHz (DS, HS, SDR12, SDR25) is based on the interrupt period generated by the card on SDMMC_D1. The host by asserting SDMMC_D2 low during the interrupt period requests the card to enter Read Wait. To exit Read Wait the host must raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z, see *Figure 289*.

Figure 289. Read Wait with SDMMC_CK < 50 MHz

For SDR50, SDR104 with a SDMMC_CK more than 50MHz, and DDR50, the card treats the Read Wait request on SDMMC_D2 as an asynchronous event. The host by asserting SDMMC_D2 low after minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, request the card to enter Read Wait. To exit Read Wait the host must raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z. The host must raise SDMMC_D2 on the SDMMC_CK clock (see *Figure 290*).

Figure 290. Read Wait with SDMMC_CK ≥ 50 MHz

In Read Wait SDMMC_D2 signaling, when RWSTART is set, the DPSM drives SDMMC_D2 after the end bit of the current received data block CRC. The Read Wait signaling on SDMMC_D2 is removed when writing 1 to the RWSTOP bit. The DPSM remains in R_W state for two more SDMMC_CK clock cycles to drive SDMMC_D2 to 1 for one clock cycle (in accordance with SDIO specification), where after the DPSM waits for a start bit from the card.

During the Read Wait signaling on SDMMC_D2 commands can be issued to the card. During the Read Wait interval, the SDMMC can detect SDIO interrupts on SDMMC_D1.

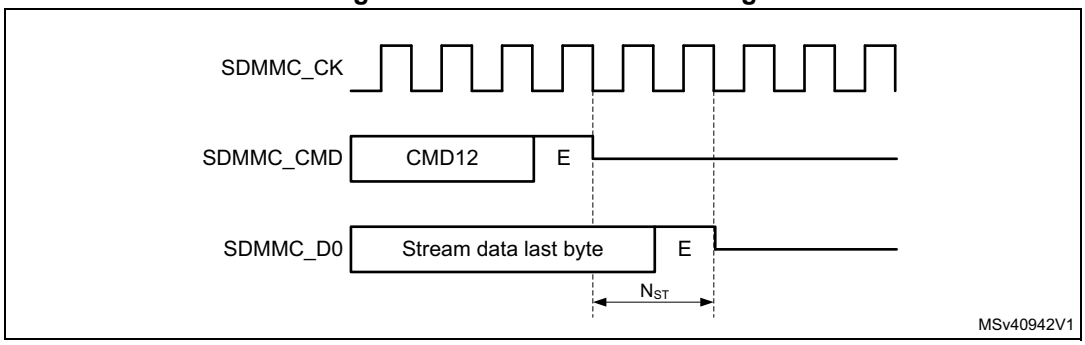
40.6.2 CMD12 send timing

CMD12 is used to stop/abort the data transfer, the card data transmission is terminated two clock cycles after the end bit of the Stop Transmission command.

Table 345. CMD12 use cases

Data operation	Stop Transmission command CMD12 Description
SDMMC stream write	The data transfer is stopped/aborted by sending the Stop Transmission command.
SDMMC open ended multiple block write	The data transfer is stopped/aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.
SDMMC block write with predefined block count	The Stop Transmission command is not required at the end of this type of multiple block write. (sending the Stop Transmission command after the card has received the last block is regarded as an illegal command.) If the card detects an error, the host must abort the operation by sending the Stop Transmission command.
SDMMC stream read	The data transfer is stopped/aborted by sending the Stop Transmission command.
SDMMC open ended multiple block read	The data transfer is stopped/aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.
SDMMC block read with predefined block count	The Stop Transmission command is not required at the end of this type of multiple block read. (sending the Stop Transmission command after the card has transmitted the last block is regarded as an illegal command.) Transaction can be aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.

All data write and read commands can be aborted any time by a Stop Transmission command CMD12. The following data abort procedure applies during an ongoing data transfer:



1. Load CMD12 Stop Transmission command in registers and set the CMDSTOP bit.
   – This causes the CPSM Abort signal to be generated when the command is sent to the DPSM.
2. Configure the CPSM to send a command immediately (clear WAITPEND bit).
   – The card, when sending data, stops data transfer 2 cycles after the Stop Transmission command end bit.
   The card when no data is being sent, does not start sending any new data.
   – The host, when sending data, sends one last data bit followed by an end bit after the Stop Transmission command end bit.
   The host when not sending data, does not start sending any new data.
3. When IDMAEN = 0, the FIFO need to be reset with FIFORST.
   – When writing data to the card. On the CMDREND flag, firmware must stop writing data to the FIFO. Subsequently the FIFO must be reset with FIFORST, this flushes the FIFO.
   – When reading data from the card. On the CMDREND flag, firmware must read the remaining data from the FIFO. Subsequently the FIFO must be reset with FIFORST.
4. When IDMAEN = 1, hardware takes care of the FIFO.
   – When writing data to the card. On the CPSM Abort signal, hardware stops the IDMA and subsequently the FIFO is flushed.
   – When reading data from the card. On the CPSM Abort signal, hardware instructs the IDMA to transfer the remaining data from the FIFO to RAM.
5. When the FIFO is empty/reset the DABORT flag is generated.

Stream operation and CMD12

To stop the stream transfer after the last byte to be transfered, the CMD12 end bit timing must be sent aligned with the data stream end of last byte. The following write stream data procedure applies:

1. Initialize the stream data in the DPSM, DTMODE = MCC stream data transfer.
2. Send the WRITE_DATA_STREAM command from the CPSM with CMDTRANS = 1.
3. Preload CMD12 in command registers, with the CMDSTOP bit set.
4. Configure the CPSM to send a command only after a wait pending (WAITPEND = 1) end of last data (according DATALENGTH).
5. Enabling the CPSM to send the STOP_TRANSMISSION command, the stream data end bit and command end bit are aligned.
   – When DATALENGTH > 5 bytes, Command CMD12 is waited in the CPSM to be aligned with the data transfer end bit.
   – When DATALENGHT < 5 bytes, Command CMD12 is started before and the DPSM remains in the Wait_S state to align the data transfer end with the CMD12 end bit.
6. The write stream data can be aborted any time by clearing the WAITPEND bit. This causes the Preloaded CMD12 to be sent immediately and stop the write data stream.

Figure 291. CMD12 stream timing

To stop the read stream transfer after the last byte, the CMD12 end bit timing must occur after the last data stream byte. The following read stream data procedure applies:

1. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   – The DPSM does not receive more data than indicated by DATALENGTH, even if the card is sending more data.
2. Send CMD12 by the CPSM.
   – CMD12 stops the card sending data.

Note: The SDMMC does not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

Block operation and CMD12

To stop block transfer at the end of the data, the CMD12 end bit must be sent after the last block end bit.

When writing data to the card the CMD12 end bit must be sent after the write data block CRC token end bit. This requires the CMD12 sending to be tied to the data block transmission timing. To stop an Open-ended Multiple block write, the following procedure applies:

1. Before starting the data transfer, set DTMODE to “block data transfer ending with STOP_TRANSMISSION command”.
2. Wait for all data to be sent by the DPSM and the CRC token to be received, (DATAEND flag).
   – The DPSM does not send more data than indicated by DATALENGTH.
3. Send CMD12 by the CPSM.
   – CMD12 sets the card to Idle mode.

When reading data from the card the CMD12 end bit must be sent earliest at the same time as the card read data block last data bit. This requires the CMD12 sending to be tied to the data block reception timing. The following stop Open-ended Multiple block read data block procedure applies:

1. Before starting the data transfer, set DTMODE to “block data transfer ending with STOP_TRANSMISSION command”.
2. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   – The DPSM does not receive more data than indicated by DATALENGTH, even if the card is sending more data.
3. Send CMD12 with CMDSTOP bit set by the CPSM.
   – CMD12 stops the Card sending more data and set the card to Idle mode. Any ongoing block transfer is aborted by the Card.

Note: The SDMMC does not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

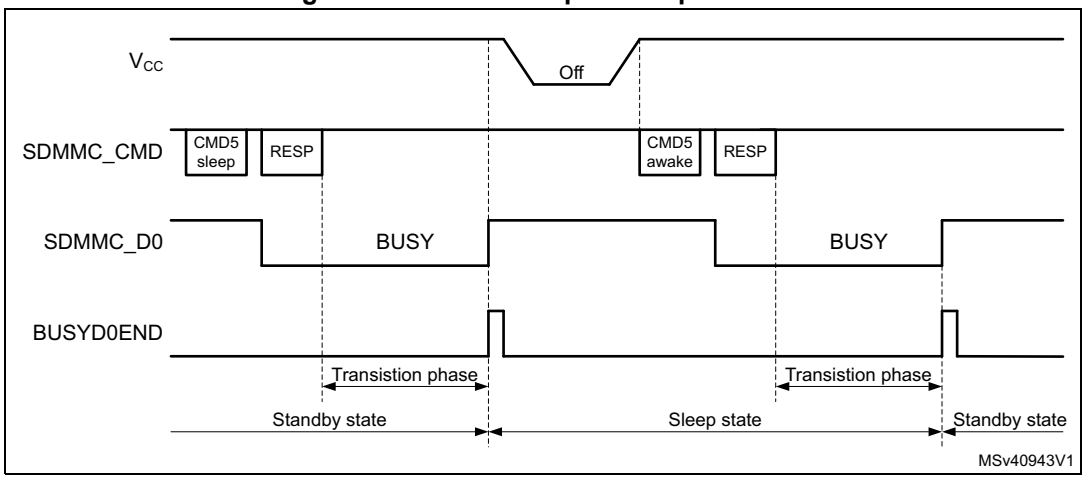
40.6.3 Sleep (CMD5)

The *e*•MMC card may be switched between a Sleep state and a Standby state by CMD5. In the Sleep state the power consumption of the card is minimized and the Vcc power supply may be switched off.

The CMD5 (SLEEP) is used to initiate the state transition from Standby state to Sleep state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Sleep state is reached when the card stops pulling down the SDMMC_DO line.

To set the card into Sleep state the following procedure applies:

1. Enable interrupt on BUSYD0END.
2. Send CMD5 (SLEEP).
3. On BUSYD0END interrupt, card is in Sleep state.
4. Vcc power supply can be switched off.



The CMD5 (AWAKE) is used to initiate the state transition from Sleep state to Standby state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Standby state is reached when the card stops pulling down the SDMMC_DO line.

To set the card into Sleep state the following procedure applies:

1. Switch on Vcc power supply and wait unit minimum operating level is reached.
2. Enable interrupt on BUSYD0END.
3. Send CMD5 (AWAKE).
4. On BUSYD0END interrupt card is in Standby state.

The Vcc power supply can be switched off only after the Sleep state has been reached. The Vcc supply must be reinstalled before CMD5 (AWAKE) is sent.

Figure 292. CMD5 Sleep Awake procedure

40.6.4 Interrupt mode (Wait-IRQ)

The host and card enter and exit interrupt mode (Wait-IRQ) simultaneously. In interrupt mode there is no data transfer. The only message allowed is an interrupt service request response from the card or the host. For the interrupt mode to work correctly the SDMMC_CK frequency must be set in accordance with the achievable SDMMC_CMD data rate in Open Drain mode, which depend on the capacitive load and pull-up resistor. The CLKDIV must be set >1, and the SETCLKRX must select either the sdmmc_io_in_ck or SDMMC_CLKin source.

The host must ensure that the card is in Standby state before issuing the CMD40 (GO_IRQ_STATE). While waiting for an interrupt response the SDMMC_CK clock signal must be kept active.

A card in interrupt mode (IRQ state):

- is waiting for an internal card interrupt event. Once the event occurs, the card starts to send the interrupt service request response. The response is sent in open-drain mode.
- while waiting for the internal card interrupt event, the card also monitors the SDMMC_CMD line for a start bit. Upon detection of a start bit the card aborts the interrupt mode and switch to Standby state.

The host in interrupt mode (CPSM Wait state waiting for interrupt):

- is waiting for a card interrupt service request response (start bit).
- while waiting for a card interrupt service request response the host may abort the interrupt mode (by clearing the WAITINT register bit), which causes the host to send a interrupt service request response R5 with RCA = 0x0000 in open-drain mode.

When sending the interrupt service request response, the sender bit-wise monitors the SDMMC_CMD bit stream. The sender whose interrupt service request response bit does not correspond to the bit on the SDMMC_CMD line stops sending. In the case of multiple senders only one successfully sends its full interrupt service request response. If the host sends simultaneously, it loses sending after the transmission bit.

To handle the interrupt mode, the following procedure applies:

1. Set the SDMMC_CK frequency in accordance with the achievable SDMMC_CMD data rate in Open-drain mode, CLKDIV must be set >1, and SETCLKRX must select the sdmmc_io_in_ck.
2. Load CMD40 (GO_IRQ_STATE) in the command registers.
3. Enable wait for interrupt by setting WAITINT register bit.
4. Configure the CPSM to send a command immediately.
   – This causes the CMD40 to be sent and the CPSM to be halted in the Wait state, waiting for a interrupt service request response.
5. To exit the wait for interrupt state (CPSM Wait state):
   – Upon the detection of an interrupt service request response start bit the CPSM moves to the Receive state where the response is received. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.
   – To abort the interrupt mode the host clears the WAITINT register bit, which causes the host to send an interrupt service request response by itself. This moves the CPSM to the Receive state. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.

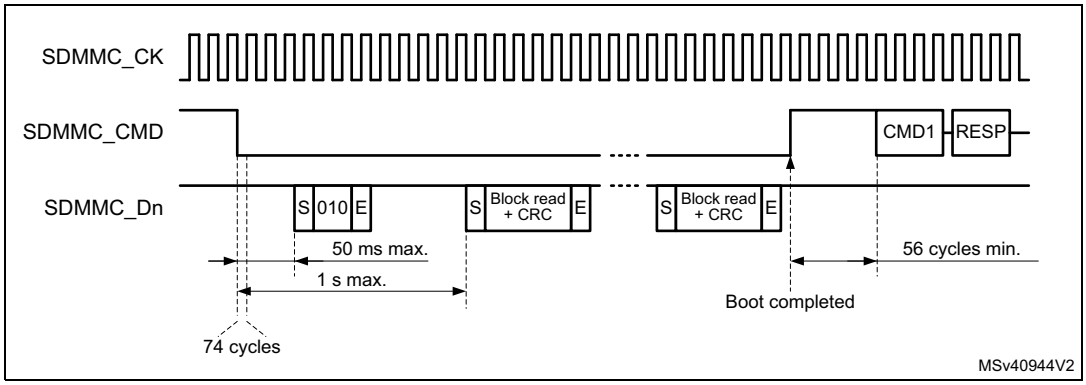
Note: On a simultaneous send interrupt service request response start bit collision the host loses the bus access after the transmission bit.

40.6.5 Boot operation

In boot operation mode the host can read boot data from the card by either one of the two boot operation functions:

- Normal boot. (keeping CMD line low)
- Alternative boot (sending CMD0 with argument 0xFFFFFFFA)

The boot data can be read according the following configuration options, depending on card register settings:



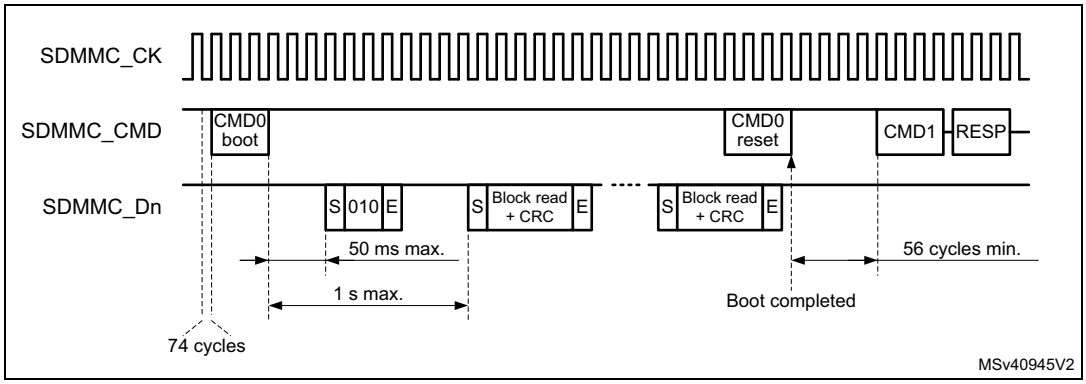
- The partition from which boot data is read (EXT_CSD Byte[179])
- The boot data size (EXT_CSD Byte[226])
- The bus configuration during boot (EXT_CSD Byte[177])
- Receiving boot acknowledgment from the card. (EXT_CSD Byte[179])

If boot acknowledgment is enabled the card send pattern 010 on SDMMC_D0 within 50ms after boot mode has been requested by either CMD line going low or after CMD0 with argument 0xFFFFFFFA. A boot acknowledgment timeout (ACKTIMEOUT) and acknowledgment status (ACKFAIL) is provided.

Normal boot operation

If the SDMMC_CMD line is held low for at least 74 clock cycles after card power-up or reset, before the first command is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD line goes low, the card starts to sent the first boot code data on the SDMMC_Dn line(s). The host must keep the SDMMC_CMD line low until after all boot data has been read. The host can terminate boot mode by pulling the SDMMC_CMD line high.

Figure 293. Normal boot mode operation



To perform the normal boot procedure the following steps needed:

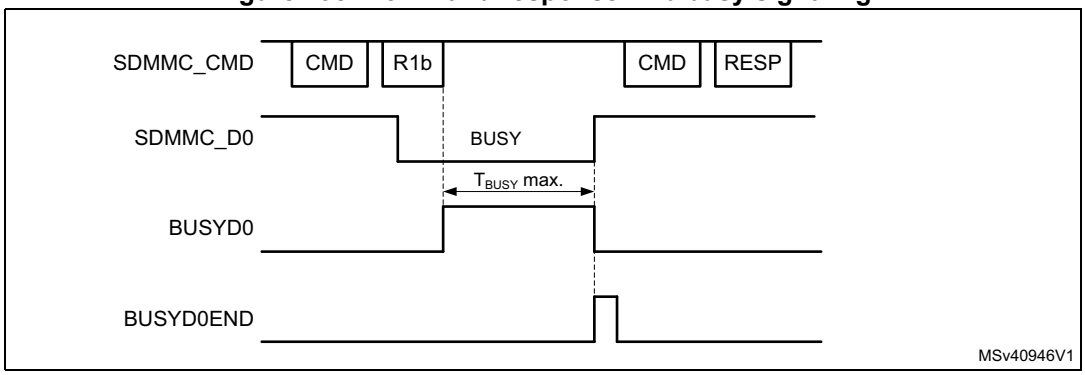
1. Reset the card.
2. if a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKFAIL and ACKTIMEOUT interrupt.
3. enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data bytes to be received in DATALENGTH.
4. Enable the DTIMEOUT, DATAEND, and CMDSENT interrupts for end of boot command confirmation.
5. Select the normal boot operation mode in BOOTMODE, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN.This causes:
   - the SDMMC_CMD to be driven low. (BOOTMODE = normal boot).
   - the ACK timeout to start.
   - DPSM to be enabled.
6. The incorrect reception of the boot acknowledgment can be detected with ACKFAIL flag or ACKTIMEOUT flag when enabled.
   - when an incorrect boot acknowledgment is received the ACKFAIL flag occurs.
   - when the boot acknowledgment is not received in time the ACKTIMEOUT flag occurs.
7. when all boot data has been received the DATAEND flag occurs.
   - when data CRC fails the DCRCFAIL flag is also generated.
   - when the data timeout occurs the DTIMEOUT flag is also generated.
8. When last data has been received, read data from the FIFO until FIFO is empty after which end of data DATAEND flag is generated.
   - SDMMC has completely received all data and the DPSM is disabled.
9. The boot procedure is terminated by firmware clearing BOOTEN, which causes the SDMMC_CMD line to go high. The CMDSENT flag is generated 56 cycles later to indicate that a new command can be sent.
   - If the boot procedure is aborted by firmware before all data has been received the CPSM Abort signal stops data reception and disables the DPSM which triggers an DABORT flag when enabled.
10. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command.

Alternative boot operation

After card power-up or reset, if the host send CMD0 with the argument 0xFFFFFFFA after 74 clock cycles before CMD0 is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD0 with argument 0xFFFFFFFA has been sent, the card starts to send the first boot code data on the SDMMC_Dn line(s). The master terminates boot operation by sending CMD0 (Reset).

Figure 294. Alternative boot mode operation

To perform the alternative boot procedure the following steps needed:



1. Move the SDMMC to power-off state, and reset the card.
2. Move the SDMMC to power-on state. This guarantees the 74 SCDMMC_CK cycles to be clocked before any command.
3. if a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKTIMEOUT flag.
4. enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data to be received in DATALENGTH. Enable the DTIMEOUT and DATAEND flags.
5. Select the alternative boot operation mode in BOOTMODE, load the CMD0 with the 0xFFFFFFFA argument in the command registers. Enable CMDSENT flag for end of boot command confirmation, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN. This causes:
   - the loaded command and argument to be sent out. (BOOTMODE = alternative boot).
   - the ACK timeout to start.
   - DPSM to be enabled.
6. When the command has been sent the CMDSENT flag is generated, at which time the BOOTEN bit must be cleared.
7. the reception of the boot acknowledgment can be detected with ACKFAIL flag when enabled.
   - when the boot acknowledgment is not received in time the ACKTIMEOUT flag occurs.
8. when all boot data has been received the DATAEND flag occurs.
   - when data CRC fails the DCRCFAIL flag is also generated.
   - when the data timeout occurs the DTIMEOUT flag is also generated.

9. When last data has been received, read data from the FIFO until FIFO is empty after which end of data DATAEND flag is generated.
   – SDMMC has completely received all data and the DPSM is disabled.
10. The BOOTEN bit must be cleared, before terminating the boot procedure by sending CMD0 (Reset) with BOOTMODE = alternative boot. This causes the CMDSENT flag to occur 56 cycles after the Command.
   – if the boot procedure is aborted by firmware before all data has been received the CPSM Abort signal stops the data transfer and disable the DPSM which triggers an DABORT flag when enabled.
11. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command. When the RESET command has been sent successfully, the BOOTMODE control bit has to be cleared to terminate the boot operation.

40.6.6 Response R1b handling

When sending commands which have a R1b response the busy signaling is reflected in the BUSYD0 register bit and the release of busy with the BUSYD0END flag. The SDMMC_D0 line is sampled at the end of the R1b response and signaled in the BUSYD0 register bit. The BUSYD0 register bit is reset to not busy when the SDMMC_D0 line release busy, at the same time the BUSYD0END flag is generated.

Figure 295. Command response R1b busy signaling

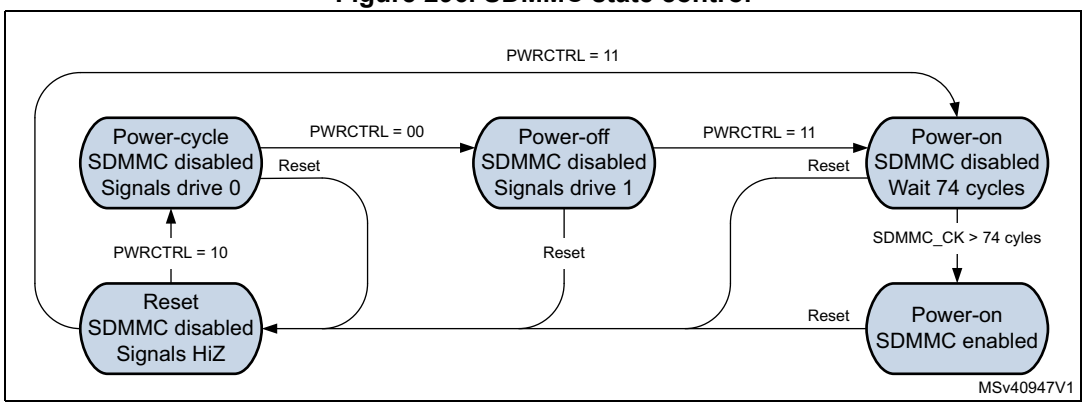
The expected maximum busy time must be set in the DATATIME register before sending the command. When enabled, the DTIMEOUT flag is set when after the R1b response busy stays active longer then the programmed time.

To detect the SDMMC_D0 busy signaling when sending a Command with R1b response the following procedure applies:

- Enable CMDREND flag.
- Send Command through CPSM.
- On the CMDREND flag check the BUSYD0 register bit.
  – If BUSYD0 signals not busy, signal busy release to firmware
  – If BUSYD0 signals busy, wait for BUSYD0END flag
- On BUSYD0END flag signal busy released to firmware.
- On DTIMEOUT flag busy is active longer then programmed time.

40.6.7 Reset and card cycle power

Reset



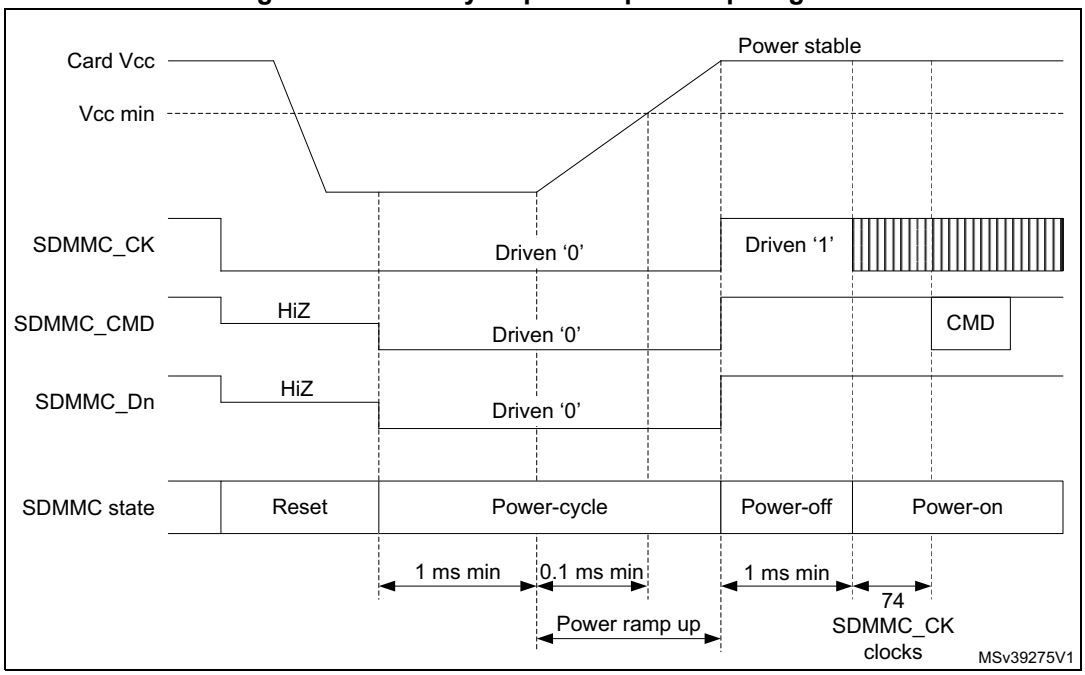
Following reset the SDMMC is in the reset state. In this state the SDMMC is disabled and no command nor data can be transfered. The SDMMC_D[7:0], and SDMMC_CMD are in HiZ and the SDMMC_CK is driven low.

Before moving to the power-on state the SDMMC must be configured.

In the power-on state the SDMMC_CK clock is running. First 74 SDMMC_CK cycles are clocked after which the SDMMC is enabled and command and data can be transfered.

The SDMMC states are controlled by Firmware with the PWRCTL register bits according *Figure 296.*.

Figure 296. SDMMC state control



Card cycle power

To perform a card cycle power the following procedure applies:

1. Reset the SDMMC with the RCC.SDMMCxRST register bit. This resets the SDMMC to the reset state and the CPSM and DPSM to the Idle state.
2. Disable the Vcc power to the card.
3. Set the SDMMC in power-cycle state. This makes that the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low, to prevent the card from being supplied through the signal lines.
4. After minimum 1 ms enable the Vcc power to the card.
5. After the power ramp period set the SDMMC to the power-off state for minimum 1 ms. The SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are set to drive 1.
6. After the 1 ms delay set the SDMMC to power-on state in which the SDMMC_CK clock is enabled.
7. After 74 SDMMC_CK cycles the first command can be sent to the card.

Figure 297. Card cycle power / power up diagram

40.7 Hardware flow control

There are two hardware flow control mechanisms:

1. Hardware flow control during data transfer:
   - Only to be used with cycle-aligned data transfers.
2. Block gap hardware flow control:
   - Only used in mode with bus speed SDR50, SDR104, HS200 and DDR50.
   - Must be used with variable delay.

40.7.1 Hardware flow control during data transfer

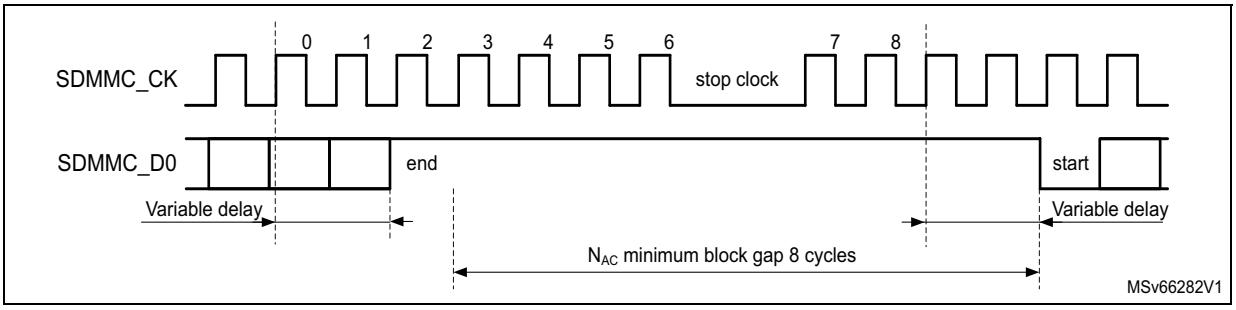
The hardware flow control during data transfer functionality is used to avoid FIFO underrun (TX mode) and overrun (RX mode) errors.

The behavior is to stop SDMMC_CK during data transfer and freeze the SDMMC state machines. The data transfer is stalled when the FIFO is unable to transmit or receive data. The data transfer remains stalled until the transmit FIFO is half full or all data according DATALENGHT has been stored, or until the receive FIFO is half empty. Only state machines clocked by SDMMC_CK are frozen, the AHB interfaces are still alive. The FIFO can thus be filled or emptied even if flow control is activated.

On an IDMA linked list transfer error, the hardware flow control is disabled. As a consequence, depending on when the IDMA linked list transfer error occurs, an underrun or overrun error may also occur (see *Section : IDMA transfer error management*).

To enable hardware flow control during data transfer, the HWFC_EN register bit must be set to 1. After reset hardware flow control is disabled.

Hardware flow control during data transfer must only be used when the SDMMC_Dn data is cycle-aligned with the SDMMC_CK. Whenever the sdmmc_fb_ck from the DLYB delay block is used, i.e in the case of SDR104 mode with a t_{OP} and Dt_{OP} delay > 1 cycle, hardware flow control during data transfer can not be used and block gap hardware flow control must be used instead.



40.7.2 Block gap hardware flow control

The block gap hardware flow control functionality is used to avoid FIFO underrun (TX mode) and overrun (RX mode) errors in SDR50, SDR104, HS200 and DDR50 mode (BUSSPEED = 1).

When transmitting, the behavior is to delay the start of a new write block and freeze the SDMMC state machines. The start of a new write block is delayed until the FIFO holds enough data according to the threshold. Only the state machines clocked by SDMMC_CK are frozen, the AHB interfaces are still alive. The FIFO can thus be filled even if flow control is activated.

When receiving, the behavior is to stop SDMMC_CK during the read block gap and freeze the SDMMC state machines. The start of a new block transfer is stalled, due to stopped clock, until the FIFO has enough free space according to the threshold. Only the state machines clocked by SDMMC_CK are frozen, the AHB interfaces are still alive. The FIFO can thus be emptied even if flow control is activated.

Figure 298. Read block gap hardware flow timing

Warning: When variable delay is used and block gap hardware flow control is enabled, sending commands during multiple block read may disturb the command response reception (CMD12 is not impacted by this).

Table 346. Data block gap hardware flow control behavior

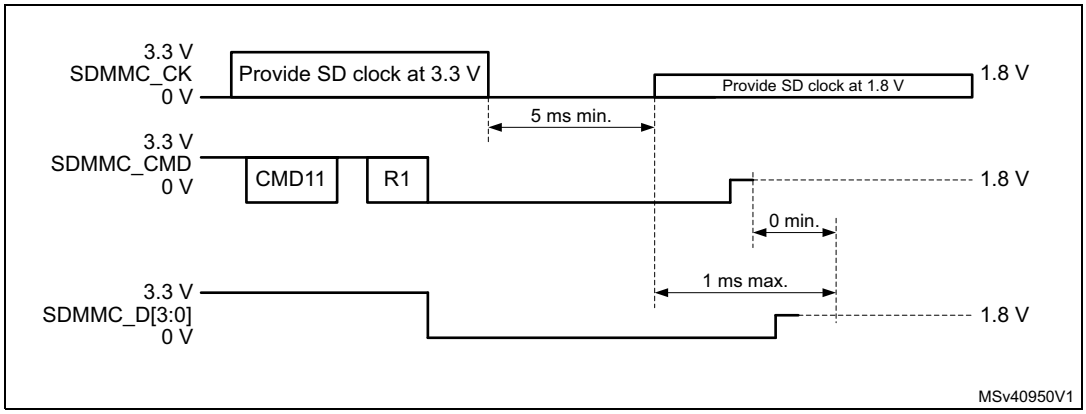
Condition (HWFC_EN = 1 and BUSSPEED = 1)	Description
Data block size ≤ FIFO threshold	New block transfer is only started when the FIFO has enough data (TX mode) / free space (RX mode) up to or more than the THR threshold. *Note: Data flow control is guaranteed. A block transfer is only stared when enough data for at least one block is available / free in the FIFO*
Data block size > FIFO threshold	New block transfer is only started when the FIFO has enough data (TX mode) / free space (RX mode) up to or more than the THR threshold. *Note: Data flow control is not guaranteed. A block transfer is started even when not enough data for one block is available / free in the FIFO. The threshold can be used to trade off transfer latency / throughput versus FIFO underrun / overrun risk.*

On an IDMA linked list transfer error, the hardware flow control is disabled. As a consequence, depending on when the IDMA linked list transfer error occurs, an underrun or overrun error may also occur (see *Section : IDMA transfer error management*).

The block gap hardware flow control is only enabled when HWFC_EN is set to 1, BUSSPEED = 1 and the THR FIFO threshold is different than 0. When BUSSPEED = 0 or FIFO threshold is set to 0, the hardware flow control is used during the data transfer. After reset, the hardware flow control is disabled.

Table 347. Hardware flow control selection

<table>
<tr><th>HWFC_EN</th><th>THR</th><th>BUSSPEED</th><th>Description</th></tr>
<tr><td>0</td><td>X</td><td rowspan="2">X</td><td>Hardware flow control disabled</td></tr>
<tr><td rowspan="3">1</td><td>0</td><td rowspan="2">Hardware flow control during data transfer enabled</td></tr>
<tr><td rowspan="2">not 0</td><td>0</td></tr>
<tr><td>1</td><td>Block gap hardware flow control enabled</td></tr>
</table>



Block gap hardware flow control must be used when the SDMMC_Dn receive data are not cycle-aligned with the SDMMC_CK. This is whenever the sdmmc_fb_ck from the DLYB delay block is used, for example in the case of SDR104 receive mode with a t_{OP} and Dt_{OP} delay > 1 cycle.

40.8 Ultra-high-speed phase I (UHS-I) voltage switch

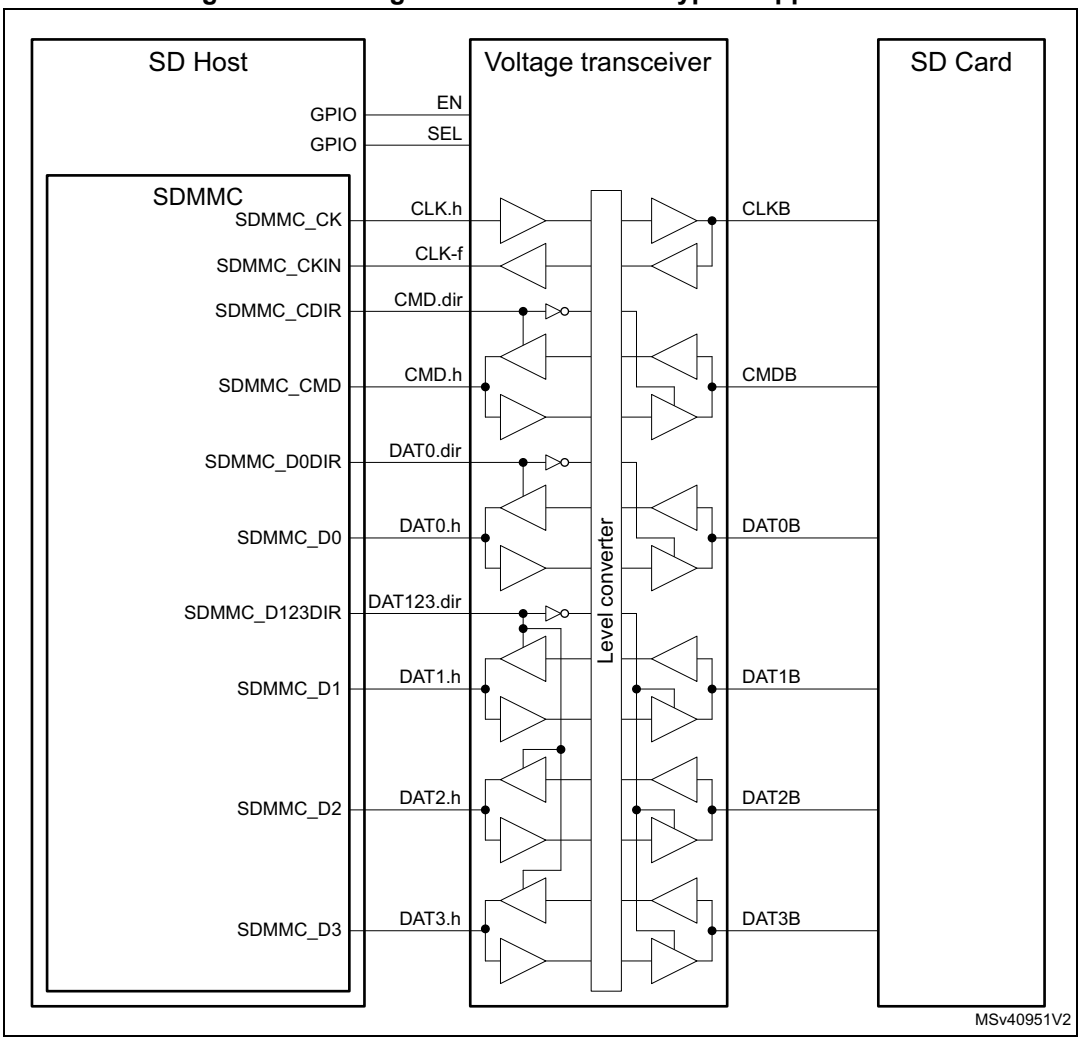
UHS-I mode (SDR12, SDR25, SDR50, SDR104, and DDR50) requires the support for 1.8 V signaling. After power up the card starts in 3.3V mode. CMD11 invokes the voltage switch

sequence to the 1.8V mode. When the voltage sequence is completed successfully the card enters UHS-I mode with default SDR12 and card input and output timings are changed.

Figure 299. CMD11 signal voltage switch sequence

To perform the signal voltage switch sequence the following steps are needed:

1. Before starting the Voltage Switch procedure, the SDMMC_CK frequency must be set in the range 100 kHz - 400 kHz.
2. The host starts the Voltage Switch procedure by setting the VSWITCHEN bit before sending the CMD11.
3. The card returns an R1 response.
   - if the response CRC is pass, the Voltage Switch procedure continues the host does no longer drive the CMD and SDMMC_D[3:0] signals until completion of the voltage switch sequence. Some cycles after the response the SDMMC_CK is stopped and the CKSTOP flag is set.
   - if the response CRC is fail (CCRCFAIL flag) or no response is received before the timeout (CTIMEOUT flag), the Voltage Switch procedure is stopped.
4. The card drives CMD and SDMMC_D[3:0] to low at the next clock after the R1 response.
5. The host, after having received the R1 response, may monitor the SDMMC_D0 line using the BUSYD0 register bit. The SDMMC_D0 line is sampled two SDMMC_CK clock cycles after the Response. The Firmware may read the BUSYD0 register bit following the CKSTOP flag.
   - When the BUSYD0 is detected low the host firmware switches the Voltage regulator to 1.8V, after which it instructs the SDMMC to start the timing critical section of the Voltage Switch sequence by setting register bit VSWITCH. The hardware continues to stop the SDMMC_CK by holding it low for at least 5 ms.
   - When the BUSYD0 is detected high the host aborts the Voltage Switch sequence and cycle power the card.
6. The card after detecting SDMMC_CK low begins switching signaling voltage to 1.8 V.
7. The host SDMMC hardware after at least 5 ms restarts the SDMMC_CK.
8. The card within 1 ms from detecting SDMMC_CK transition drives CMD and DAT[3:0] high for at least 1 SDMMC_CK cycle and then stop driving CMD and DAT[3:0].
9. The host SDMMC hardware, 1 ms after the SDMMC_CK has been restarted, the SDMMC_D0 is sampled into BUSYD0 and the VSWEND flag is set.



10. The host, on the VSWEND flag, checks SDMMC_D0 line using the BUSYD0 register bit, to confirm completion of voltage switch sequence:
    – When BUSYD0 is detected high, Voltage Switch has been completed successfully.
    – When BUSYD0 is detected low, Voltage Switch has failed, the host cycles the card power.

The minimum 5 ms time to stop the SDMMC_CK is derived from the internal un-gated SDMMC_CK clock, which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The >5 ms time is counted by 2^{12} cycles (10.24 ms @ 400 kHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time for the SDMMC_CK clock to be stopped is longer.

The maximum 1 ms time for the card to drive the SDMMC_Dn and SDMMC_CMD lines high is derived from the internal ungated SDMMC_CK which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The SDMMC checks the lines after >1 ms time which is counted by 2^9 cycles (1.28 ms @ 25 MHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time to check the lines is longer.

The signal voltage level is supported through an external voltage translation transceiver like STMicroelectronics ST6G3244ME.

Figure 300. Voltage switch transceiver typical application

To interface with an external driver (a voltage switch transceiver), next to the standard signals the SDMMC uses the following signals:

- **SDMMC_CKIN** feedback input clock
- **SDMMC_CDIR** I/O direction control for the CMD signal
- **SDMMC_D0DIR** I/O direction control for the SDMMC_D0 signal
- **SDMMC_D123DIR** I/O direction control for the SDMMC_D1, SDMMC_D2 and SDMMC_D3 signals

The voltage transceiver signals **EN** and **SEL** are to be handled through general-purpose I/O.

The polarity of the SDMMC_CDIR, SDMMC_D0DIR and SDMMC_D123DIR signals can be selected through SDMMC_POWER.DIRPOL control bit.

40.9 SDMMC interrupts

Table 348. SDMMC interrupts

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode
SDMMC	Command response CRC fail	CCRCFAIL	CCRCFAILIE	CCRCFAILC	Yes
SDMMC	Data block CRC fail	DCRCFAIL	DCRCFAILIE	DCRCFAILC	Yes
SDMMC	Command response timeout	CTIMEOUT	CTIMEOUTIE	CTIMEOUTC	Yes
SDMMC	Data timeout	DTIMEOUT	DTIMEOUTIE	DTIMEOUTC	Yes
SDMMC	Transmit FIFO underrun	TXUNDERR	TXUNDERRIE	TXUNDERRC	Yes
SDMMC	Receive FIFO overrun	RXOVERR	RXOVERRIE	RXOVERRC	Yes
SDMMC	Command reponse received	CMDREND	CMDRENDIE	CMDRENDC	Yes
SDMMC	Comand sent	CMDSENT	CMDSENTIE	CMDSENTC	Yes
SDMMC	Data transfer ended	DATAEND	DATAENDIE	DATAENDC	Yes
SDMMC	Data transfer hold	DHOLD	DHOLDIE	DHOLDC	Yes
SDMMC	Data block sent or received	DBCKEND	DBCKENDIE	DBCKENDC	Yes
SDMMC	Data transfer aborted	DABORT	DABORTIE	DABORTC	Yes
SDMMC	Transmit FIFO half empty	TXFIFOHE	TXFIFOHEIE	N/A	Yes
SDMMC	Receive FIFO half full	RXFIFOHF	RXFIFOHFIE	N/A	Yes
SDMMC	Transmit FIFO full	TXFIFOF	N/A	N/A	Yes
SDMMC	Receive FIFO full	RXFIFOF	RXFIFOFIE	N/A	Yes
SDMMC	Transmit FIFO empty	TXFIFOE	TXFIFOEIE	N/A	Yes
SDMMC	Receive FIFO empty	RXFIFOE	N/A	N/A	Yes
SDMMC	Command response end of busy	BUSYD0END	BUSYD0ENDIE	BUSYD0ENDC	Yes
SDMMC	SDIO interrupt	SDIOIT	SDIOITIE	SDIOITC	Yes
SDMMC	Boot acknowledgment fail	ACKFAIL	ACKFAILIE	ACKFAILC	Yes
SDMMC	Boot acknowledgment timeout	ACKTIMEOUT	ACKTIMEOUTIE	ACKTIMEOUTC	Yes
SDMMC	Voltage switch timing	VSWEND	VSWENDIE	VSWENDC	Yes
SDMMC	SDMM_CK stopped in voltage switch	CKSTOP	CKSTOPIE	CKSTOPC	Yes
SDMMC	IDMA transfer error	IDMATE	IDMATEIE	IDMATEC	Yes
SDMMC	IDMA buffer transfer complete	IDMABTC	IDMABTCIE	IDMABTCC	Yes

40.10 SDMMC registers

The device communicates to the system via 32-bit control registers accessible via AHB slave interface.

The peripheral registers have to be accessed by words (32-bit). Byte (8-bit) and half-word (16-bit) accesses trigger an AHB bus error.

40.10.1 SDMMC power control register (SDMMC_POWER)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIR POL	VSWI TCHEN	VSWI TCH	PWRCTRL[1:0]	
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **DIRPOL**: Data and command direction signals polarity selection

This bit can only be written when the SDMMC is in the power-off state (PWRCTRL = 00).

0: Voltage transceiver I/Os driven as output when direction signal is low.

1: Voltage transceiver I/Os driven as output when direction signal is high.

Bit 3 **VSWITCHEN**: Voltage switch procedure enable

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

This bit is used to stop the SDMMC_CK after the voltage switch command response:

0: SDMMC_CK clock kept unchanged after successfully received command response.

1: SDMMC_CK clock stopped after successfully received command response.

Bit 2 **VSWITCH**: Voltage switch sequence start

This bit is used to start the timing critical section of the voltage switch sequence:

0: Voltage switch sequence not started and not active.

1: Voltage switch sequence started or active.

Bits 1:0 **PWRCTRL[1:0]**: SDMMC state control bits

These bits can only be written when the SDMMC is not in the power-on state (PWRCTRL ≠ 11).

These bits are used to define the functional state of the SDMMC signals:

00: After reset, Reset: the SDMMC is disabled and the clock to the Card is stopped, SDMMC_D[7:0], and SDMMC_CMD are HiZ and SDMMC_CK is driven low. When written 00, power-off: the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven high.

01: Reserved (When written 01, PWRCTRL value does not change)

10: Power-cycle, the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low.

11: Power-on: the card is clocked, The first 74 SDMMC_CK cycles the SDMMC is still disabled. After the 74 cycles the SDMMC is enabled and the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are controlled according the SDMMC operation.

Any further write is ignored, PWRCTRL value keeps 11.

40.10.2 SDMMC clock control register (SDMMC_CLKCR)

Address offset: 0x004

Reset value: 0x0000 0000

This register controls the SDMMC_CK output clock, the sdmmc_rx_ck receive clock, and the bus width.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SELCLKRX[1:0]		BUS SPEED	DDR	HWFC_EN	NEG EDGE
										rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WID BUS[1:0]		Res.	PWR SAV	Res.	Res.	CLKDIV[9:0]									
rw	rw		rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **SELCLKRX[1:0]**: Receive clock selection

These bits can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

00: sdmmc_io_in_ck selected as receive clock

01: SDMMC_CKIN feedback clock selected as receive clock

10: sdmmc_fb_ck tuned feedback clock selected as receive clock

11: Reserved (select sdmmc_io_in_ck)

Bit 19 **BUSSPEED**: Bus speed for selection of SDMMC operating modes

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

0: DS, HS, SDR12, SDR25, Legacy compatible, High speed SDR, High speed DDR bus speed mode selected

1: SDR50, DDR50, SDR104, HS200 bus speed mode selected

Bit 18 **DDR**: Data rate signaling selection

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

DDR rate must only be selected with 4-bit or 8-bit wide bus mode. (WIDBUS > 00). DDR = 1 has no effect when WIDBUS = 00 (1-bit wide bus).

DDR rate must only be selected with clock division > 1 (CLKDIV > 0).

0: SDR Single data rate signaling

1: DDR double data rate signaling

Bit 17 **HWFC_EN**: Hardware flow control enable

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

0: Hardware flow control is disabled

1: Hardware flow control is enabled

When Hardware flow control is enabled, the meaning of the TXFIFOE and RXFIFOF flags change, see SDMMC status register definition in *Section 40.10.11*.

Bit 16 **NEGEDGE**: SDMMC_CK dephasing selection bit for data and command

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

When clock division = 1 (CLKDIV = 0), this bit has no effect. Data and Command change on SDMMC_CK falling edge.

0: When clock division >1 (CLKDIV > 0) and DDR = 0:

- Command and data changed on the sdmmc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
- SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

When clock division >1 (CLKDIV > 0) and DDR = 1:

- Command changed on the sdmmc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
- Data changed on the sdmmc_ker_ck falling edge succeeding a SDMMC_CK edge.
- SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

1: When clock division >1 (CLKDIV > 0) and DDR = 0:

- Command and data changed on the same sdmmc_ker_ck rising edge generating the SDMMC_CK falling edge.

When clock division >1 (CLKDIV > 0) and DDR = 1:

- Command changed on the same sdmmc_ker_ck rising edge generating the SDMMC_CK falling edge.
- Data changed on the SDMMC_CK falling edge succeeding a SDMMC_CK edge.
- SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

Bits 15:14 **WIDBUS[1:0]**: Wide bus mode enable bit

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

00: Default 1-bit wide bus mode: SDMMC_D0 used (Does not support DDR)

01: 4-bit wide bus mode: SDMMC_D[3:0] used

10: 8-bit wide bus mode: SDMMC_D[7:0] used

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PWRSAV**: Power saving configuration bit

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

For power saving, the SDMMC_CK clock output can be disabled when the bus is idle by setting PWRSAV:

0: SDMMC_CK clock is always enabled

1: SDMMC_CK is only enabled when the bus is active

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:0 **CLKDIV[9:0]**: Clock divide factor

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

This field defines the divide factor between the input clock (sdmmc_ker_ck) and the output clock (SDMMC_CK): SDMMC_CK frequency = sdmmc_ker_ck / [2 * CLKDIV].

0x000: SDMMC_CK frequency = sdmmc_ker_ck / 1 (Does not support DDR)

0x001: SDMMC_CK frequency = sdmmc_ker_ck / 2

0x002: SDMMC_CK frequency = sdmmc_ker_ck / 4

0x0XX: ..

0x080: SDMMC_CK frequency = sdmmc_ker_ck / 256

0xXXX: ..

0x3FF: SDMMC_CK frequency = sdmmc_ker_ck / 2046

Note: While the SD/SDIO card or e•MMC is in identification mode, the SDMMC_CK frequency must be less than 400 kHz.

The clock frequency can be changed to the maximum card bus frequency when relative card addresses are assigned to all cards.

At least seven sdmmc_hclk clock periods are needed between two write accesses to this register. SDMMC_CK can also be stopped during the Read Wait interval for SD I/O cards: in this case the SDMMC_CLKCR register does not control SDMMC_CK.

40.10.3 SDMMC argument register (SDMMC_ARGR)

Address offset: 0x008

Reset value: 0x0000 0000

This register contains a 32-bit command argument, which is sent to a card as part of a command message.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CMDARG[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMDARG[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CMDARG[31:0]**: Command argument

These bits can only be written by firmware when CPSM is disabled (CPSMEN = 0). Command argument sent to a card as part of a command message. If a command contains an argument, it must be loaded into this register before writing a command to the command register.

40.10.4 SDMMC command register (SDMMC_CMDR)

Address offset: 0x00C

Reset value: 0x0000 0000

This register contains the command index and command type bits. The command index is sent to a card as part of a command message. The command type bits control the command path state machine (CPSM).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMD SUS PEND
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOT EN	BOOT MODE	DT HOLD	CPSM EN	WAITP END	WAIT INT	WAITRESP[1:0]		CMD STOP	CMD TRANS	CMDINDEX[5:0]					
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **CMDSUSPEND**: The CPSM treats the command as a Suspend or Resume command and signals interrupt period start/end

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
CMDSUSPEND = 1 and CMDTRANS = 0 Suspend command, start interrupt period when response bit BS = 0.
CMDSUSPEND = 1 and CMDTRANS = 1 Resume command with data, end interrupt period when response bit DF = 1.

Bit 15 **BOOTEN**: Enable boot mode procedure

0: Boot mode procedure disabled
1: Boot mode procedure enabled

Bit 14 **BOOTMODE**: Select the boot mode procedure to be used

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0)
0: Normal boot mode procedure selected
1: Alternative boot mode procedure selected

Bit 13 **DTHOLD**: Hold new data block transmission and reception in the DPSM

If this bit is set, the DPSM does not move from the Wait_S state to the Send state or from the Wait_R state to the Receive state.

Bit 12 **CPSMEN**: Command path state machine (CPSM) enable bit

This bit is written 1 by firmware, and cleared by hardware when the CPSM enters the Idle state.
If this bit is set, the CPSM is enabled.
When DTEN = 1, no command is transfered nor boot procedure is started. CPSMEN is cleared to 0.
During Read Wait with SDMMC_CK stopped no command is sent and CPSMEN is kept 0.

Bit 11 **WAITPEND**: CPSM waits for end of data transfer (CmdPend internal signal) from DPSM

This bit when set, the CPSM waits for the end of data transfer trigger before it starts sending a command.
WAITPEND is only taken into account when DTMODE = *e*•MMC stream data transfer, WIDBUS = 1-bit wide bus mode, DPSMACT = 1 and DTDIR = from host to card.

Bit 10 **WAITINT**: CPSM waits for interrupt request

If this bit is set, the CPSM disables command timeout and waits for an card interrupt request (Response).
If this bit is cleared in the CPSM Wait state, it causes the abort of the interrupt mode.

Bits 9:8 **WAITRESP[1:0]**: Wait for response bits

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
They are used to configure whether the CPSM is to wait for a response, and if yes, which kind of response.
00: No response, expect CMDSENT flag
01: Short response, expect CMDREND or CCRCFAIL flag
10: Short response, expect CMDREND flag (No CRC)
11: Long response, expect CMDREND or CCRCFAIL flag

Bit 7 **CMDSTOP**: The CPSM treats the command as a Stop Transmission command and signals abort to the DPSM

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

If this bit is set, the CPSM issues the abort signal to the DPSM when the command is sent.

Bit 6 **CMDTRANS**: The CPSM treats the command as a data transfer command, stops the interrupt period, and signals DataEnable to the DPSM

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

If this bit is set, the CPSM issues an end of interrupt period and issues DataEnable signal to the DPSM when the command is sent.

Bits 5:0 **CMDINDEX[5:0]**: Command index

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

The command index is sent to the card as part of a command message.

Note: 1 At least seven sdmmc_hclk clock periods are needed between two write accesses to this register.

2 MultiMediaCard can send two kinds of response: short responses, 48 bits, or long responses,136 bits. SD card and SD I/O card can send only short responses, the argument can vary according to the type of response: the software distinguishes the type of response according to the send command.

40.10.5 SDMMC command response register (SDMMC_RESPCMDR)

Address offset: 0x010

Reset value: 0x0000 0000

This register contains the command index field of the last command response received. If the command response transmission does not contain the command index field (long or OCR response), the RESPCMD field is unknown, although it must contain 111111b (the value of the reserved field from the response).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RESPCMD[5:0]					
										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **RESPCMD[5:0]**: Response command index

Read-only bitfield. Contains the command index of the last command response received.

40.10.6 SDMMC response x register (SDMMC_RESPxR)

Address offset: 0x010 + 0x004 * x, (x = 1 to 4)

Reset value: 0x0000 0000

These registers contain the status of a card, which is part of the received response.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CARDSTATUS[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CARDSTATUS[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **CARDSTATUS[31:0]**: Card status according table below
See *Table 349*.

The card status size is 32 or 128 bits, depending on the response type.

Table 349. Response type and SDMMC_RESPxR registers

Register(1)	Short response	Long response
SDMMC_RESP1R	Card status[31:0]	Card status [127:96]
SDMMC_RESP2R	all 0	Card status [95:64]
SDMMC_RESP3R	all 0	Card status [63:32]
SDMMC_RESP4R	all 0	Card status [31:0](2)

1. The most significant bit of the card status is received first.
2. The SDMMC_RESP4R register LSB is always 0.

40.10.7 SDMMC data timer register (SDMMC_DTIMER)

Address offset: 0x024

Reset value: 0x0000 0000

This register contains the data timeout period, in card bus clock periods.

A counter loads the value from this register, and starts decrementing when the data path state machine (DPSM) enters the Wait_R or Busy state. If the timer reaches 0 while the DPSM is in either of these states, the timeout status flag is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATATIME[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATATIME[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATATIME[31:0]**: Data and R1b busy timeout period

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

Data and R1b busy timeout period expressed in card bus clock periods.

Note: A data transfer must be written to the data timer register and the data length register before being written to the data control register.

40.10.8 SDMMC data length register (SDMMC_DLENR)

Address offset: 0x028

Reset value: 0x0000 0000

This register contains the number of data bytes to be transferred. The value is loaded into the data counter when data transfer starts.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DATALENGTH[24:16]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATALENGTH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATALENGTH[24:0]**: Data length value

This register can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Number of data bytes to be transferred.

When DDR = 1 DATALENGTH is truncated to a multiple of 2. (The last odd byte is not transfered)

When DATALENGTH = 0 no data are transfered, when requested by a CPSMEN and CMDTRANS = 1 also no command is transfered. DTEN and CPSMEN are cleared to 0.

Note: For a block data transfer, the value in the data length register must be a multiple of the block size (see SDMMC_DCTRL). A data transfer must be written to the data timer register and the data length register before being written to the data control register.

For an SDMMC multibyte transfer the value in the data length register must be between 1 and 512.

40.10.9 SDMMC data control register (SDMMC_DCTRL)

Address offset: 0x02C

Reset value: 0x0000 0000

This register controls the data path state machine (DPSM).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FIFO RST	BOOT ACK EN	SDIO EN	RW MOD	RW STOP	RW START	DBLOCKSIZE[3:0]				DTMODE[1:0]		DTDIR	DTEN
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **FIFORST**: FIFO reset, flushes any remaining data

This bit can only be written by firmware when IDMAEN= 0 and DPSM is active (DPSMACT = 1). This bit only takes effect when a transfer error or transfer hold occurs.

0: FIFO not affected.

1: Flush any remaining data and reset the FIFO pointers. This bit is automatically cleared to 0 by hardware when DPSM gets inactive (DPSMACT = 0).

Bit 12 **BOOTACKEN**: Enable the reception of the boot acknowledgment

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Boot acknowledgment disabled, not expected to be received

1: Boot acknowledgment enabled, expected to be received

Bit 11 **SDIOEN**: SD I/O interrupt enable functions

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

If this bit is set, the DPSM enables the SD I/O card specific interrupt operation.

Bit 10 **RWMOD**: Read Wait mode

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Read Wait control using SDMMC_D2

1: Read Wait control stopping SDMMC_CK

Bit 9 **RWSTOP**: Read Wait stop

This bit is written by firmware and auto cleared by hardware when the DPSM moves from the R_W state to the Wait_R or Idle state.

0: No Read Wait stop

1: Enable for Read Wait stop when DPSM is in the R_W state.

Bit 8 **RWSTART**: Read Wait start

If this bit is set, Read Wait operation starts.

Bits 7:4 **DBLOCKSIZE[3:0]**: Data block size

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Define the data block length when the block data transfer mode is selected:

0000: Block length = 2^0 = 1 byte

0001: Block length = 2^1 = 2 bytes

0010: Block length = 2^2 = 4 bytes

0011: Block length = 2^3 = 8 bytes

0100: Block length = 2^4 = 16 bytes

0101: Block length = 2^5 = 32 bytes

0110: Block length = 2^6 = 64 bytes

0111: Block length = 2^7 = 128 bytes

1000: Block length = 2^8 = 256 bytes

1001: Block length = 2^9 = 512 bytes

1010: Block length = 2^{10} = 1024 bytes

1011: Block length = 2^{11} = 2048 bytes

1100: Block length = 2^{12} = 4096 bytes

1101: Block length = 2^{13} = 8192 bytes

1110: Block length = 2^{14} = 16384 bytes

1111: Reserved

When DATALENGTH is not a multiple of DBLOCKSIZE, the transfered data is truncated at a multiple of DBLOCKSIZE. (None of the remaining data are transfered.)

When DDR = 1, DBLOCKSIZE = 0000 must not be used. (No data are transfered)

Bits 3:2 **DTMODE[1:0]**: Data transfer mode selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

00: Block data transfer ending on block count.

01: SDIO multibyte data transfer.

10: *e*•MMC Stream data transfer. (WIDBUS must select 1-bit wide bus mode)

11: Block data transfer ending with STOP_TRANSMISSION command (not to be used with DTEN initiated data transfers).

Bit 1 **DTDIR**: Data transfer direction selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: From host to card.

1: From card to host.

Bit 0 **DTEN**: Data transfer enable bit

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0). This bit is cleared by hardware when data transfer completes.

This bit must only be used to transfer data when no associated data transfer command is used (must not be used with SD or *e*•MMC cards).

0: Do not start data transfer without CPSM data transfer command.

1: Start data transfer without CPSM data transfer command.

40.10.10 SDMMC data counter register (SDMMC_DCNTR)

Address offset: 0x030

Reset value: 0x0000 0000

This register loads the value from the data length register (see SDMMC_DLENR) when the DPSM moves from the Idle state to the Wait_R or Wait_S state. As data is transferred, the counter decrements the value until it reaches 0. The DPSM then moves to the Idle state and

when there has been no error, and no transmit data transfer hold, the data status end flag (DATAEND) is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DATACOUNT[24:16]

DATACOUNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATACOUNT[24:0]**: Data count value

When read, the number of remaining data bytes to be transferred is returned. Write has no effect.

Note: This register must be read only after the data transfer is complete, or hold. When reading after an error event the read data count value may be different from the real number of data bytes transfered.

40.10.11 SDMMC status register (SDMMC_STAR)

Address offset: 0x034

Reset value: 0x0000 0000

This register is a read-only register. It contains two types of flag:

- Static flags (bits [28, 21, 11:0]): these bits remain asserted until they are cleared by writing to the SDMMC interrupt Clear register (see SDMMC_ICR)
- Dynamic flags (bits [20:12]): these bits change state depending on the state of the underlying logic (for example, FIFO full and empty flags are asserted and deasserted as data while written to the FIFO)

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **IDMABTC**: IDMA buffer transfer complete

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 27 **IDMATE**: IDMA transfer error

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 26 **CKSTOP**: SDMMC_CK stopped in Voltage switch procedure

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 25 **VSWEND**: Voltage switch critical timing section completion
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 24 **ACKTIMEOUT**: Boot acknowledgment timeout
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 23 **ACKFAIL**: Boot acknowledgment received (boot acknowledgment check fail)
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 22 **SDIOIT**: SDIO interrupt received
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 21 **BUSYD0END**: end of SDMMC_D0 Busy following a CMD response detected
This indicates only end of busy following a CMD response. This bit does not signal busy due to data transfer. Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
0: card SDMMC_D0 signal does NOT signal change from busy to not busy.
1: card SDMMC_D0 signal changed from busy to NOT busy.

Bit 20 **BUSYD0**: Inverted value of SDMMC_D0 line (Busy), sampled at the end of a CMD response and a second time 2 SDMMC_CK cycles after the CMD response
This bit is reset to not busy when the SDMMCD0 line changes from busy to not busy. This bit does not signal busy due to data transfer. This is a hardware status flag only, it does not generate an interrupt.
0: card signals not busy on SDMMC_D0.
1: card signals busy on SDMMC_D0.

Bit 19 **RXFIFOE**: Receive FIFO empty
This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes full.

Bit 18 **TXFIFOE**: Transmit FIFO empty
This bit is cleared when one FIFO location becomes full.

Bit 17 **RXFIFOF**: Receive FIFO full
This bit is cleared when one FIFO location becomes empty.

Bit 16 **TXFIFOF**: Transmit FIFO full
This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes empty.

Bit 15 **RXFIFOHF**: Receive FIFO half full
There are at least half the number of words in the FIFO. This bit is cleared when the FIFO becomes half+1 empty.

Bit 14 **TXFIFOHE**: Transmit FIFO half empty
At least half the number of words can be written into the FIFO. This bit is cleared when the FIFO becomes half+1 full.

Bit 13 **CPSMACT**: Command path state machine active (not in Idle state)
This is a hardware status flag only, does not generate an interrupt.

Bit 12 **DPSMACT**: Data path state machine active (not in Idle state)
This is a hardware status flag only, does not generate an interrupt.

Bit 11 **DABORT**: Data transfer aborted by CMD12
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 10 **DBCKEND**: Data block sent/received
DBCKEND is set when:
- CRC check passed and DPSM moves to the R_W state
or
- IDMAEN = 0 and transmit data transfer hold and DATACOUNT >0 and DPSM moves to Wait_S.
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 9 **DHOLD**: Data transfer Hold
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 8 **DATAEND**: Data transfer ended correctly
DATAEND is set if data counter DATACOUNT is zero and no errors occur, and no transmit data transfer hold.
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 7 **CMDSENT**: Command sent (no response required)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 6 **CMDREND**: Command response received (CRC check passed, or no CRC)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 5 **RXOVERR**: Received FIFO overrun error (masked by hardware when IDMA is enabled)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 4 **TXUNDERR**: Transmit FIFO underrun error (masked by hardware when IDMA is enabled)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 3 **DTIMEOUT**: Data timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 2 **CTIMEOUT**: Command response timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
The Command Timeout period has a fixed value of 64 SDMMC_CK clock periods.

Bit 1 **DCRCFAIL**: Data block sent/received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 0 **CCRCFAIL**: Command response received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Note: FIFO interrupt flags must be masked in SDMMC_MASKR when using IDMA mode.

40.10.12 SDMMC interrupt clear register (SDMMC_ICR)

Address offset: 0x038

Reset value: 0x0000 0000

This register is a write-only register. Writing a bit with 1 clears the corresponding bit in the SDMMC_STAR status register.

Bit 3 **DTIMEOUTC**: DTIMEOUT flag clear bit
Set by software to clear the DTIMEOUT flag.
0: DTIMEOUT not cleared
1: DTIMEOUT cleared

Bit 2 **CTIMEOUTC**: CTIMEOUT flag clear bit
Set by software to clear the CTIMEOUT flag.
0: CTIMEOUT not cleared
1: CTIMEOUT cleared

Bit 1 **DCRCFAILC**: DCRCFAIL flag clear bit
Set by software to clear the DCRCFAIL flag.
0: DCRCFAIL not cleared
1: DCRCFAIL cleared

Bit 0 **CCRCFAILC**: CCRCFAIL flag clear bit
Set by software to clear the CCRCFAIL flag.
0: CCRCFAIL not cleared
1: CCRCFAIL cleared

40.10.13 SDMMC mask register (SDMMC_MASKR)

Address offset: 0x03C

Reset value: 0x0000 0000

This register determines which status flags generate an interrupt request by setting the corresponding bit to 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **IDMABTCIE**: IDMA buffer transfer complete interrupt enable
Set and cleared by software to enable/disable the interrupt generated when the IDMA has transferred all data belonging to a memory buffer.
0: IDMA buffer transfer complete interrupt disabled
1: IDMA buffer transfer complete interrupt enabled

Bit 27 Reserved, must be kept at reset value.

Bit 26 **CKSTOPIE**: Voltage switch clock stopped interrupt enable
Set and cleared by software to enable/disable interrupt caused by voltage switch clock stopped.
0: Voltage switch clock stopped interrupt disabled
1: Voltage switch clock stopped interrupt enabled

Bit 25 **VSWENDIE**: Voltage switch critical timing section completion interrupt enable
Set and cleared by software to enable/disable the interrupt generated when voltage switch critical timing section completion.
0: Voltage switch critical timing section completion interrupt disabled
1: Voltage switch critical timing section completion interrupt enabled

Bit 24 **ACKTIMEOUTIE**: Acknowledgment timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment timeout.
0: Acknowledgment timeout interrupt disabled
1: Acknowledgment timeout interrupt enabled

Bit 23 **ACKFAILIE**: Acknowledgment fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment fail.
0: Acknowledgment fail interrupt disabled
1: Acknowledgment fail interrupt enabled

Bit 22 **SDIOITIE**: SDIO mode interrupt received interrupt enable
Set and cleared by software to enable/disable the interrupt generated when receiving the SDIO mode interrupt.
0: SDIO mode interrupt received interrupt disabled
1: SDIO mode interrupt received interrupt enabled

Bit 21 **BUSYD0ENDIE**: BUSYD0END interrupt enable
Set and cleared by software to enable/disable the interrupt generated when SDMMC_D0 signal changes from busy to NOT busy following a CMD response.
0: BUSYD0END interrupt disabled
1: BUSYD0END interrupt enabled

Bits 20:19 Reserved, must be kept at reset value.

Bit 18 **TXFIFOEIE**: Tx FIFO empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO empty.
0: Tx FIFO empty interrupt disabled
1: Tx FIFO empty interrupt enabled

Bit 17 **RXFIFOFIE**: Rx FIFO full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO full.
0: Rx FIFO full interrupt disabled
1: Rx FIFO full interrupt enabled

Bit 16 Reserved, must be kept at reset value.

Bit 15 **RXFIFOHFIE**: Rx FIFO half full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO half full.
0: Rx FIFO half full interrupt disabled
1: Rx FIFO half full interrupt enabled

Bit 14 **TXFIFOHEIE**: Tx FIFO half empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO half empty.
0: Tx FIFO half empty interrupt disabled
1: Tx FIFO half empty interrupt enabled

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **DABORTIE**: Data transfer aborted interrupt enable
Set and cleared by software to enable/disable interrupt caused by a data transfer being aborted.
0: Data transfer abort interrupt disabled
1: Data transfer abort interrupt enabled

Bit 10 **DBCKENDIE**: Data block end interrupt enable
Set and cleared by software to enable/disable interrupt caused by data block end.
0: Data block end interrupt disabled
1: Data block end interrupt enabled

Bit 9 **DHOLDIE**: Data hold interrupt enable
Set and cleared by software to enable/disable the interrupt generated when sending new data is hold in the DPSM Wait_S state.
0: Data hold interrupt disabled
1: Data hold interrupt enabled

Bit 8 **DATAENDIE**: Data end interrupt enable
Set and cleared by software to enable/disable interrupt caused by data end.
0: Data end interrupt disabled
1: Data end interrupt enabled

Bit 7 **CMDSENTIE**: Command sent interrupt enable
Set and cleared by software to enable/disable interrupt caused by sending command.
0: Command sent interrupt disabled
1: Command sent interrupt enabled

Bit 6 **CMDRENDIE**: Command response received interrupt enable
Set and cleared by software to enable/disable interrupt caused by receiving command response.
0: Command response received interrupt disabled
1: command Response received interrupt enabled

Bit 5 **RXOVERRIE**: Rx FIFO overrun error interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO overrun error.
0: Rx FIFO overrun error interrupt disabled
1: Rx FIFO overrun error interrupt enabled

Bit 4 **TXUNDERRIE**: Tx FIFO underrun error interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO underrun error.
0: Tx FIFO underrun error interrupt disabled
1: Tx FIFO underrun error interrupt enabled

Bit 3 **DTIMEOUTIE**: Data timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by data timeout.
0: Data timeout interrupt disabled
1: Data timeout interrupt enabled

Bit 2 **CTIMEOUTIE**: Command timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by command timeout.
0: Command timeout interrupt disabled
1: Command timeout interrupt enabled

Bit 1 **DCRCFAILIE**: Data CRC fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by data CRC failure.
0: Data CRC fail interrupt disabled
1: Data CRC fail interrupt enabled

Bit 0 **CCRCFAILIE**: Command CRC fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by command CRC failure.
0: Command CRC fail interrupt disabled
1: Command CRC fail interrupt enabled

40.10.14 SDMMC acknowledgment timer register (SDMMC_ACKTIMER)

Address offset: 0x040

Reset value: 0x0000 0000

This register contains the acknowledgment timeout period, in SDMMC_CK bus clock periods.

A counter loads the value from this register, and starts decrementing when the data path state machine (DPSM) enters the Wait_Ack state. If the timer reaches 0 while the DPSM is in this states, the acknowledgment timeout status flag is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	ACKTIME[24:16]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw

ACKTIME[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **ACKTIME[24:0]**: Boot acknowledgment timeout period
This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
Boot acknowledgment timeout period expressed in card bus clock periods.

Note: The data transfer must be written to the acknowledgment timer register before being written to the data control register.

40.10.15 SDMMC data FIFO threshold register (SDMMC_FIFOTHRR)

Address offset: 0x044

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	THR[3:0]			
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **THR[3:0]**: FIFO threshold
This bit can only be written by software when DPSM is inactive (DPSMACT = 0).
Define the data FIFO threshold:
0b0000:threshold = 0 byte (no threshold)
Others: threshold = $2^{(N-1)}$ bytes, threshold must not be programmed bigger than the FIFO size, 256 words.
Note: When THR > DBLOCKSIZE, blocks may not be transferred.

40.10.16 SDMMC DMA control register (SDMMC_IDMACTRLR)

Address offset: 0x050

Reset value: 0x0000 0000

The receive and transmit FIFOs can be read or written as 32-bit wide registers. The FIFOs contain 32 entries on 32 sequential addresses. This enables the CPU to use its load and store multiple operands to read from/write to the FIFO.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IDMABMODE	IDMAEN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **IDMABMODE**: Buffer mode selection
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: Single buffer mode.
1: Linked list mode.

Bit 0 **IDMAEN**: IDMA enable
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: IDMA disabled
1: IDMA enabled

40.10.17 SDMMC IDMA buffer size register (SDMMC_IDMABSIZER)

Address offset: 0x054

Reset value: 0x0000 0000

This register contains the buffer size when in linked list configuration.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IDMABNDT[9:0]										Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw						

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:6 **IDMABNDT[10:0]**: Number of bytes per buffer

This 11-bit value must be multiplied by 16 to get the size of the buffer in 32-bit words and by 64 to get the size of the buffer in bytes.
Example: IDMABNDT = 0x001: buffer size = 16 words = 64 bytes.
Example: IDMABNDT = 0x400: buffer size = 16384 words = 64 Kbytes.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 5:0 Reserved, must be kept at reset value.

40.10.18 SDMMC IDMA buffer base address register (SDMMC_IDMABASER)

Address offset: 0x058

Reset value: 0x0000 0000

This register contains the memory buffer base address in single buffer configuration and linked list configuration.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IDMABASE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r

Bits 31:0 **IDMABASE[31:0]**: Buffer memory base address bits [31:2], must be word aligned (bit [1:0] are always 0 and read only)

This register can be written by firmware when DPSM is inactive (DPSMACT = 0), and can dynamically be written by firmware when DPSM active (DPSMACT = 1).

40.10.19 SDMMC IDMA linked list address register (SDMMC_IDMALAR)

Address offset: 0x064

Reset value: 0x0000 0000

IDMALA[13:0]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **ULA**: Update SDMMC_IDMALAR from linked list when in linked list mode (SDMMC_IDMACTRLR.IDMABMODE select linked list mode)
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: SDMMC_IDMALAR is not to be updated, last linked list item.
1: SDMMC_IDMALAR is to be updated from linked list table.

Bit 30 **ULS**: Update SDMMC_IDMABSIZE from the next linked list when in linked list mode (SDMMC_IDMACTRLR.IDMABMODE select linked list mode and ULA = 1)
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: SDMMC_IDMABSIZER is not to be updated from next linked list table.
1: SDMMC_IDMABSIZER is to be updated from next linked list table.

Bit 29 **ABR**: Acknowledge linked list buffer ready
This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
This bit is not taken into account when starting the first linked list buffer from the software programmed register information. ABR is only taken into account on subsequent loaded linked list items.
0: Loaded linked list buffer is not ready (this causes a linked list IDMA transfer error to be generated).
1: Loaded linked list buffer ready acknowledge. Linked list buffer data are transfered by IDMA.

Bits 28:16 Reserved, must be kept at reset value.

Bits 15:2 **IDMALA[13:0]**: Word aligned linked list item address offset
Linked list item offset pointer to the base of the next linked list item structure.
Linked list item base address is IDMABA + IDMALA.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 1:0 Reserved, must be kept at reset value.

40.10.20 SDMMC IDMA linked list memory base register (SDMMC_IDMABAR)

Address offset: 0x068

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDMABA[29:14]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDMABA[13:0]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bits 31:2 **IDMABA[29:0]**: Word aligned Linked list memory base address
Linked list memory base pointer.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 1:0 Reserved, must be kept at reset value.

40.10.21 SDMMC data FIFO registers x (SDMMC_FIFORx)

Address offset: 0x080 + 0x004 * x, (x =0 to 15)

Reset value: 0x0000 0000

The receive and transmit FIFOs can be only read or written as word (32-bit) wide registers. The FIFOs contain 16 entries on sequential addresses. This enables the CPU to use its load and store multiple operands to read from/write to the FIFO. The FIFO register interface takes care of correct data alignment inside the FIFO, the FIFO register address used by the CPU does matter.

When accessing SDMMC_FIFOR with half word or byte access an AHB bus fault is generated.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

FIFODATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **FIFODATA[31:0]**: Receive and transmit FIFO data

This register can only be read or written by firmware when the DPSM is active (DPSMACT = 1).

The FIFO data occupies 16 entries of 32-bit words.

40.10.22 SDMMC hardware configuration register 1 (SDMMC_HWCFGR1)

Address offset: 0x3F0

Reset value: 0x0000 0004

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FIFOSIZE[3:0]			
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **FIFOSIZE[3:0]**: SDMMC FIFO size

FIFO size = 2^{N+6} bytes, with N in the range 0 to 9

For FIFO size 2^6 bytes, the transfer beat is 8 (32 bytes)

For all other FIFO sizes, the transfer beat is 16 (64 bytes)

40.10.23 SDMMC version register (SDMMC_VERR)

Address offset: 0x3F4

Reset value: 0x0000 0030

41 Delay block (DLYB)

41.1 Introduction

The delay block (DLYB) is used to generate two output clocks that are dephased from 2 input clocks. The phase of each output clock must be programmed by the user application. The output clocks are then used to clock the data transmitted/received by another peripheral such as an SDMMC or Octo-SPI interface.

41.2 DLYB main features

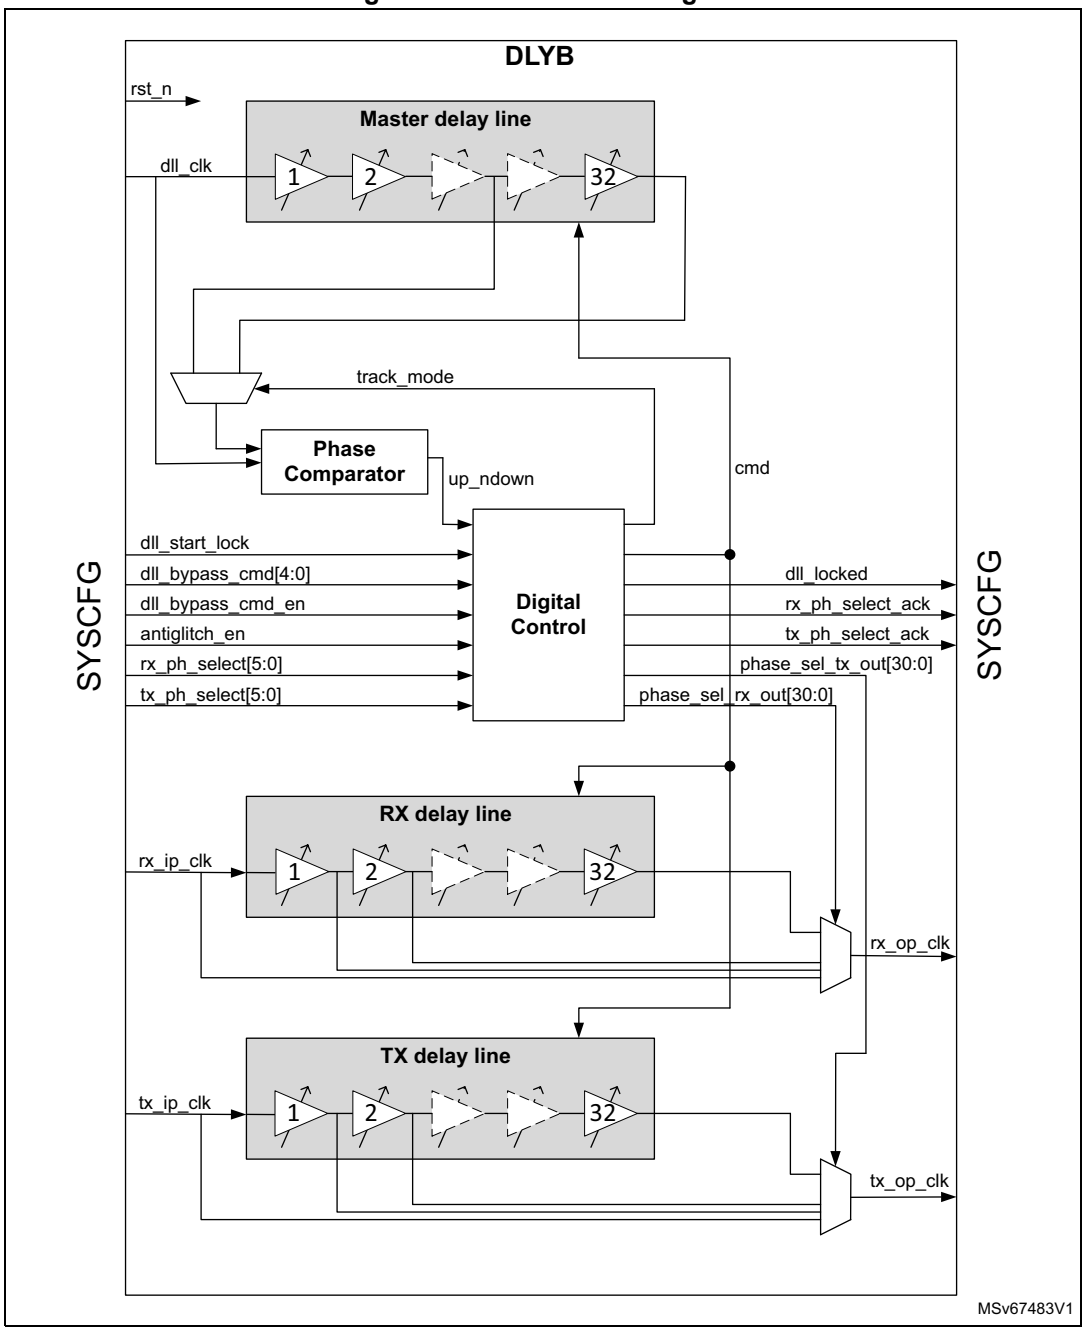
The delay block has the following features:

- Frequency range for Lock mode is [50 MHz, 208 MHz]
- 32 phases (delay taps)
- Bypass mode for operation below 50 MHz

41.3 DLYB implementation

Table 351. STM32MP23/25xx features

DLYB associated peripheral	DLYBOS1	DLYBOS2	DLYBSD1	DLYBSD2	DLYBSD3
OCTOSPI1	X	-	-	-	-
OCTOSPI2	-	X	-	-	-
SDMMC1	-	-	X	-	-
SDMMC2	-	-	-	X	-
SDMMC3	-	-	-	-	X



41.4 DLYB functional description

41.4.1 DLYB diagram

The delay block includes the following sub-blocks (shown in the figure below):

- Digital block to generate commands for delay lines and phase selection. This block embeds lock FSM.
- Delay line supporting the unit delays
- Output clock selection multiplexer

Figure 301. DLYB block diagram

41.4.2 DLYB internal signals

Table 352 lists the DLYB functional signals.

Table 352. DLYB functional signals

Signal name	Signal type	Description
dll_clk	Digital input	Free-running input clock used as reference clock for the Master delay line and FSM blocks
tx_ip_clk	Digital input	Input clock of the TX slave delay line
rx_ip_clk	Digital input	Input clock of the RX slave delay line
tx_op_clk	Digital output	Selected output clock of the TX slave delay line
rx_op_clk	Digital output	Selected output clock of the RX slave delay line
rst_n	Digital input	Asynchronous active low reset
dll_start_lock	Digital input	Enable of DLL when configured in Lock mode
dll_locked	Digital output	Lock indicator. When high, it indicates that the FSM has finished the lock sequence. The DLL can be used
tx_ph_select[5:0]	Digital input	Selection of the slave DLL phase shift over 33 for TX path 000000: 0 tap selection 000001: 1 tap selection 011111: 31 taps selection 1xxxxx: 32 taps selection
tx_ph_select_ack	Digital output	When high: phase selected by tx_ph_select is acknowledged When low: output clock tx_op_clk is tied low
rx_ph_select[5:0]	Digital input	Selection of the slave DLL phase shift over 33 for RX path 000000: 0 tap selection 000001: 1 tap selection 011111: 31 taps selection 1xxxxx: 32 taps selection
rx_ph_select_ack	Digital output	When high: phase selected by rx_ph_select is acknowledged When low: output clock rx_op_clk is tied low
antiglitch_en	Digital input	When high: output clocks (tx_op_clk or rx_op_clk) when minimum delay is selected (tx_ph_select = 0 or rx_ph_select=0) are gated to avoid any glitch when phase selection changes When low: output clocks (tx_op_clk or rx_op_clk) when minimum delay is selected (tx_ph_select = 0 or rx_ph_select=0) are not gated (possible glitches if input clocks (tx_ip_clk or rx_ip_clk) are enabled when phase selection changes)
dll_bypass_cmd_en	Digital input	Active high: use dll_bypass_cmd for command generation
dll_bypass_cmd[4:0]	Digital input	permits to force delays for all taps when dll_bypass_cmd_en high: 00000: not functional 00001: pass gate 0 is activated (min delay) 00010: pass gate 1 is activated 11000: pass gate 23 is activated 11001 to 11111: pass gate 23 is activated (max delay)

Table 353 and *Table 354* list the DLYB interconnections. The SYSCFG registers are highlighted in light gray, RCC registers in dark gray and peripheral ports in blue.

Table 353. SDMMC DLYB interconnections

41.4.3 General description

The delay block is structured around one master delay line and two slave delay lines (RX and TX) and there are two operating modes:

- Lock mode (*dll_bypass_cmd_en* = 0)
  - This mode can only be used when the frequency of dll_clk is in the range [50 MHz, 208 MHz]
  - The delay block is enabled by setting *dll_start_lock* to ‘1’.
  - The delay block locks on the frequency of the *dll_clk* input clock and compensates for voltage and temperature variations. This process determines the command to be applied to each of the 32 delay units (a.k.a. tap) of the master delay line for the total master delay to represent one period of *dll_clk*. This command is copied to each delay unit of the RX and TX delay lines. The command varies with voltage and temperature for the DLL to remain locked. This guarantees that each delay unit of the RX and TX delay lines represents 1/32th of the input clock period.
  - Independent delay values can be selected for the RX and TX delay lines by controlling *rx_ph_select[5:0]* and *tx_ph_select[5:0]* parameters. The granularity of the delay is 1/32th of the input clock period.
- Bypass mode (*dll_bypass_cmd_en* = 1)
  - This mode is required to be able to insert a delay between the *rx_ip_clk* (resp. *tx_ip_clk*) input clock and the *rx_op_clk* (resp. *tx_op_clk*) output clock when the operating frequency is lower than the minimum frequency supported by the delay block in lock mode (frequency < 50 MHz). This is necessary to support OCTOSPI devices in DTR mode at low frequency for which DQS must be delayed to sample data.
  - In this mode, delays in the RX and TX delay lines are used as “pure” delays, i.e. without trying to lock on the frequency of the *dll_clk* input clock. There is therefore no voltage nor temperature compensation in this mode and the RX and TX delay values vary with voltage and temperature. The command applied to each delay unit of the RX and TX delay lines is controlled by *dll_bypass_cmd[4:0]*. Each delay

unit includes 24 delay elements. The number of delay elements which are enabled in each delay unit depends on the value of *dll_bypass_cmd[4:0]*.

– Independent delay values can be selected for the RX and TX delay lines by controlling *rx_ph_select[5:0]* and *tx_ph_select[5:0]* parameters. The total delay inserted by the RX (resp. TX) delay line depends on *rx_ph_select[5:0]* (resp. *tx_ph_select[5:0]*) and *dll_bypass_cmd[4:0]* values.

41.4.4 Lock mode procedure

For frequencies greater or equal to 50MHz, procedure is given below:

1. When *rst_n* is low, DLYB lock FSM is put in Idle mode. Note that *dll_start_lock* must be set to ‘0’ during hard reset.
2. Once the input signal *dll_clk* is stable (after a frequency switch for example) the lock sequence can be started by setting *dll_start_lock* to ‘1’ and maintain this value.
3. During lock sequence DLYB can not be used until *dll_locked* flag is set to ‘1’.
4. Once it is done, delay line for master and slaves are PVT compensated (tracking V and T evolution but not a frequency switch).
5. Then the phase can be programmed using *tx_ph_select[5:0]* and *rx_ph_select[5:0]* input signals. The selected delays are applied to TX output clock and RX output clock once *tx_ph_select_ack* and *rx_ph_select_ack* are set to ‘1’ respectively.
6. If another lock sequence is needed, for a frequency switch for example, *dll_start_lock* signal must go to ‘0’ and sequence can be restarted with step 2.

41.4.5 Bypass mode procedure

For frequencies lower the 50 MHz, procedure is given below:

1. When *rst_n* is low, DLYB lock FSM is put in Idle mode. Note that *dll_start_lock* must be set to ‘0’ during hard reset.
2. Delay block is enabled by setting *dll_bypass_cmd_en* to ‘1’. The command applied to every delay unit is defined by *dll_bypass_cmd[4:0]* input (the value 0 is reserved and must not be used).
3. The phase can be programmed using *tx_ph_select[5:0]* and *rx_ph_select[5:0]* input signals. The selected delays are applied to TX output clock and RX output clock once *tx_ph_select_ack* and *rx_ph_select_ack* are set to ‘1’ respectively. For minimum delay, *tx_ph_select[5:0]* (resp. *rx_ph_select[5:0]*) must be set to 0.

42 Analog-to-digital converters (ADC)

42.1 Introduction

This section describes the implementation of up to 3 ADCs:

- ADC1 and ADC2 are tightly coupled
- ADC3 is controlled independently.

Each ADC consists of one 12-bit successive approximation analog-to-digital converter.

Each ADC has up to 20 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan, or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned (default configuration) 32-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows improving analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

42.2 ADC main features

- High-performance features
  - Up to 3 ADCs:
    ADC1 is connected to 18 external channels + 2 internal channels
    ADC2 is connected to 14 external channels + 6 internal channels
    ADC3 is connected to 14 external channels + 6 internal channels
  - 12, 10, 8 or 6-bit configurable resolution
  - ADC conversion time independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Management of single-ended and differential inputs (programmable per channels)
  - AHB slave bus interface to allow fast data handling
  - Offset calibration support
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Fixed latency for a trigger to start of sampling
  - Up to 4 injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Data alignment with in-built data coherency
  - Data can be managed by DMA for regular channel conversions
  - Data can be routed to MDF for post processing
  - Four dedicated data registers for the injected channels

- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (autodelayed mode)
- Oversampler
  - 32-bit data register
  - Oversampling ratio adjustable from 2 to 1024
  - Programmable data right and left shifts
- Data preconditioning
  - Gain compensation
  - Offset compensation
- Analog input channels
  - External analog inputs (per ADC): up to 18 GPIO pads
  - 1 channel for the internal reference voltage (V_{REFINT})
  - 1 channel for monitoring the external VBAT power supply pin
  - 1 channel connected to the analog positive reference voltage V_{REF+}
  - 1 channel for monitoring V_{DDCORE} internal voltage
  - 1 channel for monitoring V_{DDCPU} internal voltage
  - 1 channel for monitoring V_{DDGPU} internal voltage
- Start-of-conversion can be initiated:
  - By software for both regular and injected conversions
  - By hardware triggers with configurable polarity (internal timer events or GPIO input events) for both regular and injected conversions
- Conversion modes
  - Each ADC can convert a single channel or can scan a sequence of channels
  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode
- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
- 3 analog watchdogs per ADC
- ADC input range: $V_{SSA} \leq V_{IN} \leq V_{REF+}$

Figure 302 shows the block diagram of one ADC.

42.4.2 ADC pins and internal signals

Table 356. ADC input/output pins

Pin name	Signal type	Description
VDDA	Input, analog supply	Analog power supply and positive reference voltage for the ADC
VSSA	Input, analog supply ground	Ground for analog power supply, equal to V_{SS}.
VREF+	Input, analog reference positive	The higher/positive reference voltage for the ADC.
VREF−	Input, analog reference negative	The lower/negative reference voltage for the ADC. V_{REF-} is internally connected to V_{SSA}
ADCx_INNi/INPi	Negative/positive external analog input signals	20 negative/positive external analog input channels (refer to *Section 42.4.4: ADC connectivity* for details)

Table 357. ADC internal input/output signals

Internal signal name	Signal type	Description
$V_{INP}i$	Positive analog input channels	Positive internal analog input channels connected either to ADCx_INP*i* external channels or to internal channels.
$V_{INN}i$	Negative analog input channels	Negative internal analog input channels connected either to ADCx_INN*i* external channels or to internal channels
adc_ext_trgi	Inputs	ADC external trigger inputs for regular conversions.These inputs are shared between the ADC master and the ADC slave.
adc_jext_trgi	Inputs	ADC external trigger inputs for the injected conversions. These inputs are shared between the ADC master and the ADC slave.
adc_awdy	Output	Internal analog watchdog output signal connected to on-chip timers. (y = Analog watchdog number 1,2,3)
adc_ker_ck	Input	ADC kernel clock
adc_hclk	Input	ADC peripheral clock
adc_it	Output	ADC interrupt
adc_dma	Output	ADC DMA request
adc_dat[15:0]	Output	ADC data outputs

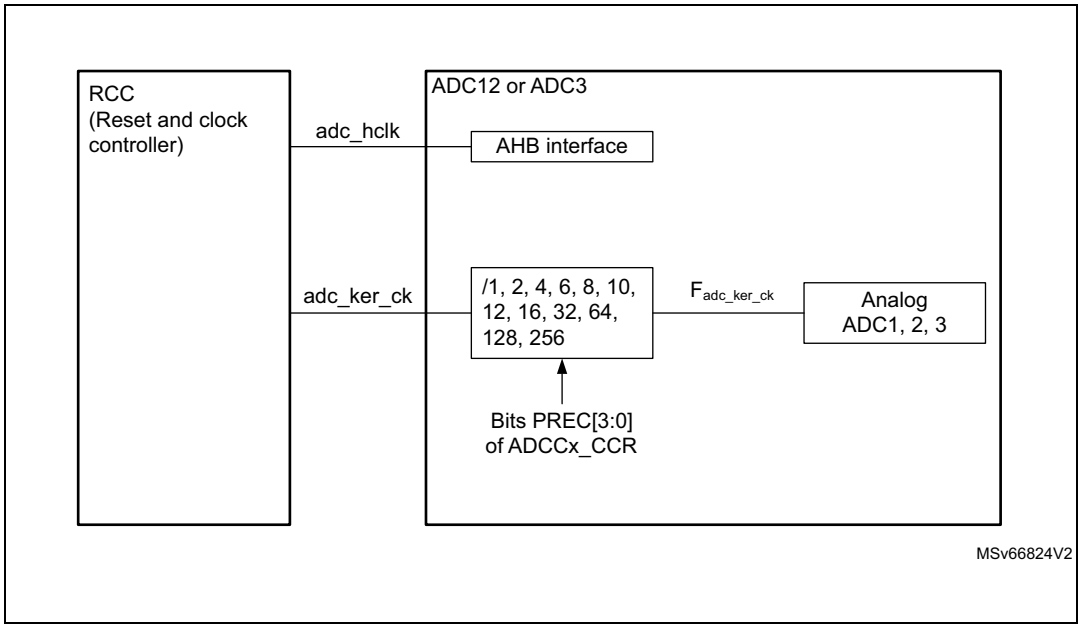
42.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC kernel clock is independent from the AHB bus clock that is used to access ADC registers.

The adc_ker_ck input clock can be selected between different clock sources (see *Figure 303: ADC clock scheme*). This selection is done in the RCC (refer to the *Section 21: Reset and clock control (RCC)* for more information):



1. The ADC clock can be provided by an internal or external clock source, which is independent and asynchronous from the AHB clock.
2. The ADC clock can be derived from AHB clock (selected in RCC).

Option **1** has the advantage of achieving the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can be divided by a 1, 2, 4, 6, 8, 12, 16, 32, 64, 128, or 256 ratio, using the prescaler configured through the PRESC[3:0] bits of the ADCC_CCR register.

Option **2** corresponds to a pseudosynchronous clock. This can be useful when the ADC is triggered by a timer and the application requires that the ADC is accurately triggered without any uncertainty (otherwise, an uncertainty of the trigger instant time is added by the resynchronizations between the two clock domains). This accurate trigger is supported only by trgo or trgo2 timer triggers.

The clock is configured through the RCC and must be compliant with the operating frequency specified in the device datasheet.

Figure 303. ADC clock scheme

Clock ratio constraint between ADC clock and AHB clock

There are no constraints to respect for the ratio between the ADC clock and the AHB clock. However, the ratio must be carefully chosen to avoid any overrun especially if the clock AHB is much slower than the ADC clock.

Constraints between ADC clocks

When several ADC interfaces are used simultaneously, it is mandatory to use the same clock source from the RCC block without prescaler ratio, for all ADC interfaces.

42.4.4 ADC connectivity

ADC inputs are connected to external channels as well as internal sources as described below.

Figure 304. ADC1 connectivity

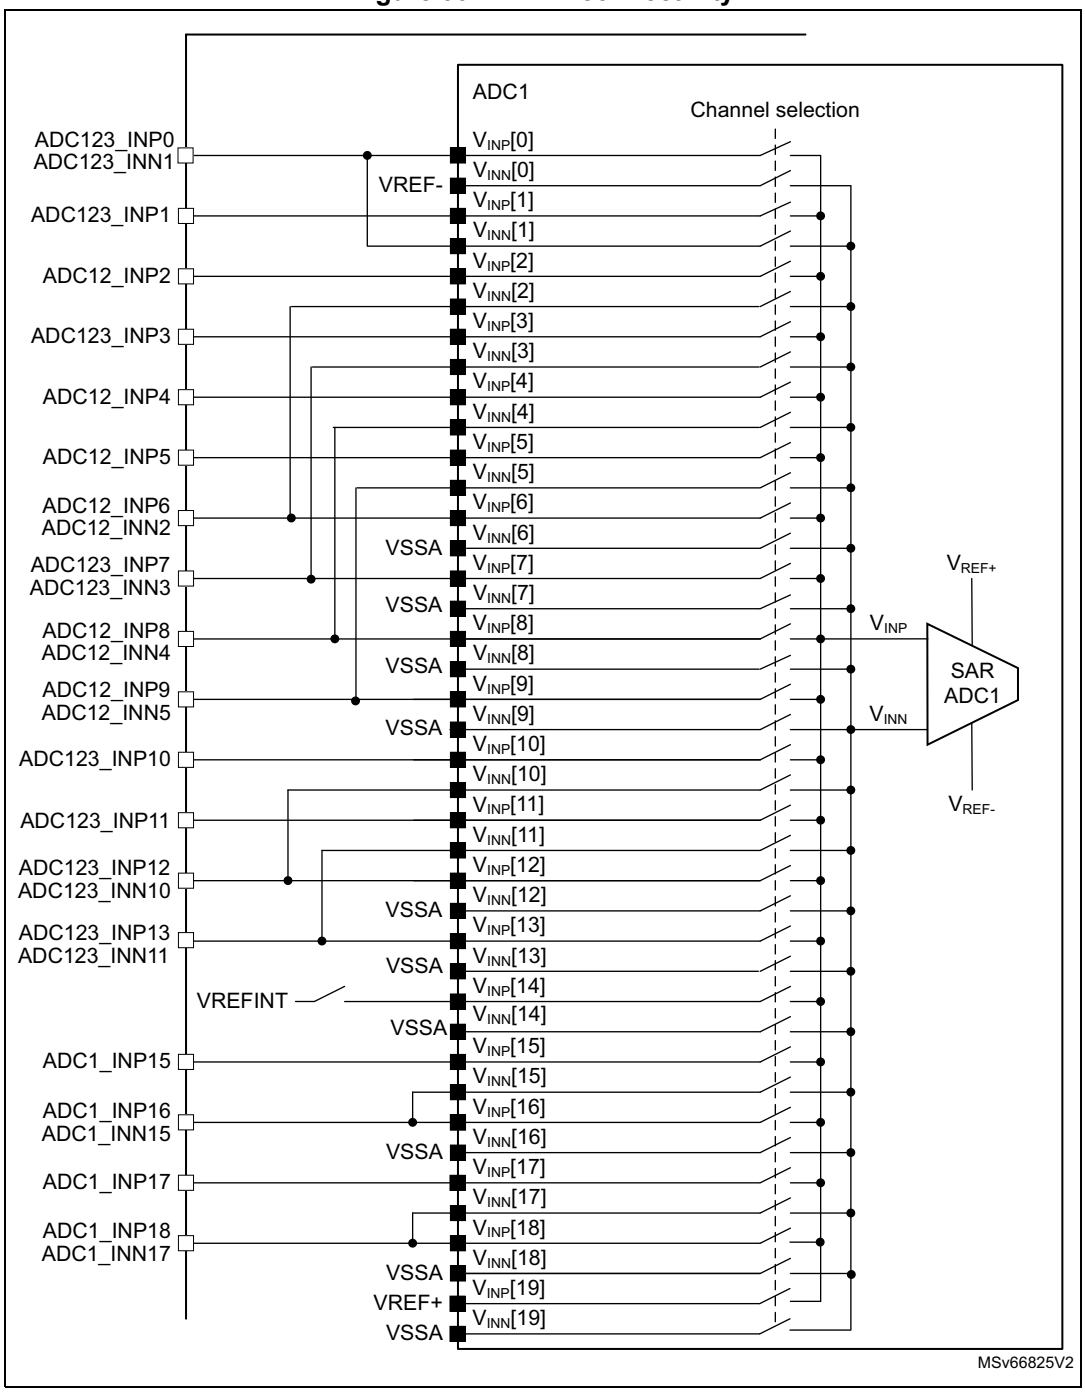


Figure 305. ADC2 connectivity

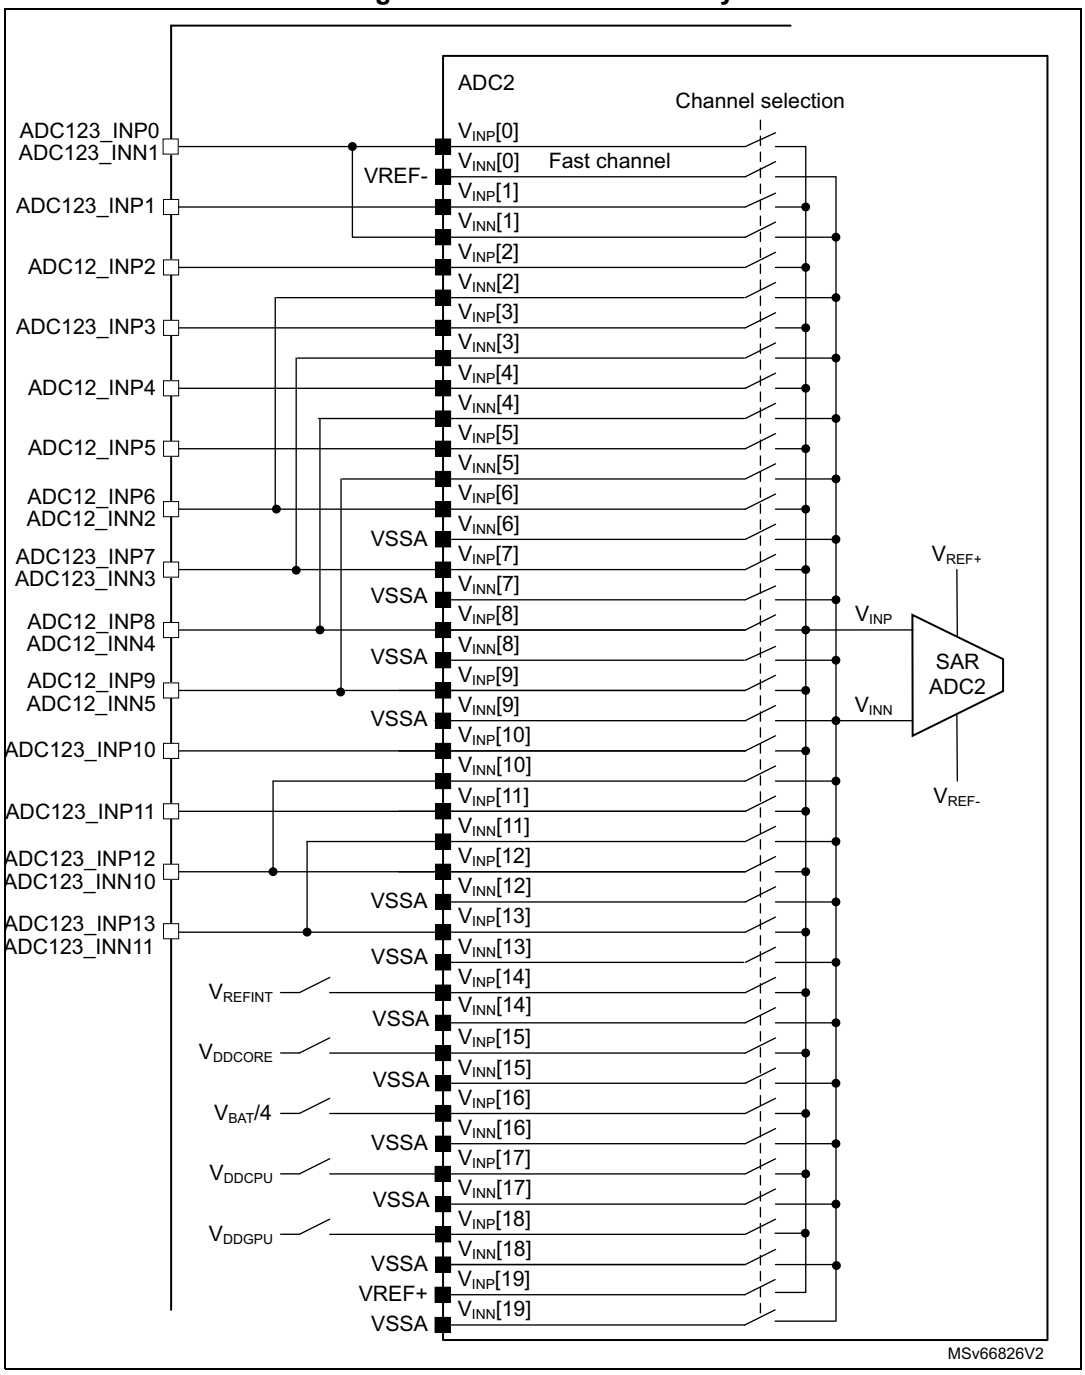

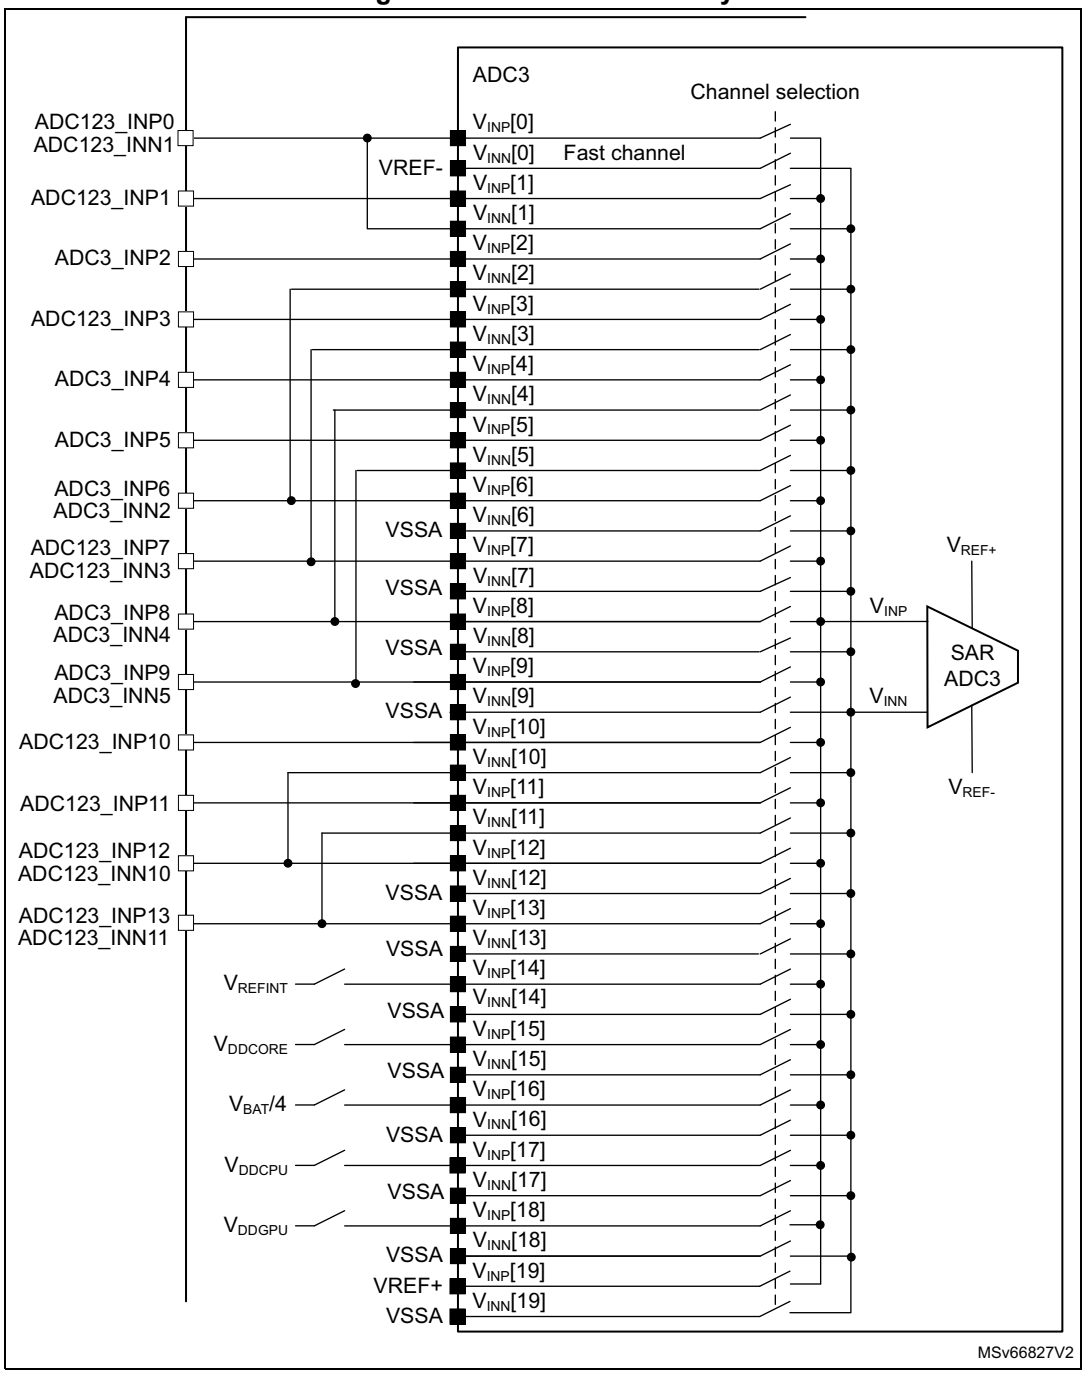

Figure 306. ADC3 connectivity

42.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states, at the exception of ADC_ISR and ADC_AWDyLTR/HTR registers for which wait cycles are added for write operations.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

42.4.6 ADC Deep-power-down mode (DEEPPWD)

By default, the ADC is in deep-power-down mode where its supply voltage is internally switched off to reduce the leakage currents (the reset state of DEEPPWD bit is 1 in the ADC_CR register).

To start ADC operations, it is first required to exit Deep-power-down mode by clearing the DEEPPWD bit.

When ADC operations are complete, the ADC can be disabled by clearing the ADEN bit of the ADC_CR register.

Power can be saved by entering ADC Deep-power-down mode again (by setting DEEPPWD of ADC_CR register). This is particularly interesting before entering Stop mode.

42.4.7 Single-ended and differential input channels

ADC channels can be configured to be either single-ended inputs or differential inputs by programming DIFSEL[i] bits in the ADC_DIFSEL register. This configuration must be programmed when no ADC conversion is ongoing. Note that the DIFSEL[i] bits corresponding to single-ended channels must be programmed at 0.

In single-ended input mode, the analog voltage to be converted for channel "*i*" is the difference between the external voltage $V_{INP[i]}$ and V_{REF-}.

In differential input mode, the analog voltage to be converted for channel "*i*" is the difference between the external voltage $V_{INP[i]}$ (positive input) and $V_{INN[i]}$ (negative input).

In differential mode, the output data are unsigned data. When $V_{INP[i]}$ equals V_{REF-}, $V_{INN[i]}$ equals V_{REF+} and the output data is 0x000 (12-bit resolution mode). When $V_{INP[i]}$ equals V_{REF+}, $V_{INN[i]}$ equals V_{REF-} and the output data is 0xFFF.

$$\text{Converted value} = \frac{\text{ADC_Full_Scale}}{2} \times \left[1 + \frac{V_{INP} - V_{INN}}{V_{REF+}}\right]$$

When the ADC is configured in differential mode, the input signals are supposed to be differential (the common-mode voltage must be fixed at $V_{REF+}/2$ voltage).

Internal channels are used in single-ended mode only.

For a complete description of how the input channels are connected for each ADC, refer to *Section 42.4.4: ADC connectivity*.

Caution: When configuring channel "*i*" in differential input mode, its negative input voltage $V_{INN[i]}$ is connected to another channel. As a consequence, this channel is no longer usable in single-ended or differential mode, and must never be configured to be converted. Some channels are shared between ADC1/ADC2/ADC3: this can make the channel on the other ADCs unusable. The only exception is interleaved mode for ADC master and the slave.

42.4.8 Calibration (ADCAL, CALADDOS, ADC_CALFACT)

A software calibration is required before launching the application. During the calibration sequence, the ADC calculates a 9-bit calibration factor, which is then internally applied to the ADC. Each ADC must follow the calibration procedure to calibrate the zero offset.

The calibration removes the offset error that may vary from chip to chip due to process or bandgap variation. It is a prerequisite to any ADC operation.

The calibration factor to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Clear ADCALDIF before launching a calibration that is applied for single-ended input conversions.
- Set ADCALDIF before launching a calibration that is applied for differential input conversions.

The calibration needs to be run by combinations of hardware and software. When the calibration procedure is complete, the calibration factor must be written to the CALFACT_S[8:0] bits for the single-ended calibration factor and CALFACT_D[8:0] for the differential calibration factor.

The calibration factor can be written only if the ADC is enabled and no conversion is ongoing (ADEN = 1, ADSTART = 0 and JADSTART = 0). It is recommended to calibrate again the ADC if V_{REF+} voltage changes of more than 10% (see *Section 42.4.32: Monitoring the internal voltage reference*).

Software procedure to calibrate the ADC

1. Ensure DEEPPWD = 0, ADEN = 1 and wait until the ADRDY bit is set.
2. Set ADCAL and ensure CALADDOS = 0.
3. Select the calibration input mode by clearing ADCALDIF (single-ended input).
4. Set the ADSTART bit in the ADC_CR register.
5. Wait until the ADSTART bit is cleared or the EOC flag is set.
6. Read the ADC_DR register, then copy the converted data to the memory.
7. Repeat from step 4 several times (for example eight times).
8. Average the data stored in memory by dividing the accumulated data by the number of the conversions
9. If the averaged data is zero, set CALADDOS. Repeat all steps from step 4.
10. Store the averaged data to CALFACT_S[8:0].
11. Select the calibration input mode by setting ADCALDIF (differential input).
12. Keep the same CALADDOS setting as the one obtained during the single-end calibration.
13. Repeat steps 4 to 8.
14. Subtract 0x7FF from the averaged data. If the result is positive, store it in the CALFACT_D[8:0] bitfield. If it is negative, set CALADDOS, then repeat steps from 4 to 8.
15. Subtract again 0x7FF from the new averaged data. The resulting value is positive. Store it in CALFACT_D[8:0].
16. CALADDOS is now set, so clear ADCALDIF, and repeat steps 4 to 8.
17. Store the averaged data in CALFACT_S[8:0].
18. Clear ADCAL bit.

Software procedure to reinject a calibration factor into the ADC

1. Ensure ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion ongoing).
2. Set ADCAL.
3. Program CALADDOS, CALFACT_S and CALFACT_D with the new calibration factors.
4. Clear ADCAL.

Note: Depending on the calibration result, the ADC full-scale output may not reach 0xFFF (12-bit mode) for single-ended mode and [0x000,0xFFF] (12-bit mode) for differential mode.

Converting single-ended and differential analog inputs with a single ADC

If the ADC has to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF = 0 and one with ADCALDIF = 1.

42.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure described in *Section 42.4.6: ADC Deep-power-down mode (DEEPPWD)*).

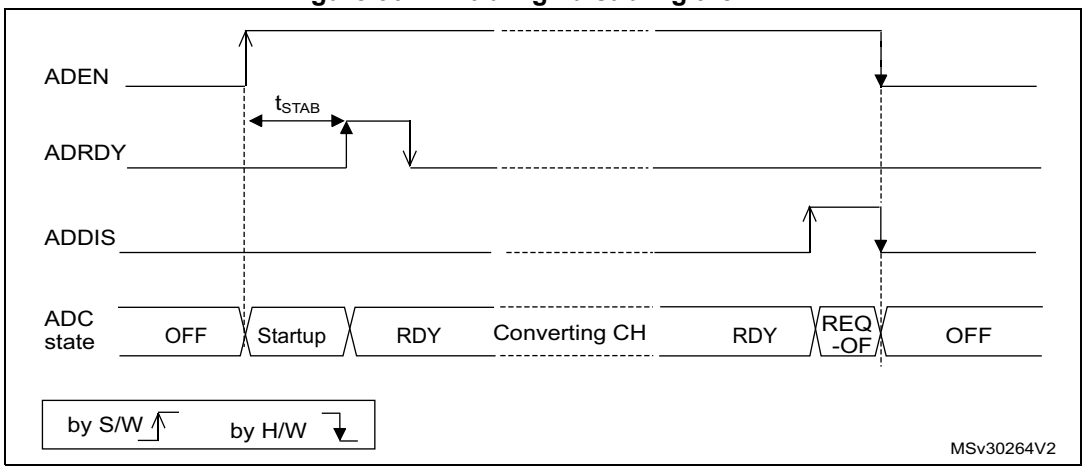
Once DEEPPWD is cleared, the ADC can be enabled. It requires a t_{STAB} stabilization time before starting converting accurately (see *Figure 307*).

Two control bits enable or disable the ADC:

- Set ADEN to enable the ADC. The ADRDY flag is set once the ADC is ready for operation.
- Set ADDIS to disable the ADC. ADEN and ADDIS are automatically deasserted by hardware as soon as the analog ADC is effectively disabled.

Regular conversions can then start either by setting ADSTART (refer to *Section 42.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)*) or when an external trigger event occurs if triggers are enabled.

Injected conversions start by setting JADSTART or when an external injected trigger event occurs, if injected triggers are enabled.



Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by programming it to 1.
2. Set ADEN.
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done by using the associated interrupt (ADRDYIE must be set).
4. Clear the ADRDY bit in the ADC_ISR register by programming it to 1 (optional).

Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to ensure that no conversion is ongoing. If required, stop all regular and injected ongoing conversions by setting ADSTP and JADSTP. Then wait until ADSTP = 0 and JADSTP = 0.
2. Set ADDIS.
3. If required by the application, wait for ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).

Figure 307. Enabling / disabling the ADC

42.4.10 Constraints when writing the ADC control bits

The software is allowed to write the RCC control bits to configure and enable the ADC clock, and the ASV bit of PWR_CR1 to enable the level shifter between V_{DD} to V_{DDA} (refer to RCC section) and configure the ADEN bit in the ADC_CR register, only if the ADC is disabled (ADEN must be cleared).

The software can then write the ADSTART, JADSTART and ADDIS control bits in the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

The following constraints apply to all the other control bits of the ADC_CFGRx, ADC_SMPRx, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy, ADC_OFCHRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if no regular conversions are ongoing (ADSTART must be cleared).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if no injected conversions are ongoing (JADSTART must be cleared).
- ADC_TRy registers can be modified when an analog-to-digital conversion is ongoing (refer to *Section 42.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)* for details).
- To modify the all above control bits when the software trigger function is used, an ADSTP or JADSTP must be issued to make sure all activities are stopped, even if ADSTART and JADSTART are cleared.

The software is allowed to write the ADSTP or JADSTP control bits in the ADC_CR register only if the ADC is enabled and if there is no pending request to disable the ADC. In addition, the software can write the ADC_JSQR register only if JADSTART is cleared and no injected conversion is ongoing. Refer to *Section 42.6.14: ADC injected sequence register (ADC_JSQR)* for additional details.

Note: There is no hardware protection to prevent forbidden write accesses to ADC control bits. In such cases, the ADC state may become unknown. To recover from this situation, the ADC must be disabled (ADEN = 0 as well as all the bits of the ADC_CR register).

42.4.11 Channel selection (SQRx, JSQRx)

The ADC features up to 20 multiplexed channels per ADC, out of which:

- Up to 18 analog inputs coming from GPIO pads (ADCx_INN/INP[i]). Depending on the device, not all of them are available on GPIO pads.
- The ADC is connected to up to 6 internal analog inputs:
  - internal reference voltage (V_{REFINT})
  - V_{BAT} monitoring channel ($V_{BAT}/4$)
  - V_{REF+} positive reference voltage
  - V_{DDCORE} voltage
  - V_{DDCPU} voltage
  - V_{DDGPU} voltage

  To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming VREFEN, VBATEN in the ADCC_CCR registers or enable option register in the ADCx_OR.

Refer to *ADC interconnection* tables in *Section 42.4.2: ADC pins and internal signals* for the connection of the above internal analog inputs to ADC pins.

The conversions can be organized in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADCx_INN/INP3, ADCx_INN/INP8, ADCx_INN/INP2, ADCx_INN/INP2, ADCx_INN/INP0, ADCx_INN/INP2, ADCx_INN/INP2, ADCx_INN/INP15.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.
- An **injected group** is composed of up to four conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while a regular conversion is ongoing. ADC regular conversions must consequently be stopped by setting ADSTP (refer to *Section 42.4.18: Stopping an ongoing conversion (ADSTP, JADSTP)*).

In addition, the ADC_JSQR register must not be modified while an injected conversion is ongoing. ADC injected conversions must consequently be stopped by setting JADSTP, except when JQDIS is cleared.

42.4.12 Channel preselection register (ADC_PCSEL)

The PCSEL bit of the ADC_PCSEL register controls the analog switch integrated in the I/O.

For each channel selected through SQRx or JSQRx bits, the corresponding PCSEL bit must be configured in advance in the ADC_PCSEL register. The ADC input multiplexer selects the ADC input according to SQRx and JSQRx configuration with very high speed. The analog switch integrated in the I/O cannot react as fast as the ADC multiplexer. To avoid the delay due to the analog switch control on the I/O, it is necessary to preselect the input channels that are selected through the SQRx and JSQRx. The selection is based on the V_{INP} of each ADC input. For example, if the ADC converts ADCx_INN/INP1, PCSEL1 bit must also be set in ADC_PCSEL register. If ADCx_INN/INP1 is configured as a differential channel, both PCSEL1 and PCSEL0 must be set, which corresponds to ADC1_INN1.

Note: Configuring the PCSEL bit is not necessary for the internal channels (such as V_{REFINT}).

42.4.13 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be sufficient for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time, which is programmable through the SMP[2:0] bits of the ADC_SMPR1 and ADC_SMPR2 registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 1.5 ADC clock cycles
- SMP = 001: 2.5 ADC clock cycles
- SMP = 010: 6.5 ADC clock cycles
- SMP = 011: 11.5 ADC clock cycles
- SMP = 100: 23.5 ADC clock cycles
- SMP = 101: 46.5 ADC clock cycles
- SMP = 110: 246.5 ADC clock cycles
- SMP = 111: 1499.5 ADC clock cycles

The total conversion time is calculated as follows:

$$T_{CONV} = \text{Sampling time} + 13.5 \text{ ADC clock cycles}$$

Example

With $F_{adc_ker_ck}$ = 30 MHz and a sampling time of 1.5 ADC clock cycles:

$$T_{CONV} = (1.5 + 13.5) \times \text{ADC clock cycles} = 15 \text{ ADC clock cycles} = 500 \text{ ns}$$

The ADC notifies the end of the sampling phase by asserting the EOSMP flag (only for regular conversion).

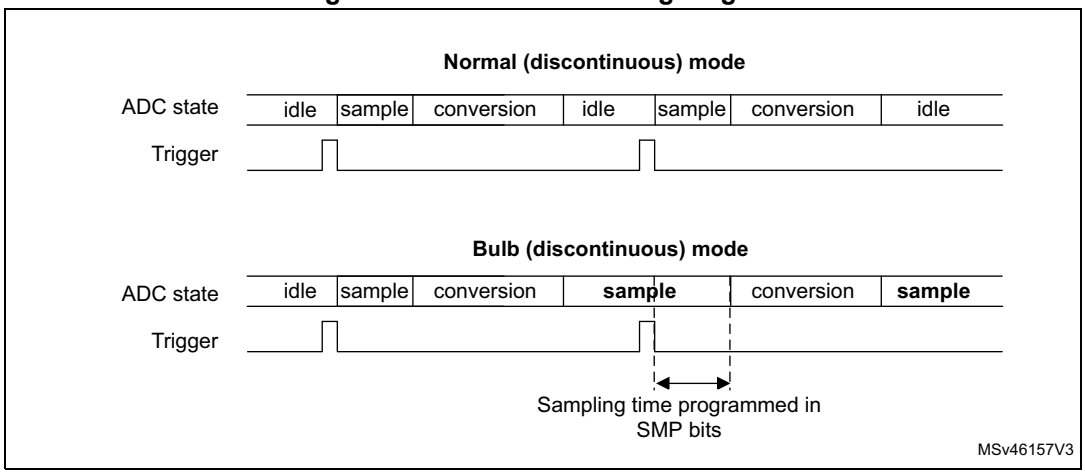
Constraints on the sampling time

For each channel, SMP[2:0] bits must be programmed to respect a minimum and a maximum sampling times as specified in the ADC characteristics section of the datasheets.

Bulb sampling mode

The bulb sampling mode enables to obtain longer sampling time.

When the BULB bit is set in the ADC_CFGR2 register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in ADC_SMPR1 register. The very first ADC conversion after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The bulb mode is effective starting from the second conversion.



The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

The bulb mode is neither compatible with the continuous conversion mode nor with the injected channel conversion.

The BULB bit can be modified only when the ADEN bit of the ADC_CR register is cleared.

When the BULB bit is set, it is not allowed to set the SMPTRIG bit in ADC_CFGR2.

Figure 308. Bulb mode timing diagram

Sampling time control trigger mode

When the SMPTRIG bit is set, the sampling time programmed through SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected (EXTEN[1:0] = 01), each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion.

Due to the synchronization mechanism, the minimum allowed pulse width is seven adc_ker_ck periods.

When a software trigger is selected (EXTEN[1:0] = 00), the software trigger is not the ADSTART bit of ADC_CR but the SWTRIG bit. The SWTRIG bit has to be set to start the sampling period, and it has to be cleared to end the sampling period and start the conversion. In this mode, the minimum sampling time is limited to seven ADC clock cycles.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is only compatible with the discontinuous mode. DISCNUM must be cleared for regular conversion mode. It is not supported for injected conversion mode and autoinjection mode.

When the SMPTRIG bit is set, setting the BULB bit is not allowed and injected conversions are not supported.

42.4.14 Single conversion mode

To enable the single conversion mode for regular channels, clear both CONT and DISCEN bits in ADC_CFGR1 register. To enable it on injected channel, clear JDISCEN bit.

In single conversion mode, the ADC performs once all the regular conversions of the programmed channels. This mode is started by one of the following events:

- ADSTART bit set in the ADC_CR register (for a regular channel)
- JADSTART bit set in the ADC_CR register (for an injected channel)
- An external hardware trigger event (for a regular or injected channel)

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit 8-level FIFO accessible through the ADC_DR register,
- The EOC (end of regular conversion) flag is set, and
- An interrupt is generated if the EOCIE bit is set.

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 32-bit ADC_JDRy registers,
- The JEOC (end of injected conversion) flag is set, and
- An interrupt is generated if the JEOCIE bit is set.

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set, and
- An interrupt is generated if the EOSIE bit is set.

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set, and
- An interrupt is generated if the JEOSIE bit is set.

The ADC then stops until a new external regular or injected trigger occurs or until the ADSTART or JADSTART bit is set again.

The single conversion mode is compatible with bulb and sampling time control trigger modes.

Note: To convert a single channel, program a sequence with a length of 1.

42.4.15 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts all the conversions of the sequence. This mode is started by setting the CONT bit of the ADC_CFGR1 register, either by an external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the eight 32-bit word FIFO accessible through the ADC_DR register.
- The EOC (end of conversion) flag is set, and
- An interrupt is generated if the EOCIE bit is set.

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set, and
- An interrupt is generated if the EOSIE bit is set.

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled, this means that it is forbidden to set both DISCEN and CONT bits.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit) (refer to Section : Autoinjection mode).

42.4.16 Starting conversions (ADSTART, JADSTART)

ADC regular conversions can be started by setting ADSTART.

When ADSTART is set, the conversion starts:

- Immediately if EXTEN[1:0] = 00 (software trigger), or
- At the next active edge of the selected regular hardware trigger, if EXTEN[1:0] is not equal to 00.

The application software starts ADC injected conversions by setting JADSTART.

When JADSTART is set, the conversion starts:

- Immediately if JEXTEN[1:0] = 00 (software trigger), or
- At the next active edge of the selected injected hardware trigger, if JEXTEN[1:0] is not equal to 00.

Note: In autoinjection mode (JAUTO = 1), use the ADSTART bit to start regular conversions followed by autoinjected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether an ADC operation is ongoing. The ADC can be reconfigured while ADSTART and JADSTART are both cleared, indicating that the ADC is idle.

ADSTART is deasserted by hardware:

- In single mode with software regular trigger (CONT = 0, EXTEN = 0x0): at any end of regular conversion sequence (EOS assertion) or at any end of subgroup processing if DISCEN = 1
- In all cases (CONT and EXTEN don’t care), after execution of the ADSTP procedure asserted by the software

Note: In continuous mode (CONT = 1), ADSTART is not deasserted by hardware when EOS is asserted because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT = 0 and EXTEN ≠ 0x00), ADSTART is not deasserted by hardware when EOS is asserted to help the software that does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

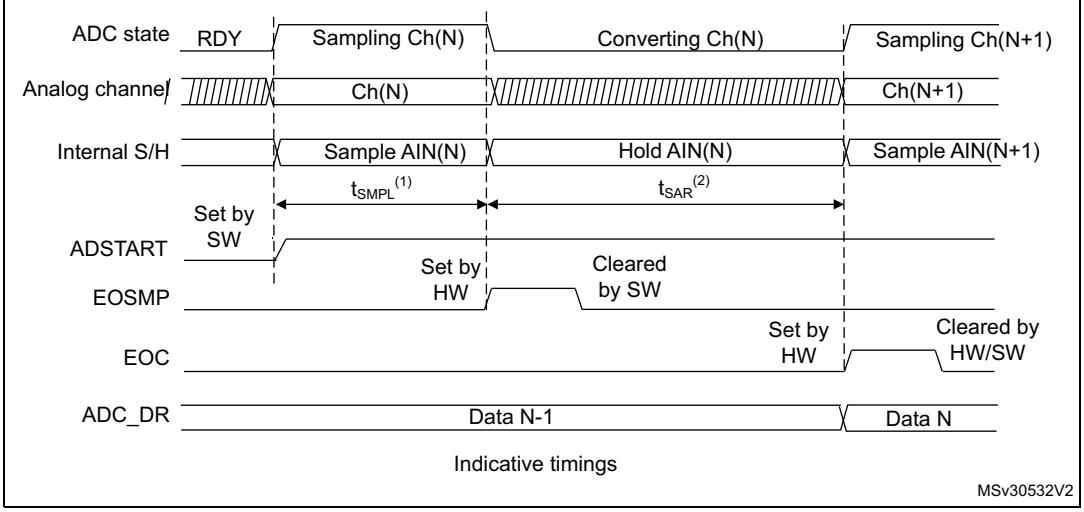
JADSTART is deasserted by hardware:

- In single mode with software injected trigger (JEXTEN = 0x0): at the end of each injected conversion sequence (JEOS assertion) or at the end of each subgroup processing if JDISCEN = 1
- In all cases (JEXTEN=x), after execution of the JADSTP procedure asserted by the software.

Note: When the software trigger is selected, the ADSTART bit must not be set if the EOC flag is still high.

In bulb mode (BULB = 1), the previous end-of-conversion automatically starts the sampling, then setting ADSTART starts the conversion including the programmed sampling time.

In sampling time control trigger mode (SMPTRIG = 1), SWTRIG bit must be set to start the conversion.



42.4.17 Timing

The elapsed time between the start of a conversion and the end of a conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

$T_{CONV} = T_{SMPL} + T_{SAR} = [1.5\ |_{min} + 13.5\ |_{12bit}] \times T_{ADC_CLK}$

$T_{CONV} = T_{SMPL} + T_{SAR} = 50\ ns\ |_{min} + 450\ ns\ |_{12bit} = 500\ ns$ (for $F_{adc_ker_ck} = 30\ MHz$)

Figure 309. Analog-to-digital conversion time

1. t_{SMPL} depends on SMP[2:0].
2. t_{SAR} depends on RES[2:0].
3. The bulb and the sampling time control trigger modes are not described in the above figure.

42.4.18 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop ongoing regular conversions by setting ADSTP and ongoing injected conversions by setting JADSTP.

Stopping conversions resets the ongoing ADC operation. The ADC can then be reconfigured (for example by changing the channel selection or the trigger). It is then ready for a new operation.

Injected conversions can be stopped while regular conversions are still ongoing and vice versa. This allows, for instance, the reconfiguration of the injected conversion sequence and triggers while regular conversions are still ongoing (and vice versa).

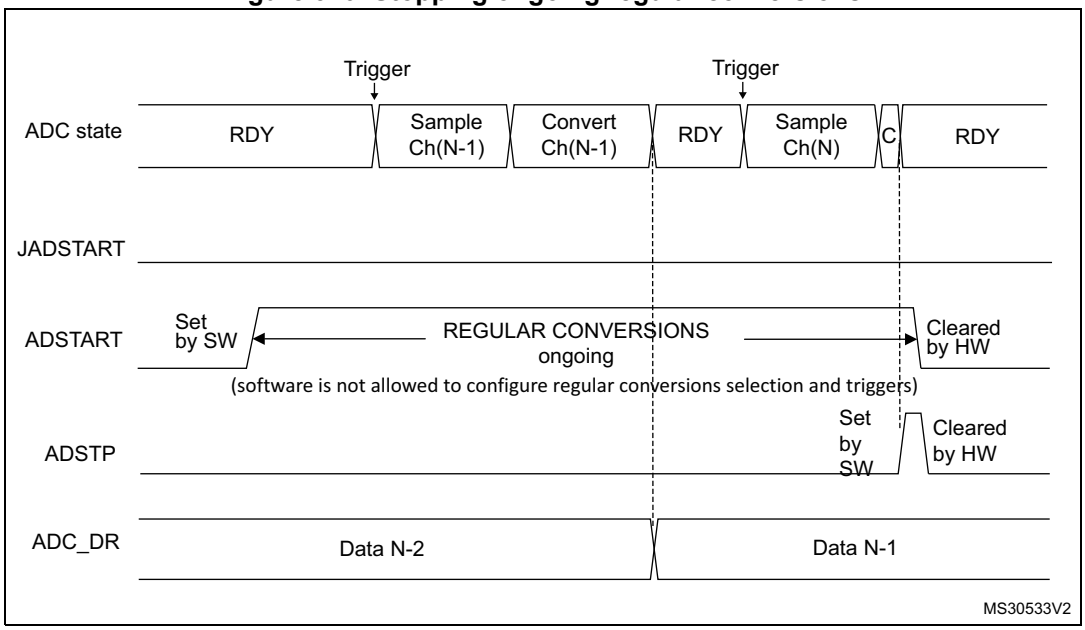
When the ADSTP bit is set by software, any ongoing regular conversion is aborted with the partial result discarded (the ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (the ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC restarts a new sequence).

Once this procedure is complete, ADSTP/ADSTART bits (for regular conversion), or JADSTP/JADSTART bits (for injected conversion) are deasserted by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

Note: In autoinjection mode (JAUTO = 1), setting the ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

Figure 310. Stopping ongoing regular conversions



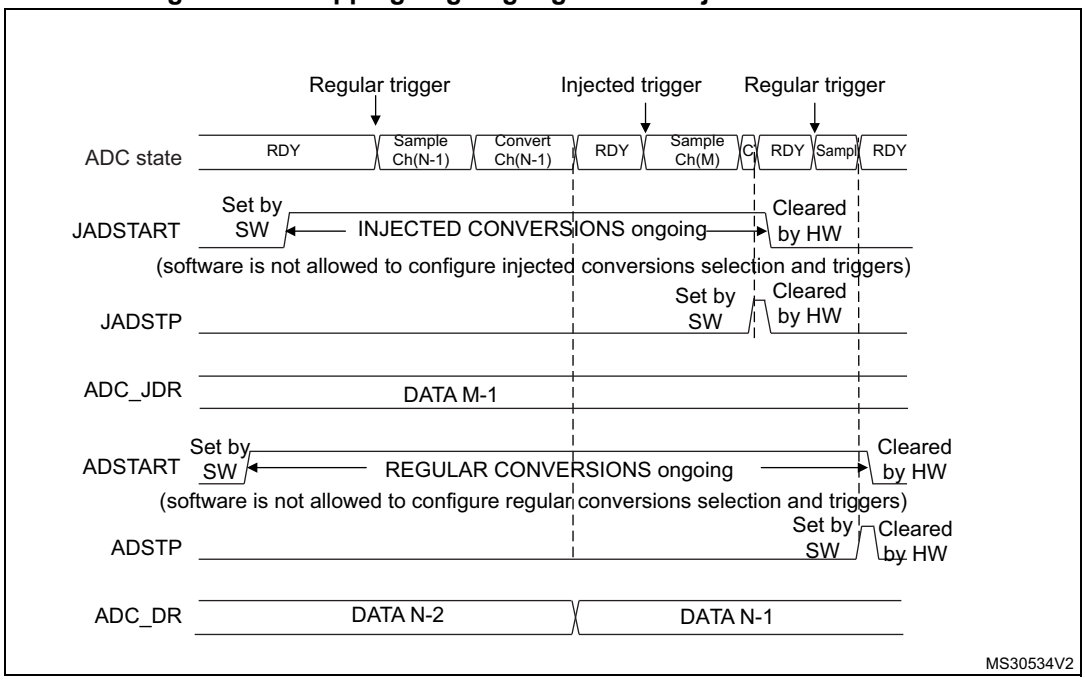


Figure 311. Stopping ongoing regular and injected conversions

42.4.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (for example timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

The regular trigger selection is effective once the software has set ADSTART while the injected trigger selection is effective once the software has set JADSTART bit.

All hardware triggers that occur while a conversion is ongoing are ignored:

- If ADSTART = 0, regular hardware triggers are ignored.
- If JADSTART = 0, injected hardware triggers are ignored.

Table 360 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

Table 360. Configuring the trigger polarity for regular external triggers

EXTEN[1:0]	Source
00	Hardware trigger detection disabled, software trigger detection enabled
01	Hardware trigger with detection on the rising edge (sampling time controlled in hardware trigger mode)
10	Hardware trigger with detection on the falling edge
11	Hardware trigger with detection on both the rising and falling edges

Note: The polarity of the regular trigger cannot be changed on-the-fly.

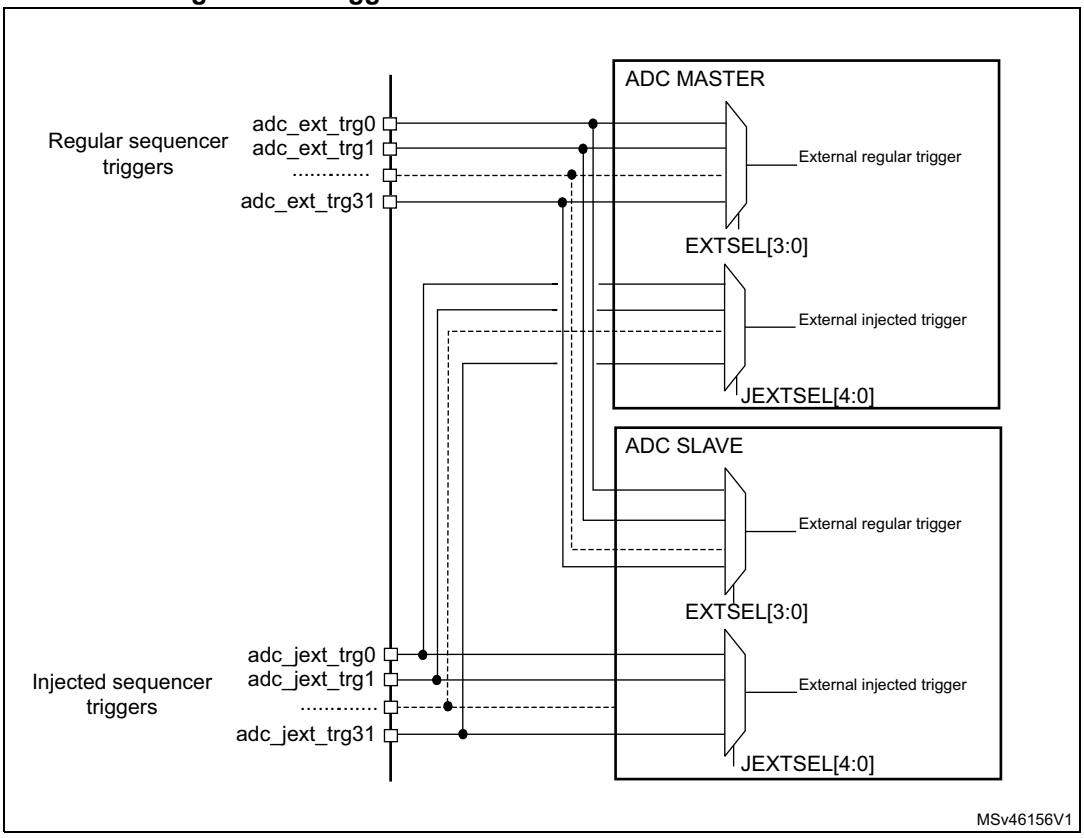

Table 361. Configuring the trigger polarity for injected external triggers

JEXTEN[1:0]	Source
00	Hardware Trigger detection disabled, software trigger detection enabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges

The EXTSEL and JEXTSEL control bits select which, out of 32 possible events, can trigger the conversion of the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.

Figure 312. Triggers shared between ADC master and slave

Refer to *ADC interconnection* tables in *Section 42.4.2: ADC pins and internal signals* for the list of the external triggers that can be used for regular conversion.

42.4.20 Injected channel management

Triggered injection mode

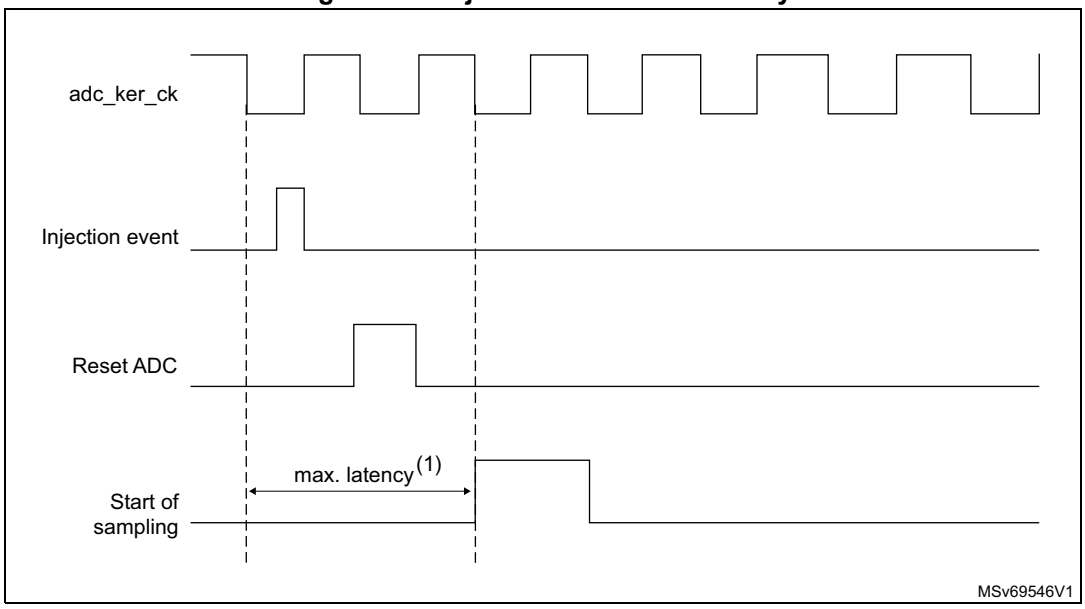
To use triggered injection, the JAUTO bit in the ADC_CFGR1 register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once if JDISCEN = 0).
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.
4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. *Figure 313* shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 30 ADC clock cycles (that is two conversions with a sampling time of 1.5 clock periods), the minimum interval between triggers must be 31 ADC clock cycles.

Autoinjection mode

If the JAUTO bit in the ADC_CFGR1 register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.



In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the autoinjected and discontinuous modes simultaneously.

Figure 313. Injected conversion latency

1. The maximum latency value can be found in the electrical characteristics of the device datasheet.

42.4.21 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR1 register.

It is used to convert a short sequence (subgroup) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR1 register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQRy registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:

- DISCEN = 1, n = 3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - First trigger: channels converted are 1, 2, 3 (an EOC event is generated at the end of each conversion).
  - Second trigger: channels converted are 6, 7, 8 (an EOC event is generated at the end of each conversion).
  - Third trigger: channels converted are 9, 10, 11 (an EOC event is generated at the end of each conversion) and an EOS event is generated after the conversion of channel 11.
  - Fourth trigger: channels converted are 1, 2, 3 (an EOC event is generated at the end of each conversion).

  - ...
- DISCEN = 0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10,11
  - First trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.

Note: The channel numbers referred to in the above example might not be available on all devices.

When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the fourth trigger reconverts the channels 1, 2 and 3 in the first subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR1 register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example:

- JDISCEN = 1, channels to be converted = 1, 2, 3
  - First trigger: channel 1 converted (a JEOC event is generated)
  - Second trigger: channel 2 converted (a JEOC event is generated)
  - Third trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: The channel numbers referred to in the above example might not be available on all devices.

When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the fourth trigger reconverts the first injected channel 1.

It is not possible to use both autoinjection mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

42.4.22 Programmable resolution (RES) - fast conversion mode

Faster conversions can be performed by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the RES[1:0] control bits. *Figure 318*, *Figure 319*, *Figure 320* and *Figure 321* show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to *Table 362*.

Table 362. T_{SAR} timings depending on resolution

RES (bits)	T_{SAR} (ADC clock cycles)	T_{SAR} (ns) at $F_{adc_ker_ck}$ = 30 MHz	T_{CONV} (ADC clock cycles) (with Sampling time= 1.5 ADC clock cycles)	T_{CONV} (ns) at $F_{adc_ker_ck}$ = 30 MHz
12	13.5 ADC clock cycles	450 ns	15 ADC clock cycles	500.0 ns
10	11.5 ADC clock cycles	383.33 ns	13 ADC clock cycles	433.33 ns
8	8.5 ADC clock cycles	203.33 ns	10 ADC clock cycles	333.33 ns
6	6.5 ADC clock cycles	216.67 ns	8 ADC clock cycles	266.66 ns

42.4.23 End of conversion and end of sampling phase (EOC, JEOC, EOSMP)

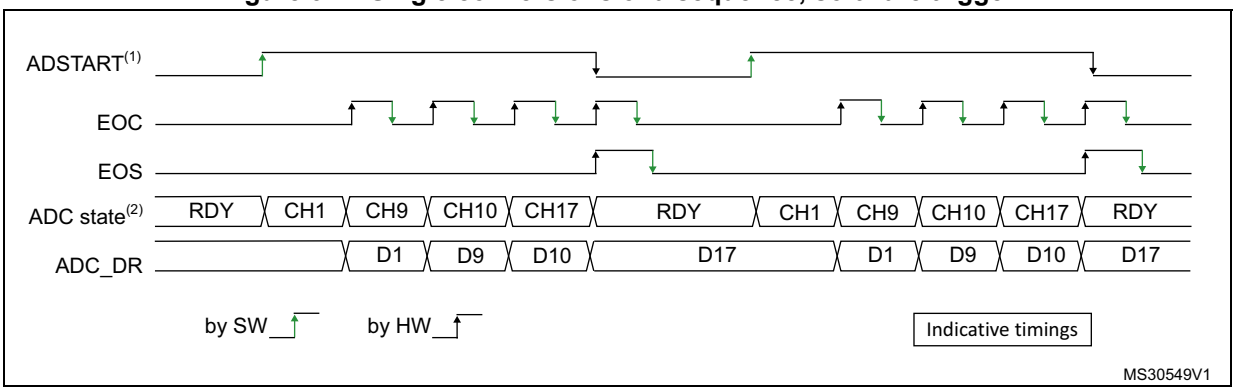
The ADC notifies the application at the end of each regular conversion (EOC) event and injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if the EOCIE bit is set. The software can clear the EOC flag either by programming it to 1 or by reading ADC_DR. If ADC_DR FIFO is not emptied, the EOC flag is set again and an interrupt can be generated again.

The ADC sets the JEOC flag as soon as new injected conversion data is available in one of the ADC_JDRy registers. An interrupt can be generated if the JEOCIE bit is set. The software can clear the JEOC flag either by programming it to 1 or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of the sampling phase by setting the EOSMP flag (for regular conversions only). The EOSMP flag is cleared by software by programming it to 1. An interrupt can be generated if the EOSMPIE bit is set.

42.4.24 End of conversion sequence (EOS, JEOS)



The ADC notifies the application at the end of each regular sequence (EOS) and injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the conversion of the last data of the regular sequence is complete. An interrupt can be generated if the EOSIE bit is set. The EOS flag is cleared by the software by programming it to 1.

The ADC sets the JEOS flag as soon as the conversion of the last data of the injected sequence is complete. An interrupt can be generated if the JEOSIE bit is set. The JEOS flag is cleared by the software by programming it to 1.

2. Channels selected = 1, 2, 3, 4; AUTDLY=0.

42.4.26 Data management

Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT, POSOFF)

Data and alignment

At the end of each regular channel conversion (when an EOC event occurs), the result of the converted data is stored in the 32-bit wide ADC_DR data register with FIFO. Since the data register has eight levels of FIFO, the EOC flag is raised again as far as the FIFO is not emptied.

At the end of each injected channel conversion (when a JEOC event occurs), the result of the converted data is stored in the 32-bit wide corresponding ADC_JDRy data register.

The OVSS[3:0] and LSHIFT[3:0] bitfields in the ADC_CFGR2 register select the alignment of the data stored after the conversion. By default, data are right-aligned. Refer to *Figure 318*, *Figure 319*, *Figure 320* and *Figure 321* for examples of data alignment.

Note: The data can be aligned in normal and oversampling mode. The OVSS[3:0] bitfield is only effective in oversampling mode.

Offset

An unsigned offset value y (y = 1, 2, 3, 4) can be applied to a channel by programming a value different from 0 in the OFFSET[21:0] bitfield of the ADC_OFRy register. The channel to which the offset is applied is programmed to the OFFSETy_CH[4:0] bits of ADC_OFCFGRy register. The offset can be positive or negative depending on the value of POSOFF bit. When POSOFF is cleared, the converted value is subtracted by the user-defined offset written in OFFSET[21:0] bits. The result can be a negative value. The read data is consequently signed and the SEXT bit represents the extended sign value.

The offset value must be lower than the maximum conversion value (for example the maximum offset value is 0xFFF in 12-bit mode).

The offset can be used to convert unsigned data to signed data (for example the offset value is equal to 0x800 in 12-bit mode).

The offset correction is also supported in oversampling mode. In this mode, the offset is subtracted when all the oversampling operations are complete.

Note: It is not allowed to select the same channel for different OFFSETy_CH[4:0] values except when OFFSET[21:0] is 0.

Table 367 describes how the computation is performed for all the possible ADC resolutions and offset settings.

Table 363. Offset computation versus data resolution

Resolution (RES[1:0] bits)	Subtraction between raw converted data and offset		Result	Comments
	Raw converted Data, left aligned	Offset		
00: 12-bit	DATA[11:0]	OFFSET[11:0]	Signed or unsigned 24-bit data, right aligned to [11:0]	-
01: 10-bit	DATA[11:2],00	OFFSET[11:2]	Signed or unsigned 24-bit data, right aligned to [9:0]	The user must configure OFFSET[1:0] to 0b00.
10: 8-bit	DATA[11:4],0000	OFFSET[11:4]	Signed or unsigned 24 bit data right aligned to [7:0]	The user must configure OFFSET[3:0] to 0b0000.
11: 6-bit	DATA[11:6],000000	OFFSET[11:6]	Signed or unsigned 24 bit data right aligned to [5:0]	The user must configure OFFSET[5:0] to 0b000000.

Figure 318, *Figure 319*, *Figure 320* and *Figure 321* show alignments for signed and unsigned data.

Figure 318. Right alignment (offset disabled, unsigned value)

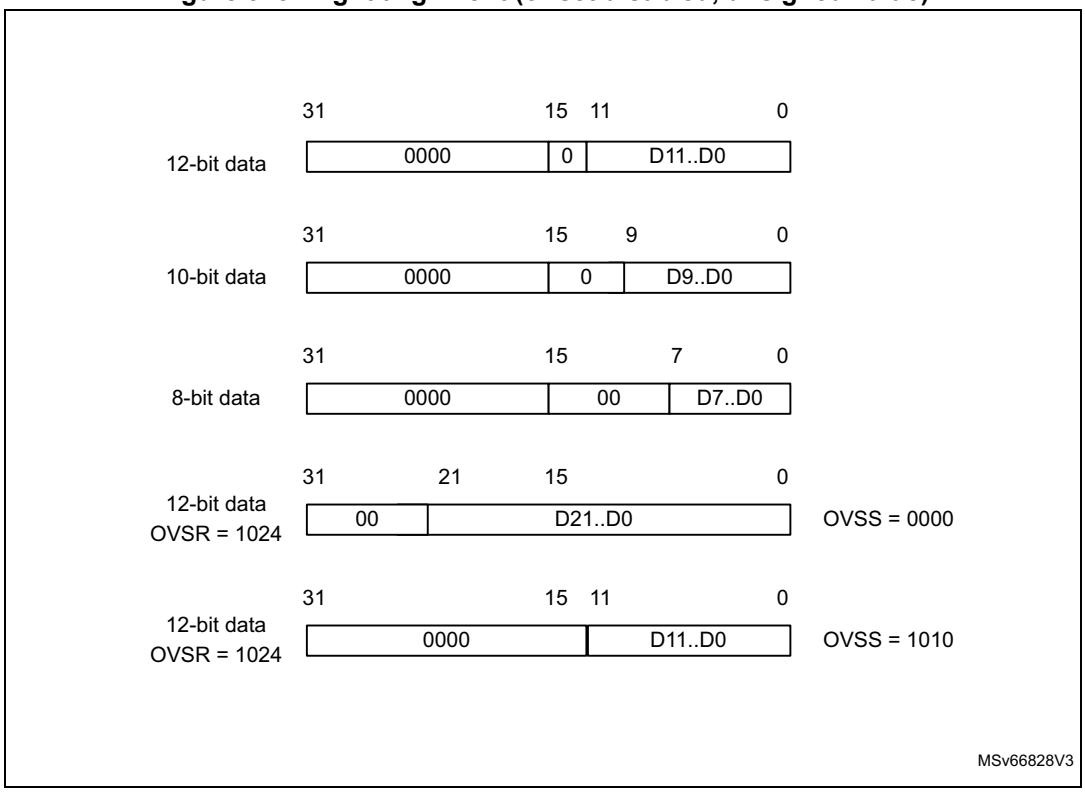

Figure 319. Right alignment (offset enabled, signed value)

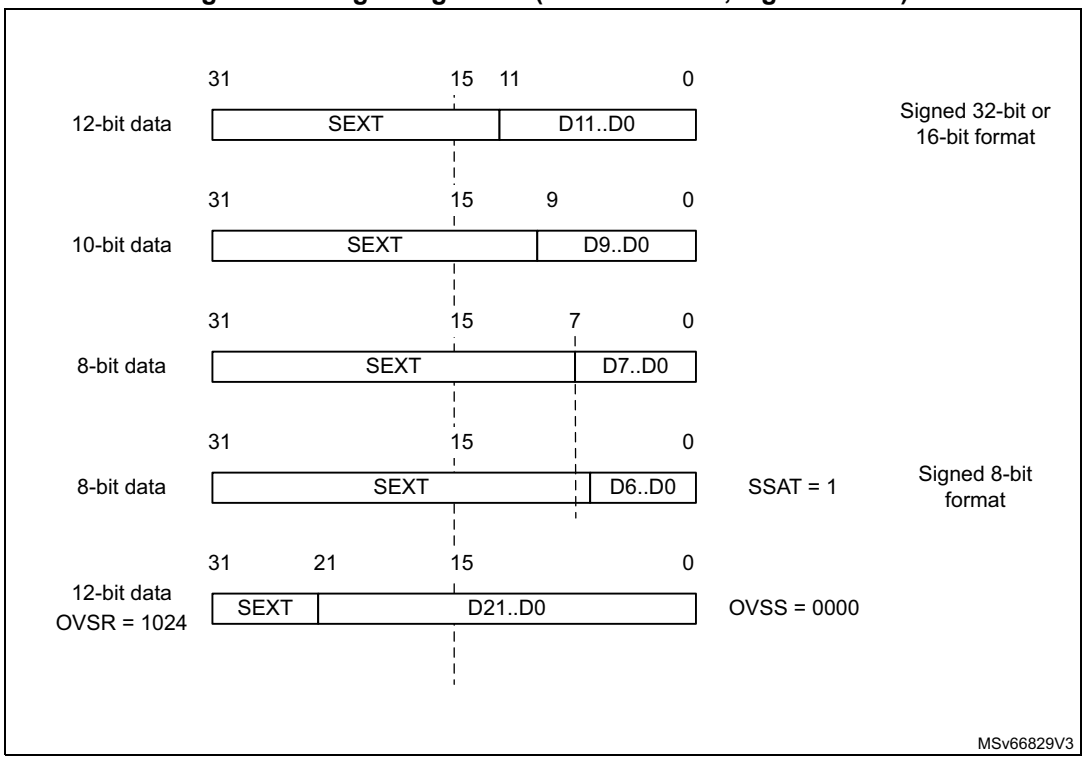

Figure 320. Left alignment (offset disabled, unsigned value)

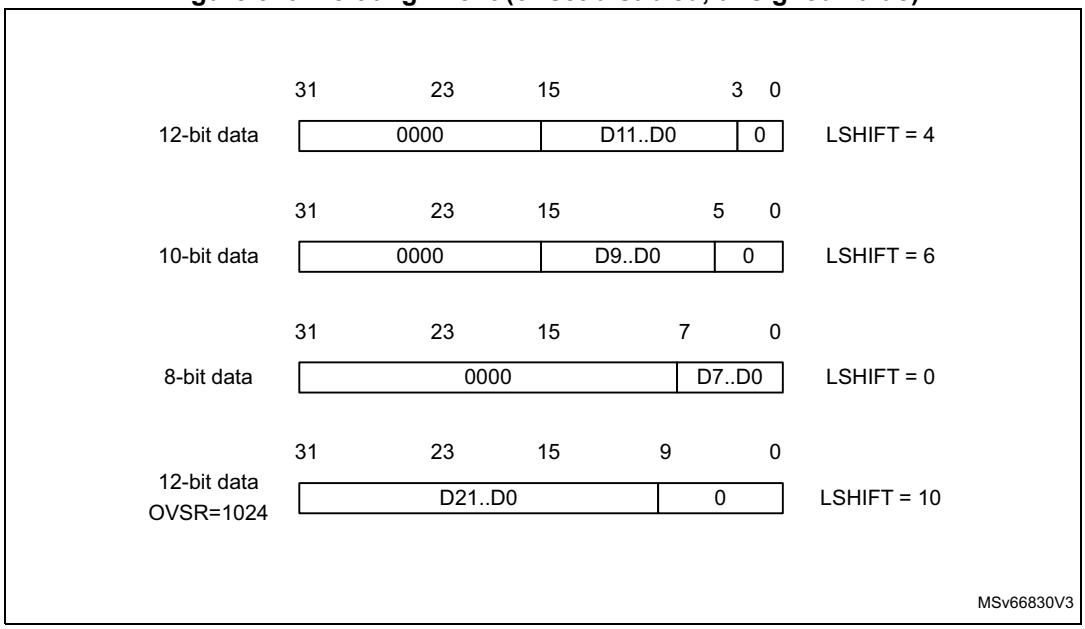

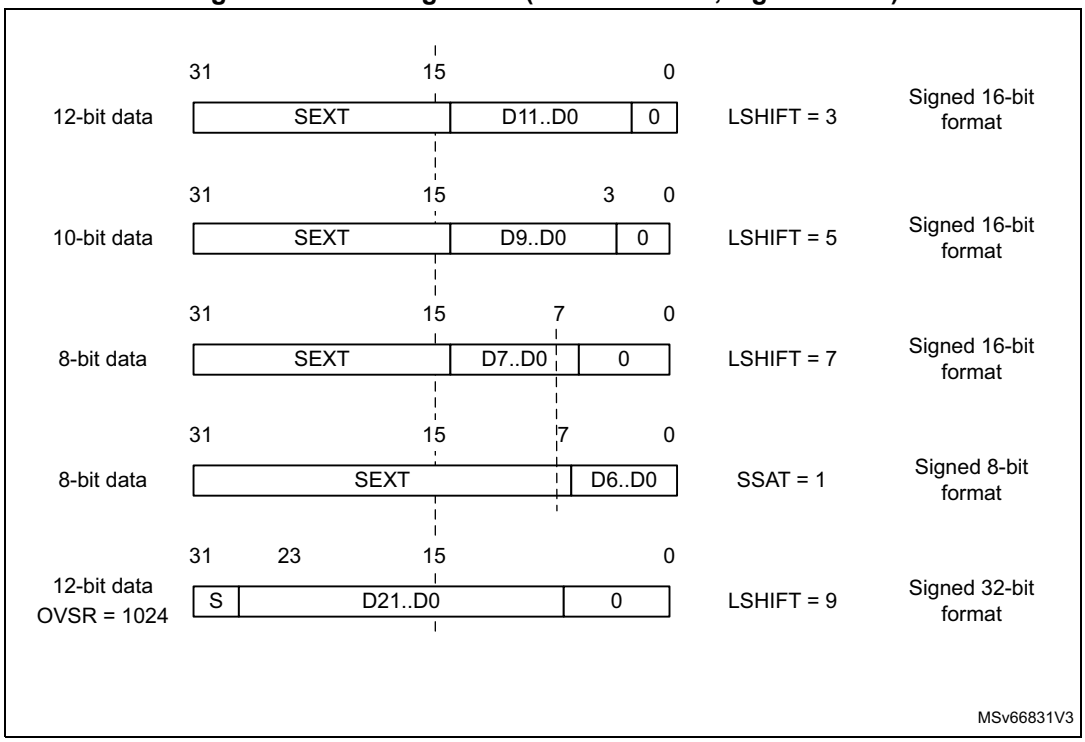

Figure 321. Left alignment (offset enabled, signed value)

Management of signed and unsigned saturation format (SSAT, USAT)

The offset correction might result in the data width to be wider than the original data.

To limit the original data width, the data saturation can be enabled through the SSAT and USAT bits of the ADC_OFCFGRy register.

Unsigned 12-bit data can be extended to 13-bit signed data by using an offset value different from 0x800.

The original data width can be preserved by setting SSAT bit to limit the data width to 12 bits.

Unsigned data can be saturated to the original data width by setting the USAT bit.

Table 364 shows the sign-extended data format corresponding to different resolutions.

Table 364.12-bit data formats

SSAT	USAT	Format	Data range (offset =0x800)
0	0	Sign-extended 13-bit significant data: SEXT[31:13] DATA[12:0]	0x0000 07FF - 0xFFFF F800
1	0	Sign-extended 12-bit significant data: SEXT[31:12] DATA[11:0]	0x7FF - 0x800

Table 364.12-bit data formats

SSAT	USAT	Format	Data range (offset =0x800)
0	1	Unsigned saturation 12-bit signification data: DATA[11:0]	0xFFF - 0x000
1	1	Reserved	-

Table 365 provides numerical examples for four different offset values.

Table 365. Numerical examples for 32-bit or 16-bit format

Raw conversion result	Offset value	Result SSAT = 0 USAT = 0	Result SSAT = 0 USAT = 1	Result SSAT = 1 USAT = 0
0xFFF	0x800	0x0000 07FF	0x07FF	0x07FF
0x800		0x0000 0000	0x0000	0x0000
0x000		0xFFFF F800	0x0000	0xF800
0xFFF	0x820	0x0000 07DF	0x07DF	0x07DF
0x800		0xFFFF FFE0	0x0000	0xFFE0
0x000		0xFFFF F7E0	0x0000	0xF7E0
0xFFF	0x7E0	0x0000 081F	0x081F	0x07FF
0x800		0x0000 0020	0x0020	0x0020
0x000		0xFFFF F820	0x0000	0xF820
0xFFF	0x020	0x0000 0FDF	0x0FDF	0x0FDF
0x800		0x0000 07E0	0x07E0	0x07E0
0x000		0xFFFF FFE0	0x0000	0xFFE0

Caution: SSAT must not be used in conjunction with USAT. No hardware check is performed to ensure that this condition is respected.

Gain compensation

When the GCOMP bit is set in the ADC_GCOMP register, the gain compensation is activated on all the converted data. After each conversion, data is calculated using the following formula.

$$DATA = DATA(\text{adc result}) \times (GCOMPCOEFF) / 4096$$

As GCOMPCOEFF can be programmed from 0 to 16383, the actual gain compensation factor can range from 0 to 3.999756.

Before storing the resulting data in RDATAx or JDATAx bitfields, the LSB−1 value is evaluated to round up the data and minimize the error.

The gain compensation is also effective for the oversampling. When the gain compensation is used in oversampling mode, the gain calculation is performed after the accumulation and

right-shift operations to minimize the power consumption (the gain calculation is done only once and not at each conversion).

The internal multiplier width is 32 bits and the input data width for the gain compensation must be less than 18 bits. When using oversampling with injected and regular conversion mode, the ROVSM bit of the ADC_CFGR2 register must be set to resume the pending conversion with the correct value.

When the gain compensation is activated, the ADC conversion latency is increased by one clock cycle. In continuous and scan conversion modes, the ADC conversion rate does not change.

ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) issues a notification that the regular converted data has not been read (by the CPU or the DMA) before the ADC_DR FIFO (eight stages) is overflowed, or adc_hclk clock is too slow to manage the data.

The OVR flag is set when a new conversion completes while ADC_DR register FIFO was full. An interrupt is generated if the OVRIE bit is set.

When an overrun condition occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting ADSTP. The OVR flag is cleared by software by programming it to 1.

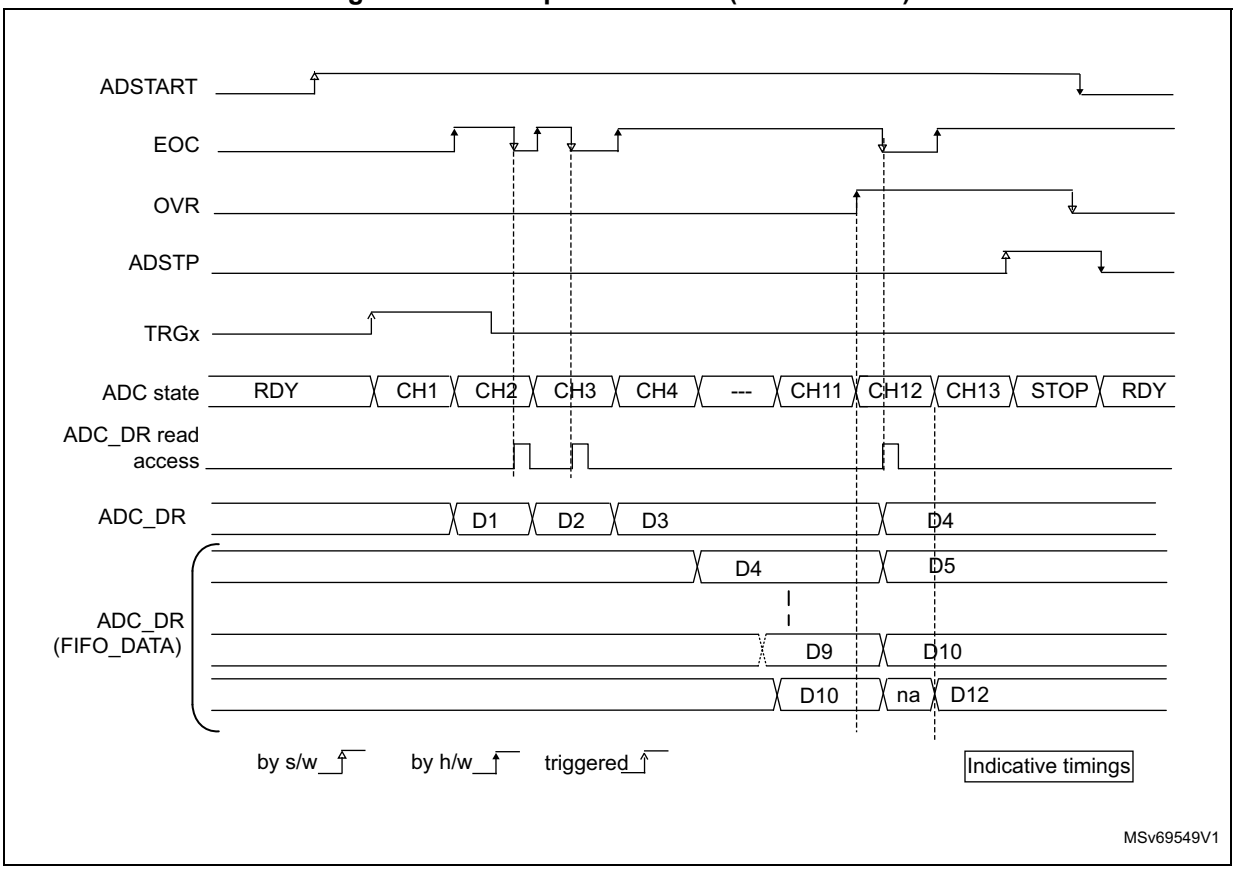
Data can be configured to be preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- OVRMOD = 0

  The overrun event preserves the data register from being overwritten: the old data are maintained up to ADC_DR FIFO depth (eight data) and the new conversion is discarded and lost. If OVR remains at 1, further conversions occur but the result data is also discarded.
- OVRMOD = 1

  The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, any further conversion is performed normally and the ADC_DR register always contains the latest converted data. In this mode, DMA burst mode nor MDF output mode cannot be supported.

Figure 322. Example of overrun (OVRMOD = 0)



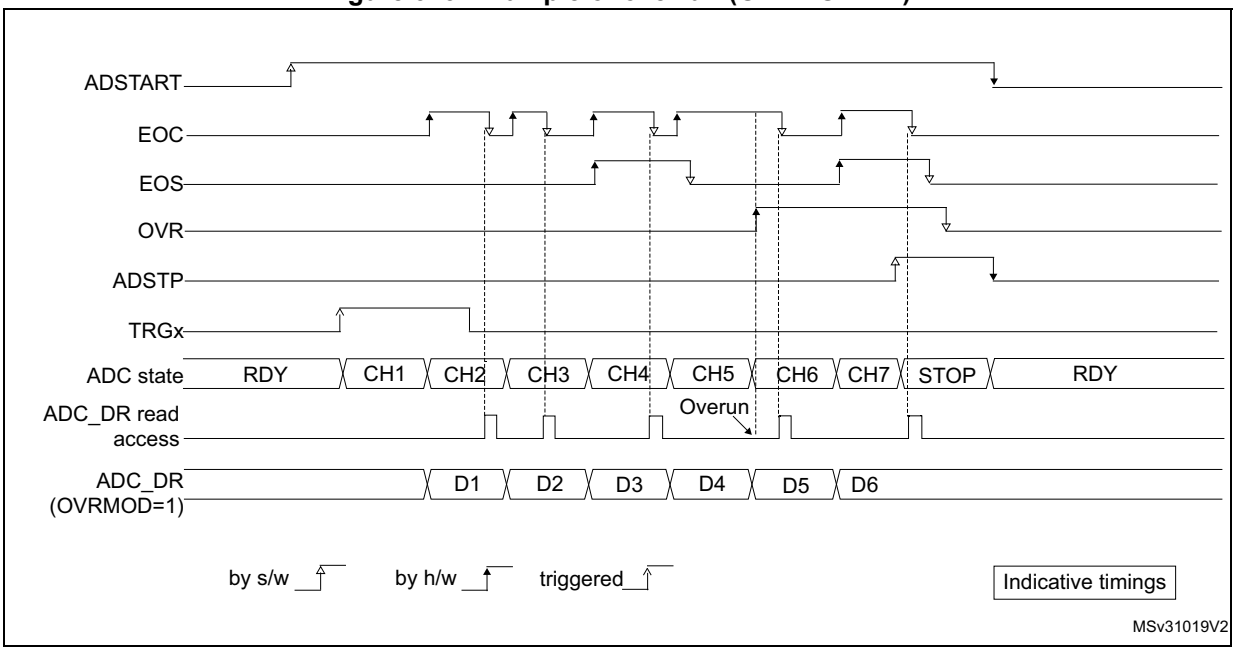


Figure 323. Example of overrun (OVRMOD = 1)

Note: Even if overrun may occur for injected channels, there is no overrun detection on these channels since there is a dedicated data register for each of the four injected channels.

Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD must be configured to 0 to manage overrun events or FIFO overflow as errors.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and the OVR flag must be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

When the DMA mode is enabled (DMNGT[1:0] = 01 or 11 in the ADC_CFGR1 register in single ADC mode), a DMA request is generated after each channel conversion. This allows the transfer of the converted data from the ADC_DR register to the destination location configured in the DMA.

Despite this, if an overrun occurs (OVR = 1) because the DMA cannot serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA, which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of the OVRMOD bit, the data are either preserved or overwritten (refer to *Section : ADC overrun (OVR, OVRMOD)*). If OVRMOD = 0 (data preserved), DMA transfer requests are blocked.

Two different DMA modes are proposed depending on the application usage. They can be configured through the DMNGT[1:0] bitfield of the ADC_CFGR1 register in single ADC mode:

- DMA one-shot mode (DMNGT[1:0] = 01)

  This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMNGT[1:0] = 11)

  This mode is suitable when programming the DMA in circular mode.

DMA one-shot mode (DMNGT[1:0] = 01)

In one-shot mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (that is when DMA_LACK interrupt occurs, see *Direct-memory controller* section) even if a new conversion has been started.

When DMA transfers are complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen,
- All ongoing conversions are aborted with the partial result discarded,
- No new DMA request is issued to the DMA controller in order to avoid generating an overrun error if there are still conversions that are started,
- The scan sequence is stopped and reset, and
- The DMA is stopped.

DMA circular mode (DMNGT[1:0] = 11)

In circular mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows the configuration of the DMA in circular mode to handle a continuous analog input data stream.

DMA with FIFO

The output data register features an eight-stage FIFO. Two different DMA requests are generated in parallel. When a data is available, an “SREQ single request” is generated. When four data are available, a “BREQ burst request” is generated. The DMA can be programmed either in single-transfer mode or in burst mode (four beats). The appropriate request line is selected by the DMA according to the mode selected. Refer to *Section Direct memory access controller* for further information.

Due to the existence of FIFO, DMA requests are generated until the FIFO is emptied. To stop DMA requests even when the FIFO is not emptied, set the ADSTP bit.

42.4.27 Managing conversions using the MDF

The ADC conversion results can be transferred directly to the MDF.

In this case, the DMNGT[1:0] bits must be set to 10.

The ADC transfers the 16 least significant bits of the regular data register to the MDF through adcx_dat[15:0] bus, which in turn resets the EOC flag once the transfer is effective.

The data format must be in 16-bit signed format:

ADC_DR[31:16] = Don’t care

ADC_DR[15] = Sign

ADC_DR[14:0] = Data

Any value above the 16-bit signed format is truncated.

To obtain a 16-bit signed format, the OFFSET function needs to be activated.

In this mode, OVRMOD = 1 is not supported.

42.4.28 Dynamic low-power features

Autodelayed conversion mode (AUTDLY)

The ADC implements an autodelayed conversion mode controlled by the AUTDLY configuration bit. Autodelayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

Regular conversion mode

When AUTDLY is set, a new conversion can start if the following conditions are met:

- All the previous data of the same group have been treated, and
- The ADC_DR register has been read or the EOC bit has been cleared (see *Figure 324*).

This is a way to automatically adapt the speed of the ADC to the speed of the system that reads the data.

The delay is inserted after each regular conversion.

Injected conversion mode

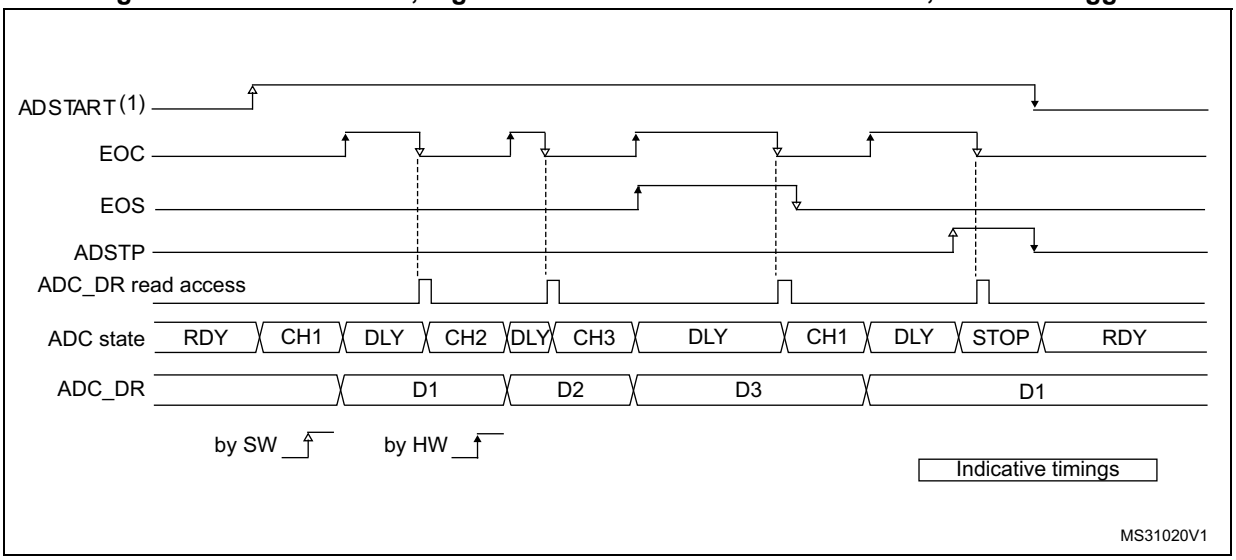
When AUTDLY is set, a new conversion can start only if the JEOS bit has been cleared (see *Figure 325*). Since there are four ADC_JDRy registers, the autodelay is performed at the end on the injected conversion sequence.

There is no delay inserted between each conversion of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored. This is not the case for software triggers for which the ADSTART and JADSTART bits can still be set during the autodelay to restart the conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

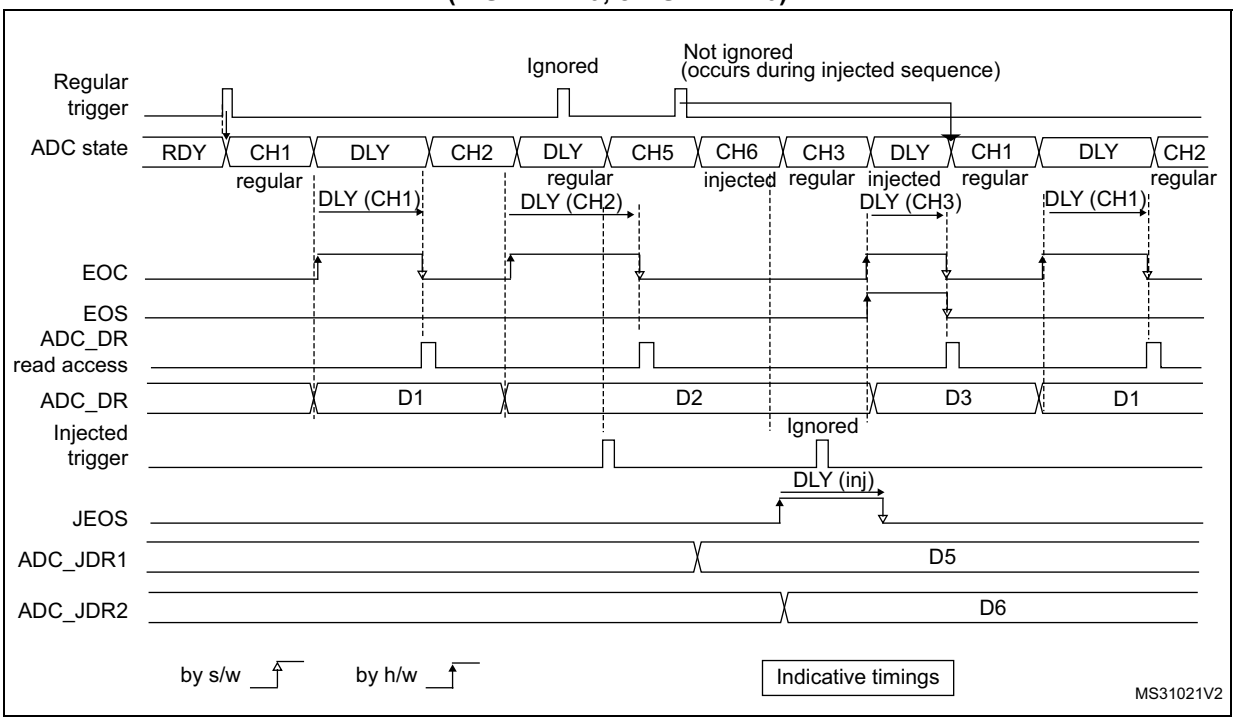
- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see *Figure 325*).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see *Figure 327*).



The behavior is slightly different in autoinjection mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see *Figure 328*).

Caution: In autoinjection mode, there is no delay between the last regular conversion and the first injected conversion. The user must clear the last EOC flag before clearing the JEOS flag, otherwise the next sequence might start before EOC flag is cleared.

In autodelay mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.



In autodelay mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

42.4.29 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

Figure 329. Analog watchdog guarded area

AWDy flag and interrupt

An interrupt can be enabled for each of the three analog watchdogs by setting AWDyIE in the ADC_IER register (y = 1, 2, 3).

AWDy (y = 1, 2, 3) flag is cleared by software by writing 1 to it, or by setting ADDIS.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

Analog watchdog filter for watchdog 1

When an ADC is configured with only one input channel (selecting several channels in scan mode is not allowed), a valid ADC conversion data range can be configured through the

ADC_AWD1LTR and ADC_AWD1HTR registers. When the conversion results have consecutively passed the threshold for more than the watchdog filter value (AWDFILT[2:0] + 1), AWD1_OUT is generated as well as the AWD1 flag. Before this value is reached, AWD1 output is not activated.

Description of analog watchdog 1

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR1 register. This watchdog monitors whether either one selected channel or all enabled channels remain within a configured voltage range (window).

Table 366 shows how the ADC_CFGR1 registers must be configured to enable the analog watchdog on one or more channels.

Table 366. Analog watchdog channel selection

Channels guarded by the analog watchdog	AWD1SGL bit	AWD1EN bit	JAWD1EN bit
None	x	0	0
All injected channels	0	0	1
All regular channels	0	1	0
All regular and injected channels	0	1	1
Single(1) injected channel	1	0	1
Single(1) regular channel	1	1	0
Single(1) regular or injected channel	1	1	1

1. Selected by the AWD1CH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog flag is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.

These thresholds are programmed through HTR[22:0] bits of the ADC_AWD1HTR register and LTR[22:0] bits of the ADC_AWD1LTR register for the analog watchdog 1.

The threshold can be up to 23 bits (12-bit resolution with oversampling, OVSR = 1024, offset and gain compensation)

When converting data with a resolution of less than 12 bits (defined by RES[1:0] bits), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data.

Table 367 describes how the comparison is performed for all the possible resolutions and for analog watchdog 1.

Table 367. Analog watchdog 1, 2, 3 comparison

Resolution (RES[1:0] bits)	Analog watchdog comparison between:		Comments
	Raw converted data, left aligned(1)	Thresholds	
00: 12-bit	DATA[11:0]	LTR[22:0] and HTR[22:0]	-
01: 10-bit	DATA[11:2],00	LTR[22:0] and HTR[22:0]	The user must configure LTR[1:0] to 0b00 and HTR[1:0] to 0b00.
10: 8-bit	DATA[11:4],0000	LTR[22:0] and HTR[22:0]	The user must configure LTR[3:0] to 0b0000 and HTR[3:0] to 0b0000.
11: 6-bit	DATA[11:6],000000	LTR[22:0] and HTR[22:0]	The user must configure LTR[5:0] to 0b000000 and HTR[5:0] to 0b000000.

1. Refer to *Section : Gain compensation* for additional details on analog watchdog comparison.

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDCH[19:0] (of ADC_AWD2CR and ADC_AWD3CR).

The corresponding watchdog is enabled when any bit of AWDCH[19:0] (of ADC_AWD2CR and ADC_AWD3CR) is set.

The threshold can be up to 23 bits (12-bit resolution with oversampling, OVSR = 1024 and offset compensation in signed format with gain compensation) and is programmed through the ADC_AWD2HTR, ADC_AWD2LTR, ADC_AWD3HTR and ADC_AWD3LTR registers.

When converting data with a resolution of less than 12 bits (defined by RES[1:0]) bits), the LSBs of the programmed threshold must be kept cleared, the internal comparison being performed on the full 12-bits converted data (left aligned).

ADCx_AWDy_OUT signal output generation

Each analog watchdog is associated with an internal hardware signal ADC_AWDy_OUT (*y* being the watchdog number), which is directly connected to the ETR input (external trigger) of some of the on-chip timers. Refer to the on-chip timers sections to understand how to select the ADC_AWDy_OUT signal as ETR.

ADC_AWDy_OUT is activated when the associated analog watchdog is enabled:

- ADC_AWDy_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADC_AWDy_OUT is reset after the end of the next guarded conversion that is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADC_AWDy_OUT is also reset when disabling the ADC (when setting ADDIS). Note that stopping regular or injected conversions (by setting ADSTP or JADSTP) has no influence on the generation of ADCx_AWDy_OUT.

Note: The AWDy flag is set by hardware and reset by software: the AWDy flag has no influence on the generation of ADC_AWDy_OUT (ex: ADC_AWDy_OUT can toggle while the AWDy flag remains at 1 if the software did not clear the flag).

The AWDy flag is cleared by programming it to 1 or by set ADDIS bit. ADSTP and JADSTP bits do not reset the AWDy flag.

Figure 330. ADC_AWDy_OUT signal generation (on all regular channels)

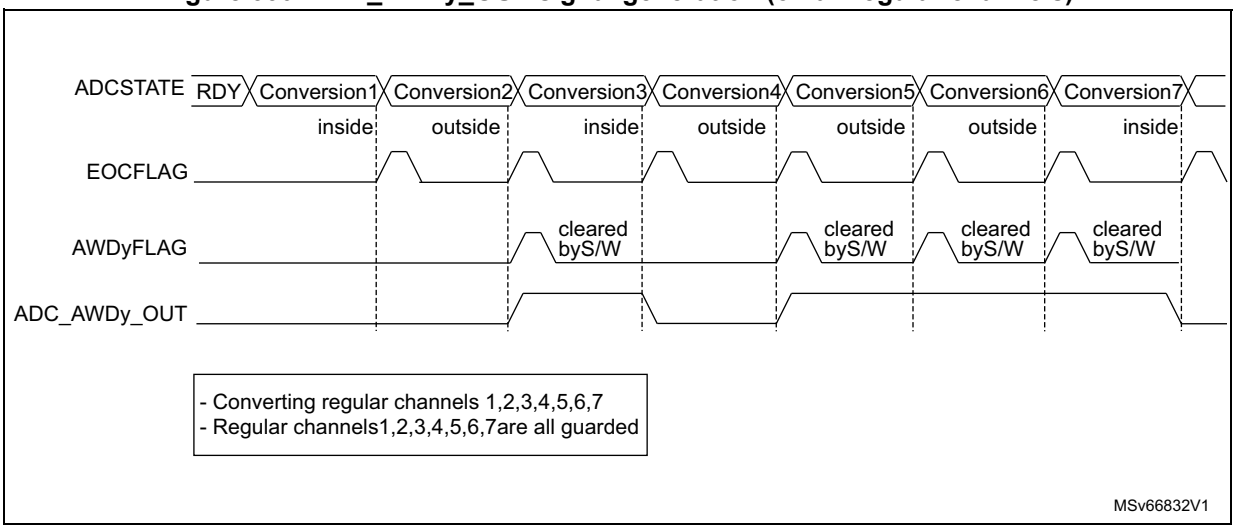

Figure 331. ADC_AWDy_OUT signal generation (AWDy flag not cleared by software)

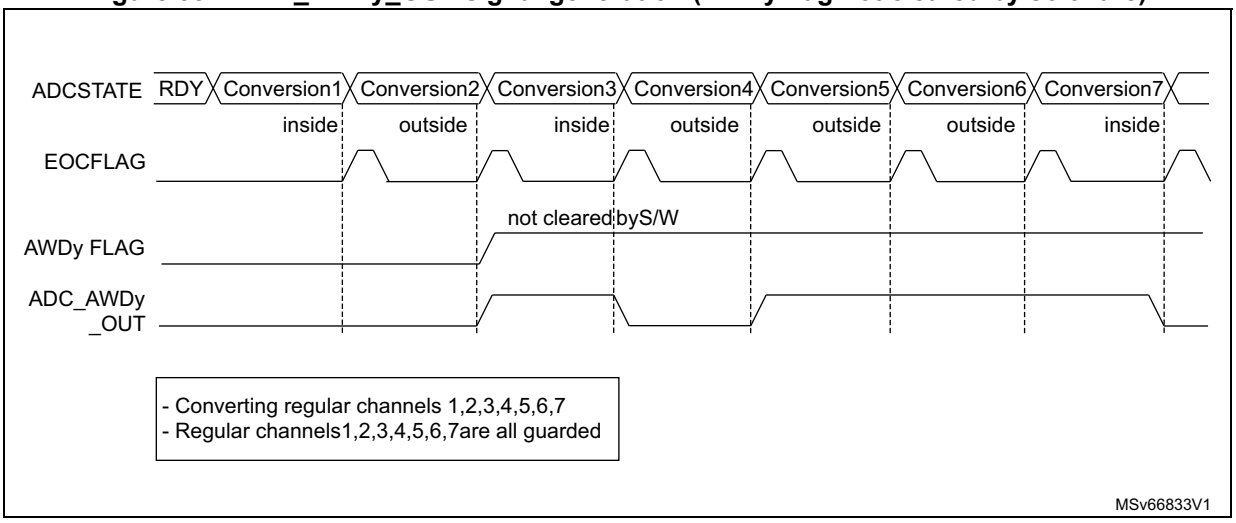

Figure 332. ADC_AWDy_OUT signal generation (on a single regular channel)

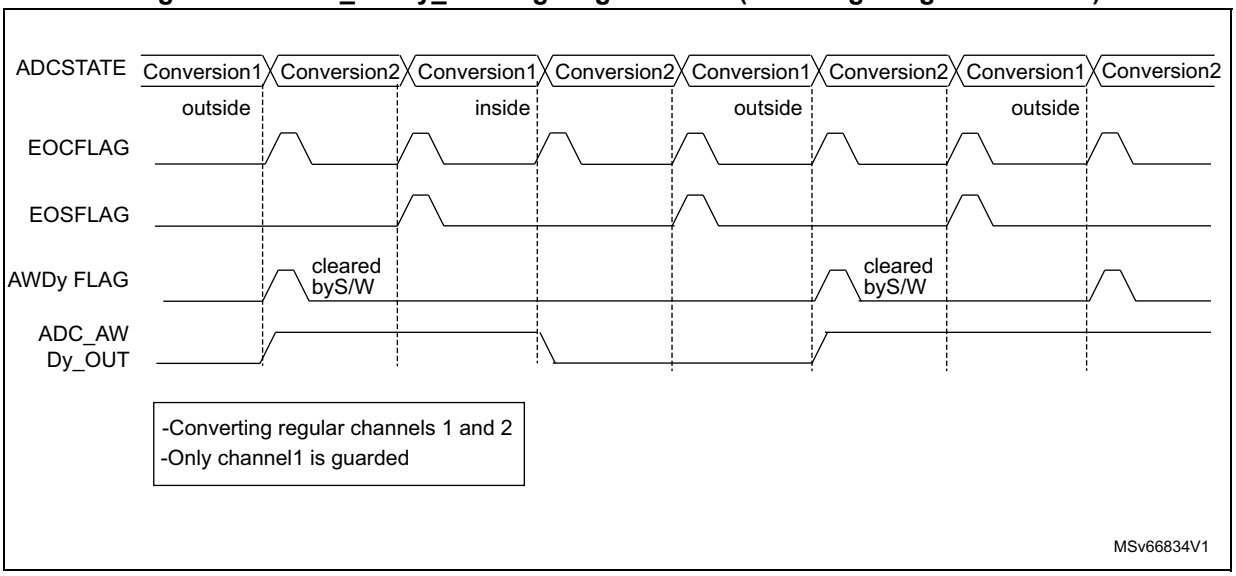

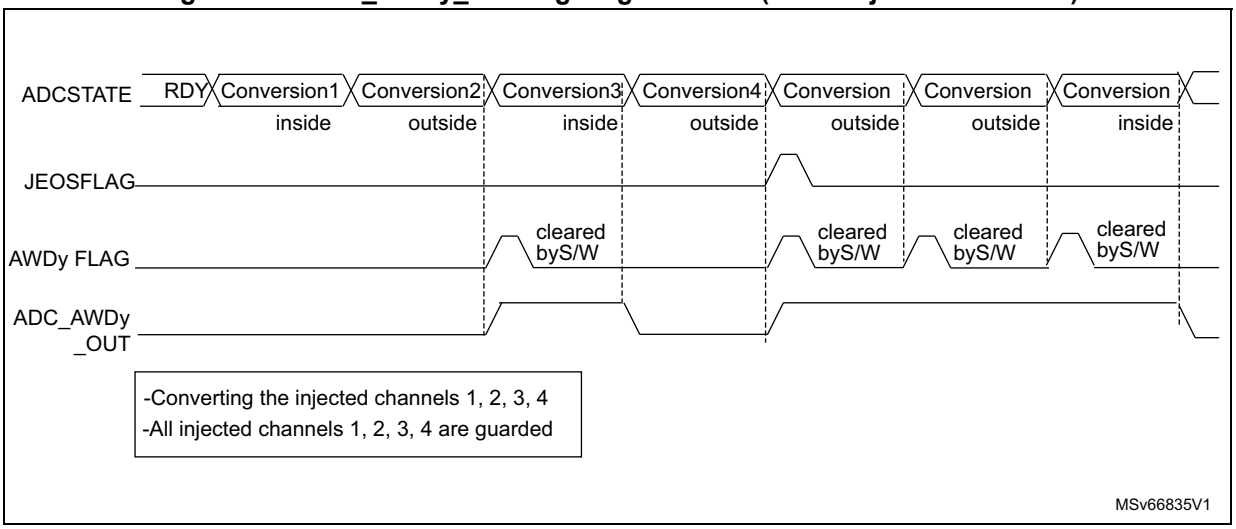

Figure 333. ADC_AWDy_OUT signal generation (on all injected channels)

Analog watchdog threshold control

LTR[22:0] and HTR[22:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTR[22:0] and HTR[22:0] are updated during the ADC conversion of the ADC guarded channel, the watchdog function is masked for this conversion. This masking is removed at the next start of conversion, resulting in analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new modified threshold, no interrupt and AWDy_OUT signal are issued. The Interrupt and the AWD generation only happen at the end of the conversion that started after the threshold update. If AWDy_OUT is already asserted, programming the new thresholds does not deassert the AWDy_OUT signal. However, the watchdog threshold must not be changed twice during the four adc_ker_ck periods.

Analog watchdog with gain and offset compensation

When the gain and offset compensation are enabled, the analog watchdog compares the data after the compensation.

42.4.30 Oversampler

The oversampling unit performs data preprocessing to offload the device. It is able to handle multiple conversions and average them into a single data with increased data width, up to 22-bit.

It provides a result with the following form, where N and M can be adjusted:

$$\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)$$

It enables the following functions to be performed by hardware: averaging, data rate reduction, SNR improvement and basic filtering.

The oversampling ratio N is defined through the OVSR[9:0] bits of the ADC_CFGR2 register. They can range from 2x to 1024x. The division coefficient *M* consists of a right bit shift up to 10 bits. It is defined through the OVSS[3:0] bits of the ADC_CFGR2 register.

The summation unit can yield a result up to 22 bits, which can be left or right shifted. When the right shift is selected, it is rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred to the ADC_DR data register.

Figure 334 gives a numerical example of the processing, from a raw 22-bit accumulated data to the final 12-bit result.

Figure 334. 12-bit result oversampling with 10-bit right shift and rounding

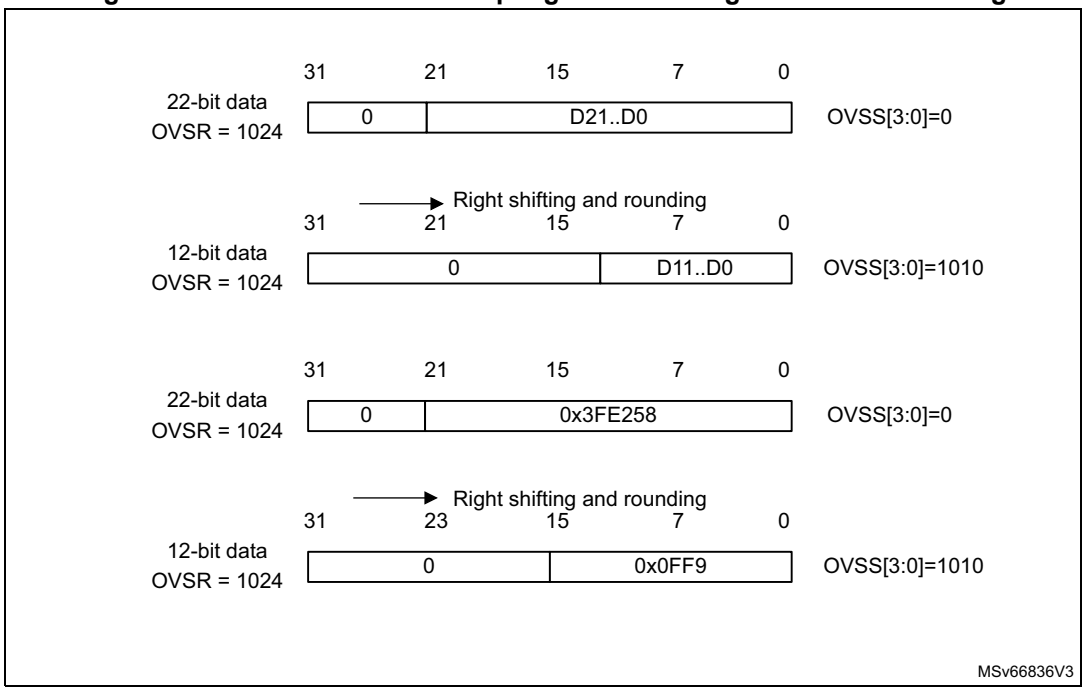

Table 322 gives data format for the various N and M combinations, for a raw conversion data equal to 0xFFF.

Table 368. Maximum output results versus N and M

Over sampling ratio	Max Raw data	No-shift OVSS = 0000	1-bit shift OVSS = 0001	2-bit shift OVSS = 0010	3-bit shift OVSS = 0011	4-bit shift OVSS = 0100	5-bit shift OVSS = 0101	6-bit shift OVSS = 0110	7-bit shift OVSS =0111	8-bit shift OVSS = 1000
x2	0x1FFE	0x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100	0x0080	0x0040	0x0020
x4	0x3FFC	0x3FFC	x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100	0x0080	0x0040
x16	0xFFF0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100
x64	0x3FFC0	0x3FFC0	0x1FFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400
x256	0xFFF00	0xFFF00	0x7FF80	0x3FFC0	0x1FFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF
x1024	0x3FFC00	0x3FFC00	0x1FFE00	0xFFF00	0x7FF80	0x3FFC0	0x1FFE0	0xFFF0	0x7FF8	0x3FFC

The conversion timing rate does not change in oversampling mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N conversion, with an equivalent delay equal to N x T_{CONV} = N x (t_{SMPL} + t_{SAR}). The flags are set as follows:

- The end of the sampling phase (EOSMP) is set after each sampling phase.
- The end of conversion (EOC) occurs once every N conversion, when the oversampled result is available.
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (that is after a total of N x sequence length conversions).

Unlike the conversion rate, the conversion latency changes in oversampling mode: each single conversion introduces an additional accumulation. As a result, an additional clock cycle is required when all the conversions are complete, after the accumulation and right-shift. The EOC flag is set two additional clock cycles after the conversion is complete.

ADC operating modes supported in oversampling mode (single ADC mode)

In oversampling mode, most of the ADC operating modes are maintained:

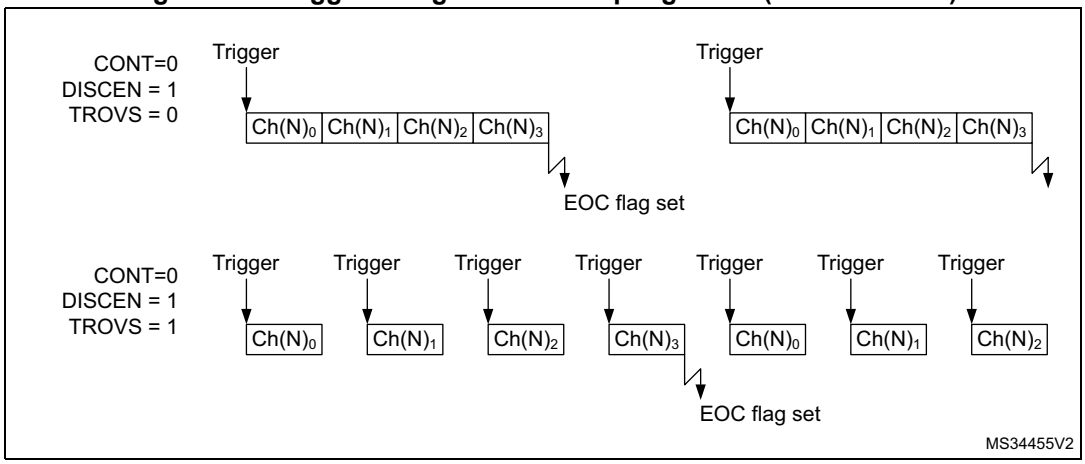
- Single or continuous conversion modes
- ADC conversions started either by software or triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits of the ADC_CFGR1 register) are accumulated, truncated, rounded, and shifted in the same way as 12-bit conversions are

Analog watchdog

The analog watchdog functionality is maintained, with the following differences:

- The RES[1:0] bits are ignored and the comparison is always done using the full 23-bit values HTR[22:0] and LTR[22:0].
- The comparison is performed on the oversampled accumulated value before shifting.

Triggered mode



The oversampling can also be used for basic filtering purpose. Although it not a very powerful filter (slow roll-off and limited stop band attenuation), it can act as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched-mode power supply). For this purpose, a specific discontinuous mode can be enabled through the TROVS bit in ADC_CFGR2, to be able to achieve an oversampling frequency defined by the user and independent from the conversion time itself. The TROVS bit is supported with hardware trigger mode.

Figure 335 shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

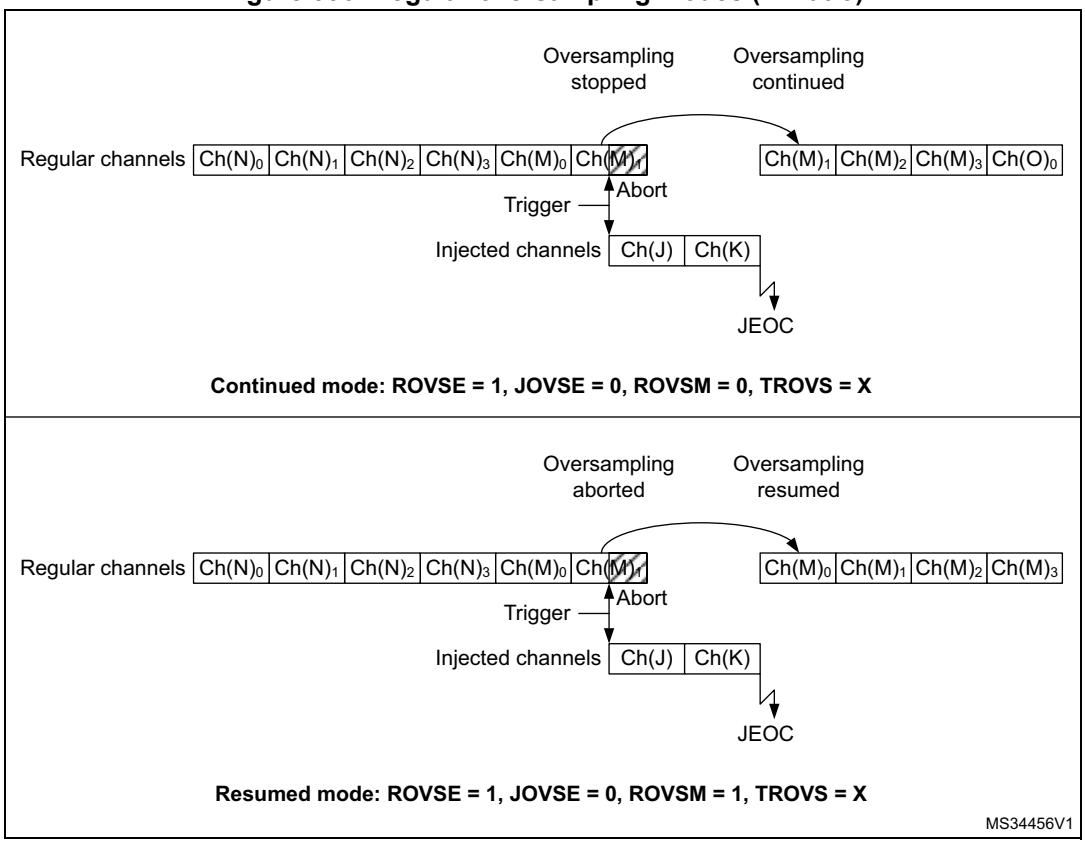
If the TROVS bit is set, neither JAUTO nor AUTODLY is supported.

Figure 335. Triggered regular oversampling mode (TROVS bit = 1)

Injected and regular sequencer management in oversampling mode

In oversampling mode, injected and regular sequencers can have different behaviors. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

Oversampling regular channels only



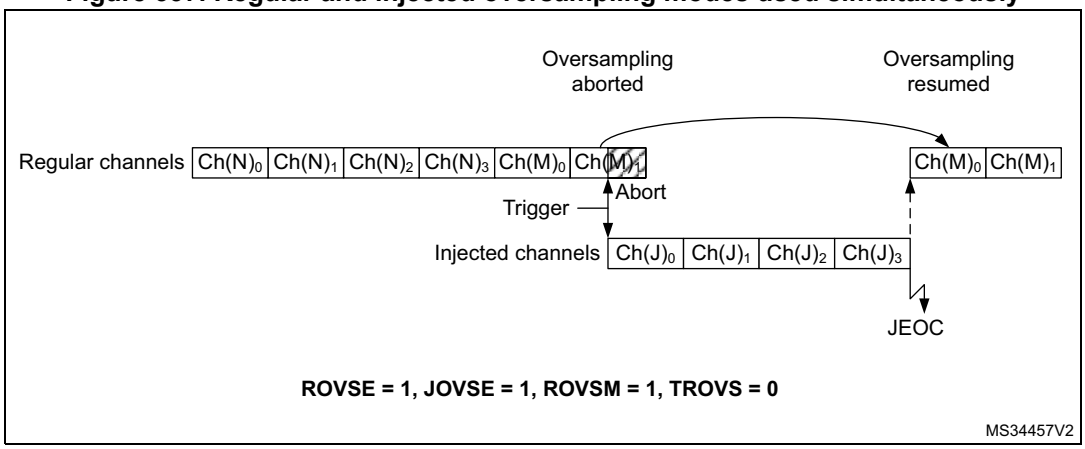
The regular oversampling mode ROVSM bit defines how the regular oversampling sequence is resumed if it is interrupted by an injected conversion:

- In continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is

complete whatever the injection frequency (providing at least one regular conversion can be complete between triggers);

- In resumed mode, the accumulation restarts from 0 (previous conversion results are ignored). This mode guarantees that all the data used for oversampling were converted back-to-back within a single time slot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be complete and the regular sequence is blocked.
- *Figure 336* gives examples for a 4x oversampling ratio.

Figure 336. Regular oversampling modes (4x ratio)



Oversampling injected channels only

The injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.

Oversampling regular and injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling must be resumed (ROVSM bit = 1), as shown in *Figure 337*.

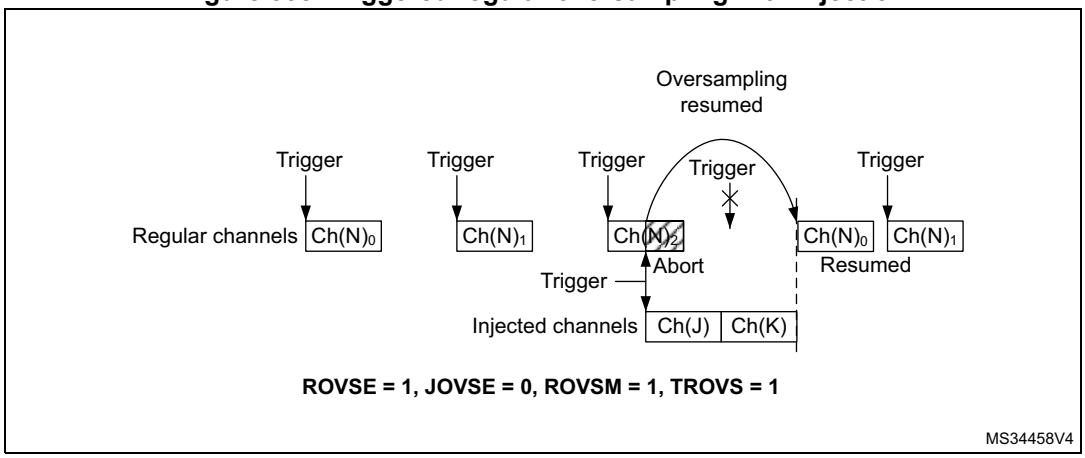


Figure 337. Regular and injected oversampling modes used simultaneously

Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled and the ROVSM bit set (Resumed mode is forced). The JOVSE bit must be reset. The behavior is shown in *Figure 338*.

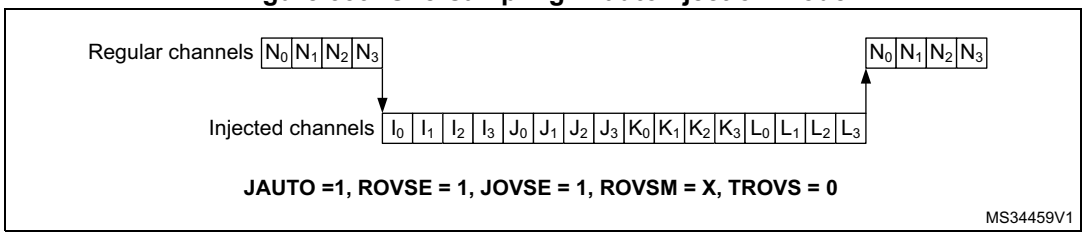

Figure 338. Triggered regular oversampling with injection

Autoinjection mode

It is possible to oversample autoinjected sequences and store all conversion results in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1. Other combinations are not supported. The ROVSM bit is ignored in autoinjection mode. *Figure 339* shows how the conversions are sequenced.

Figure 339. Oversampling in autoinjection mode

In addition, the triggered mode can be enabled using the TROVS bit. In this case, the ADC must be configured as follows: JAUTO = 1, DISCEN = 0, JDISCEN = 0, DISCNUM = 0, ROVSE = 1, JOVSE = 1 and TROVSE = 1.

Combined modes summary

Table 369 summarizes all combinations, including the modes that are not supported.

Table 369. Oversampler operating mode summary

Regular oversampling ROVSE	Injected oversampling JOVSE	Oversampler mode ROVSM 0 = continued 1 = resumed	Triggered regular mode TROVS	Comment
1	0	0	0	Regular continued mode
1	0	0	1	Not supported
1	0	1	0	Regular resumed mode
1	0	1	1	Triggered regular resumed mode
1	1	0	X	Not supported
1	1	1	0	Injected and regular resumed mode
1	1	1	1	Not supported
0	1	X	X	Injected oversampling

Table 370. DELAY bits versus ADC resolution(1)

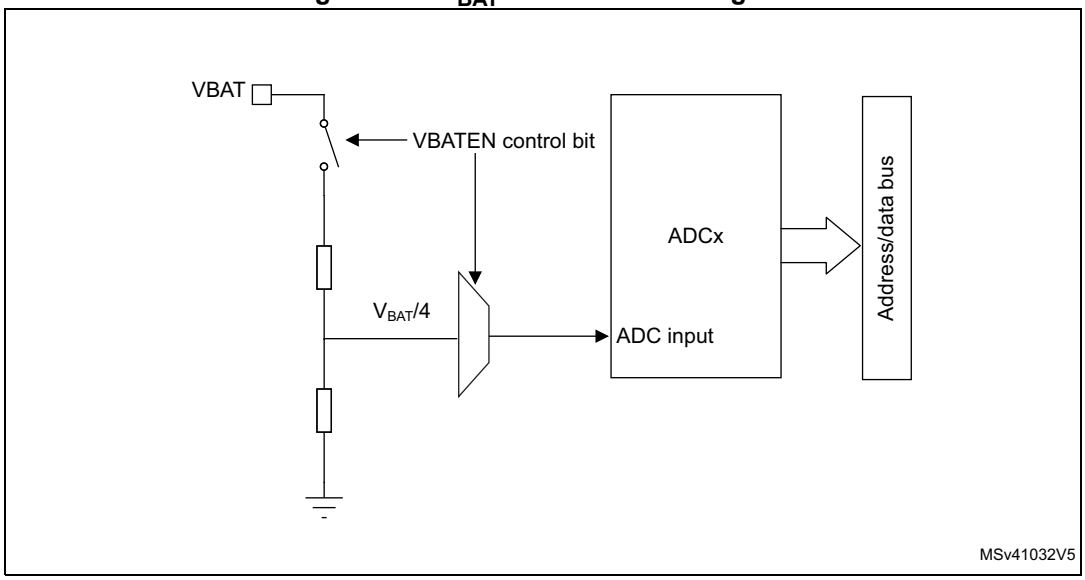
1. Preliminary information, subject to change.



42.4.31 V_{BAT} supply monitoring

The VBATEN bit in the ADCC_CCR register is used to switch to the battery voltage. As the V_{BAT} voltage can be higher than V_{DDA}, to ensure the correct operation of the ADC, the V_{BAT} pin is internally connected to a bridge divider by 4. This bridge is automatically enabled when VBATEN is set, to connect $V_{BAT}/4$ to the ADC input channels (see *Table: ADC interconnection* in *Section 42.4.2: ADC pins and internal signals* for more details). As a consequence, the converted digital value is one fourth of the V_{BAT} voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

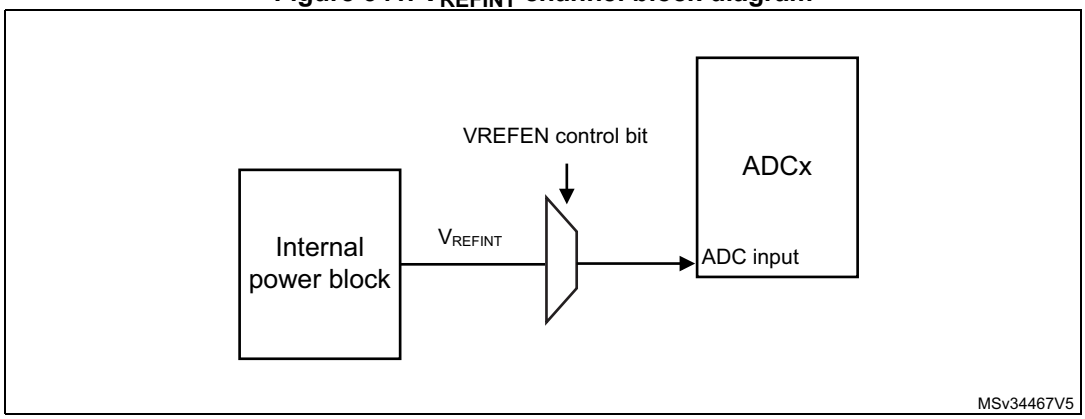
Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the $V_{BAT}/4$ voltage.

Figure 340 shows the block diagram of the V_{BAT} sensing feature.

Figure 340. V_{BAT} channel block diagram

1. The VBATEN bit must be set to enable the conversion of internal channel for V_{BAT}/4.

42.4.32 Monitoring the internal voltage reference



It is possible to monitor the internal voltage reference (V_{REFINT}) to have a reference point for evaluating the ADC V_{REF+} voltage level.

Refer to the *ADC interconnection* table in *Section 42.4.2: ADC pins and internal signals* for details on the ADC input channels to which the internal voltage reference is internally connected.

Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal voltage reference voltage.

Figure 341 shows the block diagram of the V_{REFINT} sensing feature.

Figure 341. V_{REFINT} channel block diagram

1. The VREFEN bit of the ADCC_CCR register must be set to enable the conversion of internal channels (V_{REFINT}).

Calculating the actual V_{REF+} voltage using the internal reference voltage

The power supply voltage applied to the device may be subject to variations or not precisely known. When V_{DDA} is connected to V_{REF+}, it is possible to compute the actual V_{DDA} voltage using the embedded internal reference voltage (V_{REFINT}). V_{REFINT} and its calibration data acquired by the ADC during the manufacturing process at V_{REF+} can be used to evaluate the actual V_{DDA} voltage level.

The following formula gives the actual V_{REF+} voltage supplying the device:

$$V_{REF+} = V_{REF+_Charac} \times VREFINT_CAL / VREFINT_DATA$$

Where:

- V_{REF+_Charac} is the value of V_{REF+} voltage characterized at V_{REFINT} during the manufacturing process. It is specified in the device datasheet.
- VREFINT_CAL is the VREFINT calibration value.
- VREFINT_DATA is the actual VREFINT output value converted by ADC.

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between V_{REF+} and the voltage applied on the converted channel.

For some applications, the V_{REF+} value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from V_{REF+}:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL_SCALE} \times ADC_DATA$$

By replacing V_{REF+} by the formula provided above, the absolute voltage value is given by the following formula

$$V_{CHANNELx} = \frac{V_{REF+_Charac} \times VREFINT_CAL \times ADC_DATA}{VREFINT_DATA \times FULL_SCALE}$$

For applications where V_{REF+} is known and ADC converted values are right-aligned, the absolute voltage value can be obtained by using the following formula:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL_SCALE} \times ADC_DATA$$

Where:

- VREFINT_CAL is the VREFINT calibration value.
- ADC_DATA is the value measured by the ADC on channel x (right-aligned).
- VREFINT_DATA is the actual VREFINT output value converted by the ADC.
- FULL_SCALE is the maximum digital value of the ADC output. For example with 12-bit resolution, we obtain $2^{12} - 1 = 4095$, or $2^8 - 1 = 255$ with 8-bit resolution.

Note: If ADC measurements are done using an output format other than 12-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

42.4.33 Monitoring the supply voltage

The ADCs are connected to the internal supply voltage. To use the ADC to measure this voltage, enable the connection through ADC option register.

42.5 ADC interrupts

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (ADRDY flag)
- On the end of any conversion for regular groups (EOC flag)
- On the end of a sequence of conversion for regular groups (EOS flag)
- On the end of any conversion for injected groups (JEOC flag)
- On the end of a sequence of conversion for injected groups (JEOS flag)
- When an analog watchdog detection occurs (AWD1, AWD2 and AWD3 flags)
- When the end of the sampling phase occurs (EOSMP flag)
- When the data overrun occurs (OVR flag)

Separate interrupt enable bits are available for flexibility.

Note: Interrupts are generated by the AHB clock domain. Since the ADC clock is adc_ker_ck, interrupt flags are delayed due to the synchronization between adc_ker_ck and AHB clock domains.

Table 371. ADC interrupts

Interrupt vector	Interrupt event	Event flag	Enable Control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop, Standby mode
ADC	ADC ready	ADRDY	ADRDYIE	Set by hardware and cleared by software	Yes	No
	End of conversion of a regular group	EOC	EOCIE			
	End of conversion sequence of a regular group	EOS	EOSIE			
	End of conversion of an injected group	JEOC	JEOCIE			
	End of conversion sequence of an injected group	JEOS	JEOSIE			
	Analog watchdog 1 flag is set	AWD1	AWD1IE			
	Analog watchdog 2 flag is set	AWD2	AWD2IE			
	Analog watchdog 3 flag is set	AWD3	AWD3IE			
	End of sampling phase	EOSMP	EOSMPIE			
	Overrun	OVR	OVRIE			

42.6 ADC registers (for each ADC)

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

42.6.1 ADC interrupt and status register (ADC_ISR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	AWD3	AWD2	AWD1	JEOS	JEOC	OVR	EOS	EOC	EOSMP	ADRDY
						rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **AWD3**: Analog watchdog 3 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD3LTR and ADC_AWD3HTR registers. It is cleared by software writing 1 to it.

0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 3 event occurred

Bit 8 **AWD2**: Analog watchdog 2 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD2LTR and ADC_AWD2HTR registers. It is cleared by software writing 1 to it.

0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 2 event occurred

Bit 7 **AWD1**: Analog watchdog 1 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD1LTR and ADC_AWD1HTR registers. It is cleared by software. writing 1 to it.

0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 1 event occurred

Bit 6 **JEOS:** Injected channel end of sequence flag

This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.

0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Injected conversions complete

Bit 5 **JEOC:** Injected channel end of conversion flag

This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it, or by reading the corresponding ADC_JDRy register

0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Injected channel conversion complete

Bit 4 **OVR**: ADC overrun

This bit is set by hardware when an overrun occurs on a regular channel (a new conversion has completed while the EOC flag was already set) or when adc_hclk clock is too slow to manage the data.

It is cleared by software writing 1 to it.

0: No overrun occurred (or the flag event was already acknowledged and cleared by software)

1: Overrun has occurred

Bit 3 **EOS**: End of regular sequence flag

This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.

0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Regular Conversions sequence complete

Bit 2 **EOC**: End of conversion flag

This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.

0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Regular channel conversion complete

Bit 1 **EOSMP**: End of sampling flag

This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.

0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)

1: End of sampling phase reached

Note: When the OVR flag is raised, the EOSMP flag is not generated correctly.

Bit 0 **ADRDY**: ADC ready

This bit is set by hardware after the ADC has been enabled (bit ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.

It is cleared by software writing 1 to it.

0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)

1: ADC is ready to start conversion

42.6.2 ADC interrupt enable register (ADC_IER)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	AWD3IE	AWD2IE	AWD1IE	JEOSIE	JEOCIE	OVRIE	EOSIE	EOCIE	EOSMPIE	ADRDYIE
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **AWD3IE**: Analog watchdog 3 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 3 interrupt disabled

1: Analog watchdog 3 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 8 **AWD2IE**: Analog watchdog 2 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 2 interrupt disabled

1: Analog watchdog 2 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 7 **AWD1IE**: Analog watchdog 1 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.

0: Analog watchdog 1 interrupt disabled

1: Analog watchdog 1 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 6 **JEOSIE**: End of injected sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.

0: JEOS interrupt disabled

1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 5 **JEOCIE**: End of injected conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.

0: JEOC interrupt disabled.

1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 4 **OVRIE**: Overrun interrupt enable

This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.

0: Overrun interrupt disabled

1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 3 **EOSIE**: End of regular sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.

0: EOS interrupt disabled

1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 2 **EOCIE**: End of regular conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.

0: EOC interrupt disabled.

1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 1 **EOSMPIE**: End of sampling flag interrupt enable for regular conversions

This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.

0: EOSMP interrupt disabled.

1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 0 **ADRDYIE**: ADC ready interrupt enable

This bit is set and cleared by software to enable/disable the ADC Ready interrupt.

0: ADRDY interrupt disabled

1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

42.6.3 ADC control register (ADC_CR)

Address offset: 0x008

Reset value: 0x2000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADCAL	ADCALDIF	DEEPPWD	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rs	rw	rw													

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	JADSTP	ADSTP	JADSTART	ADSTART	ADDIS	ADEN
										rs	rs	rs	rs	rs	rs

Bit 31 **ADCAL**: ADC calibration

This bit is set by software to enter ADC calibration mode.

0: Normal mode

1: Calibration mode

Note: The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN = 1, ADCAL = 1, ADSTART = 0 and JADSTART = 0 (ADC enabled, Calibration mode enabled and no conversion ongoing).

Bit 30 **ADCALDIF**: Differential mode for calibration

This bit is set and cleared by software to configure the single-ended or differential input mode for the calibration.

0: Single-ended input calibration mode when ADCAL = 1

1: Differential input calibration mode when ADCAL = 1

Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bit 29 **DEEPPWD**: Deep-power-down enable

This bit is set and cleared by software to put the ADC in Deep-power-down mode.

0: ADC not in Deep-power down

1: ADC in Deep-power-down (default reset state)

Note: The software is allowed to write this bit only when the ADC is disabled (ADCAL = 0 and ADEN =0).

Bits 28:6 Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP command).

It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be reconfigured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

When a software trigger is used, JADSTART bit is cleared by hardware, but JADSTP bit must be programmed to reconfigure the ADC.

0: No ADC stop injected conversion command ongoing

1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: In autoinjection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP command).

It is cleared by hardware when the conversion is effectively discarded. and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

When a software trigger is used, ADSTART bit is cleared by hardware. However it is necessary to write ADSTP bit to reconfigure the ADC.

0: No ADC stop regular conversion command ongoing

1: Write 1 to stop ongoing regular conversions. Read 1 means that an ADSTP command is in progress.

Note: In autoinjection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use ADSTP).

Bit 3 **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN[1:0], a conversion starts immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

This bit is cleared by hardware:

– In single conversion mode when software trigger is selected (JEXTSEL=0x0 and JDISEN = 1): at the assertion of the end of injected conversion sequence (JEOS) flag.

– In all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.

1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

Note: The software is allowed to set JADSTART only when ADEN = 1,ADDIS = 0 and JAUTO = 0 (ADC is enabled and there is no pending request to disable the ADC).

Note: In autoinjection mode (JAUTO = 1), regular and autoinjected conversions are started by setting ADSTART bit (JADSTART must be kept cleared).

Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN[1:0], a conversion starts immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

This bit is cleared by hardware:

– in single conversion mode when software trigger is selected (EXTSEL = 0x0 and DISEN = 1): at the assertion of the end of regular conversion sequence (EOS) flag.

– in all cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.

1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

Note: The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

Note: In autoinjection mode (JAUTO = 1), regular and autoinjected conversions are started by setting ADSTART bit (JADSTART must be kept cleared)

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and place it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing

1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

Note: The software is allowed to set ADDIS only when ADEN = 1, ADDIS = 0 and both ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the ADRDY flag has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)

1: Write 1 to enable the ADC.

Note: The software is allowed to set ADEN only when all the bits of ADC_CR registers are cleared (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

42.6.4 ADC configuration register (ADC_CFGR1)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	AWD1CH[4:0]					JAUTO	JAWD1EN	AWD1EN	AWD1SGL	Res.	JDISCEN	DISCNUM[2:0]			DISCEN
	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	AUTDLY	CONT	OVRMOD	EXTEN[1:0]		EXTSEL[4:0]					Res.	RES[1:0]		DMNGT[1:0]	
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog 1 channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

00000: ADC analog input channel 0 monitored by AWD1

00001: ADC analog input channel 1 monitored by AWD1

.....

10011: ADC analog input channel 19 monitored by AWD1

Others: reserved, must not be used

Note: Some channels are not connected physically. Keep the corresponding AWD1CH[4:0] setting to the reset value.

Note: The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers. The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **JAUTO:** Automatic injected group conversion

This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.

0: Automatic injected group conversion disabled

1: Automatic injected group conversion enabled

Note: The software is allowed to write this bit only when ADEN = 0, ADSTART = 0, and JADSTART = 0.

Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on injected channels

1: Analog watchdog 1 enabled on injected channels

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on regular channels

1: Analog watchdog 1 enabled on regular channels

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels

This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels

0: Analog watchdog 1 enabled on all channels

1: Analog watchdog 1 enabled on a single channel

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 21 Reserved, must be kept at reset value.

Bit 20 **JDISCEN:** Discontinuous mode on injected channels

This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.

0: Discontinuous mode on injected channels disabled

1: Discontinuous mode on injected channels enabled

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Note: It is not possible to use autoinjection mode and discontinuous mode simultaneously: the DISCEN and JDISCEN bits must be kept cleared by software when JAUTO is set.

Bits 19:17 **DISCNUM[2:0]:** Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

000: 1 channel

001: 2 channels

...

111: 8 channels

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable discontinuous mode for regular channels.

0: Discontinuous mode for regular channels disabled

1: Discontinuous mode for regular channels enabled

Note: It is not possible to have both discontinuous mode and continuous mode enabled: DISCEN and CONT cannot both be set (DISCEN takes priority).

Note: It is not possible to use autoinjection mode and discontinuous mode simultaneously: the DISCEN and JDISCEN bits must be kept cleared by software when JAUTO is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the autodelayed conversion mode.

0: Autodelayed conversion mode off

1: Autodelayed conversion mode on

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode

1: Continuous conversion mode

Note: It is not possible to have both discontinuous mode and continuous mode enabled: DISCEN and CONT cannot both be set (DISCEN takes priority).

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 12 **OVRMOD**: Overrun mode

This bit is set and cleared by software and configure the way data overrun is managed.

0: ADC_DR register is preserved with the old data when an overrun is detected.

1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

00000: adc_ext_trg0

00001: adc_ext_trg1

00010: adc_ext_trg2

00011: adc_ext_trg3

00100: adc_ext_trg4

00101: adc_ext_trg5

00110: adc_ext_trg6

00111: adc_ext_trg7

...

11111: adc_ext_trg31

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **RES[1:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

00: 12-bit

01: 10-bit

10: 8-bit

11: 6-bit

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 1:0 **DMNGT[1:0]**: Data management configuration

These bits are set and cleared by software to select how the ADC interface output data are managed.

00: Regular conversion data stored in DR only

01: DMA one-shot mode selected

10: MDF mode selected

11: DMA circular mode selected

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

42.6.5 ADC configuration register 2 (ADC_CFGR2)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
		LSHIFT[3:0]		Res.	Res.	OVSR[9:0]									
rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMPTRIG	SWTRIG	BULB	Res.	Res.	ROVSM	TROVS	OVSS[3:0]				Res.	Res.	Res.	JOVSE	ROVSE
rw	rw	rw			rw	rw	rw	rw	rw	rw				rw	rw

Bits 31:28 **LSHIFT[3:0]**: Left shift factor

This bitfield is set and cleared by software to define the left shifting applied to the final result with or without oversampling.

0000: No left shift
0001: 1-bit left shift
0010: 2-bit left shift
0011: 3-bit left shift
0100: 4-bit left shift
0101: 5-bit left shift
0110: 6-bit left shift
0111: 7-bit left shift
1000: 8-bit left shift
1001: 9-bit left shift
1010: 10-bit left shift
1011: 11-bit left shift
1100: 12-bit left shift
1101: 13-bit left shift
1110: 14-bit left shift
1111: 15-bit left shift

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:16 **OVSR[9:0]**: Oversampling ratio

This bitfield is set and cleared by software to define the oversampling ratio.

0: 1x (no oversampling)
1: 2x
2: 3x
...
1023: 1024x

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 15 **SMPTRIG**: Sampling time control trigger mode

This bit is set and cleared by software to enable the sampling time control trigger mode.

0: Sampling time control trigger mode disabled
1: Sampling time control trigger mode enabled

If EXTEN[1:0] bits are set to 01, the sampling time starts on the trigger rising edge, and the conversion starts on the trigger falling edge.

The SMPTRIG bit must not be set when the SMPTRIG bit is set.

When EXTEN[1:0] bits are set to 00, set SWTRIG to start the sampling and clear the BULB bit to start the conversion.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing). When the discontinuous mode is used, only DISCNUM[2:0] = 000 configuration is compatible with sampling time control trigger mode.

Bit 14 **SWTRIG**: Software trigger bit for sampling time control trigger mode

This bit is set and cleared by software to trigger the conversion in sampling time control trigger mode.

0: Software trigger starts the conversion for sampling time control trigger mode
1: Software trigger starts the sampling for *sampling time control trigger mode*

Note: The software is allowed to write this bit only when ADSTART = 0, JADSTART = 0 (which ensures that no conversion is ongoing), SMPTRIG = 1, and EXTEN[0:1] = 00.

Bit 13 **BULB**: Bulb sampling mode

This bit is set and cleared by software to enable the bulb sampling mode.

0: Bulb sampling mode disabled

1: Bulb sampling mode enabled. The sampling period starts just after the previous end of conversion.

BULB bit must not be set when the SWTRIG bit is set.

The very first ADC conversion is performed with the sampling time specified in SMPx bits.

Note: The software is allowed to write this bit only when ADEN = 0. When the discontinuous mode is used, only DISCNUM[2:0] = 000 configuration is compatible with bulb mode.

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **ROVSM**: Regular oversampling mode

This bit is set and cleared by software to select the regular oversampling mode.

0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)

1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing). It is recommended to clear both JOVSE and GCOMP when ROVSM = 0.

Bit 9 **TROVS**: Triggered regular oversampling

This bit is set and cleared by software to enable triggered oversampling

0: All oversampled conversions for a channel are done consecutively following a trigger

1: Each oversampled conversion for a channel needs a new trigger

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 8:5 **OVSS[3:0]**: Oversampling shift

This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.

0000: No shift

0001: 1-bit shift

0010: 2-bit shift

0011: 3-bit shift

0100: 4-bit shift

0101: 5-bit shift

0110: 6-bit shift

0111: 7-bit shift

1000: 8-bit shift

1001: 9-bit shift

1010: 10-bit shift

Other: reserved, must not be used

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **JOVSE**: Injected oversampling enable

This bit is set and cleared by software to enable injected oversampling.

0: Injected oversampling disabled

1: Injected oversampling enabled

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0 **ROVSE**: Regular oversampling enable

This bit is set and cleared by software to enable regular oversampling.

0: Regular oversampling disabled

1: Regular oversampling enabled

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing)

42.6.6 ADC sample time register 1 (ADC_SMPR1)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SMP9[2:0]			SMP8[2:0]			SMP7[2:0]			SMP6[2:0]			SMP5[2:1]	
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMP5[0]	SMP4[2:0]			SMP3[2:0]			SMP2[2:0]			SMP1[2:0]			SMP0[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 9 to 0)

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

000: 1.5 ADC clock cycles

001: 2.5 ADC clock cycles

010: 6.5 ADC clock cycles

011: 11.5 ADC clock cycles

100: 23.5 ADC clock cycles

101: 46.5 ADC clock cycles

110: 246.5 ADC clock cycles

111: 1499.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

42.6.7 ADC sample time register 2 (ADC_SMPR2)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SMP19[2:0]			SMP18[2:0]			SMP17[2:0]			SMP16[2:0]			SMP15[2:1]	
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

SMP15[0]	SMP14[2:0]			SMP13[2:0]			SMP12[2:0]			SMP11[2:0]			SMP10[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 19 to 10)

These bits are written by software to select the sampling time individually for each channel. During sampling cycles, the channel selection bits must remain unchanged.

000: 1.5 ADC clock cycles
001: 2.5 ADC clock cycles
010: 6.5 ADC clock cycles
011: 11.5 ADC clock cycles
100: 23.5 ADC clock cycles
101: 46.5 ADC clock cycles
110: 246.5 ADC clock cycles
111: 1499.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

42.6.8 ADC channel preselection register (ADC_PCSEL)

Address offset: 0x01C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PCSEL[19:16]			
												rw	rw	rw	rw

PCSEL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **PCSEL[19:0]**: Channel i (V_{INP}[i]) preselection

These bits are written by software to preselect the input channel I/O to be converted.

0: Input channel i (V_{INP}[i]) is not preselected for conversion, the result of the ADC conversion for this channel is wrong

1: Input channel i (V_{INP}[i]) is preselected for conversion

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

42.6.9 ADC regular sequence register 1 (ADC_SQR1)

Address offset: 0x030

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ4[4:0]					Res.	SQ3[4:0]					Res.	SQ2[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ2[3:0]				Res.	SQ1[4:0]					Res.	Res.	L[3:0]			
rw	rw	rw	rw		rw	rw	rw	rw	rw			rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]:** 4th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 4th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ3[4:0]:** 3rd conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 3rd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ2[4:0]:** 2nd conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 2nd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ1[4:0]:** 1st conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 1st in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **L[3:0]:** Regular channel sequence length

These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

0000: 1 conversion

0001: 2 conversions

...

1111: 16 conversions

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

42.6.10 ADC regular sequence register 2 (ADC_SQR2)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ9[4:0]					Res.	SQ8[4:0]					Res.	SQ7[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw

SQ7[3:0]				Res.	SQ6[4:0]					Res.	SQ5[4:0]				
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]:** 9th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 9th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]:** 8th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 8th in the regular conversion sequence

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]:** 7th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 7th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]:** 6th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 6th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ5[4:0]:** 5th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 5th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

42.6.11 ADC regular sequence register 3 (ADC_SQR3)

Address offset: 0x038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ14[4:0]					Res.	SQ13[4:0]					Res.	SQ12[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ12[3:0]				Res.	SQ11[4:0]					Res.	SQ10[4:0]				
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ14[4:0]:** 14th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 14th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ13[4:0]:** 13th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 13th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ12[4:0]:** 12th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 12th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ11[4:0]:** 11th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 11th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ10[4:0]:** 10th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 10th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

42.6.12 ADC regular sequence register 4 (ADC_SQR4)

Address offset: 0x03C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	SQ16[4:0]					Res.	SQ15[4:0]				
					rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:6 **SQ16[4:0]:** 16th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 16th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ15[4:0]:** 15th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 15th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

42.6.13 ADC regular data register (ADC_DR)

Address offset: 0x040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RDATA[31:0]**: Regular data converted

These bits are read-only. They contain the conversion result from the last converted regular channel. The data are left- or right-aligned as described in *Section 42.4.26: Data management*.

42.6.14 ADC injected sequence register (ADC_JSQR)

Address offset: 0x04C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JSQ4[4:0]					Res.	JSQ3[4:0]					Res.	JSQ2[4:1]			
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JSQ2[0]	Res.	JSQ1[4:0]					JEXTEN[1:0]		JEXTSEL[4:0]					JL[1:0]	
rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 **JSQ4[4:0]:** 4th conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 4th in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 **JSQ3[4:0]:** 3rd conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 3rd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 **JSQ2[4:0]:** 2nd conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 2nd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **JSQ1[4:0]:** 1st conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 1st in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 8:7 **JEXTEN[1:0]**: External trigger enable and polarity selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 6:2 **JEXTSEL[4:0]**: External trigger selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

00000: adc_jext_trg0

00001: adc_jext_trg1

00010: adc_jext_trg2

00011: adc_jext_trg3

00100: adc_jext_trg4

00101: adc_jext_trg5

00110: adc_jext_trg6

00111: adc_jext_trg7

...

11111: adc_jext_trg31

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 1:0 **JL[1:0]:** Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

42.6.15 ADC offset y configuration register (ADC_OFCFGRy)

Address offset: 0x050 + 0x004 * (y -1), (y = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OFFSET_CH[4:0]					SSAT	USAT	POS OFF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:27 **OFFSET_CH[4:0]:** Channel selection for the data offset y

These bits are written by software to define the channel to which the offset programmed in bits OFFSET[21:0] applies.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the data offset y.

Bit 26 **SSAT**: Signed saturation enable

This bit is set and cleared by software to enable the signed saturation feature.(see *Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT, POSOFF)*).

0: Offset is subtracted maintaining the data integrity and extending converted data size (13-bit signed format)

1: Offset is subtracted and result is saturated to maintain the converted data size

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **USAT**: Unsigned saturation enable

This bit is set and cleared by software to enable the unsigned saturation feature.

0: Offset is subtracted maintaining the data integrity

1: Offset is subtracted and result is saturated to maintain the converted data size

Note: The software is allowed to write these bits only when ADSTART = and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 24 **POSOFF**: Positive offset enable

This bit is set and cleared by software to enable the positive offset

0: Negative offset

1: Positive offset

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 23:0 Reserved, must be kept at reset value.

42.6.16 ADC offset y register (ADC_OFRy)

Address offset: 0x060 + 0x004 * (y -1), (y= 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OFFSET[21:16]

OFFSET[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:0 **OFFSET[21:0]:** Data offset y for the channel programmed in OFFSETy_CH[4:0] bits

These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset y must be programmed in the OFFSETy_CH[4:0] bits. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

42.6.17 ADC gain compensation register (ADC_GCOMP)

Address offset: 0x070

Reset value: 0x0000 1000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
GCOMP	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	GCOMPCOEFF[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **GCOMP:** Gain compensation mode

This bit is set and cleared by software to enable the Gain compensation mode.

0: Regular ADC operation mode

1: Gain compensation enabled and applied on all channels.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensure that no conversion is ongoing)

Bits 30:14 Reserved, must be kept at reset value.

Bits 13:0 **GCOMPCOEFF[13:0]:** Gain compensation coefficient

These bits are set and cleared by software to program the gain compensation coefficient.

00 1000 0000 0000: gain factor of 0.5

...

01 0000 0000 0000: gain factor of 1

10 0000 0000 0000: gain factor of 2

11 0000 0000 0000: gain factor of 3

...

The coefficient is divided by 4096 to get the gain factor ranging from 0 to 3.9999756

Note: This gain compensation is only applied when GCOMP bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensure that no conversion is ongoing).

42.6.18 ADC injected channel y data register (ADC_JDRy)

Address offset: 0x080 + 0x004 * (y - 1), (y = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

JDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **JDATA[31:0]:** Injected data

These bits are read-only. They contain the conversion result from injected channel y. The data are left- or right-aligned as described in *Section 42.4.26: Data management*.

42.6.19 ADC analog watchdog 2 configuration register (ADC_AWD2CR)

Address offset: 0x0A0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

AWDCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWDCH[19:0]**: Analog watchdog 2 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

AWDCH[i] = 0: ADC analog input channel i is not monitored by AWD2

AWDCH[i] = 1: ADC analog input channel i is monitored by AWD2

When AWDCH[19:0] = 000..0, the analog Watchdog 2 is disabled

Note: The channels selected by AWDCH must be also selected in the SQRi or JSQRi registers.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the analog watchdog.

42.6.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR)

Address offset: 0x0A4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWDCH[19:0]**: Analog watchdog 3 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.

AWDCH[i] = 0: ADC analog input channel i is not monitored by AWD3

AWDCH[i] = 1: ADC analog input channel i is monitored by AWD3

When AWDCH[19:0] = 000..0, the analog Watchdog 3 is disabled

Note: The channels selected by AWDCH must be also selected in the SQRi or JSQRi registers.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the analog watchdog.

42.6.21 ADC analog watchdog 1 lower threshold register (ADC_AWD1LTR)

Address offset: 0x0A8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LTR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **LTR[22:0]**: Analog watchdog 1 lower threshold

These bits are set and cleared by software to define the lower threshold for analog watchdog 1.

Refer to *Section 42.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)*.

42.6.22 ADC analog watchdog 1 higher threshold register (ADC_AWD1HTR)

Address offset: 0x0AC

Reset value: 0x003F FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

HTR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 **AWDFILT[2:0]**: Analog watchdog filtering parameter

These bits are set and cleared by software.

000: No filtering, one detection generates an AWD1 flag or an interrupt

001: two consecutive detections generate an AWD1 flag or an interrupt

...

111: Eight consecutive detections generate an AWD1 flag or an interrupt

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 28:23 Reserved, must be kept at reset value.

Bits 22:0 **HTR[22:0]**: Analog watchdog 1 higher threshold

These bits are set and cleared by software to define the higher threshold for analog watchdog 1. Refer to *Analog windows watchdog* section.

42.6.23 ADC analog watchdog 2 lower threshold register (ADC_AWD2LTR)

Address offset: 0x0B0

Reset value: 0x0000 0000

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **HTR[22:0]**: Analog watchdog 2 higher threshold

These bits are set and cleared by software to define the higher threshold for analog watchdog 2. Refer to *Analog windows watchdog* section.

42.6.25 ADC analog watchdog 3 lower threshold register (ADC_AWD3LTR)

Address offset: 0x0B8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **HTR[22:0]**: Analog watchdog 3 higher threshold

These bits are set and cleared by software to define the higher threshold for analog watchdog 3. Refer to *Analog windows watchdog* section.

42.6.27 ADC differential mode selection register (ADC_DIFSEL)

Address offset: 0x0C0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIFSEL[19:16]			
												rw	rw	rw	rw

DIFSEL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **DIFSEL[19:0]:** Differential mode for channels 19 to 0.

These bits are set and cleared by software. They allow to select if a channel is configured as single-ended or differential mode.

DIFSEL[i] = 0: ADC analog input channel is configured in single-ended mode

DIFSEL[i] = 1: ADC analog input channel i is configured in differential mode

Note: The DIFSEL bits corresponding to channels that are either connected to a single-ended I/O port or to an internal channel must be kept their reset value (single-ended input mode).

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

42.6.28 ADC calibration factors (ADC_CALFACT)

Address offset: 0x0C4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CAL ADDOS	Res.	Res.	Res.	Res.	Res.	Res.	CALFACT_D[8:0]								
rw							rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	CALFACT_S[8:0]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **CALADDOS**: Calibration additional offset

This bit is set by software to add a positive offset at the input stage of ADC for calibration purpose.

0: Calibration additional positive offset disabled

1: Calibration additional positive offset enabled

Note: The software is allowed to write these bits only when ADEN = 1, ADCAL = 1, ADSTART = 0, and JADSTART = 0 (ADC is enabled, calibration mode is selected, and no conversion is ongoing).

Bits 30:25 Reserved, must be kept at reset value.

Bits 24:16 **CALFACT_D[8:0]**: Calibration factors in differential mode

These bits are written by hardware or by software.

Once a differential input calibration is complete, they are updated by hardware with the calibration factors.

The software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored in the analog ADC, it is applied once a new differential conversion is launched.

Note: The software is allowed to write these bits only when ADEN = 1, ADCAL = 1, ADSTART = 0 and JADSTART = 0 (ADC is enabled, no calibration is ongoing and no conversion is ongoing).

Bits 15:9 Reserved, must be kept at reset value.

Bits 8:0 **CALFACT_S[8:0]**: Calibration factors In single-ended mode

These bits are written by hardware or by software.

Once a single-ended input calibration is complete, they are updated by hardware with the calibration factors.

The software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored in the analog ADC, it is applied once a new single-ended conversion is launched.

Note: The software is allowed to write these bits only when ADEN = 1, ADCAL = 1, ADSTART = 0 and JADSTART = 0 (ADC is enabled, no calibration is ongoing and no conversion is ongoing).

This bit can only be cleared by a power-on reset.

42.6.29 ADC option register (ADC_OR)

Address offset: 0x0D0

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OP4	OP3	OP2	OP1	OP0
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **OP4:** Option bit 4

This bit is set and cleared by software to enable/disable the V_{DDGPU} channel.

0: V_{DDGPU} channel disabled

1: V_{DDGPU} channel enabled

Note: This bit is only available in ADC2 and ADC3.

Bit 3 **OP3:** Option bit 3

This bit is set and cleared by software to enable/disable the V_{DDCPU} channel.

0: V_{DDCPU} channel disabled

1: V_{DDCPU} channel enabled

Note: This bit is only available in ADC2 and ADC3

Bit 2 **OP2:** Option bit 2

This bit is set and cleared by software to enable/disable the V_{DDCORE} channel.

0: V_{DDCORE} channel disabled

1: V_{DDCORE} channel enabled

Note: This bit is only available in ADC2 and ADC3.

Bit 1 **OP1:** Option bit 1

This bit is set and cleared by software to choose the ADC bandgap source

0: ADC internal bandgap disabled

1: ADC internal bandgap enabled

Note: The software is allowed to write this bit only when ADC is disabled.

Bit 0 **OP0:** Option bit 0

This bit is set and cleared by software to enable the internal reference buffer.

0: ADC internal reference voltage buffer disabled

1: ADC internal reference voltage buffer enabled

Note: The software is allowed to write this bit only when ADC is disabled.

42.7 ADC common registers

These registers define the control and status registers common to master and slave ADCs.

42.7.1 ADC common status register (ADCC_CSR)

Address offset: 0x000

Reset value: 0x0000 0000

This register provides an image of the flags of the different ADCs. Nevertheless it is read-only and does not allow to clear the different flags. Instead each flag must be cleared by writing 0 to it in the corresponding ADC_ISR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	AWD3_SLV	AWD2_SLV	AWD1_SLV	JEOS_SLV	JEOC_SLV	OVR_SLV	EOS_SLV	EOC_SLV	EOSMP_SLV	ADRDY_SLV
						r	r	r	r	r	r	r	r	r	r

Res.	Res.	Res.	Res.	Res.	Res.	AWD3_MST	AWD2_MST	AWD1_MST	JEOS_MST	JEOC_MST	OVR_MST	EOS_MST	EOC_MST	EOSMP_MST	ADRDY_MST
						r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **AWD3_SLV:** Analog watchdog 3 flag of the slave ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 24 **AWD2_SLV:** Analog watchdog 2 flag of the slave ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 23 **AWD1_SLV:** Analog watchdog 1 flag of the slave ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 22 **JEOS_SLV:** End of injected sequence flag of the slave ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 21 **JEOC_SLV:** End of injected conversion flag of the slave ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 20 **OVR_SLV:** Overrun flag of the slave ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 19 **EOS_SLV:** End of regular sequence flag of the slave ADC. This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 18 **EOC_SLV:** End of regular conversion of the slave ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 17 **EOSMP_SLV:** End of sampling phase flag of the slave ADC
This bit is a copy of the EOSMP2 bit in the corresponding ADC_ISR register.

Bit 16 **ADRDY_SLV:** Slave ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **AWD3_MST:** Analog watchdog 3 flag of the master ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 8 **AWD2_MST:** Analog watchdog 2 flag of the master ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 7 **AWD1_MST:** Analog watchdog 1 flag of the master ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 6 **JEOS_MST:** End of injected sequence flag of the master ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 5 **JEOC_MST:** End of injected conversion flag of the master ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 4 **OVR_MST:** Overrun flag of the master ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 3 **EOS_MST:** End of regular sequence flag of the master ADC
This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 2 **EOC_MST:** End of regular conversion of the master ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 1 **EOSMP_MST:** End of Sampling phase flag of the master ADC
This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 0 **ADRDY_MST:** Master ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

42.7.2 ADC common control register (ADCC_CCR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	VBATEN	Res.	VREFEN	PRESC[3]	PRESC[2]	PRESC[1]	PRESC[0]	Res.	Res.

Res.	Res.	Res.	SPRES	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
			rw												

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **VBATEN**: VBAT enable
This bit is set and cleared by software to enable/disable the V_{BAT} channel.
0: V_{BAT} channel disabled
1: V_{BAT} channel enabled
Note: V_{BAT} is not available on all ADC instances. Refer to Section 42.4.4: ADC connectivity for details.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **VREFEN**: V_{REFINT} enable

This bit is set and cleared by software to enable/disable the V_{REFINT} channel.

0: V_{REFINT} channel disabled

1: V_{REFINT} channel enabled

Note: V_{REFINT} is not available on all ADC instances. Refer to Section 42.4.4: ADC connectivity for details.

Note: The software is allowed to write this bit only when ADEN = 0.

Bits 21:18 **PRESC[3:0]**: ADC prescaler

These bits are set and cleared by software to select the frequency of the clock to the ADC. The clock is common for all the ADCs.

0000: input ADC clock not divided
0001: input ADC clock divided by 2
0010: input ADC clock divided by 4
0011: input ADC clock divided by 6
0100: input ADC clock divided by 8
0101: input ADC clock divided by 10
0110: input ADC clock divided by 12
0111: input ADC clock divided by 16
1000: input ADC clock divided by 32
1001: input ADC clock divided by 64
1010: input ADC clock divided by 128
1011: input ADC clock divided by 256
Other: reserved, must not be used

Note: The software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 17:13 Reserved, must be kept at reset value.

Bit 12 **SPRES:** Single prescaler mode

This bit is set and cleared by software to enable/disable the single prescaler mode.

0: Default prescaler configuration (each ADC might have own prescaler)

1: One prescaler configuration (both ADCs are forced to use one prescaler)

Note: The software is allowed to write this bit only when both ADC1 and ADC2 are disabled.

Bits 11:0 Reserved, must be kept at reset value.

42.7.3 ADC hardware configuration register (ADCC_HWCFGR1)

Address offset: 0x0F0

Reset value: 0x0000 0242 (ADCC12)
Reset value: 0x0000 0241 (ADCC3)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	ANAIP[3:0]				OPBITS[3:0]				ADCNUM[3:0]			
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:8 **ANAIP[3:0]**: Analog IP compatibility
0001: ADC12P18
0010: ADC12FF16/N12
0011: ADC12T40
0100: ADC12S40
0101: ADC12M40/E40
0110: ADC12M40/E40_2msps

Bits 7:4 **OPBITS[3:0]**: Number of option bits
0000: No option register implemented
0001: 1 option bit implemented in the ADC option register (ADC_OR) at address offset 0x0D0
0010: 2 option bits implemented in the ADC option register (ADC_OR) at address offset 0x0D0
0100: 4 option bits implemented in the ADC option register (ADC_OR) at address offset 0xD0

Bits 3:0 **ADCNUM[3:0]**: Number of ADCs implemented
0001: One ADC instance implemented
0010: Two ADC instances implemented
0011: Three ADCs instances implemented

42.7.4 ADC version register (ADCC_VERR)

Address offset: 0x0F4

Reset value: 0x0000 0011

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MAJREV[3:0]				MINREV[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **MAJREV[3:0]**: Major revision
These bits returns the ADC IP major revision
0001: Major revision = 1.X
0010: Major revision = 2.X
0011: Major revision = 3.X

Bits 3:0 **MINREV[3:0]**: Minor revision
These bits returns the ADC IP minor revision
0000: Minor revision = X.0
0001: Minor revision = X.1

42.7.5 ADC identification register (ADCC_IPIDR)

Address offset: 0x0F8

Reset value: 0x0011 0008

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

ID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ID[31:0]**: Peripheral identifier

These bits returns the ADC identifier.
ID[31:0] = 0x0011 0008: c7amba_aditf6

42.7.6 ADC size identification register (ADCC_SIDR)

Address offset: 0x0FC

Reset value: 0xA3C5 DD01

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **SID[31:0]**: Size Identification

SID[31:8]: fixed code that characterizes the ADCx_SIDR register. This field is always read at 0xA3C5DD.
SID[7:0]: read-only numeric field that returns the address offset (in Kbytes) of the identification registers from the IP base address:
0x01: 1 Kbytes address offset
0x02: 2 Kbytes address offset
0x04: 4 Kbytes address offset
0x08: 8 Kbytes address offset

42.8 ADC register map

ADC1 and ADC3 are master ADCs.

ADC2 operates as a slave from ADC1.

Table 372. ADC register map and reset values for each ADC

Offset	Register name reset value	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

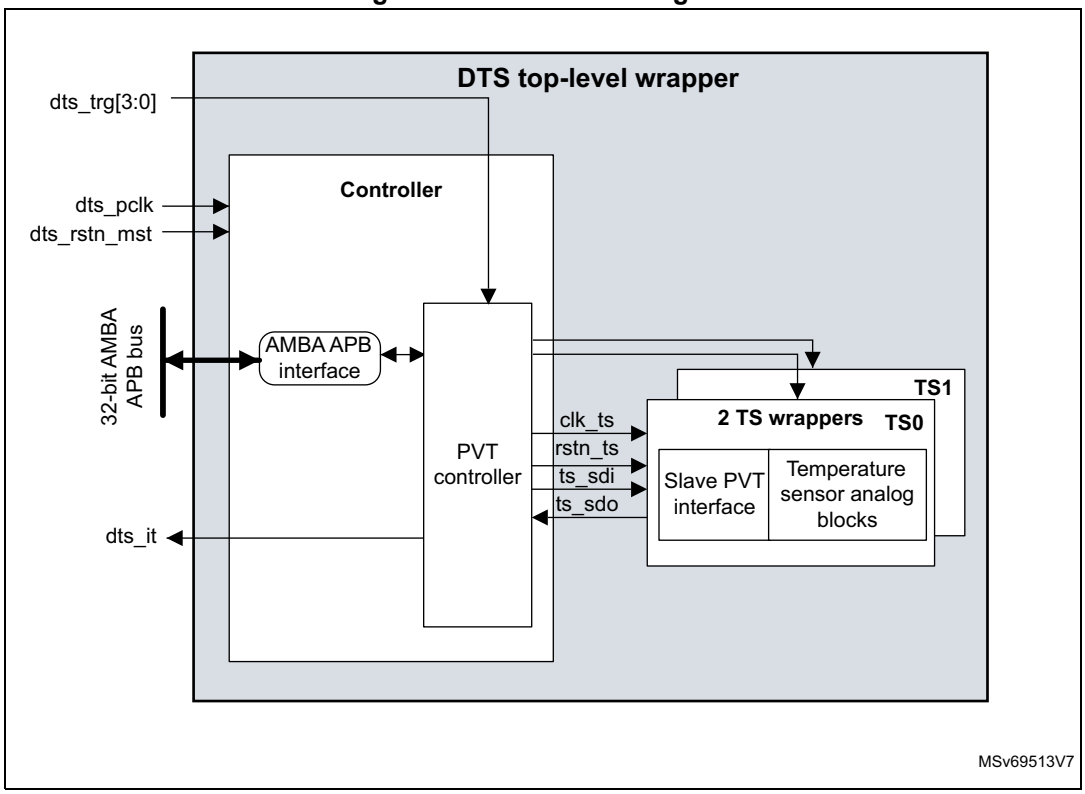
43 Digital temperature sensor (DTS)

43.1 Introduction

The DTS is a high-precision low-power junction temperature sensor (TS). It is composed of a configurable controller plus two embedded temperature sensors, TS0 and TS1. The controller features a generic interface that enables the DTS to be accessed in read and write modes, through the APB bus.

43.2 DTS main features

The temperature sensor main features are the following:



- For each sensor:
  - Two programmable (rise or fall) hardware alarms incorporating hysteresis
  - Status registers recording the minimum and maximum data values received
- A power-up timer with IRQ to support manual operation

43.3 DTS functional description

43.3.1 DTS block diagram

Figure 342 shows the DTS block diagram.

Figure 342. DTS block diagram

The DTS incorporates an APB interface configured to control two temperature sensors, TS0 and TS1, through a process, voltage and temperature (PVT) controller.

43.3.2 DTS pins and internal signals

Table 374. DTS internal input/output signals

Internal signal name	Signal type	Description
dts_pclk	Input	System (APB) clock
dts_rstn_mst	Input	Master reset (asynchronous, active low)
AMBA APB bus	Input/output	APB Interface
dts_it	Output	IRQ interrupt from the DTS peripheral
dts_trg[3:0]	Inputs	Trigger interface
Temperature sensor (TS) interface		
clk_ts	Input	Temperature sensor SDA clock
rstn_ts	Input	Temperature sensor SDA reset (asynchronous, active low)

Table 374. DTS internal input/output signals (continued)

Internal signal name	Signal type	Description
ts_sdi	Input	Temperature sensor SDA slave data Input
ts_sdo	Output	Temperature sensor SDA slave data output

43.3.3 DTS reset and clocks

DTS clocks

The primary clock is the bus interface clock that clocks most of the DTS logic. The PVT controller is a single clock domain design with the bus interface dts_pclk being the clock master. All the PVT controller internal registers are clocked on the rising edge of dts_pclk and have active low asynchronous resets.

The PVT controller also incorporates one clock synthesizer per TS block. The synthesizers generate the clock and timing strobes for the slave serial data adapters (SDA) and the clock for the embedded TS blocks (clk_ts).

The synthesizer CLK_SYNTH_HI[7:0]/CLK_SYNTH_LO[7:0] counters allow the integer division of the dts_pclk clock to generate the TS clock (clk_ts) at frequency ratios from 1/2 to 1/512 (see *DTS TSC clock synthesizer register (DTS_TSCCLKSYNTHR)*). Separate counters are used to generate timing control strobes that are aligned with the clk_ts clock. These timing strobes are used by the master serial adapters to control the sample point of the serial data inputs and the hold time of the serial data outputs.

The system clock dts_pclk frequency is determined by the RCC. CLK_SYNTH_HI[7:0] and CLK_SYNTH_LO[7:0] must be programmed so that the ratio CLK_SYNTH_HI[7:0]/CLK_SYNTH_LO[7:0] enables to obtain a clk_ts serial clock that falls within the TS operating frequency range (from 4 to 8 MHz).

The TS frequency is defined by:

$$\text{clk_ts frequency} = 1 / ((\text{CLK_SYNTH_HI[7:0]} + 1) + (\text{CLK_SYNTH_HI[7:0]} + 1)) \times \text{dts_pclk frequency}$$

For example:

For dts_pclk = 75.0 MHz and a TS operating frequency ranging between 4 and 8 MHz, setting the dts_pclk to clk_ts divider factor to 10:1 (CLK_SYNTH_HI[7:0] and CLK_SYNTH_LO[7:0] both programmed to 0x04), returns an TS operating frequency of 75.0 MHz / 10 = 7.5 MHz, which falls within the acceptable operating frequency range of 4 to 8 MHz. This enables to obtain an overall divider factor of 10 and a clk_ts serial clock duty cycle of 50/50.

For dts_pclk = 8 MHz, the configuration must be:

CLK_SYNTH_LO[7:0] = 0x0

CLK_SYNTH_HI[7:0] = 0x0

CLK_SYNTH_HOLD[3:0]= 0x1

clk_ts = 4 MHz

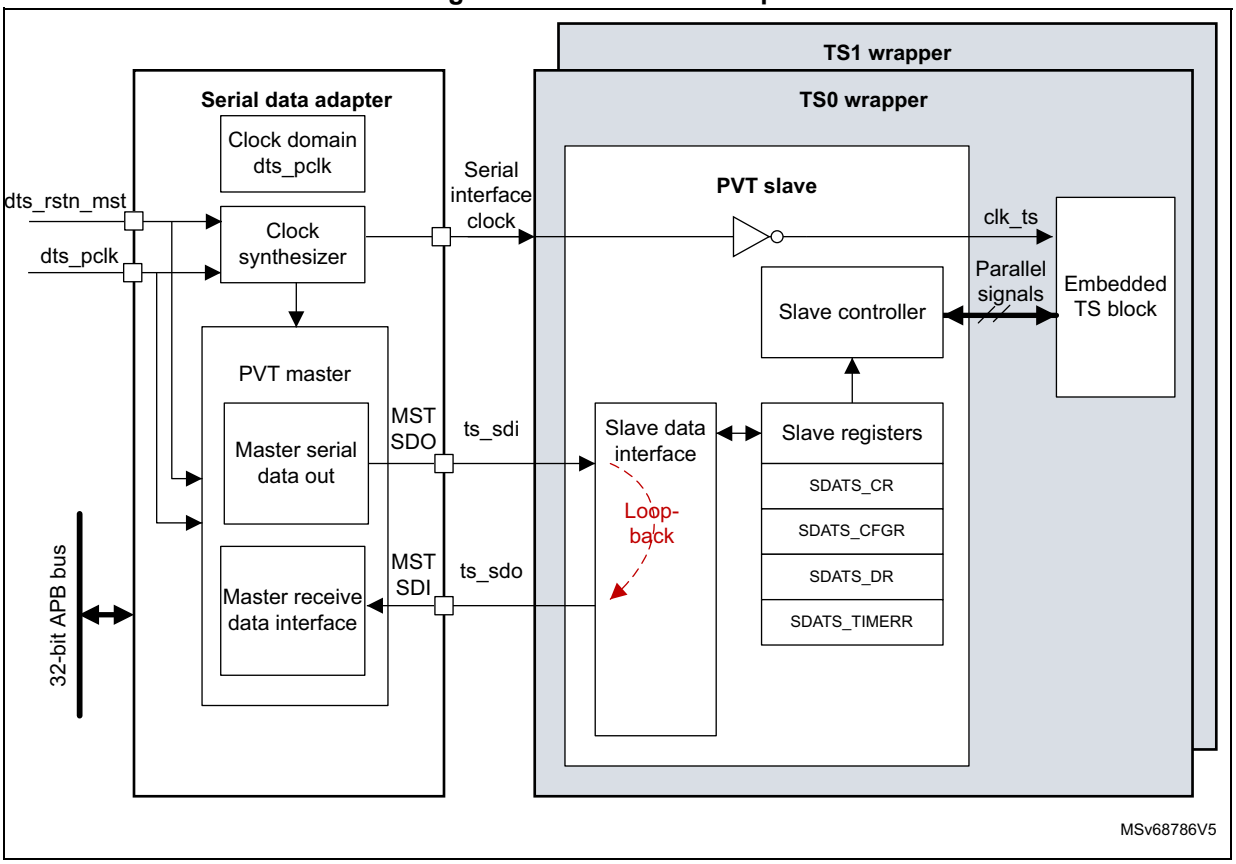
clk_ts duty cycle = 50 %

The CLK_SYNTH_HOLD[3:0] value must be programmed to accommodate the worst-case serial data path propagation delays without exceeding the synthesized clock period, this means that:

$$CLK_SYNTH_HOLD[3:0] \leq CLK_SYNTH_HI[7:0] + CLK_SYNTH_LO[7:0] + 1$$

DTS reset

The DTS is reset using the asynchronous active-low dts_rstn_mst input.



When the master dts_rstn_mst is asserted, the entire DTS is reset, all APB internal registers and the PVT controller. It also powers down and resets the embedded TS blocks.

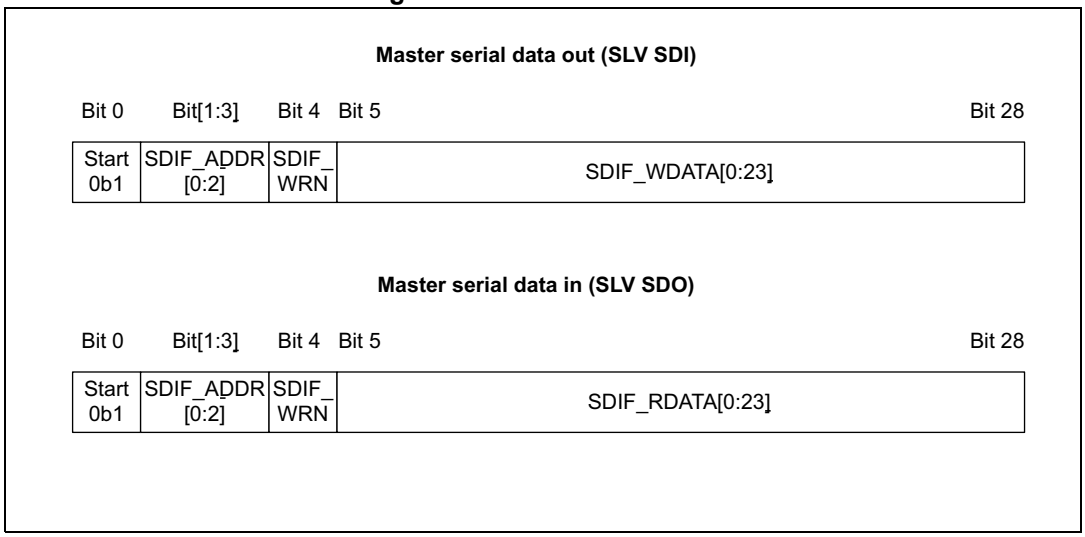
When de-asserted, the APB interface responds to requests after a three clock-cycle delay.

All the registers within the DTS and the TS block use an active low asynchronous reset scheme. Since reset assertion is fully asynchronous, the DTS incorporates dual-flop metastable real-time circuits to synchronize the internal reset de-assertion to the rising edge of dts_pclk.

43.3.4 DTS serial data adapter (SDA)

Figure 343. Serial data adapter

The serial data adapter (SDA) allows the TS blocks to be configured and controlled via serial data interfaces (SDIF). The purpose of the SDA is to minimize the number of signals that need to be routed from the PVT controller to each TS block.



A master usually transmits data to all its active PVT slave devices. However, it is possible to inhibit the programming of one or more slaves to allow different configuration options to be applied. To achieve power saving, it is also possible to disable completely a TS block by disabling its clock and forcing reset.

The serial data interface also provides loop-back functionality (shown in red in *Figure 343*) to support system integration testing without having to power up the embedded TS block.

SDA data format

The serial data streams consist of an active-high start bit, 3-bit register address (SDIF_ADDR[2:0]), register write/not read enable (SDIF_WRN), and 24-bit data field (SDIF_WDATA[23:0]). The input and output serial data stream formats are shown in *Figure 344*. It must be noted that the serial data streams are little endian, meaning that the individual data fields are shifted LSB first.

Figure 344. SDA data format

SDA read

When reading data from the SDA slave registers (SDIF_WRN = 0), the SLV SDI bit stream is shifted to SLV SDO (delayed by one clk_ts cycle) and the register read data value is output on SDIF_RDATA[23:0]. The read data value is then made available in the PVT controller DTS_TSnSDIFRDATAR register (where *n* corresponds to the TS instance number).

SDA write

When writing data to the SDA slave registers (SDIF_WRN = 1), the SLV SDI bit stream is automatically shifted to SLV SDO and SDIF_RDATA[23:0] = SDIF_WDATA[23:0]. The write data loop-back value is then made available in the corresponding PVT controller DTS_TSnSDIFRDATAR register.

A special loop-back mode is available by writing to the (read-only) SDATS_DR register when SDIF_WRN = 1 and SDIF_ADDR[2:0] = 0x3. In this mode, the loop-back data value is also written to the PVT controller TS data registers (DTS_TSnSDIFRDATAR). When writing loop-back data to the TS data registers, the SDA TS_DATA[23:0] field **must** be set to 0x0.

The DTS_TSnSDIFRDATAR loop-back functionality can be used to verify the integrity of the serial data transfer between the PVT controller and remote PVT slave devices.

The special DTS_TSnSDIFRDATAR loop-back functionality is provided to test the PVT controller operation without having to power up the embedded TS block, for example when a fault or alarm occurs.

The loop-back functionality is disabled whenever the PVT slave is configured to automatic data recovery when the TS_AUTO bit of PVT SDATS_CR register is asserted.

SDA automatic data recovery

The automatic data recovery is enabled through TS_AUTO bit of SDATS_CR register.

In automatic data recovery mode, the SDIF_LOCK flag is set in the DTS_TSCSDIF_SR register, the SDA interface becomes write-only and all SDA read requests are ignored. In this mode, the SLV automatically streams TS_DATA[23:0] to the PVT controller each time new data samples become available, while setting SDIF_ADDR[2:0] to 0x3 and SDIF_WRN to 1. The automatically recovered data are made available in the PVT controller DTS_TSnSDIFRDATAR and DTS_TSnSDIFRDATAR registers.

SDA SDIF programming

The SDA slave is accessed via the TS SDIF control register DTS_TSCSDIF_CFGR, by setting the SDIF_WDATA[23:0], the SDIF_ADDR[2:0] and the SDIF_WRN, and asserting the SDIF_PROG bit. This SDA read or write request is normally set up using a single PVT register write access.

Once a programming request has been issued, the SDIF_BUSY flag in the DTS_TSCSDIF_SR register is set, and any additional read or write programming requests is ignored until the current access completes.

SDA controller operation

The SDA slave controller features two operating modes: manual (default) and automatic. In both modes, the embedded TS block is configured through the SDATS_CFGR register.

In manual operating mode, when the TS_AUTO bit of SDATS_CR register is de-asserted, the embedded TS block is controlled directly through the SDATS_CR register fields TS_PD, TS_RSTN, TS_RUN_ONCE, TS_RUN_CONT and TS_CLOAD. In manual mode, the user is responsible for ensuring that the PD, RSTN, CLOAD and RUN signals are applied in the correct order and at appropriate times. Sample data from the TS block are captured in the SDA slave SDATS_DR register at the end of the conversion. The user must either poll the SDATS_DR register or leave sufficient time for the conversion to complete before reading the SDATS_DR register in order to recover the sample data from the slave SDA.

In automatic mode, when the TS_AUTO bit is asserted in SDATS_CR register, the embedded TS block is controlled by the slave SDA. When either TS_RUN_ONCE or TS_RUN_CONT bit of the TS_SDATS_CR register is asserted, the slave SDA sequences the PD, RSTN, CLOAD, and RUN signals that drive the TS block to perform one or more conversions. In this mode sample data from the TS block are captured in the SDA slave SDATS_DR register at the end of the conversion before being automatically streamed to the PVT controller.

In trigger mode, when a trigger is asserted at DTS top level, this value is compared to the value programmed in bits 18 to 16 (TRIG[2:0]) of the SDATS_CFGR register. If it is equal,

the TS_RUN_ONCE bit is automatically asserted. Sample data from each TS block are captured in the SDA slave SDATS_DR register at the end of the conversion.

SDA slave registers

The serial data adapter registers are accessible through the SDIF interface of the PVT controller.

Table 375. SDA slave registers

SDIF_ADDR[2:0]	Reset value	Register	Description
0x0	0x000001	SDATS_CR	TS control register (see *Table 376*)
0x1	0x000000	SDATS_CFGR	TS configuration register (see *Table 377*)
0x3	0x000000	SDATS_DR	TS data / SDA loop-back register (see *Table 378*)
0x4	-	Reserved	-
0x5	0x000000	SDATS_TIMERR	TS power-up Timer register (see *Table 376*)

Table 376. SDA TS control register (SDATS_CR)

Bitfield range	Bitfield description	Access type
Bits 23:10	Reserved, must be kept at reset value.	-
Bit 9	**TS_STOP:** TS force stop This self-clearing bit immediately returns the slave TS controller to the default TS control state and terminates any serial data activity. This is not a clean shut-down and it may invalidate any data operations currently in progress. 0: TS not stopped 1: TS stopped	rs
Bit 8	**TS_AUTO:** TS automatic mode This bit is used in conjunction with TS_RUN_CONT and TS_RUN_ONCE to automatically power up the embedded TS and run conversions. Asserting TS_RUN_CONT triggers continuous conversions, while asserting TS_RUN_ONCE triggers a single conversion. If TS_AUTO is de-asserted while conversions are running, the controller waits for any active conversions to complete and then returns to the default TS control state. 0: Automatic mode disabled 1: Automatic mode enabled	rw
Bits 7:5	Reserved, must be kept at reset value.	-
Bit 4	**TS_CLOAD:** TS configuration load This self-clearing bit provides the embedded TS cload input in the default TS control state (TS automatic mode disabled). 0: TS configuration not loaded 1: TS configuration loaded	rs

Table 376. SDA TS control register (SDATS_CR) (continued)

Bitfield range	Bitfield description	Access type
Bit 3	**TS_RUN_CONT:** TS run continuous The TS_RUN_CONT control bit is ORed with TS_RUN_ONCE in order to provide the embedded TS run input in the default TS control state (TS automatic mode disabled). This bit is active high.	rw
Bit 2	**TS_RUN_ONCE:** TS run once Provided TS_RUN_CONT is not asserted, this self-clearing bit asserts the embedded TS run input for one clock cycle when it is in the default TS control state (TS automatic mode disabled). This bit is active on the rising edge.	rs
Bit 1	**TS_RSTN:** TS reset This bit provides the embedded TS rstn input in the default TS control state (TS automatic mode must be disabled). 0: TS reset 1: TS not reset	rw
Bit 0	**TS_PD:** TS power-down This bit provides the embedded TS pd input when in the default TS control state (TS automatic mode disabled). 0: No TS power-down 1: TS power-down	rw

Table 377. SDA TS configuration register (SDATS_CFGR)

Bitfield range	Bitfield description	Access type
Bits 23:20	Reserved, must be kept at reset value.	-
Bit 19	**CLKDIS:** TS clock gating disable bit 0: Clock enabled 1: Clock disabled	rw
Bits 18:16	**TRIG[2:0]:** Trigger selection bits 000: no trigger source selected 001: dts_trg[0] selected 010: dts_trg[1] selected 011: dts_trg[2] selected 100: dts_trg[3] selected Others: Reserved, must not be used Refer to *Section 43.3.7: Temperature sensor configuration* for details.	rw

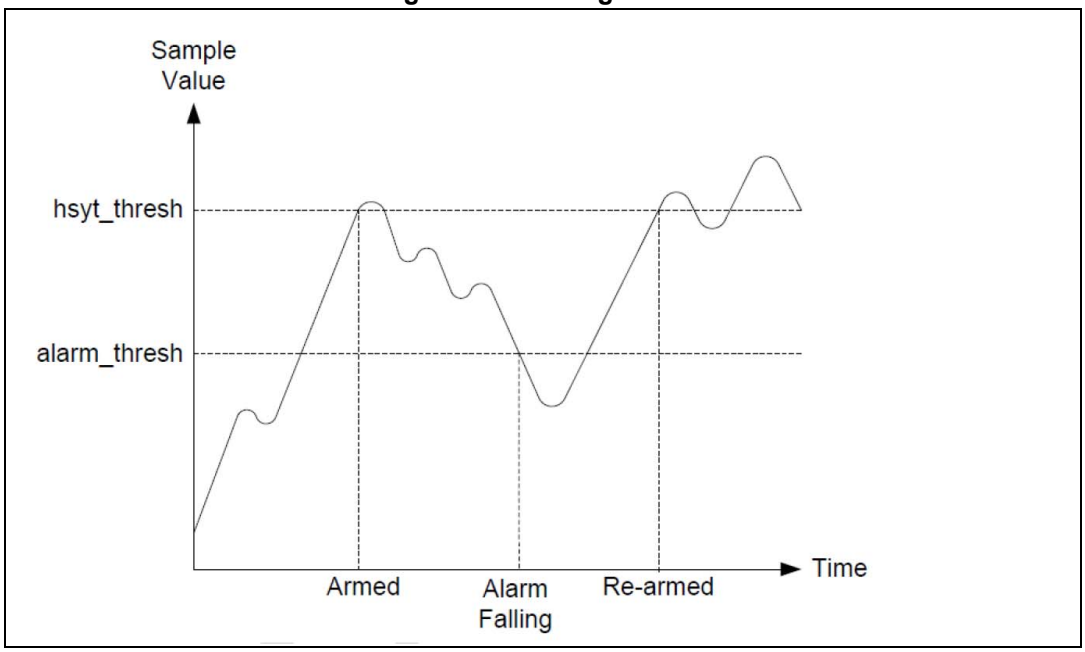
Table 377. SDA TS configuration register (SDATS_CFGR)

Bitfield range	Bitfield description	Access type
Bits 15:8	**TS1_CFG[7:0]:** TS1 configuration TS1_CFG[7:5]: TS1 resolution 000:12 bits 001:10 bits 010: 8 bits Other: reserved, must not be used TS1_CFGR[4]: TS1 output mode 0: parallel interface 1: serial interface (default) TS1_CFGR[3:0]: TS1 communication enable bit 0000: no communication 0001: communication enabled. Others: Reserved, must not be used.	rw
Bits 7:0	**TS0_CFG[7:0]:** TS0 configuration TS0_CFG[7:5]: TS0 resolution 000:12 bits 001:10 bits 010: 8 bits Other: reserved, must not be used TS0_CFGR[4]: TS0 output mode 0: parallel interface 1: serial interface (default) TS0_CFGR[3:0]: TS0 communication enable bit 0000: no communication 0001: communication enabled. Others: Reserved, must not be used.	rw

Table 378. SDA TS data register (SDATS_DR)

Bitfield range	Bitfield description	Access type
Bits 23:19	Reserved, must be kept at reset value.	-
Bit 18	**TS_DONE:** TS sample done flag This bit provides a way to identify when a new data sample has been recovered while manually polling the SDATS_DR register. In manually polling, the TS_DONE flag is cleared when the SDATS_DR register is read. The sample done flag is asserted when new sample data becomes available. It is automatically cleared in TS automatic mode as the SDATS_DR value is transmitted to the PVT controller. 0: No new data sample 1: New data sample	r
Bit 17	**TS_FAULT:** TS sample fault When asserted, this bit indicates that the embedded TS has signaled a fault. The TS_FAULT flag is updated when new data are received. 0: No TS sample fault 1: TS sample fault	r
Bit 16	**TS_TYPE:** TS sample type The TS_TYPE flag is updated when new data is received. 0: Indicates valid data 1 Indicates either analog access, signature select or fault debug mode	r
Bits 15:0	**TS_DATA[15:0]:** TS sample data	r

Table 379. SDA TS timer register (SDATS_TIMERR)



Bitfield range	Bitfield description	Access type
Bits 23:16	Reserved, must be kept at reset value.	-
Bits 15:0	**TS_PU_DLY[15:0]:** TS power-up delay The value is expressed in units of clk_ts cycles. Typical power-up delays are 256 cycles.	rw

43.3.5 Alarms

The DTS provides two alarms, alarm A and alarm B, for each TS block. The alarms feature programmable hysteresis and can be configured to detect either rising or falling sample values. They are disabled by setting the hysteresis threshold to a value that is equal to the alarm threshold (default condition). Once enabled, the alarms generate an interrupt if the value of the recovered data sample equals or exceeds the rising or falling alarm threshold. Once an alarm has been triggered, the hysteresis threshold provides a recovery window during which the alarm cannot trigger again.

Falling alarms

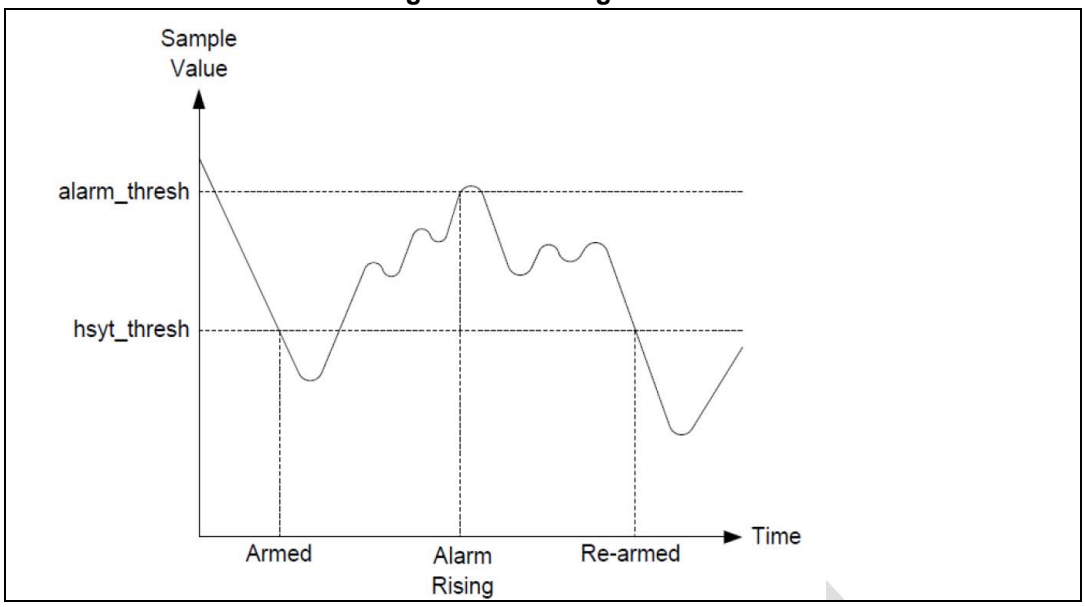


Figure 345. Falling alarms

Setting the hysteresis threshold greater than the alarm threshold creates a falling alarm. When configured as a falling alarm, the alarm is armed when the recovered sample value is greater than or equal to the hysteresis threshold. Once armed, a falling alarm triggers when the recovered sample value is less than or equal to the alarm threshold. An alarm is automatically disarmed once triggered and does not rearm until the recovered sample value is again greater than or equal to the hysteresis threshold. The alarm is also disarmed if an invalid sample value is received, that is if unexpected fault or type flags are detected.

Rising alarms

Figure 346. Rising alarms

Setting the hysteresis threshold less than the alarm threshold creates a rising alarm. When configured as a rising alarm, the alarm is armed when:

1. The associated clock synthesizer is first enabled (initial conversion).
2. The recovered sample value is less than or equal to the hysteresis threshold.
3. An invalid sample value is received, that is when an unexpected fault or type flags are detected.

Once armed, a rising alarm triggers when the recovered sample value is greater than or equal to the alarm threshold. The alarm is automatically disarmed once triggered and does not rearm until the recovered sample value is again less than or equal to the hysteresis threshold.

43.3.6 Main APB programming routines

This section gives several examples of routines to configure the PVT controller, program the SDA registers, and perform single or continuous temperature conversions.

Configure the PVT controller

1. STEP 1: Configure the PVT controller Interrupts:
   a) Write DTS_PVT_IER register:

      The timer is only intended to be used when using the TS block in bypass mode, so this interrupt must remain disabled .

   b) Write DTS_TSn_IER register:

      In the unlikely event of the TS block signaling a fault, the recovered data values are considered invalid and any active alarm is disarmed until the fault is removed. The fault IRQ is generated the first time a TS that an TS block signals a fault. If the fault is not cleared by the user, then no further interrupts are raised. It is recommended to enable always this interrupt.

2. STEP 2: Configure the PVT controller alarms:
   a) Write DTS_TSnALARMA_CFGR register:
      Alarms are enabled when the ALARM_THRESH is not equal to the HYST_THRESH.
      When enabling alarms, make sure that the corresponding IRQ is also enabled.
   b) Write DTS_TSnALARMB_CFGR register:
      Alarms are enabled when the ALARM_THRESH is not equal to the HYST_THRESH.
      When enabling alarms, make sure the corresponding IRQ is also enabled.
3. STEP 3: PVT sample control:
   a) Write DTS_TSCSMPL_CR register:
      When SMPL_DISCARD is set, TS data samples are temporarily discarded, but the sample counter continues to increment.
      When SMPL_CTR_HOLD is asserted, the sample counter is prevented from rolling over when the maximum sample count is reached.
      When SMPL_CTR_DISABLE is asserted, the sample counter is disabled.
4. STEP 4: PVT sample control:
   a) Write DTS_TSnHILORESETR for each TS instance.

Configure the SDA registers

1. STEP 1: Program the SDA registers:
   a) Read DTS_TSCSDIF_SR register:
      The SDIF_LOCK flag must be low, indicating that SDIF automatic mode has not been enabled.
      Before proceeding further, make sure that the serial data interface is inactive by checking that the SDIF_BUSY flag is low.
   b) Write DTS_TSCSDIF_CR register to fetch the remote slave SDA register value:
      SDIF_PROG = 0x1
      SDIF_WRN = 0x1
      SDIF_ADDR[2:0]: this bitfield selects the desired SDA register.
      SDIF_WDATA[23:0]: this bitfield provides the SDA write data value.
      Program the SDA register bits in the following order:
      SDATS_TIMERR register
      SDATS_CFGR register
      SDATS_CR register (see notes below).

Note: Setting the TS_AUTO bit and either TS_RUN_ONCE or TS_RUN_CONT bit in the SDATS_CR register initiates a conversion and sets the SDIF_LOCK flag. Once the SDIF_LOCK flag is set, the SDA registers become write-only.

The SDIF_WDATA[23:0] value is also reflected in the DTS_TSnSDIFRDATAR *registers.*

2. STEP 2: Read the SDA register values:
   a) Read DTS_TSCSDIF_SR register:
      The SDIF_LOCK flag must be low, indicating SDIF automatic mode has not been enabled.
      Before proceeding further, make sure the serial data interface is inactive by checking that the SDIF_BUSY flag is low.
   b) Write DTS_TSCSDIF_CR register to fetch the remote slave SDA register value:
      SDIF_PROG = 0x1
      SDIF_WRN = 0x0
      SDIF_ADDR[2:0]: this bitfield selects the desired SDA register.
      SDIF_WDATA[23:0]: this bitfield is not used and can be set to any value.

Note: Once the SDIF_LOCK flag is set, the SDA registers become write-only and any read requests is ignored.

The read data value (SDIF_RDATA[23:0]) is also reflected in the DTS_TSnSDIFRDATAR *registers.*

   c) Read the SDA register value from the DTS_TSnSDIFRDATAR register.

Run once

1. STEP 1:
   a) Read DTS_TSCSDIF_SR register:
      The SDIF_LOCK flag is low indicating that the SDIF automatic sample mode is not enabled.
      Verify that the serial data interface is not in use by checking that the SDIF_BUSY flag is low.
   b) Write DTS_TSCSDIF_CR register:
      SDIF_PROG = 0x1
      SDIF_WRN = 0x1
      SDIF_ADDR[2:0] = 0x0 to select the SDATS_CR register
      SDIF_WDATA[23:0] = 0x000104 to assert TS_AUTO and the self-clearing TS_RUN_ONCE bits
2. STEP 2: Wait for a sample done IRQ
   a) Read the DTS_TSnSDIFDONER register:
      Verify that one or more SDATS_DR registers have been updated by checking that the SDIF_SMPL_DONE flags are set to 0x1.
   b) Read the DTS_TSCSMPLCNTR register:
      The sample counter value contained in DTS_TSCSMPLCNTR increments whenever TS data (TS_DATA[23:0]) are updated.
   c) Read the DTS_TSnSDIFRDATAR register:
      Read the TS sample data, type and fault values.
      If the fault bit is set, the sample data value is unreliable, and must be discarded.
      The SDIF_SMPL_DONE flag in the DTS_TSnSDIFDONER register is automatically cleared when the SDATS_DR register is read.

Continuous run

1. STEP 1
   a) Read DTS_TSCSDIF_SR register:
      The SDIF_LOCK flag is low to indicate that the SDIF automatic sample mode is not enabled.
      Verify that the serial data interface is not in use by checking that the SDIF_BUSY flag is low.
   b) Write DTS_TSCSDIF_CR register:
      SDIF_PROG = 0x1
      SDIF_WRN = 0x1
      SDIF_ADDR[2:0] = 0x0
      SDIF_WDATA[23:0] = 0x000108 (value to assert TS_AUTO and the run continuous TS_RUN_CONT bits)
2. STEP 2: Wait for a sample done IRQ
   a) Read the DTS_TSnSDIFDONER register:
      Verify that the SDATS_DR registers have been updated by checking that the sample done SDIF_SMPL_DONE flags are set to 0x1.
   b) Read DTS_TSCSMPLCNTR register:
      The sample counter increments whenever the DTS_TSnSDIFRDATAR value is updated.
   c) Read DTS_TSnSDIFRDATAR register:
      Read the TS sample data, type and fault values.
      If the fault bit is set, the sample data value is unreliable, and must be discarded.
      The SDIF_SMPL_DONE flag in the DTS_TSnSDIFDONER register is automatically cleared when the SDATS_DR register is read.

43.3.7 Temperature sensor configuration

The temperature sensor can be configured through the internal register *SDA TS configuration register (SDATS_CFGR)*.

Selecting the conversion mode

The sensor operates only in a single mode to read the temperature value. This mode is selected by setting SDATS_CFGR[3:0] bits to 0b0001.

The temperature value is obtained using the formula provided in *Calculating the temperature*. It does not require any calibration.

Configuring the output options

The conversion time can be configures through SDATS_CFGR[7:5] bits. It can be shortened to reduce the counter output value with the drawback of degrading the temperature measurement accuracy (see *Table 380*).

The output data are available in the TS_DATA[15:0] bitfield of the SDATS_DR register.

Data can be output in parallel or serial mode depending on the setting of SDATS_CFGR[4] bit:

- 0: parallel output

  All the data bits are sent simultaneously through TS_DTA[11:0].
- 1: serial output (default mode)

  The data are sent serially on bit 11 of the TS_DATA bitfield.

  Serial data are always 12-bit wide whatever the output options. Using a lower resolution (such as 10 bits) results in similar output values with trailing zeroes.

Table 380. Output resolution configuration

Resolution	SDATS_CFGR[7:5] bits	Accuracy degradation	Comments
12 bits	0b000	-	Temperature value available on TS_DATA[11:0]
10 bits	0b001	±0.4 °C	Temperature value available on TS_DATA[11:2]
8 bits	0b010	±1.5 °C	Temperature value available on TS_DATA[11:4]
Others not allowed	0b011	-	Not allowed
	0b1XX	-	Not allowed

Calculating the temperature

The digital output is converted to an uncalibrated temperature value by using the following formula:

$$\text{Temp (°C)} = G + H \times \text{Eqbs} + J \times F_{clk_ts}$$

Where:

Temp = Temperature in degrees Celsius

Eqbs = Nbs/Cal5 – 0.5, Nbs being the digital output, TS_DATA[11:0], latched after conversion

F_{clk_ts} = Temperature sensor SDA clock frequency (in MHz)

For G, H, J and Cal5 values, please refer to device datasheet"

Configuring the triggers

Triggers can be configured through bits 18 to 16 (TRIG[2:0]) of the SDATS_CFGR register:

TRIG[2:0] = 0b001: dts_trg[0] is selected.

TRIG[2:0] = 0b010: dts_trg[1] is selected.

TRIG[2:0] = 0b011: dts_trg[2] is selected.

TRIG[2:0] = 0b100: dts_trg[3] is selected.

Disabling the clock

The TS clock can be disabled by setting the CLKDIS of the SDATS_CFGR, when the TS is not used and it does not operate in automatic mode.

43.4 DTS interrupts

The DTS provides a single active high (level) hardware interrupt output from the controller. This is the logical OR of all the embedded TS interrupt sources and the common delay timer.

The enabling, masking, and status of the interrupts are readily available through the IRQ control registers. The interrupts from each TS instance are coalesced into a single interrupt, the status of which can be observed through the DTS_TSn_ISR register. The index number of a set bit indicates the source TS number with an interrupt condition.

Each TS block can generate an interrupt based on the following sources:

- The irq_smpl indicates that sample data have been updated for the corresponding TS instance.
- The irq_alarma indicates that the recovered sample value has exceeded the programmed alarm A threshold for the corresponding TS instance.
- The irq_alarmb indicates that the recovered sample value has exceeded the programmed alarm B threshold for the corresponding TS instance.
- The irq_fault indicates that the corresponding TS instance has signaled a fault.

When an interrupt event occurs, the rising edge is detected and the corresponding flag is set in the interrupt source register, DTS_TSn_ISR. The IRQ status bits are individually gated (logical AND) with their corresponding interrupt enabled in the DTS_TSn_IER register to generate interrupt request bits. These IRQ bits are then ORed together and registered by dts_pclk to generate the interrupt outputs for IRQ control registers.

Once set the interrupt source bits are sticky, they must be cleared by writing a 1 to the corresponding bit of the DTS_TSn_ICR register. This also clears the associated IRQ if it has been enabled.

Interrupt events are triggered when the following flags are asserted or the force bits in the DTS_TSnIRQTESTR register are set. The forcing allows interrupts to be manually generated for software test purposes.

- irq_smpl: asserted whenever a new TS data sample is recovered.
- irq_alarma: asserted whenever the alarm A thresholds have been reached.
- irq_alarmb: asserted whenever the alarm B thresholds have been reached.
- irq_fault: asserted whenever the TS block asserts its fault output.

Generally, the embedded temperature sensors run continuously relying on their alarms to signal out-of-bounds conditions. The user would usually disable the sample done flags for these TS types unless they wish to log every data sample.

Table 381. DTS interrupts

Interrupt event	Event flag	Enable control bit	Interrupt clear method
irq_smpl	IRQ_STATUS_DONE	IRQ_EN_DONE	IRQ_CLEAR_DONE
irq_alarma	IRQ_STATUS_ALARMA	IRQ_EN_ALARMA	IRQ_CLEAR_ALARMA

Table 381. DTS interrupts

Interrupt event	Event flag	Enable control bit	Interrupt clear method
irq_alarmb	IRQ_STATUS_ALARMB	IRQ_EN_ALARMB	IRQ_CLEAR_ALARMB
irq_fault	IRQ_STATUS_FAULT	IRQ_EN_FAULT	IRQ_CLEAR_FAULT

43.5 DTS registers

The APB interface supports 32-bit word aligned addresses (byte access is not supported).

The memory map contains a mixture of read-only, read-write, and write-only register fields. The write-only bits are self-clearing bits that are generally used to create strobes. Reserved register fields and any undefined register addresses are read-only and return zero when read.

Table 382 shows the DTS memory map overview.

Table 382. DTS register memory map

Address boundary	Register bank	Register block size	Address locations	Description
0x0000 - 0x003F	PVT common registers	0x40	16	PVT common registers
0x0040 - 0x007F	PVT interrupt registers	0x40	16	PVT interrupt registers
0x0080 - 0x00BF	TS common registers	0x40	16	TS common registers
0x00C0 - 0x00FF	TS 0 individual registers	0x40	16	TS0 dedicated registers (such as IRQ, alarms and samples)
0x0100 - 0x013F	TS 1 individual registers	0x40	16	TS1 dedicated registers (such as IRQ, alarms and samples)

43.5.1 DTS PVT common registers

The PVT common registers are used to configure the timer and read back the lock status.

DTS PVT register lock register (DTS_PVTREG_LOCKR)

The DTS can be locked by software using the DTS_PVTREG_LOCKR register. Any write to the register locks all DTS registers except for the PVT common registers.

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LOCK[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **LOCK[31:0]:** PVT software lock register
Any write to this register locks all DTS registers except for the PVT common registers. Once locked, the DTS registers are read-only. The software lock can be removed by writing 0x1ACC E551.

DTS PVT lock status register (DTS_PVTLOCK_SR)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HW_LOCK_STATUS	SW_LOCK_STATUS
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **HW_LOCK_STATUS:** Hardware lock input status
This bit indicates the status of the hardware lock input to the PVT controller.

Bit 0 **SW_LOCK_STATUS:** Software lock input status
This bit indicates the current state of the lock register.

DTS PVT timer control register (DTS_PVTTMR_CR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TMR_RUN
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TMR_DELAY[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **TMR_RUN:** Timer count enable bit
This bit enables the timer count function.

Bits 15:0 **TMR_DELAY[15:0]:** Timer delay
This bitfield can be used to configure the timer delay.

DTS PVT timer status register (DTS_PVTTMR_SR)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TMR_DONE	TMR_BUSY
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **TMR_DONE:** Counter delay expiration flag
This bit is set when the counter delay has expired.

Bit 0 **TMR_BUSY:** Counter busy flag
This bit is set while the counter is active.

43.5.2 PVT IRQ registers

The PVT IRQ registers are present in all build configurations of the PVT controller.

DTS PVT IRQ enable register (DTS_PVT_IER)

Address offset: 0x040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS_IRQ_ENABLE	TMR_IRQ_ENABLE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **TS_IRQ_ENABLE:** TS IRQ source enable bit
Set this bit to enable the TS IRQ to the processor.

Bit 0 **TMR_IRQ_ENABLE:** Timer IRQ source enable bit
Set this bit to enable the timer IRQ to the processor.

DTS PVT IRQ timer mask register (DTS_PVTIRQTRMASKR)

Address offset: 0x050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TMR_IRQ_MASK
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **TMR_IRQ_MASK:** Timer IRQ source mask bit
Set this bit to mask the timer IRQ to the processor.

DTS PVT IRQ TS mask register (DTS_TS_MR)

Address offset: 0x054

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_IRQ_MASK	TS0_IRQ_MASK
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **TS1_IRQ_MASK:** TS1 IRQ source mask bit
Set this bit to mask TS1 IRQ to the processor.

Bit 0 **TS0_IRQ_MASK:** TS0 IRQ source mask bit
Set this bit to mask TS0 IRQ to the processor.

DTS PVT IRQ timer status register (DTS_PVTTR_SR)

Address offset: 0x060

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TMR_IRQ_STATUS
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **TMR_IRQ_STATUS:** Timer IRQ status bit after masking
This bit reflects the timer IRQ status after the mask has been applied.

DTS PVT IRQ TS status register (DTS_TS_ISR)

Address offset: 0x064

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_IRQ_STATUS	TS0_IRQ_STATUS
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **TS1_IRQ_STATUS:** TS1 IRQ status bit after masking
This bit reflects the timer IRQ status after the mask has been applied.
Note: The bit is set when the corresponding TS block has issued an IRQ interrupt to the processor.

Bit 0 **TS0_IRQ_STATUS:** TS0 IRQ status bit after masking
This bit reflects the timer IRQ status after the mask has been applied.
Note: The bit is set when the corresponding TS block has issued an IRQ interrupt to the processor.

DTS PVT IRQ timer raw status register (DTS_PVTTMRRAW_ISR)

Address offset: 0x070

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TMR_IRQ_RAW_STATUS
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **TMR_IRQ_RAW_STATUS:** TMR IRQ status bit before masking
This bit reflects the timer IRQ status before the mask is applied.

DTS PVT IRQ TS raw status register (DTS_TSRAW_ISR)

Address offset: 0x074

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_IRQ_RAW_STATUS	TS0_IRQ_RAW_STATUS
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **TS1_IRQ_RAW_STATUS:** TS1 IRQ status bit before masking
This bit reflects the timer IRQ status before the mask is applied.

Bit 0 **TS0_IRQ_RAW_STATUS:** TS0 IRQ status bit before masking
This bit reflects the timer IRQ status before the mask is applied.

43.5.3 TS common registers

DTS TSC clock synthesizer register (DTS_TSCCLKSYNTHR)

Address offset: 0x080

Reset value: 0x0001 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	CLK_SYTH_EN	Res.	Res.	Res.	Res.	CLK_SYNTH_HOLD[3:0]			
							rw					rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CLK_SYNTH_HI[7:0]								CLK_SYNTH_LO[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **CLK_SYTH_EN:** Synthesized clk_ts enable bit
0: Disabled
1: Enabled

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **CLK_SYNTH_HOLD[3:0]:** SDA master-to-SDA slave output hold delay/SDA slave-to-SDA master input setup delay
The delay is counted from the rising edge of clk_ts. It is expressed in units of dts_pclk cycles. The default value is 0b0001.

Bits 15:8 **CLK_SYNTH_HI[7:0]:** Synthesized clk_ts high period
This is a zero-Indexed value expressed in units of dts_pclk cycles.

Bits 7:0 **CLK_SYNTH_LO[7:0]:** Synthesized clk_ts low period
This is a zero-Indexed value expressed in units of dts_pclk cycles.

DTS TSC SDIF interface disable register (DTS_TSCSDIFDISABLER)

Address offset: 0x084

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_SDIF_DISABLE	TS0_SDIF_DISABLE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **TS1_SDIF_DISABLE:** TS1 serial data interface (SDIF) disable bit
When this bit is asserted, it completely disables TS1 instance by forcing TS1 clock and reset low.
0: Enabled
1: Disabled

Bit 0 **TS0_SDIF_DISABLE:** TS0 serial data interface (SDIF) disable bit
When this bit is asserted, it completely disables the selected TS0 instance by forcing TS0 clock and reset low.
0: Enabled
1: Disabled

Note: Any disable action must be applied before SDIF programming begins.

DTS TSC SDIF status register (DTS_TSCSDIF_SR)

Address offset: 0x088

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDIF_LOCK	SDIF_BUSY
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SDIF_LOCK:** SDIF locked flag
This bit is set when the slave automatic mode is requested, to indicate that the serial data interface (SDIF) is now a write-only interface (see *Section : SDA controller operation*).
In slave automatic mode, the data register (SDATS_DR) is automatically updated within the PVT controller whenever new TS data become available
0: Unlocked
1: Locked

Bit 0 **SDIF_BUSY:** SDIF busy flag
When asserted, this bit indicates either that the serial data interface (SDIF) is busy and any SDIF programming requests are ignored, or the clock synthesizer/disable SDIF state is being updated.
0: SDIF not busy/no clock synthesizer/disable SDIF state update ongoing
1: SDIF busy/clock synthesizer/disable SDIF state update ongoing

DTS TSC SDIF register (DTS_TSCSDIF_CR)

Address offset: 0x08C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SDIF_PROG	Res.	Res.	Res.	SDIF_WRN	SDIF_ADDR[2:0]			SDIF_WDATA[23:16]							
w				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SDIF_WDATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SDIF_PROG:** Serial interface program request

This self-clearing bit is ignored if the SDIF_BUSY or the SDIF_LOCK flag is set, and the request is a read request (SDIF_WRN = 0).

0: No SDIF program request

1: SDIF program requested

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 **SDIF_WRN:** Serial interface write/no read control bit

0: SDIF read

1: SDIF write

Bits 26:24 **SDIF_ADDR[2:0]:** Serial interface register address

This bitfield contains the address of the target SDIF register, SDIF_ADDR[2:0].

Bits 23:0 **SDIF_WDATA[23:0]:** Serial interface write data

This bitfield contains the write data SDIF_DATA[23:0].

DTS TSC SDIF halt register (DTS_TSCSDIFHALTR)

Address offset: 0x090

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDIF_STOP
															w

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **SDIF_STOP:** Serial data interface (SDIF) stop
This self-clearing bit immediately stops all SDIF programming activity in the unlikely event of it becoming locked. It must not be required during normal operation.
0: Not stopped
1: Stopped

DTS TSC SDIF control register (DTS_TSCSDIF_CFGR)

Address offset: 0x094

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDIF_INHIBIT[1:0]	
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **SDIF_INHIBIT[1:0]:** Serial data interface (SDIF) programming inhibit
When asserted, this bit inhibits the serial programming of the selected TS instance(s). The inhibition must be applied before SDIF programming begins.
00: No Inhibition
01: TS0 inhibited/TS1 serial programming activated (SPA)
10: TS1 inhibited/TS0 serial programming activated (SPA)
11: TS1 and TS0 inhibited

DTS TSC sample control register (DTS_TSCSMPL_CR)

Address offset: 0x0A0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SMPL_DISCARD	SMPL_CTR_HOLD	SMPL_CTR_DISABLE
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **SMPL_DISCARD:** Sample discard bit

This feature can be used to temporarily discard received data samples. When this bit is set, data recovery is disabled but the external TS may continue running.

0: Data samples not discarded

1: Data samples discarded

Bit 1 **SMPL_CTR_HOLD:** Sample counter hold bit

When this bit is asserted, the sample counter is prevented from rolling over when the maximum sample count is reached.

0: Counter not on hold

1: Counter on hold

Bit 0 **SMPL_CTR_DISABLE:** Sample counter disable bit

0: Sample counter enabled

1: Sample counter disabled

DTS TSC sample clear register (DTS_TSCSDIFSMPLCLRR)

Address offset: 0x0A4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SMPL_CNTER_CLEAR
															w

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **SMPL_CNTER_CLEAR:** Sample counter clear bit

The sample counter value is set to zero when this self-clearing bit is programmed to 1.

0: Counter value not cleared

1: Counter value cleared

DTS TSC sample count register (DTS_TSCSMPLCNTR)

Address offset: 0x0A8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

SMPL_COUNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SMPL_COUNT[15:0]:** Sample counter

The 16-bit counter increments each time a new data sample is available. The counter is cleared by writing 1 to DTS_TSCSDIFSMPLCLRR. The sample counter overflow operation is determined by SMPL_CTR_HOLD.

43.5.4 TS individual registers

DTS TSn IRQ enable register (DTS_TSn_IER)

Address offset: 0x0C0 + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											w	w		w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **IRQ_CLEAR_ALARMB:** Alarm B IRQ clear bit

Bit 3 **IRQ_CLEAR_ALARMA:** Alarm A IRQ clear bit

Bit 2 Reserved, must be kept at reset value.

Bit 1 **IRQ_CLEAR_DONE:** Sample done IRQ clear bit

Bit 0 **IRQ_CLEAR_FAULT:** Fault IRQ clear bit

DTS TSn IRQ test register (DTS_TSnIRQTESTR)

Address offset: 0x0CC + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw	rw		rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **IRQ_TEST_ALARMB:** Alarm B IRQ test bit

Bit 3 **IRQ_TEST_ALARMA:** Alarm A IRQ test bit

Bit 2 Reserved, must be kept at reset value.

Bit 1 **IRQ_TEST_DONE:** Sample done IRQ test bit

Bit 0 **IRQ_TEST_FAULT:** Fault IRQ test bit

DTS TSn SDIF RDATA register (DTS_TSnSDIFRDATAR)

Address offset: 0x0D0 + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SDIF_RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **SDIF_RDATA[23:0]:** SDIF read data

DTS TSn SDIF done register (DTS_TSnSDIFDONER)

Address offset: 0x0D4 + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDIF_SMPL_DONE
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **SDIF_SMPL_DONE:** Sample done flag

The sample done flag is asserted when a new data sample is available. The sample done flag is automatically cleared when the associated data register is read.

0: No new data sample available

1: New data sample available

DTS TSn SDIF data register (DTS_TSnSDIFDATAR)

Address offset: 0x0D8 + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SAMPLE_DATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **SAMPLE_FAULT:** Sample fault

This bit is set to indicate that the TS block has signaled a fault. The sample data must be discarded.

Bit 16 **SAMPLE_TYPE:** TS sample type

0: Indicates valid data

1: Indicates either analog access, signature select or fault debug mode

The TS_TYPE flag is updated when new data are received.

Bits 15:0 **SAMPLE_DATA[15:0]:** Sample data.

Reading this register clears the state of the SDIF_SMPL_DONE flag in DTS_TSnSDIFDONER register.

DTS TSn alarm A configuration register (DTS_TSnALARMA_CFGR)

Address offset: 0x0E0 + 0x40 * n, (n = 0 to 1)

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SMPL_HI_CLR	SMPL_LO_SET
														w	w

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SMPL_HI_CLR:** Sample high clear 0

All the bits of the stored sample high value are initialized to 0 when written.

Bit 0 **SMPL_LO_SET:** Sample Low Set

All the bits of the stored sample low value are initialized to 1 when written.

44 Voltage reference buffer (VREFBUF)

44.1 Introduction

The devices embed a voltage reference buffer which can be used as voltage reference for the on-chip ADCs, and also as voltage reference for external components through the VREF+ pin.

44.2 VREFBUF implementation

The table below describes the VREFBUF voltages typical values:

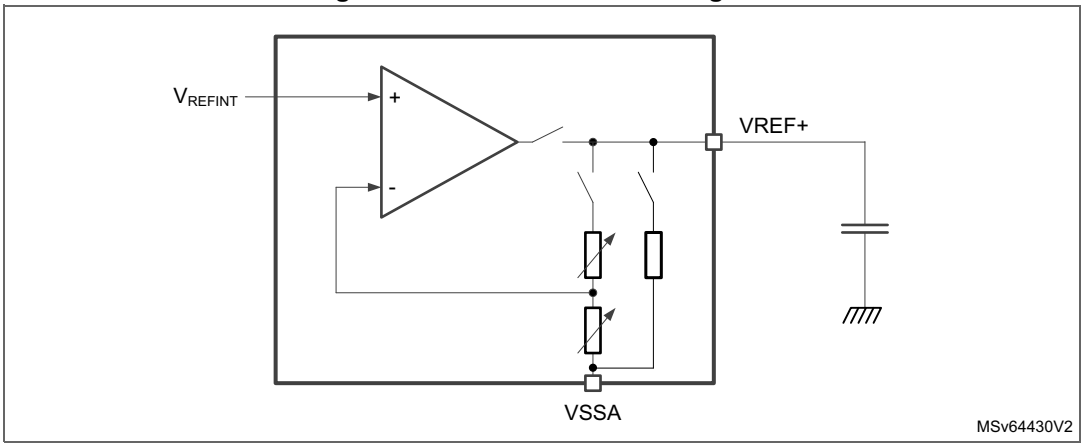

Table 387. VREFBUF typical values

Symbol	Value
VREFBUF0	1.21 V
VREFBUF1	1.5 V

Note: Refer to the product datasheet for more details.

44.3 VREFBUF functional description

Figure 347. VREFBUF block diagram

The internal voltage reference buffer is an operational amplifier, with programmable gain. The amplifier input is connected to the internal voltage reference V_{REFINT}. The VREFBUF supports four voltages[a], which are configured with VRS bits in the VREFBUF_CSR register:

- VRS = 000: VREFBUF0 voltage selected
- VRS = 001: VREFBUF1 voltage selected

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

Table 388. VREF buffer modes

ENVR	HIZ	VREF buffer configuration
0	0	VREFBUF buffer off mode: – V_{REF+} pin pulled-down to V_{SSA}
0	1	External voltage reference mode (default value): – VREFBUF buffer off – V_{REF+} pin input mode
1	0	Internal voltage reference mode: – VREFBUF buffer on – V_{REF+} pin connected to VREFBUF buffer output
1	1	Hold mode: – VREF is enable without output buffer, VREF+ pin voltage is hold with the external capacitor – VRR detection disabled and VRR bit keeps last state

After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

44.4 VREFBUF trimming

The VREFBUF output voltage is factory-calibrated by ST. At reset, and each time the VRS setting is changed, the calibration data is automatically loaded to the TRIM register.

Optionally user can trim the output voltage by changing the TRIM register bits directly. In this case, the VRS setting has no more effect on the TRIM register until the device is reset.

a. The minimum V_{DDA} voltage depends on VRS setting, refer to the product datasheet.

44.5 VREFBUF power sequence

While VREFBUF is activated, V_{DDA} supply changing from 1.8 V to 0 V can cause large current flowing from the V_{REF+} output capacitor to the V_{DDA} power domain through on-chip parasitic resistance. To avoid this current, the following procedure is required:

- While V_{DDA} is available, configure VREFBUF in buffer off mode.
- Wait for V_{REF+} to discharge (through internal pull-down) to less than 100 mV (typically 1 ms, depending on the capacitor value).
- Switch off V_{DDA} supply to 0 V.

44.6 VREFBUF registers

44.6.1 VREFBUF control and status register (VREFBUF_CSR)

Address offset: 0x00

Reset value: 0x0000 0002

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VRS[2:0]			VRR	Res.	HIZ	ENVR
									rw	rw	rw	r		rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **VRS[2:0]**: Voltage reference scale

These bits select the value generated by the voltage reference buffer.

VRS = 000: VREFBUF0 voltage selected.

VRS = 001: VREFBUF1 voltage selected.

Others: Reserved

Note: Refer to the product datasheet for each VREFBUFx voltage setting value.
The software can program this bitfield only when the VREFBUF is disabled (ENVR=0).

Bit 3 **VRR:** Voltage reference buffer ready

0: the voltage reference buffer output is not ready.

1: the voltage reference buffer output reached the requested level.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **HIZ:** High impedance mode

This bit controls the analog switch to connect or not the V_{REF+} pin.

0: V_{REF+} pin is internally connected to the voltage reference buffer output.

1: V_{REF+} pin is high impedance.

Refer to *Table 388: VREF buffer modes* for the mode descriptions depending on ENVR bit configuration.

Bit 0 **ENVR:** Voltage reference buffer mode enable

This bit is used to enable the voltage reference buffer mode.

0: Internal voltage reference mode disable (external voltage reference mode).

1: Internal voltage reference mode (reference buffer enable or hold mode) enable.

44.6.2 VREFBUF calibration control register (VREFBUF_CCR)

Address offset: 0x04

Reset value: 0x0000 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TRIM[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **TRIM[5:0]**: Trimming code

The TRIM code is a 6-bit unsigned data (minimum 000000, maximum 111111) that is set and updated according the mechanism described below.

Reset:

TRIM[5:0] is automatically initialized with the VRS = 0 trimming value stored in the OTP memory during the production test.

VRS change:

TRIM[5:0] is automatically initialized with the trimming value (corresponding to VRS setting) stored in the OTP memory during the production test.

Write in TRIM[5:0]:

User can modify the TRIM[5:0] with an arbitrary value. This is permanently disabling the control of the trimming value with VRS (until the device is reset).

Note: If the user application performs the trimming, the trimming code must start from 000000 to 111111 in ascending order.

44.6.3 VREFBUF register map

The following table gives the VREFBUF register map and the reset values.

Table 389. VREFBUF register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	Reset value																											x	x	x	x	x	x

Refer to *Section 2.4* for the register boundary addresses.

45 Multi-function digital filter (MDF)

45.1 Introduction

The multi-function digital filter (MDF) is a high-performance module dedicated to the connection of external sigma-delta (ΣΔ) modulators. It is mainly targeted for the following applications:

- audio capture signals
- motor control
- metering

The MDF features 8 digital serial interfaces (SITFx) and digital filters (DFLTx) with flexible digital processing options to offer up to 24-bit final resolution.

The DFLTx of the MDF also include the filters of the audio digital filter (ADF).

The MDF can receive, via its serial interfaces, streams coming from various digital sensors.

The MDF supports the following standards allowing the connection of various ΣΔ modulator sensors:

- SPI interface
- Manchester coded 1-wire interface
- PDM interface

A flexible bitstream matrix (BSMX) allows the connection of any incoming bitstream to any filter.

The MDF converts an input data stream into clean decimated digital data words. This conversion is done thanks to low-pass digital filters and decimation blocks. In addition it is possible to insert a high-pass filter or a DC offset correction block.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter type, filter order, decimation ratio, integrator length. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion and continuous modes. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A flexible trigger interface can be used to control the conversion start. This timing control can trigger simultaneous conversions or insert a programmable delay between conversions.

The MDF features an out-off limit detectors (OLD) function. There is one OLD for each digital filter chain. Independent programmable thresholds are available for each OLD, making it very suitable for over-current detection.

A short circuit detector (SCD) is also available for every selected bitstream. The SCD is able to detect a short-circuit condition with a very short latency. Independent programmable thresholds are offered in order to define the short circuit condition.

The digital processing is performed using only the kernel clock. The MDF requests the bus interface clock (AHB clock) only when data must be transfered or when a specific event requests the attention of the system processor.

45.2 MDF main features

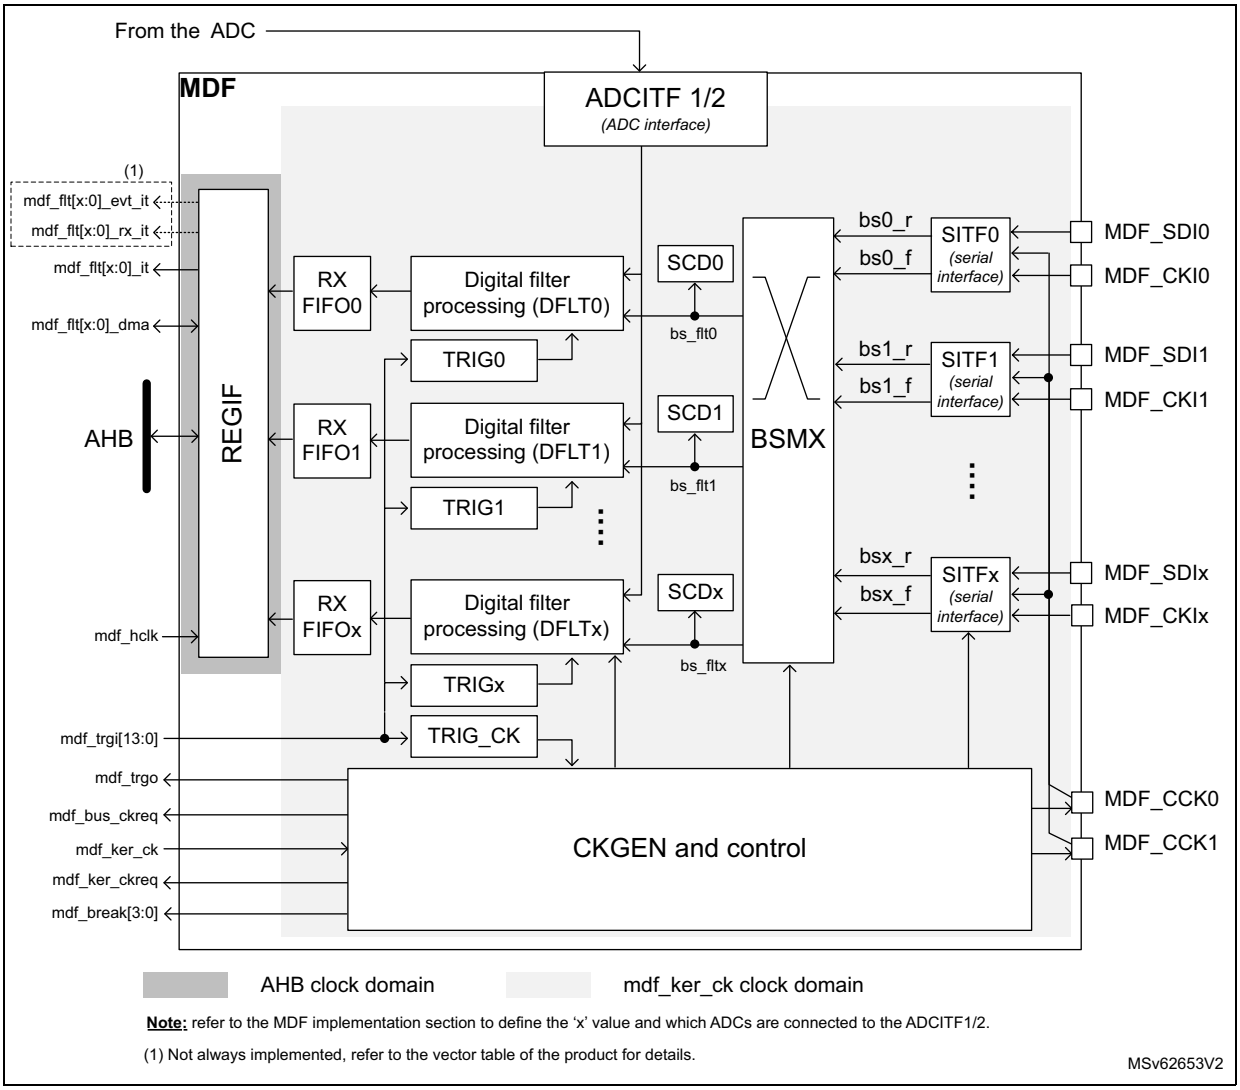
- AHB interface
- 8 serial digital inputs:
  - configurable SPI interface to connect various digital sensors
  - configurable Manchester coded interface support
  - compatible with PDM interface to support digital microphones
- 2 common clocks input/output for ΣΔ modulators
- Flexible matrix (BSMX) for connection between filters and digital inputs
- 2 inputs to connect the internal ADCs
- 8 flexible digital filter paths, including:
  - A configurable CIC filter:
    - Can be split into 2 CIC filters: high-resolution filter and out-off limit detector
    - Can be configured in $Sinc^4$ filter
    - Can be configured in $Sinc^5$ filter
    - Adjustable decimation ratio
  - A reshape filter to improve the out-off band rejection and in-band ripple
  - A high-pass filter to cancel the DC offset
  - An offset error cancellation
  - Gain control
  - Saturation blocks
  - An out-off limit detector
- Short-circuit detector
- Clock absence detector
- 16- or 24-bit signed output data resolution
- Continuous or single conversion
- Possibility to delay independently each bitstream
- Various trigger possibilities
- Break generation on out-of limit or short-circuit detector events
- Autonomous functionality in Stop modes
- DMA can be used to read the conversion data
- Interrupts services

45.3 MDF implementation

Table 390. MDF features (1)

Mode or feature	MDF1
Number of filters (DFLTx) and serial interfaces (SITFx)	8
MDF_CKI0 connected to pins	X
Sound activity detection (SAD)	-
RXFIFO depth (number of 24-bit words)	4
Number of trigger inputs	14

Table 390. MDF features (1) (continued)



Mode or feature	MDF1
ADC connected to ADCITF1	ADC1
ADC connected to ADCITF2	ADC2
Motor dedicated features (SCD, OLD, OEC, INT, snapshot, break)	X
Main path with CIC4, CIC5	X
Main path with CIC1,2, 3 or FastSinc	X
RSFLT, HPF, SAT, SCALE, DLY, Discard functions	X
Global Interrupts MDF_FLT[7:0] (mdf_it[7:0])	X
Receive interrupts MDF_RX[0:0] (mdf_rx_it[0:0])	-
Event interrupts MDF_EVT[0:0] (mdf_evt_it[0:0])	-
Autonomous in Stop 0 and Stop 1 modes	X
Autonomous in Stop 2 mode	-
All DMA channels connected	X

1. ‘X’ = supported, ‘-’ = not supported.

45.4 MDF functional description

45.4.1 MDF block diagram

Figure 348. MDF block diagram

45.4.2 MDF pins and internal signals

Table 391. MDF external pins

Name	Signal type	Comment
MDF_CKIy (y = 0 to 7)(1)	Input	Dedicated clock signals from external sensors
MDF_SDIy (y = 0 to 7)(1)	Input	Data signal from external sensors
MDF_CCKy (y = 0, 1)	Input/output	Clock outputs for external sensor, or common clock input from external sensors

1. The number of inputs available depends on the number of filters. Refer to *Section 45.3* for details.

Table 392. MDF internal signals

Name	Signal type	Comment
mdf_trgi[13:0]	Input	Trigger inputs in order to control the acquisition (see *Table 393: MDF trigger connections* for details)
mdf_trgo	Output	Trigger output for synchronizing several MDFs
mdf_break[3:0]	Output	Break signals event generation from over-current detector or short-circuit detector (see the next table for details)
mdf_flt[7:0]_dma(1)	Input/output	DMA request/acknowledge signals for each filter processing chain
mdf_flt[7:0]_it(1)	Output	Global interrupt signals, for each MDF filter
mdf_flt[7:0]_rx_it(1)(2)	Output	Receive interrupt signals, for each MDF filter.
mdf_flt[7:0]_evt_it(1)(2)	Output	Event interrupt signals, for each MDF filter.
mdf_bus_ckreq	Output	Bus interface clock request output
mdf_ker_ckreq	Output	Kernel clock request output
mdf_ker_ck	Input	Kernel clock input
mdf_hclk	Input	AHB bus interface clock input
mdf_adcitf1_dat[15:0]	Input	ADCITF1 data input
mdf_adcitf2_dat[15:0]	Input	ADCITF2 data input

1. The number of signals available depends on the number of filters. Refer to *Section 45.3* for details.
2. Not always connected. See the interrupt vector table for details.

The table below shows the way the trigger inputs of the MDF are connected.

Table 393. MDF trigger connections

Trigger name	Trigger source
mdf_trgi0	tim1_trgo2
mdf_trgi1	tim8_trgo2
mdf_trgi2	tim20_trgo2

45.4.3 Serial input interfaces (SITF)

The SITFx input interfaces allow the connection of the external sensors to the digital filters, via the bitstream matrix (BSMX). The SITFx serial interface can be configured in the following modes:

- LF_MASTER SPI mode (low-frequency)
- normal SPI mode
- Manchester mode

The amount of SITFx instances is equal to the amount of filters.

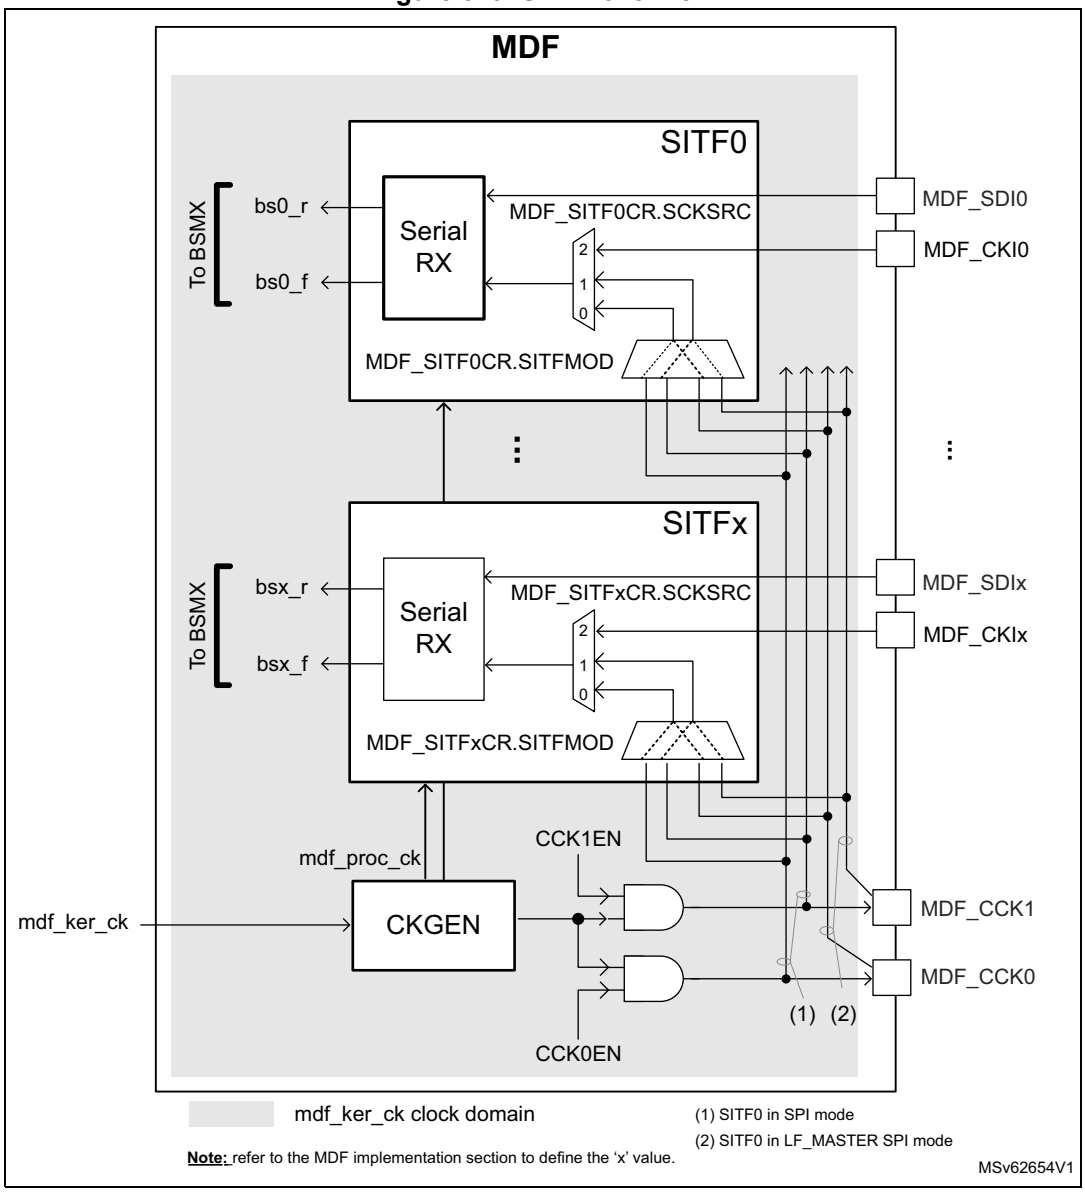
The data from each serial interface can be routed to any filter in order to perform:

- the PDM to PCM conversion
- the out-off limit detection
- the short detection

The serial interfaces are enabled by setting the corresponding SITFEN bit to 1. Once the interface is enabled, it receives serial data from the external ΣΔ modulator.

Note: Before enabling the serial interface, the user must insure that the mdf_proc_ck is already enabled (see Section 45.4.5 for details).

The SITFx are controlled via the *MDF serial interface control register x (MDF_SITFxCR)*.



As shown in *Figure 349*, for each SITF, there is a large choice of clocking possibilities:

- If the serial interface is programmed in SPI mode, the selected clock source is a copy of the clock present on MDF_CCK0 or MDF_CCK1 or MDF_CKIx pin (see 2 in *Figure 349*).
- If the serial interface is programmed in LF_MASTER SPI mode, the selected clock source must be the clock directly provided by the CCKDIV to the MDF_CCK0 or MDF_CCK1 pin (see 1 in *Figure 349*). In this case MDF_CKIx must not be selected.

See *Table 396* for additional information.

Note: Using the common clock (MDF_CCK0 or MDF CCK1) can be helpful to share the same clock between several SITFx.

Figure 349. SITFx overview

LF_MASTER and normal SPI modes

The LF_MASTER SPI mode is a special mode allowing the usage of a mdf_proc_ck clock frequency, only two times higher than the sensor clock. This mode is dedicated to low-power use-cases, using low-speed sensors.

In LF_MASTER SPI mode, the MDF must provide the bitstream clock to the external sensors via MDF_CCK0 and MDF_CCK1 pins, and receives the bitstream data via the serial data input MDF_SDIx.

For each SITFx, the application must select the same clock than the one provided to the external sensor (MDF_CCK0 or MDF_CCK1), in order to guarantee optimal timing performances. This selection is done via SCKSRC[1:0].

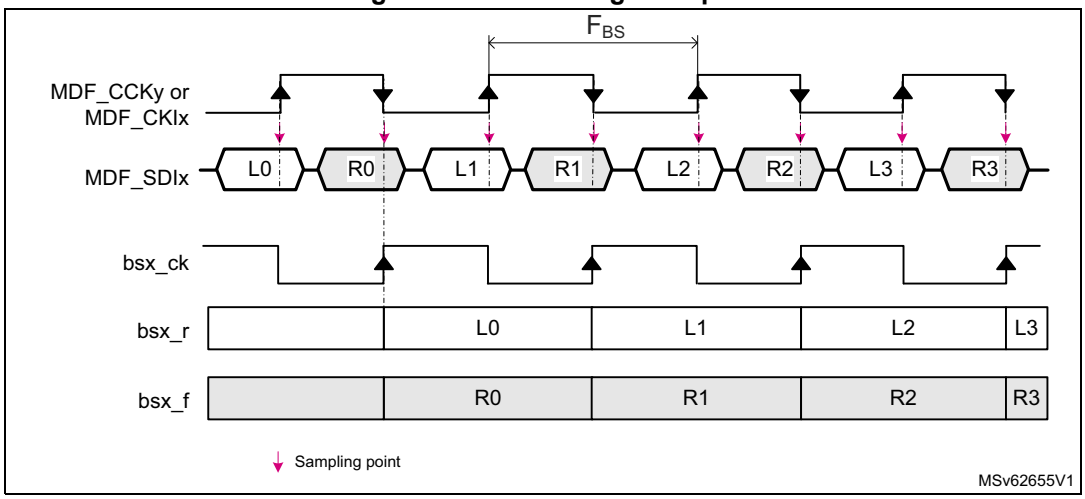
Warning: The MDF_CKIx pin cannot be used in LF_MASTER SPI mode.

The normal SPI interface is a more flexible interface than the LF_MASTER SPI, but the mdf_proc_ck frequency must be at least four times higher than the sensor clock.

The application can select MDF_CCK0, MDF_CCK1 or MDF_CKIx clock for the capture of the data received via the MDF_SDIx pin.

The MDF can generate a clock to the sensors via MDF_CCK0 or MDF_CCK1 if needed.

For all SPI modes, all SITFs can share the same clock input (MDF_CCK0 or MDF_CCK1), in order to optimize the amount of requested I/Os.



For all SPI modes, the serial data is captured using the rising and the falling edge of the selected clock. The SITFx always provides the following bitstreams:

- bitstream received using the bitstream clock falling edge (bsx_f)
- bitstream received using the bitstream clock rising edge (bsx_r)

According to the sensors connected, one of the two bitstreams may not be available.

The application can select the wanted stream via the BSMX matrix.

Figure 350. SPI timing example

To properly synchronize/receive the data stream, the frequency of the mdf_proc_ck clock must be adjusted according to the constraints listed in *Table 397*.

Clock absence detection

A no-clock-transition period may be detected when the serial interface works in normal SPI mode. This feature can be used to detect a clock failure in the SPI link.

The application can program a timeout value via the STH[4:0] bitfield of the corresponding SITFx. If the MDF does not detect clock transitions for a duration of STH[4:0] x $T_{mdf_proc_ck}$, then the CKABF flag is set.

An interrupt can be generated if CKABIE is set to 1. The STH[4:0] bitfield is in the *MDF serial interface control register x (MDF_SITFxCR)*.

When the serial interface is enabled, the CKABF flag remains to 1 until a first clock transition is detected.

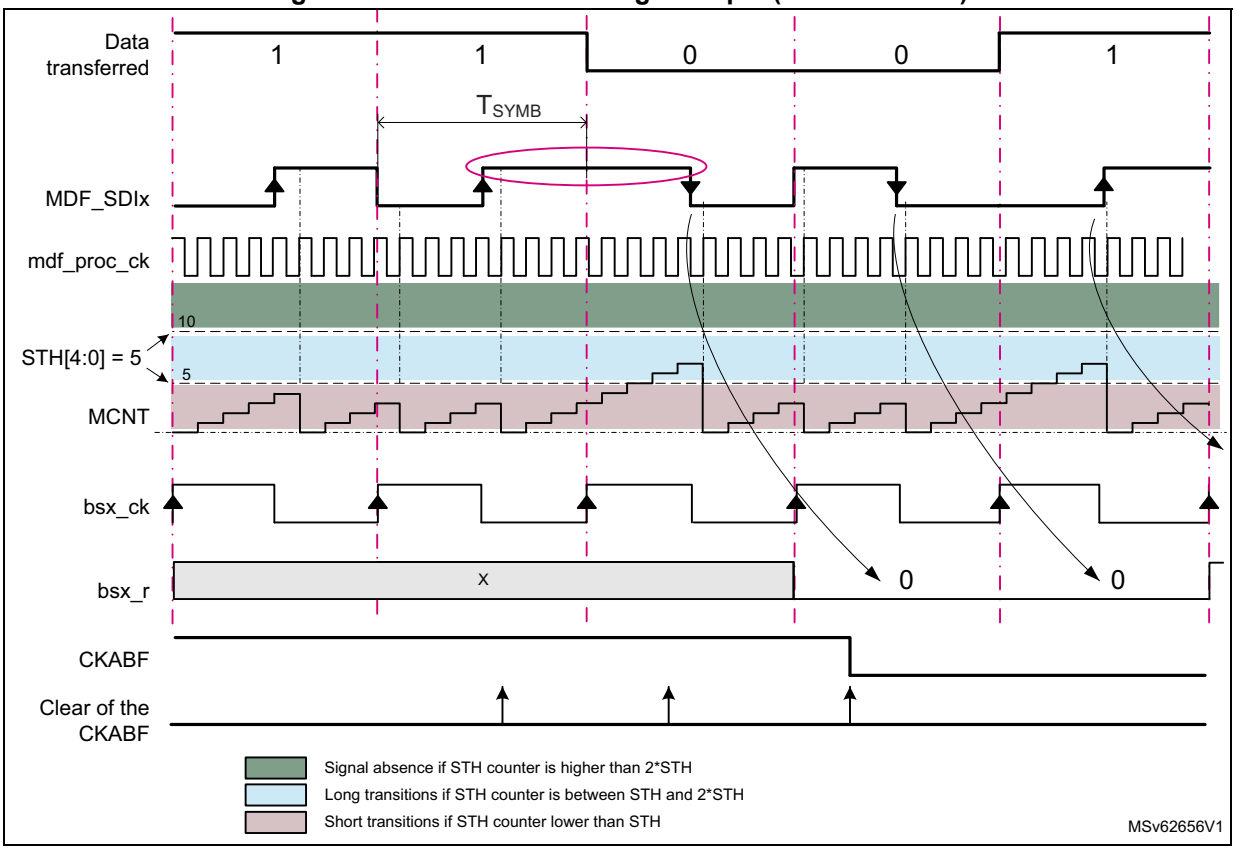
To avoid spurious clock absence detection, the following sequence must be respected:

1. Configure the serial interface in normal SPI mode and enable it.
2. Clear the CKABF flag by writing CKABF bit to 1.

   If no clock transition is detected on the serial interface, the hardware immediately sets the CKABF flag to 1.
3. Read the CKABF flag:
   - If CKABF = 1, go back to step 2.
   - If CKABF i= 0, a clock has been detected. The CKABIE bit can be set to 1 if the application wants an interrupt on detection of a clock absence.

Note: The clock absence detection feature is not available in the LF_MASTER SPI mode.

Manchester mode



In Manchester coded format, the MDF receives data stream from the external sensor via the MDF_SDIx pin only.

The MDF_CKIx pins are not needed in this mode.

Decoded data and clock signals are recovered from serial stream after Manchester decoding. They are available on bsx_r. There are two possible settings of Manchester codings:

- signal rising edge decoded as 0 and signal falling edge decoded as 1
- signal rising edge decoded as 1 and signal falling edge decoded as 0

Figure 351. Manchester timing example (SITFMOD = 11)

To decode the incoming Manchester stream, the user must program the STH[4:0] bitfield in the *MDF serial interface control register x (MDF_SITFxCR)*. The STH[4:0] bitfield is used by the SITFx to estimate the Manchester symbol length and to detect a clock absence. An internal counter (MCNT) is restarted every time a transition is detected in the MDF_SDIx input. It is used to detect short transitions, long transitions or clock absence. A long transition indicates that the data value changed. *Figure 351* shows a case where the OVR is around height and STH[4:0] = 5.

The estimated Manchester symbol rate (T_{SYMB}) must respect the following formula:

$$(STH + 1) \times T_{mdf_proc_ck} < T_{SYMB} < (2 \times STH \times T_{mdf_proc_ck})$$

It is recommended to compute STH as follows:

$$STH[4:0] = round\left(\frac{(2 \times OVR) - 1}{3}\right)$$

where OVR represents the ratio between the mdf_proc_ck frequency and the expected Manchester symbol frequency. OVR must be higher than five, and the mdf_proc_ck clock must be adjusted according to the constraints listed in *Table 397*.

The clock absence flag CKABF is set to 1 when no transition is detected during more than 2 x STH[4:0] x $T_{mdf_proc_ck}$, or when the SITFx is not yet synchronized to the incoming Manchester stream. In addition, an interrupt can be generated if the bit CKABIE is set to 1.

When the serial interface is enabled, the MDF must first be synchronized to the incoming Manchester stream. The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (pink circle in the *Figure 351*) is detected.

The end of the synchronization phase can be checked by following the software sequence:

1. Clear the CKABF flag in the *MDF DFLTx interrupt status register x (MDF_DFLTxISR)* by writing CKABF bit to 1. If the serial interface is not yet synchronized, the hardware immediately sets the CKABF flag to 1.
2. Read the CKABF flag.
   – If CKABF = 1, go back to step 1.
   – If CKABF = 0, the Manchester interface is synchronized and provides valid data.

Programming example

In the following example, the MDF kernel clock frequency ($F_{mdf_ker_ck}$) is 100 MHz and the received Manchester stream is at about 6 MHz (F_{SYMB}).

1. Provide a valid mdf_proc_ck to the SITFx.

   The mdf_proc_ck frequency must be at least six times higher than the Manchester symbol frequency (means at least 36 MHz).

   PROCDIV is programmed to 1 to perform a division by two of the kernel clock. In that case, $F_{mdf_proc_ck}$ = 50 MHz (8.33 times higher than the Manchester symbol frequency).
2. Compute STH.

   OVR is given by: OVR = $F_{mdf_proc_ck}$ / F_{SYMB} = 50 MHz / 6 MHz = 8.33.

   Then STH[4:0] = $\text{round}\left(\frac{(2 \times 8.33) - 1}{3}\right) = 5$

   The minimum allowed frequency for the Manchester stream is then:

   $1 / (2 \times STH \times T_{mdf_proc_ck})$ = 1 / (10 x 20 ns) = 5 MHz

   The maximum allowed frequency for the Manchester stream is then:

   $1 / ((STH+1) \times T_{mdf_proc_ck})$ = 1 / (6 x 20 ns) = 8.33 MHz

45.4.4 ADC slave interface (ADCITF)

The ADCs are not always connected to the MDF. Refer to *Section 45.3* to check the situation for this product.

The MDF allows the connection of up to two ADCs to the filter path. For each filter, the DATSRC[1:0] bitfield in the *MDF digital filter configuration register x (MDF_DFLTxCICR)* allows the application to select either data from the ADCs.

Warning: The MDF does not support receiving interleaved data from one of the ADCITF input.

45.4.5 Clock generator (CKGEN)

The RCC (reset and clock controller) provides the following clocks to the MDF:

- AHB clock (mdf_hclk) used for the register interface
- kernel clock (mdf_ker_ck) mainly used by all other parts of the circuit via the CKGEN

Those clocks are not supposed to be phase locked, so all signals crossing those clock domains are re-synchronized.

The clock generator (CKGEN) is responsible of the generation of the processing clock, and the clock provided to the MDF_CCK0 and MDF_CCK1 pins. All those clocks are generated from the mdf_ker_ck.

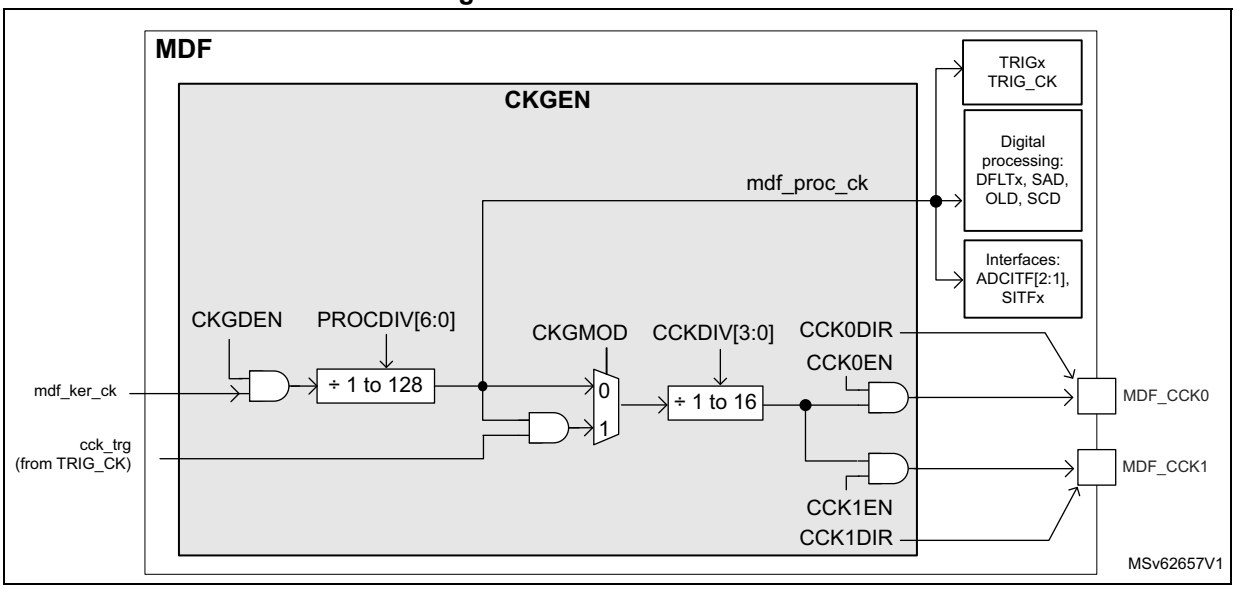
The processing clock (mdf_proc_ck) is used to run all the signals processing and to re-sample the incoming serial or parallel stream.

Note: The reshape filter (RSFLT) needs up to 24 cycles of mdf_proc_ck clock to process a sample.

To adapt the kernel clock frequency provided by the RCC, the following dividers are available:

- PROCDIV[6:0] used to adapt the kernel clock frequency to the constraints of the parallel and serial interfaces, and to the processing blocks
- CCKDIV[3:0] used to adapt the frequency of the MDF_CCK0 and MDF_CCK1 clocks

PROCDIV[6:0] and CCKDIV[3:0] must be programmed when no clock is provided to the dividers (CKGDEN = 0).



The mdf_proc_ck generation is controlled by CKGDEN.

In addition, the CKGMOD bit allows the application to define the way to trigger the CCKDIV divider:

- When CKGMOD = 0, the CCKDIV divider is started as soon as CKGDEN is set to 1.
- When CKGMOD = 1, the CCKDIV divider is started when CKGDEN is set to 1 and the programmed trigger condition occurred.

All bits and fields controlling the CKGEN are in MDF_CKGCR.

Figure 352. CKGEN overview

The trigger logic for CKGEN is handled by the TRG_CK block. As shown in *Figure 361*, the CCKDIV divider can be triggered on the rising or falling edge of one of the 16 trigger sources. When the proper trigger condition occurs, the cck_trg signal goes to high, allowing the CCKDIV divider to start. The TRG_CK logic is reset when CKGDEN is set to 0.

This feature can be helpful to synchronize the MDF_CCKy (y = 0,1) clock of several MDF instances, or to synchronize the clock generation to a timer event.

The application can control the activation of the MDF_CCK0 or MDF_CCK1 pin CCK0EN/CCK1EN and CCK0DIR/CCK1DIR bits:

- CCKyEN is used to enable the CCKDIV, and thus generates a clock for the external sensors.
- CCKyDIR is used to control the direction of the ADF_CCKy pin (input or output)

Table 396. Control of the common clock generation(1)

CCKyEN	CCKyDIR	Description
0	0	The MDF_CCKy pin is in input. An external clock can be connected to the MDF_CCKy pin and used by the SITFx in order to decode the serial stream
0	1	The MDF_CCKy pin is in output. No clock is generated, thus the MDF_CCKy pin is driven low.
1	1	The MDF_CCKy pin is in output. A clock is generated on the MDF_CCKy pin. The SITFx can use this pin as clock source in order to decode the serial stream

1. The configuration with CCKyEN = 1 and CCKyDIR = 0 must be avoided (no interest).

When CCKyDIR = 1, as soon as the CCKyEN bit is set to 1, a clock is generated to the corresponding output without any spurs.

Note: The mdf_proc_ck must be enabled (by CKGDEN = 1) before enabling other blocks (such as SITFx or DFLTx).

CKGEN activation sequence example

1. Set CKGDEN to 0.
2. Wait for CKGACTIVE = 0. If CKGDEN was previously enabled, this phase can take two periods of mdf_hclk and two periods of mdf_proc_ck.
3. Program PROCDIV[6:0], CKGMOD, CCKDIV[3:0], TRGSRC[3:0] and TRGSENS.
4. Set CKGDEN to 1.
5. Set CCKxDIR to 1 (optional).
6. Set CCKxEN to 1 (optional).

When needed, at any moment, the CCK0EN or CCK1EN value can be changed without disabling the clock generator.

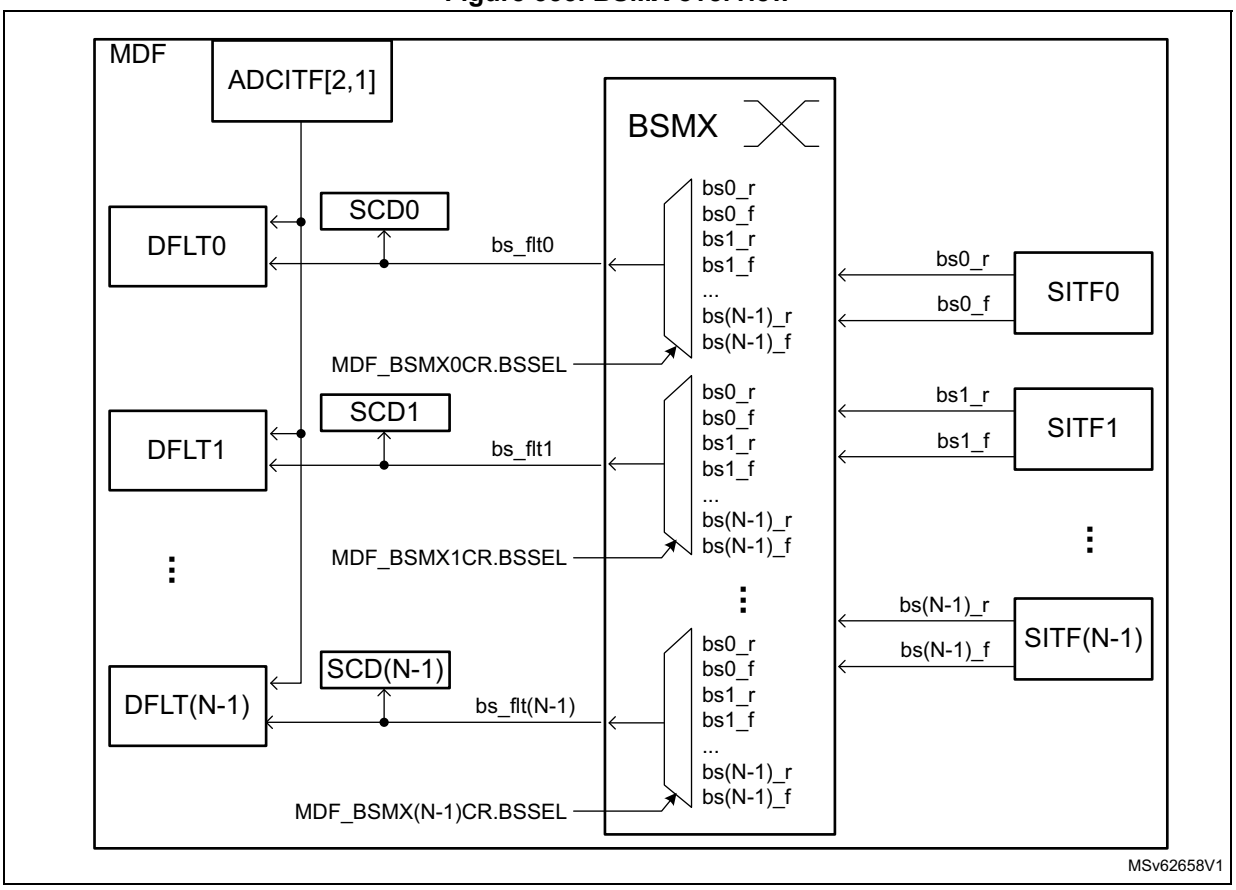
Clock frequency constraints

The table below shows the frequency constraints to receive and process properly the samples.

Table 397. Clock constraints with respect to the incoming stream(1)

SITFx mode	MDF clock constraints	
	With RSFLT disabled	With RSFLT enabled
LF_MASTER SPI	F_{MDF_CCKy} max frequency limited to 5 MHz	
	$F_{mdf_proc_ck} > 2 * F_{MDF_CCKy}$ and $F_{mdf_hclk} \geq F_{mdf_proc_ck}$	$F_{mdf_proc_ck} > 24 * F_{MDF_CCKy} / (MCICD+1)$ and $F_{mdf_proc_ck} > 2 * F_{MDF_CCKy}$ and $F_{mdf_hclk} \geq F_{mdf_proc_ck}$
MASTER SPI SLAVE SPI	F_{MDF_CKx} max frequency limited to 25 MHz	
	$F_{mdf_proc_ck} > 4 * F_{MDF_CKKy}$ and F_{mdf_hclk} higher or equal to $F_{mdf_proc_ck}$	$F_{mdf_proc_ck} > 24 * F_{MDF_CKKy} / (MCICD+1)$ and $F_{mdf_proc_ck}$ higher than 4 x F_{MDF_CKKy} and F_{mdf_hclk} higher or equal to $F_{mdf_proc_ck}$
Manchester	F_{SYMB} max frequency limited to 20 MHz	
	$F_{mdf_proc_ck}$ higher than 6 * F_{SYMB} and $F_{mdf_hclk} \geq F_{mdf_proc_ck}$	$F_{mdf_proc_ck}$ higher than 24 * $F_{MDF_CKKy} / (MCICD+1)$ and $F_{mdf_proc_ck} > 6 * F_{SYMB}$ and $F_{mdf_hclk} \geq F_{mdf_proc_ck}$

1. F_{MDF_CKKy} represents the frequency of the clock received via MDF_CKIx and MDF_CCKy, or generated via MDF_CCKy.F_{SYMB} represents the frequency of the received symbol rate for Manchester mode.



45.4.6 Bitstream matrix (BSMX)

The BSMX receives the bitstreams from all serial interfaces (SITFx) and provides the selected input to the digital filters (DFLTx) and to the short-circuit detectors (SCDx). For each filter path, any of the bitstream input can be selected.

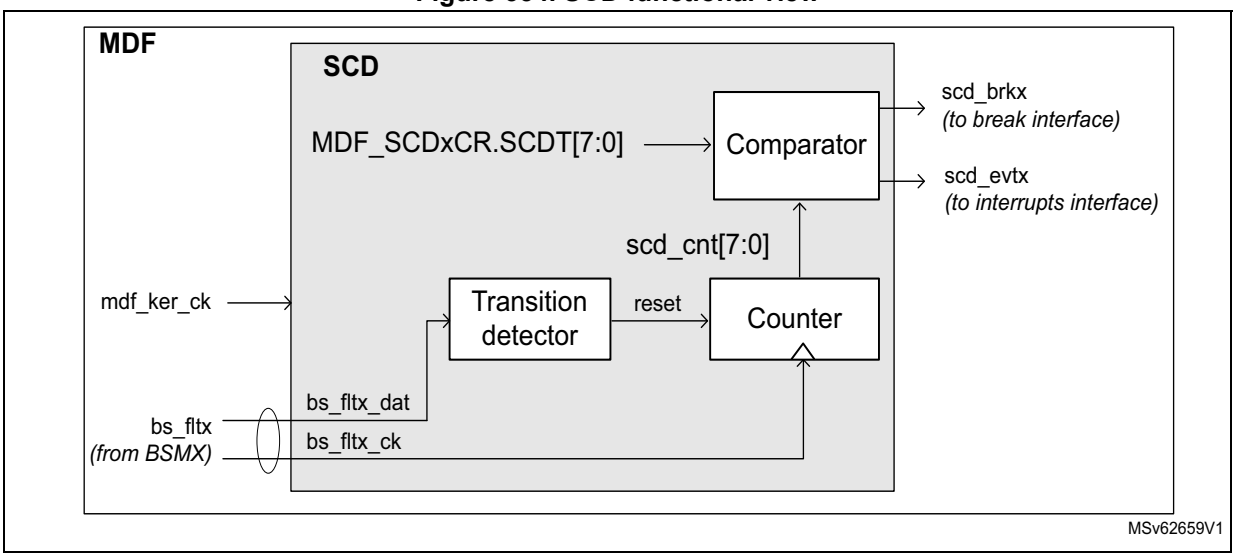
As shown in the *Figure 349*, each SITFx block provides two bitstreams (bsx_r and bsx_f) to the BSMX.

The application to select the wanted stream via the *MDF bitstream matrix control register x (MDF_BSMXxCR)*. This selection is intended to be static.

Figure 353. BSMX overview

BSMX programming sequence example

The BSSEL[4:0] bitfield cannot be changed if the corresponding SCDx, OLDx or DFLTx is enabled. The following steps are needed to change the value of BSMX, for filter path x:



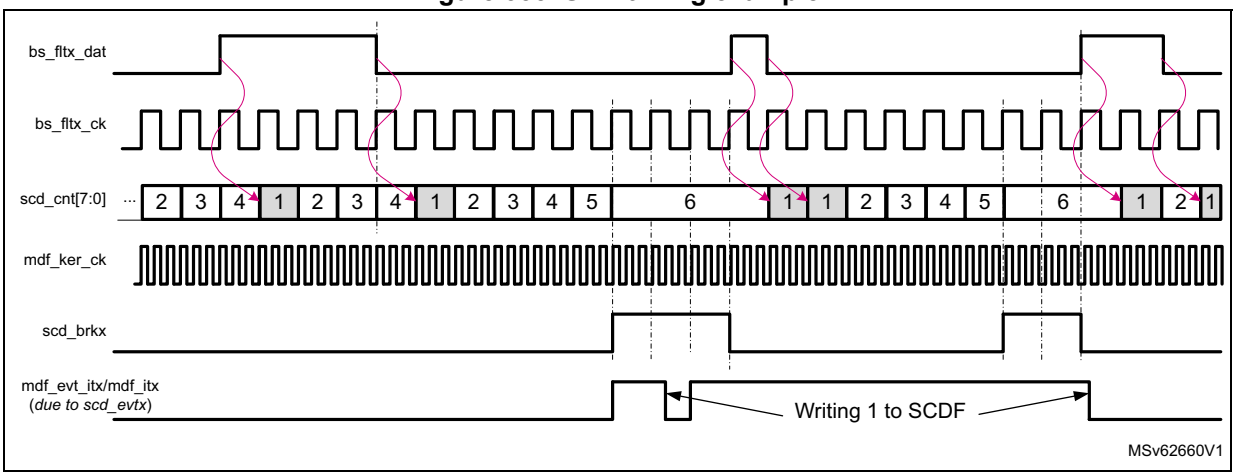
1. Set SCDEN of SCDx to 0.
2. Set DFLTEN of DFLTx to 0.
3. Set OLDEN of OLDx to 0.
4. Wait for BSMXACTIVE = 0.
5. Program BSSEL[4:0] of filter path x.
6. Set SCDEN of SCDx to 1 (optional).
7. Set DFLTEN of DFLTx to 1 (optional).
8. Set OLDEN of OLDx block to 1 (optional).

45.4.7 Short-circuit detectors (SCD)

The SCDx detects, with a very fast response time, if an analog signal reached saturated values (out-of-full scale ranges) and remained on this value for a given time.

This behavior can detect short-circuit or open-circuit errors (such as over current or over voltage). An interrupt event or/and a break signal can be generated.

Figure 354. SCD functional view



The SCDx is counting consecutive zeros or consecutive ones received from the serial interface (SITFx). A counter is restarted if there is a change in the data stream received. If this counter reaches a short-circuit threshold value (SCDT[7:0] in the *MDF short circuit detector control register x (MDF_SCDxCR)*), then a short-circuit event is invoked. Each BSMX output has its own short-circuit detector. Any BSMX output can be continuously monitored by setting the corresponding SCDEN bit to 1 in MDF_SCDxCR. Each SCD has its own threshold settings (SCDT) and its own status bit (SCDF).

The figure below shows an example where SCDT[7:0] is set to six. The break signal remains high as long as the short circuit condition is present.

No overrun event is generated when the interrupt event is pending while a new short-circuit condition is detected.

Figure 355. SCD timing example

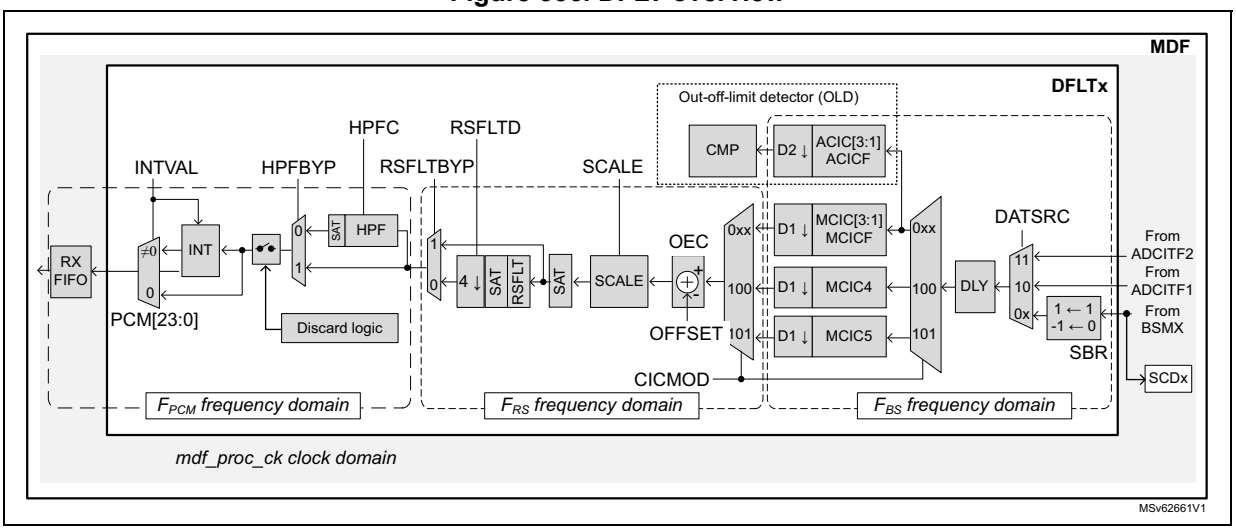
The SCDx event generated by the SCDx block can be assigned to break output signals mdf_break[3:0]. The break signal assignment to a given short-circuit detector event is done by BKSCD[3:0] in MDF_SCDxCR. The break outputs are shared with the over-current function.

Note: SCDs cannot be used to monitor the ADC data interface (ADCITF).

SCD activation sequence example

1. Enable and configure CKGEN to generate the mdf_proc_ck.
2. Set SCDEN to 0.
3. Wait for SCDACTIVE = 0. If SCDEN was previously enabled, this phase can take two periods of mdf_hclk, and two periods of mdf_proc_ck.
4. Program BKSCD[3:0] and SCDT[7:0].
5. Set SCDEN to 1.

Note: BKSCD[3:0] and SCDT[7:0] must not be changed when SCDACTIVE = 1.



45.4.8 Digital filter processing (DFLT)

The digital filter processing includes the following sub-blocks:

- symbol remap (SBR)
- source selector
- clock skipper delay (DLY)
- CIC decimation filter that can be configured:
  - in single $Sinc^4$ or $Sinc^5$ order CIC (MCIC)
  - in two CIC filters:
    - a main filter (MCIC), high resolution
    - an auxiliary filter (ACIC), low-latency, for the out-off-limit detector (OLD)
    - both MCIC and ACIC can be configured as $Sinc^1$, $Sinc^2$, $Sinc^3$ or FastSinc
- gain control (SCALE)
- signal saturation (SAT)
- reshape filter (RSFLT)
- high-pass filter (HPF)
- integrator (INT)
- receive RXFIFO

Figure 356 shows the filter-path configuration according to CICMOD[2:0]. Several configuration bits are available to configure the digital filter to the application needs.

Figure 356. DFLT overview

Symbol remap and source selection

The symbol remap (SBR) converts the bitstream selected by the BSMX into data usable by the filter path. More especially:

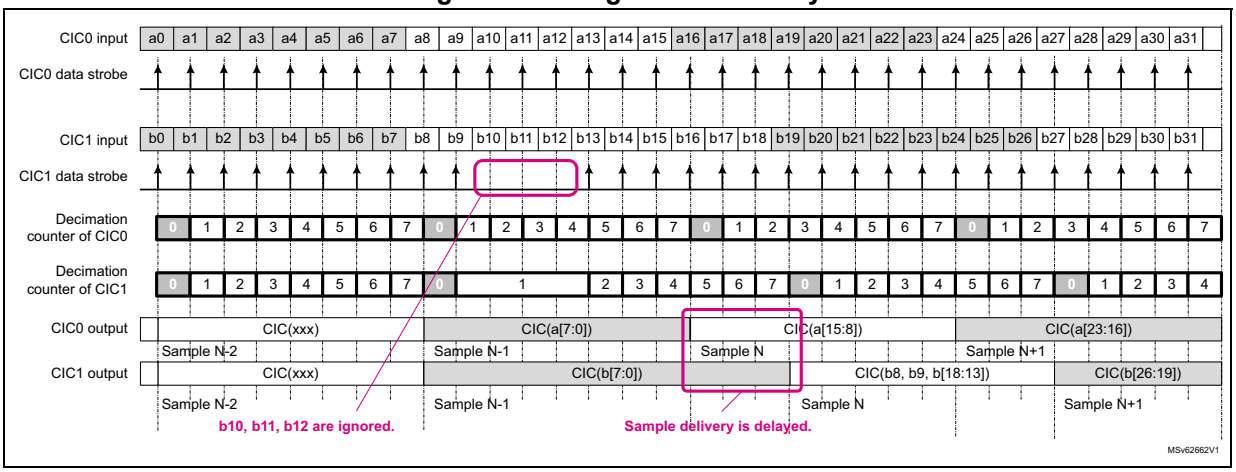
- The high levels are converted into a 16-bit signed number + 1.
- The low levels are converted into a 16-bit signed number - 1.

The signal source of the digital filter can be selected via DATSRC[1:0] between the two following:

- data coming from the BSMX
- data coming from one of the ADC interfaces (ADCITF2 or 1)

Programmable micro-delay control (DLY)

The digital filter has a delay line that allows the timing adjustment of each stream with the resolution of the bitstream clock.



This feature is particularly helpful in the case of microphone beam forming applications where delays smaller than the final sampling rate, must be applied to the incoming stream.This feature is helpful when the MDF is synchronized with other ADF or MDF blocks for a beam forming application for example.

The delay is performed by discarding a given number of samples from the selected input stream, before samples enter into the CIC filter. This data discarding is performed by skipping a given number of data strobe, preventing the CIC filter to take into account those data.

When the wanted amount of data strobe has been skipped, the next incoming samples are strobed normally.

Figure 357 shows an example of how to apply dynamically small delay to an incoming stream. For simplification, the CIC filter performs a decimation by height in this example. CIC1 represents the CIC included in the ADF and CIC0 represents a filter from another ADF or MDF instance.

Figure 357. Programmable delay

The CIC of filter 1 (CIC1) receives a command in order to skip three incoming samples. So the input samples named b10, b11 and b12 are not processed by CIC1. As a consequence, the output sample N+1 generated by CIC0 is build from input samples a[23:16] while the sample N+1 of CIC1 is build from input samples b[26:19].

Finally, the non-skipped data stream looks delayed by three bitstream periods.

Note: When the input data strobes are skipped, the decimation counter remains frozen. As a consequence, the samples delivered by the CIC1 are a bit delayed.

Warning: It is not recommended to apply a delay bigger than the programmed decimation ratio (CIC + RSFLT decimation), especially if the MDF is programmed in interleaved acquisition mode. There is a strong risk of data misalignment inside the FIFOs.

The following steps are needed to program the amount of bitstream clock periods to be skipped:

1. Wait for SKPBF equal to 0.
2. Write SKPDLY[6:0] to the wanted number of bitstream clock periods to be skipped. The SKPBF flag goes immediately to 1, indicating that the delay value entered into SKPDLY[6:0] is under process.
   - If the corresponding DFLTx is not yet enabled (DFLTEN = 0), then the DLY logic waits for DFLTEN = 1. When the application sets DFLTEN to 1, the DLY logic starts to skip the amount of wanted data strobes.
   - If the corresponding digital filter is already enabled (DFLTEN = 1), then the DLY logic immediately starts to skip the amount of wanted data strobes.

   When the MDF skipped the amount of wanted data strobes, then SKPBF goes back to 0.
3. If the application needs to skip more data strobes, then the operation must be restarted from step 1.

The effect of the delay performed with this mechanism is cumulative as long as the MDF is enabled. In a given filter, if the application performs a D1 delay, followed by a D2 delay, then all other active filters are delayed by D1 + D2.

Data coming from ADCs can also benefit of this feature.

In interleaved acquisition mode, it is up to the application to insure that the delay applied on the different microphones is in line with the depth of the RXFIFO buffers. If the relative delay between each activated filter is less than the decimation ratio, then it costs one FIFO location.

If the interleaved acquisition mode is not used, then the delay value has no impact on the RXFIFO buffering.

Note: If SKPDLY[6:0] is written when SKPBF = 1, the write operation is ignored.

Cascaded-integrator-comb (CIC) filter

The CIC digital filters are an efficient implementation of low-pass filters, often used for decimation and interpolation. The CIC frequency response is equal to a $Sinc^N$ function, this is why they are often called Sinc filters.

The $Sinc^N$ digital filter embedded into the MDF is configurable according to the application targeted.

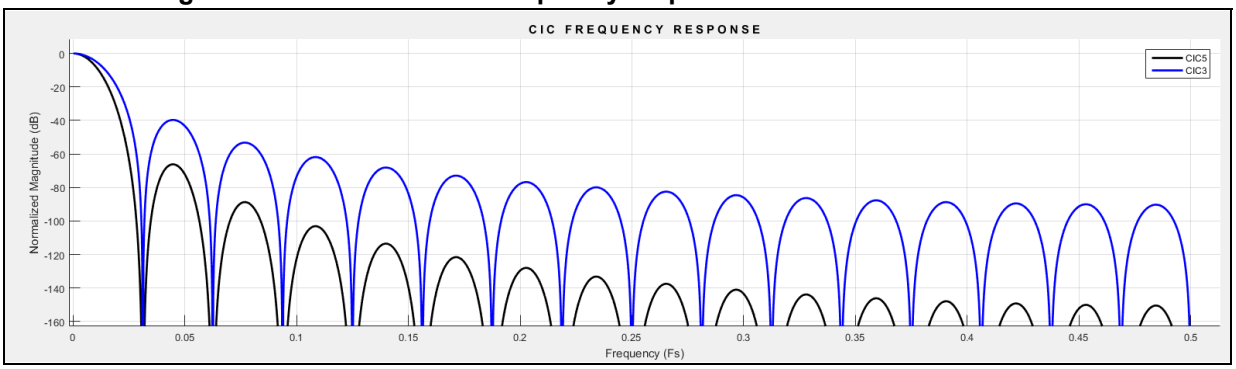
- For audio applications, such as speech capture from digital microphones, the application can select a high-resolution low-pass decimation filter by setting CICMOD to 100 or 101.
- If the targeted application is motor control or any other sensor capture, then the application can configure the CIC in order to offer a main filter path for acquisition (MCIC) and an auxiliary filter for fast-event generation (ACIC). This auxiliary filter can be used for example, to detect over-current conditions. This mode is selected by setting CICMOD[2:0] = 0xx.

When CICMOD[2:0] = 0xx, the following CIC filters are available:

- main filter (MCIC)
- auxiliary CIC filter (ACIC)

Both of them are configurable in FastSinc, $Sinc^1$ to $Sinc^3$.

When CICMOD[2:0] = 100, the CIC is configured into a single $Sinc^4$ and when CICMOD[2:0] = 101, the CIC is configured into a single $Sinc^5$ filter.



The filters have the following transfer function (impulse response in z domain):

- $Sinc^N$ filter type: $$H(z) = \left(\frac{1 - z^{-D}}{1 - z^{-1}}\right)^N$$
- FastSinc filter type: $$H(z) = \left(\frac{1 - z^{-D}}{1 - z^{-1}}\right)^2 \cdot (1 + z^{-(2 \cdot D)})$$

where N can be 1, 2, 3, 4 or 5, and D is the decimation ratio.

D is equal to MCICD+1 or ACICD+1.

Figure 358. CIC3 and CIC5 frequency response with decimation ratio = 32

CIC output data size

The size of samples delivered by the CIC (DS_{CIC}) depends on the following parameters:

- CIC order (N)
- CIC decimation ratio (D)
- data size of the input stream (DSIN)

The CIC order and decimation ratio must be programmed in order to insure that the data size does not exceed the 26-bit CIC capability.

The following formula gives the output data size (DS_{CIC}) according to the parameters above.

$$DS_{CIC} = \left(\frac{N \times Ln(D)}{Ln(2)}\right) + DS_{IN}$$

and the CIC gain is given by this formula:

$$G_{CIC} = (D)^{N}$$

The decimation ratio can be adjusted from 2 to 512 for the main CIC filter and from 1 to 32 for the auxiliary CIC filter.

The table below gives some data output size in bits for some decimation values, when the data source is a full-scale signal coming from the serial interface or from a 12-bit ADC.

Note: DS_{IN} = 1 bit for a serial bitstream but can be up to 16 bits when coming from the ADCITF.

Table 398. Data size according to CIC order and CIC decimation values

Decimation	Data size (bits) when DS_{IN} = 1 bit (data from SITFx)						Data size (bits) when DS_{IN} = 12 bits (data from ADCITF)					
	Sinc^1	Sinc^2	FastSinc	Sinc^3	Sinc^4	Sinc^5	Sinc^1	Sinc^2	FastSinc	Sinc^3	Sinc^4	Sinc^5
4	3	5	6	7	9	11	14	16	17	18	20	22
8	4	7	8	10	13	16	15	18	19	21	24	-
12	5	9	9	12	16	19	16	20	21	23	-	-
16	5	9	10	13	17	21	16	20	21	24	-	-
24	6	11	12	15	20	24	17	22	23	-	-	-
32	6	11	12	16	21	26	17	22	23	-	-	-

Table 398. Data size according to CIC order and CIC decimation values

Decimation	Data size (bits) when DS_{IN} = 1 bit (data from SITFx)						Data size (bits) when DS_{IN} = 12 bits (data from ADCITF)					
	Sinc^1	Sinc^2	FastSinc	Sinc^3	Sinc^4	Sinc^5	Sinc^1	Sinc^2	FastSinc	Sinc^3	Sinc^4	Sinc^5
64	7	13	14	19	25	-	18	24	25	-	-	-
128	8	15	16	22	-	-	19	26	-	-	-	-
256	9	17	18	25	-	-	20	-	-	-	-	-
512	10	19	20	-	-	-	21	-	-	-	-	-

The LSB part of the data provided by the CIC is not necessarily significant: it depends on the sensor performances and the ability of the CIC to reject the out-off-band noise.

The sample size at CIC output can be adjusted thanks to the SCALE block.

The table below shows the maximum allowed decimation ratio for the CIC filter, depending on the input data size. Bigger decimation ratio causes a wrap-around of the signal at CIC output, for strong input signals.

Note: The MDF cannot detect or prevent a CIC wrap-around.

Table 399. Maximum decimation ratio versus order and input data size

Filter order	Max. decimation ratio when DS_{IN} = 1 bit (SITFx)	Max. decimation ratio when DS_{IN} = 12 bits (ADCITF)	Max. decimation ratio when DS_{IN} = 16 bits (ADCITF)
Sinc^1	512	512	512
Sinc^2	512	128	32
FastSinc	512	90	22
Sinc^3	322	25	10
Sinc^4	76	11	5
Sinc^5	32	6	4

Scaling (SCALE) and saturation (SAT)

The SCALE block allows the application to adjust the amplitude of the signal provided by the CIC, by steps of 3 dB (± 0.5 dB).

The signal amplitude can be decreased by up to 8 bits (- 48.2 dB) and can be increased by up to 12 bits (+ 72.2 dB).

The gain is adjusted by the SCALE[5:0] bitfield in the *MDF digital filter configuration register x (MDF_DFLTxCICR)*.

SCALE[5:0] can be changed even if the corresponding DLFTx is enabled. During the gain transition, the signal provided by the filter is disturbed.

Due to internal resynchronization, there is a delay of some cycles of mdf_proc_ck clock between the moment where the application writes the new gain, and the moment where the gain is effectively applied to the samples. If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back SCALE[5:0] informs the application on the current gain value.

The table below shows the possible gain values.

Table 400. Possible gain values

SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)
0x20	- 48.2	0x2B	- 14.5	0x06	+ 18.1	0x11	+ 51.7
0x21	- 44.6	0x2C	- 12.0	0x07	+ 21.6	0x12	+ 54.2
0x22	- 42.1	0x2D	- 8.5	0x08	+ 24.1	0x13	+ 57.7
0x23	- 38.6	0x2E	- 6.0	0x09	+ 27.6	0x14	+ 60.2

The SAT blocks avoid having a wrap-around of the binary code when the code exceeds its maximal or minimal value.

The MDF performs saturation operations at the following levels:

- after the SCALE block (performed by the SAT block). The signal is saturated at 24 bits.
- inside the RSFLT, to insure a good filter behavior
- at the output of the HPF, to insure that the output signal does not exceed 24 bits

The SATF bit informs the application that a saturation occurred either after the SCALE, inside the RSFLT or after the HPF. In addition, an interrupt can be generated if SATIE is set to 1. As soon as a saturation is detected, the SATF flag is set to 1. It is up to the application to clear this flag in order to be able to detect a new saturation.

Those bits are in the *MDF DFLTx interrupt enable register x (MDF_DFLTxIER)* and *MDF DFLTx interrupt status register x (MDF_DFLTxISR)*.

Gain adjustment policy

To get the best MDF performances, it is important to properly adjust the gain value via SCALE[5:0].

A usual way to adjust the gain is to select the SCALE[5:0] value that gives a final signal amplitude as close as possible to the 24-bit full scale, for the maximum input signal.

A way to select the optimal gain is detailed below:

1. Check that, for the expected input signal, the data size into the CIC filter does not exceed 26 bits. This can be checked using this formula:

$$\frac{LN(SIN_{pp} \cdot D^N)}{LN(2)} < 26$$

where N represents the CIC order, D the decimation ratio and SIN_{pp} the maximum peak-to-peak amplitude of the input signal.

SIN_{pp}can take:

– a maximum peak-to-peak amplitude of 2 (± 1), for samples coming from SITF

– a maximum peak-to-peak amplitude of 4095 (+ 2047, - 2048) for samples coming from a 12-bit ADC

Example: a $Sinc^4$ can be used with a decimation ratio of 96, if the maximum input signal does not exceed ± 0.35. Indeed:

$$\frac{LN(0.7 \cdot 96^4)}{LN(2)} \sim 25.82 \text{ bits} < 26 \text{ bits}$$

2. Adjust the SCALE value.

To select the most appropriate SCALE value, the user must check if the RSFLT is used or not. If the RSFLT is used, the data size at SCALE output must not exceed 22 bits, otherwise the data size can be up to 24 bits.

The SCALE value in dB is selected using this formula:

$$SCALE_{dB} < 20 \cdot \log 10\left(\frac{2^{NB}}{SIN_{pp} \cdot D^N}\right)$$

where NB is equal to 22 if RSFLT is enabled, or 24 if RSFLT is bypassed. $SCALE_{dB}$ represents the gain value selected by SCALE[5:0].

Example: for a $Sinc^4$ with a decimation ratio of 96 and a SIN_{pp} of 0.7:

– If the RSFLT is bypassed:

$$20 \cdot \log 10\left(\frac{2^{24}}{0.7 \cdot 96^4}\right) \sim 11 \text{ dB}$$

$SCALE_{dB}$ value must be lower than - 11 dB. The closest lower value is - 12dB (SCALE[5:0] = 0x2C).

– If the RSFLT is enabled:

$$20 \cdot \log 10\left(\frac{2^{22}}{0.7 \cdot 96^4}\right) \sim 23 \text{ dB}$$

$SCALE_{dB}$ value must be lower than - 23 dB, the closest lower value is - 24.1 dB (SCALE[5:0] = 0x28).

If SCALE[5:0] is set to a higher value, then a saturation may occur. An event flag informs the user if a saturation occurred.

The table below proposes gain values for different filter configurations, when the data comes from the SITFx, according to the CIC order, and the CIC decimation ratio. This table is not exhaustive, and considers a full-scale input signal (see *Section 45.7.5* for details).

Table 401. Recommended maximum gain values versus CIC decimation ratios

CIC decimation ratio	Gain settings (dB) for configuration SITF + CICx + RSFLT (+ HPF)					Gain settings (dB) for configuration SITF + CICx (+ HPF)				
	CIC5	CIC4	CIC3	CIC2	CIC1	CIC5	CIC4	CIC3	CIC2	CIC1
8	33.6	51.7	69.7	72.2	72.2	45.7	63.7	72.2	72.2	72.2
12	18.1	39.6	60.2			30.1	51.7			
16	3.5	27.6	51.7			15.6	39.6	63.7		
20	- 6.0	21.6	48.2			6.0	33.6	60.2		
24	- 12.0	15.6	42.1	69.7		0	27.6	54.2		
28	- 20.6	9.5	36.1	66.2		- 8.5	21.6	48.2		
32	-26.6	3.5	33.6	63.7		- 14.5	15.6	45.7		
48	-	- 8.5	24.1	57.7		-	3.5	31.6	69.7	
64	-	- 20.6	15.6	51.7		-	-8.5	27.6	63.7	
128	-	-	- 2.5	39.6		-	-	9.5	51.7	
256	-	-	- 20.6	27.6		-	-	-8.5	39.6	

Reshaping filter (RSFLT)

In addition to the CIC, the MDF offers a reshaping IIR filter mainly dedicated to the audio application but also usable in other applications.

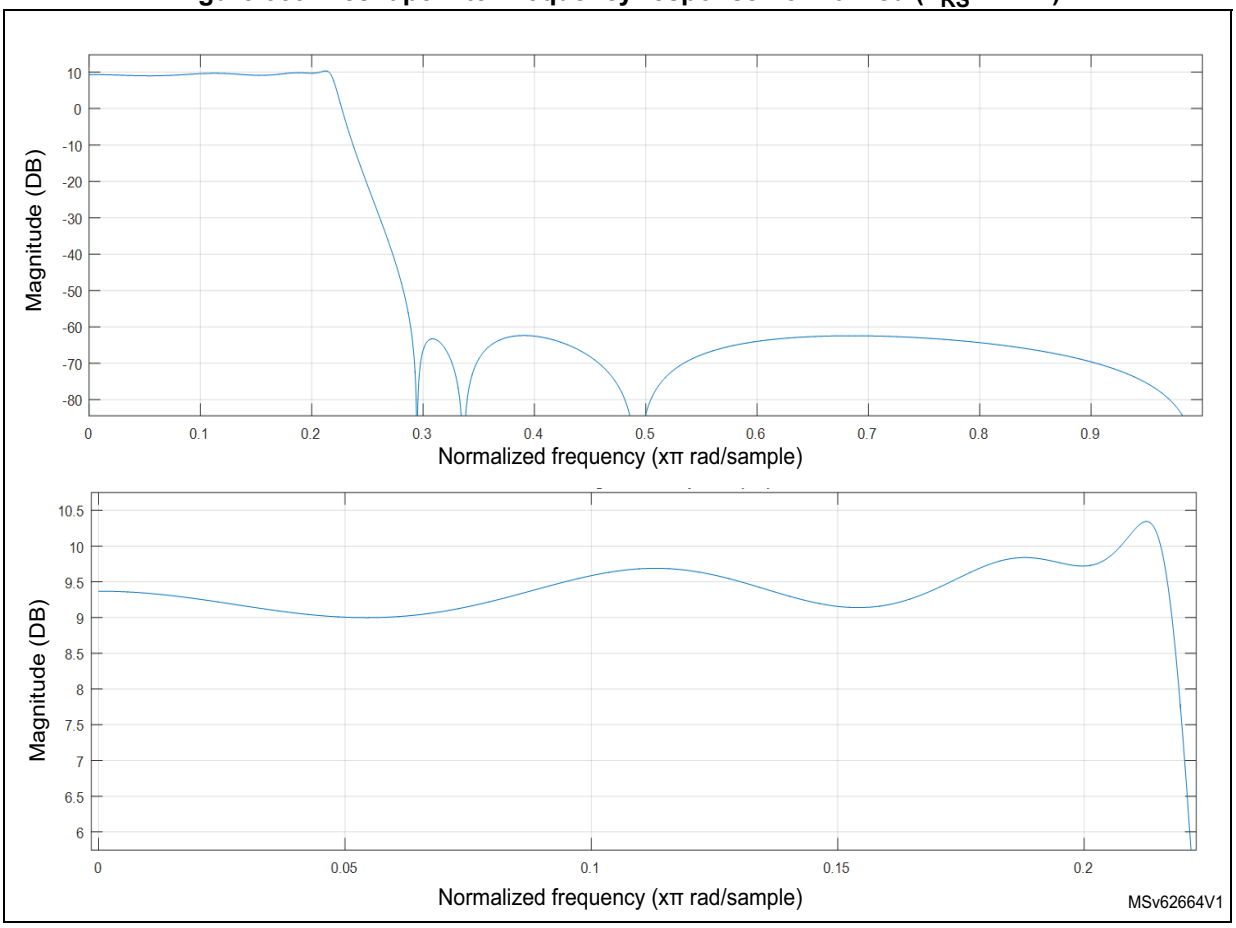
When the RSFLT is used, the sample size at its input must not exceed 22 bits.

The samples at the RSFLT output can be decimated by four or not according to the RSFLTD bit in the *MDF reshape filter configuration register x (MDF_DFLTxRSFR)*.

The RSFLT can be bypassed by setting RSFBYP to 1 in MDF_DFLTxRSFR.

The table below shows which sampling rate must be provided to the RSFLT in order to process the most common audio streams.

The RSFLT cutoff frequency (F_C) depends on the sample rates at its input (F_{RS}), and is given by the following formula:



$$F_C = 0.111 \times F_{RS}$$

Table 402. Most common microphone settings

Sample rate (kHz) at RSFLT (F_{RS})	Pass band (kHz)	D2	PCM sampling rate (kHz)
32	3.55	4	8
64	7.1	4	16
128	14.2	4	32
192	21.3	4	48

The figure below shows the frequency response of the reshape filter.

Figure 359. Reshape filter frequency response normalized (F_{RS} / 2 = 1)

The RSFLT gain is about 9.3 dB, so the output data size is a little bit lower than 24 bits for a 22-bit wide input signal.

The RSFLT takes 24 clock cycles of mdf_proc_ck clock to process one sample at F_{RS}. When the RSFLT is enabled, the application must insure that the mdf_proc_ck is at least 24 times faster F_{RS}.

The RSFLT generates an event (rfovr_evt) and sets the RFOVRF flag, if the RSFLT receives a new sample while the previous one is still under processing.

When RFOVRF is set, the samples provided by the RSFLT are invalid. The application must then stop the data acquisition and provide x a faster mdf_proc_ck clock to the RSFLT.

High-pass filter (HPF)

The high-pass filter suppresses the low-frequency content from the final output data stream in case of continuous conversion mode. The high-pass filter can be enabled or disabled via HPFBYP in the *MDF reshape filter configuration register x (MDF_DFLTxRSFR)*.

The HPF is useful when there is parasitic low-frequency noise (or DC signal) in the input data source and it must be removed from the final data.

The HPF is a first order IIR filter and the cut-off frequency can be selected via HPFC[1:0] in the *MDF reshape filter configuration register x (MDF_DFLTxRSFR)*, among the following values:

- 0.000625 x F_{PCM}
- 0.00125 x F_{PCM}
- 0.00250 x F_{PCM}
- 0.00950 x F_{PCM}

Table 403. HPF 3 dB cut-off frequencies examples

HPFC	3 dB cut-off frequency for common F_{PCM} frequencies (Hz)		
	F_{PCM} = 8 kHz	F_{PCM} = 16 kHz	F_{PCM} = 48 kHz
0	5	10	30
1	10	20	60
2	20	40	120
3	76	152	456

The HPF output is saturated at 24 bits. The SATF flag is set if a sample is saturated.

Offset error compensation (OEC)

Each digital filter has its own OEC. The offset correction is performed by subtracting to the signal provided by the CIC, the OFFSET[25:0] in the *MDF offset error compensation control register x (MDF_OECxCR)*.

Due to the internal resynchronization, there is a delay of some cycles of mdf_proc_ck clock between the moment where the application writes the new offset, and the moment where the new offset value is effectively applied to the samples. If the application attempts to write a new offset value while the previous one is not yet applied, this new offset value is ignored. Reading back OFFSET[25:0] informs the application on the current offset value.

Integrator (INT)

The INT performs additional decimation and a resolution increase of data coming from the digital filter. The INT simply performs the sum of data from a digital filter for a given number of data samples from a filter.

The INT is enabled by setting INTVAL[6:0] to a value different from 0.

The amount of integrated values can be defined by INTVAL[6:0] in the range of 2 to 128.

In order to control the data width at the integrator output, the resulting data can be divided by 1, 4, 32 or 128. This feature is controlled by INTDIV[1:0].

45.4.9 Out-of-limit detector (OLD)

The OLD triggers an event when a signal reaches or crosses given maximum and minimum threshold values. The generated event can drive an interrupt or break signals (mdf_break[3:0]) when conditions are met.

The OLD can be used only if the CIC filter is configured in motor and sensing mode (CICMOD[2:0] = 0xx).

The OLD takes the input signal selected by the main filter, process it using a $Sinc^N$ or FastSinc filter (ACIC), and compares the resulting signal to programmed thresholds.

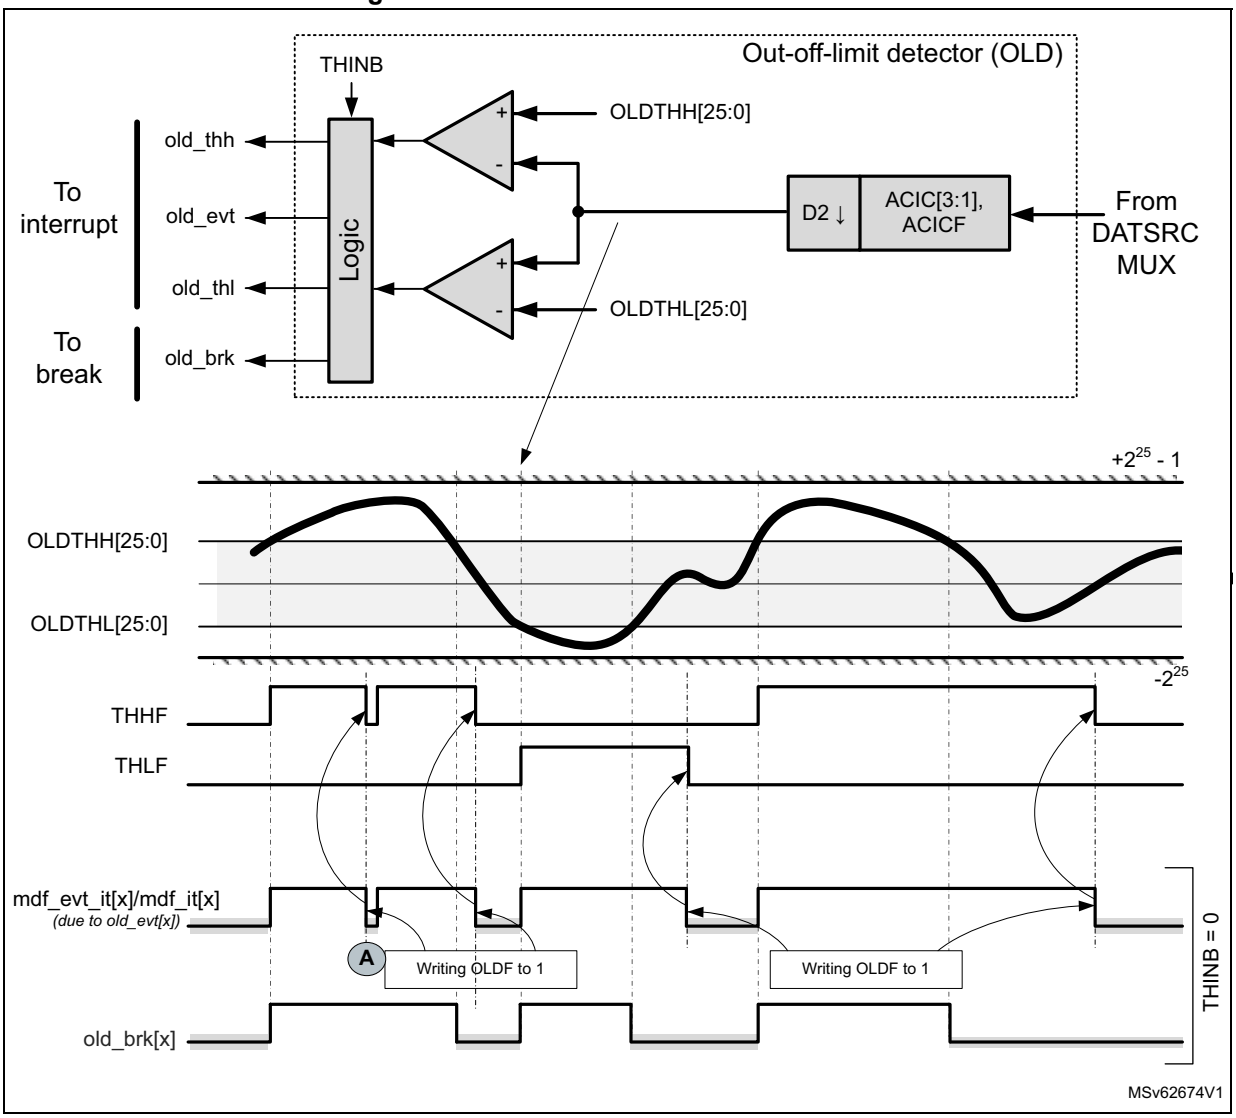
The OLD is enabled via the OLDEN bit in MDF_OLD0CR. Once enabled, the input data are continuously monitored. There is no need to have the DFLTx enabled for using the OLD function.

The MDF offers a high- and low-threshold register that are compared with given data values.

The application can generate an event if the signal is inside or outside the boundary defined by those two thresholds. This behavior is controlled via THINB in the MDF_OLD0CR.

If the application only wants to generate an event when the input signal is higher than OLDTHH, then THINB and OLDTHL must both be cleared to 0.

If the application only wants to generate an event when the input signal is lower than OLDTHH, then THINB must be set to 1 and OLDTHL must be cleared to 0.



Note: It is not recommended to set a OLDTHL to a value bigger than OLDTHH.

The response time of the OLD depends on several parameters, the most important are listed hereafter:

- sampling rate frequency used by the external sensor
- ACIC decimation ratio
- ACIC order

The OLD can be used for over-current detection but also as current limiter if the PWM signal is generated by a timer receiving a old_brk signal. Generally, to get a fast response time for over-current detection, it is recommended to use the ACIC with lowest order as possible and the minimum decimation ratio. FastSinc is also a good choice for over-current detection. The application must perform a trade-off between the filter resolution and the response time.

Figure 360. Out-of-limit detector thresholds

Status flags are available in order to inform the application that an OLD event is detected. Latched events are cleared by writing 1 into the OLDF bit.

As shown in *Figure 360*, when THINB = 0, the interrupt signal remains active as long as the signal is outside the gray area. At position A, the application clears the interrupt, but the interrupt is re-asserted because the signal is still outside the gray area. When the application clears OLDF, THHF and THLF are cleared as well.

An OLD event can be assigned to one or several break output signals (mdf_break[3:0]). The break signal assignment to a given OLD event is done by BKOLD[3:0] in the *MDF out-of limit detector control register x (MDF_OLDxCR)*.

Note: The generation of break signals is independent from the interrupts generation.

OLD activation sequence example

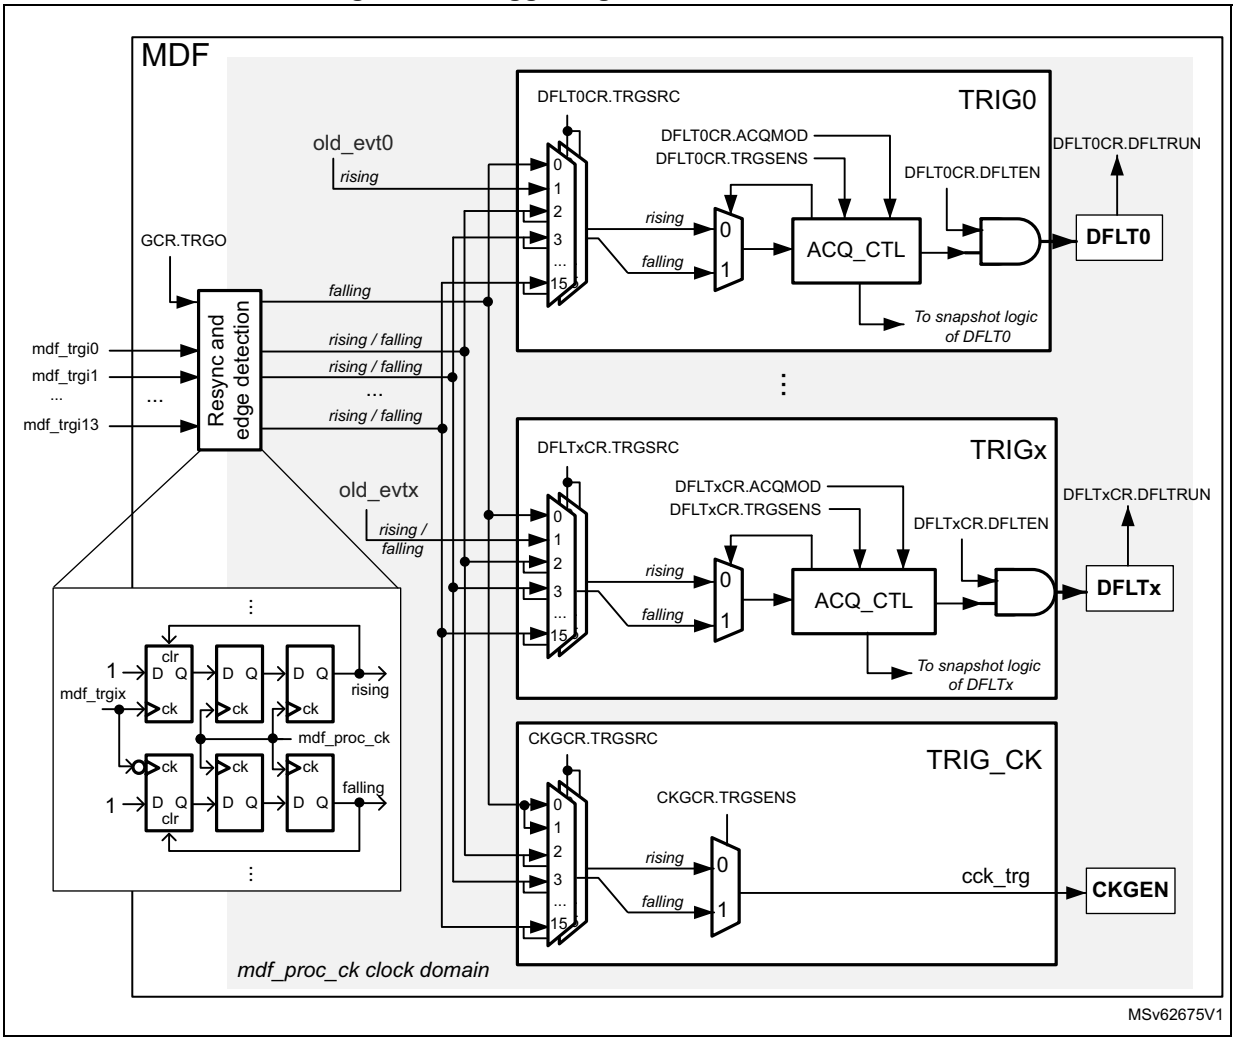
1. Enable and configure CKGEN.
2. Set OLDEN to 0.

3. Wait for OLDACTIVE = 0. If OLDEN was previously enabled, this phase can take two periods of mdf_hclk and two periods of mdf_proc_ck.
4. Program BKOLD[3:0], ACICN[1:0], ACICD[4:0], THINB,OLDTHL[25:0] and OLDTHH[25:0].
5. Set OLDEN to 1.

45.4.10 Digital filter acquisition modes

The MDF offers the following modes to perform a data capture:

- asynchronous continuous acquisition mode
- asynchronous single-shot acquisition mode
- synchronous continuous acquisition mode
- synchronous single-shot acquisition mode
- window continuous acquisition mode
- synchronous snapshot acquisition mode



For each filter, one of these modes can be selected independently.

Note: To perform a data capture, the filters, the interfaces providing the data (SITFx or ADCITF) and the CKGEN must be enabled. If needed, MDF_CCK0 or MDF_CCK1 must be enabled as well.

The filter can be stopped immediately when DFLTEN is set to 0. This resets the filters and flushes the RXFIFO of the corresponding filter path. The DFLTACTIVE flag also goes back to 0 when the RXFIFO and the filters are reset.

The figure below shows a simplified view of the trigger logic available for each filter and for the clock generator.

Figure 361. Trigger logic for DFLT and CKGEN

A block common to all TRIG blocks performs the rising and falling edges detection and the resynchronization of the input triggers to the mdf_ker_ck clock domain. This implementation allows the application to use triggers with pulse width smaller than the mdf_ker_ck period.

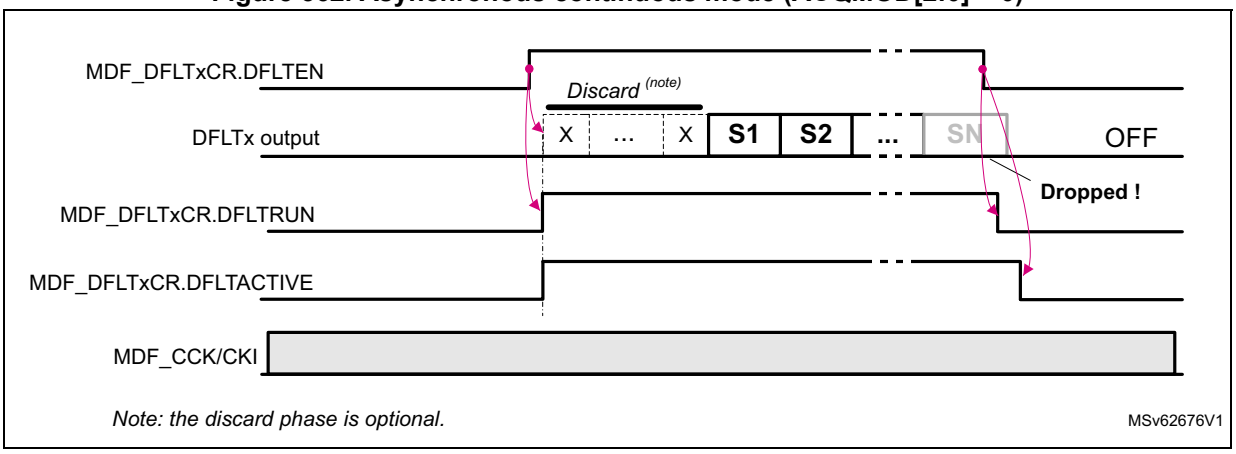
In synchronous modes, the TRIG block offers the possibility to select one of the following trigger sources:

- mdf_trgi[13:0] signals (refer to *Table 393* for the triggers connections)
- TRGO bit in MDF_GCR
- OLD event of each filter path

The edge sensitivity can also be selected, except for TRGO and OLD events.

Asynchronous continuous acquisition mode

This mode allows the application to start a continuous acquisition on one or several filters by simply writing their DFLTEN bits to 1.



The Asynchronous continuous acquisition mode is selected when ACQMOD[2:0] = 0.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN) so that the mdf_proc_ck frequency is compatible with the targeted application (see examples in *Table 407*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 0.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1 for the filters to enable, the acquisition sequence starts immediately.

The figure below shows a simplified example of the samples generated by the DFLTx.

Figure 362. Asynchronous continuous mode (ACQMOD[2:0] = 0)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Asynchronous single-shot acquisition mode

This mode allows the application to start the acquisition of one sample on one or several filters by simply writing their DFLTEN bits to 1.

The Asynchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 001.

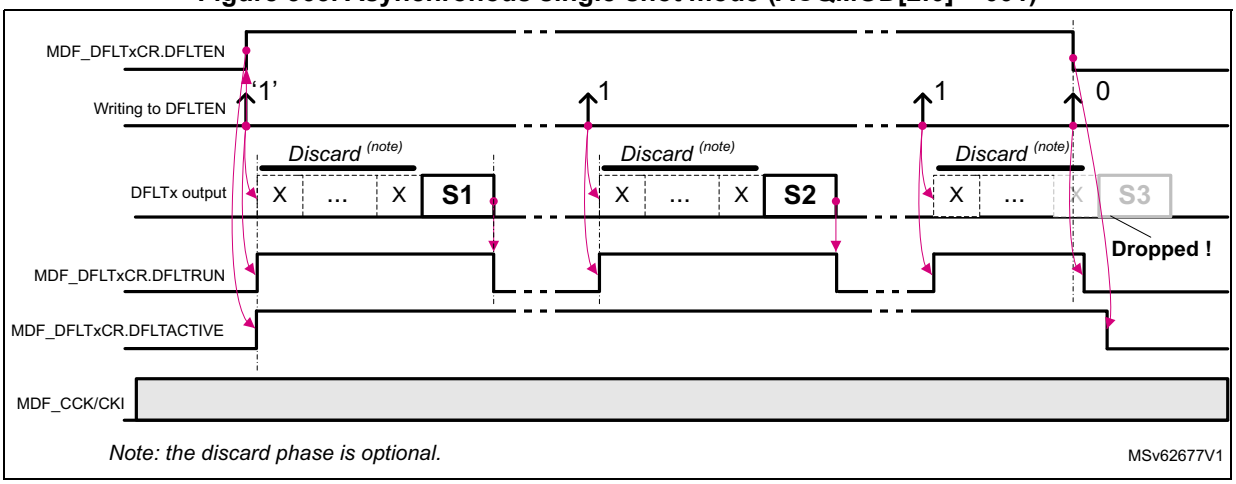
The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are cleared to 0):

1. Configure and enable the clock generator (CKGEN), so that the mdf_proc_ck frequency is compatible with the targeted application (see examples in *Table 403*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 001.
4. Set to 1 the SITFEN bit of the requested data interfaces.

5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1 for the filters to enable, each selected filter provides one data to the RXFIFO and stops the acquisition.

To trigger a new acquisition, for each filter, the application must:

1. Check that the previous acquisition is completed, by waiting that DFLTRUN = 0.
2. Set again DFLTEN to 1.



This sequence can be repeated every time a new data must be converted.

As shown in the *Figure 363*, every time DFLTEN is set to 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset, and the filter is ready to start a new conversion.

If the DFLTEN is set to 0 while an acquisition is ongoing, the ongoing conversion is stopped (in the example, S3 is lost). This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Set DFLTEN to 0.

Figure 363. Asynchronous single-shot mode (ACQMOD[2:0] = 001)

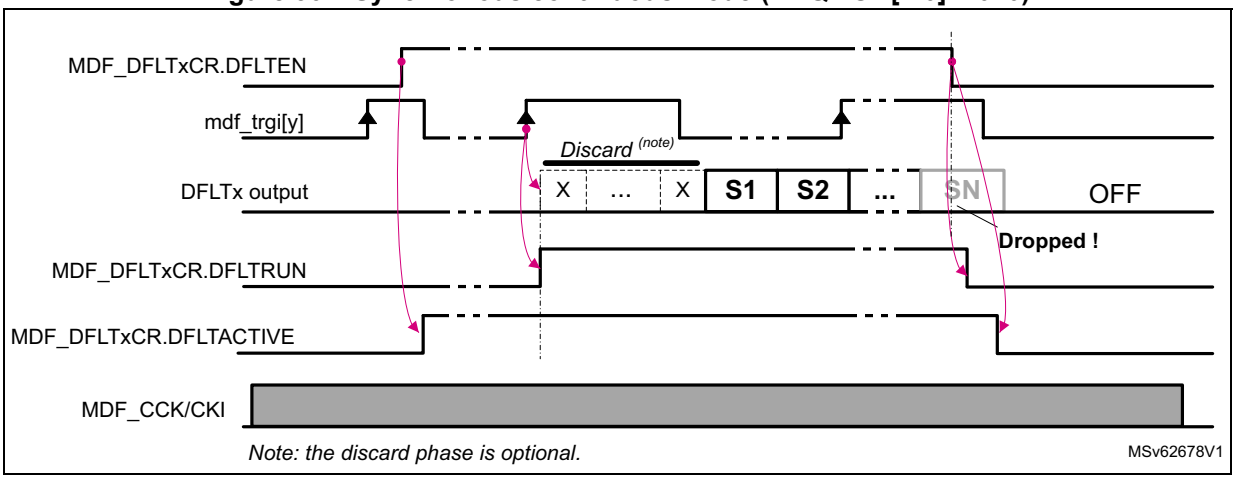
Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous continuous acquisition mode

This mode allows the application to start a continuous acquisition on one or several filters by using the following trigger sources:

- one of the mdf_trg[13:0] signals
- OLD event of the corresponding filter
- TRGO bit

The Synchronous continuous acquisition mode is selected when ACQMOD[2:0] = 010.



The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in *Table 403*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 010.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1 for the filters to enable.
8. When the trigger condition is met, the filters start the acquisition.

The TRGSENS bit allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). The first rising edge of the trigger signal is ignored because DFLTEN = 0. The next rising edge is taken into account and starts the acquisition. All other rising edges are ignored. The trigger logic is re-initialized when DFLTRUN goes back to 0.

Figure 364. Synchronous continuous mode (ACQMOD[2:0] = 010)

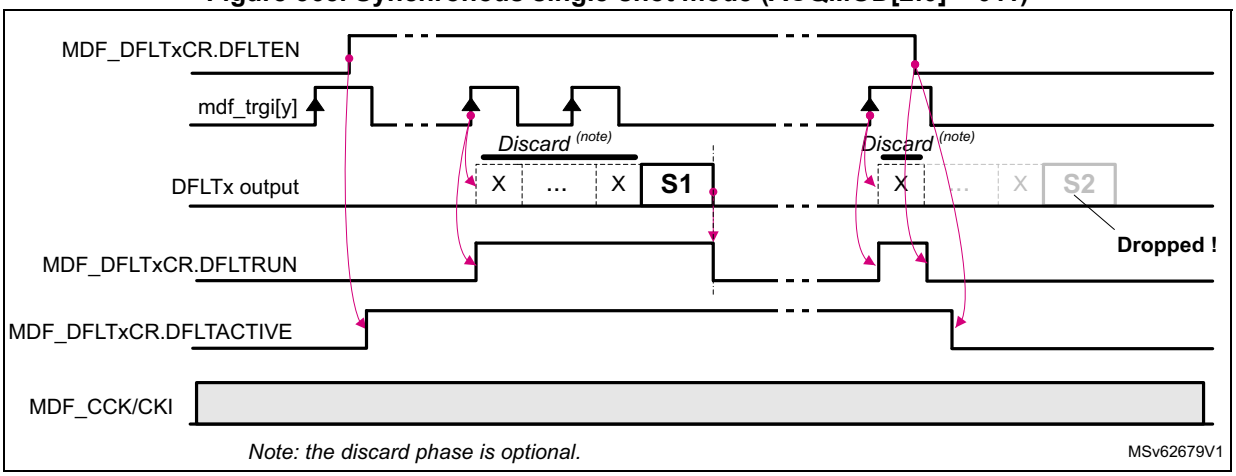
Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous single-shot acquisition mode

This mode allows the application to start a single acquisition on one or several filters by using the following trigger sources:

- one of the mdf_trg[13:0] signals
- OLD event of the corresponding filter
- TRGO bit

The Synchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 011.



The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in *Table 403*).
2. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the wanted filter configuration and set the ACQMOD[2:0] to 011.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence has been properly terminated.
7. Set DFLTEN to 1 for the filters to enable.
8. Then when the trigger condition is met, the filters start the acquisition and provide one data to the RXFIFO, then the filters are ready to accept a new trigger.

TRGSENS allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). Every time a trigger rising edge is detected with DFLTEN = 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset. DFLTRUN is set to 0 and the filter is ready to start a new conversion.

Figure 365. Synchronous single-shot mode (ACQMOD[2:0] = 011)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Figure 365 shows a case where DFLTEN is cleared to 0 while an acquisition is ongoing: thus the sample S2 is lost. This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Clear DFLTEN to 0.

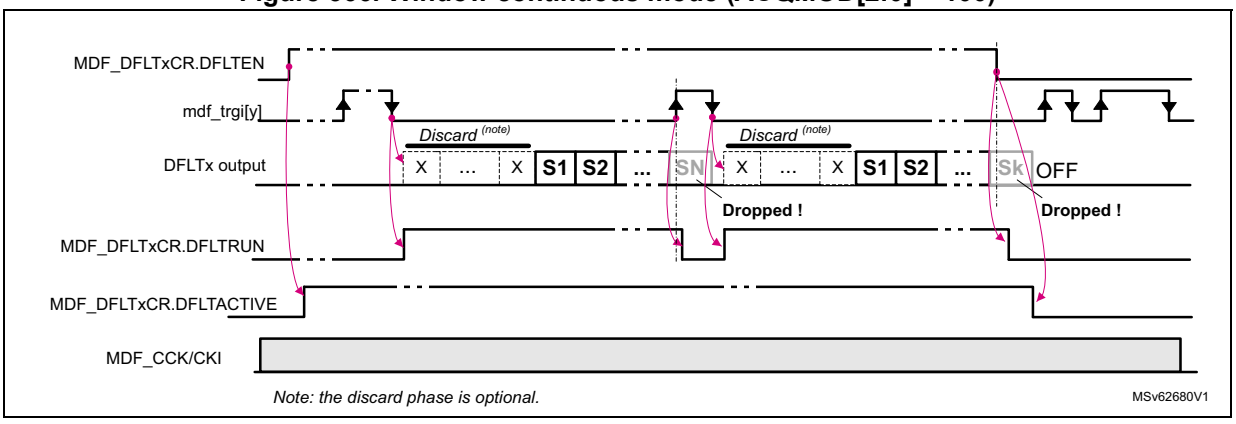
Note: The ongoing DMA transfer is properly terminated.

Window continuous acquisition mode

This mode allows the application to start or stop a continuous acquisition on one or several filters controlled by consecutive edges of one of the following trigger sources:

- one of the mdf_trg[13:0] signals
- TRGO bit

The window continuous acquisition mode is selected when ACQMOD[2:0] = 100.



The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in *Table 403*).
2. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the wanted filter settings and set the ACQMOD[2:0] to 100.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence has been properly terminated.
7. Set DFLTEN to 1 for the filters to enable.
8. If TRGSENS = 0, the acquisition starts on trigger rising edge and stops on trigger falling edge. If TRGSENS = 1, the acquisition starts on trigger falling edge and stops on trigger rising edge.

Note: The acquisition may restart if the trigger condition becomes again active.

Figure 366 shows a simplified example of window continuous acquisition mode, with TRGSENS = 1. Once DFLTEN is set to 1, the MDF waits for a falling edge on the selected trigger input. When the trigger condition is met, DFLTRUN goes to 1 and the acquisition starts. The acquisition stops if the MDF detects a rising edge on the selected trigger input. If DFLTEN is still set to 1, the MDF waits again for a falling edge on the selected trigger input.

Figure 366. Window continuous mode (ACQMOD[2:0] = 100)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA

transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous snapshot acquisition mode

In the acquisition modes described on previous sections, the application must wait for filters settlings time or the end of conversion before getting a new valid sample. For applications very critical in latency, the last valid sample can be get immediately, with an information on the age of this sample by using the snapshot acquisition mode.

In snapshot mode, the DFLTx is continuously acquiring the samples, but the processed samples are not stored into the RXFIFO. When a trigger occurs, the last valid sample, the current decimation value of MCIC and the sample counter of the INT are stored in MDF_SNPS0DR.

The possible trigger sources are the following:

- one of the mdf_trg[13:0] signals
- OLD event of the corresponding filter
- TRGO bit

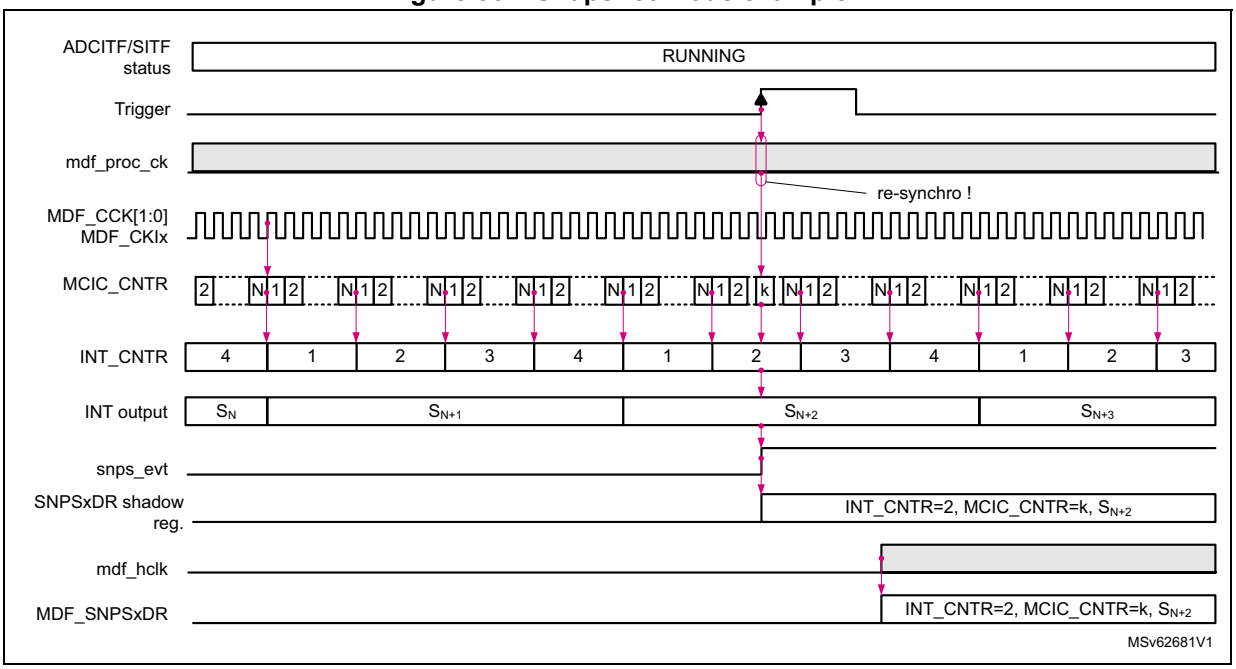
The Synchronous snapshot acquisition mode is selected when ACQMOD[2:0] = 101.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in *Table 403*).
2. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the wanted filter settings and set the ACQMOD[2:0] to 101. FTH is usually cleared to 0 to receive an interrupt as soon as the RXFIFO is not empty.
4. Set the SITFEN bit of the requested data interfaces to 1.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence has been properly terminated,
7. Set DFLTEN to 1 for the filters to enable.

When the trigger condition is met,

1. The MDF stores the last valid data provided by the corresponding filter, the value of the MCIC decimation counter, and the counter value of INT if selected by SNPSFMT into a shadow register.
2. The snps_evt is activated, indicating that a data is ready. If SSDRIE is set to 1, the MDF requests the AHB clock.
3. When the AHB clock is available the shadow register is stored in *MDF snapshot data register x (MDF_SNPSxDR)* and an interrupt is generated.
4. In the interrupt sub-routine, the application must do the following:
   a) Read the data located in MDF_SNPSxDR.
   b) Clear the SSDRF flag by writing it to 1.



As shown in the *Figure 367*, in snapshot mode, when the trigger event occurs, it is resynchronized with the processing clock (mdf_proc_ck), the decimation counter of the MCIC (MCIC_CNTR), the integrator counter (INT_CNTR) and the last valid sample (S_{N+2}), are stored into a shadow register, and the snps_evt event is generated. When the AHB

clock is available, an interrupt is generated and the shadow register is copied in MDF_SNPSxDR. The application can read immediately the sample and the timing information.

The SSOVRF overrun flag is also available, allowing the application to check if an overrun condition occurs. A snapshot overrun condition is detected when the SSDRF flag is set to 1 while a new trigger event occurs.

In that case, the new trigger event is not taken into account. The application must clear the SSOVRF flag.

Figure 367. Snapshot mode example

Note: When an activated filter did not receive a data strobe, the filter is frozen. If the interface providing the stream is not enabled (SITF or ADCITF), the filter is frozen. Once a DFLT x is activated, CIC, HPF, IIR and INT are reinitialized. For each filter a status bit indicates if the filter is currently running or not.

Starting several filters synchronously

To start the acquisition of several filters synchronously, the following sequence must be performed (assuming that DFLTEN is set to 0):

1. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
2. Set the SITFEN bit of the requested data interfaces to 1.
3. For each filter, set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. For each filter, set TRGSRC[3:0] to 0 (TRGO is selected).
5. For each filter, set TRGSENS to 0 (rising edge).
6. For each filter, set DFLTEN to 1.
7. Read TRGO bit until it is read to 0.
8. Set TRGO to 1. Then the acquisition sequence for all selected filters starts immediately.

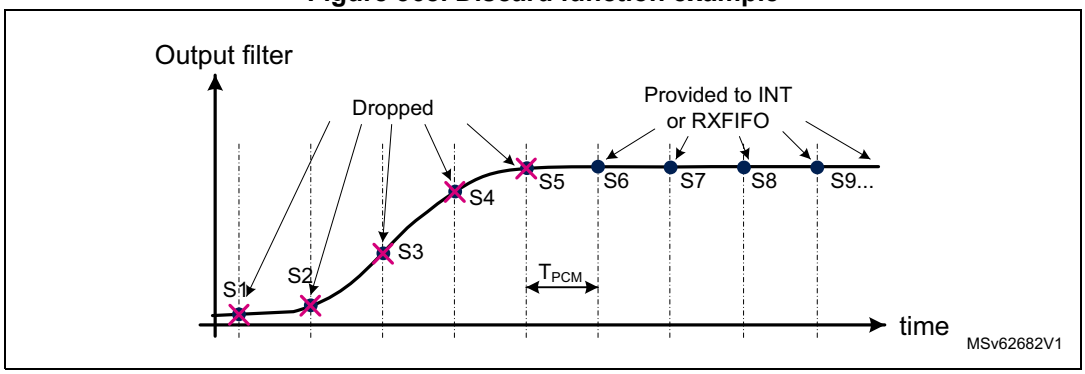
To trigger a new acquisition (in case of single-shot), the application must do the following:

1. Check that the previous acquisition is completed, by waiting DFLTRUN = 0.
2. Read TRGO until it is read to 0.
3. Set again TRGO to 1.

Discarded samples

The MDF offers the possibility to program the amount of samples to be discarded after each restart:

- to avoid capturing samples affected by the impulse response of the filter
- to delay the acquisition of filters by a specific amount of samples



The discard function is controlled via NBDIS[7:0] as follows:

- When NBDIS[7:0] = 0, the discard function is disabled.
- When NBDIS[7:0] ≠ 0, the discard function is activated in one of the following condition:
  - when the DFLTEN bit goes to 1
  - every time an acquisition is started in (A)synchronous single-shot modes

Refer to *Figure 362* to *Figure 366*, *Figure 369* and *Figure 370*.

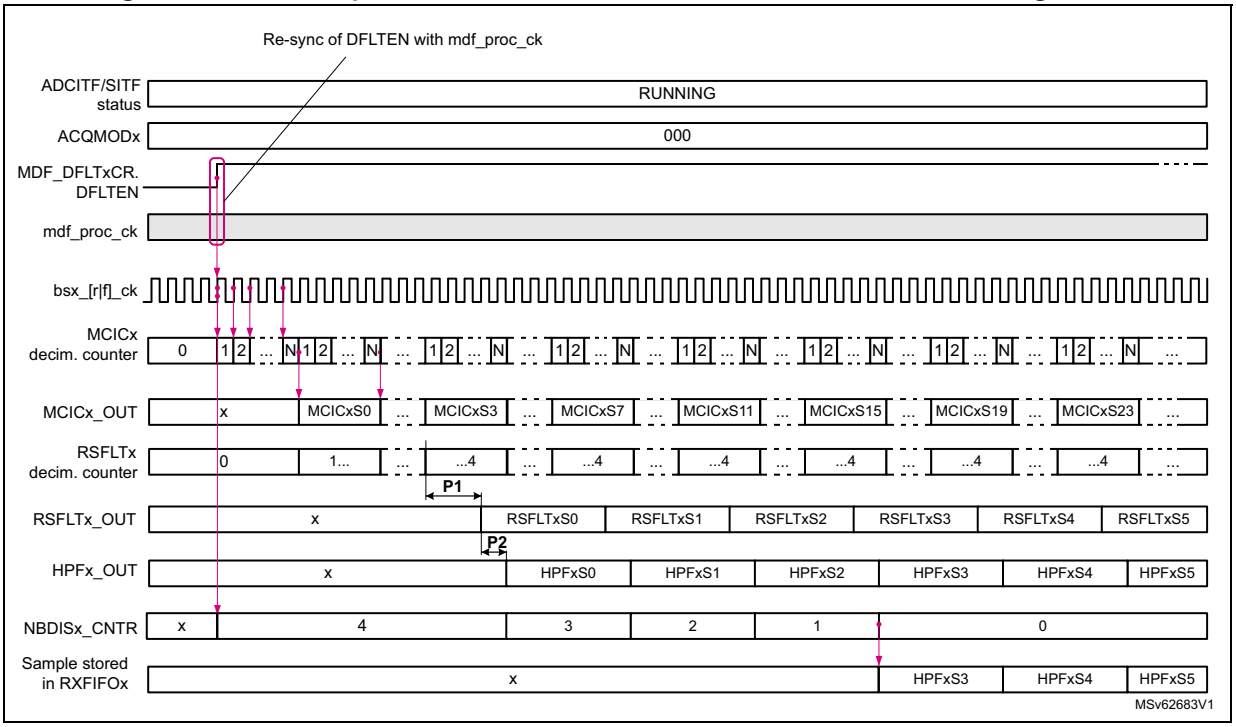
In the example shown in the figure below, the discard function is used to drop the first five samples provided by the digital filter (S1 to S5). The first sample transfered to the RXFIFO (or INT block if enabled) is S6.

Figure 368. Discard function example

Warning: All filters working in interleaved DMA mode must have the same NBDIS[7:0] value.

Data interface activation

The data interfaces are enabled by setting the corresponding SITFEN or ADCITFEN bit to 1. Once the digital filter is enabled, it receives the serial data from the external ΣΔ modulator or parallel internal data sources (ADC).



45.4.11 Start-up sequence examples

Figure 369 details an acquisition sequence start of a digital filter triggered by DFLTEN (ACQMOD[2:0] = 0), with NBDIS[7:0] = 3 (three samples to discard before acquisition).

The DFLTx is configured for audio application: MCIC, RSFLT and HPF activated.The data interface (SITFx or ADCITF) is assumed to be already activated.

Note: NBDIS[7:0] is set on purpose to a low value to simplify the drawing.

Figure 369. Start sequence with DFLTEN, in continuous mode, audio configuration

The DFLTEN bit is re-sampled into the MDF processing clock domain. When DFLTEN is detected high, the filter chain is enabled and the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

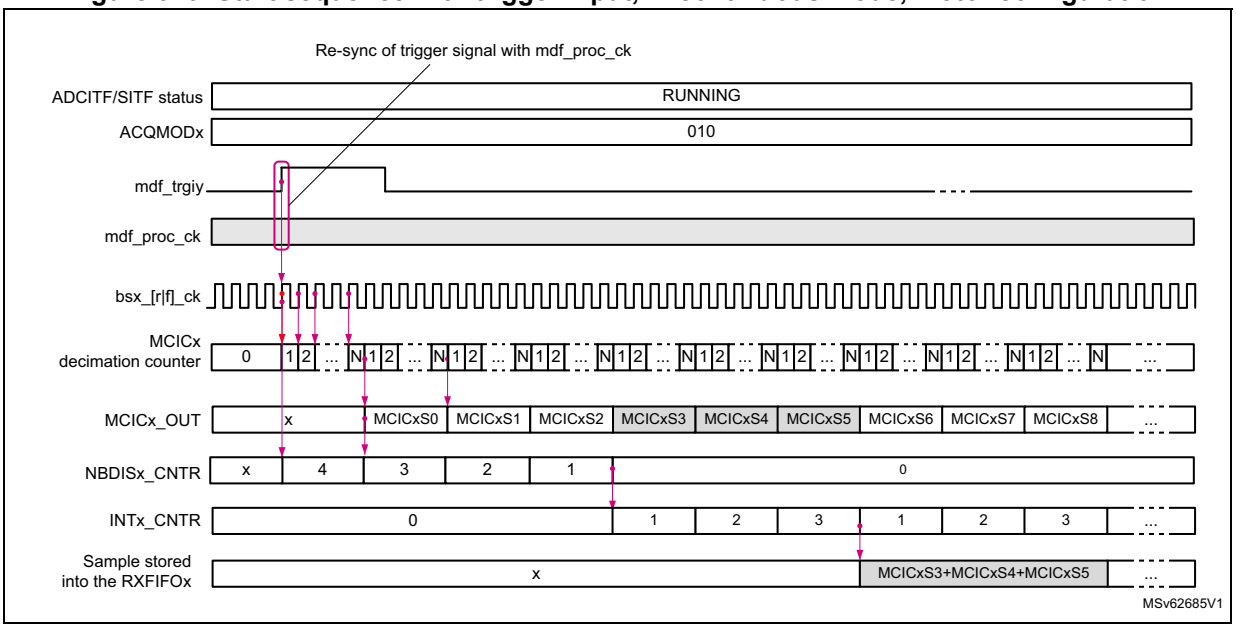
When the MCIC decimation counter reaches its programmed value N, a sample is available for the RSFLT.

The RSFLT processes all the samples provided by the MCIC and delivers a sample to the HPF every time it processes four samples (decimation by 4) The RSFLT needs up to 24 cycles of mdf_proc_ck clock before delivering a sample (P1).

The HPF processes all the samples provided by the RSFLT, but the NBDIS function prevents the data writing in the RXFIFO as long as NBDIS_CNTR does not reach 0. This counter is decremented every time the HPF delivers a sample.

When NBDIS_CNTR reaches 0, the samples provided by the HPF are stored into the RXFIFO.

The example shown in *Figure 370* is based in a motor-control filter configuration:



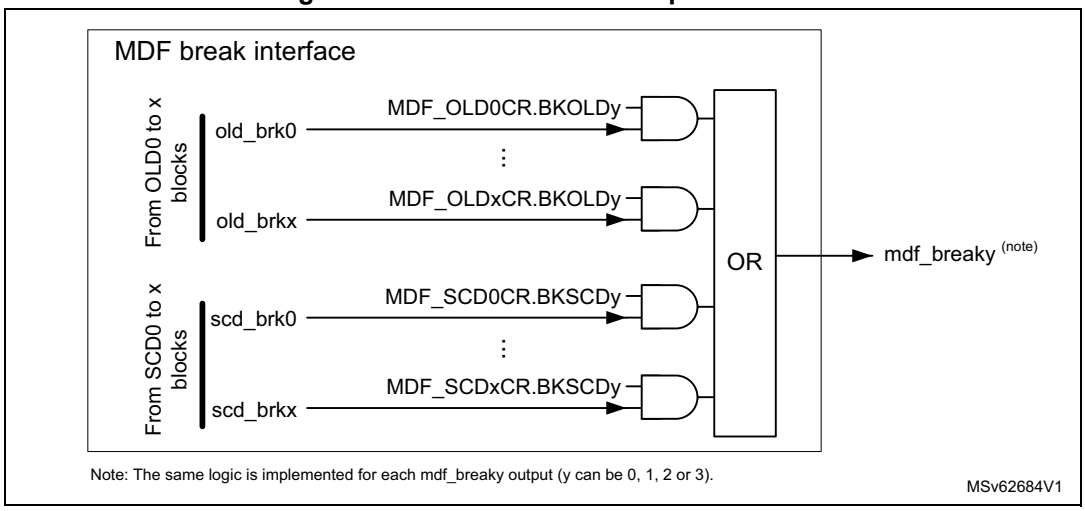
- MCIC and INT are enabled.
- SFLT and HPF are disabled.
- ACQMOD[2:0] is set to 1 and uses a mdf_trgiy input as trigger.
- NBDIS[7:0] is set to 3.
- INTVAL[6:0] is set to 2.

The mdf_trgiy input signal is re-sampled into the MDF processing clock domain to avoid any metastability issues. When the trigger condition is met (rising edge), the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

When the MCIC decimation counter reaches its programmed value N, a sample is available. The NBDIS function prevents the samples writing in the INT as long as NBDIS_CNTR does not reach 0. This counter is decremented every time the MCIC delivers a sample.

When NBDIS_CNTR reaches 0, the new samples are provided to the INT, that performs the integration of three consecutive samples and stores them into the RXFIFO.

Figure 370. Start sequence with trigger input, in continuous mode, motor configuration

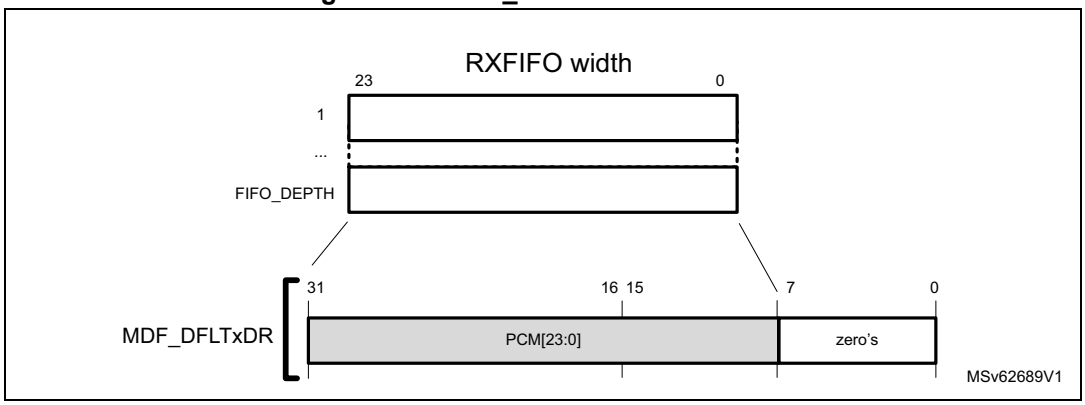


45.4.12 Break interface

The break interface merges the break events coming from the OLDx and SDCx blocks into four break signals connected to various peripherals of the product (see *Table 393* for details).

As shown in *Figure 371*, several blocks can share the same break line. A same block can also drive several break lines. The break interface is controlled via MDF_OLDxCR and MDF_SCDxCR.

Figure 371. Break interface simplified view



45.4.13 Data transfer to memory

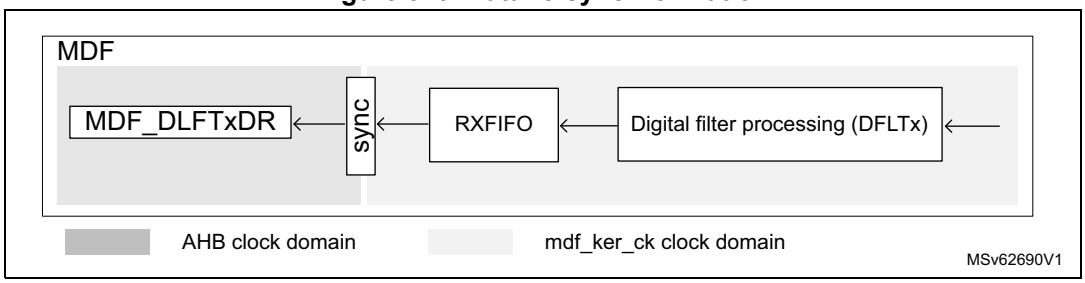
Data format

The samples processed by DFLTx are stored into a RXFIFO. The application can read the samples stored into the FIFOs via the *MDF digital filter data register x (MDF_DFLTxDR)*. The samples inside this register are signed and left aligned. The bit 31 always represents the sign.

The MDF provides 24-bit left-aligned data. Performing a 16-bit access to MDF_DFLTxDR allows the application to get the 16 most significant bits. Performing a 32-bit access to MDF_DFLTxDR allows the application to get a 24-bit data size.

Figure 372. MDF_DFLTxDR data format

Data re-synchronization



The samples stored into the RXFIFOs can be transferred into the memory by using either DMA requests or interrupt signaling.

Note: The RXFIFOs are located into the mdf_ker_ck clock domain, while MDF_DFLTxDR *are located into the mdf_hclk (AHB) clock domain.*

When the AHB clock is available, if MDF_DFLTxDR is empty and if a sample is available into the RXFIFO, this sample is transferred into MDF_DFLTxDR.

The sample transfer from the RXFIFO to MDF_DFLTxDR takes two periods of the AHB clock (mdf_hclk) and two periods of the mdf_ker_ck clock. The MDF inserts automatically wait-states if the application performs a read operation of MDF_DFLTxDR while the transfer of the new sample from the RXFIFO to MDF_DFLTxDR is not yet completed.

Figure 373. Data re-synchronization

The MDF can also combine two transfer types: the independent-transfer and the interleaved-transfer modes.

Independent-transfer mode

In this mode, each RXFIFO has its own DMA channel and its own FTHF flag event.

Both single and burst DMA transfers are supported in this mode, but the application must care about the following points:

- The RXFIFO must contain at least the same amount of samples than the burst size.
- The burst mode efficiency may be reduced due to the data re-synchronization explained in the previous section.

In addition, the application can select the RXFIFO threshold (FTH bit) to trigger the data transfer: a data transfer can be triggered as soon as the RXFIFO is not empty, or when the RXFIFO is half-full (containing depth / 2 samples).

For the DMA transfer, as soon as one of the RXFIFO reaches the threshold level, the corresponding DMA request is asserted in order to ask for data transfer. Successive DMA requests are performed as long as the corresponding RXFIFO is not empty.

The DMA mode of the RXFIFOx is enabled via the corresponding DMAEN bit in the *MDF digital filter control register x (MDF_DFLTxCR)*.

For the interrupt signaling, the following cases must be considered:

- If FTH = 0, as soon as a data is available in MDF_DFLTxDR, the corresponding FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as MDF_DFLTxDR is read.
- If FTH = 1, as soon as one of the RXFIFO reaches the threshold level and a data is available into MDF_DFLTxDR, the corresponding FTHF is set, allowing the generation of an interrupt. The FTHF flag is released as soon as one data is read. FTHF is set again if the threshold condition is met again. In this mode, every time an interrupt occurs, the application is supposed to read FIFO_SIZE / 2 data.

The independent-transfer mode must be used when the sample rates provided by each filter paths are not perfectly synchronous, or when the streams are independent. This situation may occur for example:

- when SITF is in SLAVE mode and each external sensor provides its own sampling clock

- when the decimation ratios of the DFLTx are not the same
- when all the streams are not starting at the same time

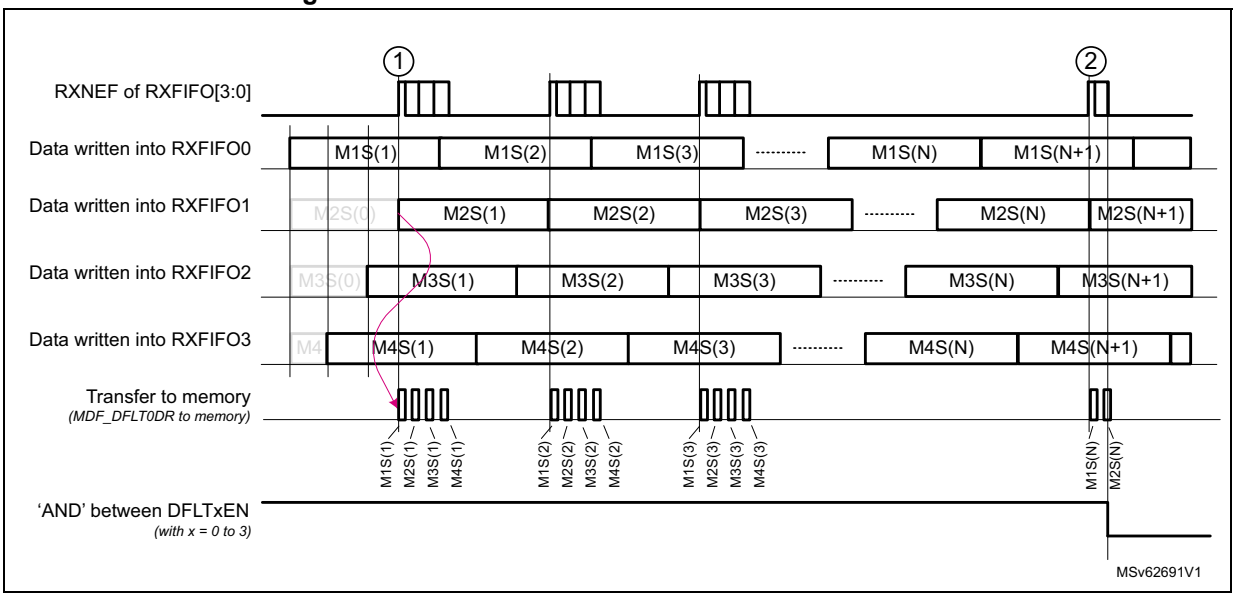
Interleaved-transfer mode

This mode optimizes the DMA request resources by sharing a single DMA request with several RXFIFOs.

Only single DMA transfers are supported in this mode.

In interleaved-transfer mode, FTH cannot be used and only the FTHF of RXFIFO0 is available for the interrupt signaling.

For the DMA transfer, when all the RXFIFOs working in interleaved-transfer mode are not empty, some DMA requests are generated in order to read sequentially one sample of each RXFIFOs, via MDF_DFLT0DR.



For the RXFIFOs working in interleaved-transfer mode, the DMA channel is enabled by setting to 1 DMAEN in MDF_DFLT0DR and by defining the amount of RXFIFOs working in interleaved mode via ILVNB[3:0]. DMAEN for the other RXFIFOs working in interleaved-transfer mode (RXFIFO 1 to ILVNB[3:0]) are not taken into account.

Figure 374 shows four RXFIFOs working in interleaved-transfer mode. Each RXFIFO has a delay due to the programming of the DLY block.

When all the RXFIFOs have at least one sample available (in this example the last FIFO receiving a sample is RXFIFO1), the MDF requests the data transfer to the memory (see 1 in *Figure 374*). In this figure, the DMA is assumed to be used for the data transfer to memory.

The acquisition can be simply stopped by setting DFTLEN to 0 for one of the filter configured in interleaved-transfer mode. In the example, when a DFLTEN is set to 0 (see 2 in *Figure 374*), the transfer to memory is immediately stopped. Samples M2S(N), M3S(N) and M4S(N) may be lost.

Figure 374. Data transfer in interleaved-transfer mode

In interrupt mode, when all the RXFIFOs working in interleaved-transfer mode have a data ready, the FTHF flag of RXFIFO0 is asserted to allow the interrupt generation. The application is then supposed to read sequentially one sample of each RXFIFOs, via MDF_DFLT0DR. The FTHF event is released when the first data is read.

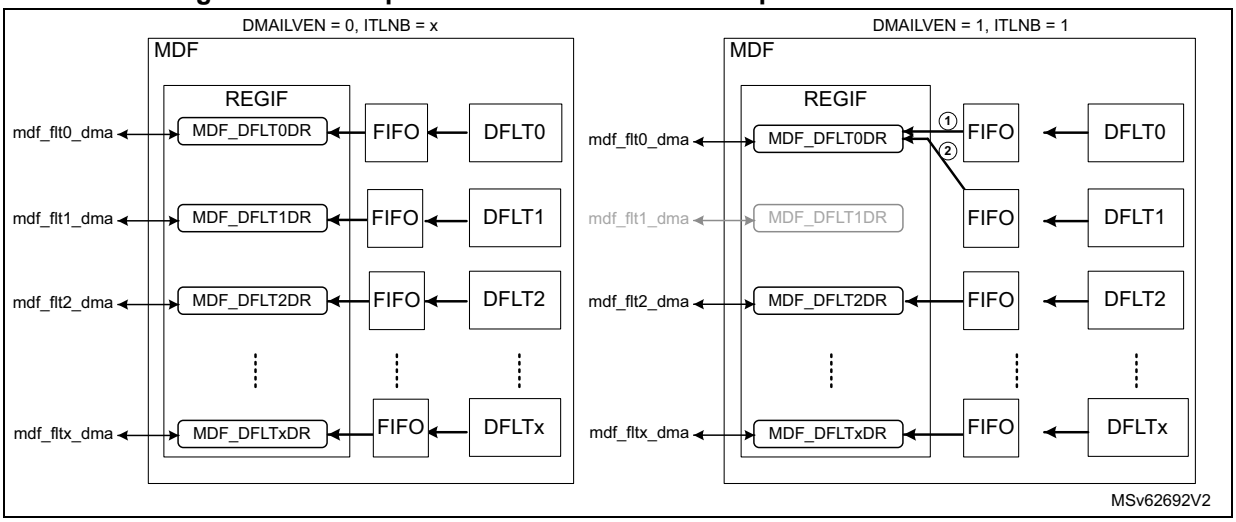
For the RXFIFOs working in interleaved-transfer mode, the interrupt mode is enabled by setting FTHIE to 1 in MDF_DFLT0DR and by defining the amount of RXFIFOs working in interleaved-transfer mode via ILVNB[3:0]. FTHIE of the other RXFIFOs working in interleaved-transfer mode (RXFIFO1 to ILVNB[3:0]) are not taken into account.

The interleaved-transfer mode can only be applied starting at RXFIFO0 up to RXFIFOk. The number of RXFIFOs working in interleaved-transfer mode are defined by ILVNB[3:0].

When ILVNB[3:0] = 0, all RXFIFOs work in independent-transfer mode.

The interleaved-transfer mode can be used only for digital filters delivering samples perfectly synchronous each other. This is typically the case of sound capture with an array of digital microphones sharing the same bitstream clock.

Caution: To make the MDF working properly in interleaved-transfer mode, the following rules must be respected:



- All filters working in interleaved-transfer mode must be all synchronized together, meaning that all filters must select the same ACQMOD[2:0] (must be equal to 010 or 011), the same trigger source and the same trigger sensitivity.
- All filters working in interleaved-transfer mode must have the same configuration.
- All sensors providing the data for the filters working in interleaved-transfer mode must use the same bitstream clock frequency.
- The maximum delay difference applied with SPKDLY[6:0] for the filters working in interleaved-transfer mode must remain strictly lower than the RXFIFO depth. Normally this delay does not need to exceed one T_{PCM} period.

Note: Both independent- and interleaved-transfer modes can work in parallel: for example, the first RXFIFOs (RXFIFO0 to RXFIFOk) may work in interleaved-transfer mode when the others (RXFIFO(k+1) to RXFIFO(N)) works in independent-transfer mode.

If the AHB clock is not present when a data transfer must be performed, the MDF first requests the AHB clock (refer to Section 45.4.5: Clock generator (CKGEN) for details).

The figure below shows the data path for a configuration in independent-transfer mode (left-hand figure) and a configuration mixing both independent- and interleaved-transfer modes (right-hand figure).

Figure 375. Data path for interleaved- and independent-transfer modes

In the right-hand figure, the DFLT0 and DFLT1 filters are configured in interleaved-transfer mode. For those filters, FTH is no longer taken into account by the hardware. The samples provided by DFLT0 and DFLT1 are read from MDF_DFLT0DR. When both RXFIFOs are no longer empty, the MDF generates two DMA requests to read the sample from DFLT0 and the sample from DFLT1. If both RXFIFOs are not empty again, the same sequence is triggered.

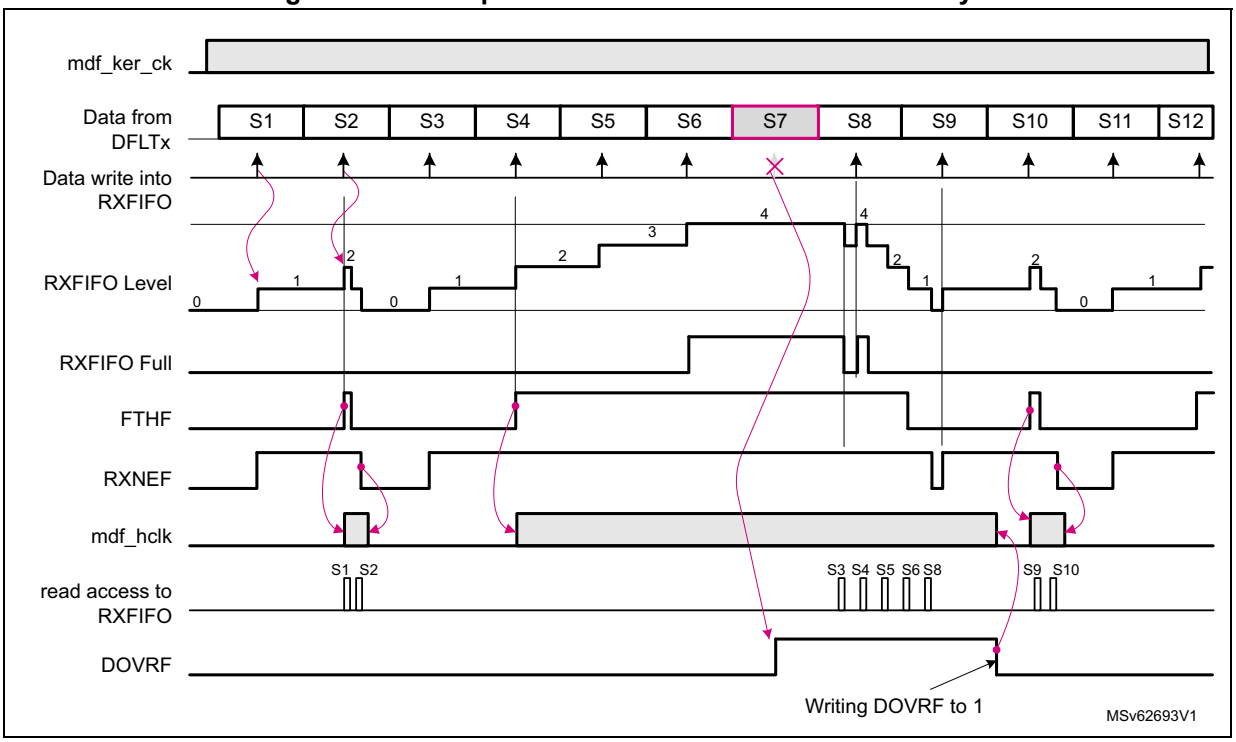
Note: When one of the filter working in interleaved-transfer mode is disabled, the data transfer to memory of all filters in interleaved-transfer mode is stopped immediately as well.

RXFIFO overrun

A RXFIFO overrun condition is detected when the RXFIFO is full and a new sample from the DFLTx must be written.

In this case, DOVRF is set and the new sample is dropped. When the RXFIFO has at least one location available, the new incoming sample is written into the RXFIFO.

Figure 376 shows an example based on a RXFIFO depth of four words and FTH set to 1, so that FTHF goes to 1 when the RXFIFO is half-full.



The S7 sample is lost due to an overrun: the RXFIFO is full while S7 must be written into the RXFIFO. The S7 write operation is not performed. DOVRF is set to 1 at the moment where the write operation was expected. The overflow event remains to 1 as long as it is not cleared by the application.

In this example, DOVRIE is set to 1 to have an interrupt if an overrun condition is detected.

After the S7 sample, the application manages to read data from the RXFIFO and the MDF can write the S8 sample and consecutive. Later, the application clears DOVR, allowing the detection of a new overrun situation.

In the mdf_hclk line, the gray boxes indicate that the MDF requested the AHB clock. The figure below shows the AHB clock available only when the MDF requests it. In real applications, the AHB clock may also be present if the MDF does not request it.

Figure 376. Example of overflow and transfer to memory

Note: If the MDF works in interleaved-transfer mode, the application must check the overrun status of all RXFIFOs that works in interleaved-transfer mode.

45.4.14 Autonomous mode

The MDF can work even if the AHB bus clock is not available (Stop modes). The MDF uses the AHB clock only for the register interface. All the processing part is clocked with the kernel clock.

In Stop mode, the MDF receives a kernel clock if the following conditions are met:

- The MDF autonomous mode is enabled in the RCC.
- The selected kernel clock source is taken from an oscillator available in Stop mode.

In Stop mode, the MDF receives the AHB clock if the following conditions are met:

- The MDF autonomous mode is enabled in the RCC.
- The MDF requests the AHB clock, in the following situations:
  - when the MDF must transfer data into the memory via the DMA

    The data are directly transferred to the SRAM thanks to the DMA while the product remains in Stop mode. The AHB clock request is maintained until the DMA transfer is completed.
  - when the MDF must generate an interrupt

    An interrupt generally wakes up the device from Stop mode, as an action from the application is needed. Once the AHB clock is available, the interrupt is

generated.The AHB clock request is maintained as long as an enabled interrupt flag is active. More precisely, when an interrupt must be generated, the MDF requests the AHB clock.

45.4.15 Register protection

The MDF embeds some hardware protection to prevent invalid situations. The table below shows the list of write-protected and unprotected fields.

Table 404. Register protection summary

Registers	Unprotected fields	Write-protected fields	Write-protection condition
MDF global control register (MDF_GCR)	TRGO	ILVNB[3:0]	DFLTACTIVE0 = 1
MDF clock generator control register (MDF_CKGCR)	CKGDEN CCK0EN CCK1EN	PROCDIV[6:0], CCKDIV[3:0], CKGMOD, TRGSRC[3:0], TRGSENS, CCK[1:0]DIR	CKGACTIVE = 1
MDF serial interface control register x (MDF_SITFxCR)	SITFEN	STH[4:0], SITFMOD[1:0], SCKSRC[1:0]	SITFACTIVEx = 1
MDF bitstream matrix control register x (MDF_BSMXxCR)	-	BSSEL[4:0]	DFLTACTIVEx = 1 or SCDACTIVEx = 1 or OLDACTIVEx = 1
MDF digital filter control register x (MDF_DFLTxCR)	DFLTEN	NBDIS[7:0], TRGSRC[3:0], TRGSENS, FTH, DMAEN, SNPSFMT, ACQMOD[2:0]	DFLTACTIVEx = 1
MDF digital filter configuration register x (MDF_DFLTxCICR)	SCALE[5:0]	MCICD[8:0], CICMOD[2:0], DATSRC[1:0]	
MDF reshape filter configuration register x (MDF_DFLTxRSFR)	-	All fields	
MDF integrator configuration register x (MDF_DFLTxINTR)	-	All fields	
MDF out-of limit detector control register x (MDF_OLDxCR)	OLDEN	ACICD[4:0], ACICN[1:0],THINB BKOLD[3:0]	OLDACTIVEx = 1
MDF OLDx low threshold register x (MDF_OLDxTHLR)	-	All fields	
MDF OLDx high threshold register x (MDF_OLDxTHHR)	-	All fields	
MDF delay control register x (MDF_DLYxCR)	-	SKPDLY[6:0]	SKPBF = 1
MDF short circuit detector control register x (MDF_SCDxCR)	SCDEN	BKSCD[3:0], SCDT[7:0]	SCDACTIVEx = 1
MDF DFLTx interrupt enable register x (MDF_DFLTxIER)	All fields	-	-

Table 404. Register protection summary (continued)

Registers	Unprotected fields	Write-protected fields	Write-protection condition
MDF DFLTx interrupt status register x (MDF_DFLTxISR)	All fields	-	-
MDF offset error compensation control register x (MDF_OECxCR)	OFFSET[25:0]	-	-

All the MDF processing is performed in the mdf_proc_ck clock domain. For that reason, enabling or disabling a MDF sub-block may take some time due to the re-synchronization between the AHB clock domain and the mdf_proc_ck clock domain. XXXACTIVE flags are available to allow the application to check that the synchronization between the two clock domains is completed.

To change a write-protected bitfield, the application must follow this sequence:

1. Set the enable bit of the sub-block to 0.
2. Wait for corresponding flag XXXACTIVE = 0.
3. Modify the wanted fields.
4. Set the enable bit of the sub-block to 1.

Refer to the description of each sub-block for more details.

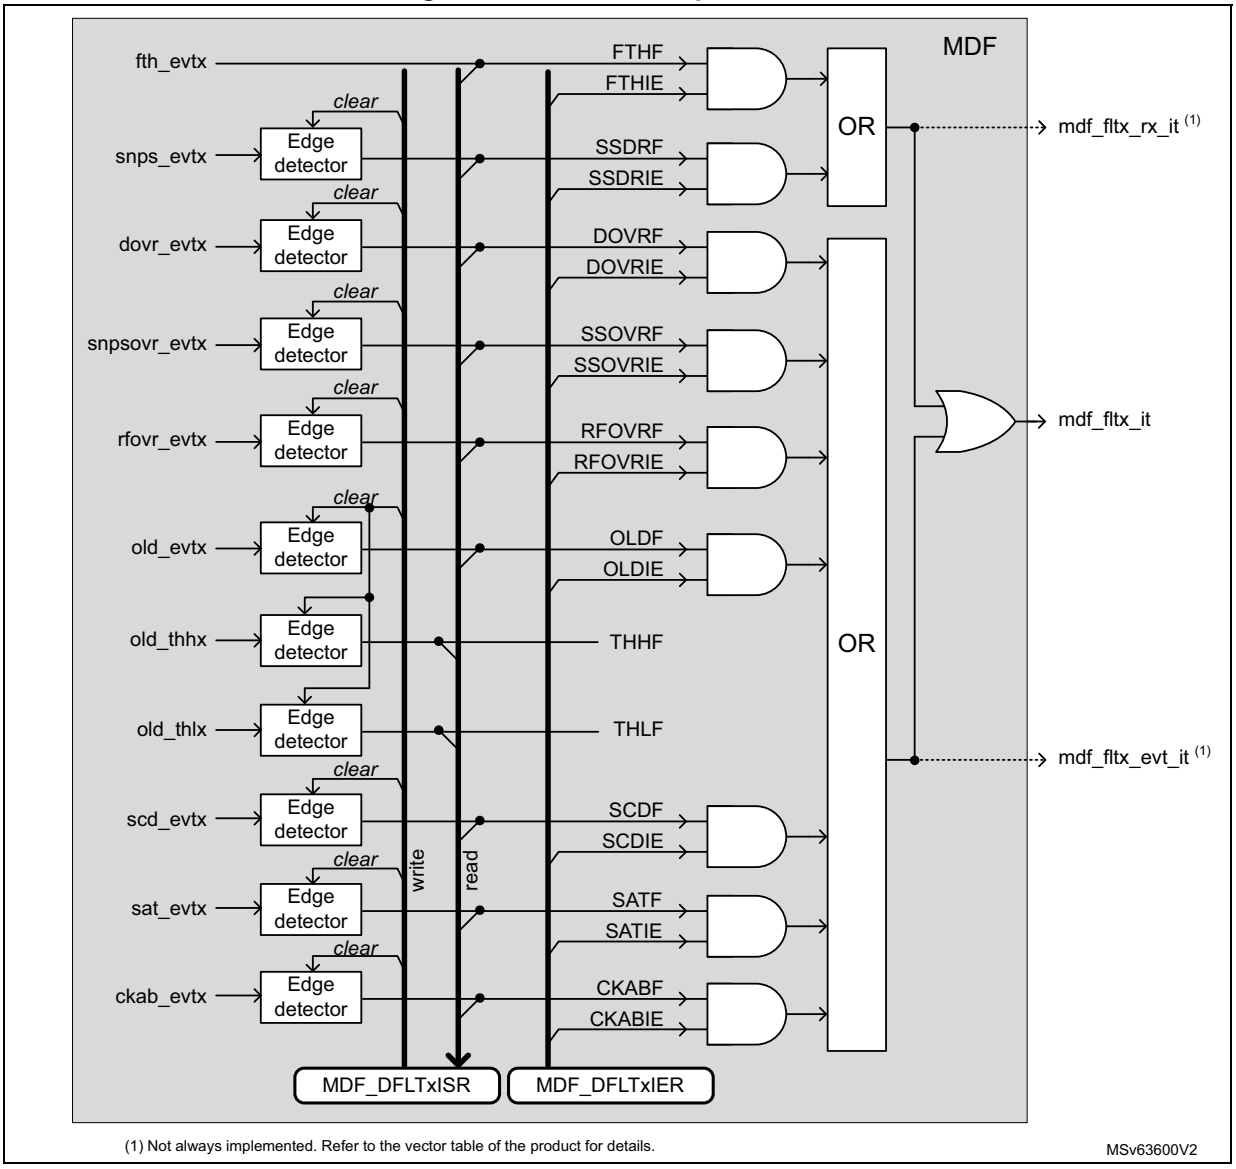
45.5 MDF low-power modes

Table 405. Effect of low-power modes on MDF

Mode	Description
Sleep	No effect. MDF interrupts cause the device to exit Sleep mode.
Stop(1)	The MDF registers content is kept. If the MDF is clocked by an internal oscillator available in Stop mode, the MDF remains active. The interrupts cause the device to exit Stop mode.
Standby	The MDF is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 45.3: MDF implementation* for details about Stop modes supported by the MDF.

45.6 MDF interrupts



To increase the CPU performance, the MDF offers the following interrupt lines per digital filter:

- receive interrupt MDF_FLTx_RX (mdf_fltx_rx_it)
- event interrupt MDF_FLTx_EVT (mdf_fltx_evt_it)
- a combination of both interrupts MDF_FLTx (mdf_fltx_it)

Note: Interrupts are not always connected to the device (see Section 45.3: MDF implementation for more details).
The status flags are available even if the corresponding interrupt enable flag is not enabled.

The interrupt interface is controlled via the *MDF DFLTx interrupt enable register x (MDF_DFLTxIER)* and the *MDF DFLTx interrupt status register x (MDF_DFLTxISR)*.

Figure 377. MDF interrupt interface

(1) Not always implemented. Refer to the vector table of the product for details.

MSv63600V2

The table below shows which interrupt line is affected by which event, and how to clear and activate each interrupt/event.

Table 406. MDF interrupt requests

Interrupt vectors		Interrupt event	Event flag	Event/interrupt clearing method	Exit Sleep mode	Exit Stop modes[1]	Exit Standby mode
MDF_FLTx[2]	MDF_FLTx_RX[3]	RXFIFO threshold reached	FTHF	Read MDF_DFLTxDR until RXFIFO level is lower than the threshold.	Yes	Yes	No
		Snapshot data ready	SSDRF	Write SSDRF to 1.			
	MDF_FLTx_EVT[4]	Snapshot data overrun	SSOVRF	Write SSOVRF to 1.			
		RXFIFO overrun	DOVRF	Write DOVRF to 1.			
		RSFLT overrun	RFOVRF	Write RFOVRF to 1.			
		Short-circuit detector	SCDF	Write SCDF to 1.			
		Saturation detection	SATF	Write SATF to 1.			
		Channel clock absence detection	CKABF	Write CKABF to 1.			
		Out-of-limit detector	OLDF	Write OLDF to 1.			
-	-		THHF	Write OLDF to 1.	-	-	-
-	-		THLF	Write OLDF to 1.	-	-	-

1. Refer to *Section 45.3: MDF implementation* for details.
2. MDF_FLTx vector corresponds to the assertion of mdf_fltx_it signal
3. MDF_FLTx_RX vector corresponds to the assertion of mdf_fltx_rx signal.
4. MDF_FLTx_EVT vector corresponds to the assertion of mdf_fltx_evt signal.

45.7 MDF application informations

45.7.1 MDF configuration examples for audio capture

Table 407 gives some examples of the MDF settings for the digital microphones, focusing on 16 and 48 kHz output data rate. In these examples, the following is expected:

- The INT block is bypassed (INTVAL = 0).
- The offset error compensation is disabled (OFFSET = 0).

Configurations #1 and #2 are for very low-power use-cases and have a reduced signal-to-noise ratio. The user must also insure that the selected digital microphone can work properly at 512 kHz. These configurations can be used for sound detection. The RSFLT is not used to reduce as much as possible the frequency of the kernel clock (mdf_ker_ck).

Configurations #3, #4, #9, #10, #11 give signal-to-noise ratios around 115 dB, with an ideal microphone model, with a sinus signal of 997 Hz. Using the RSFLT allows a good control on the in-band ripple and a good image rejection.

Configurations #7, #8, #10 give signal-to-noise ratio around 120 dB, with an ideal microphone model, using a sinus signal of 997 Hz.

Table 407. Examples of MDF settings for microphone capture

Configuration	mdf_ker_ck (MHz)	PROCDIV + 1	CCKDIV + 1	CIC order (1)	MCICD + 1	SCALE	RSFLTBYP	RSFLTD	HPFBYP	-	mdf_proc_ck (MHz)	Total dec. ratio	F_{RS} (kHz)	F_{MDF_CCKx} (MHz)	F_{PCM} (kHz)
#1	1.024	1	2	4	64	0x2D (- 8.5 dB)	1	x	x	=>	1.024	64	-	0.512	8
#2		1	2	5	32	0x2B (- 14.5 dB)						32	-		16
#3		1	2	5	16	0x01 (+ 3.5 dB)	0	0				64	32		8
#4	2.048	1	2	5	16	0x01 (+ 3.5 dB)	0	0			2.048	64	64	1.024	16
#5	3.072	1	6	5	8	0x0B (+ 33.6 dB)	0	0			3.072	32	32	0.512	8
#6		2	2	5	12	0x06 (+ 18.1 dB)						48	64	0.768	16
#7		1	2	5	24	0x2C (- 12 dB)						96		1.536	
#8	4.096	1	2	5	32	0x27 (- 26.6 dB)	0	0			4.096	128	64	2.048	16
#9	6.144	3	2	5	16	0x02 (+ 6.0 dB)	0	0			2.048	64	64	1.024	16
#10		2	2	5	24	0x2C (- 12 dB)					3.072	96		1.536	
#11		1	2	5	16	0x01 (+ 3.5 dB)					6.144	64	192	3.072	48
#12	7.680	1	2	5	20	0x2E (- 6.0 dB)	0	0			7.680	80	192	3.840	48

1. CICMOD = 100 for CIC order equal to 4. CICMOD = 101 for CIC order equal to 5.

45.7.2 Programming examples

This example describes how to capture sound from four microphones, assuming that each microphone pair shares the same data line. The MDF_SD0 and MDF_SD2 data lines are used. The microphone clock is provided by the MDF via MDF_CCK0 pin.

Table 408. Programming sequence

Operations	Comments
Adjust the proper kernel clock frequency via the RCC block	Assuming that the RCC is programmed to provide a kernel clock (mdf_ker_ck) of 12.288 MHz
Select the proper MDF kernel clock source via the RCC block	Refer to the RCC of the product.
Enable the MDF clocks via the RCC block	Refer to the RCC of the product.
Reset the MDF via the RCC block	Refer to the RCC of the product.
AFMUX programming	Program the AFMUX to select MDF_SD0, MDF_SD2 and MDF_CCK0 function.

Table 408. Programming sequence (continued)

Operations	Comments
Enable MDF processing clock: MDF_CKGCR = 0x0103 0023	PROCDIV = 1 (division by 2): mdf_proc_ck frequency is 6.144 MHz. CCKDIV = 3 (division by 4): MDF_CCK0 clock frequency is 1.536 MHz. The MDF_CCK0 pad is set in output and generates a clock so that the microphones can exit from low-power mode.
Serial interfaces configuration: MDF_SITF0CR = 0x0000 1F01 MDF_SITF2CR = 0x0000 1F01	SCKSRC = 0 to select MDF_CCK0 as serial clock. SIFTMOD = 0 to select LF_MASTER mode. Clock absence feature is not working in this mode. The serial interfaces are enabled.
Bitstream matrix configuration: MDF_BSMX0CR = 0x0000 0000 MDF_BSMX1CR = 0x0000 0001 MDF_BSMX2CR = 0x0000 0004 MDF_BSMX3CR = 0x0000 0005	DFLT0 filter takes the bitstream of SITF0, sampled on rising edge. DFLT1 filter takes the bitstream of SITF0, sampled on falling edge. DFLT2 filter takes the bitstream of SITF2, sampled on rising edge. DFLT3 filter takes the bitstream of SITF2, sampled on falling edge.
Filters configuration (CIC): MDF_DFLT0CICR = 0x02C0 1750 MDF_DFLT1CICR = 0x02C0 1750 MDF_DFLT2CICR = 0x02C0 1750 MDF_DFLT3CICR = 0x02C0 1750	SCALE = 0x2C (- 12 dB) to avoid any saturation MCICD = 0x17 (decimation by 24) CICMOD = 5 to select a $Sinc^5$ DATSCR = 0 to select data coming from BSMX
Filters configuration (RSFLT and HPF): MDF_DFLT0RSFR = 0x0000 0100 MDF_DFLT1RSFR = 0x0000 0100 MDF_DFLT2RSFR = 0x0000 0100 MDF_DFLT3RSFR = 0x0000 0100	HPFC = 1: cut-off frequency of 16 kHz * 0.00125 = 20 Hz HPFBYP = 0: HPF not bypassed RSFLTD = 0: RSFLT decimates by 4 RSFLTBYP = 0: RSFLT is not bypassed
Filters configuration (INT): MDF_DFLT0INTR = 0x0000 0000 MDF_DFLT1INTR = 0x0000 0000 MDF_DFLT2INTR = 0x0000 0000 MDF_DFLT3INTR = 0x0000 0000	INTVAL = 0: INT filter not used Other parameter is not significant.
Micro delay adjust: MDF_DLY0CR = 0x0000 0005 MDF_DLY0CR = 0x0000 0012 MDF_DLY0CR = 0x0000 0023 MDF_DLY0CR = 0x0000 0000	Initial micro-delay for each microphone, values just given as example
Offset error correction: MDF_OEC0CR = 0x0000 0000 MDF_OEC1CR = 0x0000 0000 MDF_OEC2CR = 0x0000 0000 MDF_OEC3CR = 0x0000 0000	No correction. DC offset is removed by HPF.

Table 408. Programming sequence (continued)

Operations	Comments
Short circuit detection: MDF_SCD0CR = 0x0000 0000 MDF_SCD1CR = 0x0000 0000 MDF_SCD2CR = 0x0000 0000 MDF_SCD3CR = 0x0000 0000	SCD function for each filter is disabled.
Enable interrupt events: MDF_DFLT0IER = 0x0000 0202 MDF_DFLT1IER = 0x0000 0202 MDF_DFLT2IER = 0x0000 0202 MDF_DFLT3IER = 0x0000 0202	Enable the interrupt event the application wants to handle. In this example, the SATIE and DOVRIE bits are set to 1 to have an interrupt if a saturation or an data overflow occurs.
Digital filter control: MDF_DFLT0CR = 0x0000 0027 MDF_DFLT1CR = 0x0000 0027 MDF_DFLT2CR = 0x0000 0027 MDF_DFLT3CR = 0x0000 0027 Wait for DFLTACTIVE = 0 for the filters	NBDIS = 0: no samples discarded TRGSRC = 0: TRGO selected as trigger source TRGSENS = 0: Trigger on rising edge ACQMOD = 2: Synchronous continuous acquisition mode DMAEN = 1: DMA interface enabled DFLTEN = 1: digital filter enabled
Clear status flags: MDF_DFLT0ISR = 0x0000 0FFF MDF_DFLT1ISR = 0x0000 0FFF MDF_DFLT2ISR = 0x0000 0FFF MDF_DFLT3ISR = 0x0000 0FFF	Clear all the status flags before running the filters.
Program the DMA Enable the DMA	The DMA must be programmed in order to read the data inside MDF_DFLT0DR every time a DMA request is generated. Note that when the MDF is in interleaved acquisition mode, data of filters 0, 1, 2, and 3 are read via MDF_DFLT0DR register.
Start acquisition: MDF_GCR = 0x0000 0031	ILVNB = 3: interleaved mode with DFLT0,1,2, and 3 TRGO = 1 to trigger the acquisition of all filters waiting for TRGO rising edge event

45.7.3 Connection examples

Figure 378 shows simple connection examples of the MDF to external sensors:

- Picture on the left: four digital microphones connected to the MDF

  In this connection, DMIC1 is intended to be used alone. This is why it uses a dedicated clock (MDF_CCK0). DMIC1 is also connected to a dedicated data line in case the application intends to power-down DMIC2/3/4, when only DMIC1 is used. If the application keeps DMIC2/3/4 powered, DMIC2 and DMIC1 can share the same data line, reducing the connection to four I/Os.

  If the power consumption is not an issue, when a single microphone is used, all the microphones can be connected to the same common clock (MDF_CCK0) and each

microphone pair can share the same data line. In this case, only three I/Os are required.

In this example, the data transfer to memory can be performed either using the interleaved- or the independent-transfer mode.

- Picture in the center: sensor providing several data lines with a common clock

  Each data line can represent different parameters (such as current or voltage). The common clock can be provided either by the sensor or by the MDF. The data line can be shared or not by two sensors if the sensor allows it. In the figure below, the sensor does not allow the sharing of the data lines.

  In this example, the data transfer to memory can be performed either using the interleaved- or independent-transfer mode.

- Picture on the right: two independent sensors connected to the MDF

  Each of them has its dedicated clock and data lines. In this case, the data transfer to memory must use the independent-transfer mode.

Figure 378. Sensor connection examples

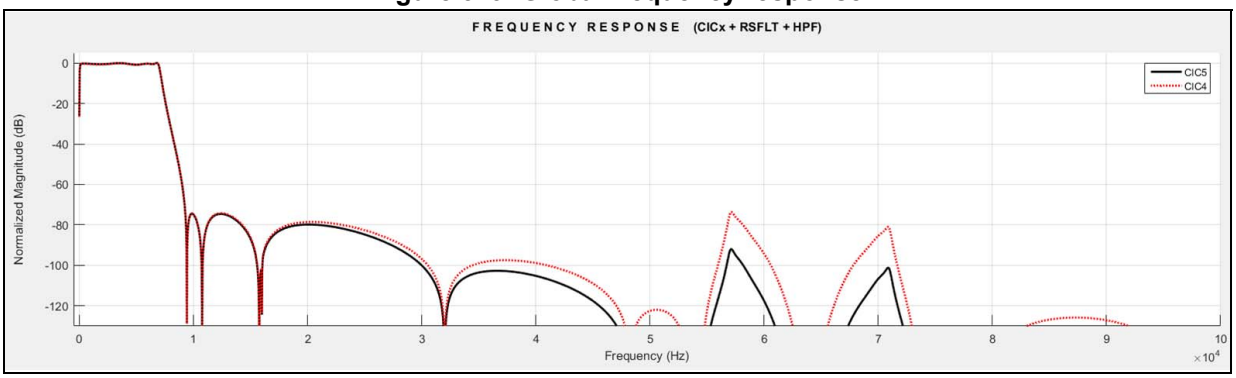
45.7.4 Global frequency response

Figure 379 shows the global frequency response for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enable with a cut-off frequency of 40 Hz

The figure below shows the theoretical frequency response using a CIC4 and a CIC5.

Figure 379. Global frequency response



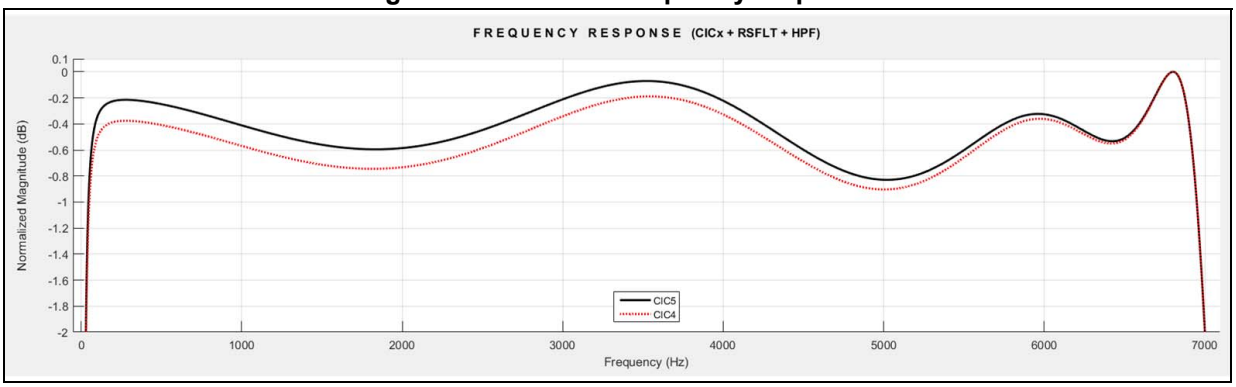


Figure 380 shows the in-band ripple for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enable with a cut-off frequency of 20 Hz

The resulting in-band ripple is ± 0.41 dB for CIC5, and ± 0.45 for CIC4.

The -3 dB cut-off frequency is 7061 Hz.

Figure 380. Detailed frequency response

45.7.5 Total MDF gain

This section details how to compute the signal level provided by the MDF according to the filter settings. The formula does not take into account the filters transfer function.

A signal level may be expressed in dBFS (decibel full scale). A 0 dBFS level is assigned to the maximum possible digital level. For example, a signal that reaches 50 % of the maximum level, has a - 6 dBFS level (6 dB below full scale).

For example, for the MDF offering a final data width of 24 bits, a signal having an amplitude of 2 * 10^6 LSB has a level of:

$$20 \times \log_{10}\left(\frac{2 \times 10^6}{2^{(24-1)}}\right) = -12.45 \text{ dBFS}$$

In addition, the data size of a signal having an amplitude (Amp) expressed in LSB is given by:

$$DS = \left(\frac{\ln(Amp)}{\ln(2)} + 1\right) \text{ bits}$$

One bit need to be added for negative values.

So a signal having an amplitude of 2 * 10^6 LSB, has a data size of 21.9 bits.

CIC gain

The CIC gain (G_{CIC} and GdB_{CIC}) can be deduced from the following formula giving data size in bits (DS_{CIC}).

$$DS_{CIC} = (N \times \log_2(D1)) + DS_{IN}$$

And the bit growth is:

$$BG_{CIC} = (N \times \log_2(D1))$$

where N represents the CIC order (selected by CICMOD[2:0]), and D1 is the decimation ratio (given by MCICD).

DS_{IN} represents the data size (in bits) of the input signal.

Warning: DS_{CIC} is very important for CIC filters. In order to work fine, DS_{CIC} must not exceed 26 bits.

$$G_{CIC} = 2^{(BG_{CIC})} = (D1)^N$$

which gives, in decibels:

$$GdB_{CIC} = 20 \times \log_{10}((D1)^N)$$

Note: The same formulas are valid for the ACIC.

Data size at SCALE output

The data size at SCALE output (including the CIC gain) is a key information as the RSFLT starts to have some saturations if the peak-to-peak signal amplitude at SCALE output is higher than 22 bits.

If the RSFLT is bypassed, then a peak-to-peak signal amplitude of 24 bits is accepted. The resulting data size is given by:

$$DS_{SCALE} = N \times \log_2(D1) + \log_2\left(10^{\frac{GDB_{SCALE}}{20}}\right) + DS_{IN}$$

The data size at SCALE output (DS_{SCALE}) is expressed in bits and GdB_{SCALE} represents the gain selected by SCALE[5:0], in dB.

RSFLT gain

The RSFLT gain in the useful bandwidth is typically 9.5 dB, but due to ripple a margin of about ± 0.5 dB must be considered. Typically, the RSFLT increases the bit size by BG_{RSFLT}:

$$BG_{RSFLT} = 10^{\frac{9.5\ dB}{20}} = 2.98 = 1.6\ bits$$

INT gain

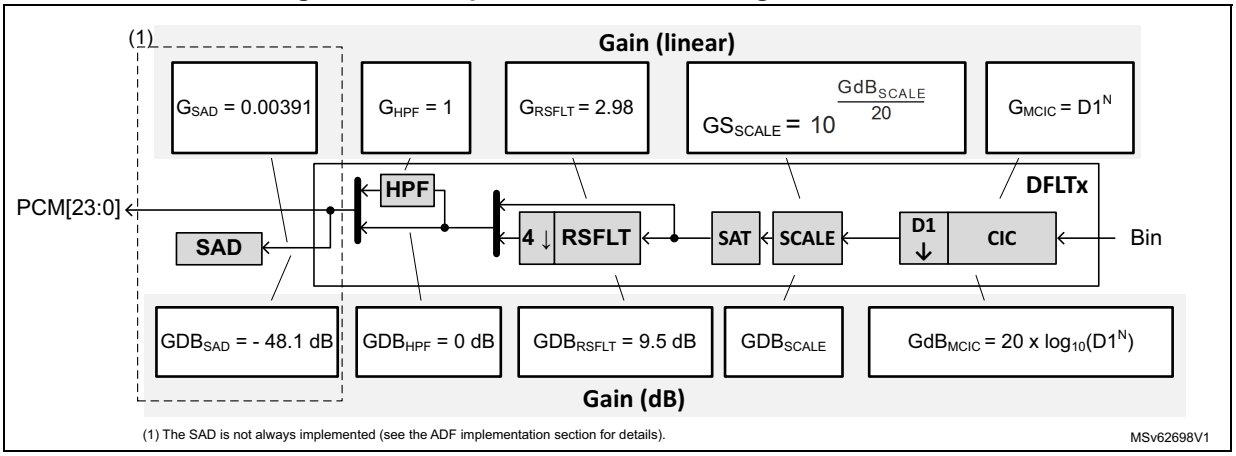
The INT block can also introduce a gain if the rescaling value is different from the integration value.

$$G_{INT} = \frac{IVAL}{IDIV}$$

and:

$$GdB_{INT} = 20 \times \log_{10}\left(\frac{IVAL}{IDIV}\right)$$

The bit growth of the INT is then given by the following formula:



$$BG_{INT} = \log_2\left(\frac{IVAL}{IDIV}\right)$$

IVAL represents the integration value selected by INTVAL[6:0], and IDIV represents the integrator output division selected by INTDIV[1:0].

Note: The HPF filter has a gain of 0 dB.

The figure below shows a simplified view of the filter path, and gives for each significant component the expression of the bit growth and the gain.

Figure 381. Simplified DFLT view with gain information

The table below summarizes the final data size for different filter configurations.

Table 409. Output signal levels

Filter configurations	Final signal level (dBFS)	Final signal size (bits)
CIC + RSFLT (+ HPF)	$SdB_{OUT} = 20 \times \log_{10}\left(\frac{2^{DS_{OUT}}}{2^{24}}\right)$	$DS_{OUT} = DS_{SCALE} + 1.6$ bits DS_{SCALE} must be lower than 22 bits.
CIC + RSFLT (+ HPF) + INT		$DS_{OUT} = DS_{SCALE} + BG_{INT} + 1.6$ bits DS_{SCALE} must be lower than 22 bits.
CIC (+ HPF) + INT		$DS_{OUT} = DS_{SCALE} + BG_{INT}$ DS_{SCALE} must be lower than 24 bits.

Example using the main filter chain

If the MDF filter is programmed as follows:

- The input signal is coming from a serial interface (DS_{IN} = 1 bit).
- CIC order = 5 (N), with a decimation value of 24 (D1).
- SCALE[5:0] is set to -12 dB.
- RSFLT is enabled and the decimation by four is enabled.
- HPF is enabled.
- INT is disabled.

Check first the data size at CIC output:

$$DS_{CIC} = (5 \times \log_2(24)) + 1 \text{ bit} = 23.92 \text{ bits}$$

The size is lower than 26 bits, so the CIC works in good conditions.

The data size at CIC output is very close to 24 bits, so the SCALE must be adjusted in order to provide a signal 22 bits max to the RSFLT. An attenuation of 12 dB is needed.

Then the signal level provided to the RSFLT is:

$$DS_{SCALE} = DS_{CIC} + \log_2\left(10^{\frac{-12}{20}}\right) = 23.92 - 1.99 = 21.93 \text{ bits}$$

At the end, the final signal amplitude is:

$$DS_{OUT} = DS_{SCALE} + 1.6 \text{ bits} = (21.93 + 1.6) = 23.52 \text{ bits}$$

or

$$SDB_{OUT} = 20 \times \log_{10}\left(\frac{2^{23.52}}{2^{24}}\right) = -2.84 \text{ dBFS}$$

The RSFLT ripple a margin of about ± 0.41 dB (in this configuration) must be considered.

Example using the OLD filter chain

In the following example, the application wants to trigger an OLD event when the voltage coming from a shunt resistor reaches ± 200 mV.

Hypothesis:

- The ΣΔ sensor is specified to support a full-scale signal of ± 350 mV.
- The ACIC decimation ratio (D2) is fixed to 32.
- The ACIC order (N) is fixed to 3.

The ΣΔ sensor provides a full-scale digital signal (amplitude of one bit) for a signal higher or equal to ± 350 mV. If the input signal is equal 200 mV, then the digital signal amplitude provided by the sensor is 200 / 350 = 0.571.

The gain of the ACIC filter is:

$G_{CIC} = (D2)^N = 32^3 = 32768$

A signal having an amplitude of 200 mV at sensor input has then an amplitude of about 32768 * 0.571 = 18725 LSB at ACIC output.

OLDTHH must be set to 18725 and OLDTHL must be set to -18725.

45.8 MDF registers

All the MDF registers must be accessed either in word (32-bit) or half-word (16-bit) formats.

The registers are described for the MDF instance having the biggest number of filters. For registers related to filters, the number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

45.8.1 MDF global control register (MDF_GCR)

Address offset: 0x000

Reset value: 0x0000 0000

This register is used for controls common to all digital filters.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ILVNB[3:0]				Res.	Res.	Res.	TRGO
								rw	rw	rw	rw				rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **ILVNB[3:0]**: Interleaved number

This bitfield is set and reset by software. it enables or disables the interleaved-transfer mode and defines how many digital filters work in this mode.
This bitfield cannot be changed when DFLTEN = 1 in MDF_DFLT0CR.
0000: Interleaved-transfer mode disabled
0001: Data from DFLT0 and DFLT1 are interleaved.
0010: Data from DFLT0, DFLT1 and DFLT2 are interleaved.
...
1111: Data from DFLT0 to DFLT15 are interleaved.

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **TRGO**: Trigger output control

This bit is set by software and reset by hardware. It is used to start the acquisition of several filters synchronously. It is also able to synchronize several MDF together by controlling the mdf_trgo signal.
0: Write 0 has no effect. Read 0 means that the trigger can be set again to 1.
1: Write 1 generates a positive pulse on mdf_trgo signal and triggers the acquisition on the enabled filters having ACQMOD[2:0] = 0x1 and selecting TRGO as trigger. Read 1 means that the trigger pulse is still active.

45.8.2 MDF clock generator control register (MDF_CKGCR)

Address offset: 0x004

Reset value: 0x0000 0000

This register is used to control the clock generator. The mdf_proc_ck clock must be enabled before enabling other MDF parts.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CKGACTIVE	PROCDIV[6:0]							Res.	Res.	Res.	Res.	CCKDIV[3:0]			
r	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRGSRC[3:0]				Res.	Res.	Res.	TRGSENS	Res.	CCK1DIR	CCK0DIR	CKGMOD	Res.	CCK1EN	CCK0EN	CKGDEN
rw	rw	rw	rw				rw		rw	rw	rw		rw	rw	rw

Bit 31 **CKGACTIVE**: Clock generator active flag

This bit is set and cleared by hardware. This flag must be used by the application to check if the clock generator is effectively enabled (active) or not. The protected fields of this function can only be updated when CKGACTIVE = 0 (refer to *Section 45.4.15* for details). The delay between a transition on CKGDEN and a transition on CKGACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.

0: The clock generator is not active and can be configured if needed.

1: The clock generator is active and protected fields cannot be configured.

Bits 30:24 **PROCDIV[6:0]**: Divider to control the serial interface clock

This bitfield is set and reset by software. It is used to adjust the frequency of the clock provided to the SITF.

$$F_{mdf_itf_ck} = \frac{F_{mdf_ker_ck}}{(PROCDIV + 1)}$$

This bitfield must not be changed if one of the filters is enabled (DFTEN = 1).

0: mdf_ker_ck provided to the SITF

1: mdf_ker_ck/2 provided to the SITF

2: mdf_ker_ck/3 provided to the SITF

...

127: mdf_ker_ck/128 provided to the SITF

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **CCKDIV[3:0]**: Divider to control the MDF_CCK clock

This bitfield is set and reset by software. It is used to adjust the frequency of the MDF_CCK clock. The input clock of this divider is the clock provided to the SITF. More globally, the frequency of the MDF_CCK is given by the following formula:

$$F_{MDF_CCK} = \frac{F_{mdf_ker_ck}}{(PROCDIV + 1) \times (CCKDIV + 1)}$$

This bitfield must not be changed if one of the filters is enabled (DFTEN = 1).

0000: The MDF_CCK clock is mdf_proc_ck.

0001: The MDF_CCK clock is mdf_proc_ck / 2.

0010: The MDF_CCK clock is mdf_proc_ck / 3.

...

1111: The MDF_CCK clock is mdf_proc_ck / 16.

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bits 15:12 **TRGSRC[3:0]**: Digital filter trigger signal selection

This bitfield is set and cleared by software.It is used to select which external signals trigger for the corresponding filter. This bitfield is not significant if CKGMOD = 0.

000x: TRGO selected

0010: mdf_trg[0] selected

0011: mdf_trg[1] selected

...

1111: mdf_trg[13] selected

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details.)

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: CKGEN trigger sensitivity selection

This bit is set and cleared by software. It is used to select the trigger sensitivity of the trigger signals. This bit is not significant if the CKGMOD = 0.

0: A rising edge event triggers the activation of CKGEN dividers.

1: A falling edge even triggers the activation of CKGEN dividers.

Note: When the trigger source is TRGO, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge. This bit can be write-protected (refer to Section 45.4.15 for details).

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CCK1DIR**: MDF_CCK1 direction

This bit is set and reset by software.It is used to control the direction of the MDF_CCK1 pin.

0: MDF_CCK1 pin direction is in input.

1: MDF_CCK1 pin direction is in output.

Note: This bit can be write-protected (refer to Section 45.4.15 for details).

Bit 5 **CCK0DIR**: MDF_CCK0 direction

This bit is set and reset by software.It is used to control the direction of the MDF_CCK0.

0: MDF_CCK0 pin direction is in input.

1: MDF_CCK0 pin direction is in output.

Note: This bit can be write-protected (refer to Section 45.4.15 for details).

Bit 4 **CKGMOD**: Clock generator mode

This bit is set and reset by software. It is used to define the way the clock generator is enabled. This bit must not be changed if one of the filters is enabled (DFTEN = 1).

0: The kernel clock is provided to the dividers as soon as CKGDEN is set to 1.

1: The kernel clock is provided to the dividers when CKGDEN is set to 1 and the trigger condition met.

Note: This bit can be write-protected (refer to Section 45.4.15 for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CCK1EN**: MDF_CCK1 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the MDF_CCK1 pin.

0: Bitstream clock not generated

1: Bitstream clock generated on the MDF_CCK1 pad

Bit 1 **CCK0EN**: MDF_CCK0 clock enable

This bit is set and reset by software.It is used to control the generation of the bitstream clock on the MDF_CCK0 pin.

0: Bitstream clock not generated

1: Bitstream clock generated on the MDF_CCK0 pad

Bit 0 **CKGDEN**: CKGEN dividers enable

This bit is set and reset by software. It is used to enable/disable the clock dividers of the CKGEN: PROCDIV and CCKDIV.

0: CKGEN dividers disabled

1: CKGEN dividers enabled

45.8.3 MDF serial interface control register x (MDF_SITFxCR)

Address offset: 0x080 + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 1F00

This register is used to control the serial interfaces (SITFx). The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw	rw	rw	rw			rw	rw		rw	rw	rw

Bit 31 **SITFACTIVE**: Serial interface active flag

This bit is set and cleared by hardware. It is used by the application to check if the serial interface is effectively enabled (active) or not. The protected fields of this function can only be updated when the SITFACTIVE is set to 0 (refer to *Section 45.4.15* for details).

The delay between a transition on SITFEN and a transition on SITFACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.

0: The serial interface is not active and can be configured if needed.

1: The serial interface is active and protected fields cannot be configured.

Bits 30:13 Reserved, must be kept at reset value.

Bits 12:8 **STH[4:0]**: Manchester symbol threshold/SPI threshold

This bitfield is set and cleared by software. It is used for Manchester mode to define the expected symbol threshold levels (refer to *Manchester mode* for details on computation).

In addition this bitfield is used to define the timeout value for the clock absence detection in Normal SPI mode. STH[4:0] values lower than four are invalid.

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **SITFMOD[1:0]**: Serial interface type

This bitfield is set and cleared by software. it is used to define the serial interface type.

00: LF_MASTER SPI mode

01: Normal SPI mode

10: Manchester mode: rising edge = logic 0, falling edge = logic 1

11: Manchester mode: rising edge = logic 1, falling edge = logic 0

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 **SCKSRC[1:0]**: Serial clock source

This bitfield is set and cleared by software. it is used to select the clock source of the serial interface.

00: Serial clock source is MDF_CCK0.

01: Serial clock source is MDF_CCK1.

1x: Serial clock source is MDF_CKIx (not allowed in LF_MASTER SPI mode).

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bit 0 **SITFEN**: Serial interface enable

This bit is et and cleared by software. It is used to enable/disable the serial interface.

0: Serial interface disabled

1: Serial interface enabled

45.8.4 MDF bitstream matrix control register x (MDF_BSMXxCR)

Address offset: 0x084 + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 0000

This register is used to select the bitstream to be provided to the corresponding digital filter and to the SCD. The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw	rw	rw	rw	rw

Bit 31 **BSMXACTIVE**: BSMX active flag

This bit is set and cleared by hardware. It is used by the application to check if the BSMX is effectively enabled (active) or not. BSSEL[4:0] can only be updated when the BSMXACTIVE is set to 0. Th is BSMXACTIVE flag is a logical OR between OLDACTIVE, DFLTACTIVE, and SCDACTIVE flags. Both of them must be set to 0 in order update BSSEL[4:0] bitfield.

0: BSMX is not active and can be configured if needed.

1: BSMX is active and protected fields cannot be configured.

Bits 30:5 Reserved, must be kept at reset value.

Bits 4:0 **BSSEL[4:0]**: Bitstream Selection

This bitfield is set and cleared by software. It is used to select the bitstream to be processed for DFLTx and SCDx. The size of this bitfield depends on the number of DFLTx instantiated. If this bitfield selects a not instantiated input, the MDF selects the valid stream bsx_f having the higher index number.

00000: bs0_r provided to DFLTx and SCDx

00001: bs0_f provided to DFLTx and SCDx

00010: bs1_r provided to DFLTx and SCDx (if instantiated)

00011: bs1_f provided to DFLTx and SCDx (if instantiated)

...

11110: bs15_r provided to DFLTx and SCDx (if instantiated)

11111: bs15_f provided to DFLTx and SCDx (if instantiated)

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

45.8.5 MDF digital filter control register x (MDF_DFLTxCR)

Address offset: 0x088 + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 0000

The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

Bit 31 **DFLTACTIVE**: Digital filter active flag

This bit is set and cleared by hardware. It indicates if the digital filter is active: can be running or waiting for events.

0: Digital filter not active (can be re-enabled again, via DFLTEN, if needed)

1: Digital filter active

Bit 30 **DFLTRUN**: Digital filter run status flag

This bit is set and cleared by hardware. It indicates if the digital filter is running or not.

0: Digital filter not running and ready to accept a new trigger event

1: Digital filter running

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:20 **NBDIS[7:0]**: Number of samples to be discarded

This bitfield is set and cleared by software. it is used to define the number of samples to be discarded every time the DFLTx is re-started.

0: No sample discarded

1: 1 sample discarded

2: 2 samples discarded

...

255: 255 samples discarded

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **SNPSFMT**: Snapshot data format

This bit is set and cleared by software. It is used to select the data format for the snapshot mode.

0: Integrator counter (INT_CNT) not inserted into MDF_SNPSxDR, leaving a data resolution of 23 bits

1: Integrator counter (INT_CNT) inserted at position [15:9] of MDF_SNPSxDR, leaving a data resolution of 16 bits.

Note: This bit can be write-protected (refer to Section 45.4.15 for details).

Bits 15:12 **TRGSRC[3:0]**: Digital filter trigger signal selection

This bitfield is set and cleared by software. It is used to select which external signals trigger the corresponding filter.

0000: TRGO selected

0001: OLDx event selected

0010: mdf_trg[0] selected

...

1111: mdf_trg[13] selected

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: Digital filter trigger sensitivity selection

this bit is set and cleared by software. It is used to select the trigger sensitivity of the external signals

0: A rising edge event triggers the acquisition.

1: A falling edge even triggers the acquisition.

Note: When the trigger source is TRGO or OLDx event, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge, when OLDx event is selected, the sensitivity is forced to rising edge.
This bit can be write-protected (refer to Section 45.4.15 for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ACQMOD[2:0]**: Digital filter trigger mode

This bitfield is set and cleared by software. It is used to select the filter trigger mode.

000: Asynchronous continuous acquisition mode

001: Asynchronous single-shot acquisition mode

010: Synchronous continuous acquisition mode

011: Synchronous, single-shot acquisition mode

100: Window continuous acquisition mode

101: Synchronous snapshot mode

Others: same a 000

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FTH**: RXFIFO threshold selection

This bit is set and cleared by software. It is used to select the RXFIFO threshold. This bit is not significant for RXFIFOs working in interleaved-transfer mode (see *Interleaved-transfer mode* for details).

0: RXFIFO threshold event generated when the RXFIFO is not empty

1: RXFIFO threshold event generated when the RXFIFO is half-full

Note: This bit can be write-protected (refer to Section 45.4.15 for details).

Bit 1 **DMAEN**: DMA requests enable

This bit is set and cleared by software. It is used to control the generation of DMA request to transfer the processed samples into the memory.

0: DMA interface for the corresponding digital filter disabled

1: DMA interface for the corresponding digital filter enabled

Note: This bit can be write-protected (refer to Section 45.4.15 for details).

Bit 0 **DFLTEN**: Digital filter enable

This bit is set and cleared by software. It is used to control the start of acquisition of the corresponding digital filter path. This bit behavior depends on ACQMOD[2:0]and external events. The serial or parallel interface delivering the samples must be enabled as well.

0: Acquisition immediately stopped

1: Acquisition immediately started if ACQMOD[2:0] = 00x or 101, or acquisition started when the proper trigger event occurs if ACQMOD[2:0] = 01x or 100.

45.8.6 MDF digital filter configuration register x (MDF_DFLTxCICR)

Address offset: 0x08C + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 0000

This register is used to control the main CIC filter.The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MCICD[7:0]								Res.	CICMOD[2:0]			Res.	Res.	DATSRC[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw			rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:20 **SCALE[5:0]**: Scaling factor selection

This bitfield is set and cleared by software. It is used to select the gain to be applied at CIC output (refer to *Table 400* for details). If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back this bitfield informs the application on the current gain value.

000000: 0 dB

000001: + 3.5 dB

000010: + 6 dB or shift left by 1 bit

...

011000: + 72 dB or shift left by 12 bits

100000: - 48.2 dB or shift right by 8 bits (default value)

100001: - 44.6 dB

100010: - 42.1 dB or shift right by 7 bits

100011: - 38.6 dB

...

101110: - 6 dB or shift right by 1 bit

101111: - 2.5 dB

Others: Reserved

Bits 19:17 Reserved, must be kept at reset value.

Bits 16:8 **MCICD[8:0]**: CIC decimation ratio selection
This bitfield is set and cleared by software. It is used to select the CIC decimation ratio. A decimation ratio smaller than two is not allowed. The decimation ratio is given by (CICDEC+1).
0: Decimation ratio is 2.
1: Decimation ratio is 2.
2: Decimation ratio is 3..
3: Decimation ratio is 4
...
511: Decimation ratio is 512.
Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **CICMOD[2:0]**: Select the CIC mode
This bitfield is set and cleared by software.It is used to select the configuration and the order of the MCIC. When CICMOD[2:0] = 0xx, the CIC is split into two filters: the main CIC (MCIC) and the auxiliary CIC (ACIC, used for the out-off limit detector).
000: CIC split in two filters and MCIC configured in FastSinc filter
001: CIC split in two filters and MCIC configured in $Sinc^1$ filter
010: CIC split in two filters and MCIC configured in $Sinc^2$ filter
011: CIC split in two filters and MCIC configured in $Sinc^3$ filter
100: CIC configured in single $Sinc^4$ filter
others: CIC configured in single $Sinc^5$ filter
Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **DATSRC[1:0]**: Source data for the digital filter
This bitfield is set and cleared by software.
0x: Stream coming from the BSMX selected
10: Stream coming from the ADCITF1 selected
11: Stream coming from the ADCITF2 selected
Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

45.8.7 MDF reshape filter configuration register x (MDF_DFLTxRSFR)

Address offset: 0x090 + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 0000

This register is used to control the reshape and HPF filters. The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

						rw	rw	rw			rw				rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:8 **HPFC[1:0]**: High-pass filter cut-off frequency

This bitfield is set and cleared by software. It is used to select the cut-off frequency of the high-pass filter. F_{PCM} represents the sampling frequency at HPF input.

00: Cut-off frequency = 0.000625 x F_{PCM}

01: Cut-off frequency = 0.00125 x F_{PCM}

10: Cut-off frequency = 0.00250 x F_{PCM}

11: Cut-off frequency = 0.00950 x F_{PCM}

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bit 7 **HPFBYP**: High-pass filter bypass

This bit is set and cleared by software. It is used to bypass the high-pass filter.

0: HPF not bypassed (default value)

1: HPF bypassed

Note: This bit can be write-protected (refer to Section 45.4.15 for details).

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **RSFLTD**: Reshaper filter decimation ratio

This bit is set and cleared by software. It is used to select the decimation ratio for the reshape filter.

0: Decimation ratio is 4 (default value).

1: Decimation ratio is 1.

Note: This bit can be write-protected (refer to Section 45.4.15 for details).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **RSFLTBYP**: Reshaper filter bypass

This bit is set and cleared by software. It is used to bypass the reshape filter and its decimation block.

0: Reshape filter not bypassed (default value)

1: Reshape filter bypassed

Note: This bit can be write-protected (refer to Section 45.4.15 for details).

45.8.8 MDF integrator configuration register x (MDF_DFLTxINTR)

Address offset: 0x094 + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 0000

This register is used to the integrator (INT) settings. The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	INTVAL[6:0]							Res.	Res.	INTDIV[1:0]	
					rw	rw	rw	rw	rw	rw	rw			rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:4 **INTVAL[6:0]**: Integration value selection

This bitfield is set and cleared by software. It is used to select the integration value.

0: The integration value is 1, meaning bypass mode (default after reset).

1: The integration value is 2.

2: The integration value is 3.

...

127: The integration value is 128.

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **INTDIV[1:0]**: Integrator output division

This bitfield is set and cleared by software. It is used to rescale the signal at the integrator output in order keep the data width lower than 24 bits.

00: The integrator data outputs are divided by 128 (default value).

01: The integrator data outputs are divided by 32.

10: The integrator data outputs are divided by 4.

11: The integrator data outputs are not divided.

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

45.8.9 MDF out-of limit detector control register x (MDF_OLDxCR)

Address offset: 0x098 + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 0000

This register is used to configure the OLDx.The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OLDACTIVE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ACICD[4:0]					Res.
r										rw	rw	rw	rw	rw	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	ACICN[1:0]		Res.	Res.	Res.	Res.	BKOLD[3:0]				Res.	Res.	THINB	OLDEN
		rw	rw					rw	rw	rw	rw			rw	rw

Bit 31 **OLDACTIVE**: OLDx active flag

This bit is set and cleared by hardware. It is used to check if the OLDx is effectively enabled (active) or not. The protected fields and registers of this function can only be updated when the OLDACTIVE is set to 0 (refer to *Section 45.4.15* for details).

The delay between a transition on OLDEN and a transition on OLDACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.

0: OLDx not active and can be configured if needed

1: OLDx active and protected fields cannot be configured

Bits 30:22 Reserved, must be kept at reset value.

Bits 21:17 **ACICD[4:0]**: OLDx CIC decimation ratio selection

This bitfield is set and cleared by software. It is used to select the decimation ratio of the ACIC. It is only taken into account by the MDF when CICMOD[2:0] = 0xx. The decimation ratio is given by (ACICD + 1).

0: Decimation ratio is 1.

1: Decimation ratio is 2.

2: Decimation ratio is 3.

3: Decimation ratio is 4.

...

31: Decimation ratio is 32.

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bits 16:14 Reserved, must be kept at reset value.

Bits 13:12 **ACICN[1:0]**: OLDx CIC order selection

This bitfield is set and cleared by software. It is used to select the ACIC type and order. It is only taken into account by the MDF when CICMOD[2:0] = 0xx.

00: FastSinc filter type

01: $Sinc^1$ filter type

10: $Sinc^2$ filter type

11: $Sinc^3$ filter type

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:4 **BKOLD[3:0]**: Break signal assignment for out-of limit detector

This bitfield is set and cleared by software.

BKOLD[i] = 0: Break signal (mdf_break[i]) not assigned to threshold event

BKOLD[i] = 1: Break signal (mdf_break[i]) assigned to threshold event

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **THINB**: Threshold In band

This bit is set and cleared by software.

0: The OLDx generates an event if the signal is lower than OLDTHL or higher than OLDTHH (default value).

1: The OLDx generates an event if the signal is lower than OLDTHH and higher than OLDTHL.

Note: This bit can be write-protected (refer to Section 45.4.15 for details).

Bit 0 **OLDEN**: OLDx enable

This bit is set and cleared by software.

0: OLDx disabled (default value)

1: OLDx enabled, including the ACIC filter working in continuous mode

45.8.10 MDF OLDx low threshold register x (MDF_OLDxTHLR)

Address offset: 0x09C + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 0000

This register is used for the adjustment of the out-off-limit low threshold. The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **OLDTHL[25:0]**: OLD low threshold value

This bitfield is set and cleared by software. OLDTHL represents a 26-bit signed value. The real threshold compared to the signal provided by the filter is OLDTHL.

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

45.8.11 MDF OLDx high threshold register x (MDF_OLDxTHHR)

Address offset: 0x0A0 + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 0000

This register is used for the adjustment of the OLDx high threshold. The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **OLDTHH[25:0]**: OLDx high threshold value

This bitfield is set and cleared by software. OLDTHH represents a 26-bit signed value. The real threshold compared to the signal provided by the filter is OLDTHH.

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

45.8.12 MDF delay control register x (MDF_DLYxCR)

Address offset: 0x0A4 + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 0000

This register is used for the adjustment stream delays. The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SKPDLY[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bit 31 **SKPBF**: Skip busy flag

This bit is set and cleared by hardware. It is used to control if the delay sequence is completed.

0: MDF ready to accept a new value into SKPDLY[6:0]

1: Last valid SKPDLY[6:0] still under processing

Bits 30:7 Reserved, must be kept at reset value.

Bits 6:0 **SKPDLY[6:0]**: Delay to apply to a bitstream

This bitfield is set and cleared by software. It defines the number of input samples that are skipped. Skipping is applied immediately after writing to this bitfield, if SKPBF = 0 and the corresponding DFLTEN = 1. If SKPBF = 1, the value written into the register is ignored by the delay state machine.

0: No input sample skipped

1: 1 input sample skipped

...

127: 127 input samples skipped

45.8.13 MDF short circuit detector control register x (MDF_SCDxCR)

Address offset: 0x0A8 + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 0000

This register is used for the adjustment stream delays. The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

rw	rw	rw	rw					rw	rw	rw	rw				rw

Bit 31 **SCDACTIVE**: SCDx active flag

This bit is set and cleared by hardware. It is used to check if the SCDx is effectively enabled (active) or not. The protected fields of this function can only be updated when the SCDACTIVE is set to 0 (refer to *Section 45.4.15* for details).

The delay between a transition on SCDEN and a transition on SCDACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.

0: SCDx not active and can be configured if needed

1: SCDx active and protected fields cannot be configured

Bits 30:20 Reserved, must be kept at reset value.

Bits 19:12 **SCDT[7:0]**: SCDx threshold

This bitfield is set and cleared by software. These bits are written by software to define the threshold counter for SCDx. If this value is reached, a short-circuit detector event occurs on a given input stream.

0: 2 consecutive 1's or 0's generate an event.

1: 2 consecutive 1's or 0's generate an event.

2: 3 consecutive 1's or 0's generate an event.

...

255: 256 consecutive 1's or 0's generate an event.

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:4 **BKSCD[3:0]**: Break signal assignment for short circuit detector

This bitfield is set and cleared by software.

BKSCD[i] = 0: Break signal (mdf_break[i]) not assigned to this SCD event

BKSCD[i] = 1: Break signal (mdf_break[i]) assigned to this SCD event

Note: This bitfield can be write-protected (refer to Section 45.4.15 for details).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **SCDEN**: SCDx enable

This bit is set and cleared by software.

0: SCDx disabled

1: SCDx enabled,

45.8.14 MDF DFLT0 interrupt enable register 0 (MDF_DFLT0IER)

Address offset: 0x0AC

Reset value: 0x0000 0000

This register is used for allowing or not the events to generate an interrupt.

Bit 11 **RFOVRIE**: Reshape filter overrun interrupt enable
This bit is set and cleared by software.
0: Reshape filter overrun interrupt disabled
1: Reshape filter overrun interrupt enabled

Bit 10 **CKABIE**: Clock absence detection interrupt enable
This bit is set and cleared by software.
0: Clock absence interrupt disabled
1: Clock absence interrupt enabled

Bit 9 **SATIE**: Saturation detection interrupt enable
This bit is set and cleared by software.
0: Saturation interrupt disabled
1: Saturation interrupt enabled

Bit 8 **SCDIE**: SCD0 interrupt enable
This bit is set and cleared by software.
0: SCD0 interrupt disabled
1: SCD0 interrupt enabled

Bit 7 **SSOVRIE**: Snapshot overrun interrupt enable
This bit is set and cleared by software.
0: Snapshot overrun interrupt disabled
1: Snapshot overrun interrupt enabled

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **OLDIE**: OLD0 interrupt enable
This bit is set and cleared by software.
0: OLD0 event interrupt disabled
1: OLD0 event interrupt enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SSDRIE**: Snapshot data ready interrupt enable
This bit is set and cleared by software.
0: Snapshot data ready interrupt disabled
1: Snapshot data ready interrupt enabled

Bit 1 **DOVRIE**: Data overflow interrupt enable
This bit is set and cleared by software.
0: Data overflow interrupt disabled
1: Data overflow interrupt enabled

Bit 0 **FTHIE**: RXFIFO threshold interrupt enable
This bit is set and cleared by software.
0: RXFIFO threshold interrupt disabled
1: RXFIFO threshold interrupt enabled

45.8.15 MDF DFLTx interrupt enable register x (MDF_DFLTxIER)

Address offset: 0x12C + 0x80 * (x - 1), (x = 1 to 7)

Reset value: 0x0000 0000

This register is used for allowing or not, the events to generate an interrupt. The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

Bit 11 **RFOVRIE**: Reshape filter overrun interrupt enable
This bit is set and cleared by software.
0: Reshape filter overrun interrupt disabled
1: Reshape filter overrun interrupt enabled

Bit 10 **CKABIE**: Clock absence detection interrupt enable
This bit is set and cleared by software.
0: Clock absence interrupt disabled
1: Clock absence interrupt enabled

Bit 9 **SATIE**: Saturation detection interrupt enable
This bit is set and cleared by software.
0: Saturation interrupt disabled
1: Saturation interrupt enabled

Bit 8 **SCDIE**: SCDx interrupt enable
This bit is set and cleared by software.
0: SCDx interrupt disabled
1: SCDx interrupt enabled

Bit 7 **SSOVRIE**: Snapshot overrun interrupt enable
This bit is set and cleared by software.
0: Snapshot overrun interrupt disabled
1: Snapshot overrun interrupt enabled

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **OLDIE**: OLDx interrupt enable
This bit is set and cleared by software.
0: OLDx event interrupt disabled
1: OLDx event interrupt enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SSDRIE**: Snapshot data ready interrupt enable
This bit is set and cleared by software.
0: Snapshot data ready interrupt disabled
1: Snapshot data ready interrupt enabled

Bit 1 **DOVRIE**: Data overflow interrupt enable
This bit is set and cleared by software.
0: Data overflow interrupt disabled
1: Data overflow interrupt enabled

Bit 0 **FTHIE**: RXFIFO threshold interrupt enable
This bit is set and cleared by software.
0: RXFIFO threshold interrupt disabled
1: RXFIFO threshold interrupt enabled

45.8.16 MDF DFLT0 interrupt status register 0 (MDF_DFLT0ISR)

Address offset: 0x0B0

Reset value: 0x0000 0000

This register contains the status flags for each digital filter path.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	RFOVRF	CKABF	SATF	SCDF	SSOVRF	THHF	THLF	OLDF	RXNEF	SSDRF	DOVRF	FTHF
				rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	r	r	rc_w1	r	rc_w1	rc_w1	r

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **RFOVRF**: Reshape filter overrun detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no reshape filter overrun is detected. Write 0 has no effect.
1: Read 1 means that reshape filter overrun is detected. Write 1 clears this flag.

Bit 10 **CKABF**: Clock absence detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no clock absence is detected. Write 0 has no effect.
1: Read 1 means that a clock absence is detected. Write 1 clears this flag.

Bit 9 **SATF**: Saturation detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no saturation is detected. Write 0 has no effect.
1: Read 1 means that a saturation is detected. Write 1 clears this flag.

Bit 8 **SCDF**: Short-circuit detector flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no SCD0 event is detected. Write 0 has no effect.
1: Read 1 means that a SCD0 event is detected. Write 1 clears this flag.

Bit 7 **SSOVRF**: Snapshot overrun flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no snapshot overrun event is detected. Write 0 has no effect.
1: Read 1 means that a snapshot overrun event is detected. Write 1 clears this flag.

Bit 6 **THHF**: High-threshold status flag

This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the high-threshold comparator when the last OLD0 event occurred. This bit gives additional information on the conditions triggering the last OLD0 event. It can be cleared by writing OLDF flag to 1.

0: The signal was lower than OLDTHH when the last OLD0 event occurred.

1: The signal was higher than OLDTHH when the last OLD0 event occurred.

Bit 5 **THLF**: Low-threshold status flag

This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the low-threshold comparator when the last OLD0 event occurred. This bit gives additional information on the conditions triggering the last OLD0 event. It can be cleared by writing OLDF flag to 1.

0: The signal was higher than OLDTHL when the last OLD0 event occurred.

1: The signal was lower than OLDTHL when the last OLD0 event occurred.

Bit 4 **OLDF**: OLD0 flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no OLD0 event is detected. Write 0 has no effect.

1: Read 1 means that an OLD0 event is detected Write 1 clears THHF, THLF and OLDF.

Bit 3 **RXNEF**: RXFIFO not-empty flag

this bit is set and cleared by hardware according to the RXFIFO level.

0: RXFIFO empty

1: RXFIFO not empty

Bit 2 **SSDRF**: Snapshot data ready flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no data is available. Write 0 has no effect.

1: Read 1 means that a new data is available. Write 1 clears this flag.

Bit 1 **DOVRF**: Data overflow flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no overflow is detected. Write 0 has no effect.

1: Read 1 means that an overflow is detected; Write 1 clears this flag.

Bit 0 **FTHF**: RXFIFO threshold flag

This bit is set by hardware and cleared by hardware when the RXFIFO level is lower than the threshold.

0: RXFIFO threshold not reached

1: RXFIFO threshold reached

45.8.17 MDF DFLTx interrupt status register x (MDF_DFLTxISR)

Address offset: 0x130 + 0x80 * (x - 1), (x = 1 to 7)

Reset value: 0x0000 0000

This register contains the status flags for each digital filter path. The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	RFOVRF	CKABF	SATF	SCDF	SSOVRF	THHF	THLF	OLDF	RXNEF	SSDRF	DOVRF	FTHF
				rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	r	r	rc_w1	r	rc_w1	rc_w1	r

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **RFOVRF**: Reshape filter overrun detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no reshape filter overrun is detected. Write 0 has no effect.
1: Read 1 means that reshape filter overrun is detected. Write 1 clears this flag.

Bit 10 **CKABF**: Clock absence detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no clock absence is detected. Write 0 has no effect.
1: Read 1 means that a clock absence is detected. Write 1 clears this flag.

Bit 9 **SATF**: Saturation detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no saturation is detected. Write 0 has no effect.
1: Read 1 means that a saturation is detected. Write 1 clears this flag.

Bit 8 **SCDF**: Short-circuit detector flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no SCD event is detected. Write 0 has no effect.
1: Read 1 means that a SCD event is detected. Write 1 clears this flag.

Bit 7 **SSOVRF**: Snapshot overrun flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no snapshot overrun event is detected. Write 0 has no effect.
1: Read 1 means that a snapshot overrun event is detected. Write 1 clears this flag.

Bit 6 **THHF**: High-threshold status flag
This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the high-threshold comparator when the last OLDx event occurred. This bit gives additional information on the conditions triggering the last OLDx event. It can be cleared by writing OLDF flag to 1.
0: The signal was lower than OLDTHH when the last OLDx event occurred.
1: The signal was higher than OLDTHH when the last OLDx event occurred.

Bit 5 **THLF**: Low-threshold status flag

This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the low-threshold comparator when the last OLDx event occurred. This bit gives additional information on the conditions triggering the last OLDx event. It can be cleared by writing OLDF flag to 1.

0: The signal was higher than OLDTHL when the last OLDx event occurred.

1: The signal was lower than OLDTHL when the last OLDx event occurred.

Bit 4 **OLDF**: OLDx flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no OLDx event is detected. Write 0 has no effect.

1: Read 1 means that an OLDx event is detected Write 1 clears THHF, THLF and OLDF.

Bit 3 **RXNEF**: RXFIFO not-empty flag

this bit is set and cleared by hardware according to the RXFIFO level.

0: RXFIFO empty

1: RXFIFO not empty

Bit 2 **SSDRF**: Snapshot data ready flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no data is available. Write 0 has no effect.

1: Read 1 means that a new data is available. Write 1 clears this flag.

Bit 1 **DOVRF**: Data overflow flag

This bit is set by hardware and cleared by software by writing this bit to 1.

0: Read 0 means that no overflow is detected. Write 0 has no effect.

1: Read 1 means that an overflow is detected; Write 1 clears this flag.

Bit 0 **FTHF**: RXFIFO threshold flag

This bit is set by hardware and cleared by hardware when the RXFIFO level is lower than the threshold.

0: RXFIFO threshold not reached

1: RXFIFO threshold reached

45.8.18 MDF offset error compensation control register x (MDF_OECxCR)

Address offset: 0x0B4 + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 0000

This register contains the offset compensation value. The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	OFFSET[25:16]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OFFSET[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **OFFSET[25:0]**: Offset error compensation
This bitfield is set and cleared by software. If the application attempts to write a new offset value while the previous one is not yet applied, this new offset value is ignored. Reading back this bitfield informs the application on the current offset value.
This bitfield represents the value to be subtracted to the signal before going to the SCALE.

45.8.19 MDF snapshot data register x (MDF_SNPSxDR)

Address offset: 0x0EC + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 0000

This register is used to read the data processed by each digital filter in snapshot mode. The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SDR[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXTSDR[6:0]							MCICDC[8:0]								
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 **SDR[15:0]**: Contains the 16 MSB of the last valid data processed by the digital filter.

Bits 15:9 **EXTSDR[6:0]**: Extended data size
If SNPSFMT = 0, this bitfield contains the bits 7 to 1 of the last valid data processed by the digital filter.
If SNPSFMT = 1, this bitfield contains the INT accumulator counter value when the last trigger event occurs (INT_CNT).

Bits 8:0 **MCICDC[8:0]**: Contains the MCIC decimation counter value when the last trigger event occurs (MCIC_CNT)

45.8.20 MDF digital filter data register x (MDF_DFLTxDR)

Address offset: 0x0F0 + 0x80 * x, (x = 0 to 7)

Reset value: 0x0000 0000

This register is used to read the data processed by each digital filter. The number of registers is equal to the amount of filters. Refer to *Section 45.3* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DR[23:8]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

NBF[7:0]								FIFO_SIZE[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 **OPTION_REGOUT[7:0]:** Support of MDF_OR register
0: MDF_OR not implemented
1: MDF_OR implemented with only one control bit at position 0
2: MDF_OR implemented, with two control bits at positions 0 and 1
...
32: MDF_OR implemented with 32 control bits at positions 0 to 31
Others: Invalid values

Bits 23:20 **SAD[3:0]**: Sound activity detection
0x0: SAD not implemented
0x1: SAD implemented

Bits 19:16 **FLT_CFG[3:0]**: Digital filter configuration
0: Reduced set of features to mainly address audio use-cases
1: Full set of features, with associated blocks for motor control applications

Bits 15:8 **NBF[7:0]**: Number of digital filter paths and serial interfaces
0x1: 1 digital filter instance implemented
0x2: 2 digital filter instances implemented
...
0x6: 6 digital filter instances implemented
...
0x10: 16 digital filter instances implemented

Bits 7:0 **FIFO_SIZE[7:0]**: FIFO size for MDF
2: the FIFO depth is 2 words
4: the FIFO depth is 4 words
8: the FIFO depth is 8 words
16: the FIFO depth is 16 words
32: the FIFO depth is 32 words
64: the FIFO depth is 64 words
Others: Invalid values

45.8.22 MDF version register (MDF_VERR)

Address offset: 0xFF4

Reset value: 0x0000 0011

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

46 Audio digital filter (ADF)

46.1 Introduction

The audio digital filter (ADF) is a high-performance module dedicated to the connection of external sigma-delta (ΣΔ) modulators. It is mainly targeted for the following applications:

- audio capture signals
- metering

The ADF features one digital serial interface (SITF0) and one digital filter (DFLT0) with flexible digital processing options in order to offer up to 24-bit final resolution.

The ADF serial interface supports several standards allowing the connection of various ΣΔ modulator sensors:

- SPI interface
- Manchester coded 1-wire interface
- PDM interface

The ADF converts an input data stream into clean decimated digital data words. This conversion is done thanks to low-pass digital filters and decimation blocks. In addition, it is possible to insert a high-pass filter.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter bypass, filter order, decimation ratio. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion and continuous modes. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A sound activity detector (SAD) is available for the detection of sounds or voice signals. The SAD is connected at the output of the DFLT0. Several parameters can be programmed in order to adjust properly the SAD to the sound environment. The SAD strongly reduces the power consumption by preventing the storage of samples into the system memory, as long as the observed signal does not match the programmed criteria.

The digital processing is performed using only the kernel clock. The ADF requests the bus interface clock (AHB clock) only when data must be transfered or when a specific event requests the attention of the system processor.

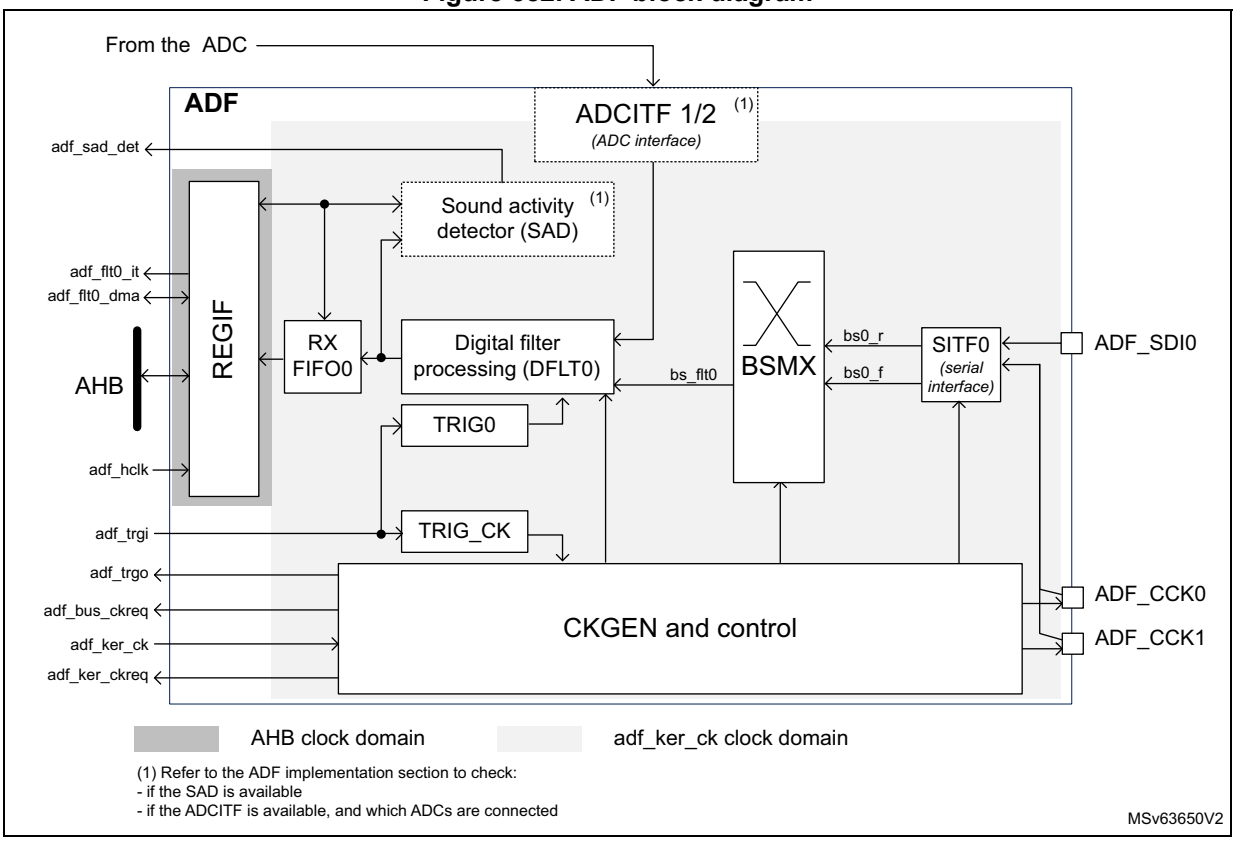
46.2 ADF main features

- AHB Interface
- 1 serial digital input:
  - configurable SPI interface to connect various digital sensors
  - configurable Manchester coded interface support
  - compatible with PDM interface to support digital microphones
- 2 common clocks input/output for ΣΔ modulators
- 1 flexible digital filter path including:
  - A MCIC filter configurable in $Sinc^4$ or $Sinc^5$ filter with an adjustable decimation ratio
  - A reshape filter to improve the out-off band rejection and in-band ripple

  - A high-pass filter to cancel the DC offset
  - Gain control
  - Saturation blocks
- Clock absence detector
- Sound activity detector
- 24-bit signed output data resolution
- Continuous or single conversion
- Possibility to delay the selected bitstream
- One trigger input
- Autonomous functionality in Stop modes
- DMA can be used to read the conversion data
- Interrupts services

46.3 ADF implementation

Table 411. ADF features (1)



Mode or feature	ADF1
Number of filters (DFLTx) and serial interfaces (SITFx)	1
ADF_CKI0 connected to pins	-
Sound activity detection (SAD)	X
RXFIFO depth (number of 24-bit words)	4
Number of trigger inputs	1
ADC connected to ADCITF1	-
ADC connected to ADCITF2	-
Motor dedicated features (SCD, OLD, OEC, INT, snapshot, break)	-
Main path with CIC4, CIC5	X
Main path with CIC1,2, 3 or FastSinc	-
RSFLT, HPF, SAT, SCALE, DLY, Discard functions	X
Global interrupts ADF_FLT[0:0] (adf_flt_it[0:0])	X
Receive interrupts ADF_RX[0:0] (adf_rx_it[0:0])	-
Event interrupts ADF_EVT[0:0] (adf_evt_it[0:0])	-
Autonomous in Stop 0, Stop 1 and Stop 2 modes	X
All DMA channels connected	X

1. ‘X’ = supported, ‘-’ = not supported.

46.4 ADF functional description

46.4.1 ADF block diagram

Figure 382. ADF block diagram

46.4.2 ADF pins and internal signals

Table 412. ADF external pins

Pin name	Pin type	Remarks
ADF_SDI0	Input	Data signal from external sensors
ADF_CCKy (y = 0,1)	Input/output	Clock outputs for external sensor, or common clock input from external sensors

Table 413. ADF internal signals

Signal name	Signal type	Remarks
adf_trgi	Input	Trigger inputs to control the acquisition (see *Table 414: ADF trigger connections* for details)
adf_trgo	Output	Trigger output for synchronizing with other MDF instances
adf_flt0_dma	Input/output	DMA request/acknowledge signals for the ADF processing chain
adf_flt0_it	Output	Global interrupt signals

Table 413. ADF internal signals (continued)

Signal name	Signal type	Remarks
adf_bus_ckreq	Output	Bus interface clock request output
adf_ker_ckreq	Output	Kernel clock request output
adf_ker_ck	Input	Kernel clock input
adf_hclk	Input	AHB bus interface clock input
adf_sad_det	Output	SAD sound detection: 1 means that detecting sound
adf_adcitf1_dat[15:0]	Input	ADCITF1 data input
adf_adcitf2_dat[15:0]	Input	ADCITF2 data input

Table 414. ADF trigger connections

Trigger name	Direction	Trigger source/destination
adf_trgi0	Input	From exti2_exti[1]

46.4.3 Serial input interface (SITF)

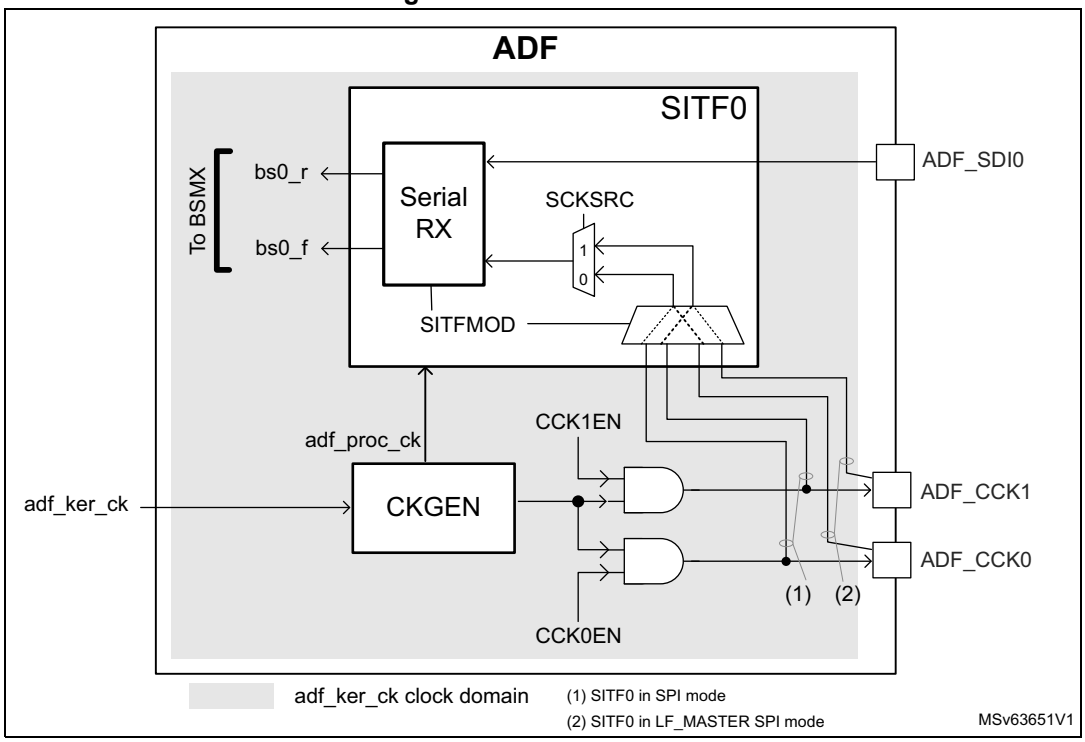
The SITF0 input interface allows the connection of the external sensor to the digital filter via the bitstream matrix (BSMX). The SITF0 can be configured in the following modes:

- LF_MASTER SPI mode (low-frequency)
- normal SPI mode
- Manchester mode

The data from the serial interface is routed to the filter in order to perform the PDM to PCM conversion and the sound activity detection.

The serial interface is enabled by setting the SITFEN bit to 1. Once the interface is enabled, it receives serial data from the external ΣΔ modulator.

Note: Before enabling the *serial interface, the user must insure that the adf_proc_ck is already enabled (see Section 46.4.5: Clock generator (CKGEN) for details).*



The SITF0 is controlled via the *ADF serial interface control register 0 (ADF_SITF0CR)*.

As shown in the *Figure 383*, ADF_CCK0 or ADF_CCK1 can be selected as clock source, in order to sample the incoming bitstream:

- If the serial interface is programmed in SPI mode, the selected clock source is a copy of the clock present on the ADF_CCK0 or ADF_CCK1 pin.
- If the serial interface is programmed in LF_MASTER SPI mode, the selected clock source is the clock directly provided by the CCKDIV to the ADF_CCK0 or ADF_CCK1 pin.

See *Table 415* for additional information.

Figure 383. SITF overview

LF_MASTER and normal SPI modes

The LF_MASTER SPI mode is a special mode allowing the use of an adf_proc_ck clock frequency, only two times bigger than the sensor clock. This mode is dedicated to low-power use-cases, using low-speed sensors.

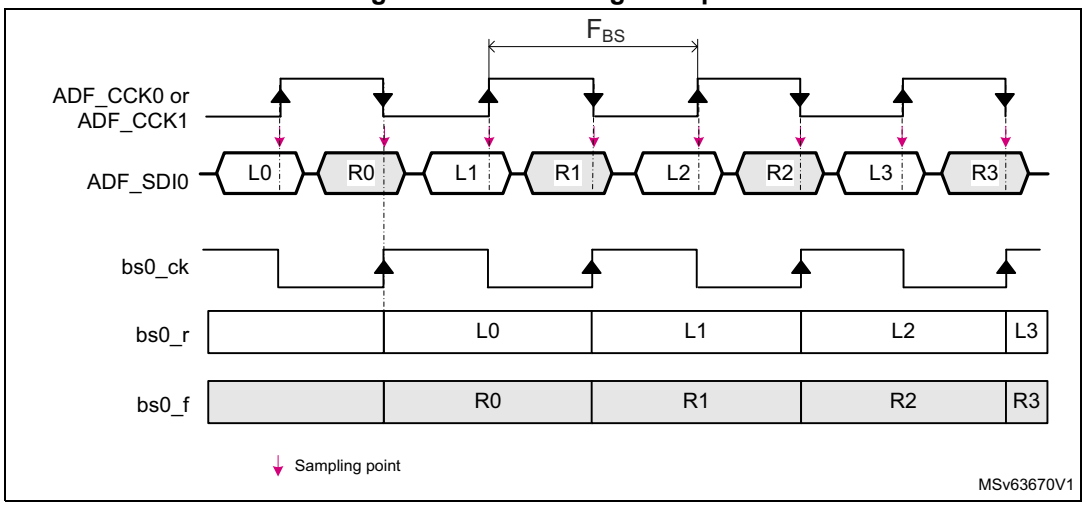
In LF_MASTER SPI mode, the ADF must provide the bitstream clock to the external sensors via ADF_CCK0 and ADF_CCK1 pins. The ADF receives the bitstream data via the serial data input ADF_SDI0.

For the SITF0, the application must select the same clock than the one provided to the external sensor (ADF_CCK0 or ADF_CCK1), in order to guarantee optimal timing performances. This selection is done via SCKSRC[1:0].

The normal SPI interface is a more flexible interface than the LF_MASTER SPI, but the adf_proc_ck frequency must be at least four times higher than the sensor clock.

The application can select ADF_CCK0 or ADF_CCK1 clock for the capture of the data received via the ADF_SDI0 pin.

The ADF can generate a clock to the sensors via ADF_CCK0 or ADF_CCK1 if needed.



For all SPI modes, the serial data is captured using the rising and the falling edge of the selected clock. The SITF0 always provides the following bitstreams:

- bitstream received using the bitstream clock falling edge (bs0_f)
- bitstream received using the bitstream clock rising edge (bs0_r)

According to the sensors connected, one of the two bitstreams may not be available.

The application can select the wanted stream via the BSMX matrix.

Figure 384. SPI timing example

To properly synchronize/receive the data stream, the adf_proc_ck frequency must be adjusted according to the constraints listed in *Table 416*.

Clock absence detection

A no-clock-transition period may be detected when the serial interface works in normal SPI mode. This feature can be used to detect a clock failure in the SPI link.

The application can program a timeout value via the STH[4:0] bitfield of the SITF0. If the ADF does not detect clock transitions for a duration of STH[4:0] x $T_{adf_proc_ck}$, then the CKABF flag is set.

An interrupt can be generated if CKABIE is set to 1. The STH[4:0] bitfield is in the *ADF serial interface control register 0 (ADF_SITF0CR)*.

When the serial interface is enabled, the CKABF flag remains to 1 until a first clock transition is detected.

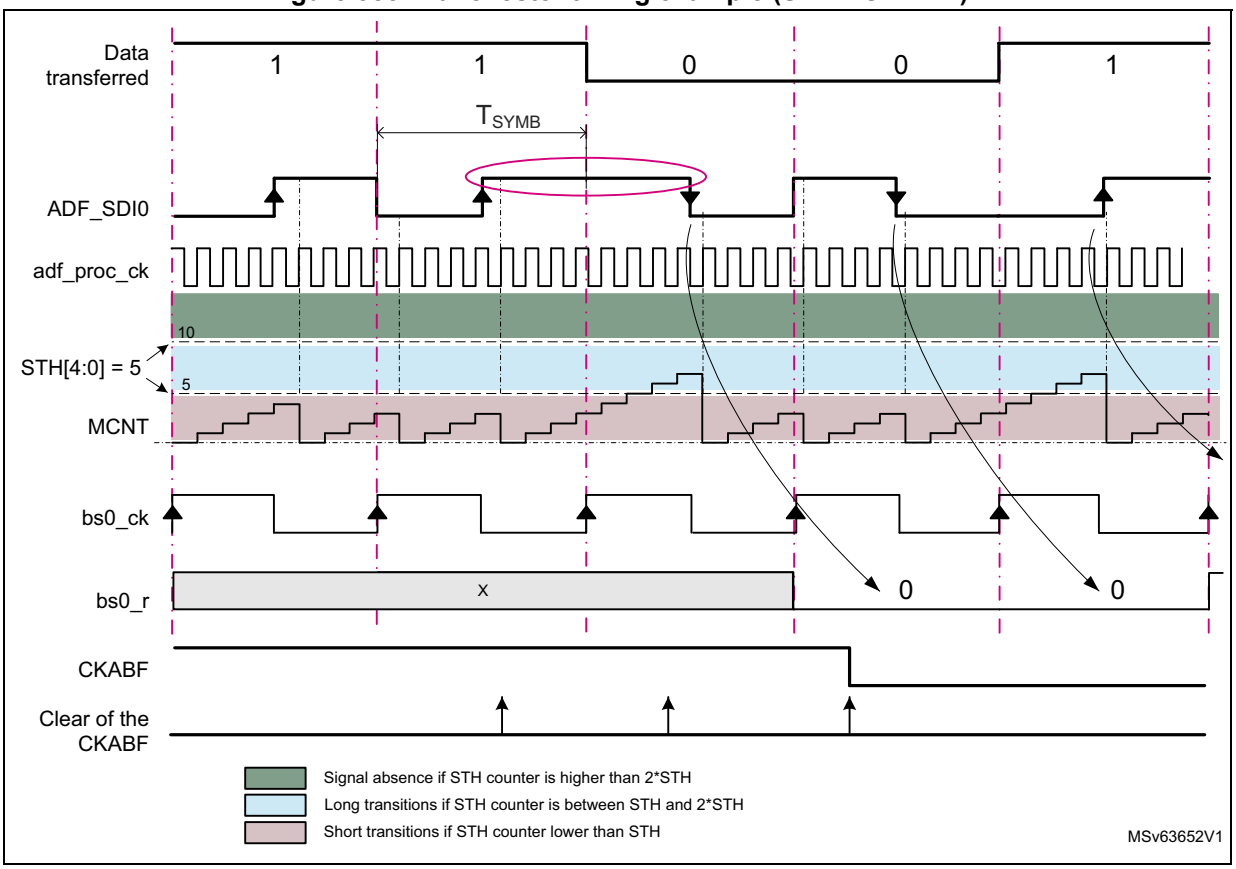
To avoid spurious clock absence detection, the following sequence must be respected:

1. Configure the serial interface in normal SPI mode and enable it.
2. Clear the CKABF flag by writing CKABF bit to 1.

   If no clock transition is detected on the serial interface, the hardware immediately sets the CKABF flag to 1.
3. Read the CKABF flag:
   - If CKABF = 1, go back to step 2.
   - If CKABF = 0, a clock has been detected. The CKABIE bit can be set to 1 if the application wants an interrupt on detection of a clock absence.

Note: The clock absence detection feature is not available in the LF_MASTER SPI mode.

Manchester mode



In Manchester coded format, the ADF receives data stream from the external sensor via the ADF_SDI0 pin only.

The ADF_CCK0 and ADF_CCK1 pins are not needed in this mode.

Decoded data and clock signals are recovered from serial stream after Manchester decoding. They are available on bs0_r. There are two possible settings of Manchester codings:

- signal rising edge decoded as 0 and signal falling edge decoded as 1
- signal rising edge decoded as 1 and signal falling edge decoded as 0

Figure 385. Manchester timing example (SITFMOD = 11)

To decode the incoming Manchester stream, the user must program STH[4:0] in the *ADF serial interface control register 0 (ADF_SITF0CR)*. The STH[4:0] bitfield is used by the SITF0 to estimate the Manchester symbol length and to detect a clock absence. An internal counter (MCNT) is restarted every time a transition is detected in the ADF_SDI0 input. It is used to detect short transitions, long transitions or clock absence. A long transition indicates that the data value changed. *Figure 385* shows a case where the OVR is around height and STH[4:0] = 5.

The estimated Manchester symbol rate (T_{SYMB}) must respect the following formula:

$$(STH + 1) \times T_{adf_proc_ck} < T_{SYMB} < (2 \times STH \times T_{adf_proc_ck})$$

It is recommended to compute STH as follows:

$$STH[4:0] = round\left(\frac{(2 \times OVR) - 1}{3}\right)$$

where OVR represents the ratio between the adf_proc_ck frequency and the expected Manchester symbol frequency. OVR must be higher than five, and the adf_proc_ck clock must be adjusted according to the constraints listed in *Table 416*.

The clock absence flag CKABF is set to 1 when no transition is detected during more than 2 x STH[4:0] x $T_{adf_proc_ck}$, or when the SITF0 is not yet synchronized to the incoming Manchester stream. In addition, an interrupt can be generated if the bit CKABIE is set to 1.

When the serial interface is enabled, the ADF must first be synchronized to the incoming Manchester stream. The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (pink circle in the *Figure 385*) is detected.

The end of the synchronization phase can be checked by following the software sequence:

1. Clear the CKABF flag in the *ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)* by writing CKABF bit to 1. If the serial interface is not yet synchronized the hardware immediately set the CKABF flag to 1.
2. Read the CKABF flag:
   – If CKABF= 1, go back to step 1.
   – If CKABF = 0, the Manchester interface is synchronized and provides valid data.

Programming example

In the following example, the ADF kernel clock frequency ($F_{adf_ker_ck}$) is 100 MHz and the received Manchester stream is at about 6 MHz (F_{SYMB}):

1. Provide a valid adf_proc_ck to the SITF0.

   The adf_proc_ck frequency must be at least six times higher than the Manchester symbol frequency (means at least 36 MHz).

   PROCDIV is programmed to 1 to perform a division by two of the kernel clock. In that case, $F_{adf_proc_ck}$ = 50 MHz (8.33 times higher than the Manchester symbol frequency).
2. Compute STH.

   OVR is given by: OVR = $F_{adf_proc_ck}$ / F_{SYMB} = 50 MHz / 6 MHz = 8.33.

   Then STH[4:0] = $\text{round}\left(\frac{(2 \times 8.33) - 1}{3}\right) = 5$

   The minimum allowed frequency for the Manchester stream is then:

   1 / (2 × STH × $T_{adf_proc_ck}$) = 1 / (10 x 20 ns) = 5 MHz

   The maximum allowed frequency for the Manchester stream is then:

   1 / ((STH+1) × $T_{adf_proc_ck}$) = 1 / (6 x 20 ns) = 8.33 MHz

46.4.4 ADC slave interface (ADCITF)

The ADCs are not always connected to the ADF. Refer to *Section 46.3* to check the situation for this product.

The ADF allows the connection of up to two ADCs to the filter path. For the filter, the DATSRC[1:0] bitfield in the *ADF digital filer configuration register 0 (ADF_DFLT0CICR)* allows the application to select data from the ADCs.

Warning: The ADF does not support receiving interleaved data from one of the ADCITF input.

46.4.5 Clock generator (CKGEN)

The RCC (reset and clock controller) provides the following clocks to the ADF:

- AHB clock (adf_hclk) used for the register interface
- kernel clock (adf_ker_ck) mainly used by all other parts of the circuit via the CKGEN

These clocks are not supposed to be phase locked, so all signals crossing those clock domains are re-synchronized.

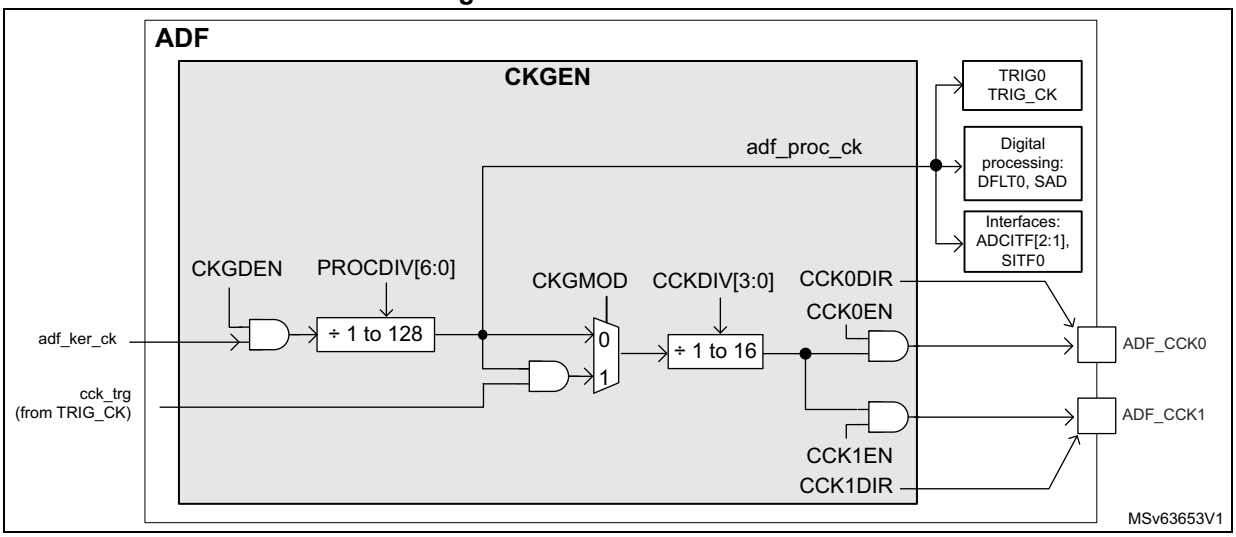
The clock generator (CKGEN) is responsible of the generation of the processing clock, and the clock provided to the ADF_CCK0 and ADF_CCK1 pins. All those clocks are generated from the adf_ker_ck.

The processing clock (adf_proc_ck) is used to run all the signal processing and to re-sample the incoming serial or parallel stream.

To adapt the kernel clock frequency provided by the RCC, the following dividers are available:

- PROCDIV[6:0] used to adapt the kernel clock frequency to the constraints of the parallel and serial interfaces, and to the processing blocks
- CCKDIV[3:0] used to adapt the frequency of the ADF_CCK0 and ADF_CCK1 clocks

PROCDIV[6:0] and CCKDIV[3:0] must be programmed when no clock is provided to the dividers (CKGDEN = 0).



The adf_proc_ck generation is controlled by CKGDEN.

In addition, the CKGMOD bit allows the application to define the way to trigger the CCKDIV divider:

- When CKGMOD = 0, the CCKDIV divider is started as soon as CKGDEN is set to 1.
- When CKGMOD = 1, the CCKDIV divider is started when CKGDEN is set to 1 and the programmed trigger condition occurred.

All the bits and fields controlling the CKGEN are in the *ADF clock generator control register (ADF_CKGCR)*.

Figure 386. CKGEN overview

The trigger logic for CKGEN is handled by the block TRG_CK. As shown in *Figure 391*, the CCKDIV divider can be triggered on the rising or falling edge of an external trigger source. When the proper trigger condition occurs, the cck_trg signal goes to high, allowing the CCKDIV divider to start. The TRG_CK logic is reset when CKGDEN is set to 0.

This feature can be helpful to synchronize the ADF_CCKy (y = 0,1) clock of several ADF instances, or to synchronize the clock generation to a timer event.

The application can control the activation of the ADF_CCK0 or ADF_CCK1 pin thanks to CCK0EN/CCK1EN and CCK0DIR/CCK1DIR bits:

- CCKyEN is used to enable the CCKDIV, and thus generates a clock for the external sensors.
- CCKyDIR is used to control the direction of the ADF_CCKy pin (input or output)

Table 415. Control of the common clock generation(1)

CCKyEN	CCKyDIR	Description
0	0	The ADF_CCKy pin is in input. An external clock can be connected to the ADF_CCKy pin and used by the SITF0 in order to decode the serial stream
0	1	The ADF_CCKy pin is in output. No clock is generated. The ADF_CCKy pin is driven low.
1	1	The ADF_CCKy pin is in output. A clock is generated on the ADF_CCKy pin. The SITF0 can use this pin as clock source in order to decode the serial stream

1. The configuration with CCKyEN = 1 and CCyDIR = 0 is not shown must be avoided (no interest).

Note: The adf_proc_ck must be enabled (by CKGDEN = 1) before enabling other blocks (such as SITF0 or DFLT0).

CKGEN activation sequence example

1. Set CKGDEN to 0.
2. Wait for CKGACTIVE = 0. If CKGDEN was previously enabled, this phase can take two periods of adf_hclk, and two periods of adf_proc_ck.
3. Program PROCDIV[6:0], CKGMOD, CCKDIV[3:0], TRGSRC[3:0], TRGSENS, CCK1EN and CCK0EN.
4. Set CKGDEN to 1.

When needed, at any moment, CCK[1:0]EN bitfield value can be changed without disabling the clock generator.

Clock frequency constraints

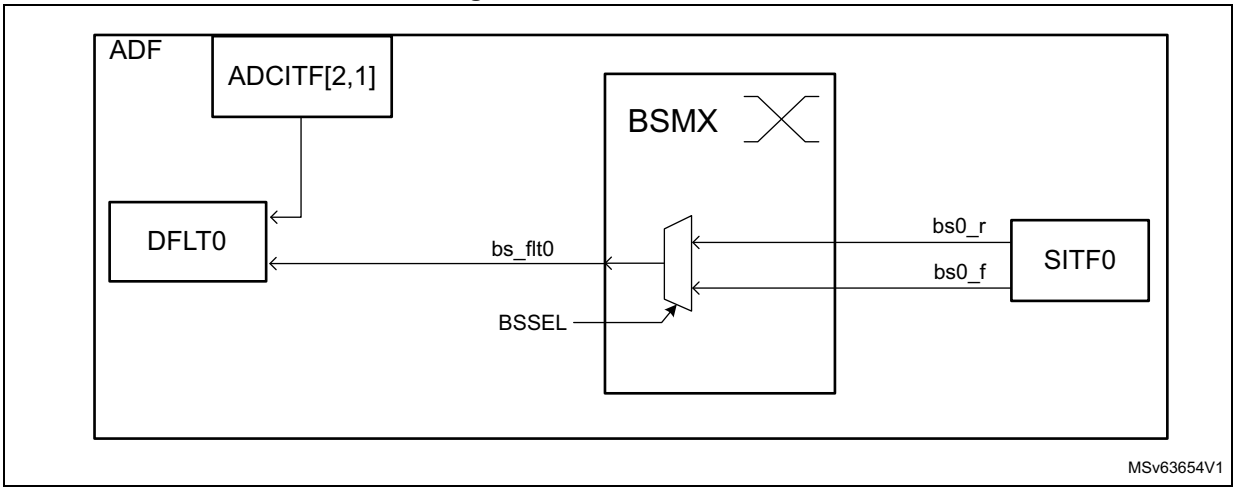
Table 416 shows the frequency constraints to receive and process properly the samples.

Note: The reshape filter (RSFLT) needs up to 24 cycles of adf_proc_ck clock to process one sample.

Table 416. Clock constraints with respect to the incoming stream(1)

SITF0 mode	ADF clock constraints	
	With RSFLT disabled	With RSFLT enabled
LF_MASTER SPI	F_{ADF_CCKy} max frequency limited to 5 MHz	
	$F_{adf_proc_ck} > 2 \times F_{ADF_CCKy}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$	$F_{adf_proc_ck} > 24 \times F_{ADF_CCKy} / (MCICD+1)$ and $F_{adf_proc_ck} > 2 \times F_{ADF_CCKy}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$
MASTER SPI SLAVE SPI	F_{ADF_CKx} max frequency limited to 25 MHz	
	$F_{adf_proc_ck} > 4 \times F_{ADF_CCKy}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$	$F_{adf_proc_ck} > 24 \times F_{ADF_CCKy} / (MCICD+1)$ and $F_{adf_proc_ck} > 4 \times F_{ADF_CCKy}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$
Manchester	F_{SYMB} max frequency limited to 20 MHz	
	$F_{adf_proc_ck} > 6 \times F_{SYMB}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$	$F_{adf_proc_ck} > 24 \times F_{ADF_CCKy} / (MCICD+1)$ and $F_{adf_proc_ck} > 6 \times F_{SYMB}$ and $F_{adf_hclk} \geq F_{adf_proc_ck}$

1. F_{ADF_CCKy} represents the frequency of clock received via ADF_CCKy, or generated via ADF_CCKy. F_{SYMB} represents the frequency of the received symbol rate for Manchester mode.



46.4.6 Bitstream matrix (BSMX)

The BSMX receives the bitstreams from the serial interface SITF0 and provides the selected stream to the digital filter DFLT0.

As shown in *Figure 382*, the SITF0 provides two bitstreams (bs0_r and bs0_f) to the BSMX.

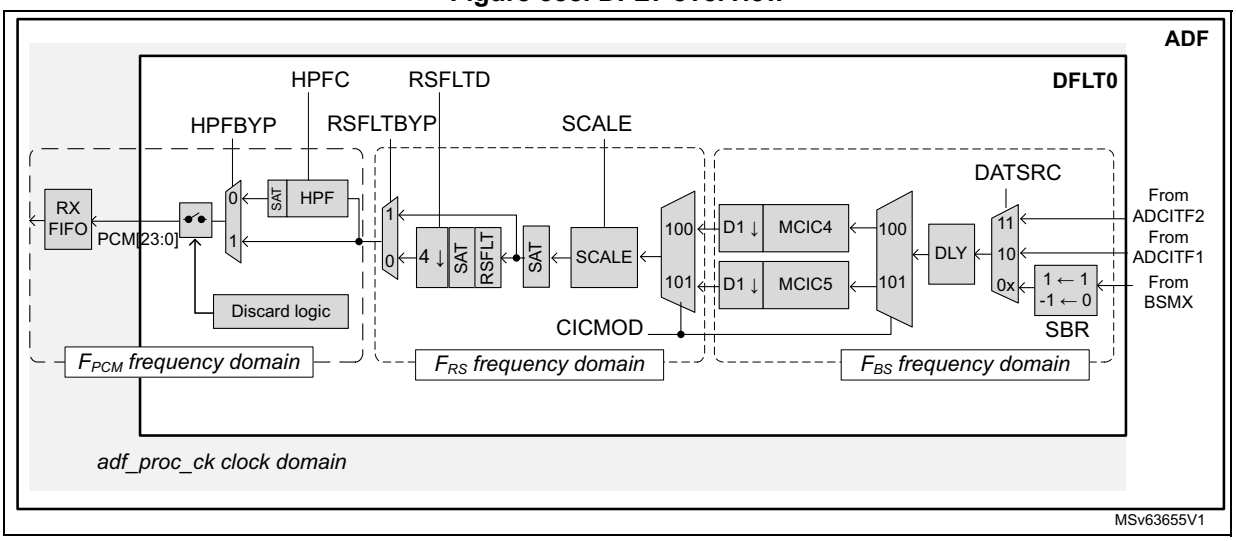
The application to select the wanted stream via the *ADF bitstream matrix control register 0 (ADF_BSMX0CR)*. This selection is intended to be static.

Figure 387. BSMX overview

BSMX programming sequence example

The BSSEL[4:0] bitfield cannot be changed if the DFLT0 is enabled. The following steps are needed to change the value of BSMX:

1. Set DFLTEN of DFLT0 to 0.
2. Wait for BSMXACTIVE = 0.
3. Program BSSEL[4:0].
4. Set DFLTEN of DFLT0 to 1.



46.4.7 Digital filter processing (DFLT)

The digital filter processing includes the following sub-blocks:

- symbol remap (SBR)
- clock skipper delay (DLY)
- MCIC decimation filter that can be configured in $Sinc^4$ or $Sinc^5$
- gain control (SCALE)
- signal saturation (SAT)
- reshape filter (RSFLT)
- high-pass filter (HPF)
- receive RXFIFO

Figure 388 shows the filter path configuration according to CICMOD[2:0]. Several configuration bits are available to configure the digital filter to the application needs.

Figure 388. DFLT overview

Symbol remap and source selection

The symbol remap (SBR) converts the bitstream selected by the BSMX into data usable by the filter path. More especially:

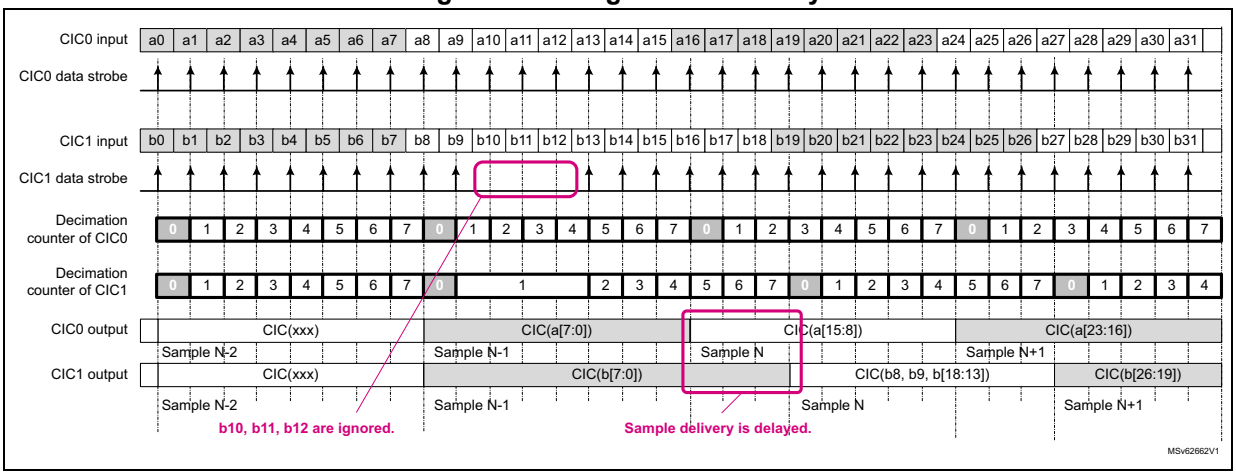
- The high levels are converted into a 16-bit signed number + 1.
- The low levels are converted into a 16-bit signed number - 1.

The signal source of the digital filter can be selected via DATSRC[1:0] between the two following:

- data coming from the BSMX
- data coming from one of the ADC interfaces (ADCITF2 or 1)

Programmable micro-delay control (DLY)

The digital filter has a delay line that allows the timing adjustment of each stream with the resolution of the bitstream clock.



This feature is particularly helpful in the case of microphone beam forming applications where delays smaller than the final sampling rate must be applied to the incoming stream. This feature can be used when the ADF is synchronized with another MDF instance (if present in the product) for a beam forming application for example.

The delay is performed by discarding a given number of samples from the selected input stream, before samples enter into the CIC filter. This data discarding is done by skipping a given number of data strobe, preventing the CIC filter to take into account those data.

When the wanted amount of data strobe has been skipped, the next incoming samples are strobed normally.

Table 389 shows an example on how to apply dynamically small delay to an incoming stream. For simplification, the CIC filter performs a decimation by height in this example. CIC1 represents the CIC included in the ADF and CIC0 represents a filter from another MDF instance (if present in the product).

Figure 389. Programmable delay

The CIC of the ADF (CIC1) receives a command in order to skip three incoming samples. So the input samples named b10, b11 and b12 are not processed by CIC1. As a consequence, the output sample N+1 generated by CIC0 is built from input samples a[23:16] while the sample N+1 of CIC1 is built from input samples b[26:19].

Finally, the non-skipped data stream looks delayed by three bitstream periods.

Note: When the input data strobes are skipped, the decimation counter remains frozen. As a consequence, the samples delivered by the CIC1 are a bit delayed.

The following steps are needed to program the amount of bitstream clock periods to be skipped:

1. Wait for SKPBF equal to 0.
2. Write SKPDLY[6:0] to the wanted number of bitstream clock periods to be skipped. The SKPBF flag goes immediately to 1, indicating that the delay value entered into SKPDLY[6:0] is under process.
   - If the DFLT0 is not yet enabled (DFLTEN = 0), then the DLY logic waits for DFLTEN = 1. When the application sets DFLTEN to 1, the DLY logic starts to skip the amount of wanted data strobes.
   - If the DFLT0 is already enabled (DFLTEN = 1), then the DLY logic immediately starts to skip the amount of wanted data strobes.

   When the ADF skipped the amount of wanted data strobes, then SKPBF goes back to 0.
3. If the application needs to skip more data strobes, then the operation must be restarted from step 1.

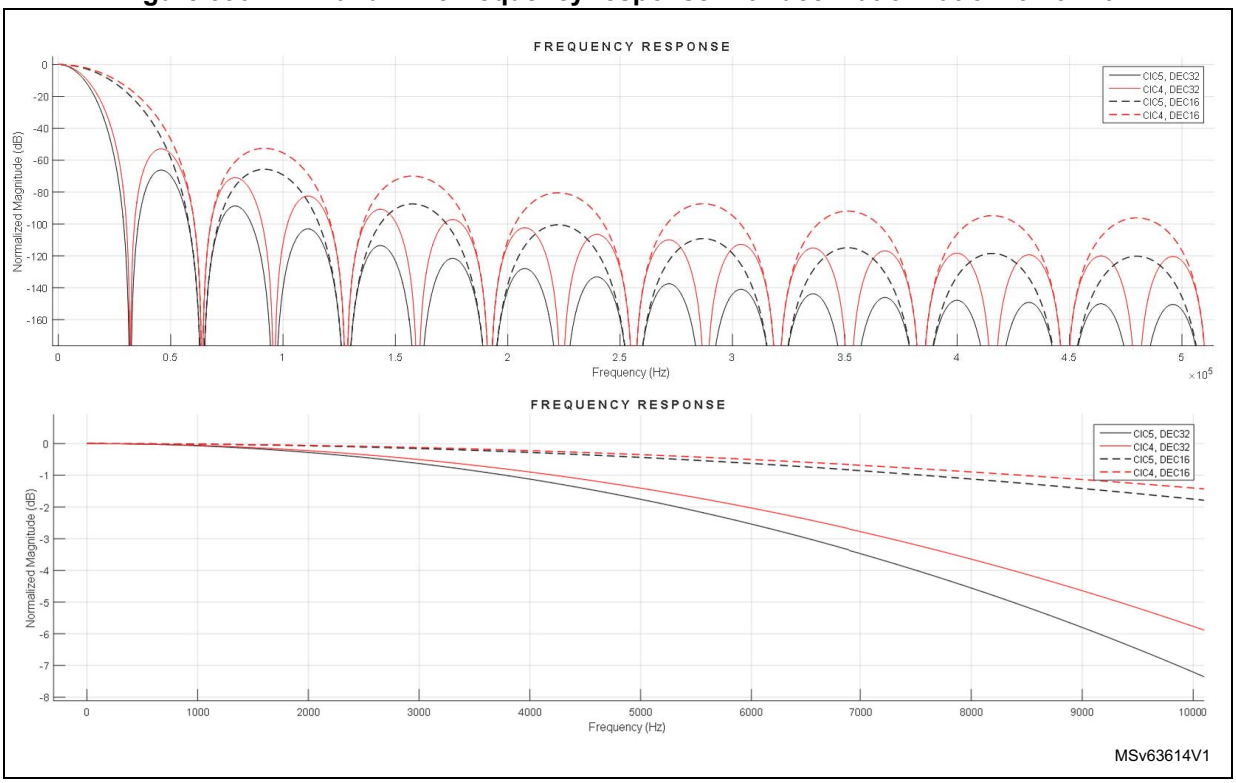
The effect of the delay performed with this mechanism is cumulative as long as the ADF is enabled. If the application performs a D1 delay followed by a D2 delay, then all other active filters are delayed by D1 + D2.

Note: If SKPDLY[6:0] is written when SKPBF = 1, the write operation is ignored.

Cascaded-integrator-comb (CIC) filter

The CIC digital filters are an efficient implementation of low-pass filters, often used for decimation and interpolation. The CIC frequency response is equal to a $Sinc^N$ function, this is why they are often called Sinc filters.

The Sinc^N digital filter embedded into the ADF can be configurable in Sinc^4 or Sinc^5, according to CICMOD:



- If CICMOD[2:0] = 4, Sinc^4 is selected.
- If CICMOD[2:0] = 5, Sinc^5 is selected.

The filters have the following transfer function:

$$H(z) = \left(\frac{1 - z^{-D}}{1 - z^{-1}}\right)^N$$

where N can be 4 or 5, and D is the decimation ratio. D is equal to MCICD+1.

Figure 390. CIC4 and CIC5 frequency response with decimation ratio = 32 or 16

CIC output data size

The size of samples delivered by the CIC (DS_{CIC}), depends on the following parameters:

- CIC order (N)
- CIC decimation ratio (D)
- data size of the input stream (DSIN)

The CIC order and decimation ratio must be programmed in order to insure that the data size does not exceed the 26-bit CIC capability.

The following formula gives the output data size (DS_{CIC}) according to the parameters above.

$$DS_{CIC} = \left(\frac{N \times Ln(D)}{Ln(2)}\right) + DS_{IN}$$

and the CIC gain is given by this formula:

$$G_{CIC} = (D)^N$$

The decimation ratio can be adjusted from 2 to 512 for the CIC filter.

Table 417 gives some data output size in bits for some decimation values, when the data source is a full-scale signal coming from the serial interface or from a 12-bit ADC.

Note: DS_{IN} = 1 bit for a serial bitstream, but can be up to 16 bits when coming from the ADCITF.

Table 417. Data size according to CIC order and CIC decimation values

Decimation	Data size (bits) when DS_{IN} = 1 bit (data from SITF0)		Data size (bits) when DS_{IN} = 12 bits (data from ADCITF)	
	Sinc^4	Sinc^5	Sinc^4	Sinc^5
4	9	11	20	22
8	13	16	24	-
10	15	18	26	-
12	16	19	-	-
16	17	21	-	-
20	19	23	-	-
24	20	24	-	-
32	21	26	-	-
48	24	-	-	-
64	25	-	-	-
76	26	-	-	-

Note: For a full-scale input signal, the decimation ratio must not exceed 76 for a Sinc^4 and 32 for a Sinc^5.

The LSB parts of the data provided by the CIC is not necessarily significant: it depends on the sensor performances and the ability of the CIC to reject the out-off band noise.

The sample size at CIC output can be adjusted thanks to the SCALE block.

Scaling (SCALE) and saturation (SAT)

The SCALE block allows the application to adjust the amplitude of the signal provided by the CIC, by steps of 3 dB (± 0.5 dB).

The signal amplitude can be decreased by up to 8 bits (- 48.2 dB), and can be increased by up to 12 bits (+ 72.2 dB).

The gain is adjusted by the SCALE[5:0] bitfield in the *ADF digital filer configuration register 0 (ADF_DFLT0CICR)*.

SCALE[5:0] can be changed even if the DFLT0 is enabled. During the gain transition, the signal provided by the filter is disturbed.

Due to internal resynchronization, there is a delay of some cycles of adf_proc_ck clock between the moment where the application writes the new gain, and the moment where the gain is effectively applied to the samples. If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back SCALE[5:0] informs the application on the current gain value.

Table 418 shows the possible gain values.

Table 418. Possible gain values

SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)	SCALE[5:0]	Gain (dB)
0x20	- 48.2	0x2B	- 14.5	0x06	+ 18.1	0x11	+ 51.7
0x21	- 44.6	0x2C	- 12.0	0x07	+ 21.6	0x12	+ 54.2
0x22	- 42.1	0x2D	- 8.5	0x08	+ 24.1	0x13	+ 57.7
0x23	- 38.6	0x2E	- 6.0	0x09	+ 27.6	0x14	+ 60.2
0x24	- 36.1	0x2F	- 2.5	0x0A	+ 30.1	0x15	+ 63.7
0x25	- 32.6	0x00	0.0	0x0B	+ 33.6	0x16	+ 66.2
0x26	- 30.1	0x01	+ 3.5	0x0C	+ 36.1	0x17	+ 69.7
0x27	- 26.6	0x02	+ 6.0	0x0D	+ 39.6	0x18	+ 72.2
0x28	- 24.1	0x03	+ 9.5	0x0E	+ 42.1	-	-
0x29	- 20.6	0x04	+ 12.0	0x0F	+ 45.7	-	-
0x2A	- 18.1	0x05	+ 15.6	0x10	+ 48.2	-	-

The SAT blocks avoid having a wrap-around of the binary code when the code exceeds its maximal or minimal value.

The ADF performs saturation operations at the following levels:

- after the SCALE block (performed by the SAT block): The signal is saturated at 24 bits.
- inside the RSFLT, to insure a good filter behavior
- at the output of the HPF, to insure that the output signal does not exceed 24 bits

The SATF bit informs the application that a saturation occurred either after the SCALE, inside the RSFLT or after the HPF. In addition, an interrupt can be generated if SATIE is set to 1. As soon as a saturation is detected, the SATF flag is set to 1. It is up to the application to clear this flag in order to be able to detect a new saturation.

Those bits are in the *ADF DFLT0 interrupt enable register (ADF_DFLT0IER)* and *ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)*.

Gain adjustment policy

To get the best ADF performances, it is important to properly adjust the gain value via SCALE[5:0].

A usual way to adjust the gain is to select the SCALE[5:0] value that gives a final signal amplitude as close as possible to the 24-bit full-scale, for the maximum input signal.

A way to select the optimal gain is detailed below:

1. Check that, for the expected input signal, the data size into the CIC filter does not exceed 26 bits. This can be checked using this formula:

$$\frac{LN(SIN_{pp} \cdot D^N)}{LN(2)} < 26$$

where N represents the CIC order, D the decimation ratio and SIN_{pp} the maximum peak-to-peak amplitude of the input signal.

SIN_{pp}can take:

– a maximum peak-to-peak amplitude of 2 (± 1), for samples coming from SITF0

– A maximum peak-to-peak amplitude of 4095 (+ 2047, - 2048), for samples coming from a 12-bit ADC

Example: a $Sinc^4$ can be used with a decimation ratio of 96, if the maximum input signal does not exceed ± 0.35. Indeed:

$$\frac{LN(0.7 \cdot 96^4)}{LN(2)} \sim 25.82 \text{ bits} < 26 \text{ bits}$$

2. Adjust the SCALE value.

   To select the most appropriate SCALE value, the user must check if the RSFLT is used or not. If the RSFLT is used, the data size at SCALE output must not exceed 22 bits, otherwise the data size can be up to 24 bits.

   The SCALE value in dB must be selected using this formula:

$$SCALE_{dB} < 20 \cdot \log 10\left(\frac{2^{NB}}{SIN_{pp} \cdot D^{N}}\right)$$

   where NB is equal to 22 if RSFLT is enabled, or 24 if RSFLT is bypassed. $SCALE_{dB}$ represents the gain value selected by SCALE[5:0].

   Example: For a $Sinc^4$ with a decimation ratio of 96 and a SIN_{pp} of 0.7.

   – If the RSFLT is bypassed:

$$20 \cdot \log 10\left(\frac{2^{24}}{0.7 \cdot 96^{4}}\right) \sim -11 \text{ dB}$$

     $SCALE_{dB}$ value must be lower than - 11 dB, the closest lower value is - 12dB (SCALE[5:0] = 0x2C).

   – If the RSFLT is enabled:

$$20 \cdot \log 10\left(\frac{2^{22}}{0.7 \cdot 96^{4}}\right) \sim -23 \text{ dB}$$

     $SCALE_{dB}$ value must be lower than - 23 dB, the closest lower value is - 24.1 dB (SCALE[5:0] = 0x28).

   If SCALE[5:0] is set to a higher value, then a saturation may occur. An event flag informs the user if a saturation occurred.

Table 419 proposes gain values for different filter configurations, when the data comes from the SITF0, according to the MCIC order, and the MCIC decimation ratio. This table is not exhaustive and considers a full-scale input signal (see *Section 46.7.5: Total ADF gain* for details).

Table 419. Recommended maximum gain values versus CIC decimation ratios

CIC decimation ratio	Gain settings (dB) for configuration SITF + CICx + RSFLT (+ HPF)		Gain settings (dB) for configuration SITF + CICx (+ HPF)	
	CIC5	CIC4	CIC5	CIC4
8	33.6	51.7	45.7	63.7
12	18.1	39.6	30.1	51.7
16	3.5	27.6	15.6	39.6
20	- 6.0	21.6	6.0	33.6
24	- 12.0	15.6	0	27.6
28	- 20.6	9.5	- 8.5	21.6

Table 419. Recommended maximum gain values versus CIC decimation ratios (continued)

CIC decimation ratio	Gain settings (dB) for configuration SITF + CICx + RSFLT (+ HPF)		Gain settings (dB) for configuration SITF + CICx (+ HPF)	
	CIC5	CIC4	CIC5	CIC4
32	- 26.6	3.5	- 4.5	15.6
48	-	- 8.5	-	3.5
64	-	- 20.6	-	- 8.5

Reshaping filter (RSFLT)

In addition to the CIC, the ADF offers a reshaping IIR filter mainly dedicated to the audio application, but also usable in other applications.

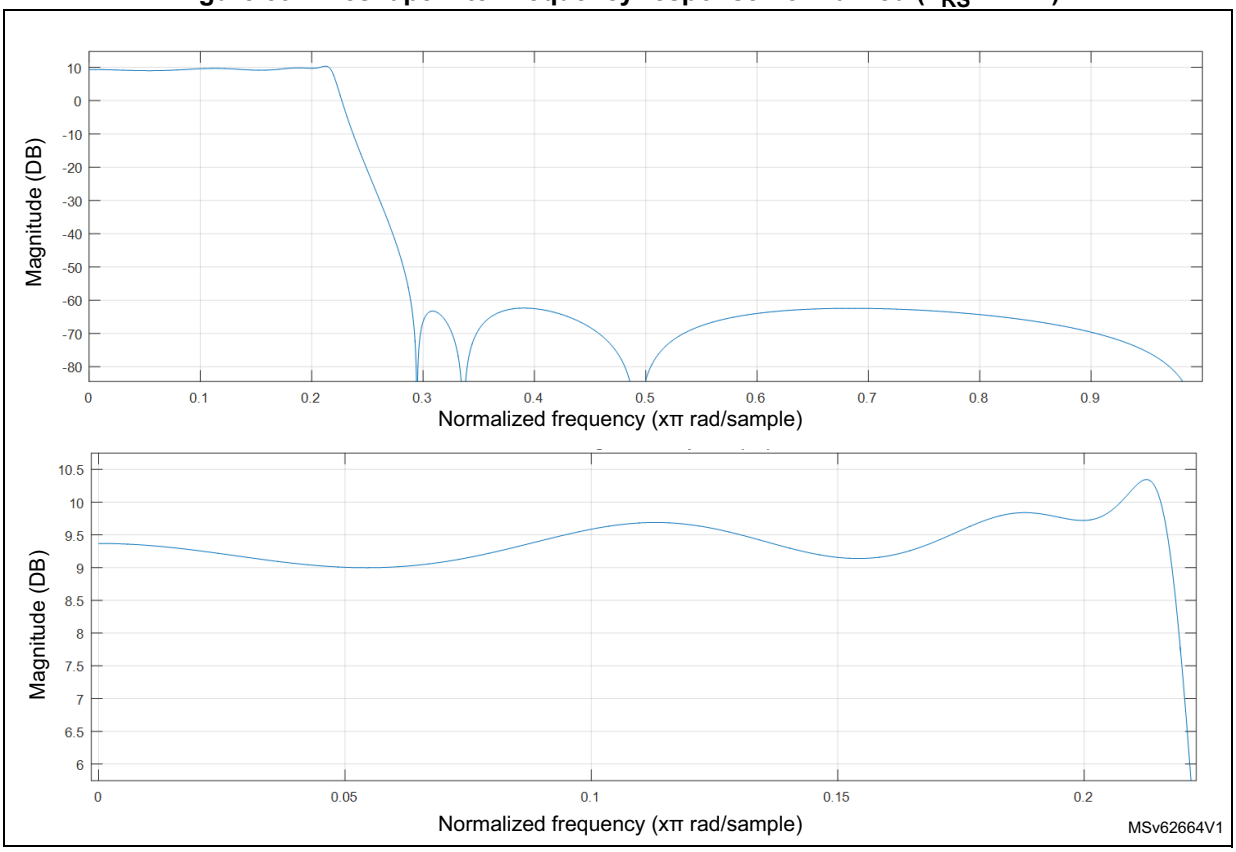
When the RSFLT is used, the sample size at its input must not exceed 22 bits.

The samples at the RSFLT output can be decimated by four or not according to the RSFLTD bit in the *ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)*.

The RSFLT can be bypassed by setting RSFBYP to 1 in the *ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)*.

Table 420 shows which sampling rate must be provided to the RSFLT in order to process the most common audio streams.

The RSFLT cutoff frequency (F_C) depends on the sample rates at its input (F_{RS}), and is given by the following formula:



$$F_C = 0.111 \times F_{RS}$$

Table 420. Most common microphone settings

Sample rate (kHz) at RSFLT (F_{RS})	Pass band (kHz)	D2	PCM sampling rate (kHz)
32	3.55	4	8
64	7.1	4	16
128	14.2	4	32
192	21.3	4	48

Table 391 shows the frequency response of the reshape filter.

Figure 391. Reshape filter frequency response normalized (F_{RS} / 2 = 1)

The RSFLT gain is close to 9.3 dB, so the output data size is a little bit lower than 24 bits for a 22-bit wide input signal.

The RSFLT takes 24 clock cycles of adf_proc_ck clock to process one sample at F_{RS}. When the RSFLT is enabled, the application must insure that the adf_proc_ck is at least 24 times faster F_{RS}.

The RSFLT generates an event (rfovr_evt) and sets the RFOVRF flag, if the RSFLT receives a new samples while the previous one is still under processing.

When RFOVRF is set, the samples provided by the RSFLT are invalid. The application must then stop the data acquisition and provides a faster adf_proc_ck clock to the RSFLT.

High-pass filter (HPF)

The high-pass filter suppresses the low-frequency content from the final output data stream in case of continuous conversion mode. The high-pass filter can be enabled or disabled via HPFBYP in the *ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)*.

The HPF is useful when there is parasitic low-frequency noise (or DC signal) in the input data source that must be removed from the final data.

The HPF is a first order IIR filter and the cut-off frequency can be selected via HPFC[1:0] in the *ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)*, among the following values:

- 0.000625 x F_{PCM}
- 0.00125 x F_{PCM}
- 0.00250 x F_{PCM}
- 0.00950 x F_{PCM}

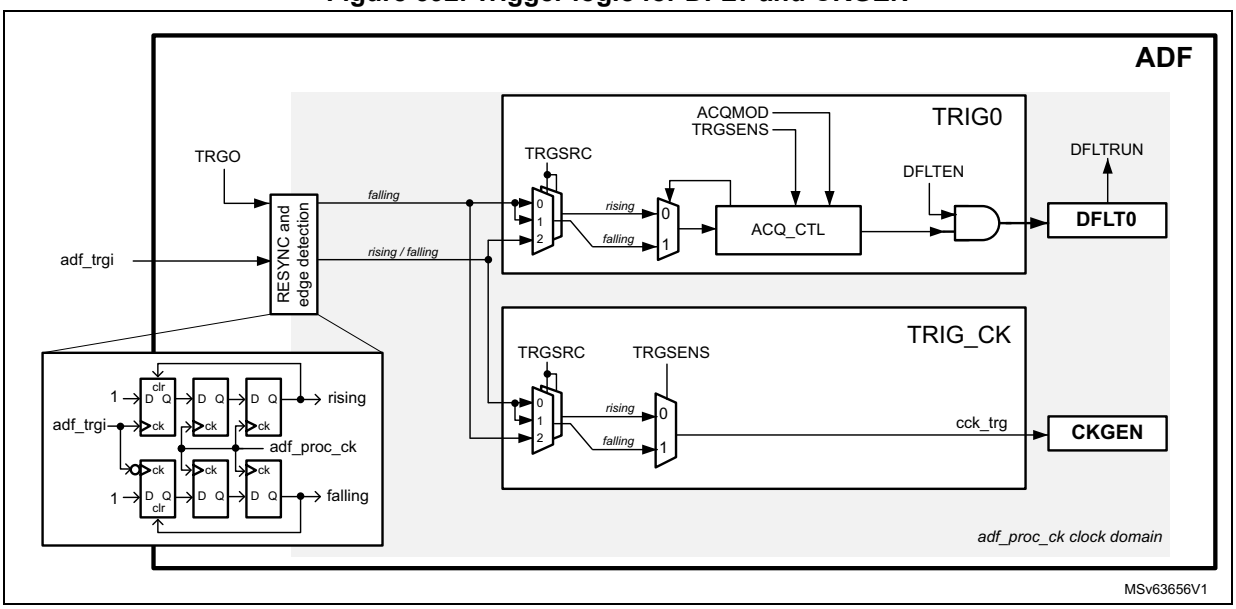
Table 421. HPF 3 dB cut-off frequency examples

HPFC	3 dB cut-off frequency for common F_{PCM} frequencies (Hz)		
	F_{PCM} = 8 kHz	F_{PCM} = 16 kHz	F_{PCM} = 48 kHz
0	5	10	30
1	10	20	60
2	20	40	120
3	76	152	456

The HPF output is saturated at 24 bits. The SATF flag is set if a sample is saturated.

46.4.8 Digital filter acquisition modes

The ADF offers the following modes to perform a data capture:



- asynchronous continuous acquisition mode
- asynchronous single-shot acquisition mode
- synchronous continuous acquisition mode
- synchronous single-shot acquisition mode
- window continuous acquisition mode

Note: To perform a data capture, the filter, the interface providing the data (SITF0 or ADCITF) and the CKGEN must be enabled. If needed, the ADF_CCK0 or ADF_CCK1 must be enabled as well.

The filter can be stopped immediately when DFLTEN is set to 0. This action resets the filter and flushes the RXFIFO. The DFLTACTIVE flag also goes back to 0 when the RXFIFO and the filter is reset.

Table 392 shows a simplified view of the trigger logic available for each filter and for the clock generator.

Figure 392. Trigger logic for DFLT and CKGEN

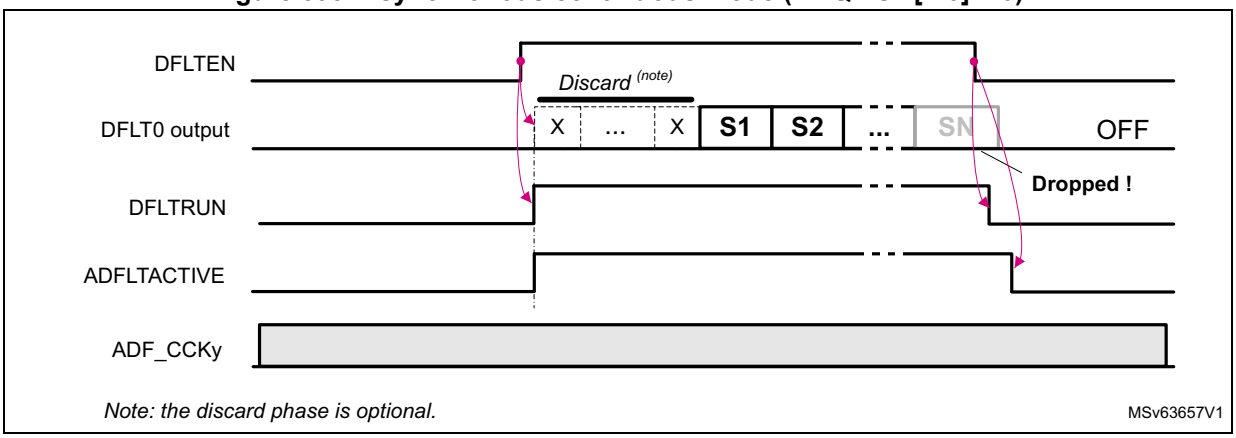
A block common to all TRIG blocks performs the rising and falling edges detection and the re-synchronization of the input trigger to the adf_ker_ck clock domain. This implementation allows the application to use triggers with pulse width smaller than the adf_ker_ck period.

In synchronous modes, the TRIG block offers the possibility to select adf_trgi or TRGO bit as trigger sources. The TRGO bit is in the *ADF global control register (ADF_GCR)*.

The edge sensitivity can also be selected.

Asynchronous continuous acquisition mode

This mode allows the application to start a continuous acquisition by simply writing the DFLTEN bit to 1.



The asynchronous continuous acquisition mode is selected when ACQMOD[2:0] = 0.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN) so that the adf_proc_ck frequency is compatible with the targeted application (see examples in *Table 425*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 0.
4. Set to 1 the SITFEN bit of the serial data interface.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1, the acquisition sequence starts immediately.

Figure 393 shows a simplified example of the samples generated by the DFLT0.

Figure 393. Asynchronous continuous mode (ACQMOD[2:0] = 0)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Asynchronous single-shot acquisition mode

This mode allows the application to start the acquisition of one sample by simply writing the DFLTEN bit to 1.

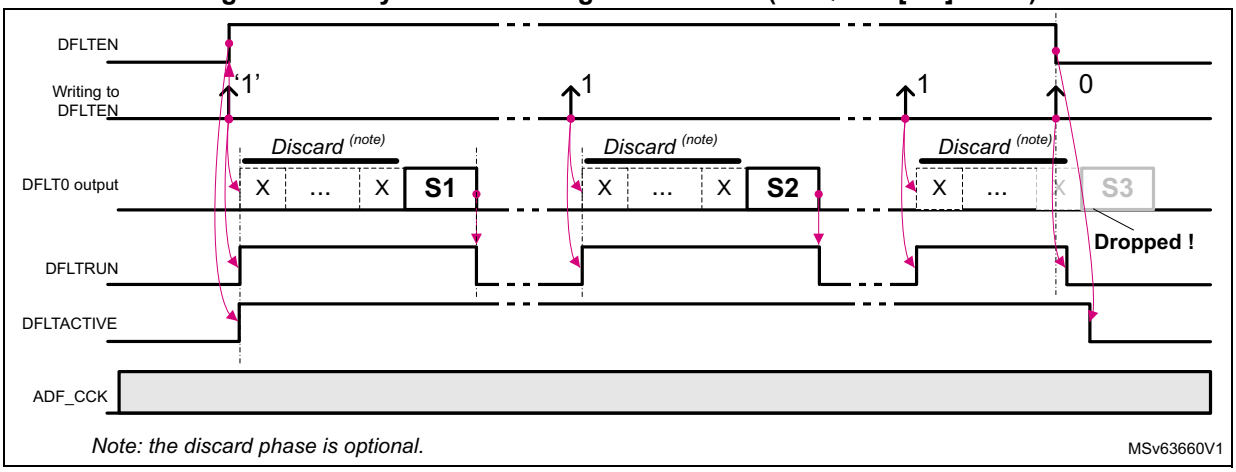
The asynchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 001.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the adf_proc_ck frequency is compatible with the targeted application (see examples in *Table 425*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 001.
4. Set to 1 the SITFEN bit.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1, the filter provides one data to the RXFIFO and stops the acquisition.

To trigger a new acquisition, the application must:

1. Check that the previous acquisition is completed, by waiting that DFLTRUN = 0.
2. Set again DFLTEN to 1.



This sequence can be repeated every time a new data must be converted.

As shown in *Figure 393*, every time DFLTEN is set to 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset, and the filter is ready to start a new conversion.

If DFLTEN is set to 0 while an acquisition is ongoing, the ongoing conversion is stopped (in the example, S3 is lost). This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Set DFLTEN to 0.

Figure 394. Asynchronous single-shot mode (ACQMOD[2:0] = 001)

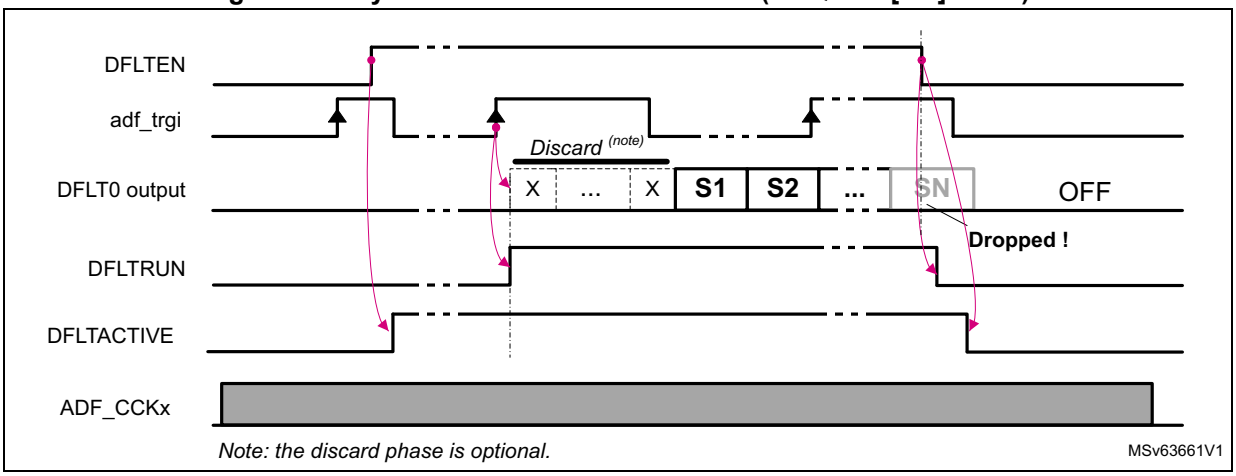
Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous continuous acquisition mode

This mode allows the application to start a continuous acquisition by using one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The Synchronous continuous acquisition mode is selected when ACQMOD[2:0] = 010.



The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in *Table 425*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 010.
4. Set to 1 the bit SITFEN.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. When the trigger condition is met, the filter starts the acquisition.

The TRGSENS bit allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

Figure 395 shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). The first rising edge of the trigger signal is ignored because DFLTEN = 0. Then the next rising edge is taken into account and starts the acquisition. All other rising edges are ignored. The trigger logic is re-initialized when DFLTRUN goes back to 0.

Figure 395. Synchronous continuous mode (ACQMOD[2:0] = 010)

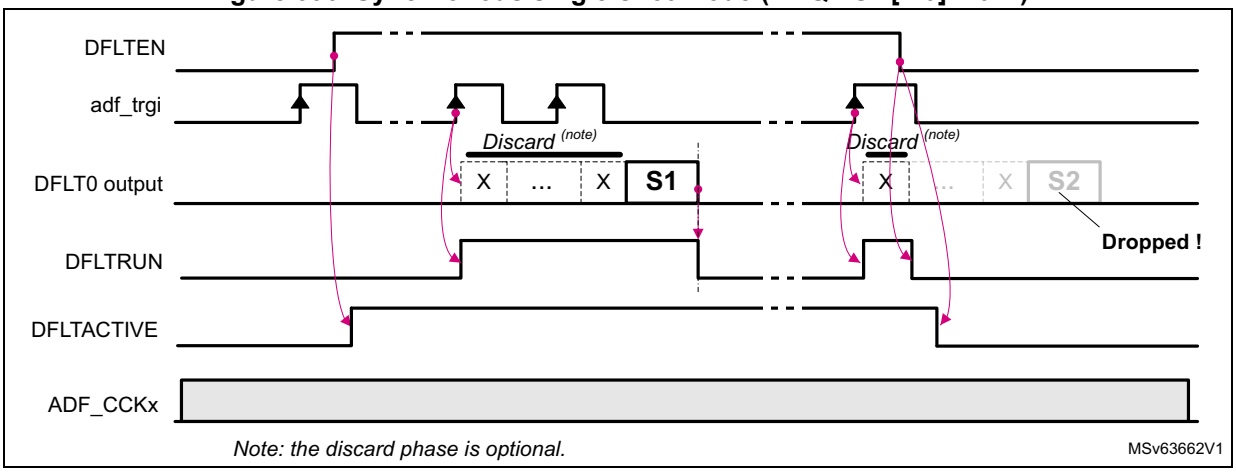
Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous single-shot acquisition mode

This mode allows the application to start a single acquisition by using one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The Synchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 011.



The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in *Table 425*).
2. Enable the CKGEN and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 011.
4. Set to 1 the SITFEN bit.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. When the trigger condition is met, the filter starts the acquisition and provides one data to the RXFIFO, then the filter is ready to accept a new trigger.

TRGSENS allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing, or if DFLTEN is set to 0.

Figure 396 shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). Every-time a trigger rising edge is detected with DFLTEN = 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset. DFLTRUN is set to 0 and the filter is ready to start a new conversion.

Figure 396. Synchronous single-shot mode (ACQMOD[2:0] = 011)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Figure 395 shows a case where the DFLTEN is set to 0 while an acquisition is ongoing (the sample S2 is lost). This situation can be avoided with the following steps:

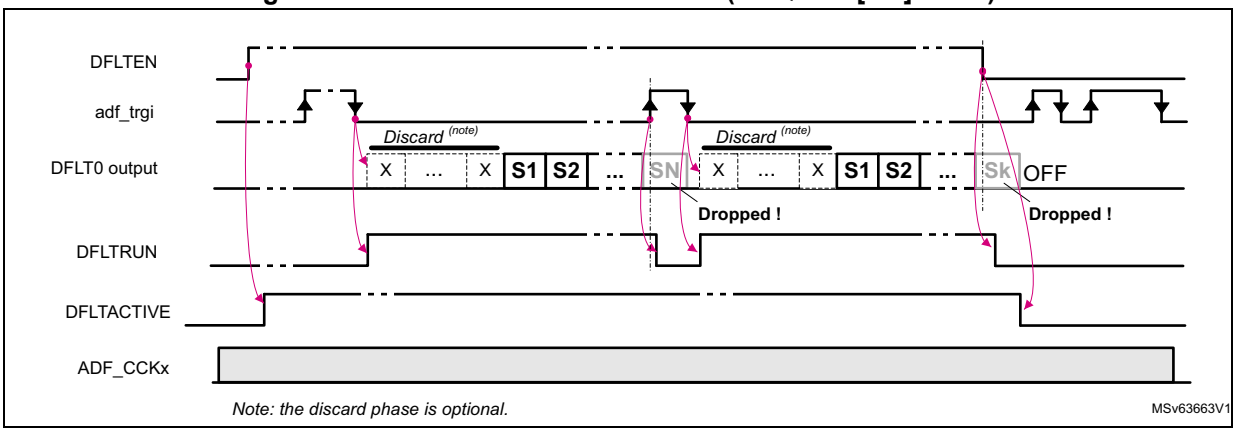
1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Clear DFLTEN to 0.

Window continuous acquisition mode

This mode allows the application to start or stop a continuous acquisition controlled by consecutive edges of one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The window continuous acquisition mode is selected when ACQMOD[2:0] = 100.



The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in *Table 425*).
2. Enable the CKGEN and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter settings and set the ACQMOD[2:0] to 100.
4. Set to 1 the SITFEN bit.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. If TRGSENS = 0, the acquisition starts on trigger rising edge and stops on trigger falling edge. If TRGSENS = 1, the acquisition starts on trigger falling edge and stops on trigger rising edge.

Note: The acquisition may restart if the trigger condition becomes again active.

Figure 397 shows a simplified example of window continuous acquisition mode, with TRGSENS = 1. Once DFLTEN is set to 1, the ADF waits for a falling edge on the selected trigger input. When the trigger condition is met, DFLTRUN goes to 1 and the acquisition starts. The acquisition stops if the ADF detects a rising edge on the selected trigger input. If DFLTEN is still set to 1, the ADF waits again for a falling edge on the selected trigger input.

Figure 397. Window continuous mode (ACQMOD[2:0] = 100)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Starting several filters synchronously

If the ADF is used with MDF instances (if present in the product), it is possible to start simultaneously the acquisition of all the filters. This synchronization capability depends on the way the triggers are connected in the product. Generally, an ADF is able to trigger MDF instances, if its adf_trgo signal is connected as trigger input to those blocks (see *Section 46.4.2: ADF pins and internal signals* to check trigger capabilities).

In the following programming example, one ADF has its adf_trgo signal connected to some MDFs. To start the acquisition of several filters synchronously, the following sequence must be performed (assuming that DFLTEN bits of the filters are set to 0):

On MDFs receiving the adf_trgo trigger:

1. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
2. Set to 1 the SITFEN bit of the requested data interfaces.
3. For each filter, set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. For each filter, set TRGSRC[3:0] in order to select the adf_trgo trigger input.
5. For each filter, set TRGSENS to 0 (rising edge).
6. For each filter, set DFLTEN to 1.

On the ADF generating the adf_trgo trigger:

1. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK[1:0] clocks.
2. Set to 1 the SITFEN bit of the requested data interfaces.
3. Set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. Set TRGSRC[3:0] to 0 (TRGO selected).
5. Set TRGSENS to 0 (rising edge).
6. Set DFLTEN to 1.
7. Read TRGO bit until it is read to 0.
8. Set TRGO to 1. Then the acquisition sequence for all selected filters starts immediately.

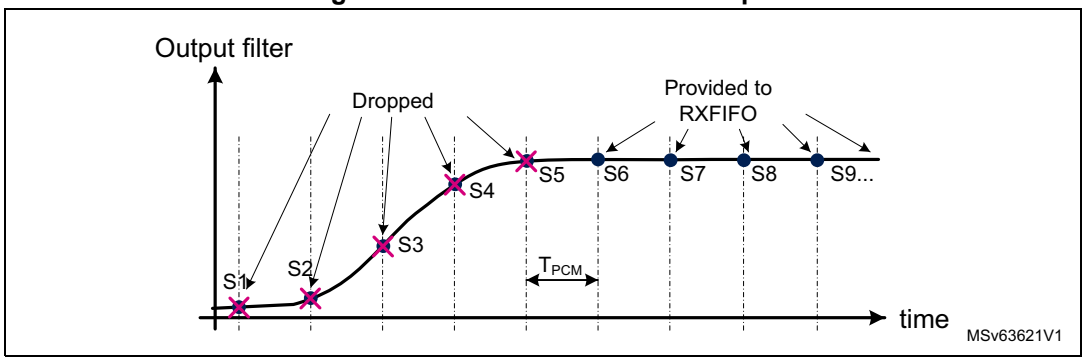
To trigger a new acquisition (in case of single-shot) the application must do the following:

1. Check that the previous acquisition is completed, by waiting DFLTRUN = 0.
2. Read TRGO until it is read to 0.
3. Set again the bit TRGO to 1.

Discarded samples

The ADF offers the possibility to program the amount of samples to be discarded after each restart:

- to avoid capturing samples affected by the impulse response of the filter
- to delay the acquisition of filters by a specific amount of samples



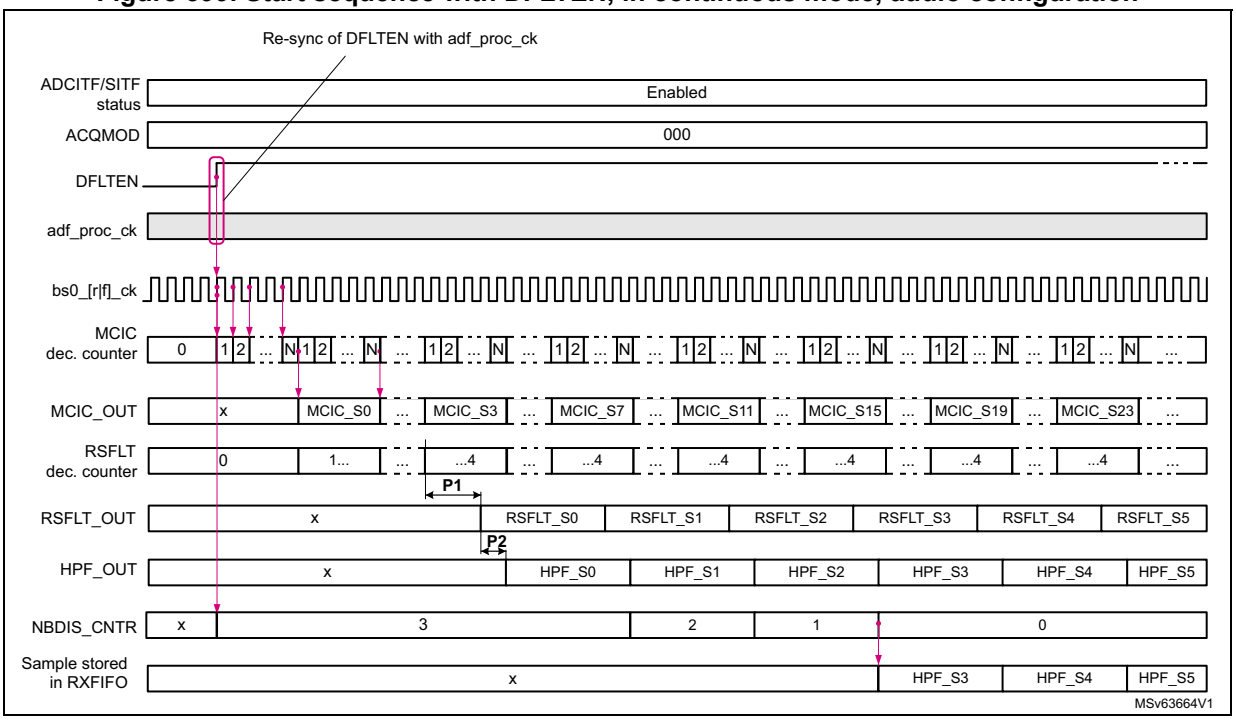
The discard function is controlled via NBDIS[7:0] as follows:

- When NBDIS[7:0] = 0, the discard function is disabled.
- When NBDIS[7:0] ≠ 0, the discard function is activated in one of the following condition:
  - when the DFLTEN bit goes to 1
  - every time an acquisition is started in (A)synchronous single-shot modes

Refer to *Figure 392* to *Figure 396*, and *Figure 398*.

In the example shown in *Figure 398*, the discard function is used to drop the first five samples provided by the digital filter (S1 to S5). The first sample transfered to the RXFIFO is S6.

Figure 398. Discard function example



46.4.9 Start-up sequence examples

Figure 399 details a start of acquisition sequence of a digital filter triggered by DFLTEN (ACQMOD[2:0] = 0), with NBDIS[7:0] = 3 (three samples to discard before acquisition).

The DFLT0 is configured for audio application: MCIC, RSFLT and HPF activated.The data interface (SITF0 or ADCITF) is assumed to be already activated.

Note: NBDIS[7:0] is set on purpose to a small value to simplify the drawing.

Figure 399. Start sequence with DFLTEN, in continuous mode, audio configuration

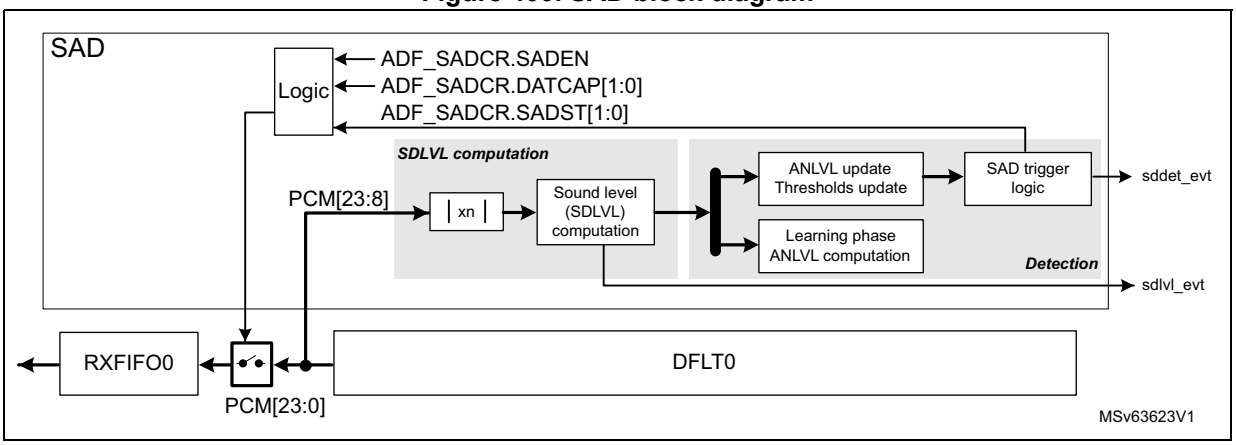
The DFLTEN bit is re-sampled into the ADF processing clock domain. When DFLTEN is detected high, the filter chain is enabled, and the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

When the MCIC decimation counter reached its programmed value N, a sample is available for the RSFLT.

The RSFLT processes all the samples provided by the MCIC, and delivers a sample to the HPF every-time it processes four samples (decimation by 4). The RSFLT needs up to 24 cycles of adf_proc_ck clock before delivering a sample (P1).

The HPF processes all the samples provided by the RSFLT, but the NBDIS function prevents the data writing in the RXFIFO as long as NBDIS_CNTR does not reach 0.

When NBDIS_CNTR reaches 0, the samples provided by the HPF are stored into the RXFIFO.



46.4.10 Sound activity detection (SAD)

The SAD is based on the computation of the ambient noise level (ANLVL) and of the short-term sound level (SDLVL). The SAD offers the following ways to detect a sound:

- when the SDLVL reaches a threshold referenced to the ambient noise level
- when the SDLVL reaches a fixed threshold
- when the ANLVL reaches a fixed threshold

As shown in *Figure 400*, the SAD takes the 16 MSB samples from the DFLT0 output.

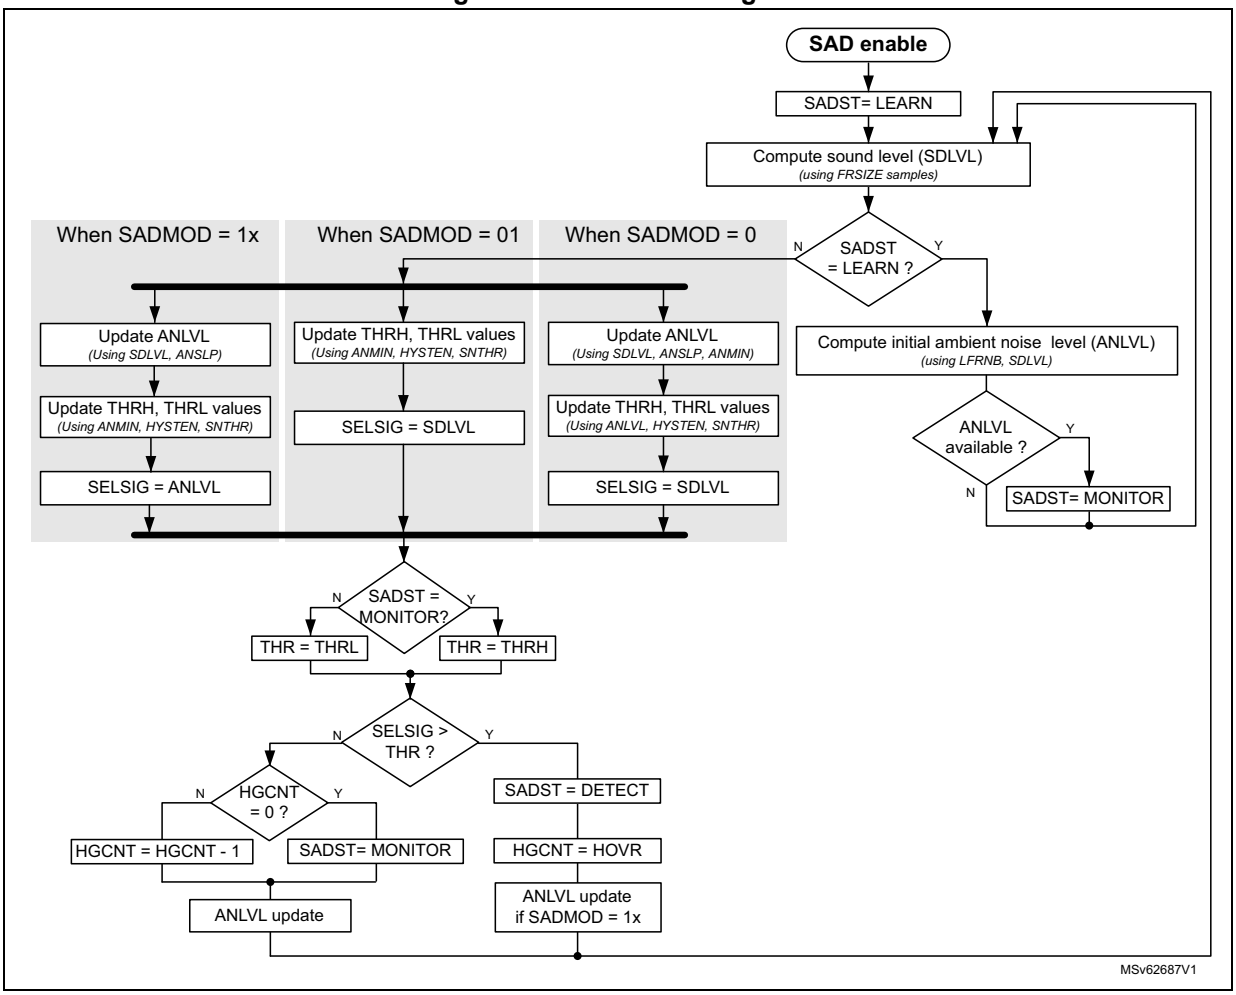
Figure 400. SAD block diagram

The SAD is highly configurable, and the application can adjust several parameters:

- SAD detection behavior (SADMOD)
- number of samples used to compute the sound level (FRSIZE)
- number of frames used to compute the ambient noise level during the learning phase (LFRNB)
- slope of the ambient noise estimator (ANSLP)
- minimum expected ambient noise level (ANMIN)
- threshold level (SNTHR)
- threshold hysteresis (HYSTEN)
- hangover window in order to filter spurious transitions between DETECT and MONITOR states (HGOVR)
- data capture mode (DATCAP)

SAD detection behavior

The SAD can use the following ways to detect a sound, selected by SADMOD[1:0]:



- When SADMOD[1:0] = 0, the SAD works like a voice-activity detection. In this mode, the SAD estimates the ambient noise level according to the computed sound level values. The threshold of the trigger is elaborated from the estimated ambient noise. Finally the current sound level is compared to this threshold. In a first approximation, the SAD triggers if the peak-to-average value of the input signal reaches a level defined by SNTHR[3:0].
- When SADMOD[1:0] = 01, the SAD compares the current sound level (SDLVL) to a fixed trigger value defined by the application via SNTHR[3:0] and ANMIN[12:0]. This mode allows a fast SAD reaction as the amount of samples used to compute the sound level can be configured via FRSIZE[2:0].
- When SADMOD[1:0] = 1x, the SAD compares the estimated ambient noise level (ANLVL) to a fixed trigger value defined by the application via SNTHR[3:0] and ANMIN[12:0]. This mode avoids unwanted triggers, due to peak levels, but the SAD reacts more slowly to an input signal variation. It is nevertheless possible to adjust the reaction time via FRSIZE[2:0] and ANSLP[2:0].

SAD states

As shown in *Figure 400*, the SAD works as follows:

1. When enabled (SADEN = 1), the SAD is first in LEARN state to perform a first estimation of the ambient noise level.
2. The SAD continuously computes the short-term sound level (SDLVL) using the samples provided by the DFLT0. The amount of samples used to compute the sound level is given by FRSIZE[2:0]. The samples processed by the DFLT0 can be transferred into the memory or not depending on DATCAP[1:0] value.
3. The initial ambient noise level (ANLVL) is computed using the consecutive sound level values. The application can define how much sound level values are used to perform the computation of this initial ambient noise estimation (LFRNB).
4. When the initial ambient noise level (ANLVL) is computed, the SAD switches to the MONITOR state.
5. Every time a new short-term sound level value is available, the SAD updates the ambient noise level and the thresholds according to the selected detection mode.
6. If the SAD triggers, then the following happens:
   – The SAD switches to DETECT state.
   – The sddet_evt event is asserted.
   – The adf_sad_det signal is set to high.
7. The hangover function insures that the DETECT state is maintained even if the sound level goes below the threshold level for a time given by HGOVR.

Figure 401. SAD flow diagram

Sound level computation (SDLVL)

Once enabled, the SAD computes continuously the sound level value. The sound level represents the average of the absolute value of an amount of PCM samples given by FRSIZE[2:0].

$$SDLVL = \frac{1}{N_{FRSIZE}} \times \sum_{n=1}^{N_{FRSIZE}} |PCM(n)|$$

where N_{FRSIZE} is the amount of PCM samples given by FRSIZE[2:0].

Ambient noise estimation (ANLVL)

The ambient noise level (ANLVL) is computed when SADMOD[1:0] is 00 or 10.

The ambient noise level is computed differently according to the state of the SAD as detailed below:

- ANLVL computation during the LEARN state

  Every time the SAD is enabled, a learning phase is initiated in order to estimate a first value of the ambient noise level. During this phase, the SAD cannot trigger.

  During the LEARN phase, the ambient noise level is computed as follows:

$$ANLVL = \frac{1}{N_{LFRNB}} \times \sum_{n=1}^{N_{LFRNB}} |SDLVL(n)|$$

  where N_{LFRNB} is the amount of frames given by LFRNB[2:0] bitfield.

- ANLVL computation during the MONITOR or DETECT state

  When the learning phase is completed, the SAD updates the ambient noise level in the following way:

  – The SAD computes the new possible values for the ambient noise level:

    ANLVL_UP = ANLVL * (1+2^(ANSLP-12))

    ANLVL_DN = ANLVL * (1-2^(ANSLP-10))

  – The ANLVL takes the ANLVL_DN value if the current sound level is lower than ANLVL_DN, otherwise ANLVL takes the value of ANLVL_UP.

    The ANLVL is not updated if the current sound level is higher than the threshold level, except if SADMOD[1:0] = 10.

  – When SADMOD[1:0] = 0, if the new ANLVL value is lower than ANMIN[12:0], ANLVL is replaced by ANMIN.

  The slope of the noise estimator can be adjusted to optimize the detection of the wanted signal. This slope is adjusted via ANSLP[2:0] in the *ADF SAD configuration register (ADF_SADCFGR)*.

Table 422 shows the allowed values according to the frame size and the sampling rate of the data observed by the SAD. The recommended values when the SADMOD[1:0] = 0 are the ones into the gray shaded cells.

Table 422. ANSLP values versus FRSIZE and sampling rates

FRSIZE	ANSLP values for Fs = 8 kHz			ANSLP values for Fs = 16 kHz		
	Slow(1)	typical(2)	Fast(3)	Slow(1)	typical(2)	Fast(3)
0 (8 samples)	0	1	2	-	0	1
1 (16 samples)	1	2	3	0	1	2
2 (32 samples)	2	3	4	1	2	3
3 (64 samples)	3	4	5	2	3	4
4 (128 samples)	4	5	6	3	4	5
5 (256 samples)	5	6	7	4	5	6
6 (512 samples)	6	7	-	5	6	7

1. The slow slope is equal to - 8.5 dB/s for the negative slope and + 2.1 dB/s for the positive slope.
2. The typical slope is equal to - 17.1 dB/s for the negative slope and + 4.2 dB/s for the positive slope.
3. The fast slope is equal to - 34.2 dB/s for the negative slope and + 8.5 dB/s for the positive slope.

The slopes can also be computed using the following formulas:

$$SLC_{UP} = 20 \times \frac{F_s}{F_{SIZE}} \times \log 10(1 + 2^{(ANSLP - 12)})$$

$$SLC_{DN} = 20 \times \frac{F_s}{F_{SIZE}} \times \log 10(1 - 2^{(ANSLP - 10)})$$

where F_S is the sampling rate of the stream observed by the SAD and F_{SIZE} is the frame size defined by FRSIZE[2:0].

Threshold computation

The way the threshold value is computed depends on SADMOD[1:0]:

- If SADMOD[1:0] = 0, THRH is obtained by multiplying the current ANLVL value with the gain defined in SNTHR[3:0].

  $$THR_H = ANLVL \times 10^{\frac{GdB_{SNTHR}}{20}}$$

  This threshold value is then compared to the current sound level (SDLVL).
- If SADMOD[1:0] = 01, THRH is obtained by multiplying the current ANMIN[12:0] with the gain defined by SNTHR[3:0].

  $$THR_H = ANMIN \times 10^{\frac{GdB_{SNTHR}}{20}}$$

  This threshold value is then compared to the current sound level (SDLVL).

- If SADMOD[1:0] = 1x, THRH is obtained by multiplying the current ANMIN[12:0] by 4.

$$THR_H = ANMIN \times 4$$

This threshold value is then compared to:

$$ANLVL \times 10^{\frac{GdB_{SNTHR}}{20}}$$

The hysteresis mode can be enabled to reduce the spurious transitions between MONITOR and DETECT states. In hysteresis mode (HYSTEN = 1), the following threshold values are used:

- THRH when the SAD is in MONITOR state.
- THRL when the SAD is in DETECT state.

Table 423 shows the thresholds values according to SNTHR.

Table 423. Threshold values according SNTHR(1)

SNTHR[3:0]	THR_H		THR_L		Comments
0	LVL + 3.5 dB	LVL x 1.5	LVL + 3.5 dB	LVL x 1.5	No hysteresis
1	LVL + 6.0 dB	LVL x 2	LVL + 3.5 dB	LVL x 1.5	Hysteresis of 2.5 dB
2	LVL + 9.5 dB	LVL x 3	LVL + 6.0 dB	LVL x 2	Hysteresis of 3.5 dB
3	LVL + 12.0 dB	LVL x 4	LVL + 9.5 dB	LVL x 3	Hysteresis of 2.5 dB
4	LVL + 15.6 dB	LVL x 6	LVL + 12.0 dB	LVL x 4	Hysteresis of 3.5 dB
5	LVL + 18.1 dB	LVL x 8	LVL + 15.6 dB	LVL x 6	Hysteresis of 2.5 dB
6	LVL + 21.6 dB	LVL x 12	LVL + 18.1 dB	LVL x 8	Hysteresis of 3.5 dB
7	LVL + 24.1 dB	LVL x 16	LVL + 21.6 dB	LVL x 12	Hysteresis of 2.5 dB
8	LVL + 27.6 dB	LVL x 24	LVL + 24.1dB	LVL x 16	Hysteresis of 3.5 dB
9	LVL + 30.1 dB	LVL x 32	LVL + 27.6dB	LVL x 24	Hysteresis of 2.5 dB

1. LVL must be replaced by ANLVL when SADMOD[1:0] = 0 and by ANMIN for other SADMOD[1:0] values.

When the hysteresis function is disabled, the SAD always use THRH.

Note: The hysteresis mode must not be used when SADMOD[1:0] = 1x.

Trigger logic

The signal compared to this threshold depends also on SADMOD[1:0].

The trigger condition is reached when the selected signal (SELSIG) is bigger than the threshold level.

If the trigger condition is met, the following happens:

- The SAD switches to DETECT state.
- The SAD refreshes the hangover counter with HGOVR.
- The sddet_evt event is asserted if the SAD transits from MONITOR to DETECT.

- The adf_sad_det signal is set to high.

The SAD remains in DETECT state as long as the trigger condition is met or the hangover down-counter is different from 0.

The sddet_evt event indicates when the SAD enters and/or exits the DETECT state. This event is used to generate an interrupt when a sound is detected or when a sound is no longer detected:

- When DETCFG = 0, the application receives an event only when the SAD enters the DETECT state.
- When DETCFG = 1, the application receives an event when the SAD enters or exits the DETECT state.

The adf_sad_det signal remains high as long as the SAD is in DETECT state.

The SAD also provides a flag indicating that a new sound level value is available (SDLVLF). The last computed sound level (SDLVL[14:0]) is available in the *ADF SAD sound level register (ADF_SADSDLVR)*, and the last computed ambient noise level (ANLVL[14:0]), in the *ADF SAD ambient noise level register (ADF_SADANLVR)*.

Note: The SAD can work even when the AHB clock is not present. In that case, the SAD does not update SDLVL[14:0] and ANLVL[14:0].

To get the latest valid SDLVL[14:0] and ANLVL[14:0] values, the application must read the ADF_SADSDLVR, and ADF_SADANLVR registers, when the SDLVLF flag goes high. This can be done in the following ways:

- by polling the SDLVLF flag:
  a) Clear the SDLVLF flag by writing SDLVLF to 1.
  b) Wait for SDLVLF = 1, by reading ADF_DFLTxISR.
  c) Read ADF_SADSDLVR and ADF_SADANLVR.
  d) Clear SDLVLF by writing it to 1.
  e) Go to step 2 if other values must to be read.
- by generating an interrupt:
  a) Read ADF_DFLTxISR.
  b) If SDLVLF = 1, read ADF_SADSDLVR and ADF_SADANLVR, and clear SDLVLF by writing it to 1.
  c) Handle other status flags and exit from ISR.

Sample transfer to memory

The SAD offers the following options to control the samples transfer from DFLT0 to the system memory:

- If DATCAP[1:0] = 1x, the samples are transferred into the system memory as soon as DFLT0 and SAD are enabled. The transfer does not depend on the SAD state.
- If DATCAP[1:0] = 01, the samples are transferred into the system memory when the SAD detects a sound (when the SAD is in DETECT state), assuming that DFLT0 and SAD are enabled.
- If DATCAP[1:0] = 0, the samples are not transferred into the memory. This mode can be used if the application only wants to observe but does not need samples for other processing.

Note: DATCAP[1:0] is taken into account only when the SADEN = 1. For example, if the SAD configuration is DATCAP[1:0] = 0, SADEN = DFLTEN = 1, and if the application sets now SADEN to 0, the samples provided by the DFLT0 are transferred to the RXFIFO.

Programming recommendations

To make the SAD function working properly, the ADF must be programmed as follows:

1. Provide the proper kernel clock (adf_ker_ck) to the ADF.
2. Configure the CKGEN and enable it.
3. Configure the SITF and enable it (note that microphones have a settling time of several milliseconds).
4. Configure the DFLT0. A typical setting is the following:
   - CIC5 with a decimation ratio of 12, 16 or 24
   - RSFLT with a decimation ratio of 4
   - HPF with HPFC = 2 or 3

   For a very-low power implementation, the RSFLT can be bypassed.
5. Set SADEN to 0.
6. Wait for SADACTIVE = 0. If SADEN was previously enabled, this phase can take two periods of adf_hclk, and two periods of adf_proc_ck.
7. Configure the SAD as follows:
   - Set DATCAP[1:0] to 0, if the application does not want to store the samples into the system memory.
   - Set DATCAP[1:0] to 01, if the application wants to store the samples into the system memory only when the SAD detects a sound.
   - Set DATCAP[1:0] to 11, if the application wants to store the samples into the system memory continuously.
8. Configure the DMA (optional).
9. Enable the SAD.
10. Enable the DFLT0.

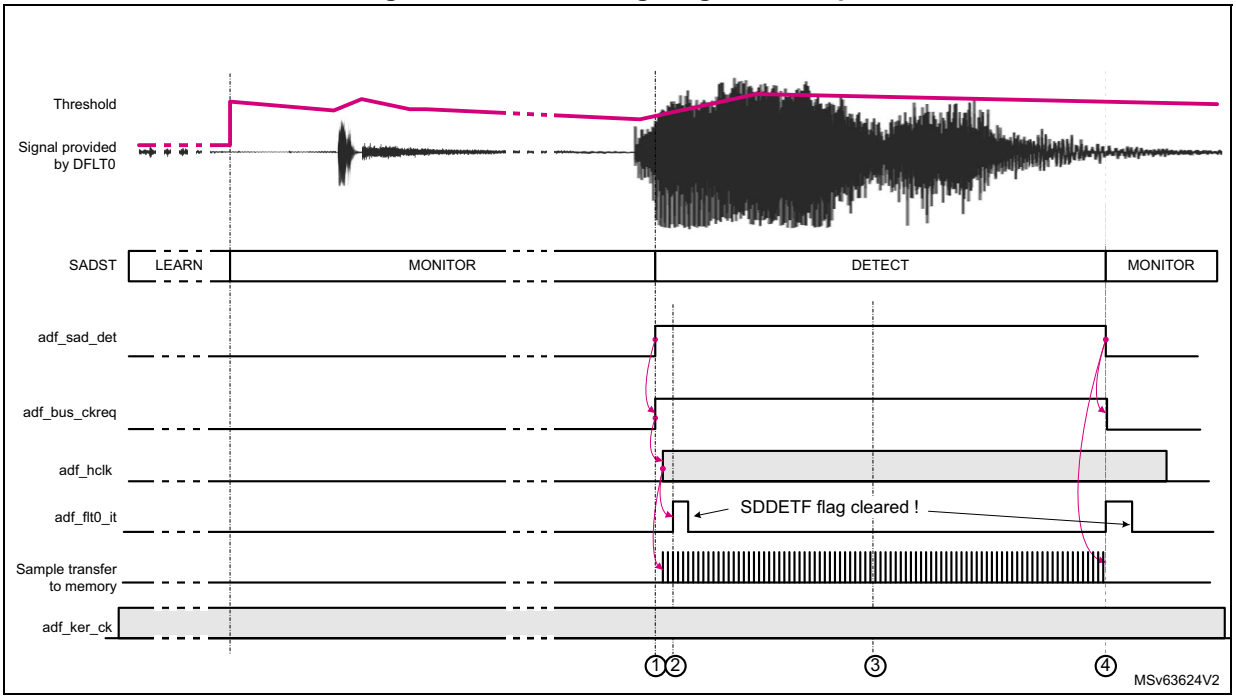


Figure 401 shows a simplified timing diagram when the SAD works with DATCAP[1:0] = 01.

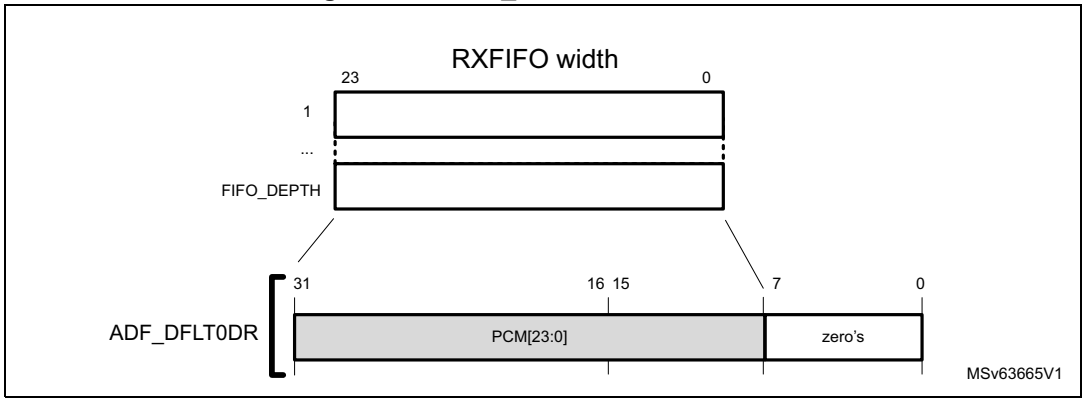
Thanks to the kernel clock (adf_ker_ck), the SAD continuously monitors the audio signal provided by the DFLT0. The threshold is also continuously updated according to the ambient noise level estimation.

- When the SAD detects a sound higher than the programmed threshold (1), the ADF requests the bus clock (adf_bus_ckreq asserted).
- When the bus clock is available (see 2 in *Figure 401*) then:
  - The data transfer to the memory is triggered.
  - The event interrupt (adf_evt_it) can be generated.
- In this example, the event interrupt (adf_evt_it) is used to wake up the application. The interrupt line is released by clearing SDDETF by writing 1 to it.
- As long as the SAD remains in DETECT state, the application waits to get enough samples and calls, for example the keyword recognition algorithm (see 3 in *Figure 401*).
- In the case shown in *Figure 402*, the SAD state (SADST) goes back to MONITOR before the keyword is recognized. If DETCFG is set to 1, an event signals when the SAD goes back to MONITOR state. The SAD stops the transfer of samples into the

memory and the application can clean up the receive buffer for the next detection (see 4 in *Figure 401*).

Figure 402. SAD timing diagram example



46.4.11 Data transfer to memory

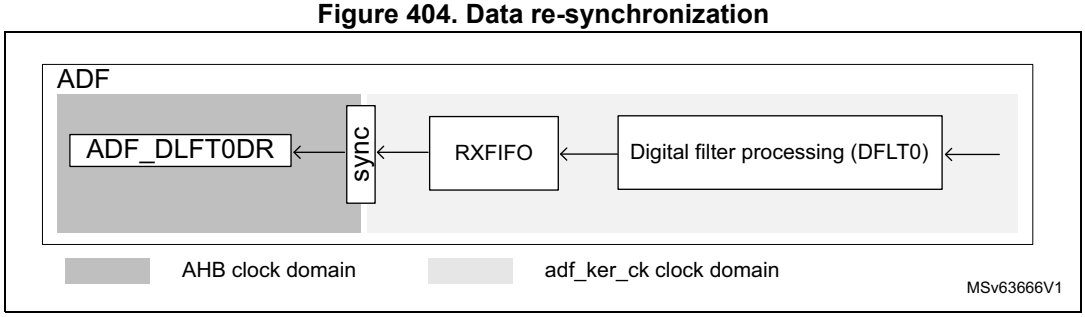
Data format

The samples processed by DFLT0 are stored into a RXFIFO. The application can read the samples stored into these FIFOs via the *ADF digital filter data register 0 (ADF_DFLT0DR)*. The samples inside this register are signed and left aligned. The bit 31 always represents the sign.

The ADF provides 24-bit left-aligned data. Performing a 16-bit access to ADF_DFLT0DR allows the application to get the 16 most significant bits. Performing a 32-bit access to ADF_DFLT0DR allows the application to get a 24-bit data size.

Figure 403. ADF_DFLTxDR data format

Data re-synchronization



The samples stored into the RXFIFO can be transferred into the memory by using either DMA requests or interrupt signaling.

Note: The RXFIFO is located into the adf_ker_ck clock domain, while ADF_DFLT0DR *is located into the adf_hclk (AHB) clock domain.*

When the AHB clock is available, if ADF_DFLT0DR is empty and if a sample is available into the RXFIFO, this sample is transferred into ADF_DFLT0DR.

The sample transfer from the RXFIFO to ADF_DFLT0DR takes two periods of the AHB clock (adf_hclk) and two periods of the adf_ker_ck clock. The ADF inserts automatically wait-states if the application performs a read operation of ADF_DFLT0DR while the transfer of the new sample from the RXFIFO to ADF_DFLT0DR is not yet completed.

Figure 404. Data re-synchronization

Data transfer

The content of the RXFIFO can be transfered to the memory either by using a DMA channel or interrupt services.

Both single and burst, DMA transfers are supported by the ADF, but the application has to care about the following points:

- The RXFIFO must contain at least the same amount of samples than the burst size.
- The burst mode efficiency may be reduced due to the data re-synchronization explained in the previous section.

Note: The burst mode is not available in all products (see the DMA section to check if the product supports it).

In addition, the application can select the RXFIFO threshold (FTH bit) in order to trigger the data transfer: a data transfer can be triggered as soon as the RXFIFO is not empty, or when the RXFIFO is half-full (containing depth/2 samples).

For the DMA transfer, as soon as one of the RXFIFO reaches the threshold level, the DMA request is asserted in order to ask for data transfer. Successive DMA requests are performed as long as the RXFIFO is not empty.

The DMA mode of the RXFIFO is enabled via the DMAEN bit in ADF_DFLT0DR.

For the interrupt signaling, the following cases must be considered:

- If FTH = 0, as soon as a data is available in ADF_DFLT0DR, the FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as ADF_DFLT0DR is read.
- If FTH = 1, as soon as the RXFIFO reaches the threshold level and a data is available in ADF_DFLT0DR, the FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as one data is read. FTHF is set again if the threshold condition is

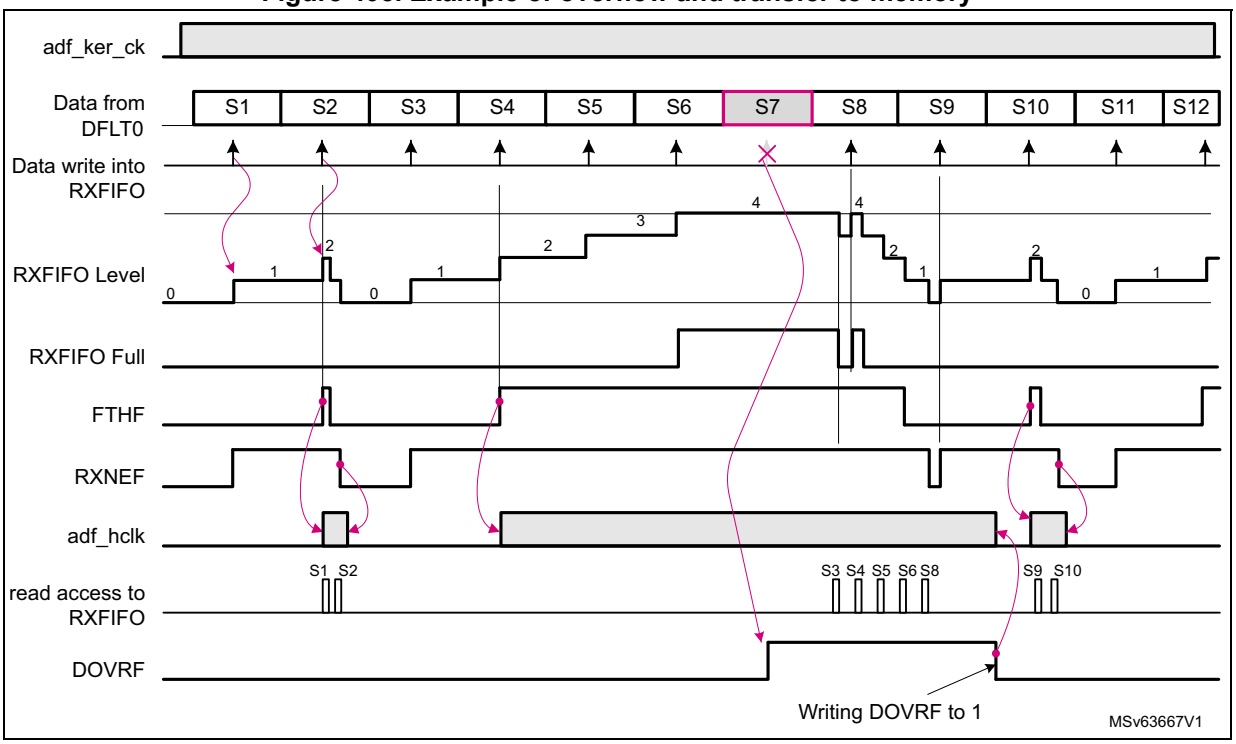
met again. In this mode, every time an interrupt occurs, the application is supposed to read FIFO_SIZE/2 data.

RXFIFO overrun

A RXFIFO overrun condition is detected when the RXFIFO is full, and a new sample from the DFLT0 must be written.

In this case, DOVRF is set and the new sample is dropped. When the RXFIFO has at least one location available, the new incoming sample is written into the RXFIFO.

Figure 405 shows an example based on a RXFIFO depth of four words and FTH set to 1, so that FTHF goes to 1 when the RXFIFO is half-full.



The S7 sample is lost due to an overrun: the RXFIFO is full while S7 must be written into the RXFIFO. The S7 write operation is not performed. DOVRF is set to 1 at the moment where the write operation was expected. The overflow event remains to 1 as long as it is not cleared by the application.

In this example, DOVRIE is set to 1 to have an interrupt if an overrun condition is detected.

After the S7 sample, the application manages to read data from the RXFIFO, and the ADF can write the S8 sample and consecutive. Later, the application clears DOVR, allowing the detection of a new overrun situation.

In the adf_hclk line, the gray boxes indicate that the ADF requested the AHB clock. *Figure 405* shows the AHB clock available only when the ADF requests it. In real applications, the AHB clock may also be present if the ADF does not request it.

Figure 405. Example of overflow and transfer to memory

46.4.12 Autonomous mode

The ADF can work even if the AHB bus clock is not available (Stop modes). The ADF uses the AHB clock only for the register interface. All the processing part is clocked with the kernel clock.

In Stop mode, the ADF receives a kernel clock if the following conditions are met:

- The ADF autonomous mode is enabled in the RCC.
- The selected kernel clock source is taken from an oscillator available in Stop mode.

In Stop mode, the ADF receives the AHB clock if the following conditions are met:

- The ADF autonomous mode is enabled in the RCC.
- The ADF requests the AHB clock in the following situations:
  - when the ADF must transfer data into memory via the DMA

    The data is directly transferred to the SRAM thanks to the DMA while the product remains in Stop mode. The AHB clock request is maintained until the DMA transfer is completed.
  - when the ADF needs to generate an interrupt

    An interrupt generally wakes up the device from Stop mode, as an action from the application is needed. Once the AHB clock is available, the interrupt is generated.The AHB clock request is maintained as long as an enabled interrupt flag is still active.

46.4.13 Register protection

The ADF embeds some hardware protection to prevent invalid situations.
Table 424 shows the list of write-protected and unprotected fields.

Table 424. Register protection summary

Registers	Unprotected fields	Write-protected fields	Write-protection condition
ADF global control register (ADF_GCR)	TRGO	-	DFLTACTIVE0 = 1
ADF clock generator control register (ADF_CKGCR)	CKGDEN CCK0EN CCK1EN	PROCDIV[6:0], CCKDIV[3:0], CKGMOD, TRGSRC[3:0], TRGSENS, CCK[1:0]DIR	CKGACTIVE = 1
ADF serial interface control register 0 (ADF_SITF0CR)	SITFEN	STH[4:0], SITFMOD[1:0], SCKSRC[1:0]	SITFACTIVEx = 1
ADF bitstream matrix control register 0 (ADF_BSMX0CR)	-	BSSEL[4:0]	DFLTACTIVEx = 1
ADF digital filter control register 0 (ADF_DFLT0CR)	DFLTEN	NBDIS[7:0], TRGSRC[3:0], TRGSENS, FTH, DMAEN, SNPSFMT, ACQMOD[2:0]	DFLTACTIVEx = 1
ADF digital filer configuration register 0 (ADF_DFLT0CICR)	SCALE[5:0]	MCICD[8:0], CICMOD[2:0], DATSRC[1:0]	
ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)	-	All fields	
ADF delay control register 0 (ADF_DLY0CR)	-	SKPDLY[6:0]	SKPBF = 1

Table 424. Register protection summary (continued)

Registers	Unprotected fields	Write-protected fields	Write-protection condition
ADF DFLT0 interrupt enable register (ADF_DFLT0IER)	All fields	-	-
ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)	All fields	-	-
ADF SAD control register (ADF_SADCR)	SADEN	FRSIZE[2:0], DETCFG, SADMOD[1:0], HYSTEN, DATCAP[1:0]	SADACTIVE = 1
ADF SAD configuration register (ADF_SADCFGR)	-	ANMIN[12:0], SNTHR[3:0], HGOVR[3:0], LFRNB[2:0], ANSLP[2:0]	SADACTIVE = 1

All the ADF processing is performed in the adf_proc_ck clock domain. For that reason, enabling or disabling an ADF sub-block may take some time due to the re-synchronization between the AHB clock domain and the adf_proc_ck clock domain. XXXACTIVE flags are available to allow the application to check that the synchronization between the two clock domains is completed.

To change a write-protected bitfield, the application must follow this sequence:

1. Set the enable bit of the sub-block to 0.
2. Wait for corresponding flag XXXACTIVE = 0.
3. Modify the wanted fields.
4. Set the enable bit of the sub-block to 1.

Refer to the description of each sub-block for details.

46.5 ADF low-power modes

Table 425. Effect of low-power modes on ADF

Mode	Description
Sleep	No effect. ADF interrupts cause the device to exit the Sleep mode.
Stop(1)	The ADF registers content is kept. Thanks to the kernel clock request feature, if the ADF is clocked by an internal oscillator available in Stop mode, the ADF remains active. The interrupts cause the device to exit Stop mode.
Standby	The ADF is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 46.3: ADF implementation* for details about Stop modes supported by the ADF.

46.6 ADF interrupts

To increase the CPU performance, the ADF offers an interrupt line (adf_flt0_it), sensitive to several events.

Note: The status flags are available even if the corresponding interrupt enable flag is not enabled.

The interrupt interface is controlled via the *ADF DFLT0 interrupt enable register (ADF_DFLT0IER)* and the *ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)*.

Figure 406. ADF interrupt interface

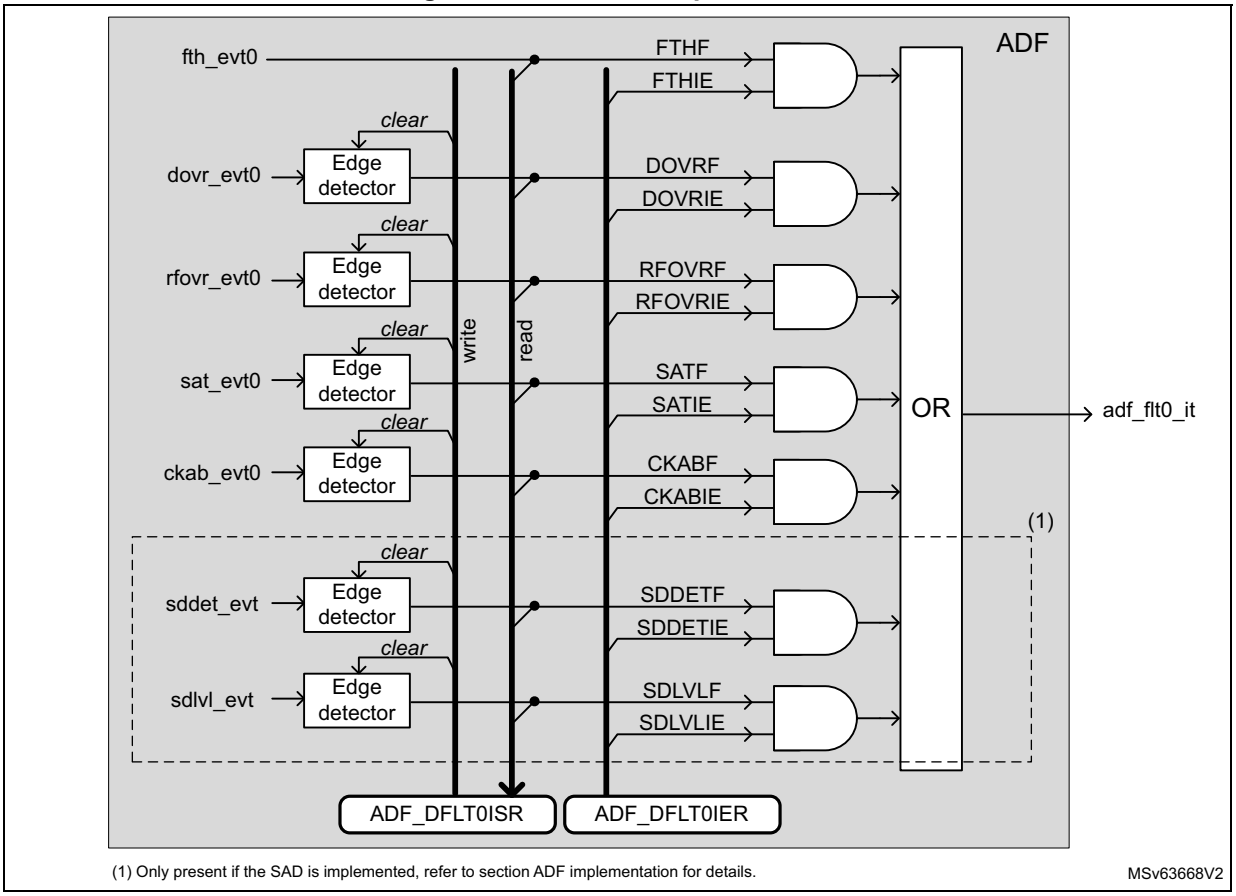


Table 426 shows which interrupt line is affected by which event, and how to clear and activate each interrupt/event.

Table 426. ADF interrupt requests

Interrupt vector	Interrupt event	Event flag	Event/interrupt clearing method	Exit Sleep mode	Exit Stop modes(1)	Exit Standby mode
ADF_FLT0(2)	RXFIFO threshold reached	FTHF	Read ADF_DFLT0DR until RXFIFO level is lower than the threshold.	Yes	Yes	No
	RXFIFO overrun	DOVRF	Write DOVRF to 1.			
	RSFLT overrun	RFOVRF	Write RFOVRF to 1.			
	Saturation detection	SATF	Write SATF to 1.			
	Channel clock absence detection	CKABF	Write CKABF to 1.			
	SAD: sound detected	SDDETF	Write SDDETF to 1.			
	SAD: sound level value available	SDLVLF	Write SDLVLF to 1.			

1. Refer to *Section 46.3: ADF implementation* for details.
2. ADF_FLT0 vector corresponds to the assertion of adf_flt0_it signal.

46.7 ADF application information

46.7.1 ADF configuration examples for audio capture

Table 427 gives some examples of the ADF settings for the digital microphones, focusing on 16 and 48 kHz output data rate.

Configurations #1 and #2 are for very low-power use-cases and have a reduced signal-to-noise ratio. The user must also insure that the selected digital microphone can work properly at 512 kHz. These configurations can be used for sound detection. The RSFLT is not used to reduce as much as possible the frequency of the kernel clock (adf_ker_ck).

Configurations #3, #4, #9, #10, #11 give signal-to-noise ratios around 115 dB, with an ideal microphone model, with a sinus signal of 997 Hz. Using the RSFLT allows a good control on the in-band ripple, and a good image rejection.

Configurations #7, #8, #10 give signal-to-noise ratio around 120 dB, with an ideal microphone model, using a sinus signal of 997 Hz.

Table 427. Examples of ADF settings for microphone capture

Configuration	adf_ker_ck (MHz)	PROCDIV + 1	CCKDIV + 1	CIC order (1)	MCICD + 1	SCALE	RSFLTBYP	RSFLTD	HPFBYP	-	adf_proc_ck (MHz)	Total dec. ratio	F_{RS} (kHz)	F_{ADF_CCKx} (MHz)	F_{PCM} (kHz)
#1	1.024	1	2	4	64	0x2D (- 8.5 dB)	1	x	x	=>	1.024	64	-	0.512	8
#2		1	2	5	32	0x2B (- 14.5 dB)						32	-		16
#3		1	2	5	16	0x01 (+ 3.5 dB)	0	0				64	32		8
#4	2.048	1	2	5	16	0x01 (+ 3.5 dB)	0	0			2.048	64	64	1.024	16
#5	3.072	1	6	5	8	0x0B (+ 33.6 dB)	0	0			3.072	32	32	0.512	8
#6		2	2	5	12	0x06 (+ 18.1 dB)						48	64	0.768	16
#7		1	2	5	24	0x2C (- 12 dB)						96		1.536

1. CICMOD = 100 for CIC order equal to 4. CICMOD = 101 for CIC order equal to 5.

46.7.2 Programming examples

Example 1

This example describes the programming of ADF for the capture of a signal coming from a digital microphone, using only the CIC4, with a decimation of 48, assuming that the kernel clock is 1.536 MHz. Typically, this configuration can be used to detect sound using the SAD.

Table 428. Programming sequence (CIC4)

Operations	Comments
Adjust the proper kernel clock frequency via the RCC	Assuming that the RCC is programmed to provide a kernel clock (adf_ker_ck) of 1.536 MHz coming from a RC oscillator.
Select the proper ADF kernel clock source via the RCC	Refer to the RCC of the product.
Enable the ADF clocks via the RCC	Refer to the RCC of the product.
Reset the ADF via the RCC	Refer to the RCC of the product.
AFMUX programming	Program the AFMUX to select ADF_SD0 and ADF_CCK0 functions.
Enable ADF processing clock: ADF_CKGCR = 0x0001 0023	PROCDIV = 0 (bypass): adf_proc_ck frequency is 1.536 MHz. CCKDIV = 1 (division by 2): ADF_CCK0 clock frequency is 768 kHz. The ADF_CCK0 pin is set in output and generates a clock so that the microphone can exit from low-power mode.
Serial interfaces configuration: ADF_SITF0CR = 0x0000 1F01	SCKSRC = 0 to select ADF_CCK0 as serial clock. SIFTMOD = 0 to select LF_MASTER SPI mode. Clock absence feature is not working in this mode. The serial interface is enabled.
Bitstream matrix configuration: ADF_BSMX0CR = 0x0000 0000	DFLT0 filter takes the bitstream of SITF0, sampled on rising edge
Filters configuration (CIC): ADF_DFLT0CICR = 0x0040 2F40	SCALE = 0x04 (12 dB): RSFLT is not enabled. Note that the gain is 8.5 dB, higher than recommended in order to improve signal accuracy for the SAD. Saturation is not an issue in this case, as only the detection of a signal much lower than the full scale is needed. MCICD = 0x2F (decimation by 48) CICMOD = 4 to select a $Sinc^4$ DATSCR = 0 to select data coming from BSMX
Filters configuration (RSFLT and HPF): ADF_DFLT0RSFR = 0x0000 0301	HPFC = 3: cut-off frequency of 16kHz * 0.0095 = 152 Hz HPFBYP = 0: HPF not bypassed RSFLTBYP = 1: RSFLT bypassed
Micro delay adjust: ADF_DLY0CR = 0x0000 0000	Not used in this example
Enable interrupt events: ADF_DFLT0IER = 0x0000 1000	Enable the interrupt events the application wants to handle. In this example, SDDETIE is set to 1 to have an interrupt if a sound is detected.

Table 428. Programming sequence (CIC4) (continued)

Operations	Comments
SAD setting: ADF_SADCR = 0x0000 1400	SADMOD = 1: Trigger based on sound level values FRSIZE = 4: Sound level computed on 128 samples HYSTEN = 0: No hysteresis DETCFG = 0: interrupt generated when the SAD enters in DETECT state DATCAP = 0: samples not transferred to memory SADEN = 0: SAD not yet enabled
SAD setting: ADF_SADCFGR = 0x0025 0001	ANMIN = 0x25: Sound threshold of 37 * 10^SNTHR/20 = 74 LSB(1) HGOVR = 0: four frames (4 x 128 = 512 samples) LFRNB = 0: Learning phase set to two frames. Not useful in this mode. ANSLP = 0: Not used in this mode SNTHR = 1: Threshold set to 6 dB (see ANMIN)
Clear status flags: ADF_DFLT0ISR = 0x0000 0FFF	Clear all the status flags before running the ADF
Enable the SAD: ADF_SADCR = 0x0000 1401 Wait for SADACTIVE flag = 1	Enable first the SAD, in order to be sure that data transfer to memory are blocked by the SAD.
Enable the filter: ADF_DFLT0CR = 0x0000 0001	NBDIS = 0: no samples discarded ACQMOD = 0: Asynchronous continuous acquisition mode DMAEN = 0: DMA interface not used DFLTEN = 1: Filter enabled

1. SNTHR and ANMIN values are computed using the same approach than in *Threshold programming with SADMOD = 01* (detection of a sound higher than 63 dBSPL).

Example 2

This example describes the programming of ADF for the capture of a signal coming from a digital microphone, using the CIC5, and the RSFLT, with a total decimation of 64.

Table 429. Programming sequence (CIC5)

Operations	Comments
Adjust the proper kernel clock frequency via the RCC	Assuming that the RCC is programmed to provide a kernel clock (adf_ker_ck) of 6.144 MHz
Select the proper ADF kernel clock source via the RCC	Refer to the RCC of the product.
Enable the ADF clocks via the RCC	Refer to the RCC of the product.
Reset the ADF via the RCC	Refer to the RCC of the product.
AFMUX programming	Program the AFMUX to select ADF_SD0 and ADF_CCK0 functions.
Enable ADF processing clock: ADF_CKGCR = 0x0201 0023	PROCDIV = 2 (division by 3): adf_proc_ck frequency is 6.144 MHz. CCKDIV = 1 (division by 2): ADF_CCK0 clock frequency is 1.024 MHz. The ADF_CCK0 pin is set in output and generates a clock so that the microphone can exit from low-power mode.

Table 429. Programming sequence (CIC5) (continued)

Operations	Comments
Serial interfaces configuration: ADF_SITF0CR = 0x0000 1F01	SCKSRC = 0 to select ADF_CCK0 as serial clock. SIFTMOD = 0 to select LF_MASTER SIPI mode. Clock absence feature is not working in this mode. The serial interface is enabled.
Bitstream matrix configuration: ADF_BSMX0CR = 0x0000 0000	DFLT0 filter takes the bitstream of SITF0, sampled on rising edge
Digital filter control: ADF_DFLT0CR = 0x0000 0006	NBDIS = 0: no samples discarded ACQMOD = 0: Asynchronous continuous acquisition mode DMAEN = 1: DMA interface not used DFLTEN = 0: Filter disabled FTH = 1: RXFIFO half-full
Filters configuration (CIC): ADF_DFLT0CICR = 0x0010 0F50	SCALE = 0x01(+3.5 dB): Output limited to 22 bits due to RSFLT. MCICD = 0xF (decimation by 16) CICMOD = 5 to select a $Sinc^5$ DATSCR = 0 to select data coming from BSMX
Filters configuration (RSFLT and HPF): ADF_DFLT0RSFR = 0x0000 0200	HPFC = 2: cut-off frequency of 16 kHz * 0.0025 = 40 Hz HPFBYP = 0: HPF not bypassed RSFLTBYP = 0: RSFLT not bypassed RSFLTD = 0: Decimation by 4
Micro delay adjust: ADF_DLY0CR = 0x0000 0000	Not used in this example
Enable interrupt events: ADF_DFLT0IER = x	Enable the interrupt events the application wants to handle.
Clear status flags: ADF_DFLT0ISR = 0x0000 0FFF	Clear all the status flags before running the ADF
Program the DMA Enable the DMA	The DMA must be programmed in order to read the data inside the ADF_DLT0DR register every time a DMA request is generated.
Start acquisition: ADF_DFLT0CR = 0x0000 0007	The ADF starts to filter data.

46.7.3 Connection examples

Figure 406 shows simple connection examples of the ADF to external sensors.

- Picture on the left: two digital microphones connected to the ADF

  In this connection, the amount of connections is optimized; DMIC1 and DMIC2 are sharing the same data line, and the same clock line. BSMX allows the application to connect the digital filter either to DMIC1 or to DMIC2. In this configuration when one of the microphone is used, the other is activated as well, as they share the same clock.
- Picture in the center: two digital microphones connected to the ADF

  In this connection, DMIC1 and DMIC2 are sharing the same data line, but have a dedicated clock line. BSMX allows the application to connect the filter either to DMIC1 or to DMIC2. When the application wants to use a microphone, it is possible to keep the other in low-power mode by forcing its clock line to 0 (CCKyEN = 0, CCKyDIR = 1).

- Picture on the right: single sensor connected to the ADF

  It is also possible to configure the CCK0 and CCK1 pins to input in order to connect sensors providing the clock.

Figure 407. Sensor connection examples

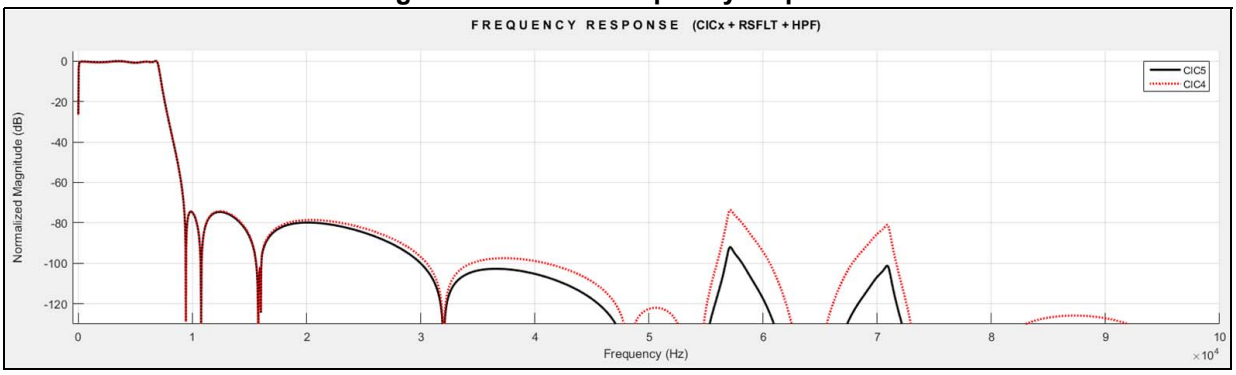
46.7.4 Global frequency response

Figure 407 shows the global frequency response for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enabled with a cut-off frequency of 40 Hz

Figure 408 shows the theoretical frequency response using a CIC4 and a CIC5.

Figure 408. Global frequency response



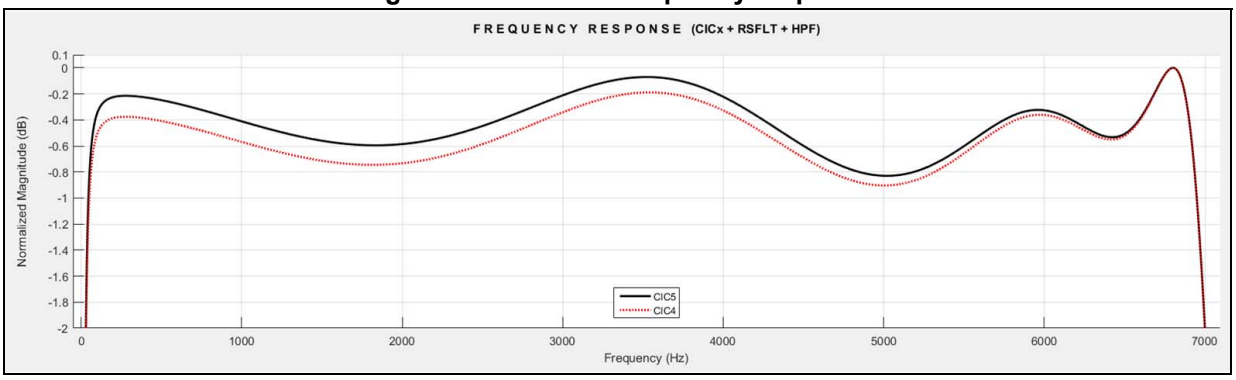


Figure 409 shows the in-band ripple for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enabled with a cut-off frequency of 20 Hz

The resulting in-band ripple is ± 0.41 dB for CIC5, and ± 0.45 dB for CIC4.

The - 3 dB cut-off frequency is 7061 Hz.

Figure 409. Detailed frequency response

46.7.5 Total ADF gain

This section details how to compute the signal level provided by the ADF according to the filter settings.

A signal level may be expressed in dBFS (decibel full scale). A 0 dBFS level is assigned to the maximum possible digital level. For example, a signal that reaches 50 % of the maximum level, has a − 6 dBFS level (6 dB below full scale).

For example, for the ADF offering a final data width of 24 bits, a signal having an amplitude of 2 * 10^6 LSB has a level of:

$$20 \times \log_{10}\left(\frac{2 \times 10^6}{2^{(24-1)}}\right) = -12.45 \text{ dBFS}$$

In addition, the data size of a signal having an amplitude (Amp) expressed in LSB is given by:

$$DS = \left(\frac{\ln(Amp)}{\ln(2)} + 1\right) \text{ bits}$$

One bit need to be added for negative values.

So a signal having an amplitude of 2 * 10^6 LSB, has a data size of 21.9 bits.

CIC gain

The CIC gain (G_{CIC} and GdB_{CIC}) can be deduced from the following formula giving data size in bits (DS_{CIC}).

$$DS_{CIC} = (N \times \log_2(D1)) + DSin$$

where N represents the CIC order (selected by CICMOD[2:0]), and D1 is the decimation ratio (given by MCICD[8:0]).

DSin represents the data size (in bits) of the signal at CIC input.

Warning: DS_{CIC} is very important for CIC filter. In order to work fine, DS_{CIC} must not exceed 26 bits.

The CIC gain G_{CIC} is given by:

$$G_{CIC} = (D1)^N$$

which gives in decibels:

$$GdB_{CIC} = 20 \times \log_{10}((D1)^N)$$

Data size at SCALE output

The data size at SCALE output (including the CIC gain), is a key information as the RSFLT starts to have some saturations, if the peak-to-peak signal amplitude at SCALE output is higher than 22 bits.

If the RSFLT is bypassed, then a peak-to-peak signal amplitude of 24 bits is accepted.

The signal amplitude at SCALE output is:

$$Asout_{SCALE} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times Asin_{DFLT}$$

GdB_{SCALE} represents the gain selected by SCALE[5:0], in dB.

$Asout_{SCALE}$ is the signal amplitude at SCALE output (in LSB), and $Asin_{DFLT}$ is the signal amplitude at CIC input (LSB).

$$DS_{SCALE} = \frac{\ln(Asout_{SCALE})}{\ln(2)} + 1$$

The data size at SCALE output (DS_{SCALE}) is expressed in bits.

RSFLT gain

The RSFLT gain in the useful bandwidth is typically 9.5 dB, but due to ripple a margin of about ± 0.41 dB must be considered.

$$G_{RSFLT} = 10^{\frac{9.5\ dB}{20}} = 2.98 \text{ typical}$$

Note: The HPF filter has a gain of 0 dB.

SAD gain

The SAD is using only the 16 MSB on the signal, as a consequence, from the SAD point of view, the truncation from 24 to 16 bits can be seen as an attenuation.

$GdB_{SAD} = -48.1dB$

and

$G_{SAD} = 0.003906$

The *Figure 410* shows a simplified view of the filter path and gives, for each significant component, the expression of the bit growth and the gain.

Figure 410. Simplified DFLT view with gain information

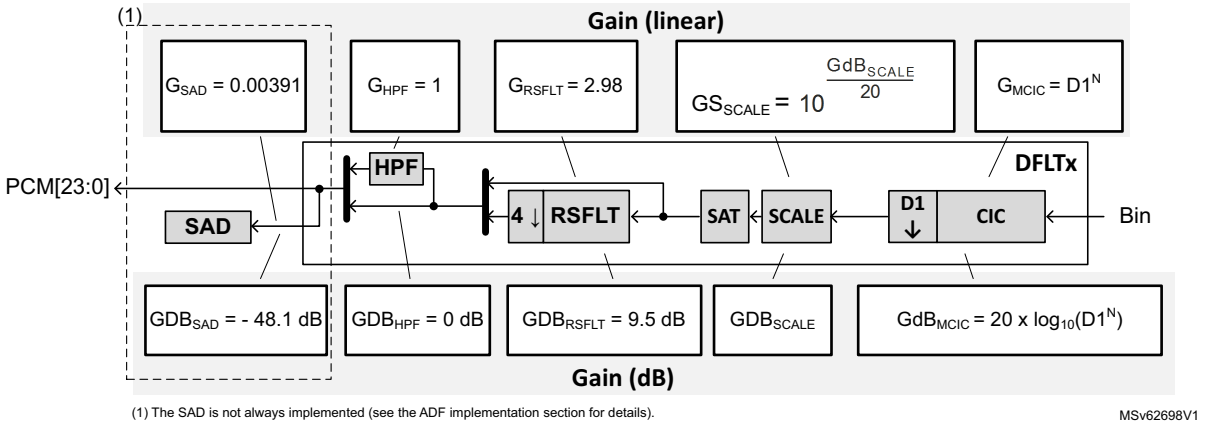

Table 430 summarizes of the final data size for different filter configurations.

Table 430. Output signal levels

Filter configurations	Final signal amplitude (LSB)
CIC + RSFLT + HPF + SAD	Samples provided to the RXFIFO: $Asout_{RXFIFO} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times 10^{\frac{9.5}{20}} \times Asin_{DFLT}$ Samples provided to the SAD: $Asout_{SAD} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times 10^{\frac{9.5}{20}} \times 0.003906 \times Asin_{DFLT}$ DS_{SCALE} must be lower than 22 bits
CIC + RSFLT (+ HPF)	$ASout_{HPF} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times 10^{\frac{9.5}{20}} \times Asin_{DFLT}$ DS_{SCALE} must be lower than 22 bits
CIC (+ HPF)	$ASout_{HPF} = D1^N \times 10^{\frac{GdB_{SCALE}}{20}} \times Asin_{DFLT}$ DS_{SCALE} must be lower than 24 bits

Example using the main filter chain

If the ADF filter is programmed as follows:

- The input signal is coming from a serial interface ($Dsin_{RSFLT}$ = 1 bit).
- CIC order = 5 (N), with a decimation value of 24 (D1).
- SCALE[5:0] is set to - 12 dB.
- RSFLT enabled, and the decimation by four is enabled.
- HPF is enabled.

Check first the data size at CIC output:

$$DS_{CIC} = (5 \times \log_2(24)) + 1 \text{ bit} = 23.92 \text{ bits}$$

The size is lower than 26 bits, so the CIC works in good conditions.

The data size at CIC output is very close to 24 bits, so the SCALE must be adjusted in order to provide a 22-bit max signal to the RSFLT. An attenuation of 12 dB is needed.

Then the signal level provided to the RSFLT is:

$$Asout_{SCALE} = 24^5 \times 10^{\frac{-12}{20}} \times 1 = 2.10^6$$

$$DS_{SCALE} = \frac{\ln(2.10^6)}{\ln(2)} + 1 = 21.93 \text{ bits}$$

If a higher gain is used, the RSFLT may saturate the output signal for strong input signals.

At the end, the final signal amplitude is:

$$Asout_{HPF} = 24^5 \times 10^{\frac{-12}{20}} \times 10^{\frac{9.5}{20}} \times 1 = 5.9711 \times 10^6$$

$$Dsout_{HPF} = \left(\frac{\ln(5.9711 \times 10^6)}{\ln(2)} + 1\right) = 23.51 \text{ bits}$$

or:

$$SDB_{OUT} = 20 \times \log_{10}\left(\frac{2^{23.51}}{2^{24}}\right) = -2.84 \text{ dBFS}$$

46.7.6 How to compute SAD thresholds

The SAD does not compute the RMS value of the converted signal, but the average of the absolute values. As a consequence, the estimated level differs from the RMS value of the signal:

- For a sine signal having an RMS value of 1, the SAD computes a level of 0.9.
- For a white or pink noise signal having an RMS value of 1, the SAD computes a level of about 0.8.

Note: FRSIZE[2:0] has a big influence on the accuracy of the level estimation: big FRSIZE[2:0] values give better results.

Threshold programming with SADMOD = 01

Consider the case of a sound capture where the application wants to wake up the system when the captured sound is bigger than 63 dBSPL.

The sound capture can be performed with a digital microphone such as the MP45DT02.

The sensitivity of this microphone is typically -26 dBFS for an input signal of 94 dBSPL.

An acoustic signal at 63 dBSPL produces a digital signal of about:
- 26 dBFS - (94 - 63) = - 57 dBFS.

- SCALE value adjustment

  For this example, the filter configuration is the following:
  - CIC5 with a decimation by 16
  - RSFLT enabled with a decimation by 4
  - HPF enabled

  A SCALE value of 3.5 dB is recommended for this configuration. As DFTL0 provides samples only used for a sound detection (samples not provided to the application), a bigger gain value can be applied: it increases the SAD accuracy and a saturation does not affect the SAD behavior (for example, a SCALE value of 15.6 dB).
- Input signal amplitude

  The input signal is - 57 dBFS, corresponding to an amplitude

  Asin = $10^{(-57/20)}$ = 0.00141 LSB.
- Signal level at SAD input

  The total filter gain for the SAD is:

$$G_{SAD} = 16^5 \times 10^{\frac{15.6}{20}} \times 10^{\frac{9.5}{20}} \times \frac{1}{256} = 73.68 \times 10^3 \text{ or } 97.3 \text{ dB}$$

  The signal amplitude received by the SAD is:

$$Ain_{SAD} = 0.00141 \times G_{SAD} \sim 104 \text{ LSB}$$

  The gain can be increased if the expected amplitude is too small. For the targeted application, 104 LSB is fine.

  If the input signal is expected to be a sine, the sound level for a signal amplitude of 104 LSB is:

$$SDLVL = \frac{Ain_{SAD} \times \sqrt{2}}{2} \times 0.9 \sim 66 \text{ LSB}$$

  where 0.9 is the correction factor to apply with respect to the RMS value.
- Program the trigger value

ANMIN and SNTHR must be programmed to trigger the SAD when the input signal level reaches 66 LSB.

For SADMOD[1:0] = 01, the threshold value is given by:

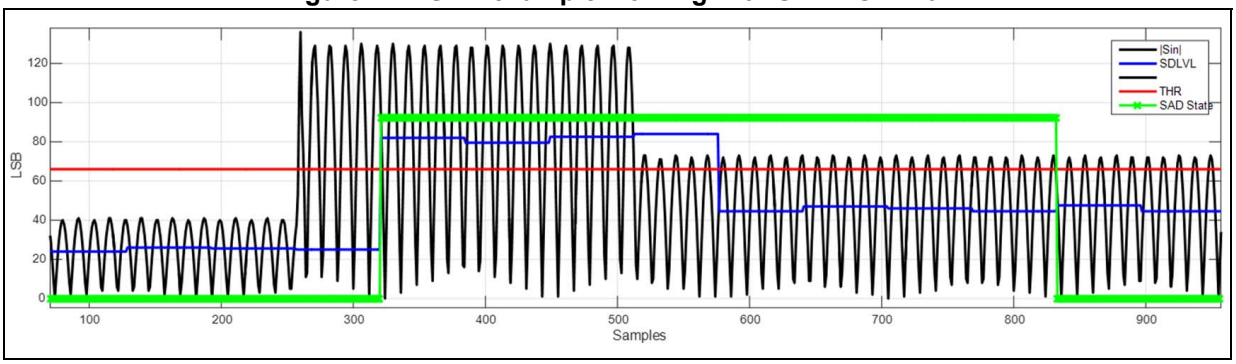
$$THRH = ANMIN \times 10^{\frac{GdB_{SNTHR}}{20}}$$

where GdB_{SNTHR} represents the decibel value selected by SNTHR[3:0].

When SNTHR[3:0] = 6 dB for example, this formula becomes:

$$THRH = 2 \times ANMIN$$

So ANMIN = THRH/2 = 66 /2 = 33 LSB.



In *Figure 410*, the trigger value (THRH in red) is fixed to 66 LSB. The input signal is at - 65dBFS during 256 samples, then its value goes to - 55 dB for 256 samples, and finally it is reduced to - 60 dBFS.

The blue curve is showing the sound level estimation (SDLVL) versus time. Fluctuation on the estimated value can be observed due to windowing effect of FRSIZE samples.

The SAD DETECT state (when green signal is high) is maintained during four additional frames due to hangover function value.

In this example ANSLP = FRSIZE = 3 (64 samples), LFRNB = 0 (2 frames), HGOVR = 0 (4 frames), SNTHR = 1 (6 dB) and ANMIN = 33.

Figure 411. SAD example working with SADMOD = 01

Threshold programming with SADMOD = 1x

Consider the case of a sound capture where the application wants to wake up the system when the captured sound is bigger than 57 dBSPL.

The sound capture can be performed with a digital microphone such as the MP45DT02. The sensitivity of this microphone is typically - 26 dBFS for an input signal of 94 dBSPL.

An acoustic signal at 57 dBSPL produces a digital signal of about:
- 26 dBFS - (94-63) = - 63 dBFS.

- Adjust SCALE value

  For this example, the filter configuration is the following:

  – CIC4 with a decimation by 48

– RSFLT bypassed
– HPF enabled

A SCALE value of 3.5 dB is recommended for this configuration. The samples provided by DFTL0 are only used for a sound detection, without providing the samples to the application, a bigger gain value can be provided: it increases the SAD accuracy and a saturation does not affect the SAD behavior (for example, a SCALE value of 24 dB).

- Input signal amplitude

  The input signal is - 63 dBFS, corresponding to an amplitude:

  Asin = $10^{(-63/20)}$ = 0.000708 LSB.

- Signal level at SAD input

  The total filter gain for the SAD is:

$$G_{SAD} = 48^4 \times 10^{\frac{24}{20}} \times 0.003906 = 328.6 \times 10^3 \text{ or } 110.3 \text{ dB}$$

The signal amplitude received by the SAD is:

$$Ain_{SAD} = 0.000708 \times G_{SAD} \sim 232 \text{ LSB}$$

The gain can be increased if the expected amplitude is too small.

If the input signal is expected to be a sine, the sound level for a signal amplitude of 232 LSB is:

$$SDLVL = \frac{Ain_{SAD} \times \sqrt{2}}{2} \times 0.9 \sim 148 \text{ LSB}$$

where 0.9 is the correction factor to apply with respect to the RMS value.

Note: ANLVL converges to average of SDLVL values, with a long constant time.
So SDLVL ~ ANLVL = 148 LSB for a constant input signal at 57 dBSPL.

- Programming trigger value

  For SADMOD = 1', the SAD compares the estimated ambient noise multiplied by the gain selected by SNTHR[3:0] to ANMIN[12:0] * 4.

  For simplification, SNTHR[3:0] is set to 1 (6 dB), meaning that ANLVL is multiplied by two.

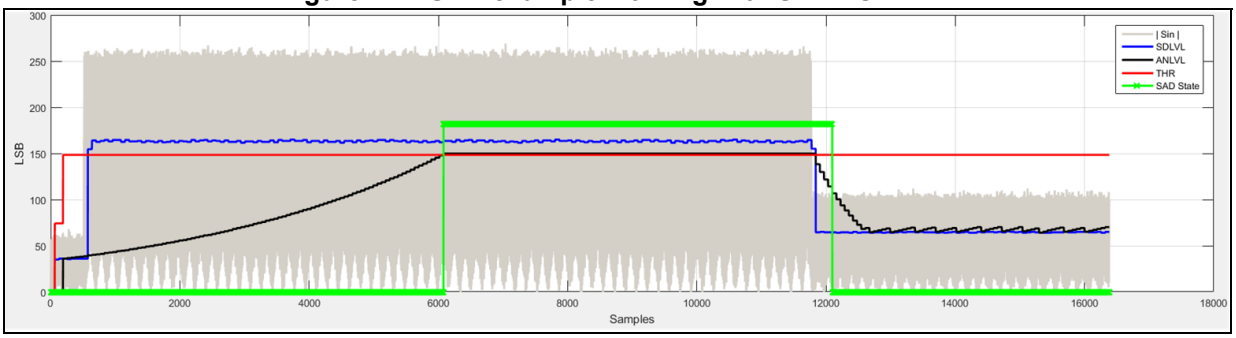
  The SAD triggers if 2 * ANLVL > THRH.

  In this mode,

$$THRH = 4 \times ANMIN$$

So the SAD triggers if:

$$ANLVL > 2 \times ANMIN$$



So ANMIN = 148 / 2 = 74 LSB

In *Figure 411*, the trigger value (THRH in red) is fixed to 148 LSB. The input signal is at - 75 dBFS during 512 samples, then its value goes to - 62 dB for 11000 samples, and finally it is reduced to - 70 dBFS.

The blue curve shows the sound level estimation (SDLVL) versus time. The black curve shows the ambient noise estimation versus time, increasing or decreasing logarithmically. During the learning phase, it reaches the SDLVL value.

In this example ANSLP = 6, FRSIZE = 3 (64 samples), LFRNB = 0 (2 frames), HGOVR = 0 (4 frames), SNTHR = 1 (6 dB) and ANMIN = 74.

Figure 412. SAD example working with SADMOD = 1x

46.8 ADF registers

All the ADF registers must be accessed either in word (32-bit) or half-word (16-bit) formats.

46.8.1 ADF global control register (ADF_GCR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TRGO
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **TRGO**: Trigger output control

This bit is set by software and reset by hardware. It is used to start the acquisition of several filters synchronously. It is also used to synchronize several ADF together by controlling the adf_trgo signal.

0: Write 0 has no effect. Read 0 means that the trigger can be set again to 1.

1: Write 1 generates a positive pulse on the adf_trgo signal and triggers the acquisition on enabled filter having their ACQMOD[2:0] = 01x and selecting TRGO as trigger. Read 1 means that the trigger pulse is still active.

46.8.2 ADF clock generator control register (ADF_CKGCR)

Address offset: 0x004

Reset value: 0x0000 0000

This register is used to control the clock generator. The clock adf_proc_ck must be enabled before enabling other ADF parts.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CKGACTIVE	PROCDIV[6:0]							Res.	Res.	Res.	Res.	CCKDIV[3:0]			
r	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRGSRC[3:0]				Res.	Res.	Res.	TRGSENS	Res.	CCK1DIR	CCK0DIR	CKGMOD	Res.	CCK1EN	CCK0EN	CKGDEN
rw	rw	rw	rw				rw		rw	rw	rw		rw	rw	rw

Bit 31 **CKGACTIVE**: Clock generator active flag

This bit is set and cleared by hardware. Ii is used by the application to check if the clock generator is effectively enabled (active) or not. The protected fields of this function can only be updated when CKGACTIVE = 0 (see *Section 46.4.13: Register protection* for details).

The delay between a transition on CKGDEN and a transition on CKGACTIVE is two periods of AHB clock and two 2 periods of adf_proc_ck.

0: The clock generator is not active and can be configured if needed.

1: The clock generator is active and protected fields cannot be configured.

Bits 30:24 **PROCDIV[6:0]**: Divider to control the serial interface clock

This bitfield is set and reset by software. It is used to adjust the frequency of the clock provided to the SITF.

$$F_{adf_itf_ck} = \frac{F_{adf_ker_ck}}{(PROCDIV + 1)}$$

This bitfield must not be changed if the filter is enabled (DFTEN = 1).

0: adf_ker_ck provided to the SITF

1: adf_ker_ck / 2 provided to the SITF

2: adf_ker_ck / 3 provided to the SITF

...

127: adf_ker_ck / 128 provided to the SITF

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **CCKDIV[3:0]**: Divider to control the ADF_CCK clock

This bitfield is set and reset by software. It is used to adjust the frequency of the ADF_CCK clock. The input clock of this divider is the clock provided to the SITF. More globally, the frequency of the ADF_CCK is given by the following formula:

$$F_{ADF_CCK} = \frac{F_{adf_ker_ck}}{(PROCDIV + 1) \times (CCKDIV + 1)}$$

This bitfield must not be changed if the filter is enabled (DFTEN = 1).

0000: The ADF_CCK clock is adf_proc_ck.

0001: The ADF_CCK clock is adf_proc_ck / 2.

0010: The ADF_CCK clock is adf_proc_ck / 3.

...

1111: The ADF_CCK clock is adf_proc_ck / 16.

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bits 15:12 **TRGSRC[3:0]**: Digital filter trigger signal selection

This bitfield is set and cleared by software. It is used to select which external signals trigger the corresponding filter. This bitfield is not significant if the CKGMOD = 0.

000x: TRGO selected

0010: adf_trg1 selected

Others: Reserved

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: CKGEN trigger sensitivity selection

This bit is set and cleared by software. It is used to select the trigger sensitivity of the trigger signals. This bit is not significant if the CKGMOD = 0.

0: A rising edge event triggers the activation of CKGEN dividers.

1: A falling edge even triggers the activation of CKGEN dividers.

Note: When the trigger source is TRGO, the sensitivity is forced to falling edge, thus TRGSENS value is not taken into account. This bit can be write-protected (see Section 46.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CCK1DIR**: ADF_CCK1 direction

This bit is set and reset by software. It is used to control the direction of the ADF_CCK1 pin.

0: The ADF_CCK1 pin direction is in input.

1: The ADF_CCK1 pin direction is in output.

Note: This bit can be write-protected (see Section 46.4.13: Register protection for details).

Bit 5 **CCK0DIR**: ADF_CCK0 direction

This bit is set and reset by software. It is used to control the direction of the ADF_CCK0 pin.

0: The ADF_CCK0 pin direction is in input.

1: The ADF_CCK0 pin direction is in output.

Note: This bit can be write-protected (see Section 46.4.13: Register protection for details).

Bit 4 **CKGMOD**: Clock generator mode

This bit is set and reset by software. It is used to define the way the clock generator is enabled. This bit must not be changed if the filter is enabled (DFTEN = 1).

0: The kernel clock is provided to the dividers as soon as CKGDEN is set to 1.

1: The kernel clock is provided to the dividers when CKGDEN is set to 1 and the trigger condition met.

Note: This bit can be write-protected (see Section 46.4.13: Register protection for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CCK1EN**: ADF_CCK1 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the ADF_CCK1 pin.

0: Bitstream clock not generated

1: Bitstream clock generated on the ADF_CCK1 pin.

Bit 1 **CCK0EN**: ADF_CCK0 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the ADF_CCK0 pin.

0: Bitstream clock not generated

1: Bitstream clock generated on the ADF_CCK0 pin

Bit 0 **CKGDEN**: CKGEN dividers enable

This bit is set and reset by software. It is used to enable/disable the clock dividers of the CKGEN: PROCDIV and CCKDIV.

0: CKGEN dividers disabled

1: CKGEN dividers enabled

46.8.3 ADF serial interface control register 0 (ADF_SITF0CR)

Address offset: 0x080

Reset value: 0x0000 1F00

This register is used to control the serial interface SITF0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SITFACTIVE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	STH[4:0]					Res.	Res.	SITFMOD[1:0]		Res.	SCKSRC[1:0]		SITFEN
			rw	rw	rw	rw	rw			rw	rw		rw	rw	rw

Bit 31 **SITFACTIVE**: Serial interface active flag

This bit is set and cleared by hardware. It is used by the application to check if the serial interface is effectively enabled (active) or not. The protected fields of this function can only be updated when SITFACTIVE is set to 0 (see *Section 46.4.13: Register protection* for details).

The delay between a transition on SITFEN and a transition on SITFACTIVE is two periods of AHB clock and two periods of adf_proc_ck.

0: The serial interface is not active, and can be configured if needed.

1: The serial interface is active and protected fields cannot be configured.

Bits 30:13 Reserved, must be kept at reset value.

Bits 12:8 **STH[4:0]**: Manchester symbol threshold/SPI threshold

This bitfield is set and cleared by software. It is used for Manchester mode to define the expected symbol threshold levels (see *Manchester mode* for details on computation).

In addition this bitfield is used to define the timeout value for the clock absence detection in Normal SPI mode. STH[4:0] values lower than four are invalid.

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **SITFMOD[1:0]**: Serial interface type
This bitfield is set and cleared by software. It is used to define the serial interface type.
00: LF_MASTER SPI mode
01: Normal SPI mode
10: Manchester mode: rising edge = logic 0, falling edge = logic 1
11: Manchester mode: rising edge = logic 1, falling edge = logic 0
Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 **SCKSRC[1:0]**: Serial clock source
This bitfield is set and cleared by software. It is used to select the clock source of the serial interface.
00: Serial clock source is ADF_CCK0.
01: Serial clock source is ADF_CCK1.
others: reserved
Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bit 0 **SITFEN**: Serial interface enable
This bit is set and cleared by software. It is used to enable/disable the serial interface.
0: Serial interface disabled
1: Serial interface enabled

46.8.4 ADF bitstream matrix control register 0 (ADF_BSMX0CR)

Address offset: 0x084

Reset value: 0x0000 0000

This register is used to select the bitstream to be provided to DFLT0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BSMXACTIVE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BSSEL[4:0]				
											rw	rw	rw	rw	rw

Bit 31 **BSMXACTIVE**: BSMX active flag
This bit is set and cleared by hardware. It is used by the application to check if the BSMX is effectively enabled (active) or not. BSSEL[4:0] can only be updated when BSMXACTIVE is set to 0. This BSMXACTIVE flag cannot go to 0 if DFLT0 is enabled.
0: BSMX is not active and can be configured if needed.
1: BSMX is active and protected fields cannot be configured.

Bits 30:5 Reserved, must be kept at reset value.

Bits 4:0 **BSSEL[4:0]**: Bitstream selection
This bitfield is set and cleared by software. It is used to select the bitstream to be processed for DFLT0.
00000: bs0_r provided to DFLT0
00001: bs0_f provided to DFLT0
others: reserved
Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

46.8.5 ADF digital filter control register 0 (ADF_DFLT0CR)

Address offset: 0x088

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DFLTACTIVE	DFLTRUN	Res.	Res.	NBDIS[7:0]								Res.	Res.	Res.	Res.
r	r			rw	rw	rw	rw	rw	rw	rw	rw				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRGSRC[3:0]				Res.	Res.	Res.	TRGSENS	Res.	ACQMOD[2:0]			Res.	FTH	DMAEN	DFLTEN
rw	rw	rw	rw				rw		rw	rw	rw		rw	rw	w

Bit 31 **DFLTACTIVE**: DFLT0 active flag

This bit is set and cleared by hardware. It indicates if DFLT0 is active: can be running or waiting for events.

0: DFLT0 not active (can be re-enabled again, via DFLTEN bit, if needed)

1: DFLT0 active

Bit 30 **DFLTRUN**: DFLT0 run status flag

This bit is set and cleared by hardware. It indicates if DFLT0 is running or not.

0: DFLT0 not running and ready to accept a new trigger event

1: DFLT0running

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:20 **NBDIS[7:0]**: Number of samples to be discarded

This bitfield is set and cleared by software. It is used to define the number of samples to be discarded every time DFLT0 is re-started.

0: No sample discarded

1: 1 sample discarded

2: 2 samples discarded

...

255: 255 samples discarded

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:12 **TRGSRC[3:0]**: DFLT0 trigger signal selection

This bitfield is set and cleared by software. It is used to select which external signals trigger DFLT0.

0000: TRGO selected

0010: adf_trgi selected

Others: Reserved

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: DFLT0 trigger sensitivity selection

This bitfield is set and cleared by software. It is used to select the trigger sensitivity of the external signals

0: A rising edge event triggers the acquisition.

1: A falling edge even triggers the acquisition.

Note: When the trigger source is TRGO, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge.
This bit can be write-protected (see Section 46.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ACQMOD[2:0]**: DFLT0 trigger mode

This bitfield is set and cleared by software. It is used to select the filter trigger mode.

000: Asynchronous continuous acquisition mode

001: Asynchronous single-shot acquisition mode

010: Synchronous continuous acquisition mode

011: Synchronous single-shot acquisition mode

100: Window continuous acquisition mode

Others: Same as 000

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details)..

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FTH**: RXFIFO threshold selection

This bit is set and cleared by software. It is used to select the RXFIFO threshold.

0: RXFIFO threshold event generated when the RXFIFO is not empty

1: RXFIFO threshold event generated when the RXFIFO is half-full

Note: This bit can be write-protected (see Section 46.4.13: Register protection for details).

Bit 1 **DMAEN**: DMA requests enable

This bit is set and cleared by software. It is used to control the generation of DMA request to transfer the processed samples into the memory.

0: DMA interface for the corresponding digital filter disabled

1: DMA interface for the corresponding digital filter enabled

Note: This bit can be write-protected (see Section 46.4.13: Register protection for details).

Bit 0 **DFLTEN**: DFLT0 enable

This bit is set and cleared by software. It is used to control the start of acquisition of the DFLT0 path. This bit behavior depends on ACQMOD[2:0] and external events. The serial or parallel interface delivering the samples must be enabled as well.

0: Acquisition immediately stopped

1: Acquisition immediately started if ACQMOD[2:0] = 00x or 101, or acquisition started when the proper trigger event occurs if ACQMOD[2:0] = 01x.

46.8.6 ADF digital filer configuration register 0 (ADF_DFLT0CICR)

Address offset: 0x08C

Reset value: 0x0000 0000

This register is used to control the main CIC filter.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	SCALE[5:0]						Res.	Res.	Res.	MCICD8
						rw	rw	rw	rw	rw	rw				rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MCICD[7:0]								Res.	CICMOD[2:0]			Res.	Res.	DATSRC[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw			rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:20 **SCALE[5:0]**: Scaling factor selection

This bitfield is set and cleared by software. It is used to select the gain to be applied at CIC output (see *Table 418* for details). If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back this bitfield informs the application on the current gain value.

000000: 0 dB
000001: + 3.5 dB
000010: + 6 dB or shift left by 1 bit
...
011000: + 72 dB or shift left by 12 bits
100000: - 48.2 dB or shift right by 8 bits (default value)
100001: - 44.6 dB
100010: - 42.1 dB or shift right by 7 bits
100011: - 38.6 dB
...
101110: -6 dB or shift right by 1 bit
101111: -2.5 dB
Others: Reserved

Bits 19:17 Reserved, must be kept at reset value.

Bits 16:8 **MCICD[8:0]**: CIC decimation ratio selection

This bitfield is set and cleared by software.It is used to select the CIC decimation ratio. A decimation ratio smaller than two is not allowed. The decimation ratio is given by (CICDEC+1).

0: Decimation ratio is 2.
1: Decimation ratio is 2.
2: Decimation ratio is 3.
3: Decimation ratio is 4.
...
511: Decimation ratio is 512.

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **CICMOD[2:0]**: Select the CIC order
This bitfield is set and cleared by software. It is used to select the order of the MCIC.
100: MCIC configured in single Sinc^4 filter
101: MCIC configured in single Sinc^5 filter
Others: Reserved
Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **DATSRC[1:0]**: Source data for the digital filter
This bitfield is set and cleared by software.
0x: Stream coming from the BSMX selected
10: Stream coming from the ADCITF1 selected
11: Stream coming from the ADCITF2 selected
Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

46.8.7 ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)

Address offset: 0x090

Reset value: 0x0000 0000

This register is used to control the reshape and HPF filter.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	HPFC[1:0]		HPFBYP	Res.	Res.	RSFLTD	Res.	Res.	Res.	RSFLTBYP
						rw	rw	rw			rw				rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:8 **HPFC[1:0]**: High-pass filter cut-off frequency
This bitfield is set and cleared by software. it is used to select the cut-off frequency of the high-pass filter. F_{PCM} represents the sampling frequency at HPF input.
00: Cut-off frequency = 0.000625 x FPCM
01: Cut-off frequency = 0.00125 x FPCM
10: Cut-off frequency = 0.00250 x FPCM
11: Cut-off frequency = 0.00950 x FPCM
Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bit 7 **HPFBYP**: High-pass filter bypass
This bit is set and cleared by software. It is used to bypass the high-pass filter.
0: HPF not bypassed (default value)
1: HPF bypassed
Note: This bit can be write-protected (see Section 46.4.13: Register protection for details).

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **RSFLTD**: Reshaper filter decimation ratio

This bit is set and cleared by software. It is used to select the decimation ratio for the reshape filter

0: Decimation ratio is 4 (default value).

1: Decimation ratio is 1.

Note: This bit can be write-protected (see Section 46.4.13: Register protection for details).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **RSFLTBYP**: Reshaper filter bypass

This bit is set and cleared by software. It is used to bypass the reshape filter and its decimation block.

0: Reshape filter not bypassed (default value)

1: Reshape filter bypassed

Note: This bit can be write-protected (see Section 46.4.13: Register protection for details).

46.8.8 ADF delay control register 0 (ADF_DLY0CR)

Address offset: 0x0A4

Reset value: 0x0000 0000

This register is used for the adjustment stream delays.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SKPBF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SKPDLY[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bit 31 **SKPBF**: Skip busy flag

This bit is set and cleared by hardware. It is used to control if the delay sequence is completed.

0: ADF ready to accept a new value into SKPDLY[6:0]

1: Last valid SKPDLY[6:0] still under precessing

Bits 30:7 Reserved, must be kept at reset value.

Bits 6:0 **SKPDLY[6:0]**: Delay to apply to a bitstream

This bitfield is set and cleared by software. It defines the number of input samples that are skipped. Skipping is applied immediately after writing to this bitfield, if SKPBF = 0 and DFLTEN = 1. If SKPBF = 1, the value written into the register is ignored by the delay state machine.

0: No input sample skipped

1: 1 input sample skipped

...

127: 127 input samples skipped

46.8.9 ADF DFLT0 interrupt enable register (ADF_DFLT0IER)

Address offset: 0x0AC

Reset value: 0x0000 0000

This register is used for allowing or not the events to generate an interrupt.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

		rw	rw	rw	rw	rw								rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **SDLVLIE**: SAD sound-level value ready enable
This bit is set and cleared by software.
0: Sound-level-ready interrupt disabled
1: Sound-level-ready interrupt enabled

Bit 12 **SDDETIE**: Sound activity detection interrupt enable
This bit is set and cleared by software.
0: Sound-trigger interrupt disabled
1: Sound-trigger interrupt enabled

Bit 11 **RFOVRIE**: Reshape filter overrun interrupt enable
This bit is set and cleared by software.
0: Reshape filter overrun interrupt disabled
1: Reshape filter overrun interrupt enabled

Bit 10 **CKABIE**: Clock absence detection interrupt enable
This bit is set and cleared by software.
0: Clock absence interrupt disabled
1: Clock absence interrupt enabled

Bit 9 **SATIE**: Saturation detection interrupt enable
This bit is set and cleared by software.
0: Saturation interrupt disabled
1: Saturation interrupt enabled

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **DOVRIE**: Data overflow interrupt enable
This bit is set and cleared by software.
0: Data overflow interrupt disabled
1: Data overflow interrupt enabled

Bit 0 **FTHIE**: RXFIFO threshold interrupt enable
This bit is set and cleared by software.
0: RXFIFO threshold interrupt disabled
1: RXFIFO threshold interrupt enabled

46.8.10 ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)

Address offset: 0x0B0

Reset value: 0x0000 0000

This register contains the status flags for the digital filter path.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	SDLVLF	SDDETF	RFOVRF	CKABF	SATF	Res.	Res.	Res.	Res.	Res.	RXNEF	Res.	DOVRF	FTHF
		rc_w1	rc_w1	rc_w1	rc_w1	rc_w1						r		rc_w1	r

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **SDLVLF**: Sound level value ready flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that new sound level value is not ready. Write 0 has no effect.
1: Read 1 means that new sound level value is ready. Write 1 clears this flag.

Bit 12 **SDDETF**: Sound activity detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no sound activity is detected. Write 0 has no effect.
1: Read 1 means that sound activity is detected. Write 1 clears this flag.

Bit 11 **RFOVRF**: Reshape filter overrun detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no reshape filter overrun is detected. Write 0 has no effect.
1: Read 1 means that reshape filter overrun is detected. Write 1 clears this flag.

Bit 10 **CKABF**: Clock absence detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no clock absence is detected. Write 0 has no effect.
1: Read 1 means that a clock absence is detected. Write 1 clears this flag.

Bit 9 **SATF**: Saturation detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no saturation is detected. Write 0 has no effect.
1: Read 1 means that a saturation is detected. Write 1 clears this flag.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **RXNEF**: RXFIFO not empty flag
This bit is set and cleared by hardware according to the RXFIFO level.
0: RXFIFO empty
1: RXFIFO not empty

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DOVRF**: Data overflow flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no overflow is detected. Write 0 has no effect.
1: Read 1 means that an overflow is detected; Write 1 clears this flag.

Bit 0 **FTHF**: RXFIFO threshold flag

This bit is set by hardware, and cleared by the hardware when the RXFIFO level is lower than the threshold.

0: RXFIFO threshold not reached

1: RXFIFO threshold reached

46.8.11 ADF SAD control register (ADF_SADCR)

Address offset: 0x0B8

Reset value: 0x0000 0000

This register is used for the configuration and the control of the sound activity detection.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SADACTIVE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	SADMOD[1:0]		Res.	FRSIZE[2:0]			HYSTEN	Res.	SADST[1:0]		DETCFG	DATCAP[1:0]		SADEN
		rw	rw		rw	rw	rw	rw		r	r	rw	rw	rw	rw

Bit 31 **SADACTIVE**: SAD Active flag

This bit is set and cleared by hardware. It is used to check if the SAD is effectively enabled (active) or not. The protected fields and registers of this function can only be updated when the SADACTIVE is set to 0 (see *Section 46.4.13: Register protection* for details).

The delay between a transition on SADEN and a transition on SADACTIVE is two periods of AHB clock and two periods of adf_proc_ck.

0: SAD not active and can be configured if needed

1: SAD active and protected fields cannot be configured.

Bits 30:14 Reserved, must be kept at reset value.

Bits 13:12 **SADMOD[1:0]**: SAD working mode

This bitfield is set and cleared by software. It is used to define the way the SAD works.

00: Threshold value computed according to the estimated ambient noise

The SAD triggers when the sound level (SDLVL) is bigger than the defined threshold. In this mode, the SAD works like a voice activity detector.

01: Threshold value equal to ANMIN[12:0], multiplied by the gain selected by SNTHR[3:0]

The SAD triggers when the sound level (SDLVL) is bigger than the defined threshold. In this mode, the SAD works like a sound detector.

1x: Threshold value given by 4 x ANMIN[12:0]

The SAD triggers when the estimated ambient noise (ANLVL), multiplied by the gain selected by SNTHR[3:0] is bigger than the defined threshold. In this mode, the SAD is working like an ambient noise estimator. Hysteresis function cannot be used in this mode.

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **FRSIZE[2:0]**: Frame size

This bitfield is set and cleared by software. it is used to define the size of one frame and also to define how many samples are taken into account to compute the short-term signal level.

000: 8 PCM samples used to compute the short-term signal level

001: 16 PCM samples used to compute the short-term signal level

010: 32 PCM samples used to compute the short-term signal level

011: 64 PCM samples used to compute the short-term signal level

100: 128 PCM samples used to compute the short-term signal level

101: 256 PCM samples used to compute the short-term signal level

11x: 512 PCM samples used to compute the short-term signal level

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bit 7 **HYSTEN**: Hysteresis enable

This bit is set and cleared by software. It is used to enable/disable the hysteresis function (see *Table 418* for details). This bit must be kept to 0 when SADMOD[1:0] = 1x.

0: Hysteresis function disabled. THR_H is always used.

1: Hysteresis function enabled. THR_H is used for MONITOR to DETECT transition and THR_L is used for DETECT to MONITOR transition.

Note: This bit can be write-protected (see Section 46.4.13: Register protection for details).

Bit 6 Reserved, must be kept at reset value.

Bits 5:4 **SADST[1:0]**: SAD state

This bitfield is set and cleared by hardware. It indicates the SAD state and is meaningful only when SADEN = 1. The SAD state can be:

- LEARN when the SAD is in learning phase or in SDLVL computation mode
- MONITOR when the SAD is in monitoring phase
- DETECT when the SAD detects a sound

00: SAD in LEARN state

01: SAD in MONITOR state

11: SAD in DETECT state

Bit 3 **DETCFG**: Sound trigger event configuration

This bit is set and cleared by software. It is used to define if the sddet_evt event is generated only when the SAD enters to MONITOR state or when the SAD enters or exits the DETECT state.

0: sddet_evt generated when SAD enters the MONITOR state

1: sddet_evt generated when SAD enters or exits the DETECT state

Note: This bit can be write-protected (see Section 46.4.13: Register protection for details).

Bits 2:1 **DATCAP[1:0]**: Data capture mode

This bitfield is set and cleared by software. It is used to define in which conditions, the samples provided by DLFT0 are stored into the memory.

00: Samples from DFLT0 not transfered into the memory

01: Samples from DFLT0 transfered into the memory when SAD is in DETECT state

1x: Samples from DFLT0 transfered into memory when SAD and DFLT0 are enabled

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bit 0 **SADEN**: Sound activity detector enable

This bit is set and cleared by software. It is used to enable/disable the SAD.

0: SAD disabled and SAD state reset

1: SAD enabled

46.8.12 ADF SAD configuration register (ADF_SADCFGR)

Address offset: 0x0BC

Reset value: 0x0000 0000

This register is used for the configuration of the sound activity detection.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	ANMIN[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	HGOVR[2:0]			Res.	LFRNB[2:0]			Res.	ANSLP[2:0]			SNTHR[3:0]			
	rw	rw	rw		rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **ANMIN[12:0]**: Minimum noise level

This bitfield is set and cleared by software. It is used to define the minimum noise level and then the sensitivity. It represents a positive number.

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **HGOVR[2:0]**: Hangover time window

This bitfield is set and cleared by software. Once the SAD state is DETECT, this parameter is used to define the amount of time the sound is allowed to remain below the threshold, before switching the SAD to MONITOR state (see FRSIZE bitfield for the description of a frame).

000: SAD back to MONITOR state if sound is below threshold for 4 frames
001: SAD back to MONITOR state if sound is below threshold for 8 frames
010: SAD back to MONITOR state if sound is below threshold for 16 frames
011: SAD back to MONITOR state if sound is below threshold for 32 frames
100: SAD back to MONITOR state if sound is below threshold for 64 frames
101: SAD back to MONITOR state if sound is below threshold for 128 frames
110: SAD back to MONITOR state if sound is below threshold for 256 frames
111: SAD back to MONITOR state if sound is below threshold for 512 frames

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **LFRNB[2:0]**: Number of learning frames

This bitfield is set and cleared by software. It is used to define the number of learning frames to perform the first estimate of the noise level.

000: 2 frames used to compute the initial noise level
001: 4 frames used to compute the initial noise level
010: 8 frames used to compute the initial noise level
011: 16 frames used to compute the initial noise level
1xx: 32 frames used to compute the initial noise level

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ANSLP[2:0]**: Ambient noise slope control

This bitfield is set and cleared by software. It is used to define the positive and negative slope of the noise estimator, in charge of updating the ANLVL (see *Ambient noise estimation (ANLVL)* for information about programming this bitfield).

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

Bits 3:0 **SNTHR[3:0]**: Signal to noise threshold

This bitfield is set and cleared by software. It is used to define THR_H (and THR_L if hysteresis is enabled). See *Table 418* for details.

0000: THR_H is 3.5 dB higher than ANLVL
0001: THR_H is 6.0 dB higher than ANLVL
0010: THR_H is 9.5 dB higher than ANLVL
0011: THR_H is 12 dB higher than ANLVL
0100: THR_H is 15.6 dB higher than ANLVL
0101: THR_H is 18 dB higher than ANLVL
0110: THR_H is 21.6 dB higher than ANLVL
0111: THR_H is 24.1 dB higher than ANLVL
1000: THR_H is 27.6 dB higher than ANLVL
1001: THR_H is 30.1dB higher than ANLVL
others: Reserved

Note: This bitfield can be write-protected (see Section 46.4.13: Register protection for details).

46.8.13 ADF SAD sound level register (ADF_SADSDLVR)

Address offset: 0x0C0

Reset value: 0x0000 0000

This register contains the short-term sound-level computed by the SAD.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	SDLVL[14:0]														
	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **SDLVL[14:0]**: Short term sound level

This bitfield is set by hardware. It contains the latest sound level computed by the SAD. To refresh this value, SDLVLF must be cleared.

46.8.14 ADF SAD ambient noise level register (ADF_SADANLVR)

Address offset: 0x0C4

Reset value: 0x0000 0000

This register contains the ambient noise level computed by the SAD.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	ANLVL[14:0]														
	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **ANLVL[14:0]**: Ambient noise level estimation

This bitfield is set by hardware. It contains the latest ambient noise level computed by the SAD. To refresh this bitfield, the SDLVLF flag must be cleared.

46.8.15 ADF digital filter data register 0 (ADF_DFLT0DR)

Address offset: 0x0F0

Reset value: 0x0000 0000

This register is used to read the data processed by the digital filter.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DR[23:8]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NBF[7:0]								FIFO_SIZE[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 **OPTION_REGOUT[7:0]:** Support of ADF_OR register
0: ADF_OR not implemented
1: ADF_OR implemented with only one control bit at position 0
2: ADF_OR implemented, with two control bits at positions 0 and 1
...
32: ADF_OR implemented with 32 control bits at positions 0 to 31
Others: Invalid values

Bits 23:20 **SAD[3:0]**: Sound activity detection
0x0: SAD not implemented
0x1: SAD implemented

Bits 19:16 **FLT_CFG[3:0]**: Digital filter configuration
0: Reduced set of features to mainly address audio use-cases
1: Full set of features, with associated blocks for motor control applications

Bits 15:8 **NBF[7:0]**: Number of digital filter paths and serial interfaces
0x1: 1 digital filter instance implemented
0x2: 2 digital filter instances implemented
...
0x6: 6 digital filter instances implemented
...
0x10: 16 digital filter instances implemented

Bits 7:0 **FIFO_SIZE[7:0]**: FIFO size for ADF
2: the FIFO depth is 2 words
4: the FIFO depth is 4 words
8: the FIFO depth is 8 words
16: the FIFO depth is 16 words
32: the FIFO depth is 32 words
64: the FIFO depth is 64 words
Others: Invalid values

46.8.17 ADF version register (ADF_VERR)

Address offset: 0xFF4

Reset value: 0x0000 0011

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.4* for the register boundary addresses.

47 Camera subsystem

47.1 Introduction

The camera subsystem is built around a double path:

- a low-resolution path, with the DCMI and a low-frequency parallel interface. It supports sensors up to 1 Mpixels @15 fps.
- a high-resolution path, with the DCMIPP and a high-frequency parallel interface or serial CSI-2 interface, either RGB or RawBayer. It targets sensors up to 5 Mpixels @30 fps.

When plugging a camera sensor, it is recommended to use the DCMIPP that supports more features and provides higher throughput than the DCMI.

The DCMI is recommended only in two noticeable cases:

- to get a backward compatibility with former platforms that embed also the DCMI
- to input the pixels from a second camera sensor (such as low resolution sensor for AI processing)

Note: The DCMIPP inputs pixels from one sensor via the CSI-2 interface, while the DCMI gets pixels from the second sensor via the parallel interface.

The DCMI path offers the following summarized maximum features:

- Target sensor: 24 Mpixel/s 16 bpp (limited by the DMA)
- Parallel input: 80 MHz on 14-bit input capability
- Central DMA to extract and dump its pixels
- Software extraction of its pixel data

The DCMIPP path offers the following summarized maximum features:

- Target sensors: 5 Mpixel at 30 fps max
- Parallel input: 120 MHz on 16-bit input capability
- Serial input: CSI-2 @2.5 Gbps/lane on 2 data lanes
- ISP (image signal processor): demosaicing, exposure, white-balance, contrast, bad-pixel
- Application pipes: 2 pipes with crop, downsize, gamma, YUV conversion, YUV420

Some over-target use cases are possible, but with specific constraints:

- sensors with resolution above 5 Mpixels
- sensors with pixel rate above 150 Mpixel/s
- double sensors in parallel

47.2 Camera path main features

47.2.1 DCMI path main features

The DCMI path shows the following features:

- 8-, 10-, 12- or 14-bit parallel interface at 80 MHz (no I/O ReTime)
- Embedded/external line and frame synchronization

- Continuous or snapshot mode
- Crop feature
- Following data formats supported (dumped in memory, extracted by software):
  - 8-, 10-, 12-, 14-bit progressive video, either monochrome or RawBayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG (in fact, any default/byte data)

See *Section 48: Digital camera interface (DCMI)* for more details.

47.2.2 DCMIPP path main features

The DCMIPP path groups the DCMIPP pixel pipeline block, its included parallel interface, and the abutted CSI-2-Host and PHY.

The parallel interface shows the following features:

- Input rate: 120 MHz up to 16-bit capability (with I/O ReTime)
- Pixel format: RGB565, 888, YUV422, RawBayer/Mono 8/10/12/14
- Synchronization: embedded versus external line and frame synchronization

See *Section 49: Digital camera interface pixel pipeline (DCMIPP)* for more details.

The CSI-2 serial interface shows the following features:

- Standard: MIPI CSI2 v1.3
- Input rate: 2 data lanes @ 2.5 Gbps/lane
- Pixel rate: if RGB888: up to 200 Mpixel/s, if RawBayer 10: up to 333 Mpixel/s
- Pixel format: any MIPI CSI2 v1.3: RGB565, 888, YUV422, RawBayer
- Miscellaneous: interlaced video, interleaved packets, virtual channels

See *Section 50: CSI-2 Host (CSI)* for more details.

DCMIPP sizings and limitations

- Camera target: 5 Mpixels (typ. 2560x2048 or 2688x1944) before decimation
- Pipe resolution: 4094x4094 pixels max
  - Demosaicing: 2688 pixels wide max line-buffers (decimation available ahead)
  - Downsize: 2688 pixels wide max line-buffers
  - YUV420: 2688 pixels wide max line-buffers.
- Pipe pixel rate: 333 Mpixel/s peak.
- AXI FIFO: 5 Kbytes available, with a flexible allocation between all outputs.
- AXI master: AXI-64 bits @ 400 MHz, with FIFO for latencies up to 2 µs, 16 outstanding.

The DCMIPP provides three different pipes to process data:

- Pipe0: to dump data without any processing, branched before any ISP

  It is aimed at dumping metadata or statistics as-is from the sensor, or at dumping the full picture as RawBayer data, for a potential long but optimal software processing.
- Pipe1: main full-featured pipe (such as ISP, then downsize, YUV-multi-planar)

  It provides a picture ready for any application (such as display, video encode, or neural processing).

- Pipe2: ancillary semi-featured pipe

  Same ISP as pipe1, then downsize, but no YUV-multiplanar. It provides an RGB output for a display use.

DCMIPP ISP capabilities common to pipe1 and 2, are the following:

- Flow selection: parallel-vs-CSI2, CSI virtual packets
- Test pattern generator to emulate an external camera sensor
- Capture mode: continuous versus snapshot mode
- Pixel extraction: RGB565, 888, YUV422, RawBayer/Mono 8/10/12/14.
- Statistic removal: to remove unused metadata (like statistics) from received pictures
- Bad-pixel removal: automatic detection and correction of bad pixels from sensor array
- Decimation: one pixel every 1/2/4/8, used to fit the max 2688 pixels
- Exposure control: to amplify the exposure from 0.0 to 255.99x
- Statistic extraction: average R,G,B,L values, dynamic bins
- Demosaicing: to convert RawBayer to RGB, per region histograms
- White-balance: to adapt to sensor white and global Illumination
- Contrast: to enhance the contrast, via luminance

The DCMIPP application capabilities, replicated for pipe1 and 2, are listed below:

- Cropping: to select a region of interest or stabilize the picture
- Downsize: box-filtering, with any decimal ratio, up to 8x8
- Gamma conversion: predistortion with gamma = 2.2 for display purposes
- YUV color conversion: to convert to YUV to later store a video-friendly buffer (pipe1 only).
- YUV422/420: chroma subsampling to YUV422 or YUV420

Output pixel format:

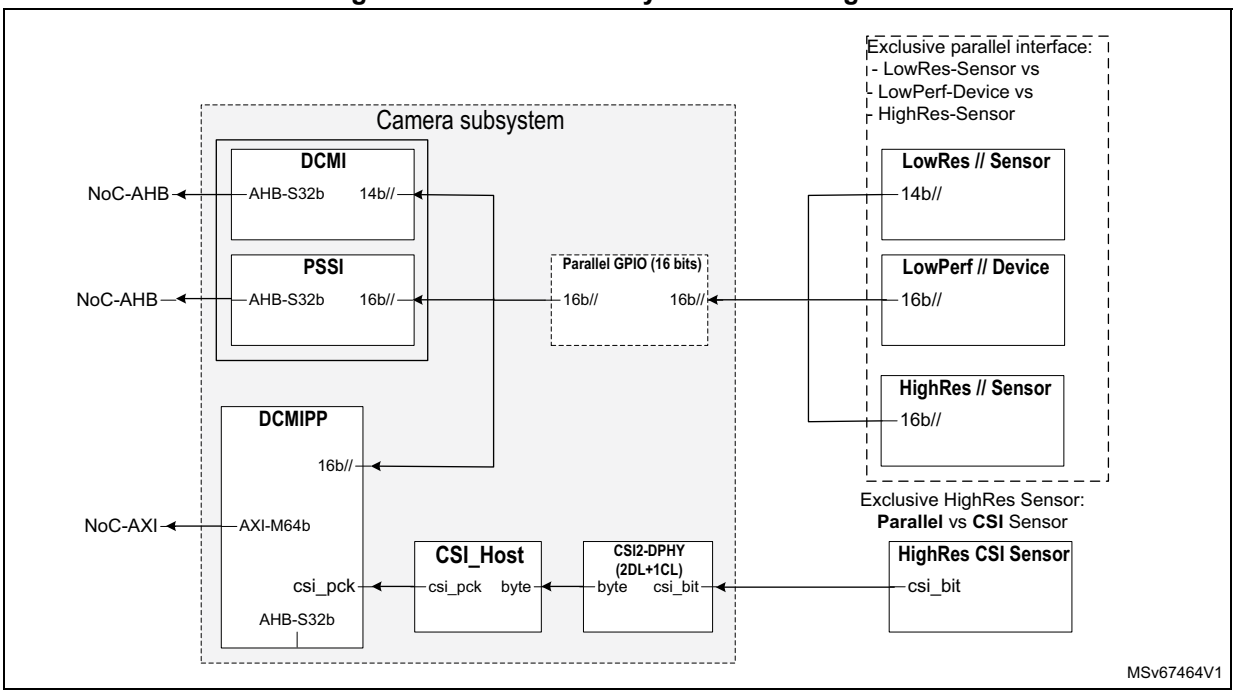
- Pipe1 and 2: 888, 565, 422-1, Y8, ARGB and RGBA (coplanar only)
- Pipe1: to adds422-2, 420-2, 420-3 (multi-planar possibility)

The full features are detailed in *Section 48: Digital camera interface (DCMI)*.

47.3 Camera subsystem implementation

47.3.1 Hardware settings

The camera subsystem is implemented with the following specific settings:



- CSI2: two data lanes (+ one clock lane) up to 2.5 Gbps/lane.
- DCMIPP FIFO: 5 Kbytes for AXI
- DCMIPP with the following subfeatures:
  - line-buffers: 2688 pixels (impacts the demosaicing, downsize, YUV420 conversion)
  - one dump pipe + two pixel pipes (pipe1 with YUV420/multi-planar only)

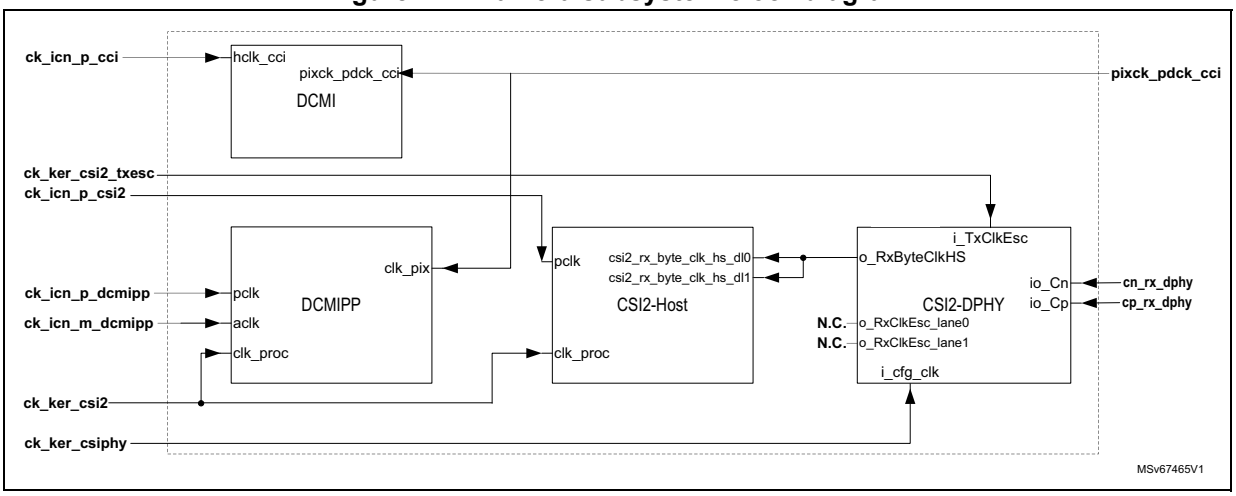
47.4 Camera subsystem functional description

47.4.1 Camera subsystem block diagram

The figure below shows the involved blocks in the camera subsystem.

Figure 413. Camera subsystem block diagram

Note: The PSSI is not used for camera purpose but rather for general-purpose parallel input (not described in this section).



47.4.2 Camera subsystem pins and external signal interface

Details about the pins can be found in the respective block sections.

47.4.3 Camera subsystem reset and clocks

The clock diagram of the camera subsystem is shown in the figure below.

Figure 414. Camera subsystem clock diagram

The above camera subsystem has been implemented with the following clock max frequencies:

- DCMI // I/F (pixck_pdck_cci): 80 MHz (no I/O ReTime: async path from pads)
- DCMIPP // I/F (pixck_pdck_cci): 120 MHz (I/O ReTime mandatory)
- CSI2 bit clock (cn/p_rx_dphy): 1250 MHz (2.5 Gbps/lane)
- CSI2 byte clock (rxbyte_clkHS): 312.5 MHz
- CSI2 TxEsc clock (ck_ker_csi2_txesc): 20 MHz
- CSI2 Cfg clock (ck_ker_csiphy): 27 MHz
- Pixel clock (ck_ker_csi2): 333 MHz
- Register clocks (ck_icn_p_*): 200 MHz (all APB/AHB register files)
- AXI clock (ck_icn_m_dcmipp): 400 MHz

47.4.4 Camera subsystem security

The security of the camera subsystem is based on the protection of its register map, and of its master access to the system interconnect, based on default RISUP and RIMU respectively.

More information can be found in *Section 6.2: Resource isolation framework (RIF)*.

The RISUP differentiates the access right of accesses performed toward the following RIF protected peripheral ID (indexes refer to *Table 38: Indexes for non-RIF-aware peripherals (RISUP)*):

- DCMIPP: tag = DCMIPP for the configuration of pixel pipelines (index 87)
- CSI2-Host: tag = CSI2H for Host and PHY configurations (index 86)
- DCMI and PSSI: tag = DCMI for its configuration, and to retrieve pixels by DMA (index 88)

The RIMU (RIMU_AXI_DCMIPP) gives the access right to the DCMIPP AXI master:

- S and P are set using the RIF RIMC_ATTR10 register.
- CID is set either by the RISA (RISUP86 register) of directly by software.

By default, the camera subsystem is expected to work in a non-secure mode:

- DCMIPP, CSI2, DCMI, and PSSI are left unprotected, so that any OS software can configure and handle the camera subsystem.
- The AXI master of the DCMIPP inherits the CID setting from its associated register map. CID = DISP or CID = VID can be allocated to its RISUP to mention that the AXI write access of the camera subsystem contains pixels (like the display system).

For secure applications, the user can put the camera subsystem in S, P, or S-and-P mode, with the following impacts:

- As a benefit, the user is sure that the content of the dumped buffer does truly come from the camera sensor:

  The output of the DCMIPP is differentiated from other masters: only the DCMIPP can write into its buffer. This buffer content is known to come from the camera sensor, which makes impossible to fill-in (by software) a fake face to be recognized.
- The camera subsystem needs to be transfered to the secure software world (with the verification implications), or the system must make sure that the access rights of the DCMIPP cannot harm the system.

The above recommended non-protected settings are shown in *Table 432: Camera subsystem RIF peripheral ID*.

The table below lists vertically all camera subsystem blocks, and horizontally the associated RIF peripheral ID.

Table color legend for the recommended settings: gray for a permanently non-protected setting, blue for a temporarily protected versus non-protected, and pink for a permanently protected state: by default, all the settings are non-protected.

Table 432. Camera subsystem RIF peripheral ID

Subsystem	Block	Address range	Start address	RISUP - slave		
				88	87	86
				DCMI_PSSI	DCMIPP	CSI2H
Camera low resolution	DCMI	Configuration	0x0000	Y	-	-
		Pixel Rx	0x0A00	Y	-	-
		Configuration	0x0B00	Y	-	-
		Data in/out	0x0C00	Y	-	-

Table 432. Camera subsystem RIF peripheral ID (continued)

Subsystem	Block	Address range	Start address	RISUP - slave		
				88	87	86
				DCMI_PSSI	DCMIPP	CSI2H
Camera high resolution	DCMIPP	Common configuration	0x0	-	Y	-
		P1 configuration	0x0	-	Y	-
		P2 configuration	0x0	-	Y	-
		P3 configuration	0x0	-	Y	-
	CSI	Configuration control	0x0000	-	-	Y
		Configuration wrap	0x1000	-	-	Y
		CSI DPHY-Rx (no register)	-	-	-	-

47.5 Camera subsystem programmable parameters

This section describes the configuration of the various main use cases supported by the camera subsystem. Its purpose is to provide the settings that are global to the camera subsystem, and not provided by the local relevant blocks.

The use cases supported by default are the following:

- low-resolution parallel camera, using the DCMI path (see *Section 47.5.1*)
- high-resolution parallel camera, using the DCMIPP path (see *Section 47.5.2*)
- high-resolution CSI2 camera, using the DCMIPP path (see *Section 47.5.3*)

Some over-target use cases are possible, but with specific constraints:

- sensors over target-resolution (above 5 Mpixels)

  The limiting factors are
  - the clock (related to max pixel rate)
  - AXI bandwidth (related to the pixel rate and pixel format of the active pipes)
  - line buffers of the demosaicing, downsize, and YUV420 chroma decimation (when active)

  To cope with these limitations, the decimation can be used, ahead of the pipes, to reduce the width and/or height of the frame, and/or deactivate the limiting operators, the demosaicing, downsize, YUV420.
- sensors over target pixel rate (above 150 Mpixel/s)
- double sensors like 3D camera (with their left and right sensors)

47.5.1 Low-resolution parallel camera and DCMI

This use case is recommended only for backward compatibility, or to grab pictures simultaneously from two sensors (a low and a high resolution).

The steps to setup this path are the following:

- Clock and reset
  - pixck_pdck_cci is provided by the sensor (via the PCB on the input I/O, 80 MHz max).
  - The RCC provides ck_icn_p_cci, that must be ≥ 2.5x pixck_pdck_cci due to the DCMI. The default clock is 200 MHz, which allows the input clock to be at 80 MHz.
  - *Section 21: Reset and clock control (RCC)* provides the needed details.
- DMA
  - The LPDMA and HPDMA retrieve pixels from the DCMI, that signals to the DMA that its FIFO is full and must be read-out.
  - *Section 27* and *Section 28* provide the needed details.

47.5.2 High-resolution parallel camera and DCMIPP

This is the default use case to grab a picture from a parallel camera (up to the target 5 Mpixels @30fps). Any RGB or RawBayer picture can be grabbed.

The steps to setup this path are the following:

- Clock and reset:
  - pixck_pdck_cci is provided by the sensor (via the PCB on the input I/O, 120 MHz max). Each pixel needs 1 to 3 cycles to get in.
  - ck_icn_p_dcmipp is provided by the RCC for the DCMIPP configuration (default is 200 MHz).
  - ck_ker_csi2 is provided by the RCC for the pixel pipelines of the DCMIPP (default is 200 MHz).
  - ck_icn_m_dcmipp is provided by the RCC for the DCMIPP AXI (default is 400 MHz).
  - *Section 21: Reset and clock control (RCC)* provides the needed details.
- DCMIPP configuration:
  - Select the parallel interface as input interface.
  - Setup the DCMIPP (parallel interface, ISP, application path, AXI-plug) as described in *Section 49: Digital camera interface pixel pipeline (DCMIPP)*.

47.5.3 High-resolution CSI2 camera and DCMIPP

This is the default use-case to grab a picture from a CSI2 camera (up to the target 5 Mpixels @30 fps). Any RGB or RawBayer picture can be grabbed.

The steps to setup this path are the following:

- Clock and reset:
  - cn/p_rx_dphy are provided by the sensor (via the PCB on the input I/O, 1.25 GHz/2.5 Gbit/s max).
  - RxByteClkHS is automatically divided (1/8) from cn/p_rx_dphy (312.5 MHz max).
  - ck_icn_p_csi2 is provided by the RCC for the CSI2-Host configuration (default 200 MHz).
  - ck_icn_p_dcmipp is provided by the RCC for the DCMIPP configuration (default 200 MHz).

  - ck_ker_csiphy is provided by the RCC for CSI2-Host in low-power (default 20 MHz).
  - ck_ker_csi2_txesc is provided by the RCC for the TxEscape mode of CSI2 (default 27 MHz).
  - ck_ker_csi2 is provided by the RCC for the pixel pipelines of the DCMIPP (default 200 MHz).
  - ck_icn_m_dcmipp is provided by the RCC for the DCMIPP AXI (default 400 MHz).
  - *Section 21: Reset and clock control (RCC)* provides the needed details.
- CSI2-Host configuration:
  - Setup the CSI2-Host (such as packet type).
- DCMIPP configuration:
  - Select the CSI2 interface as input interface.
  - Setup the DCMIPP (CSI2, ISP, application path, AXI-plug) as described in *Section 49: Digital camera interface pixel pipeline (DCMIPP)*.

47.5.4 Sensors over target resolution

The sensors over the target resolution (5 Mpixels) are supported with the following restrictions:

- CSI2 interface must be used (parallel interface quickly limited with its 120 MHz performances).
- The sensor must be able to output its bit rate onto the available two data lanes of the CSI2 link. It is recommended to use RawBayer (less bit/pixel than RGB).
- Width and height must both remain below 4094 (up to 16 Mpixels can be reached).
- Decimation is located ahead of most processing, and can be used to decrease the grabbed resolution.
- Demosaicing is limited with a max width of 2688: if demosaicing needs to be activated (RawBayer input, RGB output), then the decimation must be used to fall under that 2688 pixel limit. There is no height limit.
- Downsize and YUV420 are limited (similarly as demosaicing) to 2688, and require a decimation ahead if they need to be activated. The horizontal downsize occurs before the vertical one: the first can be used to fall below the 2688 pixels limit, before being processed by the second.
- If all demosaicing, downsize, and YUV420 are disabled. Pictures up to 4094x4094 can be received and dumped by the AXI.

After taking into account these restrictions, the configuration itself is the same as for the default high-resolution CSI2 camera, described in previous section.

47.5.5 Sensors over target pixel rate

The sensors over the target pixel rate (150 Mpixel/s average, ~200 Mpixel/s peak) are supported with the following restrictions:

- The sensor must be able to output its bit rate onto the available two data lanes of the CSI2 link.
- The peak pixel rate must remain below (with some margin) the max 333 MHz of the DCMIPP pixel clock (with a 10% margin recommended).

- DCMIPP bandwidth and FIFO allocation must be able to dump this load: it is recommended to reduce the amount of parallel dumps (best not all Pipe0, Pipe1, and Pipe2 active simultaneously). In the DCMIPP plug, more FIFO and outstanding allocation can be made in favor of the working pipe.

After taking into account these restrictions, the configuration itself is the same as for the default high-resolution CSI2 camera, described in *Section 47.5.3*.

47.5.6 Double sensors

Two sensors are simultaneously and independently supported with the following restriction:

- One sensor must be low-resolution, so that it can use the DCMI (the other sensor uses the DCMIPP).
- Two input interfaces must be available: one sensor is CSI2, and the other parallel.

The configuration of the double sensors is the same as for the default low-resolution and default high-resolution sensors, described in previous sections.

47.6 Camera subsystem interrupts

Sections for each peripheral describe in details the provided interrupts.

47.7 Camera subsystem registers

All the registers are described in sections for each peripheral.

48 Digital camera interface (DCMI)

48.1 Introduction

The digital camera is a synchronous parallel interface able to receive a high-speed data flow from an external 8-, 10-, 12- or 14-bit CMOS camera module. It supports different data formats: YCbCr4:2:2/RGB565 progressive video and compressed data (JPEG).

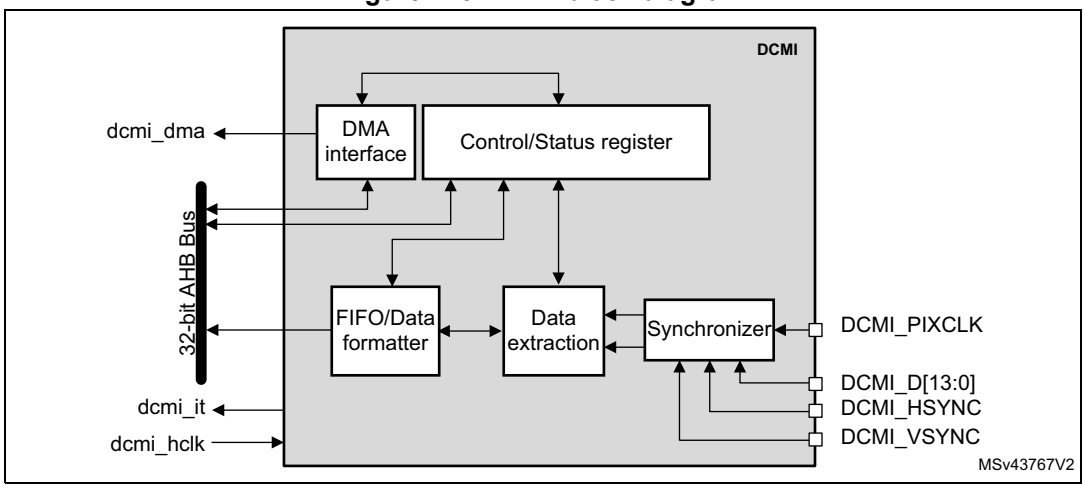
48.2 DCMI main features

- 8-, 10-, 12- or 14-bit parallel interface
- Embedded/external line and frame synchronization
- Continuous or snapshot mode
- Crop feature
- Supports the following data formats:
  - 8/10/12/14-bit progressive video: either monochrome or raw Bayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG

48.3 DCMI functional description

The digital camera interface is a synchronous parallel interface that can receive high-speed data flows. It consists of up to 14 data lines (DCMI_D[13:0]) and a pixel clock line (DCMI_PIXCLK). The pixel clock has a programmable polarity, so that data can be captured on either the rising or the falling edge of the pixel clock.

The data are packed into a 32-bit data register (DCMI_DR) and then transferred through a general-purpose DMA channel. The image buffer is managed by the DMA, not by the camera interface.



The data received from the camera can be organized in lines/frames (raw YUB/RGB/Bayer modes) or can be a sequence of JPEG images. To enable JPEG image reception, the JPEG bit (bit 3 of DCMI_CR register) must be set.

The data flow is synchronized either by hardware using the optional DCMI_HSYNC (horizontal synchronization) and DCMI_VSYNC (vertical synchronization) signals or by synchronization codes embedded in the data flow.

48.3.1 DCMI block diagram

Figure 415 shows the DCMI block diagram.

Figure 415. DCMI block diagram

48.3.2 DCMI pins and internal signals

The following table shows DCMI pins.

Table 433. DCMI input/output pins

Mode	Pin name	Signal type	Description
8 bits 10 bits 12 bits 14 bits	DCMI_D[7:0] DCMI_D[9:0] DCMI_D[11:0] DCMI_D[13:0]	Inputs	DCMI data
DCMI_PIXCLK		Input	Pixel clock
DCMI_HSYNC		Input	Horizontal synchronization / Data valid
DCMI_VSYNC		Input	Vertical synchronization

The following table shows DCMI internal signals.

Table 434. DCMI internal input/output signals

Internal signal name	Signal type	Description
dcmi_dma	Output	DCMI DMA request
dcmi_it	Output	DCMI interrupt request
dcmi_hclk	Input	DCMI interface clock

48.3.3 DCMI clocks

The digital camera interface uses two clock domains, DCMI_PIXCLK and HCLK. The signals generated with DCMI_PIXCLK are sampled on the rising edge of HCLK once they are stable. An enable signal is generated in the HCLK domain, to indicate that data coming from the camera are stable and can be sampled. The maximum DCMI_PIXCLK period must be higher than 2.5 HCLK periods.

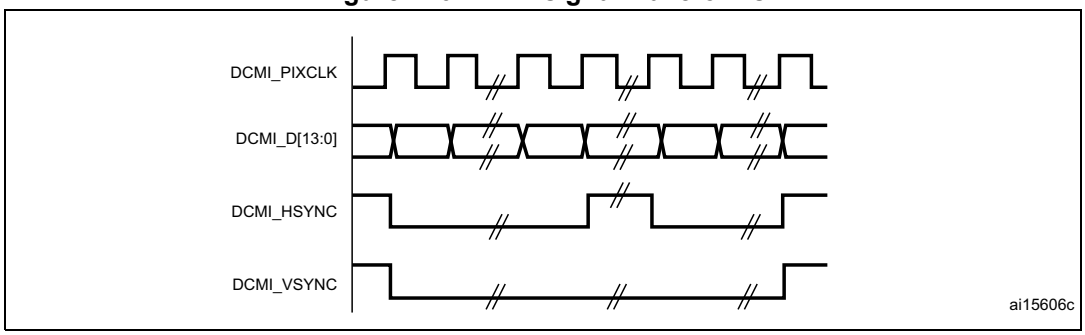
48.3.4 DCMI DMA interface

The DMA interface is active when the CAPTURE bit of the DCMI_CR register is set. A DMA request is generated each time the camera interface receives a complete 32-bit data block in its register.

48.3.5 DCMI physical interface

The interface is composed of 11/13/15/17 inputs. Only the Slave mode is supported.

The camera interface can capture 8-bit, 10-bit, 12-bit or 14-bit data depending on the EDM[1:0] bits of the DCMI_CR register. If less than 14 bits are used, the unused input pins must be connected to ground.



DCMI pins are shown in *Table 433*.

The data are synchronous with DCMI_PIXCLK and change on the rising/falling edge of the pixel clock depending on the polarity.

The DCMI_HSYNC signal indicates the start/end of a line.

The DCMI_VSYNC signal indicates the start/end of a frame

Figure 416. DCMI signal waveforms

1. The capture edge of DCMI_PIXCLK is the falling edge, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

8-bit data

When EDM[1:0] = 00 in DCMI_CR the interface captures 8 LSBs at its input (DCMI_D[7:0]) and stores them as 8-bit data. The DCMI_D[13:8] inputs are ignored. In this case, to capture a 32-bit word, the camera interface takes four pixel clock cycles.

The first captured data byte is placed in the LSB position in the 32-bit word and the 4th captured data byte is placed in the MSB position in the 32-bit word. The table below gives an example of the positioning of captured data bytes in two 32-bit words.

Table 435. Positioning of captured data bytes in 32-bit words (8-bit width)

Byte address	31:24	23:16	15:8	7:0
0	D_{n+3}[7:0]	D_{n+2}[7:0]	D_{n+1}[7:0]	D_n[7:0]
4	D_{n+7}[7:0]	D_{n+6}[7:0]	D_{n+5}[7:0]	D_{n+4}[7:0]

10-bit data

When EDM[1:0] = 01 in DCMI_CR, the camera interface captures 10-bit data at its input DCMI_D[9:0] and stores them as the 10 least significant bits of a 16-bit word. The remaining most significant bits of the DCMI_DR register (bits 11 to 15) are cleared to zero. So, in this case, a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

Table 436. Positioning of captured data bytes in 32-bit words (10-bit width)

Byte address	31:26	25:16	15:10	9:0
0	0	D_{n+1}[9:0]	0	D_n[9:0]
4	0	D_{n+3}[9:0]	0	D_{n+2}[9:0]

12-bit data

When EDM[1:0] = 10 in DCMI_CR, the camera interface captures the 12-bit data at its input DCMI_D[11:0] and stores them as the 12 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

Table 437. Positioning of captured data bytes in 32-bit words (12-bit width)

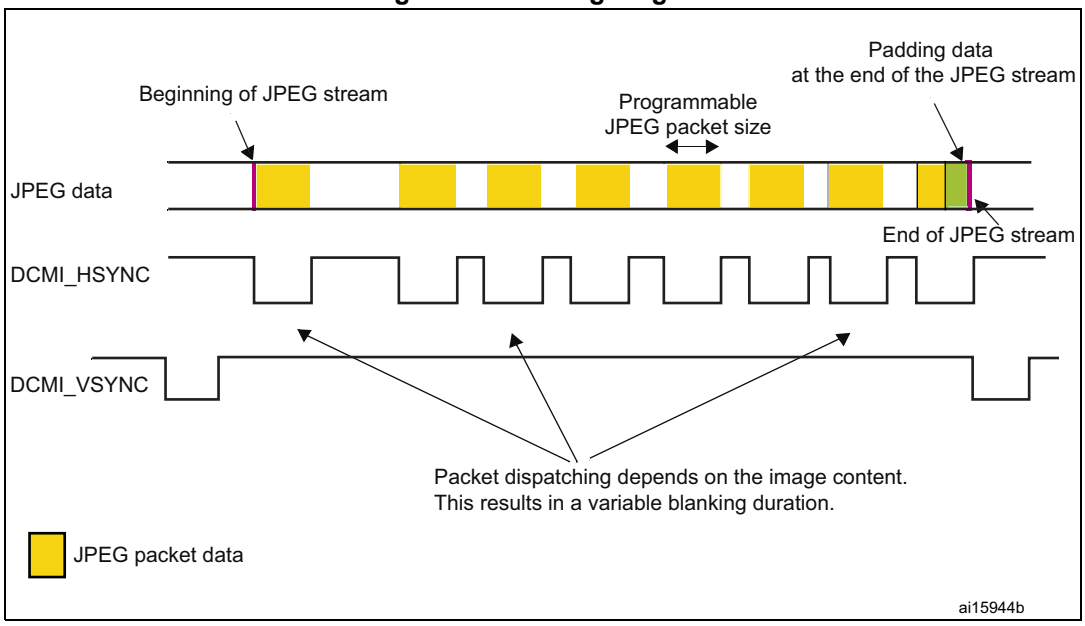
Byte address	31:28	27:16	15:12	11:0
0	0	D_{n+1}[11:0]	0	D_n[11:0]
4	0	D_{n+3}[11:0]	0	D_{n+2}[11:0]

14-bit data

When EDM[1:0] = 11 in DCMI_CR, the camera interface captures the 14-bit data at its input DCMI_D[13:0] and stores them as the 14 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

Table 438. Positioning of captured data bytes in 32-bit words (14-bit width)



Byte address	31:30	29:16	15:14	13:0
0	0	D_{n+1}[13:0]	0	D_n[13:0]
4	0	D_{n+3}[13:0]	0	D_{n+2}[13:0]

48.3.6 DCMI synchronization

The digital camera interface supports embedded or hardware (DCMI_HSYNC and DCMI_VSYNC) synchronization. When embedded synchronization is used, it is up to the digital camera module to make sure that the 0x00 and 0xFF values are used ONLY for synchronization (not in data). Embedded synchronization codes are supported only for the 8-bit parallel data interface width (that is, in the DCMI_CR register, the EDM[1:0] bits must be cleared).

For compressed data, the DCMI supports only the hardware synchronization mode. In this case, DCMI_VSYNC is used as a start/end of the image, and DCMI_HSYNC is used as a Data Valid signal. *Figure 417* shows the corresponding timing diagram.

Figure 417. Timing diagram

Hardware synchronization mode

In hardware synchronization mode, the two synchronization signals (DCMI_HSYNC/DCMI_VSYNC) are used.

Depending on the camera module/mode, data may be transmitted during horizontal/vertical synchronization periods. The DCMI_HSYNC/DCMI_VSYNC signals act like blanking signals since all the data received during DCMI_HSYNC/DCMI_VSYNC active periods are ignored.

In order to correctly transfer images into the DMA/RAM buffer, data transfer is synchronized with the DCMI_VSYNC signal. When the hardware synchronization mode is selected, and

capture is enabled (CAPTURE bit set in DCMI_CR), data transfer is synchronized with the deactivation of the DCMI_VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by DMA to successive buffers or the same/circular buffer. To allow the DMA management of successive frames, a VSIF (Vertical synchronization interrupt flag) is activated at the end of each frame.

Embedded data synchronization mode

In this synchronization mode, the data flow is synchronized using 32-bit codes embedded in the data flow. These codes use the 0x00/0xFF values that are *not* used in data anymore. There are 4 types of codes, all with a 0xFF0000XY format. The embedded synchronization codes are supported only in 8-bit parallel data width capture (in the DCMI_CR register, the EDM[1:0] bits must be cleared). For other data widths, this mode generates unpredictable results and must not be used.

Note: Camera modules can have 8 such codes (in interleaved mode). For this reason, the interleaved mode is not supported by the camera interface (otherwise, every other half-frame would be discarded).

- Mode 2

  Four embedded codes signal the following events
  - Frame start (FS)
  - Frame end (FE)
  - Line start (LS)
  - Line end (LE)

  The XY values in the 0xFF0000XY format of the four codes are programmable (see *Section 48.5.7: DCMI embedded synchronization code register (DCMI_ESCR)*).

  A 0xFF value programmed as a “frame end” means that all the unused codes are interpreted as valid frame end codes.

  In this mode, once the camera interface has been enabled, the frame capture starts after the first occurrence of the frame end (FE) code followed by a frame start (FS) code.
- Mode 1

  An alternative coding is the camera mode 1. This mode is ITU656 compatible.

  The codes signal another set of events:
  - SAV (active line) - line start
  - EAV (active line) - line end
  - SAV (blanking) - end of line during interframe blanking period
  - EAV (blanking) - end of line during interframe blanking period

This mode can be supported by programming the following codes:

- FS $\leq$ 0xFF
- FE ≤ 0xFF
- LS ≤ SAV (active)
- LE ≤ EAV (active)

An embedded unmask code is also implemented for frame/line start and frame/line end codes. Using it, it is possible to compare only the selected unmasked bits with the programmed code. A bit can therefore be selected to compare in the embedded code and

detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

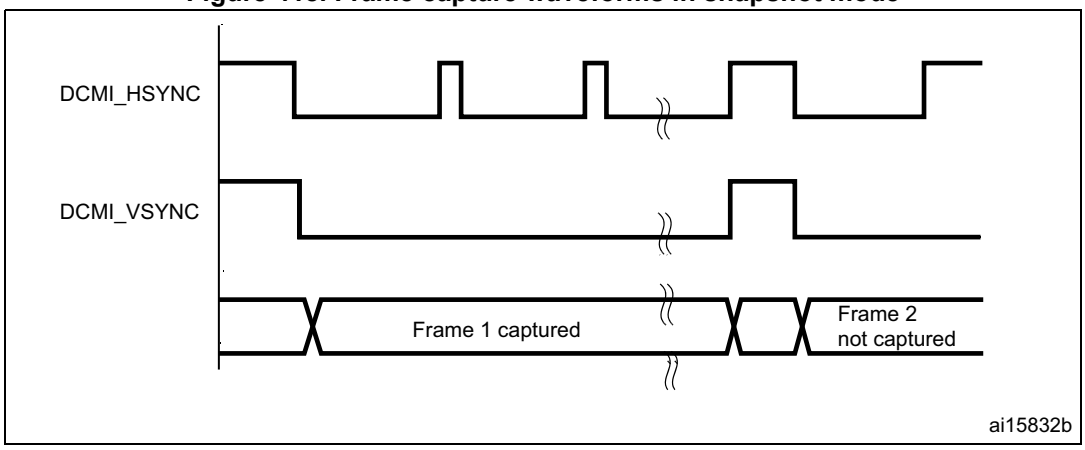
Example

FS = 0xA5

Unmask code for FS = 0x10

In this case the frame start code is embedded in the bit 4 of the frame start code.

48.3.7 DCMI capture modes



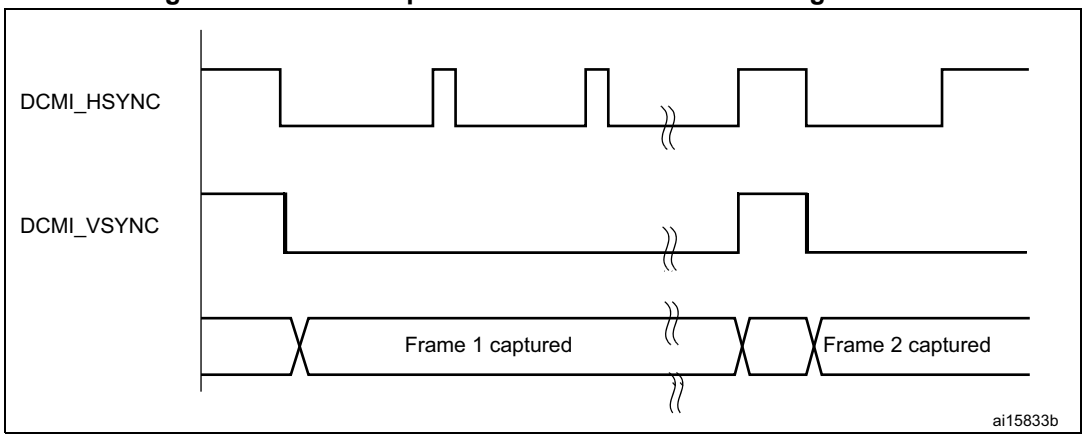
This interface supports two types of capture: snapshot (single frame) and continuous grab.

Snapshot mode (single frame)

In this mode, a single frame is captured (CM = 1 of the DCMI_CR register). After the CAPTURE bit is set in DCMI_CR, the interface waits for the detection of a start of frame before sampling the data. The camera interface is automatically disabled (CAPTURE bit cleared in DCMI_CR) after receiving the first complete frame. An interrupt is generated (IT_FRAME) if it is enabled.

In case of an overrun, the frame is lost and the CAPTURE bit is cleared.

Figure 418. Frame capture waveforms in snapshot mode



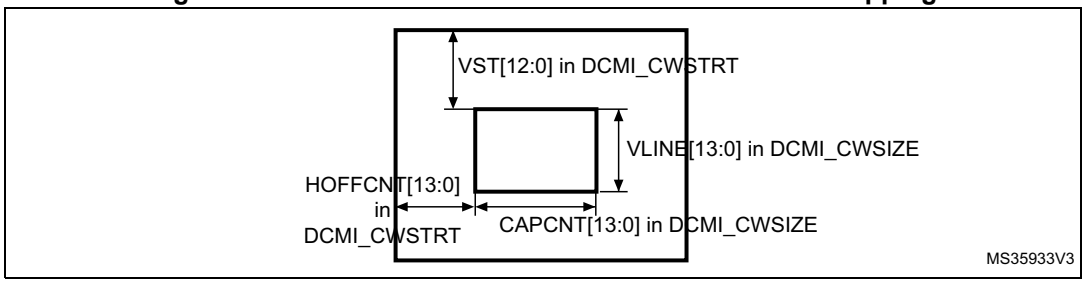
1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

Continuous grab mode

In this mode (CM bit = 0 in DCMI_CR), once the CAPTURE bit has been set in DCMI_CR, the grabbing process starts on the next DCMI_VSYNC or embedded frame start depending on the mode. The process continues until the CAPTURE bit is cleared in DCMI_CR. Once the CAPTURE bit has been cleared, the grabbing process continues until the end of the current frame.

Figure 419. Frame capture waveforms in continuous grab mode

1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.



In continuous grab mode, the FCRC[1:0] bits in DCMI_CR can be configured to grab all pictures, every second picture or one out of four pictures to decrease the frame capture rate.

Note: In the hardware synchronization mode (ESS = 0 in DCMI_CR), the IT_VSYNC interrupt is generated (if enabled) even when CAPTURE = 0 in DCMI_CR so, to reduce the frame capture rate even further, the IT_VSYNC interrupt can be used to count the number of frames between 2 captures in conjunction with the Snapshot mode. This is not allowed by embedded data synchronization mode.

48.3.8 DCMI crop feature

With the crop feature, the camera interface can select a rectangular window from the received image. The start (upper left corner) coordinates and size (horizontal dimension in number of pixel clocks and vertical dimension in number of lines) are specified using two 32-bit registers (DCMI_CWSTRT and DCMI_CWSIZE). The size of the window is specified in number of pixel clocks (horizontal dimension) and in number of lines (vertical dimension).

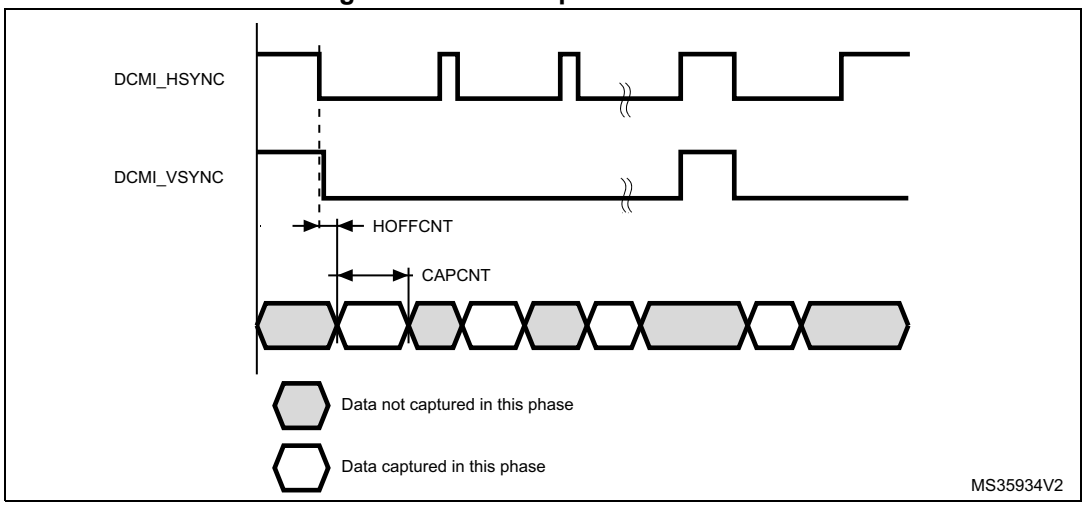


Figure 420. Coordinates and size of the window after cropping

These registers specify the coordinates of the starting point of the capture window as a line number (in the frame, starting from 0) and a number of pixel clocks (on the line, starting from 0), and the size of the window as a line number and a number of pixel clocks. The CAPCNT value can only be a multiple of 4 (two least significant bits are forced to 0) to allow the correct transfer of data through the DMA.

If the DCMI_VSYNC signal goes active before the number of lines is specified in the DCMI_CWSIZE register, then the capture stops and an IT_FRAME interrupt is generated when enabled.

Figure 421. Data capture waveforms

1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

48.3.9 DCMI JPEG format

To allow JPEG image reception, it is necessary to set the JPEG bit of the DCMI_CR register. JPEG images are not stored as lines and frames, so the DCMI_VSYNC signal is used to start the capture while DCMI_HSYNC serves as a data enable signal. The number of bytes in a line may not be a multiple of 4. This case must be carefully handled since a DMA request is generated each time a complete 32-bit word has been constructed from the captured data. When an end of frame is detected and the 32-bit word to be transferred has not been completely received, the remaining data are padded with zeros and a DMA request is generated.

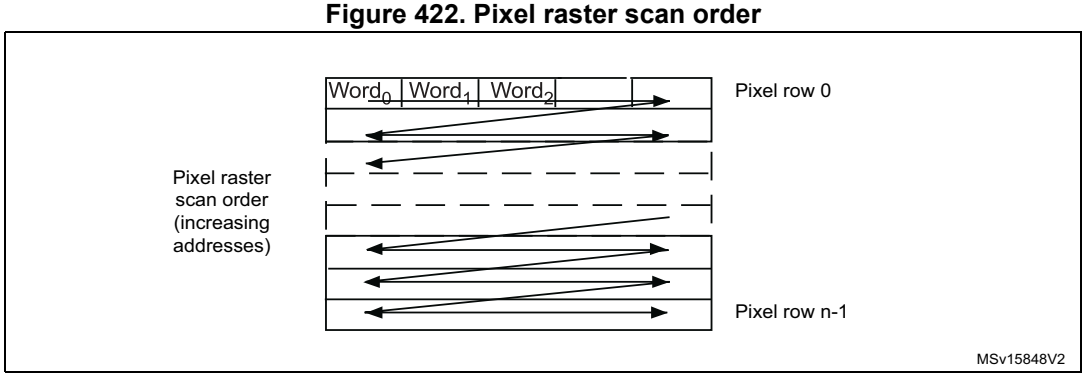
The crop feature and embedded synchronization codes cannot be used in JPEG format.

48.3.10 DCMI FIFO

A 8-word FIFO is implemented to manage data rate transfers on the AHB. The DCMI features a simple FIFO controller with a read pointer incremented each time the camera interface reads from the AHB, and a write pointer incremented each time the camera interface writes to the FIFO. There is no overrun protection to prevent the data from being overwritten if the AHB interface does not sustain the data transfer rate.

In case of overrun or errors in the synchronization signals, the FIFO is reset and the DCMI interface waits for a new start of frame.

48.3.11 DCMI data format description



Data formats

The following types of data are supported:

- 8/10/12/14-bit progressive video: either monochrome or raw Bayer format
- YCbCr 4:2:2 progressive video
- RGB565 progressive video. A pixel coded in 16 bits (5 bits for blue, 5 bits for red, 6 bits for green) takes two clock cycles to be transferred
- compressed data: JPEG

For monochrome, RGB and YCbCr, the frame buffer is stored in raster mode. 32-bit words are used. Only the little-endian format is supported.

Figure 422. Pixel raster scan order

Monochrome format

Characteristics:

- Raster format
- 8 bits per pixel

The table below shows how the data are stored.

Table 439. Data storage in monochrome progressive video format

Byte address	31:24	23:16	15:8	7:0
0	n + 3	n + 2	n + 1	n
4	n + 7	n + 6	n + 5	n + 4

RGB format

Characteristics:

- Raster format
- RGB
- Interleaved: one buffer: R, G and B interleaved (such as BRGBRGBRG)
- Optimized for display output

The RGB planar format is compatible with standard OS frame buffer display formats.

Only 16 BPP (bits per pixel): RGB565 (2 pixels per 32-bit word) is supported.

The 24 BPP (palletized format) and gray-scale formats are not supported. Pixels are stored in a raster scan order, that is from top to bottom for pixel rows, and from left to right within a pixel row. Pixel components are R (red), G (green) and B (blue). All components have the same spatial resolution (4:4:4 format). A frame is stored in a single part, with the components interleaved on a pixel basis.

The table below shows how the data are stored.

Table 440. Data storage in RGB progressive video format

Byte address	31:27	26:21	20:16	15:11	10:5	4:0
0	Red n + 1	Green n + 1	Blue n + 1	Red n	Green n	Blue n
4	Red n + 4	Green n + 3	Blue n + 3	Red n + 2	Green n + 2	Blue n + 2

YCbCr format

Characteristics:

- Raster format
- YCbCr 4:2:2
- Interleaved: one buffer: Y, Cb and Cr interleaved (such as CbYCrYCbYCr)

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). Each component is encoded in 8 bits. Luma and chroma are stored together (interleaved) as shown in the table below.

Table 441. Data storage in YCbCr progressive video format

Byte address	31:24	23:16	15:8	7:0
0	Y n + 1	Cr n	Y n	Cb n
4	Y n + 3	Cr n + 2	Y n + 2	Cb n + 2

YCbCr format - Y only

Characteristics:

- Raster format
- YCbCr 4:2:2
- The buffer only contains Y information - monochrome image

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). In this mode, the chroma information is dropped. Only the luma component of each pixel, encoded in 8 bits, is stored as shown in *Table 442*.

The result is a monochrome image having the same resolution as the original YCbCr data.

Table 442. Data storage in YCbCr progressive video format - Y extraction mode

Byte address	31:24	23:16	15:8	7:0
0	Y n + 3	Y n + 2	Y n + 1	Y n
4	Y n + 7	Y n + 6	Y n + 5	Y n + 4

Half resolution image extraction

This is a modification of the previous reception modes, being applicable to monochrome, RGB or Y extraction modes.

This mode is used to only store a half resolution image. It is selected through OELS and LSM control bits.

48.4 DCMI interrupts

Five interrupts are generated. All interrupts are maskable by software. The global interrupt (dcmi_it) is the OR of all the individual interrupts. The table below gives the list of all interrupts.

Table 443. DCMI interrupts

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exits Sleep mode	Exists Stop and Standby modes
dcmi_it	End of line	LINE_RIS	LINE_IE	Set LINE_ISC	Yes	No
	End of frame capture	FRAME_RIS	FRAME_IE	Set FRAME_ISC	Yes	No
	Overrun of data reception	OVR_RIS	OVR_IE	Set OVR_ISC	Yes	No
	Synchronization frame	VSYNC_RIS	VSYNC_IE	Set VSYNC_ISC	Yes	No
	Detection of an error in the embedded synchronization frame detection	ERR_RIS	ERR_IE	Set ERR_ISC	Yes	No

48.5 DCMI registers

Refer to *Section 1.2 on page 209* for list of abbreviations used in register descriptions. All DCMI registers must be accessed as 32-bit words, otherwise a bus error occurs.

48.5.1 DCMI control register (DCMI_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OELS	LSM	OEBS	BSM[1:0]	
											rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	ENABLE	Res.	Res.	EDM[1:0]		FCRC[1:0]		VSPOL	HSPOL	PCKPOL	ESS	JPEG	CROP	CM	CAPTURE
	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **OELS:** Odd/Even Line Select (Line Select Start)
This bit works in conjunction with the LSM field (LSM = 1).
0: Interface captures first line after the frame start, second one being dropped.
1: Interface captures second line from the frame start, first one being dropped.

Bit 19 **LSM:** Line Select mode
0: Interface captures all received lines.
1: Interface captures one line out of two.

Bit 18 **OEBS:** Odd/Even Byte Select (Byte Select Start)
This bit works in conjunction with BSM field (BSM ≠ 00).
0: Interface captures first data (byte or double byte) from the frame/line start, second one being dropped.
1: Interface captures second data (byte or double byte) from the frame/line start, first one being dropped.

Bits 17:16 **BSM[1:0]:** Byte Select mode
00: Interface captures all received data.
01: Interface captures every other byte from the received data.
10: Interface captures one byte out of four.
11: Interface captures two bytes out of four.
Note: This mode only works for EDM[1:0] = 00. For all other EDM values, this field must be programmed to the reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **ENABLE:** DCMI enable
0: DCMI disabled
1: DCMI enabled
Note: The DCMI configuration registers must be programmed correctly before enabling this bit.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 **EDM[1:0]:** Extended data mode
00: Interface captures 8-bit data on every pixel clock.
01: Interface captures 10-bit data on every pixel clock.
10: Interface captures 12-bit data on every pixel clock.
11: Interface captures 14-bit data on every pixel clock.

Bits 9:8 **FCRC[1:0]:** Frame capture rate control
These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode. They are ignored in snapshot mode.
00: All frames are captured.
01: Every alternate frame captured (50% bandwidth reduction)
10: One frame out of four captured (75% bandwidth reduction)
11: reserved

Bit 7 **VSPOL:** Vertical synchronization polarity
This bit indicates the level on the DCMI_VSYNC pin when the data are not valid on the parallel interface.
0: DCMI_VSYNC active low
1: DCMI_VSYNC active high

Bit 6 **HSPOL:** Horizontal synchronization polarity

This bit indicates the level on the DCMI_HSYNC pin when the data are not valid on the parallel interface.

0: DCMI_HSYNC active low

1: DCMI_HSYNC active high

Bit 5 **PCKPOL:** Pixel clock polarity

This bit configures the capture edge of the pixel clock.

0: Falling edge active

1: Rising edge active

Bit 4 **ESS:** Embedded synchronization select

0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the DCMI_HSYNC/DCMI_VSYNC signals.

1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.

Note: Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when the ESS bit is set.

This bit is disabled in JPEG mode.

Bit 3 **JPEG:** JPEG format

0: Uncompressed video format

1: This bit is used for JPEG data transfers. The DCMI_HSYNC signal is used as data enable. The crop and embedded synchronization features (ESS bit) cannot be used in this mode.

Bit 2 **CROP:** Crop feature

0: The full image is captured. In this case the total number of bytes in an image frame must be a multiple of four.

1: Only the data inside the window specified by the crop register is captured. If the size of the crop window exceeds the picture size, then only the picture size is captured.

Bit 1 **CM:** Capture mode

0: Continuous grab mode - The received data are transferred into the destination memory through the DMA. The buffer location and mode (linear or circular buffer) is controlled through the system DMA.

1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame and then transfers a single frame through the DMA. At the end of the frame, the CAPTURE bit is automatically reset.

Bit 0 **CAPTURE:** Capture enable

0: Capture disabled

1: Capture enabled

The camera interface waits for the first start of frame, then a DMA request is generated to transfer the received data into the destination memory.

In snapshot mode, the CAPTURE bit is automatically cleared at the end of the first frame received.

In continuous grab mode, if the software clears this bit while a capture is ongoing, the bit is effectively cleared after the frame end.

Note: The DMA controller and all DCMI configuration registers must be programmed correctly before enabling this bit.

48.5.2 DCMI status register (DCMI_SR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FNE	VSYNC	HSYNC
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FNE**: FIFO not empty

This bit gives the status of the FIFO.
1: FIFO contains valid data.
0: FIFO empty

Bit 1 **VSYNC**: Vertical synchronization

This bit gives the state of the DCMI_VSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
0: active frame
1: synchronization between frames
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.

Bit 0 **HSYNC**: Horizontal synchronization

This bit gives the state of the DCMI_HSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
0: active line
1: synchronization between lines
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.

48.5.3 DCMI raw interrupt status register (DCMI_RIS)

DCMI_RIS gives the raw interrupt status and is accessible in read only. When read, this register returns the status of the corresponding interrupt before masking with the DCMI_IER register value.

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LINE_RIS	VSYNC_RIS	ERR_RIS	OVR_RIS	FRAME_RIS
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE_RIS**: Line raw interrupt status

This bit gets set when the DCMI_HSYNC signal changes from the inactive state to the active state. It goes high even if the line is not valid.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMI_CR is set.

It is cleared by setting the LINE_ISC bit of the DCMI_ICR register.

Bit 3 **VSYNC_RIS**: DCMI_VSYNC raw interrupt status

This bit is set when the DCMI_VSYNC signal changes from the inactive state to the active state.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMI_CR.

It is cleared by setting the VSYNC_ISC bit of the DCMI_ICR register.

Bit 2 **ERR_RIS**: Synchronization error raw interrupt status

0: No synchronization error detected

1: Embedded synchronization characters are not received in the correct order.

This bit is valid only in the embedded synchronization mode. It is cleared by setting the ERR_ISC bit of the DCMI_ICR register.

Note: This bit is available only in embedded synchronization mode.

Bit 1 **OVR_RIS**: Overrun raw interrupt status

0: No data buffer overrun occurred

1: A data buffer overrun occurred and the data FIFO is corrupted.

The bit is cleared by setting the OVR_ISC bit of the DCMI_ICR register.

Bit 0 **FRAME_RIS**: Capture complete raw interrupt status

0: No new capture

1: A frame has been captured.

This bit is set when a frame or window has been captured.

In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (for example window cropped outside the frame).

The bit is cleared by setting the FRAME_ISC bit of the DCMI_ICR register.

48.5.4 DCMI interrupt enable register (DCMI_IER)

The DCMI_IER register is used to enable interrupts. When one of the DCMI_IER bits is set, the corresponding interrupt is enabled. This register is accessible in both read and write.

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LINE_IE	VSYNC_IE	ERR_IE	OVR_IE	FRAME_IE
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE_IE**: Line interrupt enable
0: No interrupt generation when the line is received
1: An Interrupt is generated when a line has been completely received.

Bit 3 **VSYNC_IE**: DCMI_VSYNC interrupt enable
0: No interrupt generation
1: An interrupt is generated on each DCMI_VSYNC transition from the inactive to the active state.
The active state of the DCMI_VSYNC signal is defined by the VSPOL bit.

Bit 2 **ERR_IE**: Synchronization error interrupt enable
0: No interrupt generation
1: An interrupt is generated if the embedded synchronization codes are not received in the correct order.
Note: This bit is available only in embedded synchronization mode.

Bit 1 **OVR_IE**: Overrun interrupt enable
0: No interrupt generation
1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received.

Bit 0 **FRAME_IE**: Capture complete interrupt enable
0: No interrupt generation
1: An interrupt is generated at the end of each received frame/crop window (in crop mode).

48.5.5 DCMI masked interrupt status register (DCMI_MIS)

This DCMI_MIS register is a read-only register. When read, it returns the current masked status value (depending on the value in DCMI_IER) of the corresponding interrupt. A bit in this register is set if the corresponding enable bit in DCMI_IER is set and the corresponding bit in DCMI_RIS is set.

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LINE_MIS	VSYNC_MIS	ERR_MIS	OVR_MIS	FRAME_MIS
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE_MIS**: Line masked interrupt status
This bit gives the status of the masked line interrupt.
0: No interrupt generation when the line is received
1: An Interrupt is generated when a line has been completely received and the LINE_IE bit is set in DCMI_IER.

Bit 3 **VSYNC_MIS**: VSYNC masked interrupt status

This bit gives the status of the masked VSYNC interrupt.

0: No interrupt is generated on DCMI_VSYNC transitions.

1: An interrupt is generated on each DCMI_VSYNC transition from the inactive to the active state and the VSYNC_IE bit is set in DCMI_IER.

The active state of the DCMI_VSYNC signal is defined by the VSPOL bit.

Bit 2 **ERR_MIS**: Synchronization error masked interrupt status

This bit gives the status of the masked synchronization error interrupt.

0: No interrupt is generated on a synchronization error.

1: An interrupt is generated if the embedded synchronization codes are not received in the correct order and the ERR_IE bit in DCMI_IER is set.

Note: This bit is available only in embedded synchronization mode.

Bit 1 **OVR_MIS**: Overrun masked interrupt status

This bit gives the status of the masked overflow interrupt.

0: No interrupt is generated on overrun.

1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received and the OVR_IE bit is set in DCMI_IER.

Bit 0 **FRAME_MIS**: Capture complete masked interrupt status

This bit gives the status of the masked capture complete interrupt

0: No interrupt is generated after a complete capture.

1: An interrupt is generated at the end of each received frame/crop window (in crop mode) and the FRAME_IE bit is set in DCMI_IER.

48.5.6 DCMI interrupt clear register (DCMI_ICR)

The DCMI_ICR register is write-only. Setting a bit of this register clears the corresponding flag in the DCMI_RIS and DCMI_MIS registers. Writing 0 has no effect.

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LINE_ISC	VSYNC_ISC	ERR_ISC	OVR_ISC	FRAME_ISC
											w	w	w	w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE_ISC**: line interrupt status clear

Setting this bit clears the LINE_RIS flag in the DCMI_RIS register.

Bit 3 **VSYNC_ISC**: Vertical Synchronization interrupt status clear

Setting this bit clears the VSYNC_RIS flag in the DCMI_RIS register.

Bit 2 **ERR_ISC**: Synchronization error interrupt status clear

Setting this bit clears the ERR_RIS flag in the DCMI_RIS register.

Note: This bit is available only in embedded synchronization mode.

Bit 1 **OVR_ISC**: Overrun interrupt status clear
Setting this bit clears the OVR_RIS flag in the DCMI_RIS register.

Bit 0 **FRAME_ISC**: Capture complete interrupt status clear
Setting this bit clears the FRAME_RIS flag in the DCMI_RIS register.

48.5.7 DCMI embedded synchronization code register (DCMI_ESCR)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEC[7:0]								LEC[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LSC[7:0]								FSC[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **FEC[7:0]**: Frame end delimiter code
This byte specifies the code of the frame end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FEC.
If FEC is programmed to 0xFF, all the unused codes (0xFF0000XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]**: Line end delimiter code
This byte specifies the code of the line end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]**: Line start delimiter code
This byte specifies the code of the line start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]**: Frame start delimiter code
This byte specifies the code of the frame start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FSC.
If FSC is programmed to 0xFF, no frame start delimiter is detected. But, the first occurrence of LSC after an FEC code is interpreted as a start of frame delimiter.

48.5.8 DCMI embedded synchronization unmask register (DCMI_ESUR)

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEU[7:0]								LEU[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LSU[7:0]								FSU[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **FEU[7:0]**: Frame end delimiter unmask

This byte specifies the mask to be applied to the code of the frame end delimiter.
0: The corresponding bit in the FEC byte in DCMI_ESCR is masked while comparing the frame end delimiter with the received data.
1: The corresponding bit in the FEC byte in DCMI_ESCR is compared while comparing the frame end delimiter with the received data.

Bits 23:16 **LEU[7:0]**: Line end delimiter unmask

This byte specifies the mask to be applied to the code of the line end delimiter.
0: The corresponding bit in the LEC byte in DCMI_ESCR is masked while comparing the line end delimiter with the received data.
1: The corresponding bit in the LEC byte in DCMI_ESCR is compared while comparing the line end delimiter with the received data.

Bits 15:8 **LSU[7:0]**: Line start delimiter unmask

This byte specifies the mask to be applied to the code of the line start delimiter.
0: The corresponding bit in the LSC byte in DCMI_ESCR is masked while comparing the line start delimiter with the received data.
1: The corresponding bit in the LSC byte in DCMI_ESCR is compared while comparing the line start delimiter with the received data.

Bits 7:0 **FSU[7:0]**: Frame start delimiter unmask

This byte specifies the mask to be applied to the code of the frame start delimiter.
0: The corresponding bit in the FSC byte in DCMI_ESCR is masked while comparing the frame start delimiter with the received data.
1: The corresponding bit in the FSC byte in DCMI_ESCR is compared while comparing the frame start delimiter with the received data.

48.5.9 DCMI crop window start (DCMI_CWSTRT)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	VST[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	HOFFCNT[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **VST[12:0]**: Vertical start line count

The image capture starts with this line number. Previous line data are ignored.
0x0000: line 1
0x0001: line 2
0x0002: line 3
....

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **HOFFCNT[13:0]**: Horizontal offset count

This value gives the number of pixel clocks to count before starting a capture.

48.5.10 DCMI crop window size (DCMI_CWSIZE)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	VLINE[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	CAPCNT[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:16 **VLINE[13:0]**: Vertical line count

This value gives the number of lines to be captured from the starting point.
0x0000: 1 line
0x0001: 2 lines
0x0002: 3 lines
....

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **CAPCNT[13:0]**: Capture count

This value gives the number of pixel clocks to be captured from the starting point on the same line. It value must corresponds to word-aligned data for different widths of parallel interfaces.
0x0000: 1 pixel
0x0001: 2 pixels
0x0002: 3 pixels
....

48.5.11 DCMI data register (DCMI_DR)

Address offset: 0x28

Reset value: 0x0000 0000

The digital camera Interface packages all the received data in 32-bit format before requesting a DMA transfer. A 8-word deep FIFO is available to leave enough time for DMA transfers and avoid DMA overrun conditions.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.4* for the register boundary addresses.

49 Digital camera interface pixel pipeline (DCMIPP)

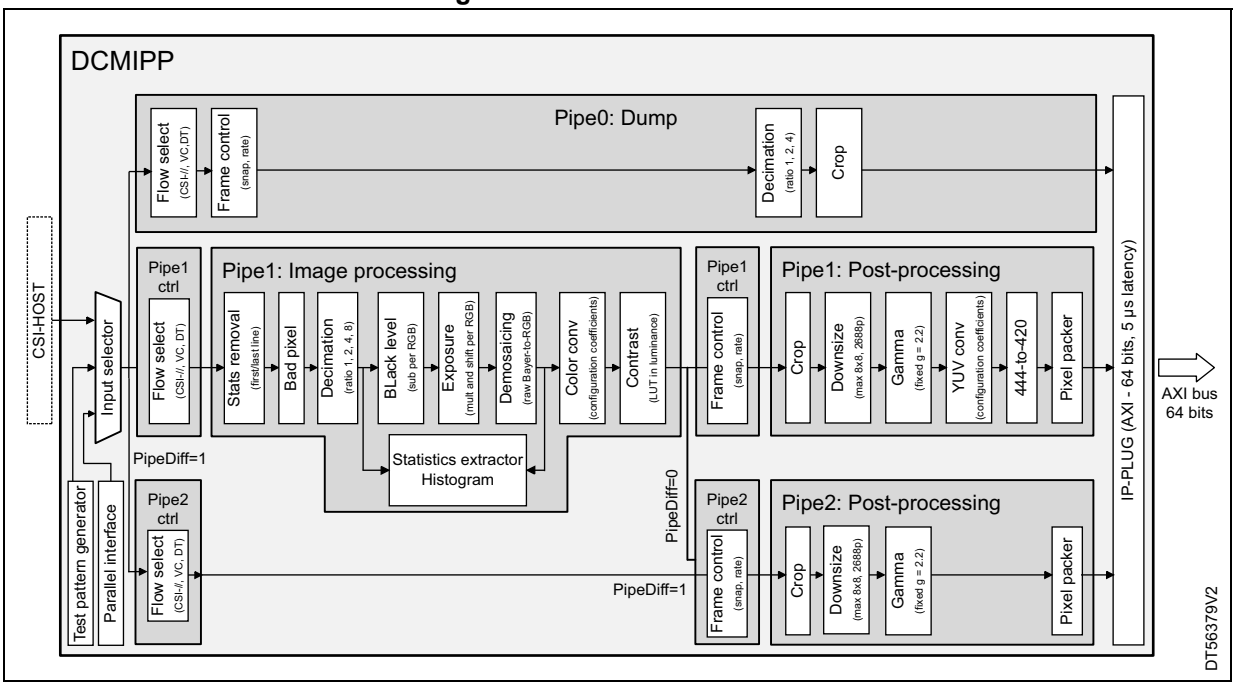
49.1 Introduction

The DCMIPP is the pixel pipeline section of a high-resolution camera subsystem: it gets pixels from a parallel or a CSI interface, and after some processing (such as decimation, cropping, downsize, color conversion, gamma correction, auto-exposure) dumps them to the memory.

DCMIPP supports multiple types of external sensors, among others:

- dumb sensors (without internal ISP), which output raw Bayer pixels
- smart sensors (with an internal ISP), which usually output RGB or YUV pixels
- smart sensors with internal compression, which output a bit-stream (such as JPEG, or H264)
- sensors with interlaced video, which output their odd and even fields sequentially

The DCMIPP input interface integrates a parallel interface (up to 16 bits at 120 MHz, with internal/external synchronization), and makes it possible to abut an external CSI-2 host (one to two data lanes, up to 2.5 Gbps/lane).



A first common part of the DCMIPP selects the input exclusively from the parallel or the CSI interfaces. Data go to dedicated pipeline(s) before they are sent to memory for further processing or display purposes.

Table 445. Available pipelines

ID	Function	Description
Pipe0	Dump pipe	Used to dump the received data as-is, without any processing (for example. without pixel extraction, no formatting), with an exception: it formats the CSI 10/12/14-bit raw Bayer components mapped unpacked into 16-bit memory words, to ease the job of a downstream application. 2D crop operation and basic decimation can be performed within this pipe.
Pipe1	Main pipe	Typically used for the main needs (such as video encode, software analysis, neural network), it allows to downsize the input, convert its color and dump to multiple pixel formats, including multi-planar ones. It can adapt the luminosity (gamma conversion) as well as auto-exposure and black level calibration based on its own embedded image processing functions, handling camera sensor without internal ISP. It can convert the raw Bayer to RGB (demosaicing). Pipe1 shares all the image processing functions with Pipe2.
Pipe2	Ancillary pipe	Typically used for ancillary needs (such as a permanent display), also allows to downsize the input and dump to several pixel formats, however restricted to coplanar ones (as specialized for display-like usage).

Figure 423 shows the DCMIPP main functions, namely the integrated parallel interface, the abutted CSI-2 host, the ISP functions in Pipe1 and shareable with Pipe2, the differentiated applicative post-processing pipelines with their crop, downsize, and pixel formatting.

Figure 423. DCMIPP overview

In the ISP processing, and therefore before the post-processing pipes (Pipe1 and Pipe2), the component dynamic is reduced to 8 bits per component. If the software intends to benefit of the wider dynamic, the input data must be dumped via Pipe0, which keeps the input pixel format (10/12/14 bpp) when storing them in memory.

Table 446. Glossary

Item	Definition
A	Alpha component, used to define transparency, opaque = 0xFF, for example ARGB.
3A (or AAA)	In ISP domain: acronym for AE-AF-AWB, algorithms automatically correcting pictures: – AE: automatic exposure control (adapts exposure or sensibility of sensor) – AF: automatic focus control (adapts the focus) – AWB: automatic white balance (adapts the color tones to have a white balance).
BPC	Bits per component (for example, RGB565 has five bits for the red component, hence 5 bpc)
BPP	Bits per pixel (for example, RGB565 has 16 bits per pixel, hence 16 bpp)
CSI	Camera serial interface, and its latest standard by MIPI®, the CSI-2 v1.3 (and v2.0)
DCMIPP_	Digital camera interface - Pixel pipeline
DT	Data type, used in the CSI-2 standard. The data type is a concept similar to the pixel format, but adds support for other data like the byte format.
Interlaced	Interlaced video: the field with odd lines is transmitted first, followed, after the last odd line, by the field with even lines. The two fields are thus consecutive but exclusive.
Interleaved	Interleaved packets, applies to CSI-2: two groups of packets transmitted by the sensor can be emitted mixed, as a packet granularity.

Table 446. Glossary (continued)

Item	Definition
ISP	Image signal processing: algorithms that retune the sensor output (through correction of pixels, demosaicing, lens-correction, light/contrast correction) to build a good quality picture.
NPU	Neural network processing engine (also known as NN, neural network).
Planar	Defines in how many sub-buffers a pixel buffer is split into: 1 (coplanar), 2 (semi-planar), 3 (full planar).
VC	Virtual channel, used in the CSI-2 standard, makes it possible to simultaneously transmit up to four parallel flows (in CSI-2 v1.3) or more (in CSI-2 v2.0).
YUV444	Pixel format, YUV color reference, all three components (Y, U, V) given per pixel.
YUV422	Pixel format, YUV color reference, chroma component (U, V) sub-sampled 1/2 in X

49.2 DCMIPP main features

- Parallel input interface:
  - Pixel rate: up to 16 bits in parallel, 100 Mpixel/s (typically 1080p30, maximum 2048x2048 on processing pipelines after decimation).
  - Pixel format: RGB565, RGB888, YUV422, raw Bayer/Mono 8/10/12/14, and ByteStream (JPEG)
- CSI-2 host input interface:
  - Pixel rate: 32 bits in parallel at 200 Mpixel/s (typically 5 MPixel x30), supports MIPI® CSI-2 v1.3
  - Pixel format: all MIPI CSI-2 v1.3, among others RGB565, RGB888, YUV422, raw Bayer (see *Table 452*)
  - Abutted CSI-2 host IP: 1-to-2 DL at up to 2.5 Gbps/lane
  - Features: Interleaved packets, four virtual channels
- Test pattern generator:
  - Color bar or square pattern, up to 16k x 16k, YUV, raw, or Mono
- Pipeline maximum resolution:
  - Dimensioned for 5 Mpixel (typically 2560 x 2048 or 2688 x 1944) before decimation
  - Maximum pipe resolution: 4094 x 4094
  - Maximum demosaicing or downsize or YUV420 width: 2688 pixels
- Pipe pixel rate: 200 Mpixel/s peak (150 Mpixel/s average + blanking)
- Maximum frame per second (fps): typical examples are defined with 30 fps, it is possible to reach higher rates (for example 120 fps) by decreasing image resolution to guarantee the maximum pixel rate constraints.
- Flow selection and frame control:
  - CSI-2 interleaved packets supported (with some restrictions)
  - Capture mode in Continuous vs. Snapshot mode
- Byte-to-pixel conversion:
  - Enables the above flexible input pixel formats to be extracted and fed to pipes
  - Non-extracted pixel formats can still be dumped via Pipe0, to allow an ad-hoc software extraction
- Statistic removal:
  - To remove unused metadata (like statistics) from received pictures
- Bad pixel removal (automatic detection and correction of bad pixels from sensor array)
- Decimation of one pixel every 1/2/4/8:
  - Decimation to fit the demosaicing (maximum 2688 pixel width)
  - Raw Bayer format support, via a decimation of components (2 by 2)
- Integrated image processing block, which makes possible to connect very low cost camera modules without any embedded ISP
  - Black level calibration
  - Statistics extraction
    - > To extract average R, G, B, L values (for auto exposure and white balance)
    - > To sort any R, G, B, L value into 12 dynamic bins (for contrast enhancement)

  - Exposure control (amplifies the exposure up to 256x)
    > To smoothly adapt to dark exposures
  - Raw Bayer to RGB conversion (demosaicing)
    > Mid quality conversion for display and software analysis purposes (high quality conversion can be done in software upon trigger, for still-image only)
    > Algorithm with a 4 x 3 heuristic analysis matrix
  - Color conversion to adapt to the sensor and tune the illumination
    > Configurable coefficients, to map any linear tuning
  - Contrast enhancement
    > Non-linear luminance tuning, linearized across eight luminance segments.
- Decimation on Pipe0 (dump pipe)
  - Pure sub-sampling, ratio 1 vs. 1, 2, 4 in X and ratio 1 vs. 1, 2 in Y (no X if CSI source)
- Parallel pipelines for parallel applications:
  - Pipe0 (for data dump) for a direct dump without processing
  - Pipe1 (for main usage) with downsize, ColorConv, decimation, multi-planar
  - Pipe2 (for ancillary usage) with downsize, decimation, coplanar
- Downsize
  - Decimation, optional pre-processing, sub-sampling ratio 1 vs. 1, 2, 4, 8 in X and Y
  - Box-filtering, with any decimal ratio up to 8x8, on Pipe1 and Pipe2
- Gamma conversion for display:
  - Non-linear transform, with seven interpolated segments, with static coefficient for G = 2.2
- Color conversion 2 for RGB to YUV conversion:
  - to/from YUV: 12 coefficients (BT.601, 709, any), with optional range ext/clamp
- Output pixel format:
  - Pipe0: any data as-is, Y/Rb: 8/10/12/14 statistics, bit streams
  - Pipe2: 888, 565, 422-1, Y8, ARGB and RGBA (coplanar only)
  - Pipe1: adds 422-2, 420-2, 420-3 (multi-planar possible) to Pipe2 formats
- AXI master:
  - Output FIFOs to drain pixel/data to the memory (linked to the memory latency) from the pipe(s)
  - The unique AXI-Master interface implements one client per pipe, with semi- or multi-planar pipes using, respectively, two or three clients
- Overrun detection:
  - Notification in case of frame impacted by pixel congestion (no impact on the following frame if the congestion cause is solved)

49.3 DCMIPP functional description

49.3.1 DCMIPP block diagram

The block diagram of the DCMIPP is shown in *Figure 424*.

Figure 424. DCMIPP block diagram

49.3.2 DCMIPP pads and internal signals

Table 447. DCMIPP input/output pads

Pin name	Signal type	Description
DCMIPP_Dn (n = 0 to 15)	Input	Bit n of the parallel data bus coming from the camera sensor
DCMIPP_PIXCLK	Input	Pixel clock sent by the master (parallel camera sensor module)
DCMIPP_VSYNC	Input	VSYNC signal (vertical synchronization) coming from the camera sensor
DCMIPP_HSYNC	Input	HSYNC signal (horizontal synchronization) coming from the camera sensor

Table 448. DCMIPP input/output pins

Internal signal name	Signal type	Description
dcmipp_pclk	Input	DCMIPP APB clock (APB bus)
dcmipp_aclk	Input	DCMIPP AXI clock (AXI bus)
dcmipp_ker_ck	Input	Interface from the CSI2 host
dcmipp_it_global	Output	DCMIPP interrupts (refer to *Table 481* for the full list of interrupt sources)
dcmipp_p0hsync_evt	Output	Pipe0 Hsync event
dcmipp_p0vsync_evt		Pipe0 Vsync event
dcmipp_p0frame_evt		Pipe0 frame end event
dcmipp_p0line_evt		Pipe0 line event
dcmipp_p1hsync_evt	Output	Pipe1 Hsync event
dcmipp_p1vsync_evt		Pipe1 Vsync event
dcmipp_p1frame_evt		Pipe1 frame end event
dcmipp_p1ine_evt		Pipe1 line event
dcmipp_p2hsync_evt	Output	Pipe2 Hsync event
dcmipp_p2vsync_evt		Pipe2 Vsync event
dcmipp_p2frame_evt		Pipe2 frame end event
dcmipp_p2line_evt		Pipe2 line event

49.3.3 DCMIPP reset and clocks

Table 449. DCMIPP clocks

Domain	Clock	Maximum frequency	Comments
Parallel	dcmipp_pxclk	120 MHz	Up to 2x 120 MB/s in 16-bit mode
Pipeline	dcmipp_ker_ck	333 MHz	Up to 333 Mpixels/s (minus the blanking)
AXI bus	dcmipp_aclk	400 MHz	SoC AXI frequency
APB bus	dcmipp_pclk	200 MHz	SoC APB frequency

Table 450. DCMIPP resets

Domain	Reset type	Comments
Parallel + Pipeline	Asynchronous	Resynchronized internally on dcmipp_pxclk/dcmipp_ker_ck
AXI bus	Synchronous	Resets directly the dcmipp_aclk domain
APB bus	Synchronous	Resets directly the dcmipp_pclk domain

Clocks and pixel rate limitations

This paragraph lists the DCMIPP limitations and bottlenecks:

- The target is to sustain an average pixel rate (PixRateAvg):
  - A 5 Mpixel sensor at 30 fps requires 150 Mpixel/s (CSI-2 interface)
  - Higher resolution sensors can be supported, but with lower FPS (for example 10 Mpixels at 15 fps)
- Vertical and horizontal blanking:
  - The full system (sensor, interface, pipe, AXI) embeds limited capacity FIFOs. The idle times that the sensor inserts during its blanking periods impact all the downstream elements, including interface, pipe, and AXI. A pixel rate (PixRatePeak) higher than average must be used. The idle time due to the blanking can reach 33% of the frame duration, sometimes more (check sensor specification).
  - PixRatePeak = 1.33 * PixRateAvg = 200 Mpixel/s in our example.
- Parallel interface clock (dcmipp_pxclk):
  - On the parallel interface, pixels are received sequentially, in one, two or three cycles. The maximum implemented clock (120 MHz) constrains the peak pixel rate, depending on the ratio of cycles per pixel.
  - PixRatePeak ≤ dcmipp_pxclk / (1, 2 or 3) = 120 / (1, 2 or 3)
  - Clock frequency:
    - > dcmipp_pxclk ≤ dcmipp_ker_ck (due to resync interface between them)
    - > dcmipp_pxclk ≤ dcmipp_aclk
  - Consequences: see *Table 451*.

Table 451. Parallel interface maximum resolution (80 MHz)

Pixel		Transmission on the interface			Resolution (30 fps), including blanking	
Format	Width (bpp)	Width	Cycles/pixel	Pixel rate	Mpixel/frame	Example
Mono/raw	8	8	1	80	2.15	1080 p
	14	14	1	80	2.15	1080 p
RGB565	16	8	2	40	1.08	720 p
		16	1	80	2.15	1080 p
RGB888	24	8	3	27	0.72	qHD
		12	2	40	1.08	720 p
YUV422	16	16	1	80	2.15	1080 p
		16	2	40	1.08	720 p
YUV444	24	12	2	40	1.08	720 p
		16	2	40	1.08	720 p

  - Clock setting: dcmipp_pxclk ≥ PixRatePeak * Ratio(1,2,3)

- Pipe clock dcmipp_ker_ck (when using the CSI-2 host interface)
  - CSI-2 PHY provides data bit at the clk_bit rate, on DL parallel data lanes.
  - Rationale: internally, the CSI-2 host interface packs the serial stream on 32-bit words, resynchronized on the pipe clock (dcmipp_ker_ck).
  - Clock setting: dcmipp_ker_ck ≥ clk_bit * DL / 32 bpp = 156.25 MHz.
  - Rationale 2: The pixel pipe processes 1 pixel/clk, so that dcmipp_ker_ck must be higher than the wanted PixRatePeak.
  - Clock setting: dcmipp_ker_ck ≥ PixRatePeak.
  - For small footprint pixels (like Raw8), the DCMIPP is limited by its maximum dcmipp_ker_clk, and can be unable to handle the maximum CSI pixel rate (clk_bit * DL / 8 bpp for Raw8).
- Downsize:
  - The line buffer of the vertical downsize operator is limited to a width of 2688 pixels after the horizontal downsize operation, limiting the resolution, when the downsizing is active, to 2688 x 1944 (1944 is the usual maximum height with a width of 2688), thus 5.1 Mpixel.
  - If a camera resolution higher than 5 Mpixel is targeted, a basic decimation has to be performed to decrease the resolution to a maximum of 5 Mpixel before processing the downsizing operation.
- AXI clock:
  - The pixels must be reclocked from the processing to the AXI domain, resulting in
    > dcmipp_ker_ck ≤ dcmipp_aclk
  - The AXI bus must drain the running pipelines. The maximum footprint of pixel (or data) pipes is 32 bpp (Pipe1 and Pipe2) and 16 bpp (Pipe0). AXI is on 64 bits, with an efficiency of 8 / 9 for the typical 64-byte burst.
  - dcmipp_aclk ≥ dcmipp_ker_ck * (32 bpp + 32 bpp + 16 bpp) / (64bit / bus) * 9 / 8 (efficiency) = dcmipp_ker_ck * 1.4.

49.3.4 DCMIPP maximum resolution

The limitations related to the maximum resolution supported by the DCMIPP are:

- Maximum width and height across pipes: 4094 x 4094 pixels
  - Registers and counters are limited to 12 bits
- Maximum performance: 333 Mpixel/s on each pipe
  - Larger pixel rate can be used, but with less pipe active or lower memory latency
  - Maximum pixel rate on each pipe must remain below the pixel clock
- Maximum width on demosaicing: 2688 components wide
  - limitation related to the Line-buffer size
- Maximum width after downsize: 2688 pixels
  - limitation related to the Line-buffer size
- Maximum width for conversion to YUV420: 2688 pixels
  - limitation related to the Line-buffer size
- Max line stride: 32767 bytes
  - Registers and counters, to handle 4094 pixels x 32 bits x 2 (provision for interleaving)

49.3.5 DCMIPP minimum requirements for frame structure

DCMIPP imposes the following minimum requirements for the frame architecture:

Blanking phase

- Dump pipe
  - The minimal duration of the blanking between two frames must be an equivalent of 666 datawords of 32 bits
- Pixel pipe
  - Vertical blanking: minimum is 5 lines. If the line is less than 12 pixels, a minimum of 24 pixels equivalent for the vertical blanking parameter is requested
  - Horizontal blanking: a minimum duration of 12 pixels is required between two lines

Data image area

- Vertical image area: minimum one line (two lines if raw Bayer conversion is active)
- Horizontal image area: minimum two pixels
- The minimum total frame size is fixed to 36 pixels

49.3.6 Description of DCMIPP pixel format support

Table 452 lists the supported pixel formats in the input interfaces (parallel, CSI), as input to the pixel Pipe1 and Pipe2, and in the three output pipes.

Table 452. Supported pixel formats

Index (1)	Pixel format	BPP	Parallel input (clk/pix)(2)	CSI input	Pipe0 output (dump)	Pipe1 and Pipe2 input	Pipe1 output (main)	Pipe2 output (ancillary)
-	Bytes (CSI: long packets and user)	8	-	Y	Y	-	-	-
13(3)	Byte stream (JPEG, compressed video)	8	Y, 1	-	Y	-	-	-
14(4)	Other data	8 to 16(4)	Y, 1	-	Y	-	-	-
5	Raw6	6	(5)	Y(6)	Y(6)	-	-	-
5	Raw7	7	(5)	Y(6)	Y(6)	-	-	-
5	Raw8	8	Y, 1	Y	Y	Y	Y	Y
6	Raw10	10	Y, 1	Y	To 16 bpc	To 8 bpc	-	-
7	Raw12	12	Y, 1	Y	To 16 bpc	To 8 bpc	-	-
8	Raw14	14	Y, 1	Y	To 16 bpc	To 8 bpc	-	-
9	Mono8	8	Y, 1	-	Y	Y	Y	Y
10	Mono10	10	Y, 1	-	To 16 bpc	To 8 bpc	-	-
11	Mono12	12	Y, 1	-	To 16 bpc	To 8 bpc	-	-
12	Mono14	14	Y, 1	-	To 16 bpc	To 8 bpc	-	-
2	RGB444	12	(5)	Y	(5)	To 8 bpc	-	-
2	RGB555	15	(5)	Y	(5)	To 8 bpc	-	-

Table 452. Supported pixel formats (continued)

Index (1)	Pixel format	BPP	Parallel input (clk/pix)(2)	CSI input	Pipe0 output (dump)	Pipe1 and Pipe2 input	Pipe1 output (main)	Pipe2 output (ancillary)
2	RGB565	16	Y, 1, 2	Y	Y	To 8 bpc	Y	Y
3	RGB666	18	(5)	Y	(5)	To 8 bpc	-	-
4	RGB888 / YUV444(6)	24	Y, 2, 3	Y	Y	Y	Y	Y
-	xRGB888 / xYUV444(6)	32	-	-	Y	-	Y	Y
-	RGBx888 / YUVx444(6)	32	-	-	Y	-	Y	Y
1	YUV422-1 (YUYV)	16	Y, 1, 2	Y	Y	Y	Y	Y
-	YUV422-2	16	-	Y(6)	Y(6)	-	Y	-
-	YUV420-2 (NV21/NV12)	12	-	Y(6)	Y(6)	-	Y	-
-	YUV420-3 (YV12)	12	-	Y(6)	Y(6)	-	Y	-
-	YUV422 10 bpc	20	-	Y(6)	Y(6)	-	-	-
-	YUV420 10 bpc	15	-	Y(6)	Y(6)	-	-	-
-	Any other CSI-2	Any	-	Y(6)	Y(6)	-	-	-

1. Index is used to link the input pixel format to the DCMIPP_PRCR register. The index has a meaning only for camera connected with the parallel interface
2. Pixel formats on 16 bpp (like RGB565 or YUV422-1) can be received either on an 8-bit interface (using 2 cycles), or on a 16-bit input interface (using one cycle). Pixel formats on 24 bpp (like RGB888) can be received either on an 8-bit interface (using three cycles), or on a 12-bit input interface (using two cycles).
3. In Byte stream mode, the bytes are dumped consecutively with only a 32-bit padding (if needed) at the end of the frame (or JPEG stream). There is no 32-bit padding operation inside the stream until the VSYNC deassertion (end of frame, or end of JPEG stream).
4. If the data format is different from those in this table, user can choose “others” configuration into bit field FORMAT in the DCMIPP_PRCR register, using bit-field EDM to select how many data bits must be captured in one pixel clock. It is possible to capture two 8-bit data mapped on 16-bit parallel input data in a single cycle (for instance FORMAT = Others, EDM = 100, i.e. 16-bit capture on each pixel clock). Data are 32-bit padded at the end of a line to have a complete line aligned on 32-bit width.
5. On the parallel interface input, some sensor pixel formats are supported by the DCMIPP, by selecting a wider pixel format in DCMIPP, by mapping the sensor wires onto the MSB of the DCMIPP interface. On the input missing pins, it is recommended to replicate the sensor MSB pins onto the missing input LSB pins. This helps achieving full dynamic on the extended pixel format. The work-around can be applied on the following formats (sensor output on left, mapping on DCMIPP format on right):
   - Raw6: Raw8 with 1-cycle input, processed as a 8 bpp
   - Raw7: Raw8 with 1-cycle input, processed as a 8 bpp
   - RGB444: RGB565 with 1-cycle input, processed as a 16 bpp
   - RGB555: RGB565 with 1-cycle input, processed as a 16 bpp
   - RGB666: RGB888 with 3-cycle input, processed as a 24 bpp
6. The same bit mapping is used for the input RGB888 and YUV444, the input xRGB and xYUV, and similarly for the outputs. The difference between RGB and YUV is the color reference, set in the color conversion that occurs after the input or before the output.

49.4 DCMIPP input and flow control

This section describes the functional elements of the DCMIPP. For each, it details the features, the software configuration, and provides a software configuration example (when needed).

49.4.1 Parallel input interface

The parallel interface is a flexible pixel interface that clocks in a bus of 8- to 16-bit in parallel, with an externally provided clock, and adds vertical and horizontal synchronization, provided either with specific pins (external sync) or flagged via specific data (as in CCIR601).

Interface (all inputs)

- Clk: clock up to 120 MHz, internally named dcmipp_pxclk
- Data: 16 IO pins, up to 120 Mbps/pin, 8- to 16-bit, pixels potentially serialized
- HSync, VSync, but no enable (EN)

Features

- Horizontal and vertical synchronization:
  - External, via the HSync and VSync pins.
  - Internal, via the CCIR601 flagging.

  Data provided during the horizontal or vertical blanking cannot be captured.
- Input pixel format (see *Section 49.3.6*)
  - Binary stream like JPG
  - Single cycle data:
    - Raw Bayer and monochrome: 8/10/12/14 bits in parallel
    - YUV422, RGB565:16 bpp on 16 bits in parallel
  - Double-cycle data:
    - YUV422, RGB565:16 bpp on 8 bits in parallel
    - RGB888/YUV444: 24 bpp on 12 bits in parallel
  - Triple-cycle data:
    - RGB888/YUV444: 24 bpp on 8 bits in parallel
- Flexible input:
  - MSB-vs-LSB bits can be swapped to ease PCB placement
  - Cycle0-vs-Cycle1 can be swapped (for 2-cycle long pixels).
  - Red-vs-blue components can be swapped (for RGB, or U-vs-V for YUV), this last swap operates only on the pixel pipes and not the dump pipe.

Hardware synchronization mode

In this mode two synchronization signals (DCMIPP_HSYNC and DCMIPP_VSYNC) are used.

Depending on the camera module/mode, data can be transmitted during horizontal/vertical synchronization periods. DCMIPP_HSYNC/DCMIPP_VSYNC act as blanking signals, as all data received during DCMIPP_HSYNC/DCMIPP_VSYNC active periods are ignored.

To correctly transfer images in the RAM buffer, data transfer is synchronized with the DCMIPP_HSYNC/DCMIPP_VSYNC signals. When the hardware synchronization mode is selected, and capture is enabled (CPTREQ bit set in DCMIPP_PxFCTCR), data transfer is synchronized with the deassertion of the DCMIPP_VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by the IP-Plug to successive buffers or the same/circular buffer.

Embedded data synchronization mode

In this synchronization mode, the data flow is synchronized using embedded 32-bit codes, using the 0x00/0xFF values not used in data anymore.There are four types of codes, all with 0xFF00 00XY format. The embedded synchronization codes are supported only in 8-bit parallel data capture (in the DCMIPP_PRCR register, the EDM[2:0] bits must be programmed to “000”). For other data widths, this mode generates unpredictable results.

Note: Camera modules generate up to eight synchronization codes when in interleaved mode, while the DCMIPP reacts to one single code. As a consequence, an interleaved flow with an embedded synchronization has one every other frame discarded as not detected.

Mode 2

Four embedded codes signal the following events:

- Frame start (FS)
- Frame end (FE)
- Line start (LS)
- Line end (LE)

The XY values in the 0xFF00 00XY format of these codes are programmable (see *Section 49.14.9*).

A 0xFF value programmed as a frame end means that all the unused codes are interpreted as valid frame end codes.

In this mode, once the camera interface has been enabled, the frame capture starts after the first occurrence of the frame end (FE) code followed by a frame start (FS) code.

Mode 1

An alternative coding is the camera mode 1. This mode is ITU656 compatible.

The codes signal another set of events:

- SAV (active line) - Line start
- EAV (active line) - Line end
- SAV (blanking) - Start of line during interframe blanking period
- EAV (blanking) - End of line during interframe blanking period

This mode can be supported by programming the following codes:

- FS ≤ 0xFF
- FE ≤ 0xFF
- LS ≤ SAV (active)
- LE ≤ EAV (active)

An embedded unmask code is also implemented for frame/line start and frame/line end codes. Using it, it is possible to compare only the selected unmasked bits with the programmed code. User can therefore select a bit to compare in the embedded code and detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

Example:

- FS = 0xA5
- Unmask code for FS = 0x10

In this case the frame start code is embedded in bit 4 of the frame start code.

Note: FEC sequence must be sent before the transfer of the first frame, otherwise other codes are not decoded and the first frame can be lost after the DCMIPP has been enabled. After the first FE sequence, the following frame is captured based on FS sequence.

Error conditions

Error conditions can be detected when using the embedding synchronization data modes. Flags PRERRF in DCMIPP_CMSR2 and ERRF in DCMIPP_PRSR are used for this function. An interruption can be triggered based on error detection if bit PRERRIE in DCMIPP_CMIER is set for the global interrupt (or bit ERRIE in DCMIPP_PRIER for a local interrupt line).

For instance, such kind of wrong sequences or values generate an error:

- FF 00 00 XY sequence detected with XY value different from the one set for FS/LS/FE/LE
- LS = 0xFF or LE = 0xFF
- If an LS or FS sequence follows an LS sequence

Software configuration

Table 453. DCMIPP_PRCR bit function

Bit ID	Function	Comments
ENABLE	Enables the parallel interface	Low-power mode when disabled.
PCKPOL	Defines clock polarity	– 0: Falling edge – 1: Rising edge
ESS	Defines if VSync and HSync synchronizations are provided by sideband (specific hardware IO) or by in-band (specific embedded codes) signals	– 0: Hardware (external) synchronization: using DCMIPP_HSYNC and DCMIPP_VSYNC pins. – 1: Embedded (internal) synchronization: using codes FSC, FEC, LSC, LEC and masks in registers DCMIPP_PRESCR and DCMIPP_PRESURy.
VSPOL, HSPOL	Defines the polarity of the IO DCMIPP_VSYNC and DCMIPP_HSYNC used for, respectively, the vertical and horizontal synchronization	– 0: Active low – 1: Active high
FORMAT	Defines the pixel format used on the IO DCMIPP_Dx	From 0 to 15
EDM	Defines the amount of valid bits received per cycle	8/10/12/14/16 bits
	The duration of a pixel is extracted by the bit-per-pixel (given by FORMAT) and bit-per-cycle (given by EDM) ratios	1, 2 or 3 cycles
SWAPBITS	Swaps the 16 bits of the parallel interface	15:0 becomes 0:15
SWAPCYCLES	Swaps, when a pixel is received in two cycles, the data from the first cycle with the data from the second cycle	Software must not activate it when a pixel is received in one or three cycles.
SWAPRB(1)	Swaps red (or V = Cr) with blue (or U = Cb) components	Operates only on pixel pipe, not on dump pipe.

1. DCMIPP_CMCR register.

The embedded synchronization codes are configured by means of DCMIPP_PRESCR and DCMIPP_PRESUR registers (see *Table 454*).

Table 454. DCMIPP_PRESCR and DCMIPP_PRESUR bit function

Bit ID	Function
FSC, FEC	Frame-start and frame-end synchronization, when embedded synchronization ESS = 1
FSU, FEU	Masks for FSC and FEC codes
LSC, LEC	Line-start and line-end synchronization, when embedded synchronization ESS = 1
LSU, LEU	Masks for LSC and LEC codes

Sequence of swap operations

The sequence of the SWAP operators on bits, cycles and RB (red vs. blue) is induced by their functionality:

- the swap on bits (MSB vs. LSB on IOs) occurs first, as operating on the IOs
- the swap on cycles occurs afterwards, as it operates on words already sampled by still raw
- the swap on the RB occurs last, as it operates on the final red and blue components.

49.4.2 Interface from CSI-2 host

The CSI-2 host and DPHY_RX (both external to the DCMIPP) provide the data from the CSI-2 camera sensor, forward them into the DCMIPP using the ISB byte header interface.

The ISB byte header features are:

- CSI-2 clock interface aligned with the DCMIPP processing clock (333 MHz)
- Data width: 32 bit (data and CSI headers are interleaved)
  - Frame synchronization short packet
  - Frame number, Data ID, and packet type are provided (see *Section 49.7.8*).
- Line Sync short packets are not received.
- Headers of data long packet:
  - Packet length, Data ID, and packet type are provided (see *Section 49.7.8*).
- Payloads of data long packet:
  - Data as 32-bit words, as collected by the CSI-2 host.
- Packet CRC is not received.

49.4.3 Test pattern generator (TPG)

This is a continuous frame generator that replaces the need, for a camera sensor, to test the DCMIPP and the system. It is located at the head of the DCMIPP pipelines, aside of the parallel interface, or the interface from the CSI-Host.

When active, frames are generated indefinitely, with a deterministic pattern, at the desired resolution, pixel format, and with a potential lifeline to show an evolution from frame to frame.

Functionality

- Configurable frame resolution (working at the pixel clock), with a configurable vertical blanking.
- Configurable pixel format: RGB888, RGB565, Raw8/10/12/14, mono, or YUV.
- Configurable pattern: color bars or color squares.
- Potential remapping of the colors to gray scales or to the YUV422 color domain.
- Potential lifeline, evolving from frame to frame. The lifeline is a horizontal bar that progressively shifts down, frame after frame. Its height is 1/64 of the frame height. The pixels in the lifeline have their component values inverted bitwise: 0xFF becomes 0x00, and red (0xFF, 0x00, 0x00) becomes cyan (0x00, 0xFF, 0xFF). The lifeline progresses downward at a speed of 1 line per frame, and restarts back at the top of the frame.

The test pattern generator generates one pixel (visible or blanking) per clock cycle of clk_proc for all formats, except RGB888, generated every two clock cycles.

Software configuration

The software configuration registers are not shadowed as assumed constants.

Table 455. DCMIPP_CMTPGCR1 and DCMIPP_CMTPGCR2 bit function

Bit ID	Function
WIDTH	Width of the visible pixels to generate per frame, up to 16383 pixels wide. The TPG adds an additional horizontal blanking, 1/8 of the width (with a minimum of 16 pixels), and one additional sync cycle. If FORMAT is YUV, WIDTH is rounded to the lower 16.
HEIGHT	Height of the visible lines to generate per frame, up to 16383 pixels wide. The TPG adds an additional vertical blanking of VBL lines.
VBL	Vertical blanking at the bottom of the frame.
FORMAT	Pixel format generated, among RGB565, RGB888, RAW, Mono, YUV422.
RT	Raw Bayer type: the sequence of components (RGGB, GRBG, GBRG, BGGR)
YT	YUV422 type: whether BT.601 or 709, and whether full or reduced range.
PATTERN	Defines the pattern used to fill the frame: – Can be a color bar pattern, with 8 vertical color bars generated. The colors, from left to right, are: white, yellow, cyan, green, pink, red, blue, black. – Can be a color square pattern, with the frame built of adjacent in 256x256 color squares, with a color gradient across each pixel.
GSEN	Transforms the color of the pattern to a grey scale.
LFLEN	Activates the lif.eline. When active, it becomes visible, and progresses indefinitely, frame after frame.
TPGEN	Activates the TPG.

After the TPG activation with ENABLE = 1, a frame is generated with the desired resolution (WIDTH, HEIGHT) and pixel format (FORMAT). If FORMAT selects a raw Bayer format, then TYPE selects the raw Bayer sequence of component.

The frame rate (FPS) is configured using the vertical blanking (VBL). One pixel (visible or in the horizontal or vertical blanking) is generated per clock cycle at the clk_proc clock (except for the RGB888, with one pixel every two clock cycle). The relation between these items is:

FPS = clk_proc / Resolution (with blanking)

= clk_proc / (WIDTH + max (16,WIDTH/8) + 1) x (HEIGHT + VBL)).

For a usecase with a large needed visible resolution (WIDTH, HEIGHT), a needed FPS, and a given constant clock frequency clk_proc, VBL is configured as follows:

VBL = (clk_proc / FPS / (WIDTH + max(16,WIDTH/8) + 1)) - HEIGHT

Note that the RGB888 FORMAT and its pixel rate are 2x lower than those for other formats:

- When RGB888 is captured on the dump pipe (P0), it is mandatory to configure RGB888 to read RGB888 on the P0 buffer. In that case, the pixel generation is 1 pix / 2 clk.
- For all the other cases, including RGB888 used on pixel pipes, it is recommended to set FORMAT = RGB565. With TPG configured as RGB565, the pixel is converted to RGB888 later in the pipe, resulting in a similar result in the pixel pipe. This permits to benefit of the full pixel rate, 1 pix / clk.

Configuration example

To generate an VGA frame at 30 fps, based on a clk_proc clock of 200 MHz, and with a raw Bayer 10 pixel format, with the sequence RGGB, configure:

- WIDTH: 640
- HEIGHT: 480
- VBL: 8766 = 200M / 30 fps / (640 + 80 +1) - 480
- FORMAT: 0x2B (= raw10)
- RT: 0 (RGGB)
- YT: 0 (not used)
- PATTERN: 0 (color bar)
- GSEN: 0 (keep the colors)
- LFLEN: 0 (no lifeline for now)
- TPGEN: 1 (test pattern generator active)

49.4.4 Input selection

Input selection block is ahead of any pipe to select the camera sensor module interface connected to the DCMIPP. Two interfaces are supported:

- Parallel interface: up to 16-bit parallel interface with physical synchronization signals (DCMIPP_VSYNC/DCMIPP_HSYNC) or software embedded ones (as in CCIR601).
- MIPI CSI-2 interface: Host ISB byte header internal connection from the CSI2 host controller placed in front of the DCMIPP.

Both interfaces are exclusive. The selected one is applied to all the input pipes.

The camera sensor interface is selected by means of bit INSEL of the DCMIPP_CMCR register.

49.4.5 Flow selection

The module, present in each pipe, handles the flow control around the CSI2 camera sensor interface. For each pipe, the software needs to configure which virtual channel (VC) and which Datatypes (DT) are processed by the pipe.

For Pipe0 and Pipe1, multiple Datatypes can be selected whereas only one virtual channel can be defined for a frame. Configuration can be changed frame by frame if the application requires it, offering some flexibility.

For Pipe2, when the pipe is independent with PIPEDIFF = 1, only one virtual channel and only one data type by frame can be selected.

The software has to reconfigure the flow selection module to handle interleaved frames from a sensor if it uses virtual channels as a mean to make the differentiation, accepting to lose frames since there can be only one virtual channel active for a given frame (it decreases the FPS).

Multiple cameras data flow can be received simultaneously through the CSI2 ISB header bus. For instance, for a system having two different camera data flows, it is possible to redirect one virtual channel on a pipe and the other one on the other pipe. It can be interesting to dump them on Pipe0, but only one frame over two since the flow selection block has to be reconfigured to switch from one VC to another one.

The flow selection module is used also to share some image processing features (demosaicing, color conversion, statistics, contrast enhancement, auto exposure, statistics removal and basic decimation) between Pipe1 and Pipe2, whatever the camera sensor interface solution (parallel interface or CSI2 interface): when bit PIPEDIFF in the DCMIPP_P1FSCR register is 0, or the input is on the parallel interface that provides unique flow, the Pipe2 samples pixels from the output of the ISP of Pipe1 (see *Figure 423*). PIPEDIFF must be reconfigured when Pipe1 and Pipe2 are disabled.

Software configuration

The following configurations must be set first, because static in the DCMIPP_PxFSCR registers:

Pipe0

- DTMODE[1:0]: Mode for CSI flow selection into that pipe
  - 0: only flow VC/DTIDA is forwarded in the pipe
  - 1: flows VC/DTIDA and/or VC/DTIDB are forwarded in the pipe
  - 2: all Datatypes of the selected virtual channel, except the VC/DTIDA or VC/DTIDB, are forwarded in the pipe
  - 3: all Datatypes of the selected virtual channel are forwarded in the pipe
- VC[1:0]: Virtual channel ID of the CSI flow to select for further processing on the pipe
- DTIDA[5:0]: Data type ID A to select in the CSI flow for further processing in the pipe
- DTIDB[5:0]: Data type ID B to select in the CSI flow for further processing in the pipe
- PIPEN: activation of the Pipes, to be set after the above configurations.

Pipe1

- DTMODE[1:0]: mode for CSI flow selection into that pipe
  - 0: only flow VC/DTIDA is forwarded in the pipe
  - 1: flows VC/DTIDA and VC/DTIDB are forwarded in the pipe
- VC[1:0]: virtual channel ID of the CSI flow to select for further processing on the pipe
- DTIDA[5:0]: data type ID A to select in the CSI flow for further processing in the pipe
- DTIDB[5:0]: data type ID B to select in the CSI flow for further processing in the pipe
- FDTFEN: when the DTIDx is detected depending on DTMODE, the software forces the data type format to the value set into FDTF[5:0] for the pixel pipe processing. It can be used, for instance, to address sensor 3D camera through specific bridge using CSI2 “user data type” to make distinction between left and right camera sensor (each camera has its own user data type value, but sharing the same pixel format).
- FDTF[5:0]: data type value to be forced
- PIPEDIFF: Pipe2 to take same input as Pipe1 or differentiated:
  - 0: Pipe1 and Pipe2 take the flow selection configuration of Pipe1. Pipe1 shares the image processing functions with Pipe2.
  - 1: Pipe1 and Pipe2 are considered as two independent pipes, without any shared configuration.
- PIPEN: activation of the pipes, to be set after the above configurations.

Pipe2

- VC[1:0]: Virtual channel ID of the CSI flow to select for further processing on the pipe.
- DTIDA[5:0]: Data type ID A to select in the CSI flow for further processing in the pipe
- FDTFEN: When the DTIDx is detected depending on DTMODE, the software forces the data type format to the value set into FDTF[5:0] for the pixel pipe processing. It can be used to address sensor 3D camera through specific bridge using CSI2 “user data type” to make distinction between left and right camera sensor for instance (each camera having its own user data type value, but sharing the same pixel format).
- FDTF[5:0]: Data type value to be forced
- PIPEN: activation of the pipes, to be set after the above configurations.

If PIPEDIFF = 0 in DCMIPP_P1FSCR, the configuration bits are directly those set in the DCMIPP_P1FSCR register.

The above bit fields are meaningful when PIPEDIFF = 1.

49.4.6 Frame counter

A frame counter is available for a tag purpose and counts all the frame received on the selected pipe.

The counter is 32-bit, read-only. It is active at least when bit PIPEN of the pipe to whom it is connected is enabled (PIPEN = 1).

It provides an (almost) unique frame number, with a loop time of 4.5 years (if 30 fps).

The counter can be incremented, depending on the PSFC in DCMIPP_CMCR, at the FrameStart event of the selected virtual channel, when a CSI-2 camera sensor is connected, or at the FrameStart event of the pipe when the camera sensor module is connected with parallel interface.

The frame counter is cleared by setting CFC in the DCMIPP_CMCR register.

Software configuration

The frame counter must be configured before it is used for the pipe. Software action(s) must be performed in the DCMIPP_CMCR register:

- Select on which pipe the frame counter is connected by configuring bit PSFC[1:0]
- Frame counter runs as soon as the selected pipe is active (PIPEN = 1)

Note: It is possible to have the Frame counter run on a pipe, while having the pipe not flowing any pixel: this is achieved with pipe enable active (PIPEN = 1) to have the frame counter run, but with CPTREQ = 0 to avoid any pixel flow.

49.4.7 Frame control

The module is replicated for each dump and pixel pipe. It handles the frame control and the capture of each pipe, grouping data into frames, and capturing them when requested.

Definitions

There are two notions of frame events

- Event used inside the hardware (provided by the input interfaces):
  - FrameStart: when a frame starts at the input of the pipes (at frame control)
    - > Parallel interface with VSync fall
    - > CSI-2 interface: SoF (Start-of-Frame) packet
  - FrameEnd: when a frame finishes at the input of pipes (at frame control)
    - > Parallel interface: VSync rise (End-of-Frame)
    - > CSI-2 interface: EoF (End-of-Frame) packet
- Events exposed to software via DCMIPP events and interrupts:
  - VSYNC
    - > When a frame starts, observed at the input of the pipes (at frame control)
    - > It indicates that the current frame has started and has sampled its shadow registers, and that the software can start to configure the next frame
    - > It is recommended to use that interrupt to trigger the software that reconfigures the DCMIPP.
  - FRAME END
    - > When a frame finishes, observed at the output of pipes (when the last pixel has been written on the AXI)
    - > It indicates that the current frame has finished writing all its data to memory, and that the application can immediately start using them
    - > It is recommended to use that interrupt to trigger the software that forwards the memory buffer to other applications

Features

- Frame delineation: allows to dump data with the required frame granularity.
  - Extracts, per pipe, the FrameStart and FrameEnd event, based on the input Start-of-Frame and End-of-Frame.
    - > The FrameStart immediately generates a VSYNC event.
    - > The FrameEnd ripples till the end of the pipe, at the pixel packer level, where it generates the FRAME event.
  - Based on the algorithm detailed in *Extraction algorithm for FrameStart and FrameEnd*.
- Capture mode: can capture a frame snapshot, or capture continuously.
- Capture rate: can capture all frames, or one out of 2, 4, 8. It is only active when the Capture mode is in Continuous mode.
- Frame status: stores infos about the last captured frame (PxLSTFRM, PxLSTLINE), re-sampled at the FrameEnd event.

Extraction algorithm for FrameStart and FrameEnd

The extraction of the FrameStart and FrameEnd is straightforward.

In CSI-2 mode, each pipe is handling a unique virtual channel ID by frame. In case of interleaved flow in input of the DCMIPP, the software can decide to:

- Dedicate each virtual channel on a single pipe in case of multiple pipes, each of them having its own virtual channel number selected
- Decide to decrease the FPS ratio by changing the pipe configuration swapping with the other virtual channel ID (mainly in case of single pipe)

The interlaced mode can be handled by the software in CSI-2 mode by changing the pipe configuration frame by frame.

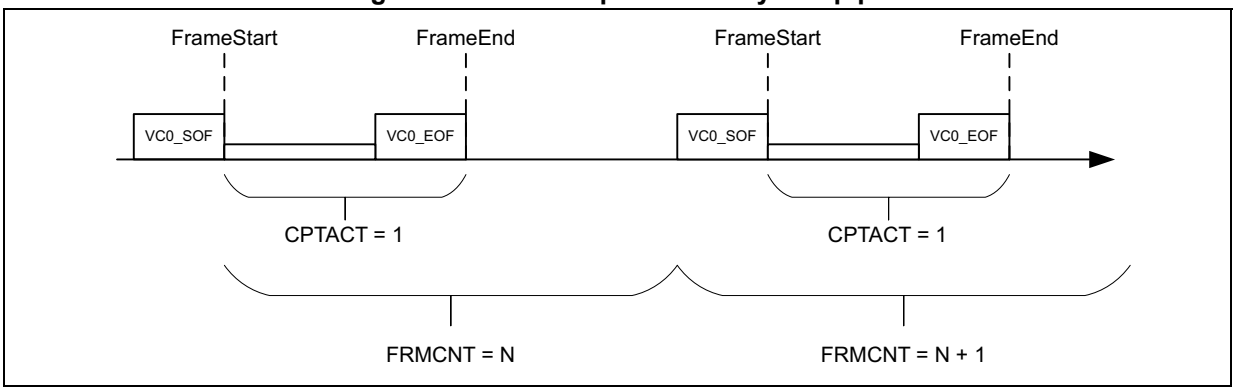
The following usecases are supported and detailed in the figures below:

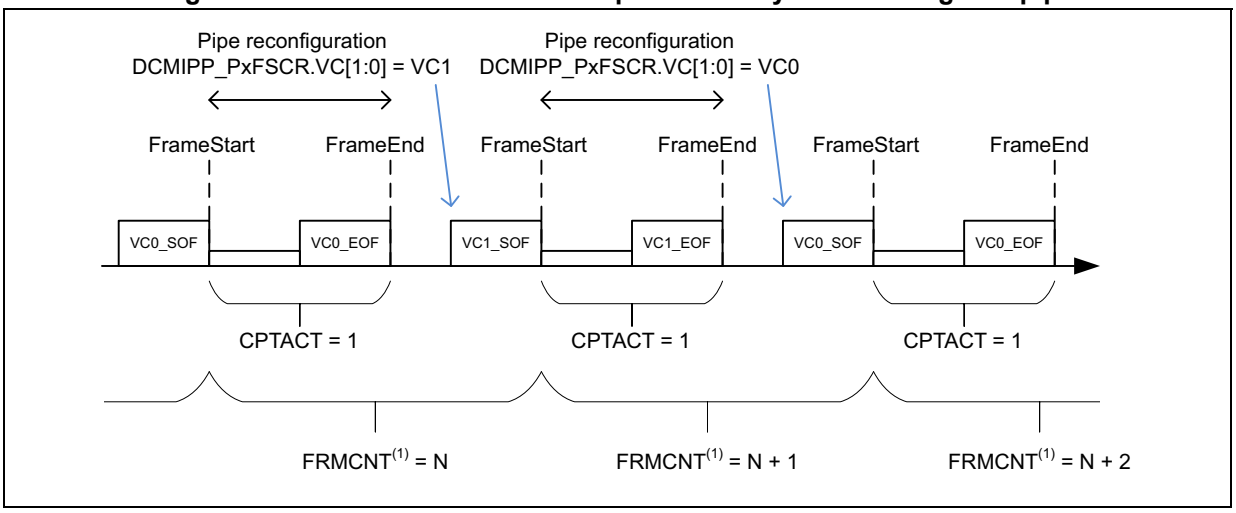
- Default single VC: straightforward behavior, support in both pixel and dump pipes (*Figure 425*)
- Overlapping VC (supported on a single pipe via the loss of one frame when switching)
  - It can be supported by affecting each VC on a dedicated pipe (*Figure 427*)
- Exclusive VC (supported in both pixel and dump pipes), see *Figure 426*:

The use cases with two exclusive VCs can be handled either using one single pipe, by reconfiguring it from frame to frame, or by splitting the flow on more than one pipe, each of them handling its own VC:

- each flow arrives exclusively in one pipe and is processed as an independent frame, with its Start-of-Frame and End-of-Frame
- FrameStart and FrameEnd are generated per VC flow.

Figure 425. VC flow processed by one pipe





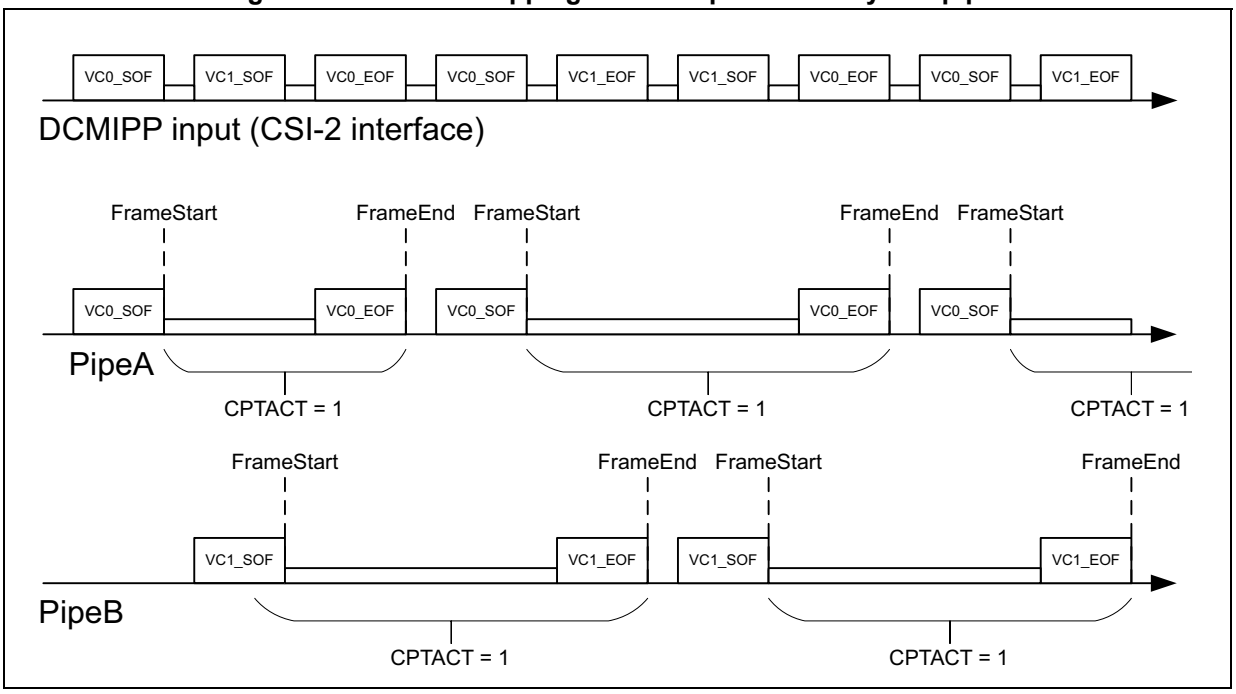


Figure 426. Two exclusive VC flows processed by one reconfigured pipe

1. If frame counter is attached to the pipe and if reset is not requested when changing VC.

Figure 427. Two overlapping VC flows processed by two pipes

Use cases

The Continuous mode is typically used to send to display or to software-analysis a continuous stream of frames.

The Snapshot mode is typically used to dump a high-resolution frame.

The Frame rate mode is typically used for a low-power continuous analysis, where only one frame every eight is dumped and analyzed.

The frame informations are typically used for interlaced video use cases, where the sensors transmit alternatively odd and even fields (top vs. bottom), and where software must be able to retrieve the type of field. Depending on the sensor, it can be retrieved from:

- the VC-ID, if the sensor uses one VC for one field and another for the other
- the LSB of the counted number of lines in that frame (indicates if the number is odd or even)
- the LSB of the frame counter extracted from the CSI information (if counting this pipe), which can be odd or even.

Software configuration

The frame control supports two different capture modes:

- Snapshot mode: the software captures single frames
- Continuous mode: the software captures a continuous sequence.

The timing diagram of these two modes is shown in *Figure 428*.

Figure 428. Snapshot (CPTMODE = 1) and Continuous (CPTMODE = 0) capture modes

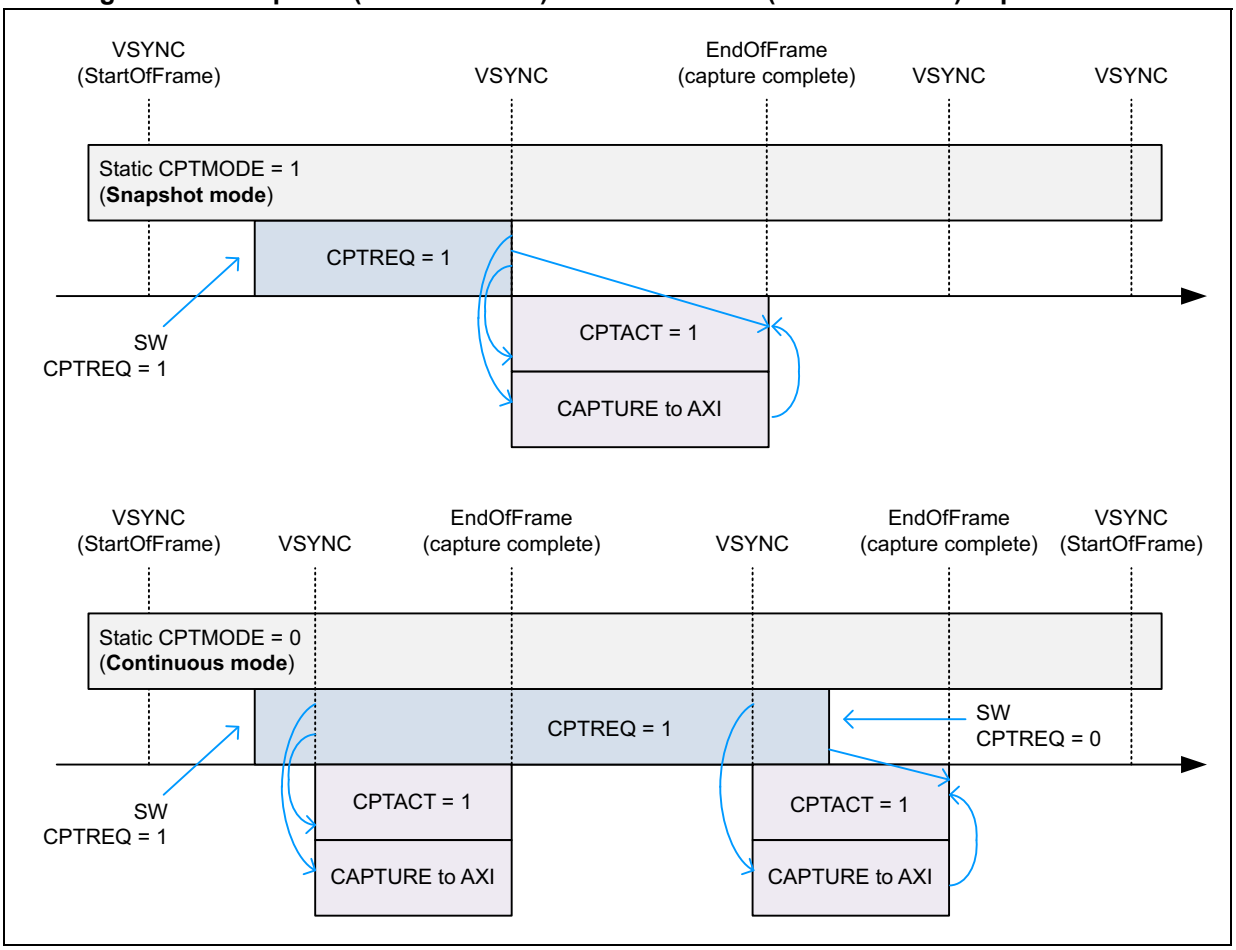

Table 456. DCMIPP_PxFCTCR bit function

Bit ID	Function	Values
CPTMODE	Capture mode	– 0: Continuous – 1: Snapshot
CPTREQ	Capture request	– 1: Capture requested
FRATE	Frame rate	– 0: Full rate capture – 1: 1/2-rate capture – 2: 1/4-rate capture – 3: 1/8-rate capture
CPTACT(1)	Capture status	– 1: Capture currently active

1. Bit read from the DCMIPP_PxSR register.

Configuration example

The software operations when using the Snapshot mode are the following:

1. Software sets CPTMODE = 1, to use the Snapshot mode.
2. Software sets PIPEN = 1, to let the flow selection send data to PipeN.
3. Software sets CPTREQ = 1, to request the capture of one frame.
4. At the first following VSync, the HW samples CPTREQ at 1, with the following impact:
   a) The capture effectively starts: pixels flow into the pipe and are dumped in memory.
   b) CPTACT is set to 1, to mention that a capture is currently ongoing, and that it is best to not modify the configuration of the pipe operators, unless shadowed.
   c) CPTREQ is reset to 0, so that only a single frame is dumped.
5. At the following capture complete interrupt
   a) CPTACT is reset to 0, to signal that the capture is over.
   b) The capture is complete, no more pixels are flowing, hence software can restart to update the configuration of non-shadowed registers without any issue, and use the captured pixels in memory. Depending upon the sensor blanking, this period can be short.
6. At the next VSync, CPTREQ usually is sampled at 0, so that no more frames are captured
   – As soon as CPTREQ is reset to 0 the software can set it again to 1, to request a capture at the following frame. It means that a continuous sequence of frame can be captured by setting again CPTREQ to 1, continuously frame after frame.

The software operations when using the Continuous mode are the following:

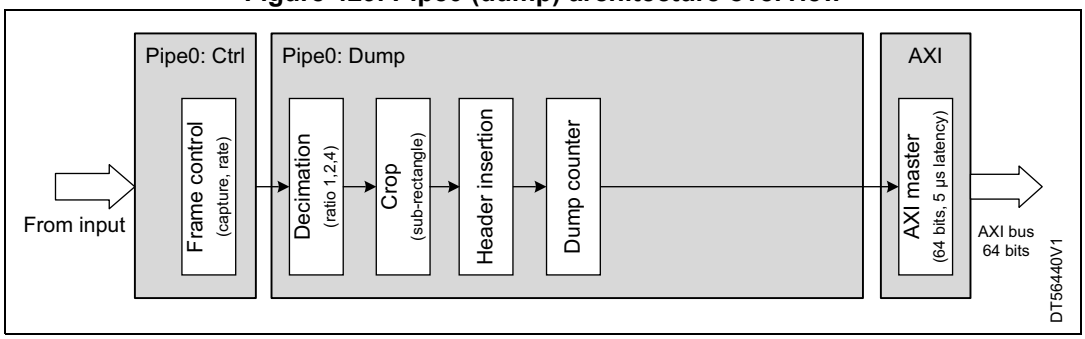
1. Software sets CPTMODE = 0, to use the Continuous mode.
2. Software sets PIPEN = 1, to let the flow selection send data to PipeN.
3. Software sets CPTREQ = 1, to request the continuous capture of frames.
4. At the first following VSync, CPTREQ is sampled at 1, with the following impact:
   – As in Snapshot mode, the capture starts, and CPTACT is set at 1.
   – Unlike the Snapshot mode, CPTREQ is not modified and remains at 1.
5. At the following capture complete interrupt:
   – As in Snapshot mode, CPTACT is reset to 0, capture stops, software can shortly reconfigure the pipes, and software can use the captured pixels.
6. At the next VSync, and as long as CPTREQ remains at 1, the capture restarts, similarly as described above.
7. To stop capturing later frames, software resets CPTREQ to 0.
   – An ongoing capture continues until completion.
8. At the next VSync, CPTREQ is sampled at 0, and the next capture does not restart.

49.4.8 Pipe deactivation

It is possible to abort a pipe to stop any frame acquisition and to potentially offer a mean to reprogram it completely (including non-shadowed registers), or to let it fully disabled for some time. The following operating mode has to be considered to correctly stop the pipe:

1. Disable the CPTREQ bit of the DCMIPP_PxFCTCR register of the corresponding pipe
2. Poll CPTACT = 0 status bit in the DCMIPP_CMSR1 register to check if the pipe is no longer active (idle state)
3. Disable PIPEN in the DCMIPP_PxFCTCR register.

When disabling the pipe, the last frame is processed completely by respecting the above operating mode.



Note: To disable the parallel interface (PREN = 0 in the DCMIPP_PxFSCR), it is recommended to first disable the pipes considering the above operation mode, before switching off the parallel interface.

49.5 Pipe0 (dump pipe)

49.5.1 Overview

Pipe0 works as a dump pipe: it extracts data from the camera sensor module and dumps them (as-is) to the targeted memory, with some basic decimation and cropping 2D operations in between.

Figure 429. Pipe0 (dump) architecture overview

Pipe0 retrieves data from the camera sensor module connected to the DCMIPP through the 16-bit parallel interface or the CSI-2 interface, by means of the CSI-2 host controller peripheral. The selection between interfaces is managed by means of bit INSEL in the DCMIPP_CMCR register.

The flow selection chooses the virtual channels and data types to be processed by the pipe from the CSI2 host controller, see *Section 49.4.5* for more details.

The frame controller handles mainly the camera acquisition mode (continuous or snapshot, frame rate), see *Section 49.4.7* for more details.

When the input data from the camera is valid and supposed to be processed by Pipe0, 2D-cropping and decimation operations can be configured by the software. A dump counter combining with a limit amount of data to be set is offered to handle unknown length of data or to avoid the amount of data to be too wide within a frame.

Pipe0 can be reconfigured from time to time. Some events can be used to trigger the software reconfiguration routines (refer to *Section 49.13.2: Interrupts*).

It is also possible to write into the shadow registers within the processing of a frame. The values are loaded into the physical register based on the start of frame event.

49.5.2 Decimation

The decimation allows to cheaply downsize a frame.

Based on parallel interface camera module:

- Factor 1x, 2x, 4x at data/byte level depending on the configuration of bit field BSM[1:0] of the DCMIPP_P0PPCR register. The decimation is not working directly at pixel level, but it is based on either byte or 16-bit word granularity (for padded raw 10, for instance) to make equivalent decimation to one pixel out of two. Bit OEBS is used to start from the odd or even byte (or data) to capture first.
- The decimation can also be based on entire line, by capturing all the lines, or one line out of two thanks to bit LSM. Here, again, choice is given to the software to reject odd or even lines within the frame by configuring bit OELS.

When the camera sensor module is designed on CSI-2 interface, the decimation can be based filter out potentially, one line out of two. Indeed, each packet is by protocol composed for an entire line.

Note: Care must be taken when the CSI-2 header is dumped, as it is 32-bit wide, and it increases by one unit the data counter, taking part of the decimation. It is advised not to use the CSI header option when decimation takes place.

Table 457. DCMIPP_P0PPCR bit function

Bit ID	Function
BSM[1:0]	To select how much byte/data have to be captured within a line. This feature is available only for a parallel interface camera module.
OEBS	Allows the user to chose if the filtering starts from the odd or the even byte.
LSM	Possibility to filter out one line out of two.
OELS	The software can select if the filtering rejects the odd or even lines.

49.5.3 Crop/statistics selection/suppression

The dump pipe (Pipe0) has the capability to handle 2-D crop processing. The vertical cropping is based on line, thanks to HSYNC event (from the physical IOs or the embedded code detection if selected). It can be extracted from the CSI-2 packet information (each packet is one line wide by protocol).

The horizontal area on which the crop is applied is based on data (32-bit wide), and not on pixels since this pipe is not directly considering the pixels. It handles the data flow with 32-bit granularity. The CROP functionality is not supported when the pipe is convoying JPEG format. The ENABLE bit must be kept cleared into DCMIPP_P0SCSZR to avoid any unpredictable behavior.

The area to be captured within the frame has to be specified configuring the registers DCMIPP_P0SCSTR and DCMIPP_P0SCSZR. The starting point on the two axis are set accordingly as well as the width in both directions. It is possible to take the data inside or outside this area by means of bit POSNEG in the DCMIPP_P0SCSZR register. Some sensors can send sensor configuration data and statistics (histogram) on the very first and last lines of a frame. By specifying active the area outside of this window selection (POSNEG = 1), only statistic data are extracted by the way, and the software can decide to apply some processing on the data to correct, such as contrast or exposure.

Features

- 2D-Crop operation with granularity:
  - Lines in the vertical axis
  - 32-bit data in the horizontal axis
- Possibility to capture data inside or outside the defined window (valid image data or statistic data)
- Cropping with 0 value for HSIZE[11:0] or VSIZE[11:0] has no crop effect to the dimension for which the 0 value has been applied (vertical or horizontal axis).

Software configuration

Registers DCMIPP_P0SCSTR and DCMIPP_P0SCSZR have to be configured to set the crop feature into the dump pipe:

1. Configure the cropped horizontal starting point with HSTART[11:0] and the width with HSIZE[11:0] (both with a 32-bit data granularity).
2. Configure the cropped lines, starting at line VSTART[11:0] and with a height of VSIZE[11:0] (both with a line granularity)
3. If any value HSIZE or VSIZE is set to 0, the hardware does not consider crop operation in the vertical or horizontal dimension for which the 0 value has been applied, so that all the pixels in that dimension are sampled.
4. Select the inner or the outer part of the window for the data capture by configuring POSNEG bit.
5. Enable the crop feature setting ENABLE bit. This bit must be cleared when JPEG is selected as the input format for Pipe0.

Note: Cropping out the picture size (with too large HSTART or VSTART) leads to a not guaranteed processed frame.

49.5.4 Header insertion

The module works on the dump pipe(s) and it optionally inserts an header before the data of a former CSI packet.

Features

- Optionally inserts non-data information to help software interpreting the following data payload. The non-data info is Frame sync short packets and Header of data long packets (both non-data info into a 32-bit word), mapped as follows:
  - Frame sync short packet: defined by Frame type = SOF or EOF
    - > bits 31:16: Frame number
    - > bits 15:8: Reserved (forced to 0)
    - > bits 7:4: Virtual channel ID in CSI-2_v1.3, bits 7:6 = 00
    - > bits 3:0: Frame type (SOF = 0x1 or EOF = 0x2)
  - Header of data long packet (defined by below Frame type = DATA)
    - > bits 31:16: Amount of bytes in the payload
    - > bits 15:8: Data type ID in CSI-2_v1.3, bits 15:14 = 00
    - > bits 7:4: Virtual channel ID in CSI-2_v1.3, bits 7:6 = 00
    - > bits 3:0: Frame type (DATA = 0x0)

To keep consistency between the amount of bytes provided by the header versus those effectively dumped, it is recommended to not activate the header insertion simultaneously with the crop or decimation, as these functions modify the amount of dumped data.

When header insertion is active, the FrameEnd packet is dumped as a header, and is considered as the unique part of an additional line, inducing an event.

Software configuration

It is configured with the DCMIPP_P0PPCR register:

- HEADEREN:
  - 0: No header insertion
  - 1: Insertion of the headers, aligned on 32 bits.

49.5.5 Dump counter

The dump counter is present on dump pipe. It is used to count the amount of data that are dumped in that frame, and to potentially limit the amount dumped if too large. It allows the software to know the size of dumped buffer, and to make sure that no dump is made out of a preallocated buffer.

It is specifically useful when dumping a content whose length is unknown prior to reception, like an encoded JPG stream. When dumping a pixel frame, the size is known thanks to the configured width and height of the frame.

The counter is counting 32-bit data for almost all the input formats, even if the value is expressed in number of bytes. The counter increment is 4-bytes granularity for all formats except the JPEG byte stream input mode, for which the counter granularity is 8-bit because the application does not know the amount of dumped data.

Features

- Dump counter, counting the amount of bytes dumped. It counts the amount of dumped 32-bit words (the increment is 4), except when connected to a parallel interface camera and dumping a 8-bit data in byte stream mode (see FORMAT bit field in the DCMIPP_PRCR register), where it counts per byte (the increment is 1).
  - The counter saturates at 0x03FF_FFFF.
  - At FrameEnd, the counter value is recopied in a readable shadow register and the counter itself is reset to start the count of the next frame.
- Dump limit, that clamps the dumped words below a maximum limit:
  - If the counter reaches the limit, all following bytes are deleted until the next VSync.
  - The counter continues to count over the limit, to indicate how many bytes have been received and must have been dumped if not deleted.
- Interrupt limit is triggered when some bytes are deleted due to dump limit crossed.
- CSI headers, when dumped (HEADEREN = 1), participate to the counted and limited data volumes.
- Monochrome or raw Bayer padding (alignment of 10/12/14 bpp to 16 bpp) is also taken into account in data volumes.

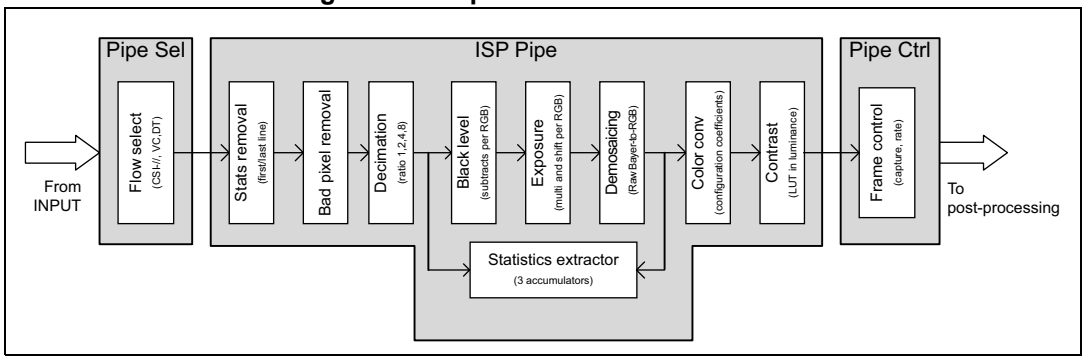
Software configuration

Table 458. DCMIPP_P0DCCNTR and DCMIPP_P0DCLMTR bit function

Bit ID	Function
ENABLE	1: Enables the limit check.
CNT	Read-only, counts the amount of data with a 4-byte granularity for most of the input formats or with an 8-bit data granularity in JPEG byte stream mode selected into DCMIPP_PRCR.FORMAT). The counter increment is based on dumped data at the pipe output standpoint. The value is expressed in bytes, whatever the input format.
LIMIT	Gives the maximum amount of 32-bit data that can be dumped. Limit value 0 is inconsistent and the processed frame is not guaranteed if ENABLE bit is set.
LIMITIE	DCMIPP_PxIER.LIMITIE bit enables the interrupt.

Note: The dump counter sees the CSI-2 packet headers as normal 32-bit words. Raw Bayer and monochrome pixels on 10/12/14 bpc are padded onto 16 bits, and are thus slightly larger than their 10/12/14 bit size.

49.6 Pipe1 (ISP part)



49.6.1 Overview

Pipe1 is a pixel pipeline in which some image processing (ISP) and post-processing functions are integrated, to relieve the software from very specific (time and memory consuming) operations. The ISP part implements functions like:

- Statistics removal within the dataflow
- Bad pixel detection to automatically remove noisy pixels
- Basic decimation to reduce high resolution camera sensor to fit with the image processing maximum resolution tolerance
- Auto exposure and statistics extraction based on pixel analysis
- Demosaicing algorithm to convert raw Bayer input pixels to RGB ones
- Color conversion and contrast enhancement functions

Pipe1 ISP block diagram is shown in *Figure 430*.

Figure 430. Pipe1 ISP architecture view

Pipe1 is the most featured pixel pipeline, even if the image processing functions can be shared with Pipe2 (refer to *Section 49.8.2*).

Pipe1 retrieves data from the camera sensor module connected to the DCMIPP with the 16-bit parallel interface or with the CSI-2 interface, thanks to the external CSI-2 host controller peripheral. The selection between interfaces is managed by means of bit INSEL in the DCMIPP_CMCR register.

The flow selection chooses the virtual channels and data types to be processed by the pipe from the CSI2 host controller. Refer to *Section 49.4.5: Flow selection* for more details.

The frame controller handles mainly the camera acquisition mode (continuous or snapshot, the frame rate). Refer to *Section 49.4.7: Frame control*.

Pipe1 can be reconfigured from time to time. Some events can be used to trigger the software reconfiguration routines (refer to *Section 49.13.2: Interrupts*).

It is also possible to write into the shadow registers during the processing of a frame. The values are loaded into the physical register based on the following start of frame event.

49.6.2 Byte-to-pixel conversion

The module works on the pixel pipes: it gets 32-bit words from the input (parallel or CSI) interfaces, extracts the pixels depending on the provided pixel format, and maps them onto the triple-component pixel pipeline, that is 14 bpc at this stage (and 8 bpc later downstream).

Functionality

- Extracts various input pixel formats to a triple R, G, B lane
  - All CSI-2 formats of versions CSI v1.3 and v2.0 are supported, except Raw 6/7 bpc, YUV422-10 bpc, YUV420 (see *Table 452*)
- YUV420-to-YUV444 conversion is not supported
  - Pipe1 and Pipe2 cannot extract and process YUV420 pixels received from the CSI interface
- YUV422-to-YUV444 conversion:
  - Done by replication of the U and V components. It thus assumes that the location of the common chroma is defined at mid-distance between the two pixels.
- Extension of short triple component (RGB/YUV) to the output triple 8 bpc:
  - The extension is done by replicating the input MSB onto the missing output LSB. The replication onto the LSB allows to map any input dynamic on the full downstream dynamic.
  - Examples of 5 and 6 bpc extended to the output 8 bpc:
    - > Input Di[4:0]: Output Do = Di[4:0] and Di[4:2]
    - > Input Di[5:0]: Output Do = Di[5:0] and Di[5:4]
- Keeps as-is the single-components, usually wide:
  - The monochrome and raw Bayer 10/12/14 bpc are fed into the pipes as-is (the monochrome assumes a Y, with U = V = 128).

Software configuration

The used pixel format depends upon the source of the pixels:

- CSI-2 interface: the pixel format is embedded in the received CSI-2 packets, and defined in the data type field of the packet header.
  - When FDTFEN = 0, the byte-to-pixel conversion uses the data type provided by the CSI-2 packet, and works automatically, without need for any configuration.
  - When FDTFEN = 1, the data type is configured by software in the FDTF field.
- Parallel interface: the pixel format is determined by the source of the pixels, i.e. the camera sensor. The byte-to-pixel extracts the pixels based on the pixel format provided by the software in the parallel interface configuration, in the field of the DCMIPP_PRCR register.

49.6.3 Statistics removal

The module is used to removing potential statistic data inserted by a sensor, prior to starting the demosaicing conversion that is multi-pixel and would be impacted by remaining statistics. It is typically used by sensors with a parallel interface, which does not have any way to distinguish between statistics and pixel data. CSI-2 sensors typically split these flows using different virtual channel IDs.

Features

- Suppression of some of the first lines of the frame.
- Suppression of the last lines of the frame, after a configured line N.

Software configuration

Table 459. DCMIPP_P1SRCR bit function

Bit ID	Values	Comments
CROPEN	1: Active	If CROPEN = 0 all pixels are fed through.
FIRSTLINEDEL	0 to 7	Amount of first lines to delete when CROPEN = 1
LASTLINE	0 to 4094	Amount of lines to keep after the removed first lines. If LASTLINE is null, all remaining lines after FIRSTLINEDEL are fed through.

Configuration example

If the received frame contains four lines of statistics, followed by 100 lines of pixels and eight lines of ancillary data, the configuration to extract the 100 lines of pixels is the following:

- CROPEN = 1, to have the removal active
- FIRSTLINEDEL = 4, to remove the first four lines
- LASTLINE = 100, to keep the next 100 lines

49.6.4 Bad pixel removal

This module aims at detecting and correcting artifacts generated by a bad pixel on the sensor array. It is based on a correlation extraction, and not on fixed locations.

Functionality

- Works for raw Bayer flows only, as RGB flows are assumed as already processed.
- Scans all the arriving components, and extracts the horizontal continuity correlation versus the two left and two right neighbors, on both the local component and on the adjacent raw Bayer component:
  - if a component is seen as too light, it is declared as bad
  - too dark components are not extracted, to avoid false positives
- A component assumed bad is replaced by the horizontal average of its two neighbors (with the same component).

Software configuration

Table 460. DCMIPP_P1BPRCR and DCMIPP_P1BPRSR bit function

Bit ID	Function
ENABLE	– 1: Active – 0: No component checked nor replaced. To be enabled only for raw Bayer flows, as it corrupts RGB flows.
STRENGTH	3 bits, 0 (high tolerance) to 7 (aggressive detection)
BADCNT	12-bit counter, reporting the amount of bad components corrected. The counter saturates at its maximum value (4095). At FrameEnd, the counter is re-clocked (the read value remains stable one full frame), even if the frame is skipped (not captured), and reset to restart accumulation at the next frame.

Configuration example

A too aggressive bad pixel detection might detect false bad pixels and erroneously correct them (it can occur for very thin light vertical lines that cannot be distinguished from bad pixels in the implemented horizontal filter). To avoid such artifacts, it is advised to setup a software loop-back that tunes the filter strength so that the detected bad pixels remain within a predefined valid range.

Start configuration (or without software feedback loop):

- ENABLE = 1 (enabled)
- STRENGTH = 0 (high tolerance)

Software feedback loop:

Assumes a maximum amount of 100 bad pixels on the array (any other value can be used).

- BADCNT read: gets the amount of corrected bad pixels of the last frame
- Low-pass filter on the BADCNT, and/or hysteresis
  - BADCNT > 100: too aggressive, decrease STRENGTH
  - BADCNT < 30: too tolerant, increase STRENGTH (assuming there are bad pixel on the array)

Note: The expected amount of bad pixels (100 in the above example) can be set to other values, or made dependent upon the equivalent gain of the sensor (analog gain, exposure duration). A high-gain picture has more noisy pixels and can accept a more aggressive filter to smooth the noise, while a low-gain picture has mostly correct pixels, only very uncorrelated pixels need to be corrected.

49.6.5 Input decimation

The decimation makes it possible to cheaply downsize a frame, by a factor 2, 4, or 8, in both horizontal and vertical directions. It supports a special mode adapted to a raw Bayer format in input.

The decimation is redundant with the downsize, that brings a higher quality (the decimation discards the data of the dropped pixels, while the downsize averages all pixels and does not lose information).

The decimation has two main usages:

- Reduces the width of very high resolution sensors to one accepted by the raw Bayer-to-RGB conversion. Indeed, the raw Bayer-to-RGB embeds a line buffer that limits its processed images to a maximum width of 2688 pixels. The decimation makes possible, for instance, to plug a 12 Mpixel sensor (4000 x 3000), decimate its width by a factor 2x to 2000 pixels wide, and have it converted to RGB.
- Complements the downsize (limited to ratio of 8 x 8), to have a combined downsizing ratio of 64 x 64. It is recommended to have the largest ratio implemented in the downsize, and the decimation complement to that. For instance, for a ratio 30x, is it recommended to have a ratio 4x in decimation, and a ratio 30 / 4 = 7.5 in the downsize.

Features

- Forwards one item every 1, 2, 4, 8 pixels, independently, vertical and horizontal.
- Supports raw Bayer formats, where RG-GB components must remain grouped. In that mode the above forwarded items are not pixels, but a double component (for example R and G or G and B for a RGGB format), in both vertical and horizontal directions. For instance, with a decimation of 2x, the input sequence R0, G0, R1, G1, R2, G2, R3, G3 gets forwarded as R0, G0, R2, G2 and not R0, R1, R2. The same applies vertically.

Software configuration

Table 461. DCMIPP_P1DECR bit function

Bit ID	Function	Value	Comments
HDEC[1:0]	Ratio (2 bits)	0	No decimation
		1	Ratio 1/2
		2	Ratio 1/4
		3	Ratio 1/8
VDEC[1:0]		0	No decimation
		1	Ratio 1/2
		2	Ratio 1/4
		3	Ratio 1/8

The raw Bayer mode in decimation is indirectly activated when the Datatype is defined as raw Bayer.

49.6.6 Statistics extraction

This module extracts several statistics across the frame, to provide inputs to the software image compensation algorithms, that configure feedbacks to the following implemented hardware modules: black level calibration, exposure compensation, white balance, and contrast enhancement.

The statistics are accumulated during a full frame, and sampled at the end of the frame, thus allows the software to have the full next frame to read the accumulated statistics, process them, define the adapted configuration for the hardware feedback modules, and to configure these modules.

Thanks the shadowing mechanism, the newly configuration parameters are active at the following frame, thus active at an average two frames after the statistics are accumulated. The statistics extraction block is considering all frames selected by means of the DCMIPP_P1FSCR configuration registers. Statistics block is running even when the frame is not supposed to be captured, respect to the DCMIPP_FCTCR configuration register.

The latency is not an issue, as the captured scene is expected to be almost static, and typical software compensation algorithms filter the statistic variations to avoid oscillations and visual artifacts (the low-pass filter typically has a one-second period).

Functionality

- Three statistics accumulators available, allowing three statistics extractions per frame.
  - Different types of statistics can be extracted frame over frame
- 32-bit accumulators, allowing to accumulate 8-bit samples over 16 Mpixels.
- Average mode, that extracts averages (accumulates component values)
  - Capability to discard extreme values (if value is <16 or >240, same for 32 or 64).
- Binning mode, which extracts presences (accumulates 256 per fit)
  - 12 available bins (values: <4, <8, <16, <32, <64, <128, and reverse to 256).
- Capability to define a sub-rectangle within the frame where statistics are extracted
  - Allows to focus the statistics on a specific region of interest.
- Raw Bayer supported, with the statistics using the specific locally available R, G, B components of the raw Bayer
- Statistics can be performed on either the input data (before any pixel modification) or after demosaicing, to benefit of a full RGB and thus luminance presence per pixel.

Software configuration

Table 462. DCMIPP_P1STyCR (y = 1, 2, 3), DCMIPP_P1STySR (y = 1, 2, 3), DCMIPP_P1STSTR and DCMIPP_P1STSZR bit function

Bit ID	Value	Comments
ENABLE	– 1: Active – 0: Bypasses R, G, B components	-
MODE	– 0: Average mode	Values of pixels are accumulated as-is.
	– 1: Bin mode	Values of pixels are used to see if the pixel fits one of the 12 bins

Table 462. DCMIPP_P1STyCR (y = 1, 2, 3), DCMIPP_P1STySR (y = 1, 2, 3), DCMIPP_P1STSTR and DCMIPP_P1STSZR bit function (continued)

Bit ID		Value	Comments
SRC (3 bits)		– (R, G, B, L)_up	– L: luminance computed as R / 4 + G / 2 + B / 4 when receiving RGB pixels, (R or G or B) when in raw Bayer mode. – Up: refers to sampling before the black level calibration (and any pixel processing). – Down: refers to sampling after demosaicing (raw Bayer to RGB conversion), thus after both the exposure and white balance compensation, and when true RGB components (and thus luminance components) are available.
		– (R, G, B, L)_down	
BINS (2 bits)	MODE = Average	– 0: AllPixels: no components are rejected – 1: NoExt16: components are rejected if < 16 or ≥ 240 – 2: NoExt32: components are rejected if < 32 or ≥ 224 – 3: NoExt64: components are rejected if < 64 or ≥ 192	Enables to reject extreme data, not accumulated for statistics. Additional statistics (with MODE = Bin) are needed to count the amount of selected pixels. BINS = 0 is likely to be the most used setting.
	MODE = Bin	– 0: Low: Accu0 counts if V < 4, Accu1 if V < 8, Accu2 if V < 16 – 1: LowMid: Accu0 counts if V < 32, Accu1 if V < 64, Accu2 if V < 128 – 2: UpMid: Accu0 counts if V ≥ 128, Accu1 if V ≥ 192, Accu2 if V ≥ 224 – 3: Up: Accu0 counts if V ≥ 240, Accu1 if V ≥ 248, Accu2 if V ≥ 252	Counts the amount of components V.
CROPEN (1 bit)		– 1: Statistics extracted from sub-rectangle – 0: Statistics extracted from whole frame	-
VSTART (12 bits)		-	Upper position of rectangle, from which statistics are extracted.
HSTART (12 bits)		-	Left position of the rectangle, from which statistics are extracted.
VSIZE (12 bits)		-	Height of the sub-rectangle, from which statistics are extracted.
HSIZE (12 bits)		-	Width of the sub-rectangle, from which statistics are extracted.
ACCU (24 bits)		-	Result of the 32-bit accumulation, re-sampled at frame boundary, and divided by 256 to fit the ACCU width of 24 bits.

Note: If HSIZE or VSIZE = 0 when the CROPEN bit is set, the block internally forces the “0” value at the maximum for the corresponding bit field (i.e. 0xFFE).

Table 463. Statistics extraction: collected data vs. modes

Mode	Average		Bin	
SRC	**RGB**	**Raw**	**RGB**	**Raw**
R, G, B up	012 = R / G / B	012 = RGB / 0 / 0	012 = R / G / B	012 = RGB / 0 / 0
L up	012 = R / 4 + G / 2 + B / 4	012 = RGB + 0 + 0	012 = R / 4 + G / 2 + B / 4	012 = RGB + 0 + 0
R, G, B down	012 = R / G / B	-	012 = R / G / B	-
L down	012 = R / 4 + G / 2 + B / 4	-	012 = R / 4 + G / 2 + B / 4	-

Configuration example for exposure control

For exposure control and white balance calibration, user would typically extract the average values of the luminance, and of the R, G, B. It can be done in a single frame capture campaign, with the following settings:

- ENABLE = 1 (enabled)
- MODE = 0 (average mode)
- SRC = 0 for red, 1 for G, 2 for B (upper values, before processing)
- BINS = 0 (all pixel values)
- CROPEN = 1 (1 below: to select a 300 x 220 close to top-left corner: 10,10)
- VSTART = 10
- HSTART = 10
- VSIZE= 220
- HSIZE= 300

After one frame (after a VSync), the Accu0, Accu1, Accu2 counters contain, respectively, the average red, green, blue accumulated across the 300 x 220 rectangle.

The value to expect from the Accu0, Accu1, Accu2 can be computed according to the following hypotheses:

- Amount of pixels: 300 x 220 (or full frame if statistics has CROPEN = 0)
- Amount of components:
  - Raw Bayer-red: 1/4, as one pixel every four in raw Bayer has a red component.
  - Raw Bayer-green: 1/2, as one pixel every two in raw Bayer has a green component.
  - Raw Bayer-blue: 1/4, as one pixel every four in raw Bayer has a blue component.
  - RGB: 1, as all pixels contain R, G, B components.
- Average value on 8 bits: 128 typically for a mid-gray picture (RGB: 128, 128, 128).
- Re-sampling: 1/256 (re-sampling accumulator to ACCU at end of frame).

The expected values in the accumulators are:

- Accu0 (red): 300 x 220 / 4 x 128 / 256 = 8250
- Accu1 (green): 300 x 220 / 2 x 128 / 256 = 16500
- Accu2 (blue): 300 x 220 / 4 x 128 / 256 = 8250

Configuration example for contrast enhancement

For contrast enhancement, the amount of pixels with a luminance inside a bin is typically extracted. As statistics are extracted 3 by 3, and as 12 bins can be accumulated, data are extracted during four consecutive frames, with three different bins for each frame.

The typical configuration is the following:

- ENABLE = 1 (enabled)
- MODE = 1 (bin mode)
- SRC = 3 (upper value, luminance selected)
- BINS = 0 (then, at next frame 1, then 2, then 3)
- CROPEN = 0 (no stat sub-rectangle)

After one frame (after a VSync), Accu0, Accu1, Accu2 counters contain the amount of pixels fitting bins <4, <8, <16, respectively.

The value to expect from the Accu0, Accu1, Accu2 can be computed by multiplying the following:

- Amount of pixels: 640 x 480 (assuming a full frame resolution of VGA).
- Amount of components: 1 (all pixels contribute to the luminance, even in raw Bayer).
- All pixels contribute to the statistics, both in raw Bayer and in RGB. In raw Bayer, a fake statistics is extracted, assuming a RGB-balanced pixel (Gray-world algorithm).
- Average value for bins: 256 (as in Bin mode, 256 is added for each fitting presence).
- Re-sampling: 1/256 (at end of frame)

The resulting value in accumulators are:

- Accu0 (bin < 4): 640 x 480 x 1 x 256 / 256 x 1% = 3072 (assuming 1% of pixels have lum < 4)
- Accu1 (bin < 8): 640 x 480 x 1 x 256 / 256 x 3% = 9000 (assuming 3% of pixels have lum < 8)
- Accu2 (bin < 16): 640 x 480 x 1 x 256 / 256 x 8% = 24000 (assuming 8% of pixels have lum < 16)

At the following frame, with BINS = 1, the statistics for luminance <32, <64, <128 are extracted, providing figures like 72k (25%), 144k (50%), and 210k (75%).

Such values indicate a median luminance ~64, as 50% of the pixels have a luminance <64.

49.6.7 Black level calibration

This module suppresses a potential positive black level offset, which happens when the sensor sends non-null pixels when capturing a black picture.

Functionality

- Subtracts an offset from the R, G, B components.
- A different constant is used for R vs. G vs. B, including within raw Bayer pixels.

Software configuration

Table 464. DCMIPP_P1BLCCR bit function

Bit ID	Value	Comments
ENABLE	– 1: Active – 0: Bypasses R, G, B components	-
BLCR	-	8-bit offset, for red
BLCG	-	8-bit offset, for green
BLCB	-	8-bit offset, for blue

The offset subtracted is aligned components MSB: for instance, if components are defined on 12 bits, the 8-bit offset subtracted for red is BLCR « 4.

Configuration example

It is possible to use the statistics extraction, to extract the long-term most-dark R, G, B components, and assign their darkness as black. Their RGB values become the black level offset for each RGB.

For a raw Bayer sensor with 12-bit components, if the measured black level offset for red is 64 (out of a maximum of 4095), configure BLCR as 16.

49.6.8 Exposure compensation and white-balance calibration

This module aims at compensating bad exposure (too short/dark or too long/light), and at compensating a bad color balance to recenter the colors to more white ones.

The exposure and white balance operations are purely linear, and do not distort colors if performed correctly.

Functionality

- Multiplies R, G, B by a configured floating-point constant.
- A different constant is used for R vs. G vs. B, including within raw Bayer pixels.

Software configuration

Table 465. DCMIPP_P1EXCR1 and DCMIPP_P1EXCR2 bit function

Bit ID	Value	Comments
ENABLE	– 1: Active – 0: Bypasses R, G, B components	-
MULTR, SHFR	-	8-bit multiplier (mantissa), and up-shift value (0, 1, 2, 3, 4, 5, 6, 7) for red components.
MULTG, SHTG	-	8-bit multiplier and exponent, for green components.
MULTB, SHTB	-	8-bit multiplier and exponent, for blue components.

The idle setting (that sends out a similar value as input) is:

- MULTR = MULTG = MULTB = 128
- SHFR = SHFG = SHFB = 0

Similar idle couples are MULTx = 64 and SHFx = 1, or 32 and 2, or 16 and 3.

Configuration example for exposure alone

It is recommended to use the exposure control in conjunction with the contrast enhancement below in the pipe: the idea is to deliberately keep an exposure lower than ideal, to avoid burning the whites: the contrast enhancement, thanks to non-linear operator on luminance, lightens the dark pixels, and reduces the dynamic of the light pixels without burning them.

It is recommended to use the statistics to extract the average luminance across the whole frame (done best by extracting the R, G, B averages, and computing the luminance from the RGB).

The idea is to push the average output luminance to 128, or if working with the contrast enhancement too, to push it to a lower value, for instance 64.

When measuring an average luminance of 26 (target is 64), the exposure factor to apply is 64 / 26 = 2.5x = 1.25x * 2, hence the following configuration must be set:

- MULTR = MULTG = MULTB = 128 * 1.25 = 160
- SHFR = SHFG = SHFB = 1

Configuration example for an additional white balance

An example of easy way to recenter the colors is using the Gray-world algorithm.

This algorithm assumes that a default scene has an inherent balance of its red, green, and blue pixels, so that the average values of the red, green, and blue components across the ideal picture are the same. If the measured averages are not the same, it means that there has been a distortion of the white balance, that must be corrected by amplifying or reducing the red, green, and blue strengths in the exposure module, thanks to the differentiated red vs. green vs. blue multipliers and exponents.

In practice this is the same approach used for the exposure compensation, but, instead of forcing the output luminance to a default target (64 in the example), user must force the red, green, and blue averages towards the same exposure target.

As an example:

- Exposure target is defined as 64.
- Measured red is 26: red factor is 64 / 26 = 2.5x, hence MULTR = 160, SHFR = 1.
- Measured green is 32: green factor is 64 / 32 = 2.0x, hence MULTG = 128, SHFG = 1.
- Measured blue is 10: blue factor is 64 / 10 = 6.4x, hence MULTB = 205, SHFB = 2.

49.6.9 Demosaicing

The module works on the pixel pipes, and implements a mid-quality conversion from raw Bayer 8 bpp to an RGB 24 bpp, with no implicit half-sizing: the output RGB pixel rate is the same as the input component rate.

The conversion targets real-time but medium quality purposes, like display or low-resolution software analysis. For higher quality conversions, it is recommended to convert the raw

Bayer in software, with higher quality algorithms but limited to non-real-time, thus still-picture applications.

The algorithm takes the surrounding 3 x 3 components in input, applies linear heuristics to determine the most likely missing components, and generates an output RGB888 pixel.

To provide the 3 x 3 input matrix to the algorithm, the demosaicing module embeds a double line-buffer, 2 x 2688 components wide. As such, it limits the maximum width of a converted demosaicing buffer to 2688 components/pixels wide. Wider camera sensor resolution can be connected and goes through the first decimation stage in front of the demosaicing operation.

Note: This demosaicing conversion algorithm can create some artifacts, like Zipper. Such artifacts are much reduced by a later downsizing or even suppressed for a 2 x 2 downsizing. Applications like display, video encode, or software analysis usually require such a downsize, so the artifacts become invisible.

The underlying heuristic filters try to extract and adapt to edges, horizontal and vertical lines, and lone pixels.

Functionality

- Input pixel format: from 1 (raw Bayer) to three (RGB/YUV) components on 8 bits
- Max input width of 2688 components
- Demosaicing conversion:
  - 2-line buffer
  - provides a 3 x 3 matrix to the algorithm + one trailing component (2 left)
  - Extraction and optimization for specific shapes:
    - > Edges (on left, right, top, bottom)
    - > Lines (horizontal and vertical)
    - > Peaking (lone pixels detection)
- Output pixel format: three RGB components on 8 bits.

Software configuration

Table 466. DCMIPP_P1DMCR bit function

Bit ID	Values	Comments
ENABLE	– 1: Active – 0: Bypasses R, G, B components.	If the camera sensor transmits an RGB or YUV frame and not raw Bayer, the demosaicing conversion must be disabled, by setting Enable = 0. All other parameters are ignored.
TYPE	– 0:RGGB – 1:GRBG – 2:GBRG – 3:BGGR	Default raw Bayer with three components (R, G, B)
EDGE	– 0: No edge detection, pure linear interpolation – 1 to 7: Relative algorithm strength (respectively 3, 4, 6, 8, 12, 16, 24)	-

Table 466. DCMIPP_P1DMCR bit function (continued)

Bit ID	Values	Comments
LINEH	– 0: No horizontal line detection, pure linear interpolation – 1 to 7: Relative algorithm strength (respectively 3, 4, 6, 8, 12, 16, 24)	-
LINEV	– 0: No vertical line detection, pure linear interpolation – 1 to 7: Relative algorithm strength (respectively 3, 4, 6, 8, 12, 16, 24)	-
PEAK	– 0: No peak detection, pure linear interpolation – 1 to 7: Relative algorithm strength (respectively 3, 4, 6, 8, 12, 16, 24)	-

The four filters, EDGE, LINEH, LINEV, PEAK, improve the zoomed accuracy of the filtered picture (thus mostly luminance correctness, like no Zipper artifact), however at the expense of some chrominance blurring or distortion. Some scenes can require specific settings:

- Scenes where chrominance distortion is very visible (like a mostly black and white scene viewed by an RGB sensor) can require lower strength of the filters.
- On the opposite, scenes heavily loaded with geometric shapes (and thus source of artifacts) can require strengthening the filters.

Globally, 6/4/4/2 is a good compromise for the filter strength.

Configuration example

If the camera sensor is raw Bayer, with a grid with a red top-left pixel, the next configuration can be used:

- ENABLE = 1 to have the demosaicing active
- TYPE = 0 to have a top-red pixel, thus a RGGB grid
- EDGE, LINEH, LINEV, PEAK = (4, 4, 4, 4) as typical setting (so an internal strength of 8 for each parameter).

49.6.10 Contrast enhancement

This module ends the image processing pipe. It makes possible to enhance the contrast of the frame, by non-linear emphasis of the luminance of the pixels, and to provide more luminance quantification steps at highly used luminances (usually central grays), by reducing the amount of quantification steps less used by the picture (usually the few very dark and very light pixels).

Functionality

- Inputs RGB from the pipe
- Computes the luminance of the local pixel
- Extracts the desired luminance increase/decrease factor, in function of the input luminance, non-linearly (using a look-up table)
- Multiplies the input RGB with the amplification factor
- Outputs the clamped RGB components on 8 bits

Software configuration

Table 467. DCMIPP_P1CTCR1,2,3 bit function

Bit ID	Values	Comments
ENABLE	– 1: Active – 0: Bypasses R, G, B components	-
LUMx (x = 0 to 8, respectively inputs at 0, 32, 64, 96, 128, 160, 192, 224, 256)	0 to 63	Amplification factor: – LUMx = 8 halves the pixel luminance – LUMx = 16 does not modify the pixel luminance – LUMx = 32 doubles the pixel luminance

Configuration example

There are multiple approaches to handle contrasts.

It is possible to flatten the spectrum of luminance density (that is, to try have a similar amount of pixel per each segment of luminance), which is to fill each of the eight segments of luminance with 12.5% of the pixels of the frame.

An intermediate approach is to proceed with only the upper and lower half pixels: half of pixels must have a luminance below and another half above the mid-dynamic (128 for 8-bit components).

It is advised to use the statistics extraction module, sample the luminance after the exposure control (to avoid an impact on the exposure compensation), and sort it in the 12 available bins (refer to *Section 49.6.6*). From the extracted bins the user must linearly extrapolate the luminance of the median of the amount of pixels. The luminance of median pixel must be increased/decreased to be moved to the targeted output median luminance, which is recommended to be the median dynamic (128).

For instance, a 400 kpixels VGA picture can have 200 kpixels below a luminance of 64, and the other 200 kpixels above that value. The ideal luminance amplification factor can be set to 128 / 64 = 2x:

- pixels darker than 64 are lightened by a factor 2x
- pixels lighter than 64 are lightened a bit less, decreasingly
- pixel of luminance of 255 get an idle, 1x, factor.

The above assertions can be used to compute the LUMx values to configure:

- Ratio 2x from lum = 0 to 64:
  - LUM0 = LUM1 = LUM2 = 32.
- Decreasing ratio from 32 to 256, best exponentially decreasing:
  - LUM3 = 27
  - LUM4 = 23
  - LUM5 = 20
  - LUM6 = 18
  - LUM7 = 17
  - LUM8 = 16 (the maximum luminance, 256, must remain idle).

49.6.11 Color conversion

This module implements a color conversion with flexible (fully programmable coefficients), which can be used to map the following features:

- YUV-to-RGB: when the pixels of a YUV-sensor are used as RGB (display, GPU)
- RGB-to-YUV: when the pixels of a RGB-sensor are used by software (for example video encode)
- Tone change: to map special color references (sepia), emphasize some tone/colors
- Monochrome: to compute a monochrome from RGB/YUV with a specific linear mix
- Expansion: to handle a YUV (or RGB) expansion or compression
- Gamma: to emulate a gamma correction via a linear scale

Features

- Linear rotation of color space: 3 x 3 matrix + 3 x 1 column.
- Clamping optional on either [16 to 235] for Y, R, G, B and [16 to 240] for U, V.

Software configuration

Table 468. DCMIPP_PxCCyy (yy = R0, R1, G0, G1, B0, B1) bit function

Bit ID	Value	Comments
ENABLE	– 1: Activates the color conversion	-
CLAMP	– 1: Clamps the output pixel, when using a reduced dynamic	-
TYPE	– 1: Clamps as RGB – 0: Clamps as YUV	-
Matrix3x3_Coeff	-	11 bits (sign, 2 int, 8 dec, with sign as complement to 2)
Added3x1_Coeff	-	10 bits (sign, 9 int, with sign as complement to 2)

Configuration example

Table 469 provides examples of the most used conversions:

- To / from RGB from/to YUV (as SDTV ITU-R BT.601 or HDTV BT.709).
- With a full (0 to 255) or a reduced (16 to 235) dynamic for Y and RGB, 16 to 240 for CbCr.
- Matrix fields are defined as XY bit fields in the color conversion coefficient registers, with X being the input R or G or B, and Y being the output R or G or B. For conversions to/from YUV, the R must be assumed as Cr (= V), G must be assumed as Y, and B must be assumed as Cb (= U).
- Coefficients are defined signed, and multiplied by 256 when there are decimals (the matrix coefficients). Negative values are on 11 bits: N11(val) = XOR (val, 0x7FF) + 1, on 10 bits for Added_Coeff: N10(val) = XOR (val, 0x3FF) + 1.

Table 469. Color conversion: examples of coefficients

Conversion	Output components	Input components				
RGB-255 to YUV601-255	-	R	G	B	Added	Clamping
	Cr	131	-110	-21	128	[0 to 255]

49.7 Pipe1 (post-processing part)

49.7.1 Overview

The post-processing Pipe1 (whose diagram is shown in *Figure 431*) is a pixel pipeline in which post-processing functions are integrated to relieve the software from very specific operations (time and memory consuming), like:

- Crop, to keep only the part of the picture required by the targeted application
- Decimation, as a cheap preprocessing before the downsize
- Downsize, to reduce the picture resolution (size reduction)
- Gamma correction before sending the data to the memory for further displaying operations
- YUV conversion with possible down-sampling option, to optimize the memory size needed to store the corresponding image or to match a YUV420 video encoder.

Figure 431. Block diagram

The applicative Pipe1 is the most featured pixel pipeline, even if the image processing functions can be shared with Pipe2 (refer to *Section 49.8.2*).

Pipe1 can be reconfigured from time to time. Some events can be used to trigger the software reconfiguration routines (refer to *Section 49.13.2*).

It is also possible to write into the shadow registers during the processing of a frame. The values are loaded into the physical register based on the following start of frame event.

49.7.2 Pixel 2D cropping

The pixel 2D cropping aims at extracting and forwarding a rectangle of pixels.

The cropping assigns an X and Y location to its input pixels, and selects a configured rectangle among the pixels, and forward the pixels of this rectangle farther in the pixel pipe. The pixels around the selected rectangle are discarded.

Functionality

- Counts lines thanks to HSync (if from parallel interface) or packets (if from CSI-2)
- Counts pixels inside a line
- Positive cropping (forwards a selected rectangle of pixels in the pipe)
- Cropping with 0 value for HSIZE[11:0] or VSIZE[11:0] forces the internal crop to get the maximum value on the parameter where the software sets to the 0 value

Software configuration

Table 470. DCMIPP_PxCRSTR and DCMIPP_PxCRSZR bit function

Bit ID	Values	Comments
ENABLE	– 1: Cropping active – 0: All data transmitted	-
HSTART, VSTART	0 to 4094	Top-left corner of the cropped rectangle.
HSIZE, VSIZE	0 to 4094	Width and height of the cropped rectangle. Can be larger than the received picture to grab everything.

If the cropped window is larger than the received window, only the received pixels are forwarded (no pixels are inserted to match the window size).

If the software sets 0 in one or both horizontal/vertical size bit fields (HSIZE, VSIZE), the crop forces internally the value to be at the maximum on the corresponding bit field.

Configuration example

To select a small rectangle (size 100 x 50), whose upper pixel is located at position (30, 10), provide the following setting:

- ENABLE = 1 to crop a sub-rectangle
- HSTART, VSTART = (30, 10) to start cropping at x = 30, y = 10 of the received picture
- HSIZE, VSIZE = (100, 50)

The most bottom-right selected pixels have a position (129, 59) from the received picture.

The frame forwarded is handled downstream in the pipe as a 100 x 50 frame.

49.7.3 Decimation pre-downsize

The decimation (prior to downsize) makes it possible to cheaply downsize a frame by a factor 2, 4, or 8x, in both horizontal and vertical directions.

The decimation is partially redundant with the downsize, that brings a higher quality (the decimation discards the data of the dropped pixels, while the downsize averages all pixels and does not lose information).

The decimation complements the downsize (limited to ratio of 8 x 8), to have a combined downsizing ratio of 64 x 64. It is recommended to have the largest ratio implemented in the higher quality downsize, and have needed the decimation complement to that. For instance, for a ratio 30x, is it recommended to have a ratio 4x in decimation, and a ratio 30 / 4 = 7.5 in the downsize.

Features

- Forwards one item (typically pixel) every 1, 2, 4, 8 pixels, independently vertical and horizontal.

Software configuration

Table 471. DCMIPP_PxDCCR bit function

Bit ID	Function	Value	Comments
HDEC[1:0]	Ratio (2 bits)	0	No decimation
		1	Ratio 1/2
		2	Ratio 1/4
		3	Ratio 1/8
VDEC[1:0]		0	No decimation
		1	Ratio 1/2
		2	Ratio 1/4
		3	Ratio 1/8

49.7.4 Downsize

This module implements a downsize based on box filtering, which allows ratios from 1x to 8x, independently, in both X and Y directions.

The box filter has properties close to a bilinear filter for small ratios (from 1x to 2x), but provides the advantage of avoiding some Moiré effect for higher ratios (from 2x to 8x) thanks to using all the samples.

Functionality

- Features:
  - Integer + decimal ratio, different vertically and horizontally.
  - Ratio: 1.0x to 8x
  - Limited to a maximum output buffer width of 2688 pixels due to the needed linebuffer.
- Operations:
  - Increments defined with 3.13 precision (<1 pixel error after maximum width of 4094)
  - Internal computations for filter defined with 3.3 precision
  - Accumulates skipped pixels to allow ratio up to 8x with saturation on 11 bits
  - Weighting of shared pixels, to allow good quality at ratio close to 1
  - Independent H filter, then V filter
  - Init phase: left of left-most pixel is aligned on input pixel (see below Pi0, Po0)

Software configuration

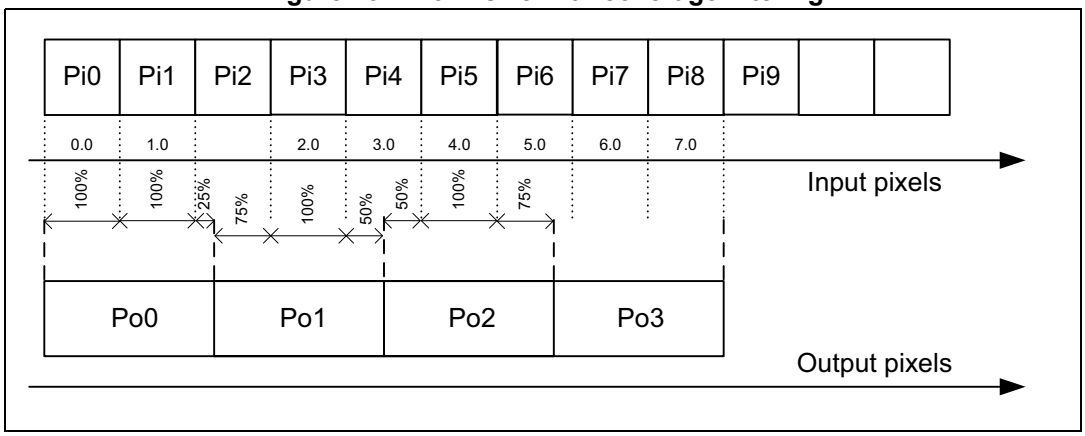

Table 472. DCMIPP_PxDSCR, DCMIPP_PxDSRTIOR, DCMIPP_PxDSSZR

Bit ID	Function	Values	Comments
ENABLE	-	– 1: Downsize active – 0: Transmission without downsize	-
HRATIO, VRATIO	Downsize ratio (respectively horizontally and vertically)	16-bit fields, used as unsigned 3 integer 13 decimal. Valid values are 8192 (= 1x) to 65535 (= 7.999x).	Key parameters that create output pixels. The optimal is computed as xRATIO = Floor (8192 * xRatioFloatingPoint), maximum value 65535 (x = H or V).
HDIV, VDIV	Inverted ratio, must be consistent with Ratio	10-bit fields, used as unsigned 10 decimal. Valid values are 128 (= inv8x) to 1023 (= inv1x).	A side parameter, impacts only the luminance of the output pixels. The optimal in function of xRATIO is xDIV = Floor((1024 * 8192 -1) / xRATIO) (x = H or V).
HSIZE, VSIZE	Final size after the downsize	-	The downsize filter clips pixels if the post-downsize size is not correct. The HSIZE and VSIZE are partially redundant vs. the cropping size divided by the downsize ratio. If VSIZE = 0 or HSIZE = 0, the filter is disabled in that dimension.

Figure 432 shows the principle of the computations:

- Po0 = (1.00 x Pi0 + 1.00 x Pi1 + 0.25 Pi2) / 2.25
- Po1 = (0.75 x Pi2 + 1.00 x Pi3 + 0.50 Pi4) / 2.25
- Po2 = (0.50 x Pi4 + 1.00 x Pi5 + 0.75 Pi6) / 2.25

Figure 432. Downsize with coverage filtering

Configuration example

- ENABLE = 1 to activate the downsize
- Downsize ratio 1x: HRATIO = VRATIO = 8192, HDIV = VDIV = 1023
- Downsize ratio 2x: HRATIO = VRATIO = 16384, HDIV = VDIV = 512
- Downsize ratio 3x: HRATIO = VRATIO = 24576, HDIV = VDIV = 341
- Downsize ratio 8x: HRATIO = VRATIO = 65535, HDIV = VDIV = 128

49.7.5 Gamma conversion

This feature implements a gamma compression on each R, G, B component, using a static gamma exponent 2.2, to store gamma-compressed pictures, as defined in the sRGB standard.

Features

- The gamma is implemented as a 7-segment linear curve.
- It crosses the following way-points, in logarithm spacing:
  - (0,0)
  - (4,39)
  - (8,53)
  - (16,72)
  - (32,99)
  - (64,136)
  - (128,186)
  - (256,256)

Software configuration

ENABLE = 1 in the DCMIPP_PxGMCR registers activate the color conversion.

49.7.6 YUV conversion

This block is a replication of the one described in *Section 49.6.11*, used to convert RGB in YUV color format (basically, since the conversion YUV to RGB is assumed to be performed by the color conversion block into the image processing main function). Bit fields are the same of the color conversion module, only the register name and the memory mapping are different. The register functions are the same, the register names are DCMIPP_P1YUVxxx instead of DCMIPP_P1CCxx.

49.7.7 Chroma down-sampling

The Chroma down-sampling module reduces the chroma resolution from its arriving YUV444 format to the potential YUV420 output, and sends them to a different channel.

Features

- Downsizes in H first, if YUV420, with (0.5 + 0.5) filter
- Downsizes in V then, if YUV420, with (0.5 + 0.5) filter
- Memory: embeds one half-line buffer for each U and V

Software configuration

Configuration is indirectly taken from the pixel packing output format, located in the DCMIPP_PxPPCR register.

- The Chroma down-sampling is active when the output pixel format is YUV422-1, YUV422-2, YUV420-2, YUV420-3.

Output

- One to three channels: RGB/Y, UV (or U) and V.

49.7.8 Pixel packing

This module works on the dump pipe (Pipe0) and pixel pipes (Pipe1 .. N), setting the arriving pixels in memory words.

Features

- Single address (single buffer base-address): if a double or triple buffer is needed, software must update the single base-address at each frame.
- Flexible pitch (line stride): width up to 4094 pixels, 32 bpp, potentially interleaved.
- Pixel format: all usual formats, as indicated in *Section 49.3.6* (Pipe1 allows semi-planar and full planar buffer, Pipe2 coplanar buffer only).
- Swap R-vs-B: swaps the red vs. the blue component.
- Padding: MSB vs. LSB padding of 10/12/14 bit onto 16 bit. (such formats are supported only on the dump pipe).
- Header enable: allows to dump (or not) the CSI packet headers, to allow software an easier extraction of data in case of Interleaved CSI packets in the captured buffer.
- Multi-line event: event generated (for DMA and INT) at each multiple of sent lines.

Note: Some features (for example padding) are available only on the dump pipe, while others (like swap R-vs-B) are available only on the pixel pipes.

Table 473. DCMIPP_PxPPCR bit function

Bit ID	Function	Value	Comments
M0A, M1A, M2A	Base address of pixel buffer in memory, 32-bit wide, aligned on 16 bytes	-	The line alignment of the pixel buffers in memory is assumed on 16 bytes. Therefore the buffer base address (i.e. M0A, M1A, M2A) must be a multiple of 16 bytes, and similarly for line PITCH.
PITCH	Address jump from line to line, up to 32 Kbyte - 1.	-	Aligned on 16 bytes.
SWAPRB	Swaps R-vs-B components (and U-vs-V, same operation if Y mapped on G) available on pixel pipe and not on dump pipe.	-	-
HEADEREN	-	– 1: Dumps headers	Feature present only in dump pipe.

Table 473. DCMIPP_PxPPCR bit function (continued)

Bit ID	Function	Value	Comments
PAD	MSB vs. LSB padding of the raw Bayer and monochrome to 16 bpp.	– 0 (align on LSB): backward compatibility with the former DCMI IP – 1 (align on MSB): easier use by software or GPU	Applies only on the dump pipe and for the 10/12/14 (not 8)-bit pixels (the pixel pipe convert pixels into 8 bpc, and padding is therefore not relevant).
FORMAT	Output pixel format	-	– Pipe0: not defined as default input format used for dump. It allows unique formats ByteData, ByteHeader and Mono/raw Bayer 8/10/12/14. – Pipe1: adds semi- and multi-planar formats: YUV 422-2, 420-2, 420-3 if Alpha or X is dumped, they are forced at 255). – Pipe2: supports coplanar pixel formats xRGB8888 (=xYUV444), RGB888 (=YUV444), RGB565, YUV422-1 and Y8.
LINEMULT	Periodicity of the line (HSync) interrupt and event, as power of 2 of LINEMULT configuration (i.e. every 1, 2, ..,128 lines).	-	-

49.7.9 Overrun detection

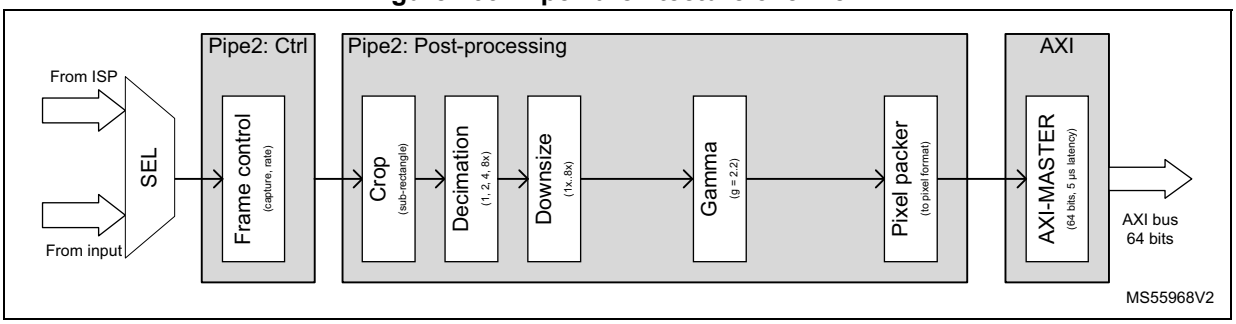
This logic handles flow-control hazards: the DCMIPP is provided a continuous flow of data (via parallel or CSI2 interfaces) without any wait/hold capability, while downstream of DCMIPP, the access to memory can be temporarily stuck.

In some cases the internal FIFOs of the DCMIPP get full and pixels may be deleted. The overrun detection logic handles such hazard at best.

Features

- Software gets warned in case of an hazard:
  - Interrupt OVR is triggered at the first deletion of a pixel, repeated at every frame, as long as the overrun hazard is present.
  - It is recommended to skip / trash the impacted frame:
    > Overflowing pixels are deleted, so that when the access to memory resumes, the remaining of the line is discarded (not written out). The normal processing resumes at the start of the next line. Potentially, several full lines can get discarded.
- No Frame-to-Frame impact in case of an hazard:
  - VSync resets what is needed in the DCMIPP, so that any hazard on a previous frame has no impact at all on the pixels dumped in next frames.

Software configuration



- Interrupt DCMIPP_PxSR.OVRF is warned in case of hazard.

49.8 Pipe2 (post-processing)

49.8.1 Overview

Pipe2, compared to Pipe1, is a lighter pixel pipeline offering no embedded image processing blocks. This pipe can work in standalone mode, or share the image processing functions with Pipe1 (refer to *Section 49.8.2*).

Figure 433. Pipe2 architecture overview

The main blocks (controller and post-processing general functions) of Pipe2 are almost the same as those of Pipe1. The flow selection and frame controller allow to configure Pipe2 behavior when it is used in standalone, meaning without image processing heritage from Pipe1. Refer to *Section 49.4.5* and *Section 49.4.6* for more details about the use cases and the configuration of the pipe.

The set of post-processing blocks is reduced compared to Pipe1, as neither the YUV conversion nor the down-sampling YUV444 to YUV420 are integrated in Pipe2. This pipe can have its own image crop area, its dedicated downsizing, and take benefit of the gamma correction, like Pipe1. Refer to *Section 49.7* and to its subsections for more details on how to use and configure by software these post-processing functions.

Software configuration

To use Pipe2 as a standalone pixel pipe, without any image processing functions shared with Pipe1, bit PIPEDIFF must be set in the DCMIPP_P1FSCR register. This bit has a meaning only when the flows can be differentiated, that is, when the camera connected and processed by the DCMIPP is a CSI2 camera interface.

In this non-shared mode, it is required that different flows are sent to Pipe1 and Pipe2, or a non-supported behavior can occur.

The flow to Pipe1 and the flow to Pipe2 may potentially be interleaved at packet level.

Pipe2 may be reconfigured time to time. Some events may be used to trigger the software reconfiguration routines (refer to *Section 49.13.2: Interrupts*).

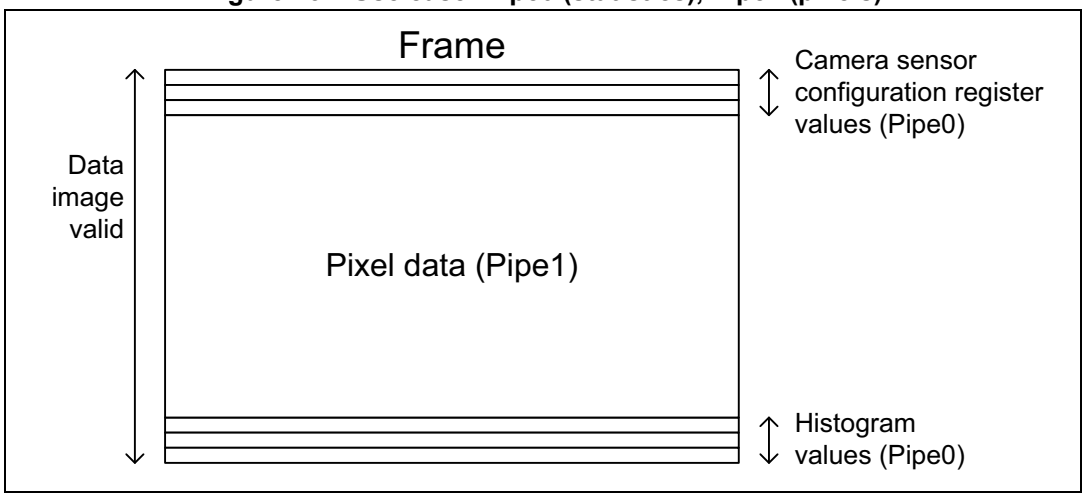
It is possible also to write into the shadow registers within the processing of a frame. The values are loaded into the physical register based on the start of frame event.

49.8.2 Pipe1 and Pipe2 sharing image processing functions

Following the application, it may be interesting to share the image processing functions belonging to Pipe1 with Pipe2 when the dataflow is shared for both. One pipe may be used for display operation, and the other one used for statistics or software analysis. In this case PIPEDIFF bit of DCMIPP_P1FSCR register must be cleared.

If the CSI-2 module is connected to the DCMIPP, the VC DT and DTMODE of Pipe2 are the same as those configured into DCMIPP_P1FSCR register, making non relevant the values for these fields into the DCMIPP_P2FSCR register. However, bits CPTREQ and CPTMODE remain active into the DCMIPP_P2FCTCR register to control the flow inside Pipe2.

49.9 Application use cases



There are several application use cases that can fit the DCMIPP architecture, a few of them are described in this section.

49.9.1 Parallel interface camera sensor module

A parallel interface camera sensor can transfer images as well as statistics. It is easier to manage the software processing by splitting the statistics and the image data on different memory storages. Two pipes are used in such case, with Pipe0 extracting the statistics and Pipe1 dealing with the image data (whatever the data format supported by the DCMIPP). Both work in parallel on the same frame, frame by frame. Each output FIFO attached to the pipe conveys the data on the targeted memory for further processing.

The camera sensor module may use some lines of the frame to transfer statistics or sensor configuration data. These lines can be placed at the beginning and at the end of the frame (see *Figure 434*), even if there is no real standard.

Figure 434. Use case: Pipe0 (statistics), Pipe1 (pixels)

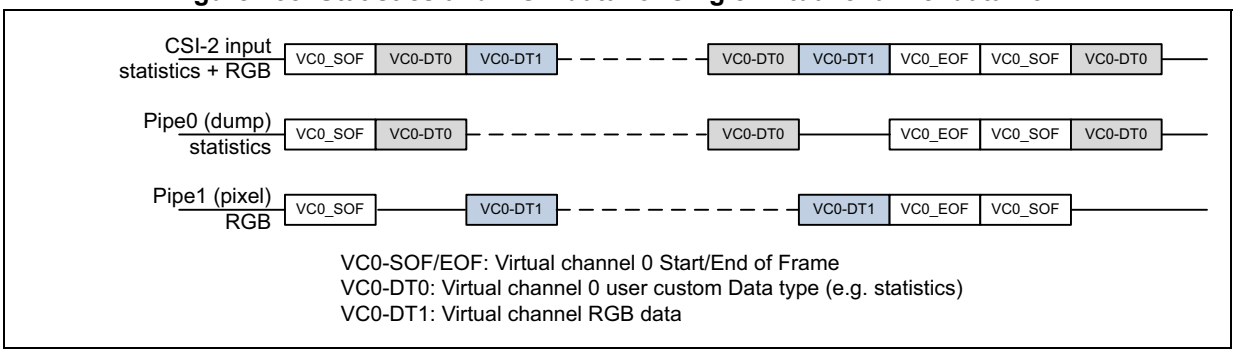
Software configuration

- Pipe0: select the crop area to extract statistics only
  - Configure HSTART[11:0] = 0 and VSTART[11:0] bits in the DCMIPP_P0SCSTR register from the line number corresponding to the first pixel data line (after first statistics line).
  - Configure HSIZE [11:0] (horizontal screen resolution in number of data 32-bit equivalent to the horizontal resolution of the screen in pixels) and VSIZE [11:0] to

the value corresponding to the offset line number from the first pixel data area. These bits are in the DCMIPP_P0SCSZR register.

– Set bit POSNEG of the DCMIPP_P0SCSZR register to reject data belonging to the rectangle defined, to keep the outside area of the rectangle, where the statistics are taken in this use case.

- Pipe1: Select the area to extract the statistics into DCMIPP_P1SRCR register, by configuring bit FIRSTLINE[11:0] and LASTLINE[11:0] (it avoids to start the image processing on statistics data). Only the pixel data are forwarded, if needed, to the image processing blocks (for example demoisaicing, auto exposure, contrast enhancement) for further processing.



49.9.2 CSI2 camera sensor module

The CSI2 protocol allows, thanks to Datatypes, to make distinction between different data categories. The application may request to handle interlaced video as well as interleaved data flow like described below.

Single virtual channel involving two pipes (for example Pipe0 and Pipe1)

- Use case: the CSI provides two data flows in parallel, typically RGB (or raw Bayer) with its sideband statistics.
- Handling: the statistics are dumped by the dump pipe, while the pixels are sent to the pixel pipes.

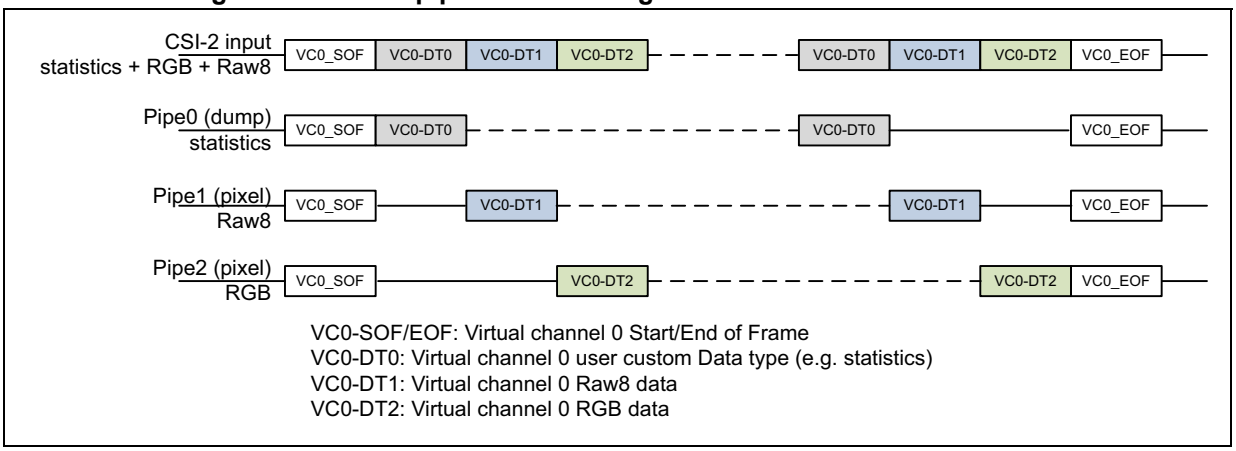


Figure 435. Statistics and RGB data for single virtual channel data flow

Single virtual channel involving three pipes (for example Pipe0, Pipe1 and Pipe2)

Another use case (*Figure 436*) employs different Datatypes in addition to the statistics within the CSI-2 flow based on a single virtual channel.

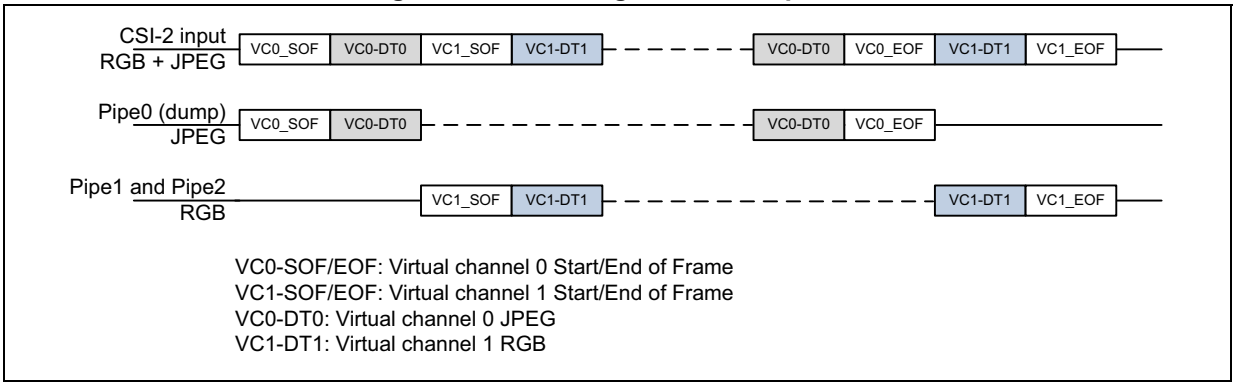
Figure 436. Three pipes within a single virtual channel in CSI2 mode

Interleaved packets (based on multiple virtual channels)

- Use case: the CSI provides two pixel flows in parallel, typically a JPG-compressed flow and an RGB888 or raw Bayer flow.
- Handling: the JPG is dumped by the dump pipe, while the pixels are sent to the pixel pipes.

Both Pipe1 and Pipe2 can process these pixels. The shared demosaicing mode can be used, hence both Pipe1 and Pipe2 benefit of the potential demosaicing conversion.

Figure 437. Handling interleaved packet



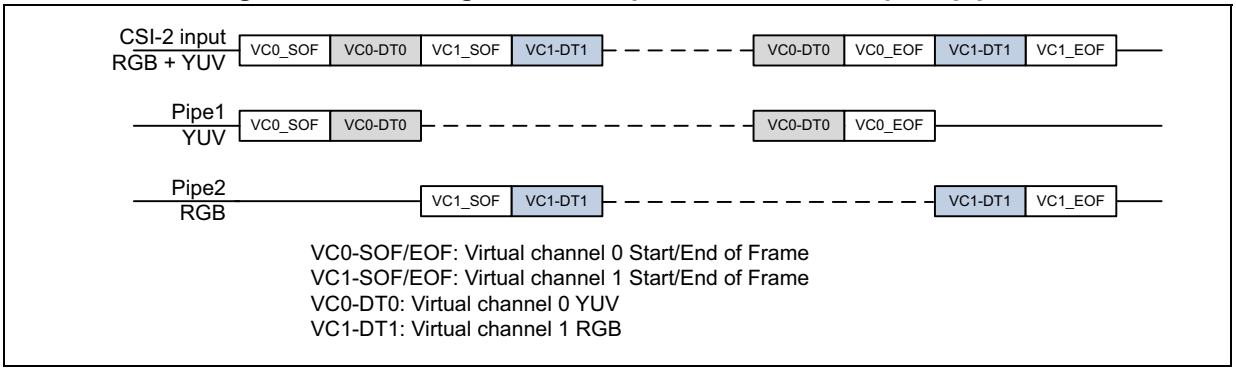


Figure 438. Handling interleaved packets across two pixel pipes

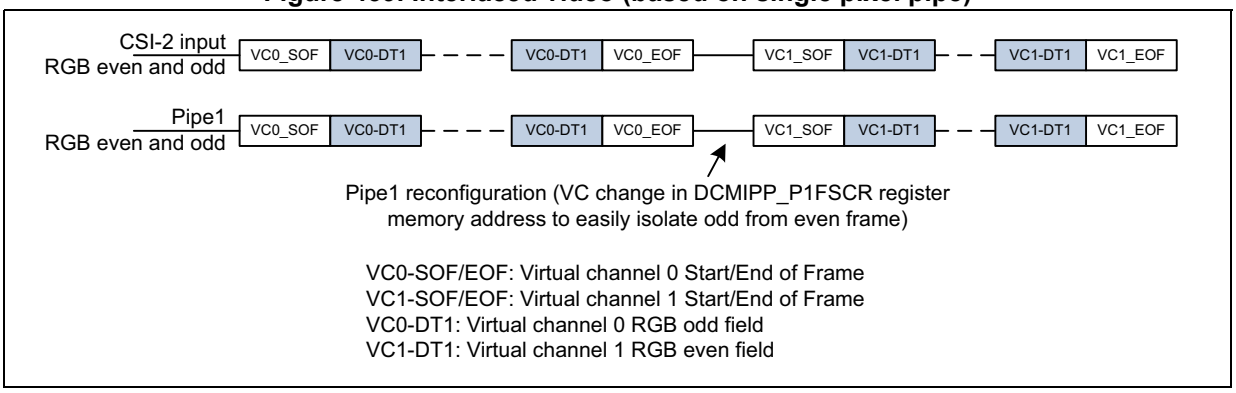
Interlaced video

- Use case: the CSI provides the odd and even frames of an interlaced video onto two different virtual channels (usually with a same data type).
- Handling: the flows of both the virtual channel of the odd field and the virtual channel of the even field are sent to the pixel pipes.
- Single pixel pipe may be configured if the image processing function is required by the application to handle both interlaced frame (refer to *Figure 439*). In such case, a pipe reconfiguration is needed frame by frame to change the virtual channel number and the address memory for the output buffer if the software distinctly keeps the odd and even frame buffers in their respective memory locations.
- Pipe1 and Pipe2 may be used if the application software does not need image processing functions (refer to *Figure 440*). Each pipe is configured with its own virtual channel and its own output buffer address in memory. The split of the odd and even frames is explicitly defined in a static way, avoiding any pipe reconfiguration between two frames.
- Interlaced video can be managed with a single virtual channel identifier, using a different data type to identify odd and even frames. In such case, the CSI2 bridge uses user Datatypes to distinguish between them.
- Limitation: the frames of the two virtual channels must be time-exclusive, by default the case for usual interlaced video sensors.

Figure 439. Interlaced video (based on single pixel pipe)



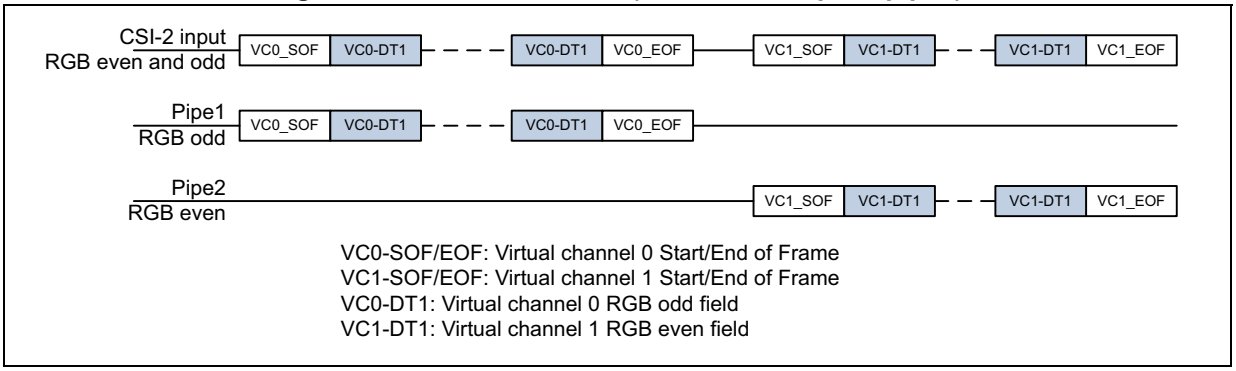


Figure 440. Interlaced video (based on two pixel pipes)

Software configuration

The following configuration must be set first into the static DCMIPP_PxFSCR and DCMIPP_CMCR registers:

- INSEL: Selects the input flow (parallel vs. CSI) in the DCMIPP_CMCR register
- DTMODE[1:0]: mode for CSI flow selection into that pipe:
  - 0: only flow VC/DTIDA is forwarded in the corresponding pipe.
  - 1: flows VC/DTIDA and/or VC/DTIDB are forwarded for Pipe0, and VC/DTIDA and VC/DTIDB for Pipe1.
  - 2: all flows, except the VCDTIDA or VCDTIDB, are forwarded in the pipe (this last setting, 3, is available only for Pipe0).
  - 3: all Datatypes from the selected virtual channel are forwarded in Pipe0. It is valid only for Pipe0 (the pixel formats that are not supported by Pixel pipes are suppressed).

  This bit field is not valid for Pipe2.
- DTIDA/DTIDB: Data type selection ID-A and ID-B for Pipe0 and Pipe1.
- DTIDA: Data type selection for the pixel Pipe2 when PIPEDIFF = 1.
- FDTFEN: Forces the value of the data type (value defined in FDTF[5:0]) to be processed by the pixel Pipe1 and Pipe2, based on the DTIDA/DTIDB detection in the flow selection block of the pipe. Not available for Pipe0.
- FDTF[5:0]: Data type value overwritten the one received by the CSI-2 physical node when equal to DTIDA/DTIDB. Not available for Pipe0.
- PIPEDIFF: Pipe2 to take same input as Pipe1 or differentiated:
  - 0: Pipe2 takes the same VC/DTIDx as well as the same FDTFEN and FDTF[5:0] configured into the DCMIPP_P1FSCR register.
  - 1: Pipe1 and Pipe2 take their own VC/DTID, FDTFEN and FDTF[5:0] values in the data flow.

After all the pipes have been configured, the processing can be activated:

- PIPEN: Set to 1 to start the frame control logic of the pipe. When reset at 0, it immediately resets the frame control logic, which results in immediately stopping an ongoing dump (CPTREQ = 0, CPTACT = 0), see *Figure 425*, *Figure 426*, *Figure 427*.
- CPTREQ: Set to 1 to activate the capture at the next start-of-frame in the DCMIPP_PxFCTCR register.

Note: To be cleanly sampled for the next frame, the VCIDA, VCIDB, DTIDA, and DTIDB fields must be updated after a VSync and after the first HSync.

Configuration example

The following list details five possible use cases, among others interlaced video and interleaved frames, and a 3D sensor (left + right eye):

- Default, with a parallel dump of statistics and processing of an image on both Pipe1 and Pipe2:
  - Image forwarded to the pixel Pipe1 and Pipe2, and processed, with the following settings:
    - Pipe1 / DTMODE = 0, to extract a single flow.
    - Pipe1 / VC / DTIDA = vv_dddddd, with VC and DTIDA matching the image flow
    - Pipe1 / PIPEDIFF = 0, to send the flow to both Pipe1 and Pipe2
  - Statistics are extracted and dumped on Pipe0 with the following config:
    - Pipe0 / DTMODE = 0, to extract a single flow.
    - Pipe0 / VC / DTIDA = vv_dddddd, with VC and DTIDA matching the statistics flow.
- Interlaced video, with the consecutive but exclusive odd and even (requiring the use of the image processing functions):
  - Interlaced video, if having differentiated VC and DT, is forwarded to the pixel Pipe1 and Pipe2, and processed, with the following settings:
    - Pipe1 / DTMODE = 0, to extract the VC /DTIDA flow
    - Pipe1 / VC/DTIDA = vv_dddddd, with VC and DTIDA matching the odd or the even field by reprogramming between two frames
    - Pipe1 / PIPEDIFF = 0, to send the flow to both Pipe1 and Pipe2
    - Pipe1 / Pipe2 / CPTMODE = 1, Snapshot mode
    - Pipe1 / Pipe2 / CPTREQ = 1 alternatively for Pipe1 and Pipe2, frame by frame
  - Any other (different) data can be potentially dumped with the following settings:
    - Pipe0 / DTMODE = 2, to extract all but flows A and B
    - Pipe0 / VCDTIDA = Pipe1 / VC / DTIDA corresponding to the odd field
    - Pipe0 / VCDTIDB = Pipe1 / VC / DTIDB corresponding to the even field

The software needs to reprogram frame to frame the DTIDx fields of the DCMIPP_P1FSCR register to select the data to process into Pipe1 or Pipe2. The software sets CPTMODE bit to work in Snapshot mode for Pipe1 and Pipe2 in the DCMIPP_P1FCTCR and DCMIPP_P2FCTCR registers. Alternatively, bit CPTREQ is set frame by frame in one pipe then in the other one to allow the acquisition of data on the allocated pipe. The data type identifying the odd or even fields needs to by updated into the DCMIPP_P1FSCR register only, as Pipe2 shares the image processing block of Pipe1.

- Interlaced video, with consecutive but exclusive odd and even (bypassing the image processing functions):
  - Interlaced video, if having differentiated VC and/or DT, is forwarded to pixel Pipe1 and Pipe2, and processed, with the following settings:
    - Pipe1 / DTMODE = 0, to extract the VC /DTIDA flow
    - Pipe1 / VC / DTIDA = vv_dddddd, with VC and DTIDA matching (for instance) the odd field data type
    - Pipe2 / DTMODE = 0, to extract the VC /DTIDA flow

> Pipe2 / VC / DTIDA = vv_dddddd, with VC and DTIDA matching (for instance) the even field data type
> Pipe1 / PIPEDIFF = 1, to consider Pipe1 and Pipe2 as totally independent
> Pipe1 / Pipe2 / CPTMODE = 0, Continuous grab mode
> Pipe1 / Pipe2 / CPTREQ = 1 to capture data corresponding to the VCDTIDA attached to the corresponding pipe

– Any other different data can be potentially dumped with the following settings:
> Pipe0 / DTMODE = 2, to extract all but flows A and B
> Pipe0 / VCDTIDA = Pipe0 / VC / DTIDA corresponding to the odd field
> Pipe0 / VCDTIDB = Pipe0 / VC / DTIDB corresponding to the even field

In this case the interlaced video must be differentiated with the data type and not with the virtual channel (since there is a single VC by pipe), if the application wants to dump data other than the odd and even frames on Pipe0.

- Interleaved flows, with a parallel dump of an RGB picture and a JPEG-encoded flow:
  – The RGB picture is extracted and forwarded to pixel Pipe1 to be processed, with the following settings:
  > Pipe1 / DTMODE = 0, to extract one flow, the RGB picture
  > Pipe1 / VC /DTIDA = vv_dddddd, with VC and DTIDA matching the RGB picture data type
  > Pipe1 / PIPEDIFF = 1, to send the RGB on Pipe1 and use Pipe2 for other purposes

  – The JPEG-encoded stream is transmitted under the CSI user-defined format, is extracted and sent to the pipe to be dumped, thanks to the following:
  > Pipe0 / DTMODE = 0, to extract one flow, the JPEG-encoded flow
  > Pipe0 / VCDTIDA = vv_dddddd, with VC and DTIDA matching the JPEG stream data type
  > Pipe0 / VCDTIDB = not used

  – Another pixel picture, like YUV, can be dumped using Pipe2, by overwriting fields:
  > Pipe2 / DTMODE = 0, to extract a second flow for the YUV picture
  > Pipe2 / VCDTIDA = vv_dddddd, with VC and DTIDA matching the YUV picture data type

- 3D sensor, with a parallel transmission of two RGB or YUV pictures: one with data type DT1 for the left eye, and one with data type DT2 for the right eye: the DCMIPP can process each eye on a different pipe (for example left eye on Pipe1 and right eye on Pipe2). Note that, as Pipe1 and Pipe2 are differentiated, the demosaicing is assigned to Pipe1 only and is not available for Pipe2. The left and right eye flows are similar (raw Bayer or RGB), hence they both need to be RGB and not raw Bayer:
  – The left eye RGB picture is extracted and forwarded to the pixel Pipe1:
  > Pipe1 / DTMODE = 0, to extract one flow, the RGB picture
  > Pipe1 / VC / DTIDA = vv_dddddd, with VC and DTIDA matching the left eye data type (DT1)
  > Pipe1 / PIPEDIFF = 1, to split and differentiate the flow between Pipe1 and Pipe2

  – The right eye RGB picture is extracted and forwarded to the pixel Pipe2:
  > Pipe2 / VC / DTIDA = vv_dddddd, with VC and DTIDA matching the right eye

data type (DT2)

- Another flow can be dumped onto the dump pipe:
  - > Pipe0 / DTMODE = 0, to extract one flow
  - > Pipe0 / VCDTIDA = vv_dddddd, with VC and DTIDA matching the flow to dump for instance

- Sensors in 3D, with left and right image inside a unique global image:
  - If the left and right images are differentiated with a left and right part of a single image, that double image can be extracted and duplicated to both the pixel pipes, and there, cropped differently at input of Pipe1 and Pipe2 respectively
- Sensors with multiple DT:
  - The sensor is supported by sending all (or most) of the flows to the dump pipe, and dumped consecutively, inserting ahead of each dumped packet an header containing the VC, DT, and packet length. See *Section 49.7.8* for more details on the header format. One or two pixel flows can still be extracted and processed by Pipe1 and Pipe2, and potentially suppressed from the extraction of the data dump, thanks to DCMIPP_PxFSCR.DTMODE.

49.9.3 Force data type format from CSI-2 data flow (pixel pipes only)

Application may require to use a user data type in the CSI-2 data flow without specifying the format used for the pixel transfer from a camera bridge to the DCMIPP, thanks to CSI-2 interface physical link.

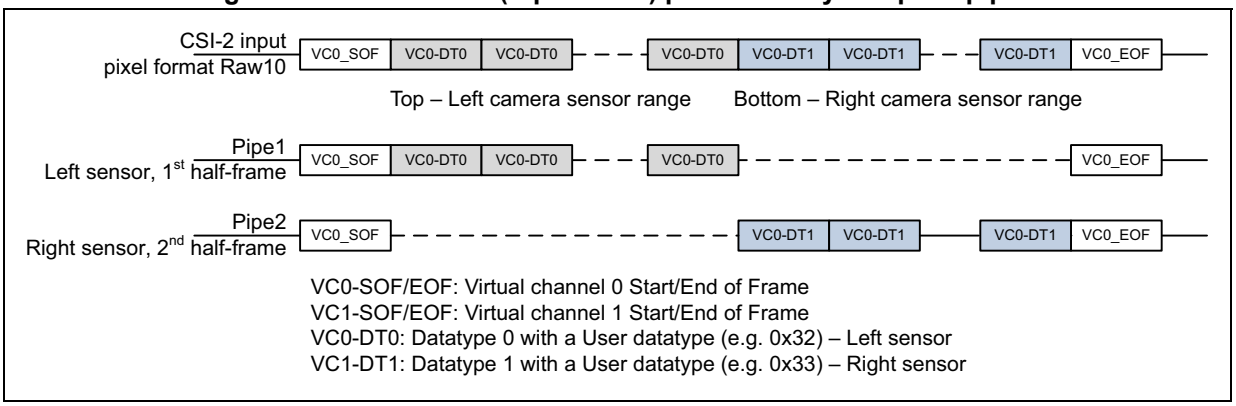
However, the pixel pipes need to know the data format to process them in a proper way along the pipeline. It is possible to force a data type by software thanks to bits FDTF[5:0] and FDTFEN[5:0]. Only the pixel pipes (Pipe1 and Pipe2) can benefit of this capability. Indeed, Pipe0 manages the data and not the pixel itself.

If FDTFEN bit is set in the DCMIPP_PxFSCR register, the data type set into DTIDA/DTIDB (coupled with DTMODE) is used to detect the data type to be overwritten by FDTF[5:0] value. The value used to force the data type must follow CSI-2 data type format specification to identify the CSI-2 normalized data format.

Note: The forced data type value is unique. This means that, if two data types have been selected to be propagated into Pipe1 (DTMODE = 1), both DTIDA and DTIDB detected in input of the pipe are considered by Pipe1 with the forced value FDTF[5:0] if bit FDTFEN is set.

If the virtual channel and data type values are identical between Pipe1 and Pipe2, the force value FDTF[5:0] needs to be aligned within these two pipes if the respective FDTFEN bits are set, otherwise the behavior is not guaranteed.

If PIPEDIFF = 1, any data type format linked to a raw format can be forced on Pipe2 since it is not sharing the demoisaicing block of Pipe1.



Typical application example: 3D sensors camera (top-bottom)

Some CSI-2 bridges concatenate data from left and right camera in a top-bottom approach. It means that within a frame, first half of the lines are the ones generated by the left camera, whereas the half last lines of a frame are attached to the right camera sensor. The bridge may typically make a distinction between lines coming from left camera and right camera by identifying the data type with a user data type value linked to a camera.

The user data type does not identify a pixel format, but rather a data linked to a camera. To help the pipeline process in a correct way the pixel, the software must inform the pipeline about the pixel format in input attached to the user Datatypes.

Let us imagine that the application has to separate pixels from the left camera from those of the right camera. Two pixel pipes can be configured for that, with, for instance, Pipe1 for left camera and Pipe2 dedicated to extract pixels from the right camera, as shown in *Figure 441*.

Figure 441. 3D sensors (top-bottom) processed by two pixel pipes

DCMIPP_P1FSCR configuration

- PIPEDIFF = 0, Pipe1 shares the demosaicing block with Pipe2 to transform, for instance, Raw10 in RGB888 for the output pixel format.
- VC = Virtual channel number
- DTMODE = 1, both Datatypes (0x32 and 0x33) selected to be propagated into Pipe1 through the demoisaicing, shared with Pipe2.
- DTIDA = 0x32, to let pixel data from the left camera sensor (identified by the user data type 0x32) to be processed by the demosaicing block, and further Pipe1 post processing stages (crop, downsize).
- DTIDB = 0x33, to let pixel data from the right camera sensor (identified by the user data type 0x33) to be processed by the demosaicing block, and further Pipe2 post processing stages (crop, downsize).
- FDTF[5:0] = 0x2B, to inform about the Raw10 data type normalized value in CSI-2 specification as input pixel format of the pipes.
- FDTFEN = 1, to force the user Datatypes DTIDA and DTIDB to be decoded as FDTF[5:0] input pixel format value.
- PIPEN = 1, to activate Pipe1.

Pipe1 crop registers (DCMIPP_P1CRSTR and DCMIPP_P1CRSZR) must be configured to crop only the first half lines of the frame corresponding to the pixels coming from the left camera sensor.

DCMIPP_P2FSCR configuration:

- VC / DTIDA / DTIDB / FDTF[5:0] / FDTFEN = don’t care since it is the same as the one defined in DCMIPP_P1FSCR (as PIPEDIFF = 0).
- PIPEN = 1 to activate Pipe2.

Pipe2 crop registers (DCMIPP_P2CRSTR and DCMIPP_P2CRSZR registers) must be configured to crop only the second half lines of the frame corresponding to the pixels coming from the right camera sensor.

49.10 Pixel format description

This section describes the pixel formats used in the parallel interface and in the pixel pipes and dump pipe. The CSI-2 pixel format is described in the CSI-2 v1.3 Standard.

The support for the pixel formats, per interface (parallel, CSI-2, pixel output, dump output) are summarized in *Table 474*, *Table 452*.

Note: In the following tables the components are represented with their symbolic color: red and Cr (= V) in red, blue and Cb (= U) in blue, green in green, and Y, monochrome, and all raw Bayer components in gray.

49.10.1 Parallel interface formats

This paragraph describes the input pixel format as supported by the parallel interface of the DCMIPP and the possible swap combinations.

Note: The parallel interface does not input specifically RGB444/RGB555 (and RGB666). However, a sensor with these output can connect them onto the DCMIPP, by selecting RGB565 (and RGB888), and by either connecting the missing bits with the MSB of the sensor output or by strapping them.

To adapt to non-standard sensors, the parallel interface is flexible and allows to swap bits, cycles, components, namely:

- Bits: LSB-vs.-MSB bits are swapped, across the whole 16-bit IO pins.
- Cycles: cycle 1/2 and cycle 2/2 are swapped. No impact for 1 or 3 cycles.
- Components: R-vs-B components are swapped (or V-vs-U if YUV).

Table 476 shows these permutations, based on the RGB565 format. It lists the sampled bits of cycles 1 and 2, on pins 0 to 7, and for each of them returns the assignation of the RGB output components.

Table 476. Parallel interface input pixel formats

1. Format identifies the value set in bitfield FORMAT[3:0] of DCMIPP_PxPPCR registers (x = 1 to 2).

49.10.3 Dump pipe formats

The dump pipe, thanks to its capability to dump, supports more formats than the pixel pipe, namely:

- CSI-2 packet headers and data
- CSI-2 raw Bayer pixels on 6/7bits (that can be dumped as-is but are not supported by the pixel pipe and hence cannot be processed as pixels).
- Monochrome and raw Bayer pixels on 10/12/14 bits, padded on 16 bpp.

Table 478 details the support for these additional pixel formats. Other formats are assumed to be pixels with the same width. The other pixel formats used by the dump pipe are similar to the pixel formats used by the pixel pipe.

Table 478. Dump pipe OUTPUT pixel formats(1)

49.10.4 AXI IP-Plug

The AXI IP-Plug dumps the data of the pipes (via the AXI) to the memory. It is unique, shared by all the pipes.

Features

- Pipe ID: AXI IP-Plug differentiates, via its ID, the source of the pipe. It allows to differentiate the QoS depending upon the clients.
- FIFOs: sized to handle up to 5 µs latencies (1 µs average round-trip + 4 µs memory slowdown), with, by default, at reset:
  a) Pipe0: 5 Gbps, thus 3.0 Kbytes
  b) Pipe1-Y/RGB: 200 Mpixel/s peak x 8 bpp, thus 3 Kbytes (if ARGB)
  c) Pipe1-U: 200 Mpixel/s peak x 32 bpp, thus 1.5 Kbytes
  d) Pipe1-V: 200 Mpixel/s peak x 4 bpp, thus 0.8 Kbytes
  e) Pipe2: 200 Mpixel/s peak x 32 bpp, thus 3.0 Kbytes
- Burst length: 64 and 128 bytes for all the pipes.
- Outstanding capability: 16 outstandings, to cope with 2 GB/s maximum bandwidth on 128 bytes bursts.
- Bandwidth limiter (via an outstanding limitation per pipe): avoids a last-line dump that would uselessly overload the memory bandwidth.
- Unique AXI-QOS: unique QOS for the DCMIPP (without differentiation between pipes that must all work correctly with their real-time constraint).

Common software configuration

The AXI IP-Plug has a common configuration in the DCMIPP_IPGR1/2/3/8 registers.

The common registers are writable only when the IP-Plug is in Idle mode (see PSTART below to lock it, or below for an example).

- MEMORYPAGE: for efficient handling of DRAM: bursts do not cross this module.
- PSTART: request to freeze the plug, to reconfigure it safely.
- IDLE: status to mention the plug is frozen, to reconfigure it safely.
- IPPID[7:0], ARCHIID[4:0], REVID[4:0], DID[5:0]: version IDs of the IP-Plug.

Per-client software configuration

The AXI IP-Plug has a per-client configuration in the registers DCMIPP_IPCxR1/2/3.

The client registers are writable only when the IP-Plug is in Idle mode (see PSTART in common registers above to lock it, or below for an example).

The clients (1..n) are numbered following the sequence Pipe0..m. Inside each pipe, there are several potential clients when the planar feature is needed.

For instance, the DCMIPP with its three pipes (Pipe0, Pipe1, Pipe2) and with Pipe1 allowing a full planar capability (three buffers: Y, U, V), has the IP-Plug clients, numbered as follows:

- Client1 = Pipe0
- Client2 = Pipe1Y/RGB
- Client3 = Pipe1U
- Client4 = Pipe1V
- Client5 = Pipe2

The configurable per-client features are the following:

- OTR: outstanding transactions per client (Outstanding = OTR + 1)
- TRAFFIC[2:0]: burst size: best select 128 bytes, thus TRAFFIC = 4
- WLRU[3:0]: proportion of total bandwidth: WLRU = BWi / sum (all BW)
- SVC: system virtual channel, keep SVC = 0
- DPREGSTART: local base-address of start of FIFO for this client
- DPREGEND: local base-address of end of FIFO (included word) for this client

Configuration computations

IP-Plug common configuration:

- PSTART: set to 1, to put IP-Plug idle and configure its registers G1/3, R1/3
- IDLE: read and wait till 1, to get it idle
- MEMORYPAGE: 4, to optimize for memory pages of 256 bytes

IP-Plug per-client configuration:

- OTR (client): outstanding per client, among a total of 16 outstandings.
  - The provided value (OTR) is the outstanding amount minus 1.
- DPREG size (client): RAM shared among client, among a total of 1440 x 64-bit words (plus 80 words to dump the histogram)
  - DPREGSTART = 0 (or after another client location).
  - DPREGEND = 127 for ((127 - 0) + 1) x 8 B = 1 KB, as example if 1 KB is assigned to this client. The value to program is 127, as the word is included. DPREGEND is defined to include the last given word of memory, so that a FIFO of 128 words (starting at 0) has DPREGEND = 127.

Each client is provided a proportion of the total FIFO size and of the total outstanding available transactions, in function of the local peak bandwidth. Indeed, the DCMIPP implements buffers to smooth the bandwidth, but they are not large enough to buffer full lines. The proportion of the peak bandwidth of each pipe is estimated as:

- PeakBandwidthProportion (= PBP) = OutputWidth (= OW) * PixelFormatSize (= PFS)
- OTR(client) = Total_OTR * PBP(client) / SumAll(PBP) - 1
- DPREG_Size(client) = Total_DPREG_Size * PBP(client) / SumAll(PBP)

As an example, an xRGB 720p display output, a VGA 422 video output (for software), and no statistics, results in:

- PBP(Display) = 1280 * 4 = 5260
- PBP(Video) = 640 * 2B = 1280
- OTR(Display) = 16 * 5260 / (5260 + 1280) - 1 = 11
- OTR(Video) = 16 * 1280 / (5260 + 1280) - 1 = 3
- DPREG_Size(Display) = 1440 * 5260 / (5260 + 1280) = 1152
- DPREG_Size(Video) = 1440 * 1280 / (5260 + 1280) = 288

Video is assigned to Pipe1 (= Client2) and display to Pipe2 (Client5):

- IP-Plug common registers:
  - DCMIPP_IPGR1.MEMORYPAGE = 2 (default, 256 bytes)
  - DCMIPP_IPGR2.PSTART = 1 (locks IP-Plug for reconfiguration)
  - DCMIPP_IPGR3.IDLE to wait until = 1 (to wait before continuing)
- Video as Pipe1, statically mapped onto IP-Plug Client2:
  - DCMIPP_IPC2R1.OTR = 3
  - DCMIPP_IPC2R1.TRAFFIC = 4 (default)
  - DCMIPP_IPC2R3.DPREGSTART = 1152
  - DCMIPP_IPC2R3.DPREGEND = 1439
- Display as Pipe2, statically mapped onto IP-Plug Client5:
  - DCMIPP_IPC5R1.OTR = 11
  - DCMIPP_IPC5R1.TRAFFIC = 4 (default)
  - DCMIPP_IPC5R3.DPREGSTART = 0
  - DCMIPP_IPC5R3.DPREGEND = 1151
- IP-Plug common registers:
  - DCMIPP_IPGR2.PSTART = 1 (unlocks IP-Plug after configuration)

Configuration example 1: Single RGB dump

It is the simplest but most usual configuration, with the DCMIPP dumping to a single xRGB buffer. It has thus a single pipe active, the dump is coplanar (no side U or V planes), and to emphasize, it does not dump separate statistics (with Pipe0), nor does use the second pixel pipe (Pipe2).

All the AXI capabilities are focused on the single active pipe, which gets all the FIFO space and outstanding capability of the DCMIPP. With this setting, a camera dump of 200 Mpixel/s peak on 32 bpp (800 MB/s bandwidth) benefits of:

- 5 Kbytes FIFO, allowing a memory peak slowdown of 6 µs (a very high value).
- 16 outstandings of 128 bytes, allowing an average memory latency of 2.5 µs (a high value).
- IP-Plug common registers:
  - DCMIPP_IPGR1.MEMORYPAGE = 2 (default, 256 bytes)
  - DCMIPP_IPGR2.PSTART = 1 (locks IP-Plug for reconfig)
  - DCMIPP_IPGR3.IDLE to wait until = 1 (to wait before continuing)
- Single dump on Pipe1 (main pipe), statically mapped onto IP-Plug Client2:
  - DCMIPP_IPC2R1.OTR = 15 (maximum assigned here)
  - DCMIPP_IPC2R1.TRAFFIC = 4 (default, 128 bytes/burst)
  - DCMIPP_IPC2R2.WLRU = 0 (not used as single client)
  - DCMIPP_IPC2R2.SVCMAPPING = 0 (non-user)
  - DCMIPP_IPC2R3.DPREGSTART = 0 (single FIFO, start at lowest)
  - DCMIPP_IPC2R3.DPREGEND = 1439 (single FIFO, end at highest)
- IP-Plug common registers:
  - DCMIPP_IPGR2.PSTART = 1 (unlocks IP-Plug after configuration)

Configuration example 2: All pipes active

This is the most flexible configuration of the DCMIPP: the five clients of the IP-Plug are configured to dump the maximum bandwidth they can receive).

Note that, as the bus capabilities are shared among the clients, that configuration is less resistant to memory latencies than the above configuration with only a single RGB dump.

The capabilities of the DCMIPP are shared among the clients with the following assumptions:

- Client1 for Pipe0: dump of raw Bayer pixels, padded to 16 bpp, BW = 2 / 12
- Client2 for Pipe1-Y: dump of ARGB pixels, on 32 bpp, BW = 4 / 12
- Client3 for Pipe1-UV: dump of UV components, on 8 bpp, BW = 1 / 12
- Client4 for Pipe1-V: dump of V component, on 4 bpp, BW = 1 / 12
- Client5 for Pipe2: dump of ARGB pixels, on 32 bpp, BW = 4 / 12

The total bandwidth proportion, when all pipes are used, is 12. As some configurations (like the outstanding capability) are divided in other granularities, Pipe1-Y/RGB has some advantages, sometimes is used alone (as in the above simpler use case).

With these settings, a camera dump of 200 Mpixel/s peak on 32 bpp (800 MB/s bandwidth) benefits, for an average pipe like Pipe2, of:

- 1.5 Kbytes FIFO, allowing a memory peak slowdown of ~2 µs
- Four outstandings of 128 bytes, with an average memory latency of 0.65 µs, (acceptable but not so large): the DCMIPP must get priority to access the memory.

It results in the following register configuration:

- IP-Plug common registers:
  - DCMIPP_IPGR1.MEMORYPAGE = 2 (default, 256 bytes)
  - DCMIPP_IPGR2.PSTART = 1 (locks IP-Plug for reconfiguration)
  - DCMIPP_IPGR3.IDLE to wait until = 1 (to wait before continuing)
- Client1 for Pipe0: (raw Bayer, 16 bpp) with 2 / 12 of the BW:
  - DCMIPP_IPC1R1.OTR = 1 (2 outstandings, among 16)
  - DCMIPP_IPC1R1.TRAFFIC = 4 (default, 128 bytes/burst)
  - DCMIPP_IPC1R2.WLRU = 2 (2 parts of BW, among 13)
  - DCMIPP_IPC1R2.SVCMAPPING = 0 (non-user)
  - DCMIPP_IPC1R3.DPREGSTART = 0 (224 parts of FIFO, among 1440)
  - DCMIPP_IPC1R3.DPREGEND = 223(224 parts of FIFO, among 1440)
- Client2 for Pipe1-Y/RGB: (ARGB, 32 bpp) with 4 / 12 of the BW:
  - DCMIPP_IPC2R1.OTR = 5 (6 outstandings, among 16)
  - DCMIPP_IPC2R1.TRAFFIC = 4 (default, 128 bytes/burst)
  - DCMIPP_IPC2R2.WLRU = 4 (4 parts of BW, among 13)
  - DCMIPP_IPC2R2.SVCMAPPING = 0 (non-user)
  - DCMIPP_IPC2R3.DPREGSTART = 224 (496 parts of FIFO, among 1440)
  - DCMIPP_IPC2R3.DPREGEND = 719 (496 parts of FIFO, among 1440)
- Client3 for Pipe1-UV: (UV, 16 bpp) with 2 / 12 of the BW:
  - DCMIPP_IPC3R1.OTR = 1 (2 outstandings, among 16)
  - DCMIPP_IPC3R1.TRAFFIC = 4 (default, 128 bytes/burst)
  - DCMIPP_IPC3R2.WLRU = 2 (2 parts of BW, among 13)
  - DCMIPP_IPC3R2.SVCMAPPING = 0 (non-user)
  - DCMIPP_IPC3R3.DPREGSTART = 720 (144 parts of FIFO, among 1440)
  - DCMIPP_IPC3R3.DPREGEND = 863 (144 parts of FIFO, among 1440)
- Client4 for Pipe1-V: (V, 8 bpp) with 1 / 12 of the BW:
  - DCMIPP_IPC4R1.OTR = 1 (2 outstandings, among 16)
  - DCMIPP_IPC4R1.TRAFFIC = 4 (default, 128 bytes/burst)
  - DCMIPP_IPC4R2.WLRU = 1 (1 part of BW, among 13)
  - DCMIPP_IPC4R2.SVCMAPPING = 0 (non-user)
  - DCMIPP_IPC4R3.DPREGSTART = 864 (80 parts of FIFO, among 1440)
  - DCMIPP_IPC4R3.DPREGEND = 943 (80 parts of FIFO, among 1440)
- Client5 for Pipe2: ((ARGB, 32 bpp) with 4 / 12 of the BW:
  - DCMIPP_IPC5R1.OTR = 3 (4 outstandings, among 16)
  - DCMIPP_IPC5R1.TRAFFIC = 4 (default, 128 bytes/burst)
  - DCMIPP_IPC5R2.WLRU = 4 (4 parts of BW, among 13)

  - DCMIPP_IPC5R2.SVCMAPPING = 0 (non-user)
  - DCMIPP_IPC5R3.DPREGSTART = 944 (496 parts of FIFO, among 1440)
  - DCMIPP_IPC5R3.DPREGEND = 1439 (496 parts of FIFO, among 1440)
- IP-Plug common registers:
  - DCMIPP_IPGR2.PSTART = 1 (unlocks IP-Plug after configuration)

49.11 Shadow registers

A dump and/or pixel pipe must have the capability to be reconfigured without stopping it. Some registers can be written in the middle of a frame without impacting the actual frame acquisition. The values are stored into some shadow registers before being written in their corresponding physical registers, based on a trigger event like described in *Table 479*.

Each physical register in the register map has its address increased by 0x200 respect to its own shadow register address.

Table 479. Shadow and physical registers

Shadow register	Physical register	Trigger event

1. Bit PIPEN of this register is not shadowed.

It is mandatory to refresh the shadow registers within a frame to prepare the context to be ready for the next start of frame, to avoid any unpredictable behavior during the acquisition. The software must then react to the following interrupt sources to launch the shadow registers accesses:

- At VSYNC interrupt (FrameStart at start of pipe) an interrupt is generated, and the software can update the shadow registers loaded into the physical registers at the end of the current frame (so active for the next frame). The software has an entire frame period to complete the update.
- At LINE interrupt line selection can be used also to trigger the software to update the physical registers with the new frame context to consider. The application code must ensure that the update takes place before the end of frame event (current frame). If not, the context can be partially considered from the next frame, dealing with inconsistent settings.

In any case, the software must ensure that the shadow registers are updated before the end of the current frame, to be active from the next frame. Updates started and not completed

before the end of current frame result in inconsistent frame acquisition for the next frame (mixing old and new configurations).

It is recommended to change non-shadowed registers when the corresponding pipe is disabled and in an idle state (refer to *Section 49.4.8: Pipe deactivation*).

49.12 DCMIPP low power modes

This section describes the behavior of the DCMIPP versus the modes listed in *Table 480*.

Table 480. DCMIPP low power modes

Mode	Description
Stop	Peripheral content is kept. It is recommended to follow the pipe(s) disabling procedure before entering it.
Standby	Powered-down. The peripherals must be reinitialized after exiting this mode.
Sleep	No effect. DCMIPP is still working in this mode, peripheral interrupts cause the device to exit it.

49.13 DCMIPP interrupts

This section describes the DCMIPP interrupts, and more globally, the features that are related to real-time, namely:

- Free-running: DCMIPP can run without CPU involvement
- Shadow registers: relieve timing constrains from the software
- Interrupts: source of interrupt
- Multiple CPU: capability for independent CPU or driver without Mutex
- Event pins: to drive external IPs, like a DMA

49.13.1 Free-running DCMIPP

After a camera flow has been configured and established, it is able to run permanently, without any software involvement. The following features are available:

- Permanent pipe activation, for Pipe0, 1, 2: when set, the respective pipe dumps frame data, for an unlimited amount of frames.
  - DCMIPP_PxFCTCR.CPTMODE = 0
  - DCMIPP_PxSR.CPTACT = 1
  - DCMIPP_PxFCTCR.FRATE = xx (depending on desired frame subsampling rate)
- No double buffered frames: the DCMIPP defines only one BaseAddress pointer for the output buffers:
  - Software can react to the VSYNC interrupt, and can decide, before the next VSYNC event, to modify the frame BaseAddress pointer.
  - If the software does not react, the capture of a frame overwrites the previous one.

49.13.2 Interrupts

The DCMIPP handles five interrupts pins, the fifth being the OR of the first four.

A register set is associated to each interrupt to provide the following functionality:

- Unmasked events: reports an event that occurred and has not yet been cleared
- Masks: to mask unwanted events
- Masked events: not readable, any active unmasked bit triggers the interrupt pin
- Clear register: write to clear any active event

The interrupt pins are active when high: they go high when triggered by an unmasked event, and remain high until all the masked events of that interrupt are cleared.

The interrupts lines and registers are:

1. Parallel interface, with the next interrupt events handled:
   - ERR: bad embedded synchronization detected.
     > Unexpected behavior in the parallel interface, usually not triggered if no issues.
     > It is due to an unexpected sensor behavior, or to a transmission error.
2. Pipe0 (dump), with the next interrupt events handled:
   - OVR: data overflow: the memory was too slow vs. received pixels.
     > Unexpected behavior in Pipe0, usually not triggered if no issues.
     > Same recommendation as for above OVR: skip the impacted frame.
   - LIMIT: received volume is larger than the maximum allowed dump volume.
     > Unexpected behavior in Pipe0, usually not triggered if no issues.
     > The transmitted flow is too long. More space must be allocated in memory to store the transmission of a next frame.
   - VSYNC: main interrupt, where most software can sit.
     > Trigger: at VSync (mid blanking), permanent (even if no dump active).
     > Typically to reconfigure slowly the pipes (at least shadow registers) for next frame
     > Typically to trigger usage of the previously captured frame.
   - FRAME: secondary interrupt, as backup for fast-software
     > Trigger: after last data dump of this pipe, inactive if no capture has occurred.
     > Typically to quickly reconfigure non-shadow registers (during only vertical blanking)
     > Typically to trigger usage of the previously captured frame.
   - LINE: interruption for stripe-based operators trigger: after every 1/2/4/8/16/32/64/128 dumped lines and last line. It is measured and extracted at end of pipe, close to output to memory.
     > Typically to trigger fast/reactive software or hardware stripe-based operators.

Note: The LINE flag (LINEF bit) is set at the end of frame, to trigger out software event when the frame height is not a multiple of the selected number of lines for which the LINEF event is triggered. The last part of the frame can, in such case, have a lower number of lines than the selection. The event/interrupt is generated even if the number of lines is incomplete. The software must consider that this last event has a lower than expected number of lines when reaching the end of frame (FRAME event).

3. Pipe1 (main pipe)
   - Same events handled as Pipe0: OVR, VSYNC, FRAME, LINE, but no LIMIT as only pixels are captured after a potential crop.
4. Pipe2 (ancillary pipe)
   - Same events handled as Pipe1: OVR, VSYNC, FRAME, LINE.
5. Common interrupt: groups the events of the above interrupts in a single register set and drives its own interrupt line.
   - The fifth interrupt is designed for systems where a single driver handles the whole DCMIPP: a single access to this interrupt status allows to retrieve the status of the whole DCMIPP.
   - The first four interrupts are designed for systems where a driver handles a pipe

and (potentially) another one drives the parallel interface. In that case, each driver handles its own individual interrupt register set, without need for semaphores to arbitrate conflicting accesses.

There is also a common interrupt that can be generated if enabled, when a transfer error is detected during an AXI transfer from the IP-Plug to memories. Error flag ATXERR in the DCMIPP_CMSR2 register is set and an interrupt can be generated to inform the software about this error status. There is no specific hardware action linked to this error, it is up to software to handle the transfer error situation.

On multiple-pipe architecture, the error informs that at least one AXI client has a transfer error, but does not identify from which client.

The DCMIPP interrupts are summarized in *Table 481*. An event that generates an interrupt does it at two locations:

– once in the common interrupt register set (when driven by a single CPU)

– once in the local interrupt register set (when driven by multiple CPUs).

Table 481 provides the local (register and bit) and global (bit only, as all bits are in the same DCMIPP_CMSR2 register) locations.

Table 481. DCMIPP interrupts

Interrupt event	Local register	Local bit	Common bit in DCMIPP_CMSR2	Event flag/interrupt clearing method	Interrupt enable control bit local/common register
Synchronization error in parallel interface	DCMIPP_PRSR	ERRF	PRERRF	Write CERRF = 1 / CPRERRF = 1	ERRIE/PRERRFIE
AXI transfer error	-	-	ATXERR	Write CATXERRF = 1	ATXERRIE
Overflow in Pipe0	DCMIPP_P0SR	OVRF	P0OVRF	Write COVRF = 1 / CP0OVRF = 1	OVRIE/P0OVRIE
Limit violation in Pipe0		LIMITF	P0LIMITF	Write CLIMITF = 1 / CP0LIMITF = 1	LIMITIE/P0LIMITIE
Frame start (VSYNC) in Pipe0		VSYNC	P0VSYNC	Write CVSYNCF = 1 / CP0VCSYNCF = 1	VSYNCIE/P0VSYNCIE
Frame end (FRAME) in Pipe0		FRAMEF	P0FRAMEF	Write CFRAMEF = 1 / CP0FRAMEF = 1	FRAMEIE/P0FRAMIE
Multi-line (LINE) in Pipe0		LINEF	P0LINEF	Write CLINEF = 1 / CP0LINEF = 1	LINEFIE/P0LINEFIE
Overflow in Pipe1	DCMIPP_P1SR	OVRF	P1OVRF	Write COVRF = 1 / CP1OVRF = 1	OVRIE/P1OVRIE
Frame start (VSYNC) in Pipe1		VSYNC	P1VSYNC	Write CLIMITF = 1 / CP1LIMITF = 1	LIMITIE/P1LIMITIE
Frame end (FRAME) in Pipe1		FRAMEF	P1FRAMEF	Write CVSYNCF = 1 / CP1VCSYNCF = 1	VSYNCIE/P1VSYNCIE
Multi-line (LINE) in Pipe1		LINEF	P1LINEF	Write CFRAMEF = 1 / CP1FRAMEF = 1	FRAMEIE/P1FRAMIE

Table 481. DCMIPP interrupts (continued)

Interrupt event	Local register	Local bit	Common bit in DCMIPP _CMSR2	Event flag/interrupt clearing method	Interrupt enable control bit local/common register
Overflow in Pipe2	DCMIPP _P2SR	OVRF	P2OVRF	Write COVRF = 1 / CP2OVRF = 1	OVRIE/P2OVRIE
Frame start (VSYNC) in Pipe2		VSYNC	P2VSYNC	Write CLIMITF = 1 / CP2LIMITF = 1	LIMITIE/P2LIMITIE
Frame end (FRAME) in Pipe2		FRAMEF	P2FRAMEF	Write CVSYNCF = 1 / CP2VCSYNCF = 1	VSYNCIE/P2VSYNCIE
Multi-line (LINE) in Pipe2		LINEF	P2LINEF	Write CFRAMEF = 1 / CP2FRAMEF = 1	FRAMEIE/P2FRAMIE

49.13.3 Event pins

Event pins are exposed to let an ancillary HW IP, like a central DMA, to synchronize with them. The event pins are the unmasked synchronization events (VSYNC, FRAME, LINE, HSYNC) of the pipes.

An internal events generates a pulse (15 APB cycles long) on its pin.

Table 482. Event connection

Pipe	Event name	Internal signal
Pipe0	HSYNC	dcmipp_p0hsync_evt
	VSYNC	dcmipp_p0vsync_evt
	Frame	dcmipp_p0frame_evt
	Line	dcmipp_p0line_evt
Pipe1	HSYNC	dcmipp_p1hsync_evt
	VSYNC	dcmipp_p1vsync_evt
	Frame	dcmipp_p1frame_evt
	Line	dcmipp_p1line_evt
Pipe2	HSYNC	dcmipp_p2hsync_evt
	VSYNC	dcmipp_p2vsync_evt
	Frame	dcmipp_p2frame_evt
	Line	dcmipp_p2line_evt

49.14 DCMIPP registers

The registers are split into groups with a same prefix, as shown in *Table 483*.

Table 483. DCMIPP registers organization

Register name	Offset	Function
DCMIPP_IP	0x000	IP-Plug registers
DCMIPP_PR	0x100	Parallel interface
DCMIPP_CM	0x200	Common registers
DCMIPP_P0	0x500	Pipe0 (dump pipe) with shadow registers
	0x700	Pipe0 (dump pipe) with physical registers
DCMIPP_P1	0x800	Pipe1 image processing with shadow registers
	0x900	Pipe1 post-processing with shadow registers
	0xA00	Pipe1 image processing with physical registers
	0xB00	Pipe1 post-processing with physical registers
DCMIPP_P2	0xC00	Pipe2 image processing with shadow registers
	0xD00	Pipe2 post-processing with shadow registers
	0xE00	Pipe2 image processing with physical registers
	0xF00	Pipe2 post-processing with physical registers
DCMIPP_	0xFF0	IP version and configuration (without prefix)

49.14.1 DCMIPP IP-Plug global register 1 (DCMIPP_IPGR1)

Address offset: 0x000

Reset value: 0x0000 0002

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	QOS_MODE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MEMORYPAGE[2:0]		
													rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **QOS_MODE:** Quality of service
Set of functions enabling to build and configure an architecture meeting bandwidth and latency requirements.

Bits 23:3 Reserved, must be kept at reset value.

Bits 2:0 **MEMORYPAGE[2:0]:** Memory page size, as power of 2 of 64-byte units:
0x0 64 bytes
0x1: 128 bytes
0x2: 256 bytes
0x3: 512 bytes
0x4: 1K bytes
0x5: 2K bytes
0x6: 4K bytes
0x7: 8K bytes

49.14.2 DCMIPP IP-Plug global register 2 (DCMIPP_IPGR2)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PSTART
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **PSTART:** Request to lock the IP-Plug, to allow reconfiguration.
0: No lock requested, IP-Plug runs on demand by background HW.
1: Lock requested: IP-Plug freezes shortly (see IDLE bit when lock is active).
PSTART must be reset to 0 after configuration is completed, to restart the IP-Plug.

49.14.3 DCMIPP IP-Plug global register 3 (DCMIPP_IPGR3)

Address offset: 0x008

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IDLE
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **IDLE:** Status of IP-Plug
0: IP-Plug is running (on demand by background HW)
1: IP-Plug is currently locked and can be reconfigured
IDLE is set after a request by setting PSTART at 1, and reset by resetting PSTART at 0.

49.14.4 DCMIPP IP-Plug identification register (DCMIPP_IPGR8)

Address offset: 0x01C

Reset value: 0xAA04 0314

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IPPID[7:0]								Res.	Res.	Res.	ARCHIID[4:0]				
r	r	r	r	r	r	r	r				r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	REVID[4:0]					Res.	Res.	DID[5:0]					
			r	r	r	r	r			r	r	r	r	r	r

Bits 31:24 **IPPID[7:0]:** IP identifier (0xAA)

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **ARCHIID[4:0]:** Architecture identifier (0x04)

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **REVID[4:0]:** Revision identifier (0x03)

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DID[5:0]:** Division identifier (0x14)

49.14.5 DCMIPP IP-Plug Clientx register 1 (DCMIPP_IPCxR1)

Address offset: 0x020 + 0x10 * (x - 1), (x = 1 to 5)

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	OTR[3:0]				Res.	Res.	Res.	Res.	Res.	TRAFFIC[2:0]		
				rw	rw	rw	rw						rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:8 **OTR[3:0]:** Maximum outstanding transactions
0: Disabled. No outstanding transaction limitation (except via FIFO size)
1: Maximum two outstanding transactions ongoing.
...
15: Maximum 16 outstanding transactions ongoing.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **TRAFFIC[2:0]:** Burst size as power of 2 of 8-byte units
0x0: 8 bytes
0x1: 16 bytes
0x2: 32 bytes
0x3: 64 bytes
0x4: 128 bytes
Other values: Reserved

49.14.6 DCMIPP IP-Plug Clientx register 2 (DCMIPP_IPCxR2)

Address offset: 0x024 + 0x10 * (x - 1), (x = 1 to 5)

Reset value: 0x0004 0000, 0x0002 0000, 0x0001 0000, 0x0001 0000, 0x0007 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WLRU[3:0]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **WLRU[3:0]:** Ratio for WLRU[3:0] arbitration
A client gets a portion of the total bandwidth = Ratio(client) / Sum(all ratios)
0x0: Ratio part = 1
0x1: Ratio part = 2
...
0xF: Ratio part = 16

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:0 Reserved, must be kept at reset value.

49.14.7 DCMIPP IP-Plug Clientx register 3 (DCMIPP_IPCxR3)

Address offset: 0x028 + 0x10 * (x - 1), (x = 1 to 5)

Reset value: 0x017F 0000, 0x02FF 0180, 0x03BF 0300, 0x041F 03C0, 0x059F 0420

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	DPREGEND[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	DPREGSTART[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:16 **DPREGEND[10:0]:** End word (AXI width = 64 bits) of the FIFO of Clientx.
The addressed word is included in the FIFO, so that next DPREGSTART is DPREGEND + 1.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **DPREGSTART[10:0]:** Start word (AXI width = 64 bits) of the FIFO of Clientx.

49.14.8 DCMIPP parallel interface control register (DCMIPP_PRCR)

Address offset: 0x104

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	SWAP BITS	SWAP CYCLES	Res.	FORMAT[7:0]							
					rw	rw		rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	ENABLE	Res.	EDM[2:0]			Res.	Res.	VSPOL	HSPOL	PCKPOL	ESS	Res.	Res.	Res.	Res.
	rw		rw	rw	rw			rw	rw	rw	rw				

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **SWAPBITS**: Swap LSB vs. MSB within each received component
0: As received
1: Swapped MSB vs. LSB

Bit 25 **SWAPCYCLES**: Swap data (cycle 0 vs. cycle 1) for pixels received on two cycles
0: Default
1: Swap active: the data of cycle 1 is used before the data of cycle 0.
The swap must not be activated by software for pixels received in one or three cycles.

Bit 24 Reserved, must be kept at reset value.

Bits 23:16 **FORMAT[7:0]**:
0x1E: YUV422
0x22: RGB565
0x24: RGB888 (= YUV444)
0x2A: RAW8
0x2B: RAW10
0x2C: RAW12
0x2D: RAW14
0x4A: monochrome 8-bit
0x4B: monochrome 10-bit
0x4C: monochrome 12-bit
0x4D: monochrome 14-bit
0x5A: byte stream (JPEG, compressed video)
Other values: data are captured and output as-is only through the data/dump pipeline (for example JPEG or byte input format).
The monochrome Y input is inserted in the pipe as YUV pixels, with the U and V components set to neutral, to represent a gray color.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **ENABLE:** Parallel interface enable
0: Parallel interface disabled to lower power consumption
1: Parallel interface enabled
The parallel interface configuration registers must be correctly programmed before enabling this bit.

Bit 13 Reserved, must be kept at reset value.

Bits 12:10 **EDM[2:0]:** Extended data mode
0x0: Interface captures 8-bit data on every pixel clock
0x1: Interface captures 10-bit data on every pixel clock
0x2: Interface captures 12-bit data on every pixel clock
0x3: Interface captures 14-bit data on every pixel clock
0x4: Interface captures 16-bit data on every pixel clock
Other values: Reserved

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **VSPOL:** Vertical synchronization polarity
This bit indicates the level on the VSYNC pin when the data are not valid on the parallel interface.
0: VSYNC active low
1: VSYNC active high

Bit 6 **HSPOL:** Horizontal synchronization polarity
This bit indicates the level on the HSYNC pin when the data are not valid on the parallel interface.
0: HSYNC active low
1: HSYNC active high

Bit 5 **PCKPOL:** Pixel clock polarity
This bit configures the capture edge of the pixel clock
0: Falling edge active
1: Rising edge active

Bit 4 **ESS:** Embedded synchronization select
0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the HSYNC/VSYNC signals.
1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.
Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when this bit is set.

Bits 3:0 Reserved, must be kept at reset value.

49.14.9 DCMIPP parallel interface embedded synchronization code register (DCMIPP_PRESCR)

Address offset: 0x108

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEC[7:0]								LEC[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LSC[7:0]								FSC[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **FEC[7:0]:** Frame end delimiter code

This byte specifies the code of the frame end delimiter. The code consists of four bytes in the form of 0xFF, 0x00, 0x00, FEC.

If FEC is programmed to 0xFF, all the unused codes (0xFF00 00XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]:** Line end delimiter code

This byte specifies the code of the line end delimiter. The code consists of four bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]:** Line start delimiter code

This byte specifies the code of the line start delimiter. The code consists of four bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]:** Frame start delimiter code

This byte specifies the code of the frame start delimiter. The code consists of four bytes in the form of 0xFF, 0x00, 0x00, FSC.

If FSC is programmed to 0xFF, no frame start delimiter is detected, but the first occurrence of LSC after an FEC code is interpreted as the start of frame delimiter.

49.14.10 DCMIPP parallel interface embedded synchronization unmask register (DCMIPP_PRESUR)

Address offset: 0x10C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEU[7:0]								LEU[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LSU[7:0]								FSU[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **FEU[7:0]:** Frame end delimiter unmask

This byte specifies the mask to be applied to the code of the frame end delimiter.

0: The corresponding bit in the FEC byte in DCMIPP_ESCR is masked while comparing the frame end delimiter with the received data.

1: The corresponding bit in the FEC byte in DCMIPP_ESCR is compared while comparing the frame end delimiter with the received data

Bits 23:16 **LEU[7:0]:** Line end delimiter unmask

This byte specifies the mask to be applied to the code of the line end delimiter.

0: The corresponding bit in the LEC byte in DCMIPP_ESCR is masked while comparing the line end delimiter with the received data

1: The corresponding bit in the LEC byte in DCMIPP_ESCR is compared while comparing the line end delimiter with the received data

Bits 15:8 **LSU[7:0]:** Line start delimiter unmask

This byte specifies the mask to be applied to the code of the line start delimiter.

0: The corresponding bit in the LSC byte in DCMIPP_ESCR is masked while comparing the line start delimiter with the received data

1: The corresponding bit in the LSC byte in DCMIPP_ESCR is compared while comparing the line start delimiter with the received data

Bits 7:0 **FSU[7:0]:** Frame start delimiter unmask

This byte specifies the mask to be applied to the code of the frame start delimiter.

0: The corresponding bit in the FSC byte in DCMIPP_ESCR is masked while comparing the frame start delimiter with the received data

1: The corresponding bit in the FSC byte in DCMIPP_ESCR is compared while comparing the frame start delimiter with the received data

49.14.11 DCMIPP parallel interface interrupt enable register (DCMIPP_PRIER)

Address offset: 0x1F4

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERRIE	Res.	Res.	Res.	Res.	Res.	Res.
									rw						

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **ERRIE:** Synchronization error interrupt enable

0: No interrupt generation

1: An interrupt is generated if the embedded synchronization codes are not received in the correct order.

This bit is available only in embedded synchronization mode.

Bits 5:0 Reserved, must be kept at reset value.

49.14.12 DCMIPP parallel interface status register (DCMIPP_PRSR)

Address offset: 0x1F8

Reset value: 0x0003 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERRF	Res.	Res.	Res.	Res.	Res.	Res.
									r						

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **VSYNC:**

This bit gives the state of the VSYNC pin with the correct programmed polarity if ENABLE bit is set into the DCMIPP_PRCR register and if the pixel clock is received. It is set during the blanking period whatever the polarity selected in VPOL bit, and cleared otherwise.

When embedded synchronization codes are used:

0: Active frame

1: Synchronization between frames

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMIPP_CR is set.

Bit 16 **HSYNC:**

This bit gives the state of the HSYNC pin with the correct programmed polarity if ENABLE bit is set into the DCMIPP_PRCR register and if the pixel clock is received. It is set during the blanking period whatever the polarity selected in HPOL bit, and cleared otherwise.

When embedded synchronization codes are used:

0: Active line

1: Synchronization between lines

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMIPP_CR is set.

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **ERRF:** Synchronization error raw interrupt status

0: No synchronization error detected

1: Embedded synchronization characters are not received in the correct order.

This bit is valid only in the embedded synchronization mode. It is cleared by writing 1 to the CERRF bit in DCMIPP_PRFCR.

This bit is available only in embedded synchronization mode.

Bits 5:0 Reserved, must be kept at reset value.

49.14.13 DCMIPP parallel interface interrupt clear register (DCMIPP_PRFCR)

Address offset: 0x1FC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CERRF	Res.	Res.	Res.	Res.	Res.	Res.
									w						

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CERRF:** Synchronization error interrupt status clear
Writing a 1 into this bit clears the ERRF bit in DCMIPP_PRSR.
This bit is available only in embedded synchronization mode.

Bits 5:0 Reserved, must be kept at reset value.

49.14.14 DCMIPP common IP HW configuration register (DCMIPP_CMHWCFGR)

Address offset: 0x200

Reset value: 0x0000 003C

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCSI	CPAR	CPIPES[1:0]		Res.	Res.
										r	r	r	r		

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CCSI:** Presence of the CSI-2 host interface
0: No input from CSI-2 host.
1: Input from CSI-2 host is implemented (independently from the presence of CSI-2 host).

Bit 4 **CPAR:** Presence of the parallel interface
0: Parallel interface input is not implemented.
1: Parallel interface input is implemented.

Bits 3:2 **CPIPES[1:0]:** Amount of instantiated pipes (either dump or pixel pipes)

Bits 1:0 Reserved, must be kept at reset value.

49.14.15 DCMIPP common configuration register (DCMIPP_CMCR)

Address offset: 0x204

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWAP RB	Res.	Res.	CFC	Res.	PSFC[1:0]		INSEL
								rw			w		rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **SWAPRB**: Swap R/U and B/V
0: RGB/VYU
1: BGR/UYV
These bits are not valid for Pipe0

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **CFC**: Clear frame counter
When this bit is set, the frame counter associated to a pipe is cleared. It resets DCMIPP_CMFRCR register. This bit is always read at 0.

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 **PSFC[1:0]**: Pipe selection for the frame counter
These bits (set and cleared by software) select on which pipe the frame counter is mapped.
00: Frame counter mapped to Pipe0
01: Frame counter mapped to Pipe1
10: Frame counter mapped to Pipe2
Other values: Reserved

Bit 0 **INSEL**: input selection
0: DCMI
1: CSI-2
This selection is common for all the pipes, meaning that the input source (DCMI or CSI) is exclusive. This bit must not be changed if one or more pipes are enabled or still in processing state after a disabling operation (corresponding CPTACT bit set into the DCMIPP_CMSR1 register).

49.14.16 DCMIPP common frame counter register (DCMIPP_CMFRCR)

Address offset: 0x208

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FRMCNT[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

FRMCNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **FRMCNT[31:0]**: Frame counter, read-only, loops around.
Incremented following VSYNC detection mapped to the pipe configured into bits PSFC[1:0] of the DCMIPP_CMCR register. The counter is cleared using the CRC bit of that register.

49.14.17 DCMIPP common test pattern generator configuration register 1 (DCMIPP_CMTPGCR1)

Address offset: 0x210

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	HEIGHT[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	WIDTH[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:16 **HEIGHT[13:0]**: Height of the visible pixels of the generated frame
Maximum value is 16383, the minimum must comply with the limitations of the DCMIPP.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **WIDTH[13:0]**: Width of the visible pixels of the generated frame
Maximum value is 16383, the minimum is 16.

49.14.18 DCMIPP common test pattern generator configuration register 2 (DCMIPP_CMTPGCR2)

Address offset: 0x214

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VBL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FORMAT[7:0]								RT[1:0]		YT[1:0]		PATTERN	GSEN	LFLEN	TPGEN
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **VBL[15:0]**: Amount of lines of the vertical blanking
Minimum value is 16.

Bits 15:8 **FORMAT[7:0]**: Pixel format generated:
0x1E: YUV422 (when selected, the YT field defines the YUV subformats)
0x22: RGB565
0x24: RGB888
0x2A: RAW8 (when selected, or RAW10/12/14, RT[1:0] gives the component sequence)
0x2B: RAW10
0x2C: RAW12
0x2D: RAW14
0x4A: monochrome 8-bit
0x4B: monochrome 10-bit
0x4C: monochrome 12-bit
0x4D: monochrome 14-bit
Other values: reserved

Bits 7:6 **RT[1:0]**: Raw Bayer type
Indicates the sequence of the R, G, G, B components. Taken in account when FORMAT is 0x2B, 0x2C, 0x2D:
0x0: RGGB
0x1: GRBG
0x2: GBRG
0x3: BGGR

Bits 5:4 **YT[1:0]**: YUV type
Indicates whether the YUV is defined as CCIR601 or 709, and whether its dynamic is full (0 to 255) or reduced (16 to 240) range.
0x0: BT.601 full range
0x1: BT.709 full range (standard for HDTV)
0x2: BT.601 reduced range (standard for SDTV)
0x3: BT.709 reduced range

Bit 3 **PATTERN**: Pattern selection, between color bars and color squares
0: color bars, with the frame divided vertically into 8 bars of the respective colors: white, yellow, cyan, green, pink, red, blue, black.
1: color squares, with the frame built of adjacent 256x256 color squares, each with a soft color gradient across each pixel. Most of the possible colors are present.

Bit 2 **GSEN**: Gray scale enable
0: disabled, with differentiated RGB colors
1: enabled, colors are converted into gray scales

Bit 1 **LFLEN**: Lifeline enable
0: disabled, the lifeline is not visible.
1: enabled, the lifeline is both visible and progressing down of one line per frame

Bit 0 **TPGEN**: Test pattern generator enable
0: disabled
1: enabled, frames are generated continuously, indefinitely

49.14.19 DCMIPP common interrupt enable register (DCMIPP_CMIER)

Address offset: 0x3F0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw				rw	rw	rw		rw	rw					

Bit 31 **P2OVRIE:** Overrun interrupt status enable for Pipe2
0: No interrupt generation
1: An interrupt is generated

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **P2VSYNCIE:** Vertical sync interrupt enable for Pipe2
0: No interrupt generation
1: An interrupt is generated

Bit 25 **P2FRAMEIE:** Frame capture complete interrupt enable for Pipe2
0: No interrupt generation
1: An interrupt is generated

Bit 24 **P2LINEIE:** Multi-line capture complete interrupt enable for Pipe2
0: No interrupt generation
1: An interrupt is generated

Bit 23 **P1OVRIE:** Overrun interrupt enable for Pipe1

Bits 22:20 Reserved, must be kept at reset value.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **P1VSYNCIE:** Vertical sync interrupt enable for Pipe1
0: No interrupt generation
1: An interrupt is generated

Bit 17 **P1FRAMEIE:** Frame capture complete interrupt enable for Pipe1
0: No interrupt generation
1: An interrupt is generated

Bit 16 **P1LINEIE:** Multi-line capture complete interrupt status clear for Pipe1
0: No interrupt generation
1: An interrupt is generated

Bit 15 **P0OVRIE:** Overrun interrupt enable for Pipe0
0: No interrupt generation
1: An interrupt is generated

Bit 14 **P0LIMITIE:** Limit interrupt enable for Pipe0
0: No interrupt generation
1: An interrupt is generated

Bits 13:11 Reserved, must be kept at reset value.

Bit 10 **P0VSYNCIE:** Vertical sync interrupt enable for Pipe0
0: No interrupt generation
1: An interrupt is generated

Bit 9 **P0FRAMEIE:** Frame capture complete interrupt enable for Pipe0
0: No interrupt generation
1: An interrupt is generated

Bit 8 **P0LINEIE:** Multi-line capture complete interrupt enable for Pipe0
0: No interrupt generation
1: An interrupt is generated

Bit 7 Reserved, must be kept at reset value.

Bit 6 **PRERRIE:** Limit interrupt enable for the parallel Interface
0: No interrupt generation
1: An interrupt is generated

Bit 5 **ATXERRIE:** AXI transfer error interrupt enable for IP-Plug
0: No interrupt generation
1: An interrupt is generated

Bits 4:0 Reserved, must be kept at reset value.

49.14.20 DCMIPP common status register 1 (DCMIPP_CMSR1)

Address offset: 0x3F4

Reset value: 0x0000 0003

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
P2CPTACT	Res.	Res.	Res.	Res.	Res.	P2LSTFRM	P2LSTLINE	P1CPTACT	Res.	Res.	Res.	Res.	Res.	P1LSTFRM	P1LSTLINE

r						r	r							r	r

Bit 31 **P2CPTACT**: Active frame capture (active from start-of-frame to frame complete) for Pipe2
0: No capture currently active
1: Capture currently active

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **P2LSTFRM**: Last frame LSB bit, sampled at frame capture complete event for Pipe2
The information is extracted from the frame data number that can be delivered by the camera through the CSI2 interface.

Bit 24 **P2LSTLINE**: Last line LSB bit, sampled at frame capture complete event for Pipe2
The first line of a frame is counted as 0.

Bit 23 **P1CPTACT**: Active frame capture (active from start-of-frame to frame complete) for Pipe1
0: No capture currently active
1: Capture currently active

Bits 22:20 Reserved, must be kept at reset value.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **P1LSTFRM**: Last frame LSB bit, sampled at frame capture complete event for Pipe1
The information is extracted from the frame data number, which can be delivered by the camera through the CSI2 interface.

Bit 16 **P1LSTLINE**: Last line LSB bit, sampled at Frame capture complete event for Pipe1

Bit 15 **P0CPTACT**: Active frame capture (active from start-of-frame to frame complete) for Pipe0
0: No capture currently active
1: Capture currently active

Bits 14:12 Reserved, must be kept at reset value.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **P0LSTFRM**: Last frame LSB bit, sampled at Frame capture complete event for Pipe0
The information is extracted from the frame data number that can be delivered by the camera through the CSI2 interface.

Bit 8 **P0LSTLINE**: Last line LSB bit, sampled at Frame capture complete event for Pipe0

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **PRVSYNC:**
This bit gives the state of the VSYNC pin with the correct programmed polarity on the parallel interface if ENABLE bit is set into the DCMIPP_PRCR register and if the pixel clock is received. It is set during the blanking period whatever the polarity selected in VPOL bit of the DCMIPP_PRCR register, and cleared otherwise.
When embedded synchronization codes are used, the meaning of this bit is the following:
0: Active frame
1: Synchronization between frames
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in the DCMIPP_PRCR register is set.

Bit 0 **PRHSYNC:**
This bit gives the state of the HSYNC pin with the correct programmed polarity on the parallel interface if ENABLE bit is set into the DCMIPP_PRCR register and if the pixel clock is received. It is set during the blanking period whatever the polarity selected in HPOL bit of the DCMIPP_PRCR register, and cleared otherwise.
When embedded synchronization codes are used the meaning of this bit is the following:
0: Active line
1: Synchronization between lines
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in the DCMIPP_PRCR register is set.

49.14.21 DCMIPP common status register 2 (DCMIPP_CMSR2)

Address offset: 0x3F8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r				r	r	r		r	r					

Bit 31 **P2OVRF:** Overrun raw interrupt status for Pipe2

0: No data buffer overrun occurred

1: A data buffer overrun occurred, and this frame data are corrupted

This bit is cleared by writing 1 to the CP2OVRF bit in DCMIPP_CMFCR.

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **P2VSYNCF:** VSYNC raw interrupt status for Pipe2

This bit is set when the VSYNC signal changes from the inactive state to the active state.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in the DCMIPP_CR register. It is cleared by writing 1 to the CP2VSYNCF bit in the DCMIPP_CMFCR register.

Bit 25 **P2FRAMEF:** Frame capture completed raw interrupt status for Pipe2

0: No capture or ongoing capture

1: All data of a frame have been captured

This bit is set when all data of a frame or window have been captured.

In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (for example window cropped outside the frame).

This bit is cleared by writing 1 to the CP2FRAMEF bit in the DCMIPP_CMFCR.

Bit 24 **P2LINEF:** Multi-line capture completed raw interrupt status for Pipe2

This bit is set when at least a line has been completed, and cleared by writing 1 to the CP2LINEF bit in the DCMIPP_CMFCR register.

The periodicity of LINEF event is configured by LINEMULT bits of the DCMIPP_P2PPCR register. When reaching end of frame, this event is triggered out to allow software action even if the LINEMULT value set is not a multiple of the total lines frame. For embedded synchronization, this bit is set only if the CAPTURE bit in the DCMIPP_CR register is set.

Bit 23 **P1OVRF:** Overrun raw interrupt status for Pipe1

0: No data buffer overrun occurred

1: A data buffer overrun occurred and this frame data are corrupted

This bit is cleared by writing 1 to the CP1OVRF bit in the DCMIPP_CMFCR register.

Bits 22:20 Reserved, must be kept at reset value.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **P1VSYNCF:** VSYNC raw interrupt status for Pipe1

This bit is set when the VSYNC signal changes from inactive to active state. In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in the DCMIPP_CR register. It is cleared by writing 1 to the CP1VSYNCF bit in the DCMIPP_CMFCR register.

Bit 17 **P1FRAMEF:** Frame capture completed raw interrupt status for Pipe1

0: No capture or ongoing capture

1: All data of a frame have been captured

This bit is set when all data of a frame or window have been captured. In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (for example window cropped outside the frame). This bit is cleared by writing 1 to the CP1FRAMEF bit in the DCMIPP_CMFCR register.

Bit 16 **P1LINEF:** Multi-line capture completed raw interrupt status for Pipe1

This bit is set when one/more lines have been completed. The periodicity of LINEF event is configured by LINEMULT bits into DCMIPP_P1PPCR register. When reaching end of frame, this event is triggered out to allow software action even if the LINEMULT value set is not a multiple of the total lines frame. In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMIPP_CR is set. It is cleared by writing 1 to the CP1LINEF bit in the DCMIPP_CMFCR register.

Bit 15 **P0OVRF:** Overrun raw interrupt status for Pipe0

0: No data buffer overrun occurred

1: A data buffer overrun occurred and this frame data are corrupted

This bit is cleared by writing 1 to the CP0OVRF bit in the DCMIPP_CMFCR register.

Bit 14 **P0LIMITF:** Limit raw interrupt status for Pipe0

This bit is set when the data counter DCMIPP_P0DCCNT reaches its maximum value DCMIPP_P0DCLIMIT. It is cleared by writing 1 to the CP0LIMITF bit in the DCMIPP_CMFCR register.

Bits 13:11 Reserved, must be kept at reset value.

Bit 10 **P0VSYNCF:** VSYNC raw interrupt status for Pipe0

This bit is set when the VSYNC signal changes from the inactive state to the active state.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMIPP_CR. It is cleared by writing 1 to the CP0VSYNCF bit in the DCMIPP_CMFCR register.

Bit 9 **P0FRAMEF:** Frame capture completed raw interrupt status for Pipe0

0: No capture or ongoing capture

1: All data of a frame have been captured

This bit is set when all data of a frame or window have been captured.

In case of a cropped window, this bit is set at the end of line of the last line in the crop, even if the captured frame is empty (for example window cropped outside the frame).

This bit is cleared by writing 1 to the CP0FRAMEF bit in the DCMIPP_CMFCR register.

Bit 8 **P0LINEF:** Multi-line capture completed raw interrupt status for Pipe0

This bit is set when one/more lines have been completed. The periodicity of LINEF event is configured by LINEMULT bits into DCMIPP_P0PPCR register. When reaching end of frame, this event is triggered out to allow software action even if the LINEMULT value set is not a multiple of the total lines frame.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit in the DCMIPP_CR register is set. It is cleared by writing 1 to the CP0LINEF bit in the DCMIPP_CMFCR register.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **PRERRF:** Synchronization error raw interrupt status for the parallel interface.
0: No synchronization error detected
1: Embedded synchronization characters are not received in the correct order.
This bit is valid only in the embedded synchronization mode. It is cleared by writing 1 to the CPRERRF bit in the DCMIPP_CMFCR register.
This bit is available only in embedded synchronization mode.

Bit 5 **ATXERRF:** AXI transfer error interrupt status flag for the IP-Plug.
0: No AXI transfer error detected
1: AXI transfer error occurred on an AXI client. This bit signals an error on a client without any specific hardware action, the software must handle the situation (normally used when debugging software application code).
This bit is cleared by writing 1 to CATXERRF bit in the DCMIPP_CMFCR register.

Bits 4:0 Reserved, must be kept at reset value.

49.14.22 DCMIPP common interrupt clear register (DCMIPP_CMFCR)

Address offset: 0x3FC

Reset value: 0x0000 0000

w	w				w	w	w		w	w					

Bit 31 **CP2OVRF:** Overrun interrupt status clear
Writing 1 into this bit clears the P2OVRF bit in the DCMIPP_CMSR2 register

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **CP2VSYNCF:** Vertical synchronization interrupt status clear
Writing 1 into this bit clears the P2VSYNCF bit in the DCMIPP_CMSR2 register

Bit 25 **CP2FRAMEF:** Frame capture complete interrupt status clear
Writing 1 into this bit clears the P2FRAMEF bit in the DCMIPP_CMSR2 register

Bit 24 **CP2LINEF:** Multi-line capture complete interrupt status clear
Writing 1 into this bit clears P2LINEF in the DCMIPP_CMSR2 register

Bit 23 **CP1OVRF:** Overrun interrupt status clear
Writing 1 into this bit clears the P1OVRF bit in the DCMIPP_CMSR2 register

Bits 22:20 Reserved, must be kept at reset value.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **CP1VSYNCF:** Vertical synchronization interrupt status clear
Writing 1 into this bit clears the P1VSYNCF bit in the DCMIPP_CMSR2 register

Bit 17 **CP1FRAMEF:** Frame capture complete interrupt status clear
Writing 1 into this bit clears the P1FRAMEF bit in the DCMIPP_CMSR2 register

Bit 16 **CP1LINEF:** Multi-line capture complete interrupt status clear
Writing 1 into this bit clears P1LINEF in the DCMIPP_CMSR2 register

Bit 15 **CP0OVRF:** Overrun interrupt status clear
Writing 1 into this bit clears the P0OVRF bit in the DCMIPP_CMSR2 register

Bit 14 **CP0LIMITF:** limit interrupt status clear
Writing 1 into this bit clears P0LIMITF in the DCMIPP_CMSR2 register

Bits 13:11 Reserved, must be kept at reset value.

Bit 10 **CP0VSYNCF:** Vertical synchronization interrupt status clear
Writing 1 into this bit clears the P0VSYNCF bit in the DCMIPP_CMSR2 register.

Bit 9 **CP0FRAMEF:** Frame capture complete interrupt status clear
Writing 1 into this bit clears the P0FRAMEF bit in the DCMIPP_CMSR2 register.

Bit 8 **CP0LINEF:** Multi-line capture complete interrupt status clear
Writing 1 into this bit clears P0LINEF in the DCMIPP_CMSR2 register

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CPRERRF:** Synchronization error interrupt status clear
Writing 1 into this bit clears the PRERRF bit in the DCMIPP_CMSR2 register.
This bit is available only in embedded synchronization mode.

Bit 5 **CATXERRF:** AXI transfer error interrupt status clear
Writing 1 into this bit clears the ATXERRF bit in the DCMIPP_CMSR2 register.

Bits 4:0 Reserved, must be kept at reset value.

49.14.23 DCMIPP Pipe0 HW configuration register (DCMIPP_P0HWCFGR)

Address offset: 0x400

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

		r		r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **CVP:** Capability for pipeline virtualization
0: No virtualization for the pipe
1: Virtualization mechanism implemented for the pipe

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **CROI[3:0]:** Capability for ROI: defines the number of ROIs in the pipe

Bits 7:6 **CGM[1:0]:** Capability for gamma conversions
00: No gamma conversion
01: Gamma conversion with three interpolated segments
10, 11: Reserved.

Bits 5:4 **CRB[1:0]:** Capability for demosaicing
00: No demosaicing
01: Demosaicing with 2018-03 algorithm (Matrix 3 x 3 with Edge/LineHV/Peak)
10, 11: Reserved

Bit 3 **DBM:** Double buffer mode
0: No Double buffer mode supported
1: Double buffer mode supported

Bit 2 **CDS:** Capability for downsize filter
0: No downsize filter, basic decimation instead
1: Downsize filter based on a BoxFilter

Bits 1:0 **CPLA[1:0]:** Capability for planar buffers
00: Capability to dump to a coplanar buffer only
01: Capability to dump to a semi-planar buffer (i.e. YUV420-2)
10: Capability to dump to full-planar buffer (i.e. YUV420-3)
11: Reserved

49.14.24 DCMIPP Pipe0 flow selection configuration register (DCMIPP_P0FSCR)

Address offset: 0x404

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PIPEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VC[1:0]		Res.	DTMODE[1:0]	
rw											rw	rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	DTIDB[5:0]						Res.	Res.	DTIDA[5:0]					
		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bit 31 **PIPEN**: Activation of PipeN
0: Pipe disabled
1: Pipe enabled, can start capturing with CPTMODE, CPTREQ, CPTACK

Note: This bit is not shadowed, differently from all other bits in this register.

Bits 30:21 Reserved, must be kept at reset value.

Bits 20:19 **VC[1:0]**: Flow selection mode
Virtual channel ID of the CSI flow to select for further processing on the pipe.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DTMODE[1:0]**: Flow selection mode
00: Only flow DTIDA from the selected virtual channel is forwarded in the pipe
01: Flows DTIDA and/or DTIDB from the selected virtual channel are forwarded in the pipe
10: All data types from the selected virtual channel (except the DTIDA or DTIDB) are forwarded in the pipe
11: All data types of the selected virtual channel VC are forwarded in the pipe

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **DTIDB[5:0]**: Data type selection ID B
Data type ID of the CSI flow to select.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DTIDA[5:0]**: Data type selection ID A
Data type ID of the CSI flow to select.

49.14.25 DCMIPP Pipe0 flow control configuration register (DCMIPP_P0FCTCR)

Address offset: 0x500

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPT REQ	CPT MODE	FRATE[1:0]	
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **CPTREQ:** Capture requested
0: Capture not requested for next frame
1: Capture requested for next frame
When PIPEN = 1 and CPTREQ = 1. the pipe waits for the first VSync, automatically starts a capture, and sets CPTACT = 1 to mention it.
In Snapshot mode the CPTREQ bit is cleared at the start of the first received frame.
In Continuous grab mode, the capture remains active and CPTREQ = 1 until the software clears CPTREQ: the capture stops and CPTACT is reset at the end of the ongoing frame.
The DCMI and pipe configuration registers must be correctly programmed before enabling this bit.

Bit 2 **CPTMODE:** Capture mode
0: Continuous grab mode - The received data are transferred into the destination memory through the AXI master.
1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame, and then transfers a single frame through the AXI master. At the end of the frame, the CPTACT bit is automatically reset.

Bits 1:0 **FRATE[1:0]:** Frame capture rate control

These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode, ignored in Snapshot mode.

00: All frames are captured

01: one out of two frames captured (50% bandwidth reduction)

10: one out of four frames captured (75% bandwidth reduction)

11: one out of eight frames captured (87% bandwidth reduction)

49.14.26 DCMIPP Pipe0 statistic/crop start register (DCMIPP_P0SCSTR)

Address offset: 0x504

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	VSTART[11:0]

Res.	Res.	Res.	Res.	HSTART[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **VSTART[11:0]**: Vertical start, from 0 to 4094 pixels high

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSTART[11:0]**: Horizontal start, from 0 to 4094 words wide

49.14.27 DCMIPP Pipe0 statistic/crop size register (DCMIPP_P0SCSZR)

Address offset: 0x508

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ENABLE	POSNEG	Res.	Res.	VSIZE[11:0]											
rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HSIZE[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **ENABLE**:

This bit is set and cleared by software.

0: Bypass. All the data are computed, if the statistic data are sent within the frame, they are sent to the processing pipe as pixels data.

1: Enable. Depending on bit POSNEG value, the rectangle defined by VSIZE, HSIZE, VSTART and HSTART can be used to extract or to remove some data (statistical extraction or removal, or basic 2D crop features).

if POSNEG = 0, the data inside the rectangle area are transmitted (it can correspond to a statistical data removal, or as a crop feature in a data valid image area).

if POSNEG = 1, the data outside of the rectangle area are transmitted (it can correspond to a statistical data extraction, rejecting all data inside the window).

This bit must be kept cleared if the input format is JPEG, to avoid unpredictable behavior of the pipe.

Bit 30 **POSNEG**:

This bit is set and cleared by software. It has a meaning only if ENABLE bit is set.

0: Positive area, the rectangle defined by VSIZE, HSIZE, and VSTART, HSTART

1: Negative area, the area excluding the rectangle defined by VSIZE, HSIZE, and VSTART, HSTART

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:16 **VSIZE[11:0]**: Vertical size, from 0 to 4094 pixels high

If the value is maintained at 0 when enabling the crop by means of ENABLE bit, the crop operation is not performed on vertical direction.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSIZE[11:0]**: Horizontal size, from 0 to 4094 word wide (data 32-bit)

If the value is maintained at 0 when enabling the crop by means of ENABLE bit, the crop operation is not performed on horizontal direction.

49.14.28 DCMIPP Pipe0 dump counter register (DCMIPP_P0DCCNTR)

Address offset: 0x5B0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	CNT[25:16]									
						r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **CNT[25:0]**: Number of data dumped during the frame.

The size of the data is expressed in bytes. It counts only the data selected by means of the CROP 2D function. The counter saturates at 0x3FFFFFF. Granularity is 32-bit for all the formats except for the byte stream formats (for example JPEG) having byte granularity.

49.14.29 DCMIPP Pipe0 dump limit register (DCMIPP_P0DCLMTR)

Address offset: 0x5B4

Reset value: 0x00FF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ENABLE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LIMIT[23:16]

LIMIT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **ENABLE**:
0: Disabled, no check on the amount of 32-bit words transmitted
1: Enabled, check done versus limit

Bits 30:24 Reserved, must be kept at reset value.

Bits 23:0 **LIMIT[23:0]**: Maximum number of 32-bit data that can be dumped during a frame, after the crop 2D operation.

49.14.30 DCMIPP Pipe0 pixel packer configuration register (DCMIPP_P0PPCR)

Address offset: 0x5C0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw	rw		rw	rw	rw	rw	rw	rw	rw					rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 Reserved, must be kept at reset value.

Bits 15:13 **LINEMULT[2:0]**: Amount of capture completed lines for LINE event and interrupt
0x0: Event after one line
0x1: Event after two lines
0x2: Event after four lines
0x3: Event after eight lines
0x4: Event after sixteen lines
0x5: Event after 32 lines
0x6: Event after 64 lines
0x7: Event after 128 lines

Bit 12 Reserved, must be kept at reset value.

Bit 11 **OELS:** Odd/even line select (line select start)
This bit works in conjunction with LSM field (LSM = 1).
0: Interface captures first line after the frame start, second one is dropped
1: Interface captures second line from the frame start, first one is dropped

Bit 10 **LSM:** Line select mode
0: Interface captures all received lines
1: Interface captures one line out of two

Bit 9 **OEBS:** Odd/even byte select (byte select start)
This bit works in conjunction with BSM field (BSM ≠ 00)
0: Interface captures the first data (byte or double byte) from the frame/line start, the second one is dropped
1: Interface captures the second data (byte or double byte) from the frame/line start, the first one is dropped
This bit has a meaning only if INSEL = 0 into the DCMIPP_CMCR register.

Bits 8:7 **BSM[1:0]:** Byte select mode
00: Interface captures all received data
01: Interface captures 1 data out of 2
10: Interface captures one byte out of four
11: Interface captures two bytes out of four
Modes 10 and 11 work only with EDM [2:0] = 000 into the DCMIPP_PRCR register.
This bit has a meaning only if INSEL = 0 into the DCMIPP_CMCR register

Bit 6 **HEADEREN:** CSI header dump enable
0: CSI-2 headers are not dumped
1: CSI-2 headers are dumped as a 32-bit word.
This setting is ignored for parallel interface mode, as there are no headers.

Bit 5 **PAD:** Pad mode for monochrome and raw Bayer 10/12/14 bpp (MSB vs. LSB alignment)
0: Aligns on LSB (and pads null bits on MSB), for backward compatibility with former DCMI.
1: Aligns on MSB (and pads null bits on LSB), for better ease of software or GPU.

Bits 4:1 Reserved, must be kept at reset value.

Bit 0 **SWAPYUV:** Swaps, within a 32-bit word, byte 0-vs-1 and byte 2-vs-3. It corresponds, for YUV422 pixels formats, to swap between UYVY and YUYV.
0: Outputs the provided words, as described in *Section 49.10: Pixel format description*.
1: Swaps the bytes from provided words, byte 0-vs.-1 and 2-vs.-3

49.14.31 DCMIPP Pipe0 pixel packer Memory0 address register 1 (DCMIPP_P0PPM0AR1)

Address offset: 0x5C4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
M0A[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
M0A[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r	r	r

Bits 31:0 **M0A[31:0]**: Memory0 address
Base address of memory area 0, to whom data are written. It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0.

49.14.32 DCMIPP Pipe0 status Memory0 address register (DCMIPP_P0STM0AR)

Address offset: 0x5D0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
M0A[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **M0A[31:0]**: Memory0 address

Base address of memory area 0, to whom data are written. It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0.

The register returns the status of the last captured frame.

49.14.33 DCMIPP Pipe0 interrupt enable register (DCMIPP_P0IER)

Address offset: 0x5F4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR IE	LIMIT IE	Res.	Res.	Res.	VSYNC IE	FRAME IE	LINE IE
								rw	rw				rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OVRIE:** Overrun interrupt enable

0: No interrupt generation

1: An interrupt is generated if the AXI master is unable to transfer the last data before new data (32-bit) are received.

Bit 6 **LIMITIE:** Limit interrupt enable

0: No interrupt generation when the limit is reached

1: An interrupt is generated when the limit is reached

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **VSYNCIE:** VSYNC interrupt enable

0: No interrupt generation

1: An interrupt is generated on each VSYNC (captured or not)

Bit 1 **FRAMEIE:** Frame capture completed interrupt enable

0: No interrupt generation

1: An interrupt is generated after the full capture of a cropped frame

Bit 0 **LINEIE:** Multi-line capture completed interrupt enable
0: No interrupt generation when the line is received
1: An interrupt is generated after the full capture of a group of lines (or last line reached)

49.14.34 DCMIPP Pipe0 status register (DCMIPP_P0SR)

Address offset: 0x5F8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPTACT	Res.	Res.	Res.	Res.	Res.	LST FRM	LST LINE
								r						r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR F	LIMIT F	Res.	Res.	Res.	VSYNC F	FRAME F	LINE F
								r	r				r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **CPTACT:** Capture immediate status
0: Capture currently inactive
1: Capture currently active
This bit is automatically reset at the end of frame capture complete event (after all the data of that frame have been captured and the IP-Plug has started to emit the last burst on the AXI, usually before the next VSync).

Bits 22:20 Reserved, must be kept at reset value.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **LSTFRM**: Last frame LSB bit, sampled at frame capture complete event. The information is extracted from the frame data number that can be delivered by the camera through the CSI2 interface.

Bit 16 **LSTLINE**: Last line LSB bit, sampled at frame capture complete event.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **OVRF:** Overrun raw interrupt status
0: No data buffer overrun occurred
1: A data buffer overrun occurred and this frame data are corrupted
This bit is cleared by writing 1 to the COVRF bit in the DCMIPP_P0FCR register.

Bit 6 **LIMITF:** Limit raw interrupt status
This bit is set when the data counter DCMIPP_PxDCCNTR reaches its maximum value DCMIPP_PxDCLIMITR.
It is cleared by writing 1 to the CLIMITF bit in the DCMIPP_P0FCR register.

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **VSYNCF:** VSYNC raw interrupt status
This bit is set when the VSYNC signal changes from the inactive state to the active state. In case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMIPP_CR.
It is cleared by writing 1 to the CVSYNCF bit in the DCMIPP_P0FCR register.

Bit 1 **FRAMEF:** Frame capture completed raw interrupt status

0: No capture or ongoing capture

1: All data of a frame have been captured

This bit is set when all data of a frame or window have been captured. In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (for example window cropped outside the frame).

This bit is cleared by writing 1 to the CFRAMEF bit in DCMIPP_P0FCR.

Bit 0 **LINEF:** Multi-line capture completed raw interrupt status

This bit is set when one/more lines have been completed. For the JPEG mode, this bit is raised at the end of the frame.

The periodicity of LINEF event is configured by LINEMULT bits into DCMIPP_P0PPCR register. When reaching end of frame, this event is triggered out to allow software action even if the LINEMULT value set is not a multiple of the total lines frame.

In case of embedded synchronization, this bit is set only if the CAPTURE bit in the DCMIPP_CR register is set. It is cleared by writing 1 to the CLINEF bit in the DCMIPP_P0FCR register.

49.14.35 DCMIPP Pipe0 interrupt clear register (DCMIPP_P0FCR)

Address offset: 0x5FC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COVRF	CLIMITF	Res.	Res.	Res.	CVSYNCF	CFRAMEF	CLINEF
								w	w				w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **COVRF:** Overrun interrupt status clear

Writing 1 into this bit clears the OVRF bit in the DCMIPP_P0SR register.

Bit 6 **CLIMITF:** limit interrupt status clear

Writing 1 into this bit clears LIMITF in the DCMIPP_P0SR register.

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **CVSYNCF:** Vertical synchronization interrupt status clear

Writing 1 into this bit clears the VSYNCF bit in the DCMIPP_P0SR register.

Bit 1 **CFRAMEF:** Frame capture complete interrupt status clear

Writing 1 into this bit clears the FRAMEF bit in the DCMIPP_P0SR register.

Bit 0 **CLINEF:** Multi-line capture complete interrupt status clear

Writing 1 into this bit clears LINEF in the DCMIPP_P0SR register.

49.14.36 DCMIPP Pipe0 current flow selection configuration register (DCMIPP_P0CFSCR)

Address offset: 0x604

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PIPEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VC[1:0]		Res.	DTMODE[1:0]	
r											r	r		r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	DTIDB[5:0]						Res.	Res.	DTIDA[5:0]					
		r	r	r	r	r	r			r	r	r	r	r	r

Bit 31 **PIPEN**: Current activation of PipeN
0: Pipe disabled
1: Pipe enabled, can start capturing with CPTMODE, CPTREQ, CPTACK.

Bits 30:21 Reserved, must be kept at reset value.

Bits 20:19 **VC[1:0]**: Current flow selection mode
Virtual channel ID of the CSI flow to select for further processing on the pipe.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DTMODE[1:0]**: Flow selection mode
00: Only flow DTIDA from the selected virtual channel is forwarded in the pipe.
01: Flows DTIDA and/or DTIDB from the selected virtual channel are forwarded in the pipe.
10: All Datatypes from the selected virtual channel, except the DTIDA or DTIDB are forwarded into the pipe.
11: All Datatypes of the selected virtual channel VC are forwarded in the pipe.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **DTIDB[5:0]**: Current data type selection ID B
Data type ID of the CSI flow to select.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DTIDA[5:0]**: Current data type selection ID A
Data type ID of the CSI flow to select.

49.14.37 DCMIPP Pipe0 current flow control configuration register (DCMIPP_P0CFCTCR)

Address offset: 0x700

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPT REQ	CPT MODE	FRATE[1:0]	
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **CPTREQ:** Capture requested

0: Capture not requested for next frame.

1: Capture requested for next frame.

When PIPEN = 1, and when the CPTREQ is set to 1 the pipe waits for the first VSync, and automatically starts a capture and sets CPTACT = 1 to mention it.

In Snapshot mode the CPTREQ bit is automatically cleared at the start of the first frame received.

In continuous grab mode the capture remains active and CPTREQ = 1, until the software clears CPTREQ: the capture stops and CPTACT is reset at the end of the ongoing frame.

The DCMI and pipe configuration registers must be correctly programmed before enabling this bit.

Bit 2 **CPTMODE:** Capture mode

0: Continuous grab mode - The received data are transferred into the destination memory through the AXI master.

1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame, and then transfers a single frame through the AXI master. At the end of the frame the CPTACT bit is automatically reset.

Bits 1:0 **FRATE[1:0]:** Frame capture rate control

These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode, ignored in Snapshot mode.

00: all frames are captured

01: one out of two frames captured (50% bandwidth reduction)

10: one out of four frames captured (75% bandwidth reduction)

11: one out of eight frames captured (87% bandwidth reduction)

49.14.38 DCMIPP Pipe0 current statistic/crop start register (DCMIPP_P0CSCSTR)

Address offset: 0x704

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	VSTART[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HSTART[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **VSTART[11:0]**: Current vertical start, from 0 to 4094 pixels high

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSTART[11:0]**: Current horizontal start, from 0 to 4094 words wide

49.14.39 DCMIPP Pipe0 current statistic/crop size register (DCMIPP_P0CSCSZR)

Address offset: 0x708

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ENABLE	POSNEG	Res.	Res.	VSIZE[11:0]											
r	r			r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HSIZE[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **ENABLE**: Current value of the ENABLE bit

0: Bypass. All data are computed, if the statistics data are sent within the frame, they are sent to the processing pipe as pixels data.

1: Enable: Depending on bit POSNEG value, the rectangle defined by the VSIZE, HSIZE, VSTART, HSTART can be used to extract or to remove certain amount of data (statistical extraction or removal, or basic 2D crop features)

if POSNEG = 0, the data inside the rectangle area are transmitted (can correspond to a statistical data removal, or as a crop feature in a data valid image area).

if POSNEG = 1, the data outside of the rectangle area are transmitted (can correspond to a statistical data extraction, rejecting all data inside the window)

Bit 30 **POSNEG**: Current value of the POSNEG bit

This bit has a meaning only if ENABLE bit is set.

0: Positive area. The rectangle defined by VSIZE,HSIZE, and VSTART, HSTART is the active area.

1: Negative area. The active area is the area excluding the rectangle defined by VSIZE, HSIZE, and VSTART, HSTART.

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:16 **VSIZE[11:0]**: Current vertical size, from 0 to 4094 pixels high.

If the value is maintained at 0 when enabling the crop by means of the ENABLE bit, the value is forced internally at 0xFFE which is the maximum value.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSIZE[11:0]**: Current horizontal size, from 0 to 4094 word wide (data 32-bit).

If the value is maintained at 0 when enabling the crop by means of the ENABLE bit, the value is forced internally at 0xFFE, which is the maximum value.

49.14.40 DCMIPP Pipe0 current pixel packer configuration register (DCMIPP_P0CPPCR)

Address offset: 0x7C0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LINEMULT[2:0]			Res.	OELS	LSM	OEBS	BSM[1:0]		HEADER EN	PAD	Res.	Res.	Res.	Res.	SWAP YUV
r	r	r		r	r	r	r	r	r	r					r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:13 **LINEMULT[2:0]**: Current amount of capture completed lines for LINE event and interrupt
0x0: Event after every line
0x1: Event after two lines
0x2: Event after four lines
0x3: Event after eight lines
0x4: Event after sixteen lines
0x5: Event after 32 lines
0x6: Event after 64 lines
0x7: Event after 128 lines

Bit 12 Reserved, must be kept at reset value.

Bit 11 **OELS:** Current odd/even line select (ine select start)
This bit works in conjunction with LSM field (LSM = 1)
0: Interface captures the first line after the frame start, the second one is dropped
1: Interface captures the second line from the frame start, the first one is dropped
This bit has a meaning only if INSEL = 0 in the DCMIPP_CMCR register.

Bit 10 **LSM:** Current Line select mode
0: Interface captures all received lines
1: Interface captures one line out of two
This bit has a meaning only if INSEL = 0 in the DCMIPP_CMCR register.

Bit 9 **OEBS:** Current odd/even byte select (byte select start)
This bit works in conjunction with BSM field (BSM ≠ 00)
0: Interface captures the first data (byte or double byte) from the frame/line start, the second one is dropped
1: Interface captures the second data (byte or double byte) from the frame/line start, the first one is dropped
This bit has a meaning only if INSEL = 0 in the DCMIPP_CMCR register.

Bits 8:7 **BSM[1:0]:** Current Byte select mode
00: Interface captures all received data
01: Interface captures one data out of two
10: Interface captures one byte out of four
11: Interface captures two bytes out of four
Modes 10 and 11 work only with EDM [2:0] = 000 into the DCMIPP_PRCR register.
This bit has a meaning only if INSEL = 0 into the DCMIPP_CMCR register

Bit 6 **HEADEREN:** Current CSI header dump enable
0: CSI-2 headers are not dumped.
1: CSI-2 headers are dumped as 32-bit words.
This setting is ignored for Parallel interface mode, as there are no headers.

Bit 5 **PAD:** Current Pad mode for monochrome and raw Bayer 10/12/14 bpp (MSB vs. LSB alignment)
0: Aligns on LSB (and pads null bits on MSB), for backward compatibility with former DCMI
1: Aligns on MSB (and pads null bits on LSB), for better ease of software or GPU

Bits 4:1 Reserved, must be kept at reset value.

Bit 0 **SWAPYUV:** *S*waps, within a 32-bit word, byte 0 vs. 1 and byte 2 vs. 3. It corresponds, for YUV422 pixels formats, to swap between UYVY and YUYV.
0: Outputs the provided words, as described in *Section 49.10: Pixel format description*.
1: Swaps the bytes from provided words, byte 0 vs. 1 and 2 vs. 3.

49.14.41 DCMIPP Pipe0 current pixel packer Memory0 address register 1 (DCMIPP_P0CPPM0AR1)

Address offset: 0x7C4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
M0A[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
M0A[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **M0A[31:0]**: Memory0 address

Base address of the current memory area 0, to whom data are written. It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0.

49.14.42 DCMIPP Pipex HW configuration register (DCMIPP_PxHWCFGR)

Address offset: 0x800 + (x - 1) * 0x400, (x = 1 to 2)

Reset value: 0x0000 0056, 0x0000 0044

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CFOC	CLS	CHS

		r		r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **CFOC:** Capability for focus extraction
- 0: Focus extraction not supported
- 1: Focus extraction supported

Bit 17 **CLS:** Capability for lens shading
- 0: Lens shading not supported
- 1: Lens shading supported

Bit 16 **CHS:** Capability to extract histograms
- 0: Histogram extraction not supported
- 1: Histogram extraction supported

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **CVP:** Capability for pipeline virtualization
- 0: No virtualization for the pipe
- 1: Virtualization mechanism implemented for the pipe

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **CROI[3:0]:** Capability for ROI: defines the number of ROIs in the pipe

Bits 7:6 **CGM[1:0]:** Capability for gamma conversions
00: No gamma conversion
01: Gamma conversion with seven interpolated segments
10, 11: Reserved

Bits 5:4 **CRB[1:0]:** Capability for demosaicing
00: No demosaicing
01: Demosaicing with 2018-03 algorithm (Matrix 3 x 3 with Edge/LineHV/Peak)
10, 11: Reserved

Bit 3 **DBM:** Double buffer mode
0: No Double buffer mode supported
1: Double buffer mode supported

Bit 2 **CDS:** Capability for downsize filter
0: No downsize filter, basic decimation instead
1: Downsize filter based on a BoxFilter

Bits 1:0 **CPLA[1:0]:** Capability for planar buffers
00: Capability to dump to a coplanar buffer only
01: Capability to dump to a semi-planar buffer (i.e. YUV420-2)
10: Capability to dump to full-planar buffer (i.e. YUV420-3)
11: Reserved

49.14.43 DCMIPP Pipe1 flow selection configuration register (DCMIPP_P1FSCR)

Address offset: 0x804

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PIPEN	FDTFEN	FDTF[5:0]						Res.	Res.	Res.	VC[1:0]		PIPEDIFF	DTMODE[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw				rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	DTIDB[5:0]						Res.	Res.	DTIDA[5:0]					
		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bit 31 **PIPEN**: Activation of PipeN
0: Pipe disabled
1: Pipe enabled, can start capturing with CPTMODE, CPTREQ, CPTACK

Bit 30 **FDTFEN**: Force Datatype format enable
0: Disable force Datatype format. The Datatype format used by the pipe is the one defined into DTIDx1: Enable force Datatype format. When the Datatype DTIDx is detected by the pipe, the real pixel format considered by the pipe is the one set into the FDTF[5:0] bit field instead of the physical one received by the CSI2 Host. It allows to handle, for instance, 3D sensors camera using user data type in bottom-up approach, and to explicitly define the pixel format to be handled by the pipe. Note that the flow is first selected using the DTMODE and DTIDA/B, and then, if selected, its data type may be forced with the to FDTC using FDTFEN = 1.

Bits 29:24 **FDTF[5:0]**: Force Datatype format
Forcing the Datatype format. This Datatype overwrites the one received by the CSI2-HOST by specifying the pixel format to consider. The value must follow the CSI2 Datatype format definition in the CSI2 standard. This bit field has no meaning if the FDTFEN bit is cleared.

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:19 **VC[1:0]**: Flow selection mode
Virtual channel ID of the CSI flow to select for further processing on the pipe.

Bit 18 **PIPEDIFF:** Differentiates Pipe2 from Pipe1
0: Pipe2 receives the same data as Pipe1 (data filtered by Pipe1 configuration for VC and DTIDA/DTIDB and DTMODE mode, as well as FDTF and FDTFEN bit).
1: Pipe1 gets pixels only from VC and DT configured in Pipe1, processed by all blocks belonging to the image processing functional block (demosaicing, auto exposure, statistics, contrast enhancement). Pipe2 gets pixels only from VC/DTID and FDTFEN/FDTF bits configured in Pipe2, processed from Crop. There are no shared functions with Pipe1, fully independent.
This bit must be kept cleared when INSEL = 0 into the DCMIPP_CMCR register.

Bits 17:16 **DTMODE[1:0]**: Flow selection mode
00: Only flow DTIDA from the selected virtual channel is forwarded in the pipe
01: Flows DTIDA and/or DTIDB from the selected virtual channel are forwarded in the pipe
Other values: Reserved.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **DTIDB[5:0]**: Data type selection ID B
Data type ID of the CSI flow to select.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DTIDA[5:0]**: Data type selection ID A
Data type ID of the CSI flow to select.

49.14.44 DCMIPP Pipe1 stat removal configuration register (DCMIPP_P1SRCR)

Address offset: 0x820

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CROP EN	FIRSTLINEDEL[2:0]			LASTLINE[11:0]											
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **CROPEN**: Crop line enable
0: No crop (all pixels are fed through)
1: Crop

Bits 14:12 **FIRSTLINEDEL[2:0]**: Amount of first lines to delete when CROPEN = 1

Bits 11:0 **LASTLINE[11:0]**: Amount of following lines to keep when CROPEN = 1. If LASTLINE = 0 all pixels after FIRSTLINEDEL are fed through.

49.14.45 DCMIPP Pipe1 bad pixel removal control register (DCMIPP_P1BPRCR)

Address offset: 0x824

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	STRENGTH[2:0]			ENABLE
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:1 **STRENGTH[2:0]**: Strength (aggressiveness) of the bad pixel detection
0x0: The filter is fairly tolerant: only a few pixels are declared bad, due to their high noise
...
0x7: The filter is very aggressive: many pixels are declared bad, even if only slightly noisy.

Bit 0 **ENABLE**:
0: Bypass: bad pixel removal is not active, all pixels are transmitted through
1: Enable: if bad pixel are detected, they are replaced by corrected pixels
Bad pixel detection must be enabled only for raw Bayer flows, as it corrupts RGB flows.

49.14.46 DCMIPP Pipe1 bad pixel removal status register (DCMIPP_P1BPRSR)

Address offset: 0x828

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	BADCNT[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **BADCNT[11:0]**: Amount of detected bad pixels
Counts the amount of bad pixels detected in each frame, and if too many, saturates at its maximum value (4095). It is reclocked at the frame end, to remain stable for reading during the next frame.

49.14.47 DCMIPP Pipe1 decimation register (DCMIPP_P1DECR)

This register controls the input decimation.

Address offset: 0x830

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VDEC[1:0]		HDEC[1:0]		ENABLE
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:3 **VDEC[1:0]**: Vertical decimation ratio

0x0: All pixels are transmitted, no vertical decimation

0x1: one line out of two transmitted (for raw Bayer data, two lines of components every four)

0x2: one line out of four transmitted (for raw Bayer data, two lines of components every eight)

0x3: one line out of eight transmitted (for raw Bayer data, two lines of components every 16)

Bits 2:1 **HDEC[1:0]**: Horizontal decimation ratio

0x0: All pixels are transmitted, no horizontal decimation

0x1: one line out of two transmitted (for raw Bayer data, two lines of components every four)

0x2: one line out of four transmitted (for raw Bayer data, two lines of components every eight)

0x3: one line out of eight transmitted (for raw Bayer data, two lines of components every 16)

Bit 0 **ENABLE**:

0: Bypass: decimation is not active, all pixels are transmitted

1: Enable: one pixel every 1, 2, 4, or 8, in H and V is transmitted, following HDEC and VDEC

49.14.48 DCMIPP Pipe1 black level calibration control register (DCMIPP_P1BLCCR)

Address offset: 0x840

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BLCR[7:0]								BLCG[7:0]

BLCB[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	ENABLE
rw	rw	rw	rw	rw	rw	rw	rw								rw

Bits 31:24 **BLCR[7:0]**: Black level calibration - Red

Value subtracted from the red input MSB component, whether it is on 8, 10, 12, 14 bits.

Bits 23:16 **BLCG[7:0]**: Black level calibration - Green

Value subtracted from the green input MSB component, whether it is on 8, 10, 12, 14 bits.

Bits 15:8 **BLCB[7:0]**: Black level calibration - Blue
Value subtracted from the blue input MSB component, whether it is on 8, 10, 12, 14 bits.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**: Black level calibration
0: Bypass: black level calibration is not active, all pixels are transmitted non-modified.
1: Enable: the BLC R, G, B are subtracted.

49.14.49 DCMIPP Pipe1 exposure control register 1 (DCMIPP_P1EXCR1)

Address offset: 0x844

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **SHFR[2:0]**: Exposure shift - Red
0x0, 0x1, 0x2, 0x3, 0x4, 0x5, 0x6, 0x7: exposure of reds is increased, respectively, by a factor 1x, 2x, 4x, 8x, 16x, 32x, 64x, 128x.

Bits 27:20 **MULTR[7:0]**: Exposure multiplier - Red
Value that is multiplied for the red input components, whether it is on 8, 10, 12, 14 bits.
Multiplying by 64 reduces the exposure (darkens the reds) by a factor 2x.
Multiplying by 128 does not modify the exposure (keeps the reds as-is).
Multiplying by 255 increase the exposure (lightens the reds) by a factor ~2x.

Bits 19:1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**: Exposure control (multiplication and shift) of all red, green and blue
0: Bypass: exposure multiplier and shift are not applied
1: Enable: the exposure multiplication and shift is applied

49.14.50 DCMIPP Pipe1 exposure control register 2 (DCMIPP_P1EXCR2)

Address offset: 0x848

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SHFG[2:0]			MULTG[7:0]								Res.	Res.	Res.	Res.

Res.	SHFB[2:0]			MULTB[7:0]								Res.	Res.	Res.	Res.
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **SHFG[2:0]**: Exposure shift - Green

0x0, 0x1, 0x2, 0x3, 0x4, 0x5, 0x6, 0x7: Exposure of greens is increased, respectively, by a factor 1x, 2x, 4x, 8x, 16x, 32x, 64x, 128x.

Bits 27:20 **MULTG[7:0]**: Exposure multiplier - Green

Value that is multiplied for the green input components, whether it is on 8, 10, 12, 14 bits.
Multiplying by 64 reduces the exposure (darkens the greens) by a factor 2x.
Multiplying by 128 does not modify the exposure (keeps the greens as-is).
Multiplying by 255 increases the exposure (lightens the greens) by a factor ~2x.

Bits 19:15 Reserved, must be kept at reset value.

Bits 14:12 **SHFB[2:0]**: Exposure shift - Blue

0x0, 0x1, 0x2, 0x3, 0x4, 0x5, 0x6, 0x7: exposure of blues is increased, respectively, by a factor 1x, 2x, 4x, 8x, 16x, 32x, 64x, 128x.

Bits 11:4 **MULTB[7:0]**: Exposure multiplier - Blue

Value that is multiplied for the blue input components, whether it is on 8, 10, 12, 14 bits.
Multiplying by 64 reduces the exposure (darkens the blues) by a factor 2x.
Multiplying by 128 does not modify the exposure (keeps the blues as-is).
Multiplying by 255 increases the exposure (lightens the blues) by a factor ~2x.

Bits 3:0 Reserved, must be kept at reset value.

49.14.51 DCMIPP Pipe1 statistics1 control register (DCMIPP_P1ST1CR)

Address offset: 0x850

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

								rw	rw	rw	rw	rw	rw		rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **MODE**: Statistics mode

0: Average: accumulates the 8-bit component value of the considered pixel components.
Typically used to extract the average value of R, G, B, or luminance across the picture, and to drive the exposure control and the white balance.
1: Bins: accumulates 256 for each considered pixel component fitting a bin dynamic.
Typically used to extract how many pixel components fall into the various dynamic bins, and to drive the contrast enhancement.

Bits 6:4 **SRC[2:0]**: Statistics source

0x0, 0x1, 0x2, 0x3: components are sampled before the black level calibration and exposure, and sample, respectively, red, green, blue, and luminance (computed as R / 4 + G / 2 + B / 4). For raw Bayer formats, only one component is available by pixel.
0x4, 0x5, 0x6, 0x7: components are sampled after demosaicing, and sample, respectively, red, green, blue, and luminance.

Bits 3:2 **BINS[1:0]**: Current bin definition
Condition: MODE = Bins
0x0: LowerBins: Accu0 (1, 2) is incremented of 256 if Component <4 (<8, <16)
0x1: LowMid Bins: Accu0 (1, 2) is incremented of 256 if Component <32 (<64, <128)
0x2: UpMid Bins: Accu0 (1, 2) is incremented of 256 if Component >127 (>191, >224)
0x3: UpBins: Accu0 (1, 2) is incremented of 256 if Component >239 (>247, >251)
Condition: MODE = Average
0x0: All Pixels: Accu is incremented of Component, if 0 ≤ Component < 256.
0x1: NoExt16: Accu is incremented of Component, if 16 ≤ Component < 240
0x2: NoExt32: Accu is incremented of Component, if 32 ≤ Component < 224
0x3: NoExt64: Accu is incremented of Component, if 64 ≤ Component < 192

Bit 1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**:
0: Disabled: statistics are not accumulated
1: Enable: statistics are accumulated

Bits 24:23 Reserved, must be kept at reset value.

Bits 22:17 **LUM6[5:0]**: Luminance increase for input luminance of 192 (increase is idle with LUMx = 16)

Bits 16:15 Reserved, must be kept at reset value.

Bits 14:9 **LUM7[5:0]**: Luminance increase for input luminance of 224 (increase is idle with LUMx = 16)

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:1 **LUM8[5:0]**: Luminance increase for input luminance of 256 (increase is idle with LUMx = 16)

Bit 0 Reserved, must be kept at reset value.

49.14.70 DCMIPP Pipex flow control configuration register (DCMIPP_PxFCTCR)

Address offset: 0x900 + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPT REQ	CPT MODE	FRATE[1:0]	
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **CPTREQ:** Capture requested

0: Capture not requested for next frame

1: Capture requested for next frame

When PIPEN = 1, and when the CPTREQ is set to 1, the pipe waits for the first VSync, then automatically starts a capture and sets CPTACT = 1 to mention it.

In Snapshot mode, the CPTREQ bit is automatically cleared at the start of the first frame received.

In continuous grab mode, the capture remains active and CPTREQ = 1, until the software clears CPTREQ: the capture stops and CPTACT is reset at the end of the ongoing frame.

The DCMI and pipe configuration registers must be correctly programmed before enabling this bit.

Bit 2 **CPTMODE:** Capture mode

0: Continuous grab mode. The received data are transferred into the destination memory through the AXI master.

1: Snapshot mode (single frame). Once activated, the interface waits for the start of frame, and then transfers a single frame through the AXI master. At the end of the frame, the CPTACT bit is automatically reset.

Bits 1:0 **FRATE[1:0]:** Frame capture rate control

These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode, ignored in Snapshot mode.

00: All frames are captured

01: one out of two frames captured (50% bandwidth reduction)

10: one out of four frames captured (75% bandwidth reduction)

11: one out of eight frames captured (87% bandwidth reduction)

49.14.71 DCMIPP Pipex crop window start register (DCMIPP_PxCRSTR)

Address offset: 0x904 + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	HSIZE[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **ENABLE**:
0: Bypass, all pixels are transmitted through (no need to set any start and size values)
1: Enable, only the rectangle defined by VSIZE, HSIZE, VSTART, HSTART is transmitted.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **VSIZE[11:0]**: Vertical size, from 0 to 4094 pixels high. If the value is maintained at 0 when enabling the crop thanks to the ENABLE bit, the value is forced internally at 0xFFE, which is the maximum value.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSIZE[11:0]**: Horizontal size, from 0 to 4094 pixels wide. If the value is maintained at 0 when enabling the crop by means of the ENABLE bit, the value is forced internally at 0xFFE, which is the maximum value.

49.14.73 DCMIPP Pipex decimation register (DCMIPP_PxDCCR)

This register controls decimation, prior to downsize (to complement it).

Address offset: 0x90C + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VDEC[1:0]		HDEC[1:0]		ENABLE
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:3 **VDEC[1:0]**: Vertical decimation ratio
- 0x0: all pixels are transmitted, no vertical decimation
- 0x1: one line out of two transmitted
- 0x2: one line out of four transmitted
- 0x3: one line out of eight transmitted

Bits 2:1 **HDEC[1:0]**: Horizontal decimation ratio
- 0x0: all pixels are transmitted, no horizontal decimation
- 0x1: one line out of two transmitted
- 0x2: one line out of four transmitted
- 0x3: one line out of eight transmitted

Bit 0 **ENABLE**:
- 0: Bypass: decimation is not active, all pixels are transmitted
- 1: Enable: one pixel every 1, 2, 4 or 8, in H and V is transmitted, following HDEC and VDEC

49.14.74 DCMIPP Pipex downsize configuration register (DCMIPP_PxDSCR)

Address offset: 0x910 + 0x400 * (x - 1) (x = 1 to 2)

Reset value: 0x0000 0000

The division factor is an unsigned integer based on the source/destination ratio:

div = max (int (1024 / (source / destination)), 1023)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LINEMULT[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWAP RB	FORMAT[3:0]			
rw	rw	rw									rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 Reserved, must be kept at reset value.

Bits 15:13 **LINEMULT[2:0]**: Amount of capture completed lines for LINE Event and Interrupt
0x0: Event after one line
0x1: Event after two lines
0x2: Event after four lines
0x3: Event after eight lines
0x4: Event after sixteen lines
0x5: Event after 32 lines
0x6: Event after 64 lines
0x7: Event after 128 lines

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **SWAPRB**: Swaps R-vs-B components if RGB, and U-vs-V components if YUV
0: No swap of R-vs-B (U-vs-V)
1: Swap active

Bits 3:0 **FORMAT[3:0]**: Memory format
0x0: RGB888 or YUV444 1-buffer
0x1: RGB565 1-buffer
0x2: ARGB8888 (with A = 0xFF)
0x3: RGBA8888 (with A = 0xFF)
0x4: monochrome Y8 or G8 1-buffer
0x5: YUV444 1-buffer (32 bpp, FOURCC = AYUV, with A = 0xFF)
0x6: YUV422 1-buffer (16 bpp, FOURCC = YUYV)
0x7: YUV422 2-buffer (16 bpp, FOURCC = none)
0x8: YUV420 2-buffer (12 bpp, FOURCC = NV21), NV12 available with SWAPRB = 1
0x9: YUV420 3-buffer (12 bpp, FOURCC = YV12)
0xA: YUV422 1-buffer (16 bpp, FOURCC = UYVY)
Other formats are reserved and not supported.

49.14.86 DCMIPP Pipe1 pixel packer Memory0 address register 1 (DCMIPP_P1PPM0AR1)

Address offset: 0x9C4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
M0A[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
M0A[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r	r	r

Bits 31:0 **M0A[31:0]**: Memory0 address
Base address of memory area 0, to whom data are written. It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0.

49.14.87 DCMIPP Pipex pixel packer Memory0 pitch register (DCMIPP_PxPPM0PR)

Address offset: 0x9CC + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	PITCH[14:0]														
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **PITCH[14:0]**: Number of bytes between the address of two consecutive lines.
It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0. It ranges to 32 Kbytes, to allow a double-width buffer, containing a 4-kpixel wide 32 bpp picture.

49.14.88 DCMIPP Pipex status Memory0 address register (DCMIPP_PxSTM0AR)

Address offset: 0x9D0 + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

M0A[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **M0A[31:0]**: Memory0 address

Base address of memory area 0, to whom data are written. It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0. The register returns the status of the last captured frame.

49.14.89 DCMIPP Pipex pixel packer Memory1 address register 1 (DCMIPP_PxPPM1AR1)

Address offset: 0x9D4 + 0x200 * (x - 1), (x = 1 to 1)

Reset value: 0x0000 0000

Res.	PITCH[14:0]														
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **PITCH[14:0]**: Number of bytes between the address of two consecutive lines.
It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0. It ranges to 32 Kbytes, to allow a double-width buffer, containing a 4-kpixel wide 32 bpp picture. PITCH is used also for Memory2 (there is no need to differentiate the pitch of Memory1/Memory2).

49.14.91 DCMIPP Pipex status Memory1 address register (DCMIPP_PxSTM1AR)

Address offset: 0x9E0 + 0x400 * (x - 1), (x = 1 to 1)

Reset value: 0x0000 0000

M2A[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **M2A[31:0]**: Memory2 address

Base address of memory area 0, to whom data are written. It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0. The register returns the status of the last captured frame.

49.14.94 DCMIPP Pipe1 interrupt enable register (DCMIPP_P1IER)

Address offset: 0x9F4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVRIE	Res.	Res.	Res.	Res.	VSYNCIE	FRAMEIE	LINEIE
								rw					rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OVRIE:** Overrun interrupt enable

0: No interrupt generation

1: An interrupt is generated if the AXI master is unable to transfer the last data before new data (32-bit) are received.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **VSYNCIE:** VSYNC interrupt enable
0: No interrupt generation
1: An interrupt is generated on each VSYNC (captured or not)

Bit 1 **FRAMEIE:** Frame capture completed interrupt enable
0: No interrupt generation
1: An interrupt is generated after the full capture of a cropped frame

Bit 0 **LINEIE:** Multi-line capture completed interrupt enable
0: No interrupt generation when the line is received
1: An interrupt is generated after the full capture of a group of lines (or last line reached)

49.14.95 DCMIPP Pipe1 status register (DCMIPP_P1SR)

Address offset: 0x9F8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPTACT	Res.	Res.	Res.	Res.	Res.	LSTFRM	LSTLINE
								r						r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVRF	Res.	Res.	Res.	Res.	VSYNCF	FRAMEF	LINEF
								r					r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **CPTACT:** Capture immediate status
0: Capture currently inactive
1: Capture currently active
This bit is automatically reset at the end of Frame capture complete event (after all the data of that frame have been captured, usually before the next VSync).

Bits 22:20 Reserved, must be kept at reset value.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **LSTFRM**: Last frame LSB bit, sampled at frame capture complete event. The information is extracted from the frame data number, which can be delivered by the camera through the CSI2 interface.

Bit 16 **LSTLINE**: Last line LSB bit, sampled at frame capture complete event.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **OVRF:** Overrun raw interrupt status
0: No data buffer overrun occurred
1: A data buffer overrun occurred and this frame data are corrupted.
This bit is cleared by writing 1 to the COVRF bit in DCMIPP_P1FCR.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **VSYNCF:** VSYNC raw interrupt status
This bit is set when the VSYNC signal changes from the inactive state to the active state.
In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMIPP_CR.
It is cleared by writing 1 to the CVSYNCF bit in DCMIPP_P1FCR.

Bit 1 **FRAMEF:** Frame capture completed raw interrupt status
0: no capture or ongoing capture
1: all data of a frame have been captured
This bit is set when all data of a frame or window have been captured.
In case of a cropped window, this bit is set at the end of line of the last line in the crop, even if the captured frame is empty (for example window cropped outside the frame).
This bit is cleared by writing 1 to the CFRAMEF bit in DCMIPP_P1FCR.

Bit 0 **LINEF:** Multi-line capture completed raw interrupt status
This bit is set when one/more lines have been completed. The periodicity of LINEF event is configured by LINEMULT bits into DCMIPP_P1PPCR. When reaching end of frame, this event is triggered out to allow software action even if the LINEMULT value set is not a multiple of the total lines frame.
In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMIPP_CR is set. It is cleared by writing 1 to the CLINEF bit in DCMIPP_P1FCR.

49.14.96 DCMIPP Pipe1 interrupt clear register (DCMIPP_P1FCR)

Address offset: 0x9FC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COVRF	Res.	Res.	Res.	Res.	CVSYNCF	CFRAMEF	CLINEF
								w					w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **COVRF:** Overrun interrupt status clear
Writing 1 into this bit clears the OVRF bit in the DCMIPP_P1SR register.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CVSYNCF:** Vertical synchronization interrupt status clear
Writing 1 into this bit clears the VSYNCF bit in the DCMIPP_P1SR register.

Bit 1 **CFRAMEF:** Frame capture complete interrupt status clear
Writing 1 into this bit clears the FRAMEF bit in the DCMIPP_P1SR register.

Bit 0 **CLINEF:** Multi-line capture complete interrupt status clear
Writing 1 into this bit clears LINEF in the DCMIPP_P1SR register.

49.14.97 DCMIPP Pipe1 current flow selection configuration register (DCMIPP_P1CFSCR)

Address offset: 0xA04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PIPEN	FDTFEN	FDTF[5:0]						Res.	Res.	Res.	VC[1:0]		PIPEDIFF	DTMODE[1:0]	
r	r	r	r	r	r	r	r				r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	DTIDB[5:0]						Res.	Res.	DTIDA[5:0]					
		r	r	r	r	r	r			r	r	r	r	r	r

Bit 31 **PIPEN**: Current activation of PipeN

0: Pipe disabled

1: Pipe enabled, can start capturing with CPTMODE, CPTREQ, CPTACK.

Bit 30 **FDTFEN**: Current force data type format enable

0: Disable force data type format. The data type format used by the pipe is the one defined into DTIDx

1: Enable force data type format. When the data type DTIDx is detected by the pipe, the real pixel format considering by the pipe is the one set into the FDTF[5:0] bit field instead of the physical one received by the CSI2 host. It allows to handle, for instance, 3D sensors camera with user data type in bottom-up approach, and to explicitly define the pixel format to be handled by the pipe.

Bits 29:24 **FDTF[5:0]**: Current force data type format

Forcing the data type format. This data type overwrites the one received by the CSI2-HOST by specifying the pixel format to consider. The value must follow the CSI2 data type format definition in the CSI2 standard. This bit field has no meaning if the FDTFEN bit is cleared.

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:19 **VC[1:0]**: Current flow selection mode

Virtual channel ID of the CSI flow to select for further processing on the pipe.

Bit 18 **PIPEDIFF:** Current differentiates Pipe2 vs. Pipe1

0: Pipe2 gets Pipe1 pixels after their processing in shared Gamma, StatRemoval, Demosaicing. Pipe2 shares the same VC DTID of Pipe1 when a CSI2 camera sensor is plugged.

1: Pipe1 gets pixels from only VC/DTID configured in Pipe1, processed by all including Gamma, StatRemoval, Demosaicing. Pipe2 gets pixels from only VC/DTID configured in Pipe2, processed from Crop only (Gamma common with Pipe1, no StatRem, no demosaicing)

Bits 17:16 **DTMODE[1:0]**: Flow selection mode

00: Only flow DTID A from the selected virtual channel is forwarded in the pipe.

01: Flows DTIDA and DTIDB from the selected virtual channel are forwarded in the pipe. This combination is valid only if the FDTFEN bit is set.

Other values: Reserved.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **DTIDB[5:0]**: Current data type ID B

Data type ID of the CSI flow to select.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DTIDA[5:0]**: Current data type ID A
Data type ID of the CSI flow to select.

49.14.98 DCMIPP Pipe1 current bad pixel removal register (DCMIPP_P1CBPRCR)

Address offset: 0xA24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	STRENGTH[2:0]			ENABLE
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:1 **STRENGTH[2:0]**: Current strength (aggressiveness) of the bad pixel detection:
0x0: the filter is fairly tolerant: only a few pixels are declared bad, due to their high noise.
0x7: the filter is very aggressive: many pixels are declared bad, even if only slightly noisy.

Bit 0 **ENABLE**: Current status of enable bit
0: Bypass: bad pixel removal is not active, all pixels are transmitted through
1: Enable: if bad pixel are detected, they are replaced by corrected pixels.
(bad pixel detection must be enabled only for raw Bayer flows, as it would corrupt RGB flows)

49.14.99 DCMIPP Pipe1 current black level calibration control register (DCMIPP_P1CBLCCR)

Address offset: 0xA40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BLCR[7:0]								BLCG[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BLCB[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	ENABLE
r	r	r	r	r	r	r	r								r

Bits 31:24 **BLCR[7:0]**: Current black level calibration - Red
Value that is subtracted from the red input components, whether it is on 8,10,12,14 bits.

Bits 23:16 **BLCG[7:0]**: Current black level calibration - Green
Value that is subtracted from the green input components, whether it is on 8,10,12,14 bits.

Bits 15:8 **BLCB[7:0]**: Current black level calibration - Blue
Value that is subtracted from the blue input components, whether it is on 8,10,12,14 bits.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**: For current black level calibration
0: Bypass: black level calibration is not active, all pixels are transmitted non-modified.
1: Enable: the BLCR, G, B are subtracted.

49.14.100 DCMIPP Pipe1 current exposure control register 1 (DCMIPP_P1CEXCR1)

Address offset: 0xA44

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SHFR[2:0]			MULTR[7:0]								Res.	Res.	Res.	Res.
	r	r	r	r	r	r	r	r	r	r	r				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ENABLE
															r

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **SHFR[2:0]**: Current exposure shift - Red
0x0, 0x1, 0x2, 0x3, 0x4, 0x5, 0x6, 0x7: exposure of reds is increased, respectively, by a factor 1x, 2x, 4x, 8x, 16x, 32x, 64x, 128x.

Bits 27:20 **MULTR[7:0]**: Current exposure multiplier - Red
Value that is multiplied for the red input components, whether it is on 8,10,12,14 bits.
Multiplying by 64 reduces the exposure (darkens the reds) by a factor 2x.
Multiplying by 128 does not modify the exposure (keeps the reds as-is).
Multiplying by 255 increases the exposure (lightens the reds) by a factor ~2x.

Bits 19:1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**: for exposure control (multiplication and shift)
0: Bypass: exposure multiplier and shift are not applied.
1: Enable: the exposure multiplication and shift is applied.

49.14.101 DCMIPP Pipe1 current exposure control register 2 (DCMIPP_P1CEXCR2)

Address offset: 0xA48

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SHFG[2:0]			MULTG[7:0]								Res.	Res.	Res.	Res.
	r	r	r	r	r	r	r	r	r	r	r

Res.	SHFB[2:0]			MULTB[7:0]								Res.	Res.	Res.	Res.
	r	r	r	r	r	r	r	r	r	r	r				

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **SHFG[2:0]**: Current exposure shift - Green

0x0, 0x1, 0x2, 0x3, 0x4, 0x5, 0x6, 0x7: exposure of greens is increased, respectively, by a factor 1x, 2x, 4x, 8x, 16x, 32x, 64x, 128x.

Bits 27:20 **MULTG[7:0]**: Current exposure multiplier - Green

Value that is multiplied for the green input components, whether it is on 8,10,12,14 bits.
Multiplying by 64 reduces the exposure (darkens the greens) by a factor 2x.
Multiplying by 128 does not modify the exposure (keeps the greens as-is).
Multiplying by 255 increases the exposure (lightens the greens) by a factor ~2x.

Bits 19:15 Reserved, must be kept at reset value.

Bits 14:12 **SHFB[2:0]**: Current exposure shift - Blue

0x0, 0x1, 0x2, 0x3, 0x4, 0x5, 0x6, 0x7: exposure of blues is increased, respectively, by a factor 1x, 2x, 4x, 8x, 16x, 32x, 64x, 128x.

Bits 11:4 **MULTB[7:0]**: Current exposure multiplier - Blue

Value that is multiplied for the blue input components, whether it is on 8,10,12,14 bits.
Multiplying by 64 reduces the exposure (darkens the blues) by a factor 2x.
Multiplying by 128 does not modify the exposure (keeps the blues as-is).
Multiplying by 255 increases the exposure (lightens the blues) by a factor ~2x.

Bits 3:0 Reserved, must be kept at reset value.

49.14.102 DCMIPP Pipe1 current statistics 1 control register (DCMIPP_P1CST1CR)

Address offset: 0xA50

Reset value: 0x0000 0000

ACCU[7:0]								MODE	SRC[2:0]			BINS[1:0]		Res.	ENABLE
r	r	r	r	r	r	r	r	r	r	r	r	r	r		r

Bits 31:8 **ACCU[23:0]**: Current accumulation result, divided by 256.

Bit 7 **MODE**: Current statistics mode

0: Average: accumulates the 8-bit component value of the considered pixel components.
It is typically used to extract the average value of R, G, B, or luminance across the picture, and to drive the exposure control and the white balance.
1: Bins: accumulates 256 for each considered pixel component fitting a bin dynamic.
It is typically used to extract how many pixel components fall into the various dynamic bins. It is usually used to drive the contrast enhancement.

Bits 6:4 **SRC[2:0]**: Current source of statistics

0x0, 0x1, 0x2, 0x3: components are sampled before the black level calibration and exposure, and sample, respectively, the red, green, blue components, and luminance (computed as R / 4 + G / 2 + B / 4).
0x4, 0x5, 0x6, 0x7: components are sampled after the black level calibration and exposure, and sample, respectively, red, green, blue and luminance.

Bits 3:2 **BINS[1:0]**: Current bin definition

Condition: MODE = Bins
0x0: LowerBins: Accu0 (1, 2) is incremented of 256 if Component <4 (<8, <16)
0x1: LowMid Bins: Accu0 (1, 2) is incremented of 256 if Component <32 (<64, <128)
0x2: UpMid Bins: Accu0 (1, 2) is incremented of 256 if Component >127 (>191, >224)
0x3: UpBins: Accu0 (1, 2) is incremented of 256 if Component >239 (>247, >251)
Condition: MODE = Average
0x0: AllPixels: Accu is incremented of Component, if 0 ≤ Component < 256
0x1: NoExt16: Accu is incremented of Component, if 16 ≤ Component < 240
0x2: NoExt32: Accu is incremented of Component, if 32 ≤ Component < 224
0x3: NoExt64: Accu is incremented of Component, if 64 ≤ Component < 192

Bit 1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**: Current enable bit value

0: Disabled: statistics are not accumulated
1: Enable: statistics are accumulated

Res.	Res.	Res.	Res.	HSIZE[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **CROPEN**: Current CROPEN bit value

0: Bypass, all pixels are used to compute the statistics.

1: Enable, only the rectangle defined by VSTART, HSTART, VSIZE, HSIZE, are used for statistics.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **VSIZE[11:0]**: Current vertical size, from 0 to 4094 pixels high

If the value is maintained at 0 when enabling the crop by means of the CROPEN bit, the value is forced internally at 0xFFE, which is the maximum value.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSIZE[11:0]**: Current horizontal size, from 0 to 4094 pixels wide

If the value is maintained at 0 when enabling the crop by means of the CROPEN bit, the value is forced internally at 0xFFE, which is the maximum value.

49.14.107 DCMIPP Pipe1 current ColorConv configuration register (DCMIPP_P1CCCCR)

Address offset: 0xA80

Reset value: 0x0000 0000

													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **CLAMP**: Clamp the output samples

This bit indicates the current value applied.

0: Not activated (clamped to [0;255] by default)

1: Activated, depending on TYPE

Bit 1 **TYPE**: Output samples type used while CLAMP is activated
This bit indicates the current value applied
0: clamped to [16;235] for Y and to [16;240] for U and V
1: clamped to [16;235] for R, G and B

Bit 0 **ENABLE**: Current value applied
0: ColorConv is bypassed
1: ColorConv is enabled

49.14.108 DCMIPP Pipe1 current ColorConv red coefficient register 1 (DCMIPP_P1CCCRR1)

Address offset: 0xA84

Reset value: 0x0000 0000

Coefficients of the ColorConv, in signed 2.8 format (1.0 is coded by 0x100):

int_value = int(float_value * (1 « 8) + 0.5**)**

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPT REQ	CPT MODE	FRATE[1:0]	
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **CPTREQ:** Capture requested

0: Capture not requested for next frame.

1: Capture requested for next frame.

When PIPEN = 1, and when the CPTREQ is set to 1 the pipe waits for the first VSync, and automatically starts a capture and sets CPTACT= 1 to mention it.

In Snapshot mode, the CPTREQ bit is automatically cleared at the start of the first frame received.

In continuous grab mode, the capture remains active and CPTREQ = 1, until the software clears CPTREQ: the capture stops and CPTACT is reset at the end of the ongoing frame.

The DCMIPP and pipe configuration registers must be correctly programmed before enabling this bit.

Bit 2 **CPTMODE:** Capture mode

0: Continuous grab mode - Received data are transferred into the destination memory through the AXI master.

1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame and then transfers a single frame through the AXI master. At the end of the frame, the CPTACT bit is automatically reset.

Bits 1:0 **FRATE[1:0]:** Frame capture rate control

These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode, ignored in Snapshot mode.

00: all frames are captured

01: one out of two frames captured (50% bandwidth reduction)

10: one out of four frames captured (75% bandwidth reduction)

11: one out of eight frames captured (87% bandwidth reduction)

49.14.118 DCMIPP Pipex current crop window start register (DCMIPP_PxCCRSTR)

Address offset: 0xB04 + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	HSTART[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **VSTART[11:0]**: Current vertical start, from 0 to 4094 pixels high

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSTART[11:0]**: Current horizontal start, from 0 to 4094 pixels wide

49.14.119 DCMIPP Pipex current crop window size register (DCMIPP_PxCCRSZR)

Address offset: 0xB08 + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	HSIZE[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **ENABLE**: Current ENABLE bit value.
0: Bypass, all pixels are transmitted through (no need to set any start and size values)
1: Enable, only the rectangle defined by VSIZE, HSIZE, VSTART, HSTART is transmitted.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **VSIZE[11:0]**: Current vertical size, from 0 to 4094 pixels high

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSIZE[11:0]**: Current horizontal size, from 0 to 4094 pixels wide

49.14.120 DCMIPP Pipex current decimation register (DCMIPP_PxCDCCR)

This register controls decimation, prior to downsize (to complement it).

Address offset: 0xB0C + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VDEC[1:0]		HDEC[1:0]		ENABLE
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:3 **VDEC[1:0]**: Vertical decimation ratio
0x0: All pixels are transmitted, no vertical decimation
0x1: one line out of two transmitted
0x2: one line out of four transmitted
0x3: one line out of eight transmitted

Bits 2:1 **HDEC[1:0]**: Horizontal decimation ratio
0x0: All pixels are transmitted, no horizontal decimation
0x1: one line out of two transmitted
0x2: one line out of four transmitted
0x3: one line out of eight transmitted

Bit 0 **ENABLE**:
0: Bypass: decimation is not active, all pixels are transmitted
1: Enable: one pixel every 1, 2, 4 or 8, in H and V is transmitted, following HDEC and VDEC

49.14.121 DCMIPP Pipex current downsize configuration register (DCMIPP_PxCDSCR)

Address offset: 0xB10 + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

The division factor is an unsigned integer based on the source/destination ratio:

div = max(int(024 / (source/destination)), 1023)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						r	r	r	r	r	r	r	r	r	r

Bit 31 **ENABLE**: Current value of bit ENABLE
0: Down scaler is bypassed
1: Down scaler is enabled

Bits 30:26 Reserved, must be kept at reset value.

Bits 25:16 **VDIV[9:0]**: Current vertical division factor, from 128 (8x) to 1023 (1x)

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **HDIV[9:0]**: Current horizontal division factor, from 128 (8x) to 1023 (1x)

49.14.122 DCMIPP Pipex current downsize ratio register (DCMIPP_PxCDSRTIOR)

Address offset: 0xB14 + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

The down scale ratio is expressed in unsigned 3.13 format:

ratio = max(int((source / destination) * 8192), 8 * 8192 - 1)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LINEMULT[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWAP RB	FORMAT[3:0]			
r	r	r									r	r	r	r	r

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 Reserved, must be kept at reset value.

Bits 15:13 **LINEMULT[2:0]**: Amount of capture completed lines for LINE Event and Interrupt
- 0x0: Event after one line
- 0x1: Event after two lines
- 0x2: Event after four lines
- 0x3: Event after eight lines
- 0x4: Event after sixteen lines
- 0x5: Event after 32 lines
- 0x6: Event after 64 lines
- 0x7: Event after 128 lines

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **SWAPRB**: Swaps R-vs-B components if RGB, and U-vs-V components if YUV
0: No swap of R-vs-B (U-vs-V)
1: Swap active

Bits 3:0 **FORMAT[3:0]**: Memory format
0x0: RGB888 or YUV444 1-buffer
0x1: RGB565 1-buffer
0x2: ARGB8888 (with A = 0xFF)
0x3: RGBA8888 (with A = 0xFF)
0x4: monochrome Y8 or G8 1-buffer
0x5: YUV444 1-buffer (32 bpp, FOURCC = AYUV, with A = 0xFF)
0x6: YUV422 1-buffer (16 bpp, FOURCC = YUYV)
0x7: YUV422 2-buffer (16 bpp, FOURCC = none)
0x8: YUV420 2-buffer (12 bpp, FOURCC = NV21), NV12 available with SWAPRB = 1
0x9: YUV420 3-buffer (12 bpp, FOURCC = YV12)
0xA: YUV422 1-buffer (16 bpp, FOURCC = UYVY)
Other formats are reserved and not supported.

49.14.125 DCMIPP Pipe1 current pixel packer Memory0 address register 1 (DCMIPP_P1CPPM0AR1)

Address offset: 0xBC4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
M0A[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

M0A[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **M0A[31:0]**: Memory0 address
Base address of current memory area 0, to whom data are written.
It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0.

49.14.126 DCMIPP Pipex current pixel packer Memory0 pitch register (DCMIPP_PxCPPM0PR)

Address offset: 0xBCC + 0x400 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	PITCH[14:0]														
	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **PITCH[14:0]**: Current number of bytes between the address of two consecutive lines.
It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0. It ranges to 32 Kbytes, to allow a double-width buffer, containing a 4-kpixel wide 32 bpp picture.

49.14.127 DCMIPP Pipex current pixel packer Memory1 address register 1 (DCMIPP_PxCPPM1AR1)

Address offset: 0xBD4 + 0x400 * (x - 1), (x = 1 to 1)

Reset value: 0x0000 0000

M2A[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **M2A[31:0]**: Memory 2 address

Base address of current memory area 2 where data are written. It is assumed to be a multiple of 16, hence its bits [3:0] are always at 0x0.

49.14.130 DCMIPP Pipe2 flow selection configuration register (DCMIPP_P2FSCR)

Address offset: 0xC04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PIPEN	FDTFEN	FDTF[5:0]						Res.	Res.	Res.	VC[1:0]		Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw				rw	rw			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTIDA[5:0]					
										rw	rw	rw	rw	rw	rw

Bit 31 **PIPEN**: Activation of PipeN

0: PipeN disabled

1: PipeN enabled, can start capturing with CPTMODE, CPTREQ, CPTACK

Bit 30 **FDTFEN**: Force data type format enable

0: Disable force data type format. The data type format used by the pipe is the one defined into DTIDx

1: Enable force data type format. When the data type DTIDA is detected by the pipe, the real pixel format considered by the pipe is the one set into the FDTF[5:0] bit field instead of the physical one received by the CSI2 host.

This bit has no meaning if PIPEDIFF = 0 in the DCMIPP_P1FSCR register.

Bits 29:24 **FDTF[5:0]**: Force data type format

This data type overwrites the one received by the CSI2 Host by specifying the pixel format to consider. The value must follow the CSI2 data type format definition in the CSI2 standard. This bit field has no meaning if the FDTFEN bit is cleared.

These bits have no meaning if PIPEDIFF = 0 in the DCMIPP_P1FSCR register.

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:19 **VC[1:0]**: Flow selection mode
Virtual channel ID of the CSI flow to select for further processing on the pipe.
These bits have no meaning if PIPEDIFF = 0 into DCMIPP_P1FSCR, hence the pipe takes the value VC[1:0] configured into the DMCIPP_P1FSCR register.

Bits 18:6 Reserved, must be kept at reset value.

Bits 5:0 **DTIDA[5:0]**: Data type ID
Data type ID of the CSI flow to select.
These bits have no meaning if PIPEDIFF = 0 into DCMIPP_P1FSCR, hence the pipe takes the value of VC and DTIDA[5:0] / DTIDB[5:0] configured into the DMCIPP_P1FSCR register.

49.14.131 DCMIPP Pipe2 pixel packer configuration register (DCMIPP_P2PPCR)

Address offset: 0xDC0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LINEMULT[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWAP RB	FORMAT[3:0]			
rw	rw	rw									rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:13 **LINEMULT[2:0]**: Amount of capture completed lines for LINE event and interrupt
0x0: Event after every line
0x1: Event after two lines
0x2: Event after four lines
0x3: Event after eight lines
0x4: Event after sixteen lines
0x5: Event after 32 lines
0x6: Event after 64 lines
0x7: Event after 128 lines

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **SWAPRB**: Swaps R-vs-B components if RGB, and if YUV, swaps U-vs-V components
0: No swap of R-vs-B (U-vs-V)
1: Swap active.

Bits 3:0 **FORMAT[3:0]**: Memory format (only coplanar formats are supported in Pipe2)
0x0: RG/B888 or YUV444 1-buffer
0x1: RGB565 1-buffer
0x2: ARGB8888
0x3: RGBA8888
0x4: monochrome Y8 or G8 1-buffer
0x5: YUV444 1-buffer (FOURCC = AYUV)
0x6: YUV422 1-buffer (FOURCC = YUYV)
Other formats are reserved and not supported.

49.14.132 DCMIPP Pipe2 pixel packer Memory0 address register 1 (DCMIPP_P2PPM0AR1)

Address offset: 0xDC4

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVRIE	Res.	Res.	Res.	Res.	VSYNCIE	FRAMEIE	LINEIE
								rw					rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OVRIE:** Overrun interrupt enable
0: No interrupt generation
1: An interrupt is generated if the AXI master is unable to transfer the last data before new data (32-bit) are received

Bits 6:3 Reserved, must be kept at reset value.

Bit 2 **VSYNCIE:** VSYNC interrupt enable
0: No interrupt generation
1: An interrupt is generated on each VSYNC (captured or not)

Bit 1 **FRAMEIE:** Frame capture completed interrupt enable
0: No interrupt generation
1: An interrupt is generated after the full capture of a cropped frame

Bit 0 **LINEIE:** Multi-line capture completed interrupt enable
0: No interrupt generation when the line is received
1: An interrupt is generated after the full capture of a group of lines (or last line reached)

49.14.134 DCMIPP Pipe2 status register (DCMIPP_P2SR)

Address offset: 0xDF8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPTACT	Res.	Res.	Res.	Res.	Res.	LSTFRM	LSTLINE
								r						r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVRF	Res.	Res.	Res.	Res.	VSYNCF	FRAMEF	LINEF
								r					r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **CPTACT:** Capture immediate status
0: Capture currently inactive
1: Capture currently active
This bit is automatically reset at the end of frame capture complete event (after all the data of that frame have been captured, usually before the next VSync).

Bits 22:20 Reserved, must be kept at reset value.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **LSTFRM**: Last frame LSB bit, sampled at frame capture complete event. The information is extracted from the frame data number which can be delivered by the camera through the CSI2 interface.

Bit 16 **LSTLINE**: Last line LSB bit, sampled at frame capture complete event.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **OVRF:** Overrun raw interrupt status
0: No data buffer overrun occurred
1: A data buffer overrun occurred and data of this frame are corrupted
This bit is cleared by writing 1 to the COVRF bit in the DCMIPP_P2FCR register.

Bits 6:3 Reserved, must be kept at reset value.

Bit 2 **VSYNCF:** VSYNC raw interrupt status

This bit is set when the VSYNC signal changes from the inactive state to the active state. In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in the DCMIPP_CR register. It is cleared by writing 1 to the CVSYNCF bit in the DCMIPP_P2FCR register.

Bit 1 **FRAMEF:** Frame capture completed raw interrupt status

0: No capture or ongoing capture

1: All data of a frame have been captured

This bit is set when all data of a frame or window have been captured.

In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (for example window cropped outside the frame).

This bit is cleared by writing 1 to the CFRAMEF bit in DCMIPP_P2FCR.

Bit 0 **LINEF:** Multi-line capture completed raw interrupt status

This bit is set when one/more lines have been completed.

The periodicity of LINEF event is configured bu LINEMULT bits into DCMIPP_P1PPCR register. When reaching end of frame, this event is triggered out to allow software action even if the LINEMULT value set is not a multiple of the total lines frame.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit in the DCMIPP_CR register is set.

It is cleared by writing 1 to the CLINEF bit in the DCMIPP_P2FCR register.

49.14.135 DCMIPP Pipe2 interrupt clear register (DCMIPP_P2FCR)

Address offset: 0xDFC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COVRF	Res.	Res.	Res.	Res.	CVSYNCF	CFRAMEF	CLINEF
								w					w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **COVRF:** Overrun interrupt status clear

Writing 1 into this bit clears the OVRF bit in the DCMIPP_P2SR register.

Bits 6:3 Reserved, must be kept at reset value.

Bit 2 **CVSYNCF:** Vertical synchronization interrupt status clear

Writing 1 into this bit clears the VSYNCF bit in the DCMIPP_P2SR register.

Bit 1 **CFRAMEF:** Frame capture complete interrupt status clear

Writing 1 into this bit clears the FRAMEF bit in the DCMIPP_P2SR register.

Bit 0 **CLINEF:** Multi-line capture complete interrupt status clear

Writing 1 into this bit clears LINEF in the DCMIPP_P2SR register.

49.14.136 DCMIPP Pipe2 current flow selection configuration register (DCMIPP_P2CFSCR)

Address offset: 0xE04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PIPEN	FDTFEN	FDTF[5:0]						Res.	Res.	Res.	VC[1:0]		Res.	Res.	Res.
r	r	r	r	r	r	r	r				r	r			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTIDA[5:0]					
										r	r	r	r	r	r

Bit 31 **PIPEN**: Current activation of PipeN

0: Pipe disabled

1: Pipe enabled, can start capturing with CPTMODE, CPTREQ, CPTACK.

Bit 30 **FDTFEN**: Current force data type format enable

0: Disable force data type format. The data type format used by the pipe is the one defined into DTIDx

1: Enable force data type format. When data type DTIDA is detected by the pipe, the real pixel format considering by the pipe is the one set into the FDTF[5:0] bit field instead of the physical one received by the CSI2 host.

This bit has no meaning if PIPEDIFF = 0 in the DCMIPP_P1FSCR register.

Bits 29:24 **FDTF[5:0]**: Current force data type format

Forcing the data type format. This data type overwrites the one received by the CSI2-HOST by specifying the pixel format to consider. The value must follow the CSI2 data type format definition in the CSI2 standard. This bit field has no meaning if the FDTFEN bit is cleared, or if PIPEDIFF = 0 in the DCMIPP_P1FSCR register.

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:19 **VC[1:0]**: Current flow selection mode

Virtual channel ID of the CSI flow to select for further processing on the pipe. These bits have no meaning if PIPEDIFF = 0 into DCMIPP_P1FSCR. For this configuration the pipe takes the value VC[1:0] configured in the DMCIPP_P1FSCR register.

Bits 18:6 Reserved, must be kept at reset value.

Bits 5:0 **DTIDA[5:0]**: Current data type ID

Data type ID of the CSI flow to select. For this configuration the pipe takes the value DTIDA[5:0] configured in the DMCIPP_P1FSCR register.

49.14.137 DCMIPP Pipe2 current pixel packer configuration register (DCMIPP_P2CPPCR)

Address offset: 0xFC0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LINEMULT[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWAP RB	FORMAT[3:0]			
r	r	r									r	r	r	r	r

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 Reserved, must be kept at reset value.

Bits 15:13 **LINEMULT[2:0]**: Amount of capture completed lines for LINE event and interrupt
0x0: Event after every line
0x1: Event after two lines
0x2: Event after four lines
0x3: Event after eight lines
0x4: Event after sixteen lines
0x5: Event after 32 lines
0x6: Event after 64 lines
0x7: Event after 128 lines

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **SWAPRB**: Swaps R-vs-B components if RGB, and if YUV, swaps U-vs-V components
0: No swap of R-vs-B (U-vs-V)
1: Swap active.

Bits 3:0 **FORMAT[3:0]**: Memory format (only coplanar formats are supported in Pipe2)
0x0: RG/B888 or YUV444 1-buffer
0x1: RGB565 1-buffer
0x2: ARGB8888
0x3: RGBA8888
0x4: monochrome Y8 or G8 1-buffer
0x5: YUV444 1-buffer (FOURCC = AYUV)
0x6: YUV422 1-buffer (FOURCC = YUYV)
Other formats are reserved and not supported.

49.14.138 DCMIPP Pipe2 current pixel packer Memory0 address register 1 (DCMIPP_P2CPPM0AR1)

Address offset: 0xFC4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			r				r				r		r	r	r

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **STV**: Statistic version

0: Statistic extraction (with three accumulators) is implemented

1: Statistic and histogram extractions are implemented

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **TPG**: Test pattern generator

0: TPG is not implemented

1: TPG is implemented

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **MCU**: Macroblock unit as pixel format
0: MCU is not implemented
1: MCU is implemented

Bits 19:13 Reserved, must be kept at reset value.

Bit 12 **ADDMOD**: Address modulo computation to access a small buffer in streaming featured
0: Address modulo is not implemented
1: Address modulo is implemented

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **PROCCLK**: Processing clock linked to AXI clock featured
0: Independent processing clock not connected to AXI
1: Processing clock is directly the AXI

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **DBMFT**: Double buffer mode featured

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **VPFT[2:0]**: Virtual pipe function

49.14.141 DCMIPP hardware configuration register 1 (DCMIPP_HWCFGR1)

Address offset: 0xFF0

Reset value: 0x0031 3131

Bits 31:28 **ROI2NB[3:0]**: Number of ROIs for Pipe2

Bits 27:24 **ROI1NB[3:0]**: Number of ROIs for Pipe1

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **PLANARFT[1:0]**: Buffer features for Pipe1
00: Coplanar
01: Semiplanar
10: Reserved
11: Full planar (one buffer per component)

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **RB2RGB**: Raw Bayer to RGB feature (demosaicer)

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **DSP2FT**: Down-sampling feature for the pixel Pipe2

Bit 12 **DSP1FT**: Down-sampling feature for the pixel Pipe1

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **IPPLUGCFG**: IP-Plug configuration

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **PIPENB[1:0]**: Number of pipes

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **CSIFT**: CSI2 host protocol compliant

49.14.142 DCMIPP version register (DCMIPP_VERR)

Address offset: 0xFF4

Reset value: 0x0000 0030

50 CSI-2 Host (CSI)

50.1 Introduction

The camera serial interface 2 (CSI-2) is a part of a group of communication protocols defined by the MIPI® Alliance. The MIPI® CSI-2 Host controller is a digital core that implements all protocol functions defined in the MIPI® CSI-2 specification.

It provides an interface between the system and the MIPI® D-PHY, allowing communication with a CSI-2 compliant camera.

50.2 Standard and references

- MIPI Alliance Specification for Camera Serial Interface 2 (CSI-2) v1.3 - 29 May 2014
- MIPI Alliance Specification for D-PHY v1.2 - 01 August 2014

50.3 Glossary

Table 485. Glossary of terms

Term	Definition
D-PHY_RX	D-PHY physical layer receiver
EOF	End of frame
EOT	End of transmission
ESC	Escape mode for the D-PHY_RX
HS	High speed
ISB	Imaging system bus
LLP	Low-level protocol
LP	Low power
PHY	Physical layer
PPI	Phy protocol interface
RX	Receiver
SOF	Start of frame
SOT	Start of transmission

50.4 CSI-2 Host main features

- Compliant with MIPI Alliance standard (see *Section 50.2*)
- Interface with MIPI D-PHY (see *Section 50.2*)
- Up to two D-PHY data lanes supported (up to 2.5 Gbit/s per lane in high-speed (HS) mode and 10 Mbit/s in low-power (LP) mode)
- Data transmission in HS and LP modes supported by the D-PHY
- Escape mode (ESC) and ultra-low-power state mode (ULPS) supported
- CSI-2 lane management layer connected to the D-PHY_RX to merge 1 or 2 data lanes in a single 32-bit ISB-Byte bus
- ECC and error correction capabilities
- CRC check capability
- CSI-2 virtual channel and data type filtering supporting interleaved data
  - Up to 4 virtual channels
  - Support the data formats specified into the MIPI Alliance standard for CSI-2 v1.3 (18 data formats, plus the user defined ones)
- Up to 7 independent data types
- Programmable interrupts:
  - 4 timer interrupts mapped on a selected virtual channel with starting point from SOF (start of frame) or EOF (end of frame)
  - 4 line/byte counter interrupts mapped on a selected virtual channel to trigger an event
- ISB-Byte header generation for internal connection with the DCMIPP peripheral

50.5 CSI-2 Host functional description

50.5.1 General description

The MIPI CSI-2 Host controller offers a means to connect cameras to capture and dispatch a robust header with ECC correction and data payload with checksum.
A D-PHY_RX receiver fills out the role of interfacing the external serial camera devices with the embedded CSI-2 Host controller:

- D-PHY receiver:

  This is a D-PHY_RX receiver composed of two unidirectional data lanes, and one clock lane. It operates in slave mode with HS and LP mode capabilities. The D-PHY drives a PPI interface to communicate with the CSI-2 Host.
- CSI-2 lane merger:

  Up to two data lane inputs to increase data rate while avoiding high clock rates

  The lane manager function collects incoming bytes from N (N = 1 to 2) lanes.
  It consolidates them by merging operations into a complete packet provided to the CSI-2 low-level protocol decoder (LLP), to decompose the meaning of each data packet thanks to the CSI-2 protocol specification.
- CSI-2 clock changer:

  The clock changer moves the data transfer from an input clock domain from D-PHY_RX to a clock_proc domain before being processed by the LLP.

- CSI-2 low-level protocol decoder (LLP)

  The low-level protocol is a byte-orientated packet-based protocol that supports the transport of arbitrary data using short and long packet formats.

  It generates an ISB-byte header data for further processing, with data integrity check or miscellaneous integrity checks.

  It supports data interleaving through the support of up to four virtual channels and many data type formats.

  The LLP offers interrupt generation capability, depending on specific events such as line/byte detection within a frame, or a time-base event selected from a SOF or an EOF.

The CSI-2 Host-controller register bank is configured and accessed by the APB bus interface.

A block diagram of the CSI-2 Host is shown in the figure below.

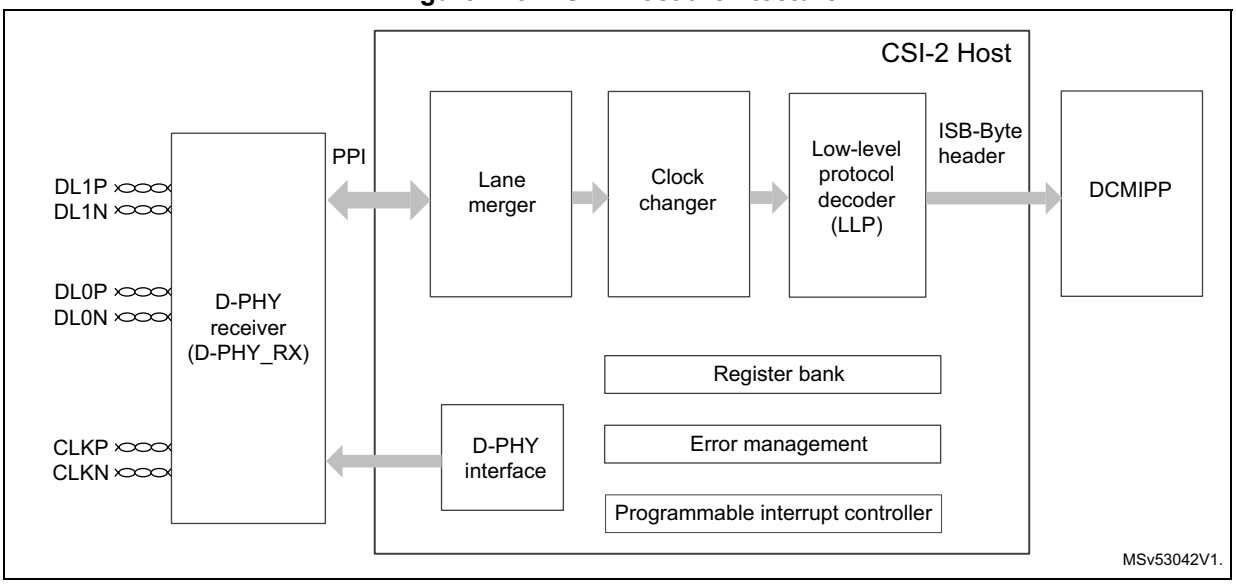

Figure 442. CSI-2 Host block diagram

50.5.2 System level architecture

The figure below shows the CSI-2 Host architecture.

Figure 443. CSI-2 Host architecture

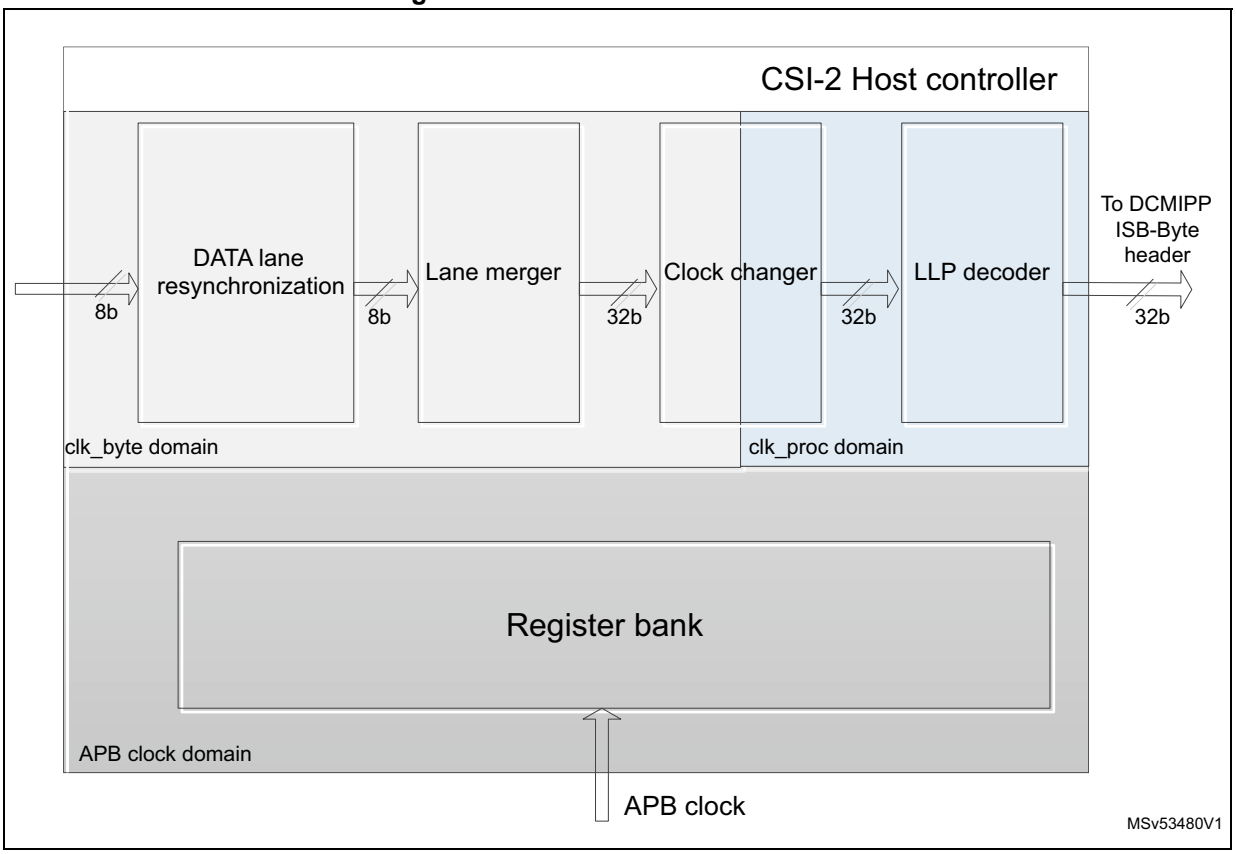
The blocks shown have the following functions:

- D-PHY_RX is a slave receiver device that connects external serial cameras to the CSI-2 Host controller. It is based on unidirectional slave data lanes and clock lanes to handle data transmission from the CSI-2 protocol-based camera devices to subsystems for data processing (handled by the DCMIPP).
- The D-PHY interface manages D-PHY_RX register accesses. It also allows the block to be configured to raise interrupts on the detection of some errors during reception. It highlights the status of the physical lines up to the software layers.
- The lane merger module packs the data coming from the two D-PHY_RX data lanes, if required to do so for increased data rates. It generates a data flow based on an ISB-Byte protocol, which is not linked to any protocol at this point. The data is only identified as a control or a data packet for the clock changer module.
- The clock changer module manages data crossing from the D-PHY_RX clock domain to the clk_proc clock domain.
- The LLP handles data filtering to serve the data-interleaving capability of the DCMIPP. It can filter data from external devices depending on virtual channel identifiers, or on data-type format selection. It also executes, depending on the input pixel format, data reordering in order to optimize the data storage, for instance in memories.
- The CSI-2 Host manages also various errors coming (not exclusively) from the D-PHY_RX physical layer. It can detect error conditions in the received header or a short packet in a frame. ECC is implemented to correct one bit error in the header. A CRC checksum is also implemented to detect any data corruption during the data payload reception. The 16-bit CRC value is located into the packet footer.
  The CSI-2 Host also ensures that specific timings within the data reception are properly in line with the CSI-2 specification. All error conditions and associated interrupts are detailed in *Section 50.8*.

- A specific module generates interrupts following the detection of selected events in a frame. For a given virtual channel, these events may be triggers based on line- and byte-number detection within the frame, or counters from dedicated timers reaching a number of cycles (clk_proc) from an SOF or an EOF.
- Data is filtered out by the LLP, and sent to the DCMIPP in a format that is quite similar to the CSI-2 protocol, but without CRC (packet footer) and ECC information inside the packet header. The data type and the virtual channel are also sent to the DCMIPP to handle the interleaved transmission of different image data formats within the same video data stream.

50.5.3 CSI-2 Host reset and clocks

There are two reset sources:



- hardware asynchronous reset which is resynchronized on clk_byte and clk_proc clock domain (processing clock) to reset the flops connected to these clock domains
- APB reset from the reset and clock controller unit to reset mainly all the registers

There are three clocks to serve the CSI-2 Host controller (see *Figure 444*):

- clk_byte: derived from the D-PHY_RX clock lane, and used by the lane merger module and the clock changer module
- clk_proc: used by the kernel of the LLP

  Resynchronization between the clk_byte domain and the clk_proc domain is handled by the clock changer module.
- PCLK clock: APB clock used to access to the register bank

Figure 444. CSI-2 Host clock domain

The D-PHY_RX supports up to 2.5 Gbit/s per data lane: the maximum frequency on the D-PHY_RX clock is 2.5 Gbits / 8 to output a byte = 312 MHz.

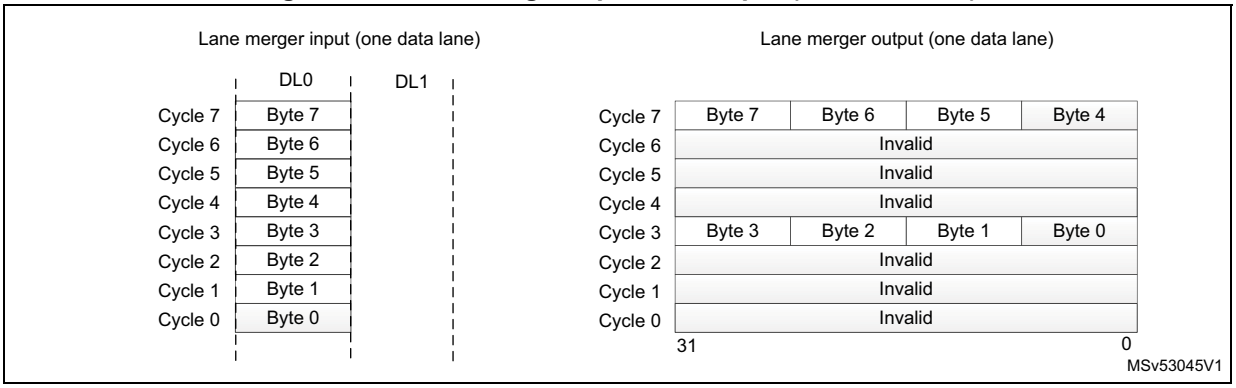
50.5.4 Lane merger

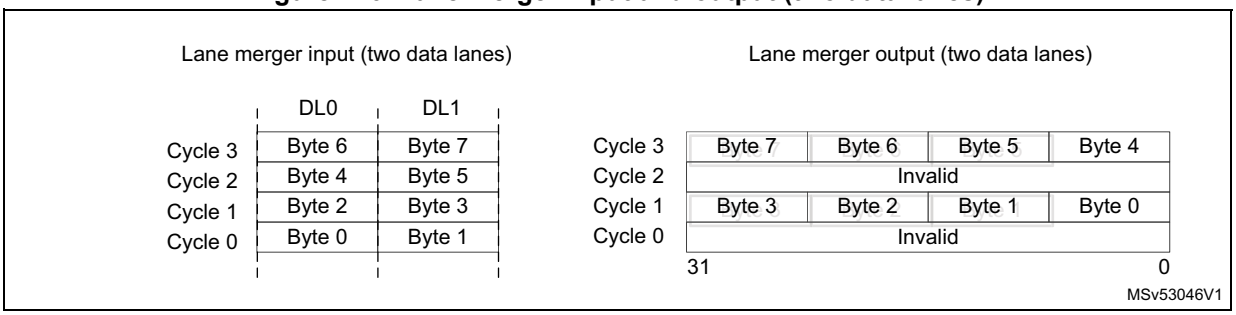
Applications requiring more bandwidth than the one provided by a single data lane may expand the data path to more lanes in order to increase the attainable data rate. The lane merger supports then up to two data lanes.

The lane merger module converts the D-PHY_RX PPI protocol into a byte-oriented bus to be sent to the LLP.

The lane merger parallelizes the bytes to 32 bits in parallel to build a 32-bit output as shown in the figures below. The cycle number does not account for module internal latency.

Figure 445. Lane merger input and output (one data lane)





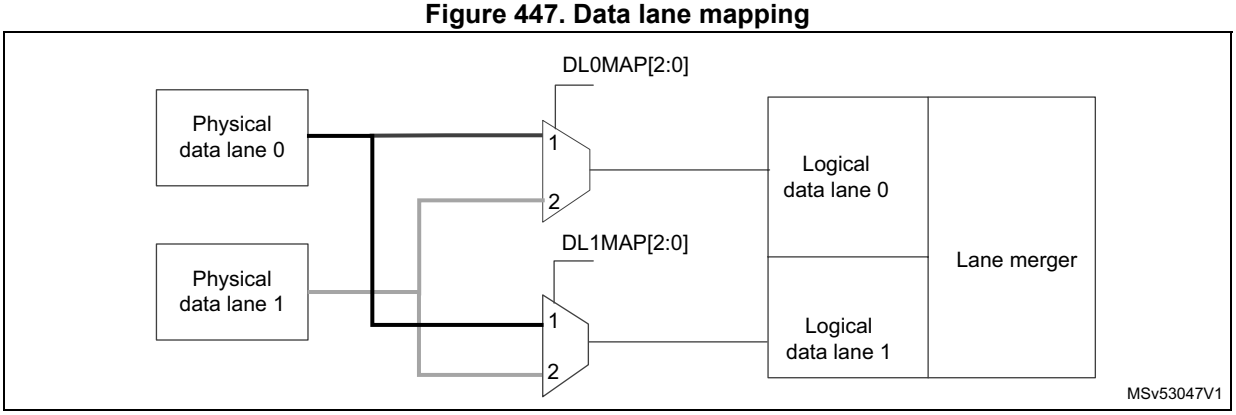


Figure 446. Lane merger input and output (two data lanes)

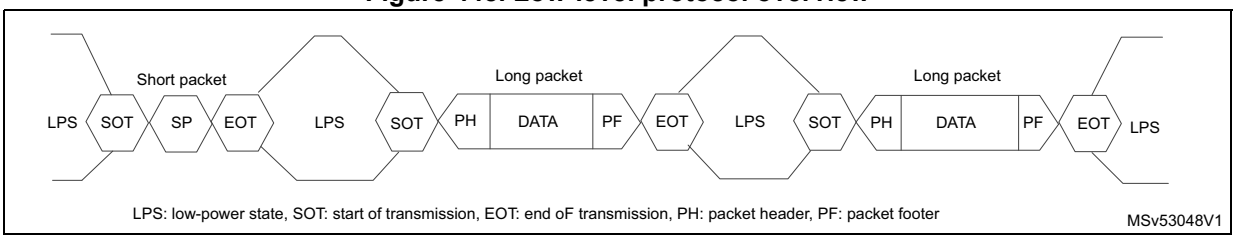
LANENB[2:0] in CSI_LMCFGR configures the number of data lanes used in the application. The software needs to map the physical data lanes input to the lane merger logical data lanes, using DL0MAP[2:0] and DL1MAP[2:0] as shown in the figure below.

Figure 447. Data lane mapping

50.5.5 Clock changer

The clock changer module changes the clock frequency from the input clock domain linked to the D-PHY_RX PPI protocol, to the output clock domain based on clk_proc clock domain (reference clock for the LLP).



An integrated FIFO receives data from the input clock domain and realigns it to the output clock domain.

50.5.6 Low-level protocol (LLP)

The LPP module retrieves the raw data from the lane merger, and decodes the data flow respect to the CSI-2 low-level protocol. The software selects which data in the data interleaving flow need to be sent to the DCMIPP without being filtered out. The LLP is compliant with the MIPI CSI-2 specification as described in *Section 50.2*.

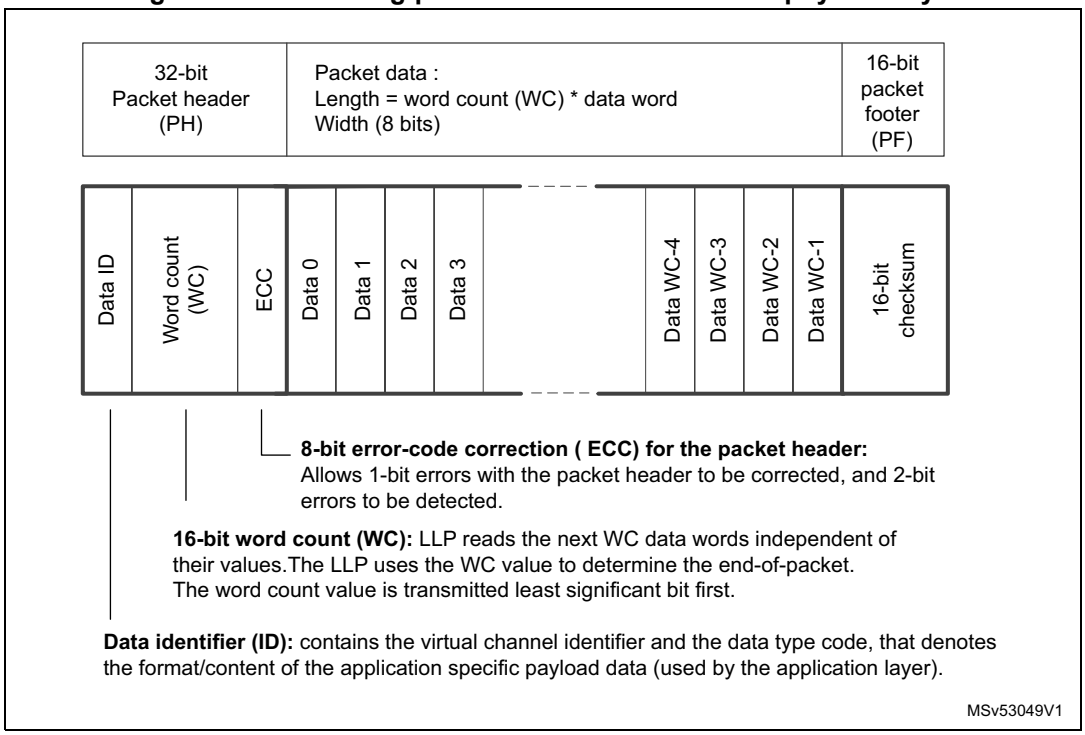
A data integrity check is done thanks to an ECC code for packet header error correction, and a 16-bit CRC checksum code for payload error detection. All these errors are flagged into specific registers, and may trig interruption for specific software action needs (see *Section 50.8* for more details).

Figure 448. Low-level protocol overview

The CSI-2 low-level protocol is mainly composed by short and long packets, each of them having a well identified role.

Long packet

The long packet format is presented in *Figure 449*. It contains a data ID that is composed of a virtual channel number for which the data packets are attached, and the corresponding data type. The LLP module filters data out by configuring CSI_VCxCFGRy registers (x = 0 to 3, y = 1 to 4), and VCxSTART/VCxSTOP bits in CSI_CR register.



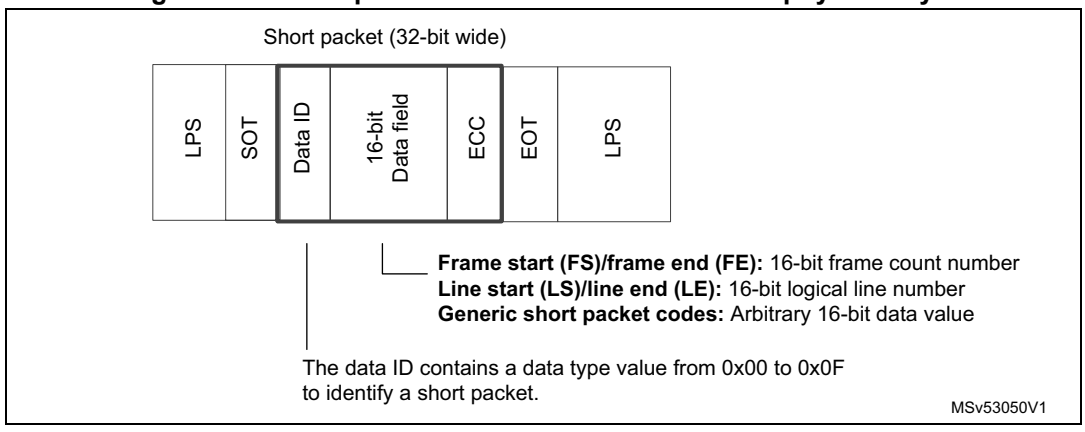
The word-count field allows the LLP to determine the data-payload width before detecting the packet footer and the EOT. This information is used to detect shorter-than-expected packets, and to trigger a corresponding error (refer to *Section 50.8*).

The ECC corrects a single erroneous bit in the packet header in the case of data corruption. An error is raised if there are two errors in total (the LLP decoder immediately stops the current frame), because only one bit can be corrected.

The packet data corresponds to the data payload for a given virtual channel and for an identified data type.

To complete the long-packet reception block, a packet footer that contains a 16-bit CRC checksum is received and compared to that which is internally calculated by the LLP, to check the data integrity of the received data payload.

Figure 449. CSI2- long-packet structure for a D-PHY physical layer

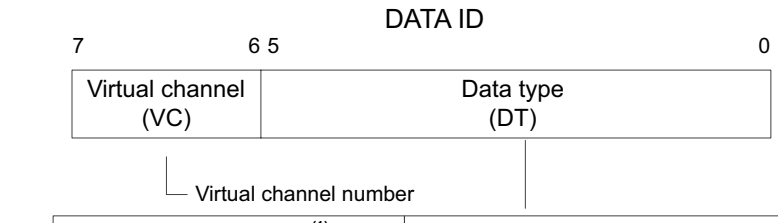


Short packet

The CSI-2 short-packet format for a D-PHY physical layer is shown in *Figure 450*.

It is similar to the long packet header, except that the word count field is replaced by a 16-bit data field. The ECC 8-bit code is present to secure headers having potential bit corruption.

Figure 450. Short-packet structure based on D-PHY physical layer



Data ID field

The 8-bit data ID field comprises 2 bits for the virtual channel number coding, and 6 bits to identify the packet data type (short or long packet), and the payload data packet format in the case of long packet reception.

The LLP filters subsequent packets depending on the user configuration indicated in the previously received data ID field (see *Figure 451*).

Figure 451. DATA ID structure in short or long packet format

Data type classes (1)	Description
0x00 to 0x07	Synchronization short packet data types
0x08 to 0x0F	Generic short packet data types
0x10 to 0x17	Generic long packet data types
0x18 to 0x1F	YUV data
0x20 to 0x27	RGB data
0x28 to 0x2F	RAW data
0x30 to 0x37	User defined byte-based data
0x38 to 0x3F	Reserved

(1) Refer to the MIPI Alliance specification for the CSI-2 to have the detail of each intermediate value not described in this table.

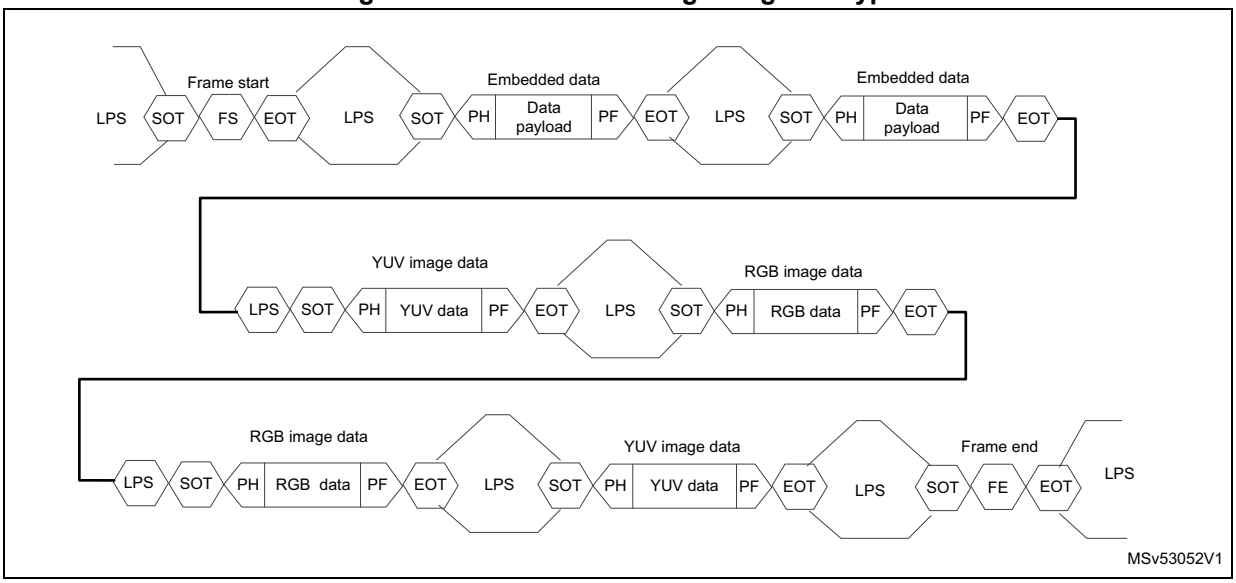
MSv53051V1

Data type field

The data type (DT) fields are configured by the application code to determine which data types are processed by the LLP for a given virtual channel. CSI_VCxCFGRy registers are used to configure the data types to be considered by the LLP.

Each virtual channel is managed independently, and up to seven different virtual-channel data types can be declared in parallel. All data type input to the LLP that are not defined for a given virtual channel are filtered out by the LLP module and discarded.

Data types in the video data flow are located:



- in the data ID packet for a short packet
- in the packet header (PH) for a long packet format

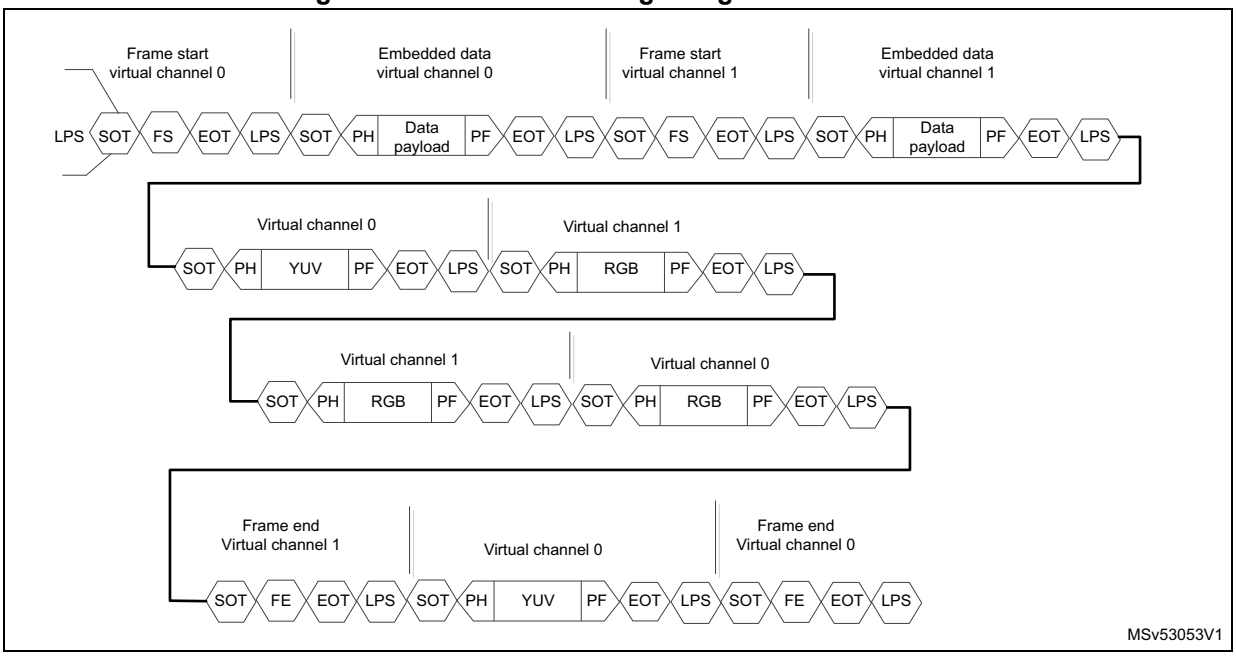
Data interleaving: data-type based

In the video data flow, the transmitter can merge, on the same physical node, multi-device data transmissions having different data types. The LLP filters out these multi-device flows depending on the application configuration. A typical video data flow interleaving multiple data types is shown in *Figure 452*.

The application software must configure CSI_VCxCFGRy registers to enable data types for a virtual channel, and to set data-type formats to be processed. The LLP reorders the input data in a format that optimizes memory usage (see *Figure 452* to *Figure 460*).

Figure 452. Data interleaving using data type

Data interleaving: virtual channels



The data interleaving in the video data flow can also be managed by the virtual channel ID. Each external device can have a specific virtual channel identifier in order for the software layer or the DCMIPP to properly handle data packets belonging to a device.

The application code defines which of the virtual channels have to be considered by the LPP without any filtering operation. The CSI_CR register must be configured accordingly by activating the virtual channel (via VCxSTART), or by setting VCxSTOP to deactivate the virtual channel.

The virtual channel number is encapsulated in the data ID packet in short or long packet.

A typical data interleaving case is illustrated in *Figure 453*.

Figure 453. Data interleaving using virtual channels

Data formats

The LLP, in addition to a data-flow filter role, handles data reordering for memory optimization, storage, or post-processing purposes.

The CSI-2 Host controller is compliant with the MIPI Alliance CSI-2 specification. It mainly supports the following data formats:

- BPP6 (for example RAW6, RGB666)
- BPP7 (for example RAW7)
- BPP8 (for example RAW8, YUV 8-bits, RGB444, RGB555, RGB565, RGB888, JPEG)
- BPP10 (for example RAW10, YUV 10-bits)
- BPP12 (for example RAW12)
- BPP14 (for example RAW14)
- BPP16 (for example RAW16)

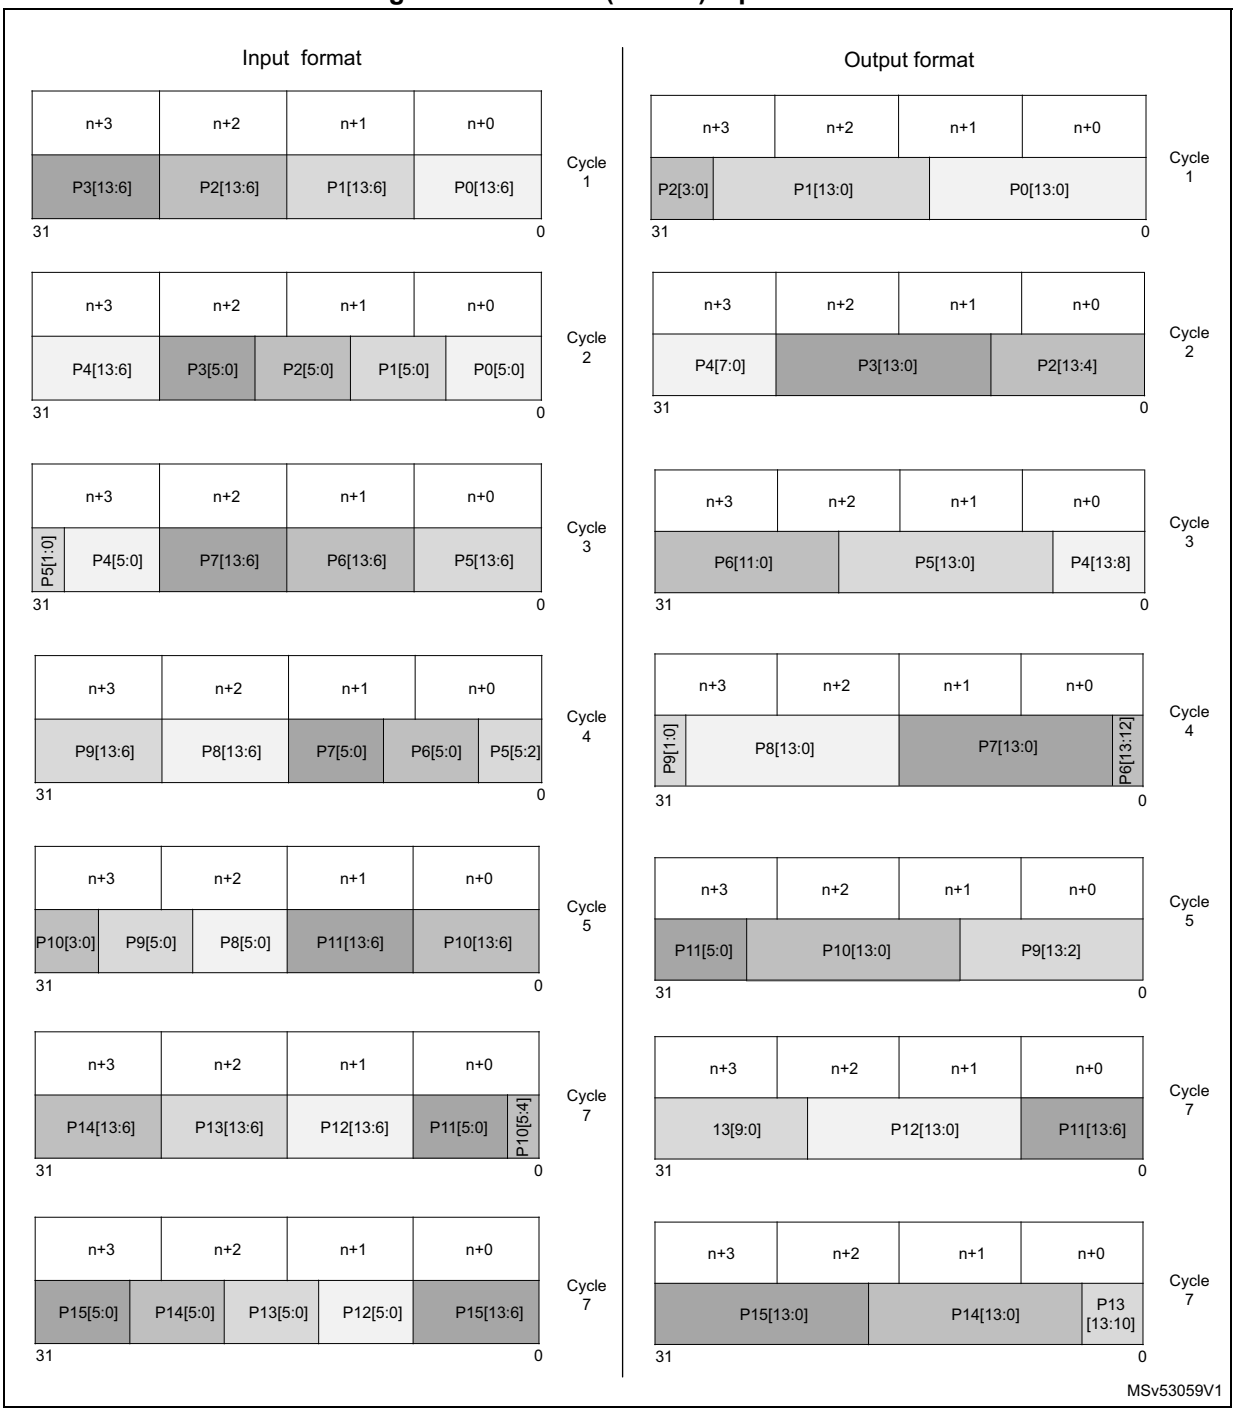

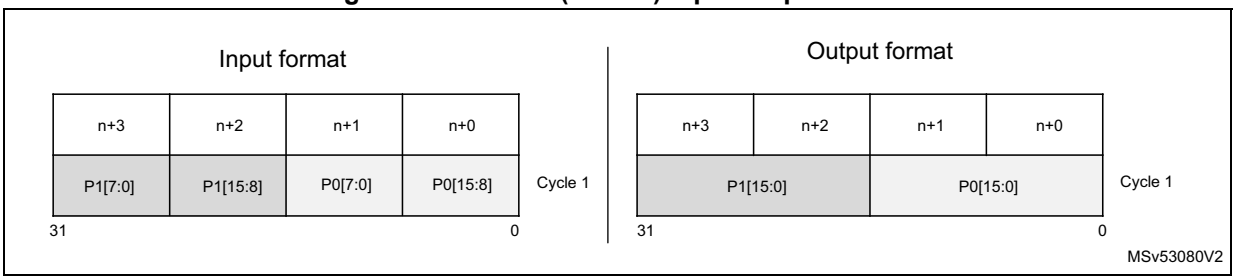

Figure 460. Raw16 (BPP16) input/output format

50.5.7 CSI-2 Host protocol output

The CSI-2 Host controller generates ISB-Byte header data according to CSI_VCxCFGRy. The ISB-Byte header generation respects the following rules:

- ISB-Byte header channel number is identical to the CSI-2 virtual channel and data type (LSB aligned).
- ISB-Byte header data type is identical to CSI-2 data type (LSB aligned).
- ISB-Byte header frame number is identical to the CSI-2 frame number.
- ISB-Byte header count is identical to CSI-2 word count.
- The format is updated according to CSI_VCxCFGRy configuration.

The only differences between the ISB-Byte data flow in input to the LLP and the ISB-Byte header bus at the output are listed below:

- There is no ECC information in the data corresponding to the short packet information.
- The packet footer (containing the CRC-16 value) is not transmitted, or forwarded on the output since the decoder already checked it from the input, and raised an error if the data payload is corrupted.
- The data payload output format is reordered and compared to the input data format of the LLP in order to ease pixels storage in memory for further hardware/software post-processing.
- Only identified virtual channels and their selected data types are generated on the output.

The ISB-Byte header is used by the DCMIPP peripheral to handle post-processing data from the external devices.

50.6 CSI-2 Host programming guide

50.6.1 CSI-2 PHY setup

The following actions are required to setup the CSI-2 PHY:

1. Quit the hardware reset state with PEN = 0x01 in CSI_PRCR.
2. Configure frequency settings with:
   – DLD = 0x00 in CSI_PFCR (to remain in Rx)
   – HSFR in CSI_PFCR that depends on the bit-rate expected on the data lanes
   – CCFR = RoundUp((F - 17) × 4) in CSI_PFCR (F = configuration clock frequency)
3. Configure internal registers via the test interface, with TRSEN = TCKEN = 0x0 in CSI_PTCR0.

50.6.2 CSI-2 Host controller setup and data reception start

The D-PHY RX software initialization is required to set up the CSI-2 Host controller.

Lane-merger configuration (static configuration)

The lane merger must be configured while CSIEN = 0 in CSI_CR, and when the D-PHY_RX is not streaming (when it is not providing a clock).

To map the physical data lane to the logical data lane, the lane merger needs to be configured through DL0MAP and DL1MAP in CSI_LMCFGR. In addition, the number of valid data lanes must be configured through LANENB in the same register.

LLP configuration

1. Configure the watchdog value in CSI_WDR. This corresponds to the maximum number of clock cycles between two packets before an input frame is considered erroneous and the transmission failed. It can be left at 0x0 to disable the watchdog feature.
2. Enable the CSI-2 Host controller with CSIEN = 1 in CSI_CR.
3. Configure the selected virtual channels in CSI_VCxCFGRy.

   If all data types must be captured with the same format, in CSI_VCxCFGR1:
   - Set ALLDT = 0x011.
   - Select the format with CDTFT[4:0].

   If only a few data types are to be captured, or if the format is not identical for all data types, then up to seven data types can be selected:
   - Set ALLDT = 0x0 in CSI_VCxCFGR1.
   - Set DTyEN = 0x1 (y = 0 to 6) in CSI_VCxCFGR1 for the data types used.
   - Set DTy[5:0] in CSI_VCxCFGRy to the selected data type.
   - Set DTyFT[4:0] in CSI_VCxCFGRy to the selected format.
4. Depending on application requirements, specific software actions may detect particular events in a frame, and trigger a corresponding interrupt, with the following:
   - Set LINECNT[15:0] and BYTECNT[15:0] in CSI_LBxCFGR to trigger an event when the data corresponding to a specific byte within a specific line is detected by the LLP. Up to four independent triggers can be programmed and linked to a selected virtual channel through LBxVC[1:0] in CSI_PRGITR. The selected trigger can be enabled by setting LBxEN in the same register.
   - Set COUNT[24:0] in CSI_TIMxCFGR to trigger an event after a specified number of clock cycles (clk_proc) from an SOF or an EO, depending on TIMxEOF and TIMxEN in CSI_PRGITR. Up to four independent timer triggers can be programmed and linked to a selected virtual channel through TIMxVC[1:0] in CSI_PRGITR.
5. Enable interrupt sources for which the code needs to make specific actions, by configuring CSI_IER0 and CSI_IER1 registers.
6. D-PHY_RX lanes can be enabled by setting DL0EN and/or DL1EN, and CLEN in CSI_PCR.
7. Start the virtual channel by setting VCxSTART = 0x1 in CSI_CR.

50.6.3 Data reception stop

To stop data reception, set VCxSTOP = 1 in CSI_CR. The data reception stops at the end of the current frame. The virtual channel status can be retrieved from VCxSTATEF in CSI_SR0.

Note: A virtual channel cannot start before it has been completely stopped (VCxSTATEF = 0 in CSI_SR0).

50.7 CSI-2 Host low-power modes

Table 486. Effect of low-power modes on CSI-2 Host controller

Mode	Description
Sleep	No effect. The CSI-2 host interrupts cause the device to exit the Sleep mode.
Stop	The CSI-2 host is in power-down, and must be reinitialized after exiting Stop mode.
Standby	The CSI-2 host is in power-down, and must be reinitialized after exiting Standby mode.

50.8 CSI-2 Host interrupts and errors

Few events can generate an error flag or an interrupt from the CSI-2 Host controller interrupt handler.

The table below defines the error sources flagged by the CSI-2 HOST controller.
The content of CSI_ERR1 and CSI_ERR2 registers can be used to know exactly from which virtual number and data types a particular error appeared and has been detected. It can be used as debug purpose too.

Table 487. List of errors detected by the CSI-2 Host controller

Error description	Bit name	Register
Virtual channel number on which a data ID information error is detected	IDVCERR[1:0]	CSI_ERR1
Data type for which a data ID information error is detected	IDDTERR[5:0]	
Virtual channel number for which the ECC has corrected one bit in error	CECCVCERR[1:0]	
Data type for which the ECC has corrected one bit in error	CECCDTERR[5:0]	
Virtual channel number for which a CRC error is detected	CRCVCERR[1:0]	
Data type for which a CRC error is detected	CRCDTERR[5:0]	
Virtual channel number on which the invalid synchronization has been detected	SYNCVCERR[1:0]	CSI_ERR2
Virtual channel number on which a watchdog error has been detected	WDVCERR[1:0]	
Virtual channel number on which a shorter packet than expected has been detected	SPKTVCERR[1:0]	
Data type for which the shorter packet than expected error has been detected	SPKTDTERR[5:0]	

The table below shows the interrupt sources that are triggered by the CSI-2 Host controller if the corresponding bit is enabled.

Table 488. List of events that trigger an interrupt

Interrupt flag	Register	Interrupt sources
SYNCERRF	CSI_SR0	Synchronization error. The interrupt is enabled if SYNCERRIE is set in CSI_IER0(1).
WDERRF		Watchdog error. The interrupt is enabled if WDERRIE is set in CSI_IER0(1).
SPKTERRF		Shorter packet than expected error. The interrupt is enabled if SPKTERRIE is set in CSI_IER0 register(1).
IDERRF		Data ID information error. The interrupt is enabled if IDERRIE is set in CSI_IER0(1).
CECCERRF		Corrected ECC error. The interrupt is enabled if CECCERRIE is set in CSI_IER0(1).
ECCERRF		ECC error. The interrupt is enabled if ECCERRIE is set in CSI_IER0(1).
CRCERRF		CRC error. The interrupt is enabled if CRCERRIE is set in CSI_IER0(1).
CCFIFOFF		Clock changer FIFO full event. The interrupt is enabled if CCFIFOFFIE is set in CSI_IER0(2).
SPKTF		Short packet detection. The interrupt is enabled if SPKTIE is set in CSI_IER0(2).
EOF3F		EOF on virtual channel 3. The interrupt is enabled if EOF3IE is set in CSI_IER0(2).
EOF2F		EOF on virtual channel 2. The interrupt is enabled if EOF2IE is set in CSI_IER0(2).
EOF1F		EOF on virtual channel 1. The interrupt is enabled if EOF1IE is set in CSI_IER0(2).
EOF0F		EOF on virtual channel 0. The interrupt is enabled if EOF0IE is set in CSI_IER0(2).
SOF3F		SOF on virtual channel 3. The interrupt is enabled if SOF3IE is set in CSI_IER0(2).
SOF2F		SOF on virtual channel 2. The interrupt is enabled if SOF2IE is set in CSI_IER0(2).
SOF1F		SOF on virtual channel 1. The interrupt is enabled if SOF1IE is set in CSI_IER0(2).
SOF0F		SOF on virtual channel 0. The interrupt is enabled if SOF0IE is set in CSI_IER0(2).
TIM3F		Timer 3 counter value reached. The interrupt is enabled if TIM3IE is set in CSI_IER0(2).
TIM2F		Timer 2 counter value reached. The interrupt is enabled if TIM2IE is set in CSI_IER0(2).
TIM1F		Timer 1 counter value reached. The interrupt is enabled if TIM1IE is set in CSI_IER0(2).
TIM0F		Timer 0 counter value reached. The interrupt is enabled if TIM0IE is set in CSI_IER0(2).
LB3F		Line/byte event 3 reached. The interrupt is enabled if LB3IE is set in CSI_IER0(2).
LB2F		Line/byte event 2 reached. The interrupt is enabled if LB2IE is set in CSI_IER0(2).
LB1F		Line/byte event 1 reached. The interrupt is enabled if LB1IE is set in CSI_IER0(2).
LB0F		Line/byte event 0 reached. The interrupt is enabled if LB0IE is set in CSI_IER0(2).

Table 488. List of events that trigger an interrupt (continued)

Interrupt flag	Register	Interrupt sources
ECTRLDL1F	CSI_SR1	Error control on data line 1. The interrupt is enabled if ECTRLDL1IE is set in CSI_IER1.
ESYNCESCDL1F		Low-power data transmission synchronization error on data line 1. The interrupt is enabled if ESYNCESCDL1IE is set in CSI_IER1.
EESCDL1F		Escape entry error on data line 1. The interrupt is enabled if EESCDL1IE is set in CSI_IER1.
ESOTSYNCDL1F		SOT synchronization error on data line 1. The interrupt is enabled if ESOTSYNCDL1IE is set inCSI_IER1.
ESOTDL1F		SOT error on data line 1. The interrupt is enabled if the bit ESOTDL1IE is set into CSI_IER1.
ECTRLDL0F		Error control on data line 0. The interrupt is enabled if the bit ECTRLDL0IE is set into CSI_IER1.
ESYNCESCDL0F		Low-power data transmission synchronization error on data line 0. The interrupt is enabled if the bit ESYNCESCDL0IE is set into CSI_IER1.
EESCDL0F		Escape entry error on data line 0. The interrupt is enabled if EESCDL0IE is set in CSI_IER1.
ESOTSYNCDL0F		SOT synchronization error on data line 0. The interrupt is enabled if ESOTSYNCDL0IE is set in CSI_IER1.
ESOTDL0F		SOT error on data line 0. The interrupt is enabled if ESOTDL0IE is set in CSI_IER1.

1. Refer to *Section 50.8.1: Error handling*.
2. Refer to *Section 50.8.2: Interrupt handling*.

50.8.1 Error handling

Details of the errors are given in CSI_ERR1 and CSI_ERR2.

Note: Except for data ID information, all other errors can occur during the product life, and must be handled by the software.

Corrected ECC error

When this error is detected, the CECCERR interrupt is triggered if CECCERRIE = 1 in CSI_IER0. This is an information event rather than a real error, as the CSI-2 Host controller successfully recovered the ECC error, so the frame is processed properly. Some details of the error are located in CECCVCERR and CECCDTERR in CSI_ERR1:

ECC error

When a multi-bit ECC error is detected, the ECCERR interrupt is triggered if ECCERRIE = 1 in CSI_IER0. As all virtual channels are potentially corrupted, the LPP immediately stops the current frames.

The CSI-2 Host controller restarts each enabled virtual channel on the next SOF packet of each channel. The software must perform the necessary error management (such as resetting some peripherals after this error detection). No details are available for the error as the relevant information is corrupted.

CRC error

When a CRC error is detected, the CRCERR interrupt is triggered if CRCERRIE = 1 in CSI_IER0. As the frame envelope is not corrupted, the CSI-2 Host controller does not stop the frame processing. The software must perform the necessary error management (such as reseting some peripherals, possibly including the CSI-2 Host controller). Details are available for this error in CRCVCERR and CRCDTERR in CSI_ERR1.

Data ID information

When a reserved data type is detected, the IDERR interrupt is triggered if IDERRIE = 1 in CSI_IER0. This is an information event rather than a real error, as the hardware processes this packet as for any non-erroneous packet.Details for the error are available in IDVCERR and IDDTERR in CSI_ERR1.

Invalid synchronization

When an invalid synchronization is detected, the SYNCERR interrupt is triggered if SYNCERRIE = 1 in CSI_IER0. An invalid synchronization is either an SOF short packet during a frame, or an EOF short packet during an inter-frame. It is an information event rather than a real error, as the hardware is able to handle such an error:

- An SOF short packet during a frame is interpreted as back-to-back EOF and SOF. It behaves accordingly (ISB-Byte header EOF, ISB-Byte header SOF, and so on). The SOFx interrupt is generated in addition to the SYNCERR one if SOFxIE = 1 in CSI_IER0.
- An EOF short packet during an inter-frame is ignored (no EOFx interrupt is generated whatever the state of EOFx in CSI_IER0). Details for the error are available in SYNCVCERR in CSI_ERR2.

Shorter than expected packet

When a shorter-than-expected packet is received, the SPKTERR interrupt is triggered if SPKTERRIE = 1 in CSI_IER0. The packet is padded up to its theoretical size, and the frame is processed as if no error occurred. The software must perform the necessary error management (such as reseting some peripherals, possibly including the CSI decoder). Details for the error are available in SPKTVCERR and SPKTDTERR in CSI_ERR2.

Watchdog

When the time between two packets of a given virtual channel is longer than the programmed watchdog (CNT[31:0] in CSI_WDR), the WDERR interrupt is triggered if WDERRIE = 1 in CSI_WDR. As the corresponding virtual channel stream is corrupted, the CSI2 Host controller immediately stops processing this virtual channel. The software must perform the necessary error management (such as reseting some peripherals after this error detection), before restarting the CSI-2 Host. Details for the error are available in WDVCERR in CSI_ERR2.

50.8.2 Interrupt handling

The CSI-2 Host controller offers many interrupt sources that can be activated if the associated enable bit is set. Some interrupt sources are linked to an error detection from the D-PHY physical layer or the CSI-2 Host controller (refer to *Section 50.8.1*).

Short packet interrupt

This interrupt notifies the software that a generic short packet has been received. The software can retrieve the associated data in CSI_SPDFR. This register value is overwritten with each new generic short packet.

SOF and EOF interrupts

The CSI-2 Host controller generates an SOF interrupt for each SOF short packet received. It also generates an EOF interrupt for each EOF short packet, independently for all four virtual channels. These interrupts are generated even if the virtual channel is disabled. The software must mask or ignore these interrupts if they are not needed.

Line/byte programmable interrupts

The CSI-2 Host controller provides four interrupts that can be programmed to be triggered at any point during the active data of a frame. In order to set a programmable line/byte interrupt, the software must follow these steps:

1. Select a virtual channel by setting LBxVC[1:0] in CSI_PRGITR.
2. Select the frame location at which the interrupt is triggered by setting LINECNT and BYTECNT in CSI_LBxCFGRy.
3. Enable the line/byte counting by setting LBxEN in the CSI_PGRITR register. This bit must be set only when the CSI-2 is enabled.
4. Enable the interrupt by setting LBxIE in CSI_IER0.
5. The interrupt is generated starting from the next frame on the selected virtual channel.

In order to stop a programmable interrupt, the software must reset the LBxIE bit in the CSI_IER0 register. It immediately stops the interrupt.

Note: All four line/byte programmable interrupts are independent.

Timer-based programmable interrupts

The CSI-2 Host controller provides four interrupts that can be programmed to be triggered based on a timer. In order to set a programmable timer based interrupt, the software must select a virtual channel by setting TIMxVC[1:0] in CSI_PRGITR. The following steps must be followed, while the CSI-2 is disabled:

1. Select the starting event of the timer with TIMxEOF in CSI_PRGITR.
2. Select the timer duration by setting COUNT[24:0] in CSI_TIMxCFGR.
3. Select and enable counting by setting TIMxEN in CSI_PRGITR.
4. Enable the interrupt by setting TIMxIE in CSI_IER0.
5. The interrupt is generated starting from the next frame on the selected virtual channel.

In order to stop a programmable interrupt, the software must reset the TIMxIE bit in the CSI_IER0 register. It immediately stops the interrupt.

Note: All four timer-based programmable interrupts are independent.

If the timer is set to a value longer than the frame period, the interrupt may not be generated for all frames.

Clock-changer FIFO full interrupt

The clock changer is also built around a FIFO which is never full in normal conditions. If the overall system works very slowly (for example due to the CSI-2 and DCMIPP processing clock frequency being set to an inadequate frequency, system-bus bandwidth availability, and so on), the clock-changer FIFO may become full. In this case, an interrupt is set if CCFIFOFIE = 1 in CSI_IER0.

50.9 CSI-2 Host registers

50.9.1 CSI-2 Host control register (CSI_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VC3 STOP	VC3 START	Res.	Res.	VC2 STOP	VC2 START	Res.	Res.	VC1 STOP	VC1 START	Res.	Res.	VC0 STOP	VC0 START	Res.	CSIEN
w	w			w	w			w	w			w	w		rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **VC3STOP**: Virtual channel 3 stop

The CSI-2 decoder stops the virtual channel 3.

0: No effect

1: Pulse generation to stop the virtual channel 3 processing

Note: The CSI-2 decoder stops processing the virtual channel 3 after the next EOF event (or immediately if the Stop command is issued during frame blanking).

A write operation into this bit must not be simultaneous with a write into VC3START.

Reading this bit returns 0.

Bit 14 **VC3START**: Virtual channel 3 start

The CSI-2 decoder processes the virtual channel 3 according to CSI_VC3CFGRx (x = 0..3).

0: No effect

1: Pulse generation to start the virtual channel 3 processing

Note: The CSI-2 decoder starts processing the virtual channel 3 after the next SOF event.

A write operation into this bit must not be simultaneous with a write into VC3STOP.

Reading this bit returns 0.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **VC2STOP**: Virtual channel 2 stop
The CSI-2 decoder stops the virtual channel 2.
0: No effect
1: Pulse generation to stop the virtual channel 2 processing
Note: The CSI-2 decoder stops processing the virtual channel 2 after the next EOF event (or immediately if the Stop command is issued during frame blanking).
A write operation into this bit must not be simultaneous with a write into VC2START.
Reading this bit returns 0.

Bit 10 **VC2START**: Virtual channel 2 start
The CSI-2 decoder processes the virtual channel 2 according to CSI_VC2CFGRx (x = 0..3).
0: No effect
1: Pulse generation to start the virtual channel 2 processing
Note: The CSI-2 decoder starts processing the virtual channel 2 after the next SOF event.
A write operation into this bit must not be simultaneous with a write into VC2STOP.
Reading this bit returns 0.

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **VC1STOP**: Virtual channel 1 stop
The CSI-2 decoder stops the virtual channel 1.
0: No effect
1: Pulse generation to stop the virtual channel 1 processing
Note: The CSI-2 decoder stops processing the virtual channel 1 after the next EOF event (or immediately if the Stop command is issued during frame blanking).
A write operation into this bit must not be simultaneous with a write into VC1START.
Reading this bit returns 0.

Bit 6 **VC1START**: Virtual channel 1 start
The CSI-2 decoder processes the virtual channel 1 according to CSI_VC1CFGRx (x = 0..3).
0: No effect
1: Pulse generation to start the virtual channel 1 processing
Note: The CSI-2 decoder starts processing the virtual channel 1 after the next SOF event.
A write operation into this bit must not be simultaneous with a write into VC1STOP.
Reading this bit returns 0.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **VC0STOP**: Virtual channel 0 stop
The CSI-2 decoder stops the virtual channel 0.
0: No effect
1: Pulse generation to stop the virtual channel 0 processing
Note: The CSI-2 decoder stops processing the virtual channel 0 after the next EOF event (or immediately if the Stop command is issued during frame blanking).
A write operation into this bit must not be simultaneous with a write into VC0START.
Reading this bit returns 0.

Bit 2 **VC0START**: Virtual channel 0 start
he CSI-2 decoder processes the virtual channel 0 according to CSI_VC 0CFGRx (x = 0..3).
0: No effect
1: Pulse generation to start the virtual channel 0 processing
Note: The CSI-2 decoder starts processing the virtual channel 0after the next SOF event.
A write operation into this bit must not be simultaneous with a write into VC0STOP.
Reading this bit returns 0.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CSIEN**: CSI-2 enable

This bit enables the CSI-2 peripheral for processing the data flow coming from the camera through the D-PHY_RX.

0: CSI-2 disabled

1: CSI-2 enabled

50.9.2 CSI-2 Host DPHY_RX control register (CSI_PCR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DL1EN	DL0EN	CLEN	PWR DOWN
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **DL1EN**: D-PHY_RX data lane 1 enable

This bit enables the data lane 1 for the D-PHY_RX.

0: Data lane 1 module is in shutdown mode.

1: Enable the data lane 1 module.

Bit 2 **DL0EN**: D-PHY_RX data lane 0 enable

This bit enables the data lane 0 for the D-PHY_RX.

0: Data lane 0 module is in shutdown mode.

1: Enable the data lane 0 module.

Bit 1 **CLEN**: Clock lane enable

This bit enables the clock lane module of the D-PHY_RX.

0: Clock lanes disabled

1: Clock lanes enabled

Bit 0 **PWRDOWN**: Power down

This bit keeps the D-PHY_RX in power-down state.

0: Active state

1: Power down the D-PHY_RX

50.9.3 CSI-2 Host virtual channel x configuration register 1 (CSI_VCxCFGR1)

Address offset: 0x10 + 0x10 * x, (x = 0 to 3)

Reset value: 0x0000 0000

Any change in this register while the virtual channel x is running is ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DT0FT[4:0]					Res.	Res.	DT0[5:0]					
			rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	CDTFT[4:0]					DT6EN	DT5EN	DT4EN	DT3EN	DT2EN	DT1EN	DT0EN	ALLDT
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **DT0FT[4:0]**: Data type 0 format

These bits configure the input pixel format for the virtual channel x on data type 0.
00000: (BPP6) 6-bit words (for example RAW6, RGB666)
00001: (BPP7) 7-bit words (for example RAW7)
00010: (BPP8) 8-bit words (for example RAW8, YUV 8 bits, RGB888, RGB444, RGB555, RGB565, JPEG)
00011: (BPP10) 10-bit words (for example RAW10, YUV 10 bits)
00100: (BPP12) 12-bit words (for example RAW12)
00101: (BPP14) 14-bit words (for example RAW14)
00110: (BPP16) 16-bit words (for example RAW16)
Others: reserved and must not be used

Note: The format selection is valid only if ALLDT = 0 and DT0EN = 1. These bits have no effect if ALLDT = 1.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **DT0[5:0]**: Data type 0 class selection for virtual channel x

These bits select the data type 0 class and subclass for the virtual channel x according to the MIPI specification for CSI-2.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **CDTFT[4:0]**: Common format for all data types

These bits are configured to select which input pixel format is applied for all the seven data type on virtual channel x.
00000: (BPP6) 6-bit words (for example RAW6, RGB666)
00001: (BPP7) 7-bit words (for example RAW7)
00010: (BPP8) 8-bit words (for example RAW8, YUV 8 bits, RGB888, RGB444, RGB555, RGB565, JPEG)
00011: (BPP10) 10-bit words (for example RAW10, YUV 10 bits)
00100: (BPP12) 12-bit words (for example RAW12)
00101: (BPP14) 14-bit words (for example RAW14)
00110: (BPP16) 16-bit words (for example RAW16)
Others: Reserved

Note: The format selection is valid only if ALLDT = 1. These bits have no effect if ALLDT = 0.

Bit 7 **DT6EN**: Data type 6 enable

This bit enables the data type 6 for the virtual channel x. The data type format is applied with respect to the configuration of DT6[5:0] and DT6FT[4:0] in CSI_VCxCFGR4.

0: Data type 6 for virtual channel x is disabled.

1: Data type 6 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 6 **DT5EN**: Data type 5 enable

This bit enables the data type 5 for the virtual channel x. The data type format is applied with respect to the configuration of DT5[5:0] and DT5FT[4:0] in CSI_VCxCFGR4.

0: Data type 5 for virtual channel x is disabled.

1: Data type 5 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 5 **DT4EN**: Data type 4 enable

This bit enables the data type 4 for the virtual channel x. The data type format is applied with respect to the configuration of DT4[5:0] and DT4FT[4:0] in CSI_VCxCFGR3.

0: Data type 4 for virtual channel x is disabled.

1: Data type 4 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 4 **DT3EN**: Data type 3 enable

This bit enables the data type 3 for the virtual channel x. The data type format is applied with respect to the configuration of DT3[5:0] and DT3FT[4:0] in CSI_VCxCFGR3.

0: Data type 3 for virtual channel x is disabled.

1: Data type 3 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 3 **DT2EN**: Data type 2 enable

This bit enables the data type 2 for the virtual channel x. The data type format is applied with respect to the configuration of DT2[5:0] and DT2FT[4:0] in CSI_VCxCFGR2.

0: Data type 2 for virtual channel x is disabled.

1: Data type 2 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 2 **DT1EN**: Data type 1 enable

This bit enables the data type 1 for the virtual channel x. The data type format is applied with respect to the configuration of DT1[5:0] and DT1FT[4:0] in CSI_VCxCFGR2.

0: Data type 1 for virtual channel x is disabled.

1: Data type 1 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 1 **DT0EN**: Data type 0 enable

This bit enables the data type 0 for the virtual channel x. The data type format is applied with respect to the configuration of DT0[5:0] and DT0FT[4:0] in CSI_VCxCFGR1.

0: Data type 0 for virtual channel x is disabled.

1: Data type 0 for virtual channel x is enabled.

Note: This bit has no effect if ALLDT = 1.

Bit 0 **ALLDT**: All data types enable for the virtual channel x

This bit allows to capture all data types according to CDTFT[4:0] for the virtual channel x.

0: Data type capture managed individually

1: All data types captured for virtual channel x

50.9.4 CSI-2 Host virtual channel x configuration register 2 (CSI_VCxCFGR2)

Address offset: 0x14 + 0x10 * x, (x = 0 to 3)

Reset value: 0x0000 0000

Any change in this register while the virtual channel x is running is ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DT2FT[4:0]					Res.	Res.	DT2[5:0]					
			rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

			rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **DT2FT[4:0]**: Data type 2 format

These bits configure the input pixel format for the virtual channel x on data type 2.
00000: (BPP6) 6-bit words (for example RAW6, RGB666)
00001: (BPP7) 7-bit words (for example RAW7)
00010: (BPP8) 8-bit words (for example RAW8, YUV 8 bits, RGB888, RGB444, RGB555, RGB565, JPEG)
00011: (BPP10) 10-bit words (for example RAW10, YUV 10 bits)
00100: (BPP12) 12-bit words (for example RAW12)
00101: (BPP14) 14-bit words (for example RAW14)
00110: (BPP16) 16-bit words (for example RAW16)
Others: Reserved and must not be used.

Note: The format selection is valid only if ALLDT = 0 and DT2EN = 1. These bits have no effect if ALLDT = 1.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **DT2[5:0]**: Data type 2 class selection for virtual channel x

These bits select the data type 2 class and subclass for the virtual channel x according to the MIPI specification for CSI- 2.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DT1FT[4:0]**: Data type 1 format

These bits configure the input pixel format for the virtual channel x on data type 1.
00000: (BPP6) 6-bit words (for example RAW6, RGB666)
00001: (BPP7) 7 -it words (for example RAW7)
00010: (BPP8) 8 -it words (for example RAW8, YUV 8 bits, RGB888, RGB444, RGB555, RGB565, JPEG)
00011: (BPP10) 10-bit words (for example RAW10, YUV 10 bits)
00100: (BPP12) 12 -it words (for example RAW12)
00101: (BPP14) 14 -it words (for example RAW14)
00110: (BPP16) 16 -it words (for example RAW16)
Others: Reserved and must not be used.

Note: The format selection is valid only if ALLDT = 0 and DT1EN = 1. These bits have no effect if ALLDT = 1.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DT1[5:0]**: Data type 1 class selection for virtual channel x

These bits select the data type 1 class and subclass for the virtual channel x according to the MIPI specification for CSI- 2.

50.9.5 CSI-2 Host virtual channel x configuration register 3 (CSI_VCxCFGR3)

Address offset: 0x18 + 0x10 * x, (x = 0 to 3)

Reset value: 0x0000 0000

Any change in this register while the virtual channel x is running is ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **DT4FT[4:0]**: Data type 4 format

These bits configure the input pixel format for the virtual channel x on data type 4.
00000: (BPP6) 6-bit words (for example RAW6, RGB666)
00001: (BPP7) 7-bit words (for example RAW7)
00010: (BPP8) 8-bit words (for example RAW8, YUV 8 bits, RGB888, RGB444, RGB555, RGB565, JPEG)
00011: (BPP10) 10-bit words (for example RAW10, YUV 10 bits)
00100: (BPP12) 12-bit words (for example RAW12)
00101: (BPP14) 14-bit words (for example RAW14)
00110: (BPP16) 16-bit words (for example RAW16)
Others: Reserved and must not be used.

Note: The format selection is valid only if ALLDT = 0 and DT4EN = 1. These bits have no effect if ALLDT = 1.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **DT4[5:0]**: Data type 4 class selection for virtual channel x

These bits select the data type 4 class and subclass for the virtual channel x according to the MIPI specification for CSI-2.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DT3FT[4:0]**: Data type 3 format

These bits configure the input pixel format for the virtual channel x on data type 3.
00000: (BPP6) 6-bit words (for example RAW6, RGB666)
00001: (BPP7) 7-bit words (for example RAW7)
00010: (BPP8) 8-bit words (for example RAW8, YUV 8 bits, RGB888, RGB444, RGB555, RGB565, JPEG)
00011: (BPP10) 10-bit words (for example RAW10, YUV 10 bits)
00100: (BPP12) 12-bit words (for example RAW12)
00101: (BPP14) 14-bit words (for example RAW14)
00110: (BPP16) 16-bit words (for example RAW16)
Others: Reserved and must not be used.

Note: The format selection is valid only if ALLDT = 0 and DT3EN = 1. These bits have no effect if ALLDT = 1.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DT3[5:0]**: Data type 3 class selection for virtual channel x

These bits select the data type 3 class and subclass for the virtual channel x according to the MIPI specification for CSI-2.

50.9.6 CSI-2 Host virtual channel x configuration register 4 (CSI_VCxCFGR4)

Address offset: 0x1C + 0x10 * x, (x = 0 to 3)

Reset value: 0x0000 0000

Any change in this register while the virtual channel x is running is ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **DT6FT[4:0]**: Data type 6 format

These bits configure the input pixel format for the virtual channel x on data type 6.
00000: (BPP6) 6-bit words (for example RAW6, RGB666)
00001: (BPP7) 7-bit words (for example RAW7)
00010: (BPP8) 8-bit words (for example RAW8, YUV 8 bits, RGB888, RGB444, RGB555, RGB565, JPEG)
00011: (BPP10) 10-bit words (for example RAW10, YUV 10 bits)
00100: (BPP12) 12-bit words (for example RAW12)
00101: (BPP14) 14-bit words (for example RAW14)
00110: (BPP16) 16-bit words (for example RAW16)
Others: Reserved and must not be used.

Note: The format selection is valid only if ALLDT = 0 and DT6EN = 1. These bits have no effect if ALLDT = 1.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **DT6[5:0]**: Data type 6 class selection for virtual channel x

These bits select the data type 6 class and subclass for the virtual channel x according to the MIPI specification for CSI-2.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DT5FT[4:0]**: Data type 5 format

These bits configure the input pixel format for the virtual channel x on data type 5.
00000: (BPP6) 6-bit words (for example RAW6, RGB666)
00001: (BPP7) 7-bit words (for example RAW7)
00010: (BPP8) 8-bit words (for example RAW8, YUV 8 bits, RGB888, RGB444, RGB555, RGB565, JPEG)
00011: (BPP10) 10-bit words (for example RAW10, YUV 10 bits)
00100: (BPP12) 12-bit words (for example RAW12)
00101: (BPP14) 14-bit words (for example RAW14)
00110: (BPP16) 16-bit words (for example RAW16)
Others: Reserved.

Note: The format selection is valid only if ALLDT = 0 and DT5EN = 1. These bits have no effect if ALLDT = 1.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DT5[5:0]**: Data type 5 class selection for virtual channel x

These bits select the data type 5 class and subclass for the virtual channel x according to the MIPI specification for Camera Serial Interface 2.

50.9.7 CSI-2 Host line byte x configuration register (CSI_LBxCFGR)

Address offset: 0x50 + 0x04 * x, (x = 0 to 3)

Reset value: 0x0000 0000

Any change in this register while LBxEN bit is set into the CSI_PRGITR is ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LINECNT[15:0]

BYTECNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **LINECNT[15:0]**: Line counter

These bits select the line number, associated to LINECNT[15:0], to trigger, if enabled, the corresponding line/byte interruption flag based on the selected virtual channel identified in CSI_PRGITR.

Bits 15:0 **BYTECNT[15:0]**: Byte counter

These bits select the byte number, associated to BYTECNT[15:0], to trigger, if enabled, the corresponding line/byte interruption flag based on the selected virtual channel identified in CSI_PRGITR.

50.9.8 CSI-2 Host timer x configuration register (CSI_TIMxCFGR)

Address offset: 0x60 + 0x04 * x, (x = 0 to 3)

Reset value: 0x0000 0000

COUNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **COUNT[24:0]**: Clock cycle counter

This register is used to specify how many clock cycles (clk_proc) the timer needs to count from a SOF on the considered virtual channel, before triggering the associated interrupt flag if enabled in CSI_PRGITR. The interruption is generated if TIMxIE is set in CSI_IER0.

50.9.9 CSI-2 Host lane merger configuration register (CSI_LMCFGR)

Address offset: 0x70

Reset value: 0x4321 0200

This register must not be modified while the CSI-2 is enabled.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					rw	rw	rw								

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:20 **DL1MAP[2:0]**: Physical mapping of logical data lane 1

These bits are used to map the physical data lane 1 on the logical data lane.
001: Physical data lane 1 connected to logical data lane 0
010: Physical data lane 1 connected to logical data lane 1
Others: Reserved

Note: This field value must be different from DL0MAP[2:0].

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **DL0MAP[2:0]**: Physical mapping of logical data lane 0

These bits are used to map the physical data lane 0 on the logical data lane.
001: Physical data lane 0 connected to logical data lane 0
010: Physical data lane 0 connected to logical data lane 1
Others: Reserved

Note: This field value must be different from DL1MAP[2:0].

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **LANENB[2:0]**: Number of lanes

These bits are used to specify the number of lanes used for the data reception.
001: 1 lane for the reception
010: 2 lanes for the reception
Others: Reserved

Bits 7:0 Reserved, must be kept at reset value.

50.9.10 CSI-2 Host program interrupt register (CSI_PRGITR)

Address offset: 0x74

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw		rw	rw	rw		rw	rw	rw		rw	rw	rw		rw	rw

Bit 31 **TIM3EN**: TIM3 base time enable

This bit is used to enable the mechanism of event generation starting from SOF or EOF depending on TIM3EOF. An interrupt is generated if TIM3IE is set int CSI_IER0.
0: Timer 3 clock cycle counter not active
1: Timer 3 clock cycle counter active

Note: Enabling this bit locks TIM3EOF and TIM3VC[1:0] values.
The counting starts from the next frame after setting this bit.
This bit must be written only when the CSI-2 is disabled.

Bit 30 **TIM3EOF**: TIM3 base time starting from the EOF

This bits is used to select the starting point of the counter on the selected virtual channel.
0: SOF selected as starting point for the counter
1: EOF selected as starting point for the counter

Note: The write access to this bit is ignored if TIM3EN = 1 in CSI_PRGITR.
This bit must be written only when the CSI-2 is disabled.

Bits 29:28 **TIM3VC[1:0]**: TIM3 base time linked to a virtual channel

These bits are used to select from which of the virtual channels the TIM3 counter is linked.
00: Virtual channel 0 used to generate the TIM3 event
01: Virtual channel 1 used to generate the TIM3 event
10: Virtual channel 2 used to generate the TIM3 event
11: Virtual channel 3 used to generate the TIM3 event

Note: The write access to these bits is ignored if TIM3EN = 1 in CSI_PRGITR.
These bits must be written only when the CSI-2 is disabled.

Bit 27 **TIM2EN**: TIM2 base time enable

This bit is used to enable the mechanism of event generation starting from SOF or EOF depending on TIM2EOF. An interrupt is generated if TIM2IE is set in CSI_IER0.

0: Timer 2 clock cycle counter not active.

1: Timer 2 clock cycle counter active

Note: Enabling this bit locks TIM2EOF and TIM2VC[1:0] values.

The counting starts from the next frame after setting this bit.

This bit must be written only when the CSI-2 is disabled.

Bit 26 **TIM2EOF**: TIM2 base time starting from the EOF

This bits is used to select the starting point of the counter on the selected virtual channel.

0: SOF selected as starting point for the counter

1: EOF selected as starting point for the counter

Note: The write access to this bit is ignored if TIM2EN = 1 in CSI_PRGITR.

This bit must be written only when the CSI-2 is disabled.

Bits 25:24 **TIM2VC[1:0]**: TIM2 base time linked to a virtual channel

These bits are used to select from which of the virtual channels the TIM2 counter is linked.

00: Virtual channel 0 used to generate the TIM2 event

01: Virtual channel 1 used to generate the TIM2 event

10: Virtual channel 2 used to generate the TIM2 event

11: Virtual channel 3 used to generate the TIM2 event

Note: The write access to these bits is ignored if TIM2EN = 1 in CSI_PRGITR.

These bits must be written only when the CSI-2 is disabled.

Bit 23 **TIM1EN**: TIM1 base time enable

This bit is used to enable the mechanism of event generation starting from SOF or EOF depending on TIM1EOF. An interrupt is generated if TIM1IE is set in CSI_IER0.

0: Timer 1 clock cycle counter not active.

1: Timer 1 clock cycle counter active

Note: Enabling this bit locks TIM1EOF and TIM1VC[1:0] values.

The counting starts from the next frame after setting this bit.

This bit must be written only when the CSI-2 is disabled.

Bit 22 **TIM1EOF**: TIM1 base time starting from the EOF

This bits is used to select the starting point of the counter on the selected virtual channel.

0: SOF selected as starting point for the counter

1: EOF selected as starting point for the counter

Note: The write access to this bit is ignored if TIM1EN = 1 in CSI_PRGITR.

This bit must be written only when the CSI-2 is disabled.

Bits 21:20 **TIM1VC[1:0]**: TIM1 base time linked to a virtual channel

These bits are used to select from which of the virtual channels the TIM1 counter is linked.

00: Virtual channel 0 used to generate the TIM1 event

01: Virtual channel 1 used to generate the TIM1 event

10: Virtual channel 2 used to generate the TIM1 event

11: Virtual channel 3 used to generate the TIM1 event

Note: The write access to these bits is ignored if TIM1EN = 1 in CSI_PRGITR.

These bits must be written only when the CSI-2 is disabled.

Bit 19 **TIM0EN**: TIM0 base time enable

This bit is used to enable the mechanism of event generation starting from SOF or EOF depending on TIM0EOF. An interrupt is generated if TIM0IE is set in CSI_IER0.

0: Timer 0 clock cycle counter not active

1: Timer 0 clock cycle counter active

Note: Enabling this bit locks TIM0EOF and TIM0VC[1:0] values.

The counting starts from the next frame after setting this bit.

This bit must be written only when the CSI-2 is disabled.

Bit 18 **TIM0EOF**: TIM0 base time starting from the EOF

This bits is used to select the starting point of the counter on the selected virtual channel.

0: SOF selected e as starting point for the counter

1: EOF selected as starting point for the counter

Note: The write access to this bit is ignored if TIM0EN = 1 in CSI_PRGITR.

This bit must be written only when the CSI-2 is disabled.

Bits 17:16 **TIM0VC[1:0]**: TIM0 base time linked to a virtual channel

These bits are used to select from which of the virtual channels the TIM0 counter is linked.

00: Virtual channel 0 used to generate the TIM0 event

01: Virtual channel 1 used to generate the TIM0 event

10: Virtual channel 2 used to generate the TIM0 event

11: Virtual channel 3 used to generate the TIM0 event

Note: The write access to these bits is ignored if TIM0EN = 1 in CSI_PRGITR.

These bits must be written only when the CSI-2 is disabled.

Bit 15 **LB3EN**: Line/byte 3 counter enable

This bit is used to enable the mechanism of event generation at any location in the frame corresponding to the value set in CSI_LB3CFGR. An interrupt is generated if LB3IE is set in CSI_IER0.

0: Line/byte 3 counter stopped

1: Line/byte 3 counter active

Note: Enabling this bit locks LB3VC[1:0] value.

The counter starts from the next frame after setting this bit.

This bit must be set only when the CSI-2 is enabled.

Bit 14 Reserved, must be kept at reset value.

Bits 13:12 **LB3VC[1:0]**: Line/byte counter 3 linked to a virtual channel

These bits are used to select from which of the virtual channels the line/byte counter 3 is linked.

00: Virtual channel 0 used to generate the line/byte counter 3 event

01: Virtual channel 1 used to generate the line/byte counter 3 event

10: Virtual channel 2 used to generate the line/byte counter 3 event

11: Virtual channel 3 used to generate the line/byte counter 3 event

Note: The write access to these bits is ignored if LB3EN = 1 in CSI_PRGITR.

Bit 11 **LB2EN**: Line/byte 2 counter enable

This bit is used to enable the mechanism of event generation at any location in the frame corresponding to the value set in CSI_LB2CFGR. An interrupt is generated if LB2IE is set in CSI_IER0.

0: Line/byte 2 counter stopped

1: Line/byte 2 counter active

Note: Enabling this bit locks LB2VC[1:0] value.

The counter starts from the next frame after setting this bit.

This bit must be set only when the CSI-2 is enabled.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **LB2VC[1:0]**: Line/byte counter 2 linked to a virtual channel

These bits are used to select from which of the virtual channels the line/byte counter 2 is linked.

00: Virtual channel 0 used to generate the line/byte counter 2 event

01: Virtual channel 1 used to generate the line/byte counter 2 event

10: Virtual channel 2 used to generate the line/byte counter 2 event

11: Virtual channel 3 used to generate the line/byte counter 2 event

Note: The write access to these bits is ignored if LB2EN = 1 in CSI_PRGITR.

Bit 7 **LB1EN**: Line/byte 1 counter enable

This bit is used to enable the mechanism of event generation at any location in the frame corresponding to the value set in CSI_LB1CFGR. An interrupt is generated if LB1IE is set in CSI_IER0.

0: Line/byte 1 counter stopped

1: Line/byte 1 counter active

Note: Enabling this bit locks LB1VC[1:0] value.

The counter starts from the next frame after setting this bit.

This bit must be set only when the CSI-2 is enabled.

Bit 6 Reserved, must be kept at reset value.

Bits 5:4 **LB1VC[1:0]**: Line/byte counter 1 linked to a virtual channel

These bits are used to select from which of the virtual channels the line/byte counter 1 is linked.

00: Virtual channel 0 used to generate the line/byte counter 1 event

01: Virtual channel 1 used to generate the line/byte counter 1 event

10: Virtual channel 2 used to generate the line/byte counter 1 event

11: Virtual channel 3 used to generate the line/byte counter 1 event

Note: The write access to these bits is ignored if LB1EN = 1 in CSI_PRGITR.

Bit 3 **LB0EN**: Line/byte 0 counter enable

This bit is used to enable the mechanism of event generation at any location in the frame corresponding to the value set in CSI_LB0CFGR. An interrupt is generated if LB0IE is set in CSI_IER0.

0: Line/byte 0 counter stopped

1: Line/byte 0 counter active

Note: Enabling this bit locks LB0VC[1:0] value.

The counter starts from the next frame after setting this bit.

This bit must be set only when the CSI-2 is enabled.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **LB0VC[1:0]**: Line/byte counter 0 linked to a virtual channel

These bits are used to select from which of the virtual channels the line/byte counter 0 is linked.

00: Virtual channel 0 used to generate the line/byte counter 0 event

01: Virtual channel 1 used to generate the line/byte counter 0 event

10: Virtual channel 2 used to generate the line/byte counter 0 event

11: Virtual channel 3 used to generate the line/byte counter 0 event

Note: The write access to these bits is ignored if LB0EN = 1 in CSI_PRGITR.

50.9.11 CSI-2 Host watchdog register (CSI_WDR)

Address offset: 0x78

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CNT[31:0]**: Watchdog counter

These bits contains the maximum number of clock cycles (clk_proc) between an EOF and a SOF for a given channel before triggering an interrupt if WDERRIE = 1 in CSI_IER0.

The value 0x000000 disables the watchdog counter.

50.9.12 CSI-2 Host interrupt enable register 0 (CSI_IER0)

Address offset: 0x80

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SYNCERRIE**: Invalid synchronization error interrupt enable

This bit enables the interrupt generation when an invalid synchronization is detected.

It can be a SOF short packet during a frame, or and EOF short packet during an inter-frame.

0: Interrupt on invalid synchronization error disabled

1: Interrupt on invalid synchronization error enabled

Bit 29 **WDERRIE**: Watchdog error interrupt enable
This bit enables the interrupt generation when the time between two packets for a virtual channel is longer than the programmed watchdog.
0: Interrupt on watchdog error disabled
1: Interrupt on watchdog error enabled

Bit 28 **SPKTERRIE**: Short packet error interrupt enable
This bit enables the interrupt generation based on a reception of a shorter packet than expected.
0: Interrupt on short packet error disabled
1: Interrupt on short packet error enabled

Bit 27 **IDERRIE**: Data type ID error interrupt enable
This bit enables the interrupt generation based on a detection of a reserved data type.
0: Interrupt on reception of reserved data type disabled
1: Interrupt on reception of reserved data type enabled

Bit 26 **CECCERRIE**: Corrected ECC error interrupt enable
This bit enables the interrupt generation based on a corrected ECC error detection.
0: Interrupt on corrected ECC error detection disabled
1: Interrupt on corrected ECC error detection enabled

Bit 25 **ECCERRIE**: ECC error interrupt enable
This bit enables the interrupt generation based on an ECC error detection.
0: Interrupt on ECC error detection disabled
1: Interrupt on ECC error detection enabled

Bit 24 **CRCERRIE**: CRC error interrupt enable
This bit enables the interrupt generation based on CRC error detection on a long packet reception.
0: Interrupt on CRC error detection disabled
1: Interrupt on CRC error detection enabled

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **CCFIFOFIE**: Clock changer FIFO full interrupt enable
This bit enables the interrupt generation based on clock changer FIFO full detection.
0: Interrupt on clock changer FIFO full detection disabled
1: Interrupt on clock changer FIFO full detection enabled

Bits 20:17 Reserved, must be kept at reset value.

Bit 16 **SPKTIE**: Short packet interrupt enable
This bit generates an interrupt which notifies that a generic short packet has been received by the CSI-2 Host.
0: Short packet detection interrupt disabled
1: Short packet detection interrupt enabled

Bit 15 **EOF3IE**: EOF for virtual channel 3 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding an EOF on the virtual channel 3.
0: EOF on virtual channel 3 interrupt disabled
1: EOF on virtual channel 3 interrupt enabled

Bit 14 **EOF2IE**: EOF for virtual channel 2 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding an EOF on the virtual channel 2.
0: EOF on virtual channel 2 interrupt disabled
1: EOF on virtual channel 2 interrupt enabled

Bit 13 **EOF1IE**: EOF for virtual channel 1 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding an EOF on the virtual channel 1.
0: EOF on virtual channel 1 interrupt disabled
1: EOF on virtual channel 1 interrupt enabled

Bit 12 **EOF0IE**: EOF for virtual channel 0 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding an EOF on the virtual channel 0.
0: EOF on virtual channel 0 interrupt disabled
1: EOF on virtual channel 0 interrupt enabled

Bit 11 **SOF3IE**: SOF for virtual channel 3 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding a SOF on the virtual channel 3.
0: SOF on virtual channel 3 interrupt disabled
1: SOF on virtual channel 3 interrupt enabled

Bit 10 **SOF2IE**: SOF for virtual channel 2 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding a SOF on the virtual channel 2.
0: SOF on virtual channel 2 interrupt disabled
1: SOF on virtual channel 2 interrupt enabled

Bit 9 **SOF1IE**: SOF for virtual channel 1 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding a SOF on the virtual channel 1.
0: SOF on virtual channel 1 interrupt disabled.
1: SOF on virtual channel 1 interrupt enabled.

Bit 8 **SOF0IE**: SOF for virtual channel 0 interrupt enable
This bit enables the interrupt generation when the CSI-2 Host is decoding a SOF on the virtual channel 0.
0: SOF on virtual channel 0 interrupt disabled
1: SOF on virtual channel 0 interrupt enabled

Bit 7 **TIM3IE**: Timer 3 interrupt enable
This bit enables the interrupt generation from the timer 3 linked to the virtual channel number configured by TIM3VC in CSI_PRGITR. The interrupt raises when the timer 3 value reaches the value configured in CSI_TIM3CFGR.
0: Timer 3 interrupt disabled
1: Timer 3 interrupt enabled

Bit 6 **TIM2IE**: Timer 2 interrupt enable
This bit enables the interrupt generation from the timer 2 linked to the virtual channel number configured by TIM2VC in CSI_PRGITR. The interrupt raises when the timer 2 value reaches the value configured in CSI_TIM2CFGR.
0: Timer 2 interrupt disabled
1: Timer 2 interrupt enabled

Bit 5 **TIM1IE**: Timer 1 interrupt enable

This bit enables the interrupt generation from the timer 1 linked to the virtual channel number configured by TIM1VC in CSI_PRGITR. The interrupt raises when the timer 1 value reaches the value configured in CSI_TIM1CFGR.

0: Timer 1 interrupt disabled

1: Timer 1 interrupt enabled

Bit 4 **TIM0IE**: Timer 0 interrupt enable

This bit enables the interrupt generation from the timer 0 linked to the virtual channel number configured by TIM0VC in CSI_PRGITR. The interrupt raises when the timer 0 value reaches the value configured in CSI_TIM0CFGR.

0: Timer 0 interrupt disabled

1: Timer 0 interrupt enabled

Bit 3 **LB3IE**: Line/byte counter 3 interrupt enable

This bit enables the interrupt generation when the active frame of the virtual channel configured by LB3VC in CSI_PRGITR reaches the line/byte number programmed in CSI_LB3CFGR.

Bit 2 **LB2IE**: Line/byte counter 2 interrupt enable

This bit enables the interrupt generation when the active frame of the virtual channel configured by LB2VC in CSI_PRGITR reaches the line/byte number programmed in CSI_LB2CFGR.

Bit 1 **LB1IE**: Line/byte counter 1 interrupt enable

This bit enables the interrupt generation when the active frame of the virtual channel configured by LB1VC in CSI_PRGITR reaches the line/byte number programmed in CSI_LB1CFGR.

Bit 0 **LB0IE**: Line/byte counter 0 interrupt enable

This bit enables the interrupt generation when the active frame of the virtual channel configured by LB0VC in CSI_PRGITR reaches the line/byte number programmed in CSI_LB0CFGR.

50.9.13 CSI-2 Host interrupt enable register 1 (CSI_IER1)

Address offset: 0x84

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **ECTRLDL1IE**: D-PHY_RX lane 1 control error interrupt enable
This bit enables the D-PHY_RX control error interrupt detected on lane 1 consecutive to an incorrect line state sequence.
0: Lane 1 control error interrupt disabled
1: Lane 1 control error interrupt enabled

Bit 11 **ESYNCESCDL1IE**: D-PHY_RX lane 1 low-power data transmission synchronization error interrupt enable
This bit enables the interrupt generation when the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends on lane 1.
0: Lane 1 low-power data transmission interrupt error disabled
1: Lane 1 low-power data transmission Interrupt error enabled

Bit 10 **EESCDL1IE**: D-PHY_RX lane 1 escape entry error interrupt enable
This bit enables the interrupt generation when an unrecognized escape entry command is received on lane 1.
0: Lane 1 unrecognized escape entry command interrupt error disabled
1: Lane 1 unrecognized escape entry command interrupt error enabled

Bit 9 **ESOTSYNCDL1IE**: SOT synchronization interrupt error enable on lane 1
This bit enables the interrupt generation when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization cannot be expected.
0: Lane 1 SOT synchronization interrupt error disabled
1: Lane 1 SOT synchronization interrupt error enabled

Bit 8 **ESOTDL1IE**: SOT error interrupt enable on lane 1
This bit enables the interrupt generation when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization can still be achieved.
0: Lane 1 SOT interrupt error disabled
1: Lane 1 SOT interrupt error enabled

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **ECTRLDL0IE**: D-PHY_RX lane 0 control error interrupt enable
This bit enables the D-PHY_RX control error interrupt detected on lane 0 consecutive to an incorrect line state sequence.
0: Lane 0 control error interrupt disabled
1: Lane 0 control error interrupt enabled

Bit 3 **ESYNCESCDL0IE**: D-PHY_RX lane 0 low power data transmission synchronization error interrupt enable
This bit enables the interrupt generation when the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends on lane 1.
0: Lane 0 low-power data transmission interrupt error disabled
1: Lane 0 low-power data transmission Interrupt error enabled

Bit 2 **EESCDL0IE**: D-PHY_RX lane 0 escape entry error interrupt enable
This bit enables the interrupt generation when an unrecognized escape entry command is received on lane 0.
0: Lane 0 unrecognized escape entry command interrupt error disabled
1: Lane 0 unrecognized escape entry command interrupt error enabled

Bit 1 **ESOTSYNCDL0IE**: SOT synchronization interrupt error enable on lane 0
This bit enables the interrupt generation when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization cannot be expected.
0: Lane 0 SOT synchronization interrupt error disabled
1: Lane 0 SOT synchronization interrupt error enabled

Bit 0 **ESOTDL0IE**: SOT error interrupt enable on lane 0
This bit enables the interrupt generation when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization can still be achieved.
0: Lane 0 SOT interrupt error disabled
1: Lane 0 SOT interrupt error enabled

50.9.14 CSI-2 Host status register 0 (CSI_SR0)

Address offset: 0x90

Reset value: 0x0000 0000

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SYNCERRF**: Invalid synchronization error flag
This bit indicates an invalid synchronization is detected. It can be a SOF short packet during a frame, or and EOF short packet during an inter-frame.

Bit 29 **WDERRF**: Watchdog error flag
This bit indicates that the time between two packets for a virtual channel is longer than the programmed watchdog.

Bit 28 **SPKTERRF**: Short packet error flag
This bit indicates a reception of a shorter packet than expected.

Bit 27 **IDERRF**: Data type ID error flag
This bit indicates a detection of a reserved data type.

Bit 26 **CECCERRF**: Corrected ECC error flag
This bit indicates a corrected ECC error detection took place in the frame.

Bit 25 **ECCERRF**: ECC error flag
This bit indicates that an ECC error has been detected.

Bit 24 **CRCERRF**: CRC error flag
This bit indicates a CRC error detection on a long packet reception.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **CCFIFOFF**: Clock changer FIFO full flag
This bit indicates a FIFO full detection in the clock changer.

Bit 20 **VC3STATEF**: Virtual channel 3 state flag
This bit indicates the state of the virtual channel 3.
0: Virtual channel inactive
1: Virtual channel active

Bit 19 **VC2STATEF**: Virtual channel 2 state flag
This bit indicates the state of the virtual channel 2.
0: Virtual channel inactive
1: Virtual channel active

Bit 18 **VC1STATEF**: Virtual channel 1 state flag
This bit indicates the state of the virtual channel 1.
0: Virtual channel inactive
1: Virtual channel active

Bit 17 **VC0STATEF**: Virtual channel 0 state flag
This bit indicates the state of the virtual channel 0.
0: Virtual channel inactive
1: Virtual channel active

Bit 16 **SPKTF**: Short packet flag
This bit notifies that a generic short packet has been received by the CSI-2 Host.

Bit 15 **EOF3F**: EOF flag for virtual channel 3
This bit notifies that the CSI-2 Host decodes an EOF on the virtual channel 3.

Bit 14 **EOF2F**: EOF flag for virtual channel 2
This bit notifies that the CSI-2 Host is decoding an EOF on the virtual channel 2.

Bit 13 **EOF1F**:EOF flag for virtual channel 1
This bit notifies that the CSI-2 Host is decoding an EOF on the virtual channel 1.

Bit 12 **EOF0F**: EOF flag for virtual channel 0
This bit notifies that the CSI-2 Host is decoding an EOF on the virtual channel 0.

Bit 11 **SOF3F**: SOF flag for virtual channel 3
This bit notifies that the CSI-2 Host is decoding a SOF on the virtual channel 3.

Bit 10 **SOF2F**: SOF flag for virtual channel 2
This bit notifies that the CSI-2 Host is decoding a SOF on the virtual channel 2.

Bit 9 **SOF1F**: SOF flag for virtual channel 1
This bit notifies that the CSI-2 Host is decoding a sSOF on the virtual channel 1.

Bit 8 **SOF0F**: SOF flag for virtual channel 0
This bit notifies that the CSI-2 Host is decoding a SOF on the virtual channel 0.

Bit 7 **TIM3F**: Timer 3 flag
This bit indicates that the timer 3 linked to the virtual channel configured by TIM3VC in CSI_PRGITR reaches the value programmed in CSI_TIM3CFGR.

Bit 6 **TIM2F**: Timer 2 flag
This bit indicates that the timer 2 linked to the virtual channel configured by TIM2VC in CSI_PRGITR reaches the value programmed in CSI_TIM2CFGR.

Bit 5 **TIM1F**: Timer 1 flag
This bit indicates that the timer 1 linked to the virtual channel configured by TIM1VC in CSI_PRGITR reaches the value programmed in CSI_TIM1CFGR.

Bit 4 **TIM0F**: Timer 0 flag
This bit indicates that the timer 0 linked to the virtual channel configured by TIM0VC in CSI_PRGITR reaches the value programmed in CSI_TIM0CFGR.

Bit 3 **LB3F**: Line/byte counter 3 flag
This bit notifies that the active frame of the virtual channel configured by LB3VC in CSI_PRGITR has reached the line/byte number programmed in th CSI_LB3CFGR.

Bit 2 **LB2F**: Line/byte counter 2 flag
This bit notifies that the active frame of the virtual channel configured by LB2VC in CSI_PRGITR has reached the line/byte number programmed in CSI_LB2CFGR.

Bit 1 **LB1F**: Line/byte counter 1 flag
This bit notifies that the active frame of the virtual channel configured by LB1VC in CSI_PRGITR has reached the line/byte number programmed in CSI_LB1CFGR.

Bit 0 **LB0F**: Line/byte counter 0 flag
This bit notifies that the active frame of the virtual channel configured by LB0VC in CSI_PRGITR has reached the line/byte number programmed in CSI_LB0CFGR.

50.9.15 CSI-2 Host status register 1 (CSI_SR1)

Address offset: 0x94

			r	r	r	r	r				r	r	r	r	r

Bit 31 **ACTCLF**: D-PHY_RX receiver clock active flag
This bit indicates the status of RxClkactiveHs D-PHY_RX signal.

Bit 30 **ULPNCLF**: D-PHY_RX receiver Ultra-Low power state (not) on clock lane.
This bit indicates the status of RxUlpsClkNot D-PHY_RX signal.

Bit 29 **ULPNACTF**: D-PHY_RX receiver ULP state (not) active
This bit indicates the status of UlpsactiveNotC D-PHY_RX signal.

Bit 28 **STOPCLF**: D-PHY_RX receiver in stop state for the clock lane
This bit indicates the status of StopStateC D-PHY_RX signal.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **ULPNDL1F**: D-PHY_RX receiver ultra-low-power state (not) active on data lane 1
This bit indicates the status of UlpsActiveNot_D_lane1 D-PHY_RX signal.

Bit 25 **STOPDL1F**: D-PHY_RX receiver data lane 1 in stop state
This bit indicates the status of StopState_D_lane1 D-PHY_RX signal.

Bit 24 **SKCALDL1F**: D-PHY_RX lane 1 high-speed skew calibration
This bit indicates the status of RxSkewCalHS_lane1 D-PHY_RX signal.

Bit 23 **SYNCDL1F**: D-PHY_RX lane 1 receiver synchronization observed
This bit indicates the status of RXSyncHS_lane1 D-PHY_RX signal.

Bit 22 **ACTDL1F**: D-PHY_RX lane 1 high-speed reception active
This bit indicates the status of RxActiveHS_lane1 D-PHY_RX signal.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **ULPNDL0F**: D-PHY_RX receiver ultra-low-power state (not) active on data lane 0
This bit indicates the status of UlpsActiveNot_D_lane0 D-PHY_RX signal.

Bit 19 **STOPDL0F**: D-PHY_RX receiver data lane 0 in stop state
This bit indicates the status of StopState_D_lane0 D-PHY_RX signal.

Bit 18 **SKCALDL0F**: D-PHY_RX lane 0 high-speed skew calibration
This bit indicates the status of RxSkewCalHS_lane0 D-PHY_RX signal.

Bit 17 **SYNCDL0F**: D-PHY_RX lane 0 receiver synchronization observed
This bit indicates the status of RXSyncHS_lane0 D-PHY_RX signal.

Bit 16 **ACTDL0F**: D-PHY_RX lane 0 high-speed reception active
This bit indicates the status of RxActiveHS_lane0 D-PHY_RX signal.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **ECTRLDL1F**: D-PHY_RX lane 1 control error flag
This bit indicates that the D-PHY_RX detected on lane 1 an incorrect line state sequence.

Bit 11 **ESYNCESCDL1F**: D-PHY_RX lane 1 low-power data transmission synchronization error flag
This bit notifies a synchronization error when the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends on lane 1.

Bit 10 **EESCDL1F**: D-PHY_RX lane 1 escape entry error flag
This bit notifies an escape entry error when an unrecognized escape entry command is received on lane 1.

Bit 9 **ESOTSYNCDL1F**: SOT synchronization error flag on lane 1
This bit indicates a SOT synchronization error when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization cannot be expected.

Bit 8 **ESOTDL1F**: SOT error flag on lane 1
This bit notifies a SOT error when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization can still be achieved.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **ECTRLDL0F**: D-PHY_RX lane 0 control error flag
This bit indicates that the D-PHY_RX detected on lane 0 an incorrect line state sequence.

Bit 3 **ESYNCESCDL0F**: D-PHY_RX lane 0 low-power data transmission synchronization error flag
This bit notifies a synchronization error when the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends on lane 0.

Bit 2 **EESCDL0F**: D-PHY_RX lane 0 escape entry error flag
This bit notifies an escape entry error when an unrecognized escape entry command is received on lane 0.

Bit 1 **ESOTSYNCDL0F**: SOT synchronization error flag on lane 0
This bit indicates a SOT synchronization error when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization cannot be expected.

Bit 0 **ESOTDL0F**: SOT error flag on lane 0
This bit notifies a SOT error when the high-speed SOT leader sequence is corrupted in a such way that the proper synchronization can still be achieved.

Bit 30 **CSYNCERRF**: Clear invalid synchronization error flag
Write 1 clears SYNCERRF flag in CSI_SR0.

Bit 29 **CWDERRF**: Clear watchdog error flag
Write 1 clears WDERRF flag in CSI_SR0.

Bit 28 **CSPKTERRF**: Clear short packet error flag
Write 1 clears SPKTERRF flag in CSI_SR0.

Bit 27 **CIDERRF**: Clear data type ID error flag
Write 1 clears CIDERRF flag in CSI_SR0.

Bit 26 **CCECCERRF**: Clear corrected ECC error flag
Write 1 clears CCECCERRF flag in CSI_SR0.

Bit 25 **CECCERRF**: Clear ECC error flag
Write 1 clears CECCERRF flag in CSI_SR0.

Bit 24 **CCRCERRF**: Clear CRC error flag
Write 1 clears CRCERRF flag in CSI_SR0.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **CCCFIFOFF**: Clear clock changer FIFO full flag
Write 1 clears CCFIFOFF flag in CSI_SR0.

Bits 20:17 Reserved, must be kept at reset value.

Bit 16 **CSPKTF**: Clear short packet flag
Write 1 clears SPKTF flag in CSI_SR0.

Bit 15 **CEOF3F**: Clear EOF flag for virtual channel 3
Write 1 clears EOF3F flag in CSI_SR0.

Bit 14 **CEOF2F**: Clear EOF flag for virtual channel 2
Write 1 clears EOF2F flag in CSI_SR0.

Bit 13 **CEOF1F**: Clear EOF flag for virtual channel 1
Write 1 clears EOF1F flag in CSI_SR0.

Bit 12 **CEOF0F**: Clear EOF flag for virtual channel 0
Write 1 clears EOF0F flag in CSI_SR0.

Bit 11 **CSOF3F**: Clear SOF flag for virtual channel 3
Write 1 clears SOF3F flag in CSI_SR0.

Bit 10 **CSOF2F**: Clear SOF flag for virtual channel 2
Write 1 clears SOF2F flag in CSI_SR0.

Bit 9 **CSOF1F**: Clear SOF flag for virtual channel 1
Write 1 clears SOF1F flag in CSI_SR0.

Bit 8 **CSOF0F**: Clear SOF flag for virtual channel 0
Write 1 clears SOF0F flag in CSI_SR0.

Bit 7 **CTIM3F**: Clear timer 3 flag
Write 1 clears TIM3F flag in CSI_SR0.

Bit 6 **CTIM2F**: Clear timer 2 flag
Write 1 clears TIM2F flag in CSI_SR0.

Bit 5 **CTIM1F**: Clear timer 1 flag
Write 1 clears TIM1F flag in CSI_SR0.

Bit 4 **CTIM0F**: Clear timer 0 flag
Write 1 clears TIM0F flag in CSI_SR0.

Bit 3 **CLB3F**: Clear line/byte counter 3 flag
Write 1 clears LB3F flag in CSI_SR0.

Bit 2 **CLB2F**: Clear line/byte counter 2 flag
Write 1 clears LB2F flag in CSI_SR0.

Bit 1 **CLB1F**: Clear line/byte counter 1 flag
Write 1 clears LB1F flag in CSI_SR0.

Bit 0 **CLB0F**: Clear line/byte counter 0 flag
Write 1 clears LB0F flag in CSI_SR0.

50.9.17 CSI-2 Host flag clear register 1 (CSI_FCR1)

Address offset: 0x104

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

			w	w	w	w	w				w	w	w	w	w

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **CECTRLDL1F**: Clear D-PHY_RX lane 1 control error flag
Write 1 clears ECTRLDL1F flag in CSI_SR1.

Bit 11 **CESYNCESCDL1F**: Clear D-PHY_RX lane 1 low-power data transmission synchronization error flag
Write 1 clears ESYNCESCDL1F flag in CSI_SR1.

Bit 10 **CEESCDL1F**: Clear D-PHY_RX lane 1 escape entry error flag
Write 1 clears the EESCDL1F flag in the CSI_SR1 register

Bit 9 **CESOTSYNCDL1F**: Clear SOT synchronization error flag on lane 1
Write 1 clears ESOTSYNCDL1F flag in CSI_SR1.

Bit 8 **CESOTDL1F**: Clear SOT error flag on lane 1
Write 1 clears ESOTDL1F flag in CSI_SR1.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **CECTRLDL0F**: Clear D-PHY_RX lane 0 control error flag
Write 1 clears ECTRLDL0F in CSI_SR1.

Bit 3 **CESYNCESCDL0F**: Clear D-PHY_RX lane 0 low-power data transmission synchronization error flag
Write 1 clears ESYNCESCDL0F flag in CSI_SR1.

Bit 2 **CEESCDL0F**: Clear D-PHY_RX lane 0 escape entry error flag
Write 1 clears EESCDL0F flag in CSI_SR1.

Bit 1 **CESOTSYNCDL0F**: Clear SOT synchronization error flag on lane 0
Write 1 clears ESOTSYNCDL0F flag in CSI_SR1.

Bit 0 **CESOTDL0F**: Clear SOT error flag on lane 0
Write 1 clears ESOTDL0F flag in CSI_SR1.

50.9.18 CSI-2 Host short packet data field register (CSI_SPDFR)

Address offset: 0x110

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VCHANNEL[1:0]		DATATYPE[5:0]					
								r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAFIELD[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **VCHANNEL[1:0]**: Virtual channel
This bit indicates which is the virtual channel number decoded in the last generic short packet data field reception. Write to this bit has no effect.

Bits 21:16 **DATATYPE[5:0]**: Data type class
This bit indicates which is the data type class and subclass (according to the MIPI specification for CSI-2) decoded in the last generic short packet data field reception. Write to this bit has no effect.

Bits 15:0 **DATAFIELD[15:0]**: Data field
This bit indicates which is the current data field decoded in the last generic short packet data field reception. Write to this bit has no effect.

50.9.19 CSI-2 Host error register 1 (CSI_ERR1)

Address offset: 0x114

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IDVCERR[1:0]		IDDTERR[5:0]					
								r	r	r	r	r	r	r	r

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **IDVCERR[1:0]**: Virtual channel having ID error
This bit indicates for which virtual channel an ID error has been detected.
IDERRF is set in CSI_SR0 to highlight the error.

Bits 21:16 **IDDTERR[5:0]**: Data type in error
This bit indicates for which data type an ID error has been detected.
IDERRF is set in CSI_SR0 to highlight the error.

Bits 15:14 **CECCVCERR[1:0]**: Virtual channel having a corrected ECC error
This bit indicates for which virtual channel a corrected ECC error has been detected.
CECCERRF is set in CSI_SR0 to highlight the error.

Bits 13:8 **CECCDTERR[5:0]**: Data type having a corrected ECC error
This bit indicates for which data type a corrected ECC error has been detected.
CECCERRF is set in CSI_SR0 to highlight the error.

Bits 7:6 **CRCVCERR[1:0]**: Virtual channel having a CRC error
This bit indicates for which virtual channel a CRC error has been detected.
CRCERRF is set in CSI_SR0 to highlight the error.

Bits 5:0 **CRCDTERR[5:0]**: Data type having a CRC error
This bit indicates for which data type a CRC error has been detected.
CRCERRF is set in CSI_SR0 to highlight the error.

50.9.20 CSI-2 Host error register 2 (CSI_ERR2)

Address offset: 0x118

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SPKTVCERR [1:0]		SPKTDTERR [5:0]					
								r	r	r	r	r	r	r	r

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:18 **SYNCVCERR[1:0]**: Virtual channel having synchronization error

This bit indicates for which virtual channel a synchronization error has been detected. SYNCERRF is set in CSI_SR0 to highlight the error.

Bits 17:16 **WDVCERR[1:0]**: Virtual channel having a watchdog error

This bit indicates for which virtual channel a watchdog error has been detected. WDERRF is set in CSI_SR0 to highlight the error.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:6 **SPKTVCERR[1:0]**: Virtual channel having a short packet error

This bit indicates for which virtual channel a short packet error has been detected. SPKTERRF is set in CSI_SR0 to highlight the error.

Bits 5:0 **SPKTDTERR[5:0]**: Data type having a short packet error

This bit indicates for which data type a shorter packet than expected error has been detected. SPKTERRF is set in CSI_SR0 to highlight the error.

50.9.21 CSI-2 Host hardware configuration register (CSI_HHWCFGR)

Address offset: 0x0FF0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MAJREV[3:0]				MINREV[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **MAJREV[3:0]**: Major revision
This field returns the major revision of the CSI-2 Host.

Bits 3:0 **MINREV[3:0]**: Major revision
This field returns the minor revision of the CSI-2 Host.

50.9.23 CSI-2 Host identification register (CSI_HIPIDR)

Address offset: 0x0FF8

Reset value: 0x0016 2011

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ID[31:0]**: Identification code
This field returns the identification code of the CSI-2 Host.

50.9.24 CSI-2 Host size identification register (CSI_HSIDR)

Address offset: 0x0FFC

Reset value: 0xA3C5 DD04

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

SID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **SID[31:0]**: Size and ID

This field returns the size and the ID of the CSI-2 Host.

50.10 CSI PHY registers

50.10.1 CSI PHY reset control register (CSI_PRCR)

Address offset: 0x1000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PEN	Res.
														rw	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **PEN**:

When set to 0, this bit places the digital section of the D-PHY in the reset state.

0: PHY is disabled (in reset state).

1: PHY is enabled (out of reset state).

Bit 0 Reserved, must be kept at reset value.

50.10.2 CSI PHY mode control register (CSI_PMCR)

Address offset: 0x1004

Reset value: 0x0001 1003

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TUEXDL0
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	TUESDL0	Res.	Res.	Res.	RTDL0	Res.	Res.	Res.	DTDL	Res.	FTXSMDL0	FRXMDL1	FRXMDL0
			rw				rw				rw		rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **TUEXDL0**: Tx ULP exit sequence data lane 0
This bit initiates the transmission of the ULP exit sequence.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **TUESDL0**: Tx ULP escape-mode data lane 0

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **RTDL0**: Turn-around request data lane 0
This bit is used to indicate that the protocol layer needs to turn the lane around, allowing from the other side to start transmitting the data.
0: No request
1: Request for turn-around for DL0

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **DTDL**: Disable turn-around data lane 0
This bit is used to prevent the bi-directional lane from processing a turn-around request in the lane interconnect
0: Disabled
1: Enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FTXSMDL0**: Force to Tx Stop mode the data lane 0
0: Disabled
1: Enabled

Bit 1 **FRXMDL1**: Force to Rx mode the data lane 1
Module 0 into receive mode/wait for stop state.
0: Disabled
1: Enabled

Bit 0 **FRXMDL0**: Force to Rx mode the data lane 0
Module 0 into receive mode/wait for stop state.
0: Disabled
1: Enabled

50.10.3 CSI PHY frequency control register (CSI_PFCR)

Address offset: 0x1008

Reset value: 0x0000 0017

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	HSFR[6:0]							Res.	Res.	CCFR[5:0]					
	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **DLD**: Data lane direction of lane 0
0: Rx
1: Tx

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **HSFR[6:0]**: PHY high-speed frequency range selection
Must be set when the CSI PHY is in power-down, and must not change during operation.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **CCFR[5:0]**: Configuration clock frequency range selection
Must be set at value = round (Fcfg_clk(MHz) - 17) * 4.

50.10.4 CSI PHY test control register 0 (CSI_PTCR0)

Address offset: 0x1010

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TDI[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **TWM**: Test-interface write mode selector
0: Data write operation is set on the rising edge of the testclk signal.
1: Address write operation is set on the falling edge of the testclk signal.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **TDI[7:0]**: Test-interface data in

50.10.6 CSI PHY test status register (CSI_PTSR)

Address offset: 0x1018

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LANES[3:0]				TECHNO[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **LANES[3:0]**: Amount of CSI data lanes (excluding the clock lane)
0x0: Lane information not provided
0x1: One CSI data lane implemented
0x2: Two CSI data lanes implemented
0x4: Four CSI data lanes implemented

Bits 3:0 **TECHNO[3:0]**: Technology
This field returns the technology used.
0x0: Technology information not provided
0x1: Reserved for 40nm PHY
0x2: 16FF Synopsys PHY.

50.10.8 CSI-2 Host version register (CSI_VERR)

Address offset: 0x1FF4

Reset value: 0x0000 0010

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MAJREV[3:0]				MINREV[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **MAJREV[3:0]**: Major revision
This field returns the major revision of the CSI-2 Host.

Bits 3:0 **MINREV[3:0]**: Major revision
This field returns the minor revision of the CSI-2 Host.

50.10.9 CSI-2 Host identification register (CSI_IPIDR)

Address offset: 0x1FF8

Reset value: 0x0016 2011

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ID[31:0]**: Identification code
This field returns the identification code of the CSI-2 Host.

50.10.10 CSI-2 Host size identification register (CSI_SIDR)

Address offset: 0x1FFC

Reset value: 0xA3C5 DD08

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SID[31:16]

Refer to *Section 2.4* for the register boundary addresses.

51 Parallel synchronous slave interface (PSSI)

The PSSI peripheral and the DCMI (digital camera interface) use the same circuitry. As a result, these two peripherals cannot be used at the same time: when using the PSSI, the DCMI registers cannot be accessed, and vice-versa.

In addition, the PSSI and the DCMI share the same alternate functions and interrupt vector (see *Section 51.3.2: PSSI pins and internal signals*).

51.1 Introduction

The PSSI is a generic synchronous 8/16-bit parallel data input/output slave interface. It enables the transmitter to send a data valid signal that indicates when the data is valid, and the receiver to output a flow control signal that indicates when it is ready to sample the data.

51.2 PSSI main features

The PSSI peripheral main features are the following:

- Slave mode operation
- 8-bit or 16-bit parallel data input or output
- 8-word (32-byte) FIFO
- Data enable (PSSI_DE) and Ready (PSSI_RDY) alternate function

  When selected, these signals can either enable the transmitter to indicate when the data is valid, allow the receiver to indicate when it is ready to sample the data, or both.

51.3 PSSI functional description

The PSSI is a synchronous parallel slave interface that can send or receive high-speed data flows. It consists of up to 16 data lines (PSSI_D[15:0]) plus a clock line (PSSI_PDCK). The clock polarity can be configured so that data can be captured or transmitted on either the clock rising or falling edge.

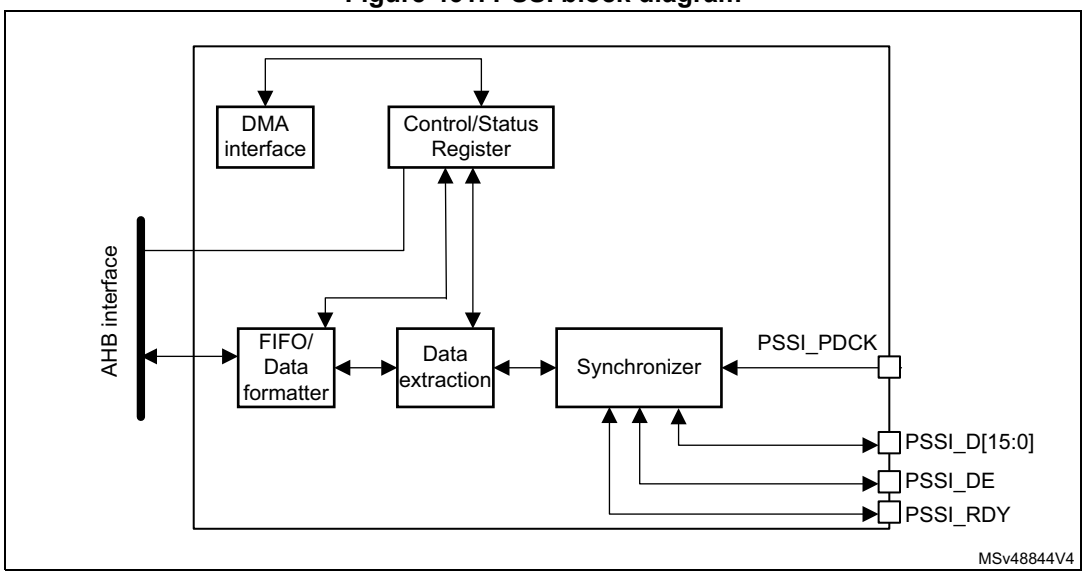
Usually, a general-purpose DMA channel is used to pass 32-bit packed data via the data register (PSSI_DR).

The data flow can either be continuous or synchronized by hardware using the optional PSSI_DE (Data enable), and PSSI_RDY (Ready) signals.

Figure 461 shows the PSSI block diagram.

51.3.1 PSSI block diagram

Figure 461. PSSI block diagram



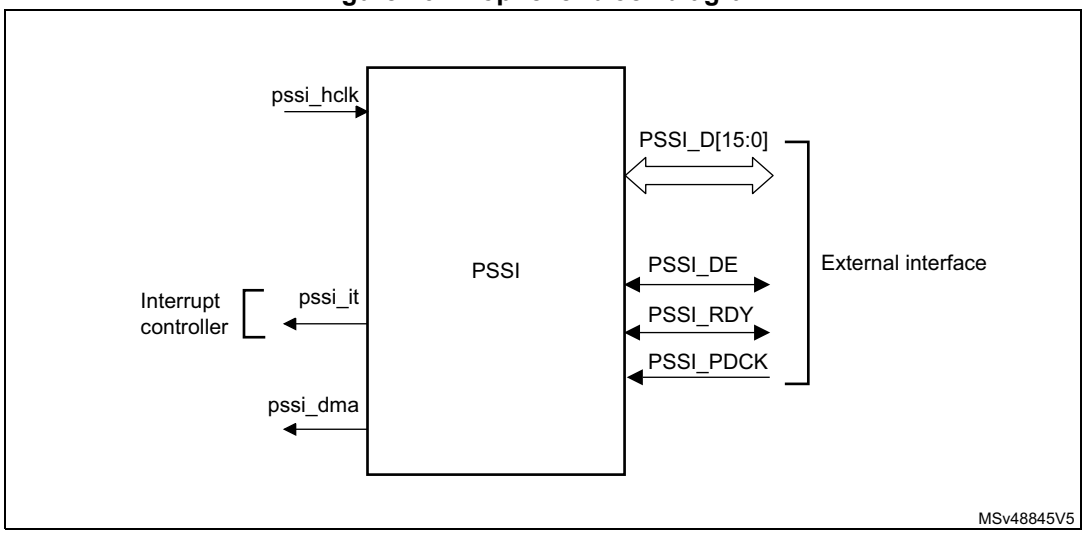


Figure 462. Top-level block diagram

51.3.2 PSSI pins and internal signals

The PSSI interface is composed of 19 pins, though nine signals are enough to transfer parallel data. *Table 490* shows the PSSI pins.

When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, the alternate functions and the interrupt vector are associated with the PSSI. Otherwise, they are associated with the DCMI. The DCMI ENABLE bit (bit 15 of DCMI_CR) and the PSSI ENABLE bit (bit 14 of PSSI_CR) must not be set to 1 at the same time. As an example, if a GPIO is configured to use the alternate function PSSI_PDCK/DCMI_PIXCK, it is the PSSI_PDCK function which becomes active if PSSI_CR/ENABLE is set to 1.

Table 490. PSSI input/output pins

PSSI signal name	DCMI signal it is shared with	Signal type	Description
PSSI_PDCK	DCMI_PIXCK	Input	Parallel data clock input
PSSI_D[15:0]	DCMI_D[13:0]	Input/output	Data output when transmitting, data input when receiving
PSSI_DE	DCMI_HSYNC	Input/output	Data enable signal
PSSI_RDY	DCMI_VSYNC	Input/output	Ready signal

Table 491 shows the PSSI internal input/output signals.

Table 491. PSSI internal input/output signals

Internal signal name	Signal type	Description
pssi_it	Output	Interrupt
pssi_dma	Output	DMA request
pssi_hclk	Input	AHB clock

51.3.3 PSSI clock

The AHB clock frequency must be at least 2.5 times higher than the PSSI_PDCK frequency. At frequency ratios lower than 2.5, data might be corrupted or lost during transfers.

Data transfers are synchronous with PSSI_PDCK. The PSSI_PDCK polarity can be configured as follows, through CKPOL bit (bit 5 of PSSI_CR):

- When CKPOL = 0
  - Input pins are sampled on PSSI_PDCK falling edge
  - Output pins are driven on PSSI_PDCK rising edge
- When CKPOL = 1
  - Input pins are sampled on PSSI_PDCK rising edge
  - Output pins are driven on PSSI_PDCK falling edge

51.3.4 PSSI data management

Data direction

The direction of data transfers is configured through the OUTEN control bit (bit 31 of PSSI_CR):

- When OUTEN is cleared to 0 (default setting), the PSSI operates in receive mode and the data is input on the data pins.
- When OUTEN is set to 1, the peripheral operates in transmit mode and the data is output on the data pins.

OUTEN can be modified only when the ENABLE bit is cleared to 0.

Data register and DMA

Data are transferred from/to the FIFO using the PSSI_DR data register:

- In receive mode, data must be read from the FIFO by reading PSSI_DR.
- In transmit mode, data must be written to the FIFO by writing into PSSI_DR.

Word (32-bit) accesses to PSSI_DR and half-word (16-bit) accesses to PSSI_DR[15:0] are permitted in all modes. Byte (8-bit) accesses to PSSI_DR[7:0] are permitted only when the PSSI is configured to transfer 8 bits at a time (EDM=00 in the PSSI_CR register).

To reduce the load on the CPU, it is recommended to use the DMA to transfer data from/to the PSSI FIFO. When it is used, the DMA must be configured to transfer data via the PSSI_DR register. Using 32-bit transfers optimizes bandwidth and reduces the bus load. However, 8-bit and 16-bit transfers are also permitted.

To use the DMA, set the PSSI DMA enable bit (DMAEN in PSSI_CR) to 1 (default setting). When DMAEN is set to 1, a DMA transfer is initiated when the FIFO is ready for a 32-bit transfer (four valid bytes in receive mode or four empty bytes in transmit mode). As a result, in receive mode, no DMA transfers are initiated if there are three bytes or fewer in the FIFO, even if the DMA is configured to perform 8-bit transfers.

The RTT4B and RTT1B status bits (PSSI_SR) are useful when the CPU directly perform transfers to and from the FIFO. RTT4B set to 1 indicates that the FIFO is ready to transfer four bytes: at least four valid bytes in the FIFO in receive mode or at least four free bytes in transmit mode. RTT1B set to 1 indicates that the FIFO is ready to transfer one byte: at least one valid byte in the FIFO in receive mode or at least one free byte in transmit mode.

8-bit data

The PSSI parallel interface can transfer either 8-bit (using D[7:0]) or 16-bit data (using D[15:0]) depending on the EDM[1:0] control bits (bits 11:10 of PSSI_CR). If the 8-bit configuration is selected (EDM[1:0] set to 00), the unused D[15:0] pins can be used for GPIO or other functions.

When EDM[1:0] in PSSI_CR are programmed to 00, the interface transfers 8 bits using the D[7:0] pins. In this case, D[15:8] are not used and four PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant byte (bits 7:0) correspond to the first byte transferred, and the most-significant byte (bits 31:28) corresponds to the forth byte transferred. *Table 492* illustrates the positioning of the data bytes in two 32-bit words.

Table 492. Positioning of captured data bytes in 32-bit words (8-bit width)

Byte address	31:24	23:16	15:8	7:0
0	D_{n+3}[7:0]	D_{n+2}[7:0]	D_{n+1}[7:0]	D_n[7:0]
4	D_{n+7}[7:0]	D_{n+6}[7:0]	D_{n+5}[7:0]	D_{n+4}[7:0]

16-bit data

When EDM[1:0] in PSSI_CR are programmed to 11, the interface transfers 16 bits using the D[15:0] pins. In this case, two PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant half word (bits 15:0) correspond to the first half word transferred, and the most-significant half-word (bits 31:16) corresponds to the second half word transferred. *Table 493* illustrates the positioning of the data in two 32-bit words.

Table 493. Positioning of captured data bytes in 32-bit words (16-bit width)

Byte address	31:16	15:0
0	D_{n+1}[15:0]	D_n[15:0]
4	D_{n+3}[15:0]	D_{n+2}[15:0]

FIFO data buffer and error conditions

An eight-word FIFO helps improving performance and avoids overruns and underruns.

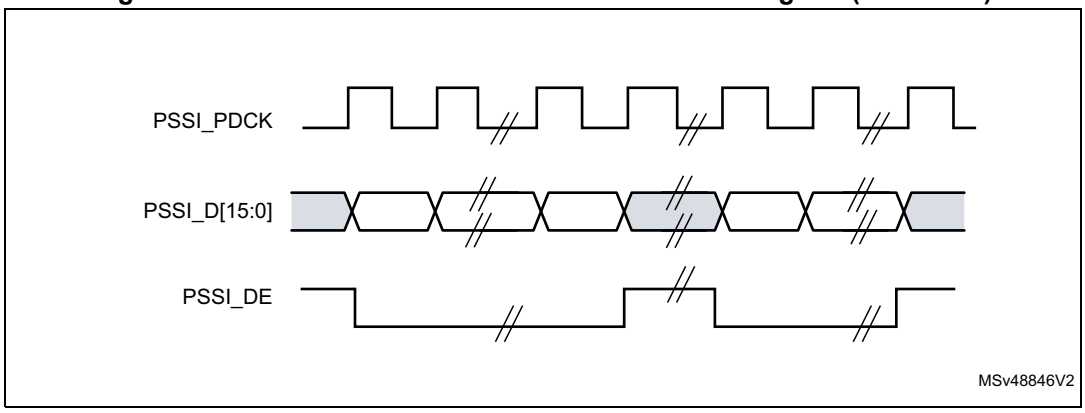
If the ready signal (PSSI_RDY) is disabled in receive mode, an overrun error is generated when a clock active edge occurs when the FIFO is full. In this case, the input data is lost.

If the data enable signal (PSSI_DE) is disabled in transmit mode, an underrun error is generated when a clock active edge occurs when the FIFO is empty. In this case, unpredictable data are output.

The OVR_RIS status bit indicates that either an overrun or an underrun occurred. An interrupt can be generated when these events occur.

51.3.5 PSSI optional control signals

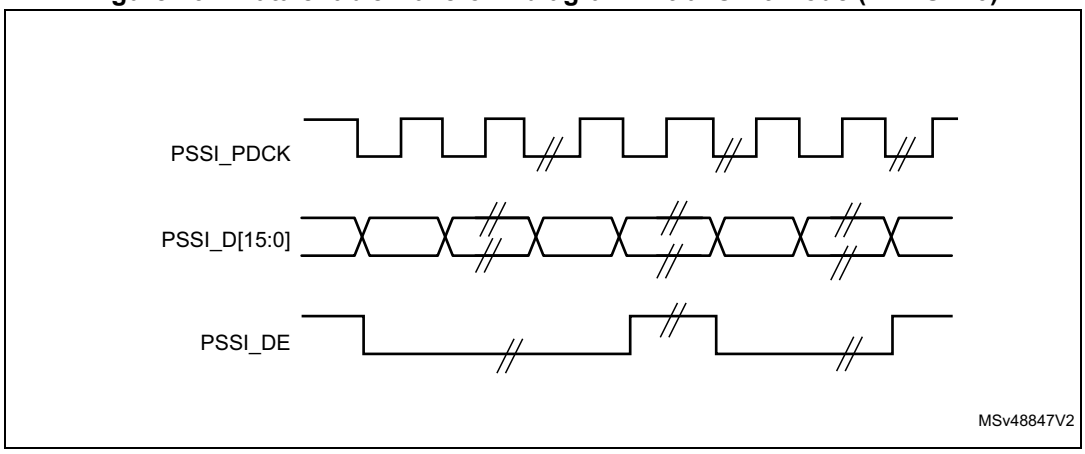
Data Enable (PSSI_DE) alternate function input



The data enable signal, PSSI_DE, is an optional signal. It is driven by the data source/transmitter in order to indicate that the data is valid to be transferred during the current cycle. When PSSI_DE is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG (bits 20:18 of PSSI_CR) control bits. PSSI_DE polarity is configured through DEPOL control bit (bit 6 of PSSI_CR). PSSI_DE is active low when DEPOL is cleared to 0, and high when DEPOL is et to 1.

The direction of the PSSI_DE signal is defined by the OUTEN value. It is the same as the data direction.



If the PSSI_DE alternate function input is enabled (through DERDYCFG) in receive mode (OUTEN cleared to 0), the PSSI samples PSSI_DE on the same PSSI_PDCK edge as the one used for sampling the data (D[15:0]). If PSSI_DE is active, the sampled data is saved in the FIFO. Otherwise, the sampled data is considered invalid and discarded. The transmitting device can use PSSI_DE as a data valid signal, driving it inactive when the data in the current cycle is not valid. This flow control function allows avoiding underrun errors.

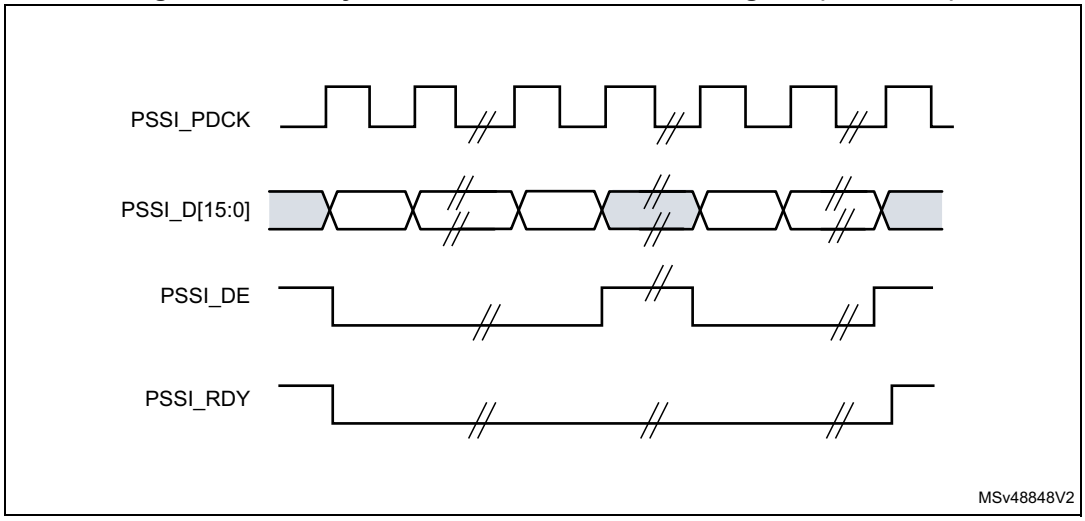
Figure 463. Data enable in receive mode waveform diagram (CKPOL=0)

If the PSSI_DE alternate output function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI drives PSSI_DE on the same PSSI_PDCK edge that the one used to drive the data (D[15:0]). If a new 8 or 16-bit data (as programmed in the EDM[1:0] control bits in PSSI_CR) is available for transmission in the internal FIFO, this data is output on the data outputs (D[15:0]) and the PSSI_DE output becomes active on the current PSSI_PDCK edge. Otherwise (if the TX FIFO is empty), the D[15:0] outputs remains unchanged on the next clock edge and the PSSI_DE output becomes inactive.

Figure 464. Data enable waveform diagram in transmit mode (CKPOL=0)

Ready (PSSI_RDY) alternate function output

The ready signal, PSSI_RDY, is an optional signal. It is driven by the receiving device and indicates whether data is being accepted in the current cycle. When PSSI_RDY is inactive, it means that the data must not be sampled by the receiver at the next clock edge.



This alternate function signal can be enabled using the DERDYCFG control bits (bits 20:18 of PSSI_CR). PSSI_RDY polarity is configured through the RDYPOL control bit (bit 6 of PSSI_CR). PSSI_RDY is active low when RDYPOL is cleared to 0, and high when RDYPOL set to 1.

The direction of the PSSI_RDY signal is defined by the OUTEN (bit 31 of PSSI_CR). It is set in the opposite direction compared to the PSSI_DE and data signals.

If the PSSI_RDY alternate output function is enabled (through DERDYCFG) in receive mode (OUTEN=0), the PSSI drives PSSI_RDY one PSSI_PDCK half cycle after it samples

the data (D[15:0]). If the FIFO has enough free space to receive more data, the PSSI drives the PSSI_RDY signal active. Otherwise, if the FIFO is full and cannot accept more data, the PSSI drives the PSSI_RDY signal inactive. The transmitting device must repeat the current data in the next cycle when it detects that PSSI_RDY is inactive. This flow control function allows the PSSI to avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

Figure 465. Ready in receive mode waveform diagram (CKPOL=0)

If the PSSI_RDY alternate input function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI samples the PSSI_RDY signal on the opposite PSSI_PDCK edge to the one at which D[15:0] are driven. If the PSSI_RDY signal is inactive, the PSSI keeps the same data (D[15:0]) and PSSI_DE signals that valid data are available during the next PSSI_PDCK clock cycle. Otherwise, if PSSI_RDY signal is sampled as active, the next data from the TX FIFO (if available) is output on the data outputs (D[15:0]). If no new data are available in the TX FIFO, the PSSI keeps the data output values and outputs the PSSI_DE signal as inactive (if enabled).

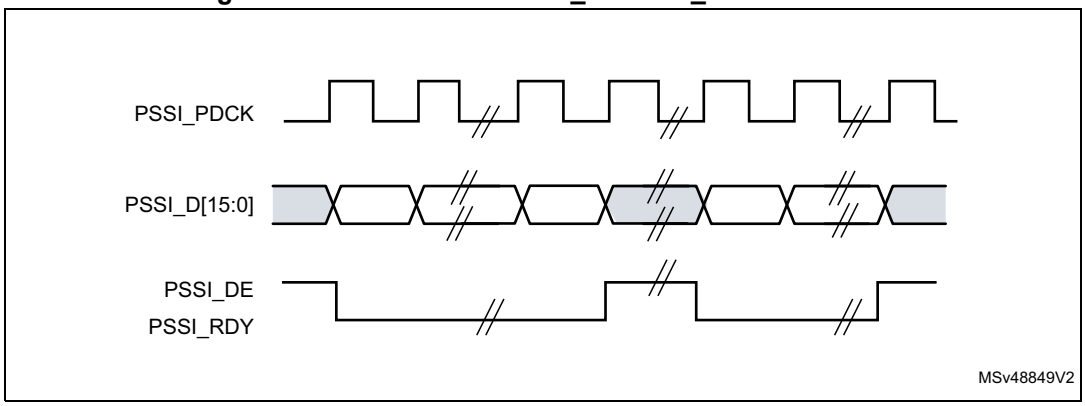
The receiving device uses the PSSI_RDY to control the data flow and avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

Bidirectional PSSI_DE/PSSI_RDY signal

A single pin can be used for both data enable (PSSI_DE) and ready (PSSI_RDY) functions if DEPOL and RDYPOL are both set to 1 and DERDYCFG is set to 111 or 100 in the PSSI_CR register. In this case, the GPIO corresponding to selected alternate function (PSSI_DE when DERDYCFG=111 or PSSI_RDY when DERDYCFG=100) must be configured as open-drain. The other device must also be configured to drive the line as open-drain, and a weak pull-up must be applied to the line.

The signal thus becomes bidirectional. If either the sender drives the line low (to indicate that the data is not valid) or the receiver drives the line low (to indicate that it is not sampling the current data), then both devices know that the data is not being transferred in the current cycle.

Figure 466. Bidirectional PSSI_DE/PSSI_RDY waveform



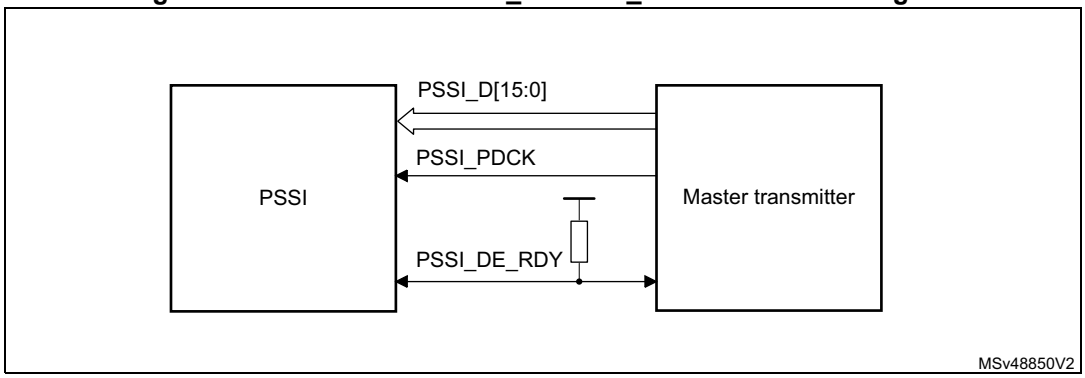


Figure 467. Bidirectional PSSI_DE/PSSI_RDY connection diagram

51.4 PSSI interrupts

The PSSI generates only one interrupt (IT_OVR). It is consequently equivalent to the global interrupt (pssi_it). Refer to *Table 494* for the list of interrupts.

The PSSI and the DCMI share the same interrupt vector. When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, these interrupts are triggered by the PSSI. Otherwise, they are controlled by the DCMI.

The DCMI ENABLE bit (bit 14 of DCMI_CR) and PSSI ENABLE bit must not be set to 1 at the same time.

Table 494. PSSI interrupt requests

Interrupt acronym	Shared with DCMI	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from low-power mode
IT_OVR	IT_OVR	indicates overrun in receive mode or underrun in transmit mode	OVR_RIS	OVR_IE	OVR_ISC	NA

51.5 PSSI registers

An 8-bit write or a 16-bit write operation to any PSSI register besides PSSI_DR, results in a bus error. 32-bit read and write operations are permitted.

51.5.1 PSSI control register (PSSI_CR)

Address offset: 0x00

Reset value: 0x4000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OUTEN	DMAEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DERDYCFG[2:0]			Res.	Res.
rw	rw										rw	rw	rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	ENABLE	Res.	Res.	EDM[1:0]		Res.	RDYPOL	Res.	DEPOL	CKPOL	Res.	Res.	Res.	Res.	Res.
	rw			rw	rw		rw		rw	rw					

Bit 31 **OUTEN:** Data direction selection bit
0: Receive mode: data is input synchronously with PSSI_PDCK
1: Transmit mode: data is output synchronously with PSSI_PDCK

Bit 30 **DMAEN:** DMA enable bit
0: DMA transfers are disabled. The user application can directly access the PSSI_DR register when DMA transfers are disabled.
1: DMA transfers are enabled (default configuration). A DMA channel in the general-purpose DMA controller must be configured to perform transfers from/to PSSI_DR.

Bits 29:21 Reserved, must be kept at reset value.

Bits 20:18 **DERDYCFG[2:0]:** Data enable and ready configuration
000: PSSI_DE and PSSI_RDY both disabled
001: Only PSSI_RDY enabled
010: Only PSSI_DE enabled
011: Both PSSI_RDY and PSSI_DE alternate functions enabled
100: Both PSSI_RDY and PSSI_DE features enabled - bidirectional on PSSI_RDY pin (see *Bidirectional PSSI_DE/PSSI_RDY signal on page 2825*)
101: Only PSSI_RDY function enabled, but mapped to PSSI_DE pin
110: Only PSSI_DE function enabled, but mapped to PSSI_RDY pin
111: Both PSSI_RDY and PSSI_DE features enabled - bidirectional on PSSI_DE pin (see *Bidirectional PSSI_DE/PSSI_RDY signal on page 2825*)
When the PSSI_RDY function is mapped to the PSSI_DE pin (settings 101 or 111), it is still the RDYPOL bit which determines its polarity. Similarly, when the PSSI_DE function is mapped to the PSSI_RDY pin (settings 110 or 111), it is still the DEPOL bit which determines its polarity.

Bits 17:15 Reserved, must be kept at reset value.

Bit 14 **ENABLE:** PSSI enable

0: PSSI disabled

1: PSSI enabled

The contents of the FIFO are flushed when ENABLE is cleared to 0.

Note: When ENABLE=1, the content of PSSI_CR must not be changed, except for the ENABLE bit itself. All configuration bits can change as soon as ENABLE changes from 0 to 1.

The DMA controller and all PSSI configuration registers must be programmed correctly before setting the ENABLE bit to 1.

The ENABLE bit and the DCMI ENABLE bit (bit 15 of DCMI_CR) must not be set to 1 at the same time.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 **EDM[1:0]:** Extended data mode

00: Interface captures 8-bit data on every parallel data clock

01: Reserved, must not be selected

10: Reserved, must not be selected

11: The interface captures 16-bit data on every parallel data clock

Bit 9 Reserved, must be kept at reset value.

Bit 8 **RDYPOL:** Ready (PSSI_RDY) polarity

This bit indicates the level on the PSSI_RDY pin when the data are not valid on the parallel interface.

0: PSSI_RDY active low (0 indicates that the receiver is ready to receive)

1: PSSI_RDY active high (1 indicates that the receiver is ready to receive)

Bit 7 Reserved, must be kept at reset value.

Bit 6 **DEPOL:** Data enable (PSSI_DE) polarity

This bit indicates the level on the PSSI_DE pin when the data are not valid on the parallel interface.

0: PSSI_DE active low (0 indicates that data is valid)

1: PSSI_DE active high (1 indicates that data is valid)

Bit 5 **CKPOL:** Parallel data clock polarity

This bit configures the capture edge of the parallel clock or the edge used for driving outputs, depending on OUTEN.

0: Falling edge active for inputs or rising edge active for outputs

1: Rising edge active for inputs or falling edge active for outputs.

Bits 4:0 Reserved, must be kept at reset value.

51.5.2 PSSI status register (PSSI_SR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RTT1B	RTT4B	Res.	Res.
												r	r		

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RTT1B:** FIFO is ready to transfer one byte

1: FIFO is ready for a one byte (32-bit) transfer. In receive mode, this means that at least one valid data byte is in the FIFO. In transmit mode, this means that there is at least one byte free in the FIFO.

0: FIFO is not ready for a 1-byte transfer

Bit 2 **RTT4B:** FIFO is ready to transfer four bytes

1: FIFO is ready for a four-byte (32-bit) transfer. In receive mode, this means that at least four valid data bytes are in the FIFO. In transmit mode, this means that there are at least four bytes free in the FIFO.

0: FIFO is not ready for a four-byte transfer

Bits 1:0 Reserved, must be kept at reset value.

51.5.3 PSSI raw interrupt status register (PSSI_RIS)

Address offset: 0x08

Reset value: 0x0000 0000

PSSI_RIS gives the raw interrupt status. This register is read-only. When read, it returns the status of the corresponding interrupt before masking with the PSSI_IER register value.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR_RIS	Res.
														r	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_RIS:** Data buffer overrun/underrun raw interrupt status

0: No overrun/underrun occurred

1: An overrun/underrun occurred: overrun in receive mode, underrun in transmit mode. This bit is cleared by writing a 1 to the OVR_ISC bit in PSSI_ICR.

Bit 0 Reserved, must be kept at reset value.

51.5.4 PSSI interrupt enable register (PSSI_IER)

Address offset: 0x0C

Reset value: 0x0000 0000

The PSSI_IER register is used to enable interrupts. When one of the PSSI_IER bits is set, the corresponding interrupt is enabled. This register is accessible both in read and write modes.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR_IE	Res.
														rw	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_IE:** Data buffer overrun/underrun interrupt enable
0: No interrupt generation
1: An interrupt is generated if either an overrun or an underrun error occurred.

Bit 0 Reserved, must be kept at reset value.

51.5.5 PSSI masked interrupt status register (PSSI_MIS)

This PSSI_MIS register is read-only. When read, it returns the current masked status value of the corresponding interrupt (depending on the value in PSSI_IER). A bit in this register is set if the corresponding enable bit in PSSI_IER is set and the corresponding bit in PSSI_RIS is set.

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR_MIS	Res.
														r	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_MIS:** Data buffer overrun/underrun masked interrupt status
This bit is set to 1 only when PSSI_IER/OVR_IE and PSSI_RIS/OVR_RIS are both set to 1.
0: No interrupt is generated when an overrun/underrun error occurs
1: An interrupt is generated if there is either an overrun or an underrun error and the OVR_IE bit is set in PSSI_IER.

Bit 0 Reserved, must be kept at reset value.

51.5.6 PSSI interrupt clear register (PSSI_ICR)

Address offset: 0x14

Reset value: 0x0000 0000

The PSSI_ICR register is write-only. Writing a 1 into a bit of this register clears the corresponding bit in the PSSI_RIS and PSSI_MIS registers. Writing a 0 has no effect. Reading this register always gives zeros.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVR_ISC	Res.
														w	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_ISC:** Data buffer overrun/underrun interrupt status clear
Writing this bit to 1 clears the OVR_RIS bit in PSSI_RIS.

Bit 0 Reserved, must be kept at reset value.

51.5.7 PSSI data register (PSSI_DR)

Address offset: 0x28

Reset value: 0x0000 0000

In receive mode (OUTEN = 0), the DMA controller must read the received data from this register. Write operations to PSSI_DR result in an error response. When more bytes than the number of valid bytes are read in the FIFO, the invalid bytes return zeros.

In transmit mode (OUTEN = 1), the DMA controller must write the data to be transmitted into this register. Read operations to PSSI_DR result in an error response.

32-bit, 16-bit, and 8-bit accesses are all supported for PSSI_DR. For instance, 16-bit read/write operations remove/add two bytes from/to the FIFO. However, 8-bit accesses are permitted only when the PSSI is configured to transfer 8 data bits at a time (EDM=00 in PSSI_CR). 8-bit accesses to PSSI_DR when EDM is not set to 0 result in an error response.

All accesses must include byte 0: 8-bit accesses must be performed to bits 7 to 0 and 16-bit accesses from bits 15 to 0. Accesses that do not include byte 0 results in an error response.

Accessing PSSI_DR when ENABLE bit in PSSI_CR is set to 0 results in an error response.

52 Display subsystem

52.1 Introduction

The display subsystem is targeted to drive up to 1536p60 display panels, through three different interfaces: parallel interface, LVDS, and DSI. It supports fairly advanced on-the-fly compositions to offload the GPU and optimize the use of the system bandwidth: up to three layers, rescale, mirror, rotation90, and a final YUV conversion.

The display subsystem reads pixels via the LTDC, and outputs them with the following capabilities:

- parallel: 1080p60-RGB888
- LVDS: 1536p60-RGB888
- MIPI DSI: 1536p60-RGB888

Some over-target non-guaranteed use cases are possible, but with specific constraints:

- Drive simultaneously three panels, using the three interfaces (parallel, LVDS, DSI), with a same content.
- Drive simultaneously two parallel LVDS panels, using each one link, with a reduced resolution and a same content.
- Drive a 4 k panel via the DSI, with a limited features and performances: one layer, no resize, no rotation, 30 fps, and non-standardized blanking sizes.

The display subsystem can also display a secure layer with data that cannot be read by non-secure application, and with the display guaranteed stable.

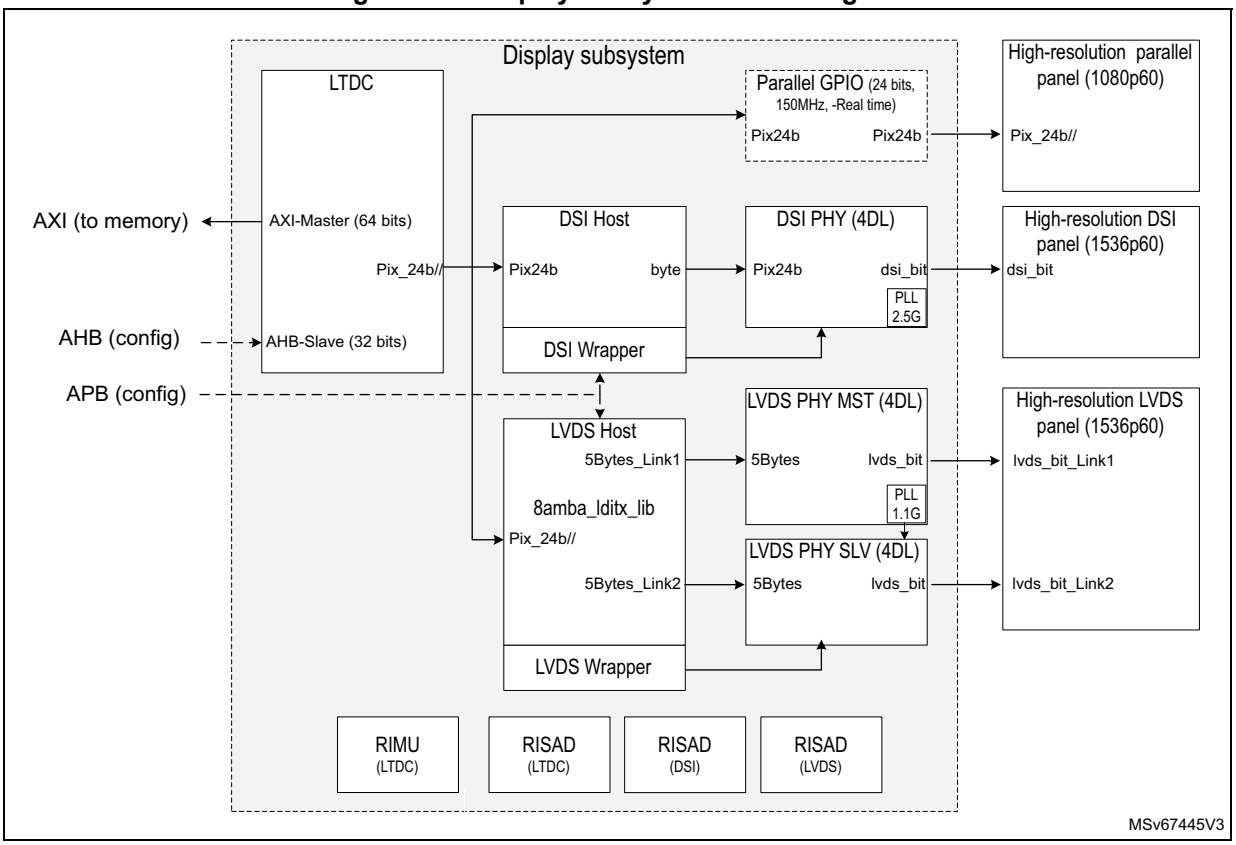
52.2 Display subsystem main features

The display subsystem is built around LTDC, DSI, and LVDS:

- LTDC: handles display composition and rotation
  - Composition: 3 layers
  - Input pixel format: flexible format, including YUV420 full-planar on layer 1.
  - Secure layer: protected access to buffer and configuration registers.
  - Rotation and mirror: 90 and 270 degrees, horizontal and vertical
  - Upsize
  - Miscellaneous: color lookup-table, color keying, Gamma
  - 1080p60 max performance
- LTDC parallel interface (integrated inside the LTDC):
  - Standard: 24 bpp + H,V synchronization signals with ReTime
  - Output rate: 150 Mpixel/s
  - Resolution: 1920x1080 at 60 fps max, with HDMI blankings
  - Pixel formats: RGB888, 666, 565, YUV422-16 bits/BT601/709

- DSI: handles the MIPI DSI protocol and PHY
  - Standard: MIPI DSI v1.3
  - Output rate: 4 data lanes @2.5 Gbps/lane
  - Resolution example: 1080p60-RGB888:with 891 Mbps/lan (4 lanes), 1536p60-RGB888: supported with 1316 Mbps/lane (4 lanes)
  - Pixel formats: RGB888
- LVDS: handles the LVDS FPD or OpenLDI protocol and PHY
  - Standard: FPD-1 and OpenLDI (resp.: 781 and 1100 Mbps/lane)
  - Hardware: 2 links (4 data lanes + 1 clock lane, up to 1.1 Gbps/lane)
  - Output rate: 2 links FPD-1 224 Mpixel/s, 1 link FPD-1: 112 Mpixel/s
  - Resolution: 2 links: 1536p60-RGB888 ma, x1 link: 1080p60-RGB888 max
  - Pixel format: RGB888/666, JEIDA/VESA.
  - Double display: capable (limitation to same content on both display).

52.3 Display subsystem implementation



The implementation is described in *Section 55: DSI Host (DSI)*, *Section 53: LCD-TFT display controller (LTDC)*, and *Section 54: LVDS display interface transmitter (LVDS)*.

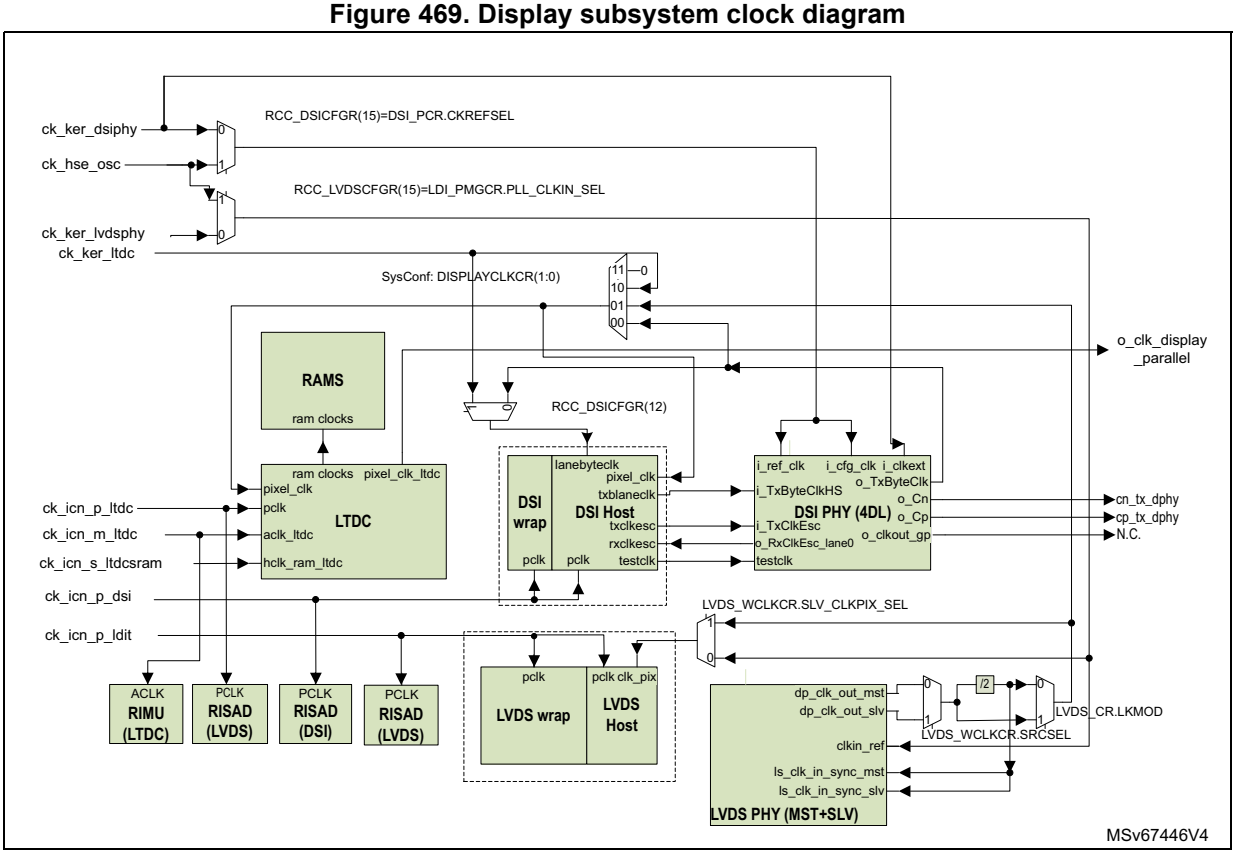
52.4 Display subsystem functional description

52.4.1 Display subsystem block diagram

The figure below shows the involved functional blocks in the display subsystem:

Figure 468. Display subsystem block diagram

Blocks in the above figure are shown with their instance/design names:



- LTDC: composition and rotation engine, includes a parallel interface
- Parallel GPIO: Parallel I/O-ring of the device with up to 24 bpp + HV synchronization
- DSI Host: DSI-Host
- DSI Wrapper: side registers for the DSI interface, handles smart panel trigger
- DSI DPHY: DSI DPHY-Rx with 4DL+1CL, @2.5 Gbps/lane
- LVDS Host: LVDS-Host, handles JEIDA/VESA, dual link, and dual panel
- LVDS Wrapper: side registers for the LVDS interface
- LVDS PHY: 2x LVDS link (4DL+1CL), including the 7x serialization
- RIMU/RISAD: RIF security logic, configured to the specific display needs

52.4.2 Display subsystem pins and external signal interface

The details of the pins and external signal interface of the display subsystem can be found in the respective functional block sections in this reference manual.

52.4.3 Display subsystem clocks

Figure 469. Display subsystem clock diagram

The display subsystem is implemented with the following clock max frequencies:

- RCC pixel clock (ck_ker_ltdc): 314 MHz
- LTDC pixel clock (pixel_clk): 314 MHz
- LTDC parallel interface (o_clk_display_par.): 150 MHz (I/O ReTime mandatory)
- DSI bit clock (cn/p_tx_dphy): 2.5Gbps/lane (1.250 GHz)
- DSI byte clock (TxByteClk/txblaneclk) 314 MHz
- DSI config and ref clock (from ck_ker_dsiphy): min = 17 MHz, max = 27 MHz
- LVDS bit clock (internal): 1.1 Gbps/lane
- LVDS pixel clock (o_lvds_pll_dp_clk_out): 314 MHz
- Register clocks (ck_icn_p_*): 200 MHz (all APB / AHB register files)
- AXI-Master clock (ck_icn_m_ltdc): 400 MHz
- AHB-Slave clock (ck_icn_s_ltdcsram): 200 MHz (not connected to system)

52.4.4 Display subsystem security

This section is an application of RIF security architecture (see *Section 6.2: Resource isolation framework (RIF)*). The security of the display subsystem is based on the protection of its register map and its master access to the system interconnect, based on default RISUP and RIMU respectively.

The RISUP differentiates the access right of accesses performed toward the following RIF protected peripheral ID (see *Table 38: Indexes for non-RIF-aware peripherals (RISUP)*):

- LTDC common: LTDC common registers, about panel info, synchronization, interface
- LTDC_L1L2 (layer 1 and 2): for the window of any two default applications
- LTDC_L3: LTDC layer 3, for the window of a potentially secure application, or any default application if there is no secure layer
- LTDC_ROT: LTDC rotation, with information about the rotation buffers
- DSI common: DSI common registers for DSI-wrapper and DSI-Host
- DSI_TRIG: DSI Wrapper trigger-A to update a smart panel
- DSI_RD: DSI-Host read access to a smart panel
- LVDS: LVDS registers, for Host, Wrapper, and PHY registers

The RIMU (RIMU_AXI_LTDC) differentiates the bus transactions emitted by the following AXI masters:

- RIMU_L1L2: read access only for layer 1 and 2, always non-protected
- RIMU_L3: read access only for layer 3, potentially protected
- RIMU_ROT: write of blended pixels, and read of to-be-rotated pixels, potentially protected, because containing blended pixels of the protected layer 3

Security configuration of devices with never-secure display content

The security setup of devices that are never required to display any secure content is detailed below (the display subsystem works by default in a non-protected mode):

- The display subsystem configuration space is set as non-protected.

  The default operating system (OS) software has a full access and can configure/handle all peripherals of the display subsystem.
- The layer 3 (which has a hardware secure capability) can be reused as a default layer, like layer 1 and 2, and can display the content of any application.

Note: Layer 3 is not fully featured, and lacks the resize and multi-planar capabilities of layers 1/2.

- The LTDC AXI-master emits by default non-protected accesses. It inherits NP and NS modes from its associated RIF peripheral ID.

  The AXI CID = DISP can be associated to the three AXI clients, via the RIMU, to tag that the AXI transaction contains pixels.

Security configuration of devices with a temporary secure content

For devices that temporarily display a secure content, it is expected that the secure content is displayed during short periods.

The working principle of the display subsystem is to segregate configuration spaces:

- The secure layer 3 is always protected.
- Never-secure layers 1 and 2 are always non-protected.
- The intermediate common features (such as panel data, synchronization) are usually non-protected and handled by the OS (when no secure content is displayed), but temporarily protected (with no OS access) during the short period when a secure content is displayed via layer 3. Removing the access of the non-protected OS guarantees that a malware does not impact the stability of the displayed protected content.
- A few minor items get specifically protected or open, as detailed below.

The configuration of the display subsystem for a secure content is the following:

- Layer 3 is set permanently protected:
  - RIF LTDC_L3 RISUP peripheral ID must be set as protected (S and/or P flags).
  - RIF LTDC_L3 RIMU AXI-Master emits protected transactions (tagged as S a/o P), which allow it to retrieve the protected layer 3 pixels from their protected memory buffer. The RIMU must be updated by a trusted domain application using RIFSC_RIMC_ATTR12.

    The recommendation is to use a secure, privileged (optional), and CID = 0x4 setup that is configured in RIFSC_RISC_PER120_CIDCFGR (and optionally RIFSC_RISC_PER120_SEMCR). With this secure setup, the application must make sure that CID4 has access to the secure pixels area.
  - Only a secure software is able to configure the layer 3 parameters (such as width, height, buffer address), so that the characteristics of the layer 3 are guaranteed.
  - The interrupt bank B is associated automatically with the layer 3, and gets permanently protected and devoted to the secure software handling layer 3. The secure software must thus handle and be driven by that interrupt bank B.
  - The LTDC features that must allow data-evasion get also protected (automatically, as associated with the layer 3 rights), with an access allowed only to the secure software. These features are the CRC (which allows the displayed frames to be signed mainly for test purposes), the blend-order (which is used to hide the protected content below some malware layer faking the protected content).
- Layers 1 and 2 are set permanently as non-protected:
  - RIF LTDC_L1L2 RISUP peripheral ID is set as not protected.
  - RIF LTDC_L1L2 RIMU AXI-master keeps its initial setup in RIFSC_RIMC_ATTR11, and emits only non-protected transactions which is enough to retrieve pixels from any application buffer.
  - The default OS drivers handle the layer 1 and 2 parameters (such as width, height, buffer address).
  - The interrupt bank A is associated automatically with layer 1 and 2, and keeps an non-protected open access. The OS must then handle and be driven by that Interrupt bank A to globally drive the display.
- Common registers must be set at boot as non-protected, temporarily:
  - Most non-layer peripheral indexes are concerned: RIF LTDC common, DSI common, LDITX.
  - This allows the default OS to boot the display subsystem, and to handle it.
- Common registers must be set as protected when displaying a protected content:
  - RIF LTDC common, DSI common, and LDITX must be set protected before starting to display a protected content, and be unprotected after the protected content has finished to be updated. The LTDC common and DSI common configuration spaces keep a permanent read-access for non-secure or unprivileged software.
  - The protection restricts the write accesses only: it removes the access of the non-protected OS, and so guarantees that a malware does not impact the stability of the displayed protected content. The LTDC common and DSI common configuration spaces keep a permanent read-access for non-secure or unprivileged software (PRDENy bits in RISAB_CIDxRDCFGR can be used).

  - The protection does not restrict the read accesses: the OS is usually unaware of the status of the protected layer 3 that is handled by a different, secure, software. The read access capability for the OS allow the display drivers to remain. somehow stable, although the write access of the display drivers is not performed.

- Rotation configuration registers must be protected:
  - RIF LTDC_ROT must be protected.
  - RIF LTDC_ROT RIMU AXI-Master must be configured to emit only protected transactions (tagged as S a/o P), which allow it to write and read-back the protected rotation memory buffer. The RIMU must be updated by trusted domain application using RIFSC_RIMC_ATTR13.

    It is recommended a setup secure, privileged (optional) and CID = 0x4, that is configured in RIFSC_RISC_PER121_CIDCFGR and optionally RIFSC_RISC_PER121_SEMCR. With this setup, a secure application must make sure CID4 has access to the secure pixels area.
  - The protection of the configuration space of the LTDC_ROT allows the allocation of secure buffers to store the blended/pre-rotated frame in a secure place, with LTDC performing secure transaction to write and then read these pixels. A malware cannot access these pixels that contain a blended secure content.
  - It is recommended to let the OS initialize openly these registers at boot, and then get the registers permanently protected. The rotation buffer pointers are indeed expected to remain constant.
- Read-access to a smart panel via DSI must be protected:
  - RIF DSI_RD must be protected, using the corresponding RIFSC_RISC_PER123_CIDCFGR and RIMC_PRIVCFGR registers.
  - The protection of the configuration space of the DSI_RD allows only secure software to access these registers and read data/pixels from a smart panel.
  - It is advised to allow the OS to retrieve at boot some needed display information. After, The DSI_RD configuration space can be either permanently protected, or protected on demand (when a secure content is displayed).

The above recommended settings for the device with temporary secure layer are shown in the figure below.

Figure 470. Display RIF peripheral ID

The table below lists vertically all the functional blocks of the display subsystem. It also lists horizontally the associated RIF peripheral ID.

Note: Table color legend for recommended settings:

- green for a permanently non-protected setting

- blue for a temporarily protected versus non-protected

- purple for a permanently protected state

52.5 Display subsystem programmable parameters

Steps to configure the various main use cases supported by the display subsystem are detailed below. They provide the global picture and settings of the display subsystem (not repeating information available in the local sections).

The default use cases supported by the display subsystem are one of the following:

- Parallel-interface display use case
- LVDS display (FPD-1 or OpenLDI) use case
- DSI display use case

Other non-default use cases can be supported, with specific constraints:

- Drive of three panels interfaces in parallel (Parallel-interface, LVDS, DSI), but with the same content.
- Drive of two LVDS panels in parallel, using each one link, but with a reduced resolution.

These use cases are reviewed one by one in the next sections.

52.5.1 Parallel-interface display

This is the default use case to drive a display panel or bridge through the parallel interface. It allows panels to be driven up to 1080p60 (150 Mpixel/s), with either RGB888 or YUV422.

The RCC provides a pixel clock that drives both the LTDC and its synchronous parallel interface. Aside, the LTDC needs an AXI-Master clock to fetch pixels, and an APB-Slave clock to get configured.

The steps to follow are detailed below:

1. Setup security settings, with or without a secure layer depending on application needs, as described in *Figure 468*.
2. Clock and reset:
   - ck_ker_dsiblane clock, provided by the RCC, as output pixel clock.

     One PLL of the RCC needs to be allocated to the display subsystem to provide the clock that is exactly at the wanted pixel rate for the output display. For instance, a standard 1080p60 requires a 148,50 MHz clock.
   - DISPLAYCLKCR(1:0) setting = 0x2, to select the above ck_ker_dsiblane as input for the pixel_clk of the LTDC.
   - o_clk_display_parallel, is driven automatically by the LTDC (after some gating) from its above provided pixel_clock (from the RCC ck_ker_dsiblane).
   - ck_icn_p_ltdc is provided by the RCC to allow the LTDC configuration (default 200 MHz).
   - ck_icn_m_ltdc is provided by the RCC to allow the LTDC AXI to work (default 400 MHz).

   See *Section 21: Reset and clock control (RCC)* for more details.
3. LTDC configuration:
   - Setup the LTDC (such as input layers, display information, parallel interface, AXI settings) as described in the LTDC section.
4. Signal polarity:

   The polarities of the signals are impacted by the fact that the LTDC parallel interface signals are reclocked in the IO-ReTime logic, downstream of the LTDC. It results the following when configuring the polarities to match the panel on the parallel interface:
   - The clock polarity (rising-vs-falling edge) must be configured in the IO-ReTime only (see *Section 24: General-purpose I/Os (GPIO)*), and not in the LTDC output logic. The clock polarity logic in the LTDC must remain in its default post-reset state.
   - The polarity of the Vs, Hs, and De synchronization signals, unlike for the clock polarity, can be configured directly in the LDTC output stage (see *Section 53: LCD-TFT display controller (LTDC)*).
5. I/O configuration:

   Allocate an alternate GPIO bank to the display subsystem, with usually 28 pins needed: 24 pins for RGB888 and 4 others for the ancillary: HSync, VSync, DataEnable, and clock.

52.5.2 LVDS display

This is the default use case to drive a display panel through the LVDS interface, with either the FPD-1 or OpenLDI protocol.

It allows panels to be driven up to 1536p60 (~200 Mpixel/s) with a dual link or 1080p60 (150 Mpixel/s) with a single link. The output is either RGB888 (four data lanes and one clock lane) or RGB666 (using three data lanes and one clock lane).

The clocks global shaping is as follows:

- The PLL integrated in one of the LVDS links generates a bit clock (typically from 700 MHz to 1.1 GHz) that is sent to both LVDS links (when both are needed), and there drives the LVDS PHY data lanes.
- The bit clock is also divided by seven to provide a pixel clock that is used in both the LVDS Host and the LTDC (which are synchronous).
- Aside, the LTDC needs an AXI-Master clock to fetch pixels, and an APB-Slave clock to get configured. The LVDS Host needs also a clock for its configuration.

The steps to setup that path are the following:

1. Setup the security settings, with or without a secure layer depending on the product needs, as described in *Figure 468*.
2. Clock and reset:
   - i_lvdsphy_pll_clkin = 0x1 to select the ck_hse_osc as reference for the LVDS PLL. Instead, with i_lvdsphy_pll_clkin = 0x0, the ck_ker_lvdsphy clock can be selected from the RCC, but that increases the jitter, thus less recommended.
   - DISPLAYCLKCR(1:0) = 0x1 to select the LVDS pixel clock (generated by the LVDS PLL then divided by seven) as input for the pixel_clk of the LTDC.
   - i_lditx_pixclk_sel = 0x1, to select the LVDS pixel clock (generated by the LVDS PLL then divided by seven) as input for the clk_pix of the LVDS Host.

     In low-power, when the LVDS PLL is off, and when a clock is needed for some configuration, i_lditx_pixclk_sel can be set to 0x0 to select the PLL reference clock.
   - i_lvds_dp_clk_sel = 1/1 when in Dual link mode. i_lvds_dp_clk_sel = 1/2 when in Single link mode.

     The LVDS PLL (typically at 784 Mbit/s for FPD-1) indeed provides a double-rate pixel clock (at 1/3.5 bit rate, thus 224 MHz):

     - in Dual link mode, the LTDC and LVDS Host must provide pixels at 224 Mpixel/s (which are then split by the LVDS Host, at 112 Mpixel/s toward each link), thus using a 1/1 division.

     - in Single link mode, the LTDC and LVDS Host must provide pixels at 112 Mpixel/s (which are forwarded by the LVDS Host at the same rate to the link), thus using a 1/2 division from 224 to 112.
   - ck_icn_p_ltdc is provided by RCC to allow the configuration of the LTDC (default 200 MHz).
   - ck_icn_m_ltdc is provided by RCC to allow the LTDC AXI to work (default 400 MHz).

   See *Section 21: Reset and clock control (RCC)* for more details.

3. LVDS configuration: The LVDS Host and PLL can be configured though their register set, described in *Section 54: LVDS display interface transmitter (LVDS)*. Two important configurations are:
   – the link mode to reflect that LVDS is used in Single versus Dual link mode
   – the JEIDA versus VESA bit placement of the RGB888 onto the LVDS data lanes
4. LTDC configuration:
   – Setup the LTDC (such as input layers, display information, parallel interface, AXI settings) as described in *Section 53: LCD-TFT display controller (LTDC)*.

52.5.3 DSI display

This is the default use case to drive a display panel through the MIPI DSI interface, with either the Video mode (default here) or Command mode (additional configuration needed).

It allows panels to be driven like up to very-high resolutions thanks to its theoretical 10Gbit/s interface output rate (4DL@2.5 Gbit/s/lane). In practice, the LTDC is limited to a max pixel rate of 312.5 Mpixel/s, which allows resolutions of 1080p60, 1536p60 (219 Mpixel/s, 4DL@1316 Mbps/lane). The display subsystem is balanced for display resolutions up to 1536p60, although some feature limitations can be used to rise to higher resolutions.

The clocks global shaping is as follows:

- The PLL integrated in the DSI DPHY-Tx generates a bit-clock (usually, around 1000 Mbit/s/lane for a display panel, and up to 2.5 Gbit/s/lane for a bridge) that drives the PHY bit lanes.
- That clock is also divided by eight to provide a DSI word32b clock, which is fed into the DSI Host.
- The DSI Host resynchronizes data from a LTDC pixel24b clock to the DSI word32b clock.
- The LTDC must be provided the above-mentioned pixel clock, that may be provided either by the RC,C or be directly the DSI word clock. Using the RCC clock usually allows a finer frequency selection (as not constrained by bit rates constraints), but does preempt a PLL from the RCC.

  The LTDC pixel clock frequency is constrained/related to the DSI word clock, so that the LTDC equivalent bit rate (LTDC pixel clock rate x 24 bpp) is lower than the DSI output bit rate (N data lanes x DSI bit rate).

  Although the horizontal blanking period can be used to smooth the LTDC bit rate, it is recommended to have the DSI bit rate be always larger than the peak LTDC bit rate.

  As example, for a 1080p60 display:
  – average pixel rate: 125 Mpixel/s (= 1920x1080)
  – peak pixel rate (with blanking): 148.5 Mpixel/s (CEA HDTV Standard)
  – The RCC generates a 148.5 MHz pixel clock.
  – The LTDC generates a 148.5 Mpixel/s 24bpp (= 3564 Mbit/s).
  – The DSI word32 clock must be above 111.3 MHz.
  – The DSI bit rate must be above or equal to 891 Mbit/s (on four data lanes).
- Similar computations are valid when less than four data lanes are used on the DSI: DSI words become respectively 24, 16, and 8 bits with 3DL, 2DL, and 1DL, with an according impact on the LTDC pixel rate.
- Aside, the LTDC needs an AXI-Master clock to fetch pixels, and an APB-Slave clock to get configured. The LVDS Host needs also a clock for its configuration.

The steps to setup that path are the following:

1. Setup the security settings, with or without a secure layer depending on application needs, as described in *Figure 468*.
2. Clock and reset:
   - RCC_DSICFGR(15) = DSIPHYCKREFEL = 0x1 to select the ck_hse_osc as reference for the DSI PLL. Instead, with RCC_DSICFGR(15) = DSIPHYCKREFEL = 0x0, the ck_ker_dsiphy clock can be selected from the RCC, but that increase the jitter, thus less recommended.
   - DISPLAYCLKCR(1:0) = 0x2, to select the RCC ck_ker_dsiblane as input for the pixel_clk of the LTDC. With DISPLAYCLKCR(1:0) = 0x0, the DSI word clock must be selected.
   - i_dsiblane_clk_sel =0x0, to select the DSI word clock for the DSI Host.

     In low-power mode, when the DSI PLL is off, i_dsiblane_clk_sel =0x1 allows the ck_ker_dsiblane to continue to drive the DSI Host internal logic.
   - ck_icn_p_dsi is provided by the RCC to allow the configuration of the DSI Host (default is 200 MHz).
   - ck_icn_p_ltdc is provided by the RCC to allow the configuration of the LTDC (default is 200 MHz).
   - ck_icn_m_ltdc is provided by the RCC to allow the LTDC AXI to work (default is 400 MHz).

   See *Section 21: Reset and clock control (RCC)* for more details.
3. DSI Host configuration (see *Section 55: DSI Host (DSI)*).
4. DSI Wrapper configuration:
   - The DSI wrapper among others differentiates between Video mode (default) and Command mode (specific).
5. LTDC configuration:
   - Setup the LTDC (such as input layers, display information, parallel interface, AXI Settings) as described in *Section 53: LCD-TFT display controller (LTDC)*.

52.5.4 Three panel interfaces in parallel

The display subsystem allows pixels to be sent in parallel across its three different interfaces: parallel, LVDS, and DSI. A major constraint is that all three displays must show exactly the same pixel content (and resolution) and synchronization characteristics (thus blanking).

This is achieved simply by having the following:

- The LVDS PLL bit clock is the Master clock.
- The LVDS Host and LTDC are slaved on that clock (see the LVDS setup above), as LTDC and LVDS Host are synchronous.
- The LTDC generates a pixel flow that follows the LVDS requirements (such as resolution, blanking, pixel rate).
- The LTDC parallel interface works by default, and feeds directly the GPIO with that pixel flow. The parallel interface follows then the LVDS requirements.
- The DSI PLL is activated in parallel, to provide a DSI bit clock and word clock.
- The DSI Host works also by default, and resynchronizes the LTDC pixels into the DSI domain. The DSI timings follow then the LVDS ones.

- Vs, Hs, and De polarities are configured as such:
  - The LTDC is configured to match the polarities expected by the panel on the parallel interface.
  - The LVDS Host is then configured to match the polarities expected by the LVDS panel. The LVDS Host polarity settings have to take into account the polarities already configured in the LTDC for the parallel interface (as signals coming into the LVDS Host are the ones output on the parallel interface).
  - The DSI Host must have the input polarity of its Vs, Hs, and De signals to be configured to compensate the polarity set in the LTDC (like for the LVDS Host, signals coming into the DSI Host are the ones output on the parallel interface).

Ideally, a standard normalized display resolution must be used, like 1080p60:

- LVDS PLL runs at 519.75 MHz.
- LVDS PHY (both links): 519.75 Mbit/s (= 74.25 Mpixel/s/link, so 148.5 Mpixel/s)
- LVDS pixel clock: 148.5 MHz
- LTDC pixel clock: 148.5 MHz
- DSI word clock: 111.375 MHz (or a bit higher if convenient)
- DSI bit clock: 891 Mbps/lane (or a bit higher if convenient

The precise configuration is done following details provided in *Section 52.5.1*, *Section 52.5.2*, and *Section 52.5.3*.

52.5.5 Two LVDS panels in parallel

The display subsystem allows the pixels to be sent in parallel across its two parallel interface LVDS links. The content is the same, and the maximum resolution is the one of each link (1080p60).

Note: This use case is not exclusive with the above Section 52.5.4, which allows four parallel panels to be driven in parallel (parallel, DSI, two LVDS).

The two LVDS in parallel are achieved by configuring the LVDS by default, with the only except being to have both links enabled (to output the pixels), but configuring the link mode setting in single link mode. It results in the following:

- LVDS PLL bit clock, by default, is the Master clock (typically at 728 Mbit/s/lane). Both LVDS links follow that clock.
- LVDS pixel clock, unlike usual, is generated as in single link mode (with a division by two) to reach 112 MHz.
- LTDC pixel clock, by default, uses the LVDS pixel clock.

Following items are in addition to the configuration detailed in *Section 52.5.2*:

- The two links are enabled.
- The LVDS pixel clock divider is set to divide by two.
- The LVDS Host is configured as driving with link mode = single link.

52.6 Display subsystem interrupts

The interrupts are described in sections of peripherals in this reference manual.

52.7 Display subsystem registers

All registers are described in:

- *Section 53: LCD-TFT display controller (LTDC)*

53 LCD-TFT display controller (LTDC)

53.1 LTDC introduction

The LTDC (liquid crystal display - thin film transistor) display controller provides a parallel digital RGB (Red, Green, Blue) and signals for horizontal, vertical synchronization, pixel clock and data enable as output to interface directly to a variety of LCD-TFT panels.

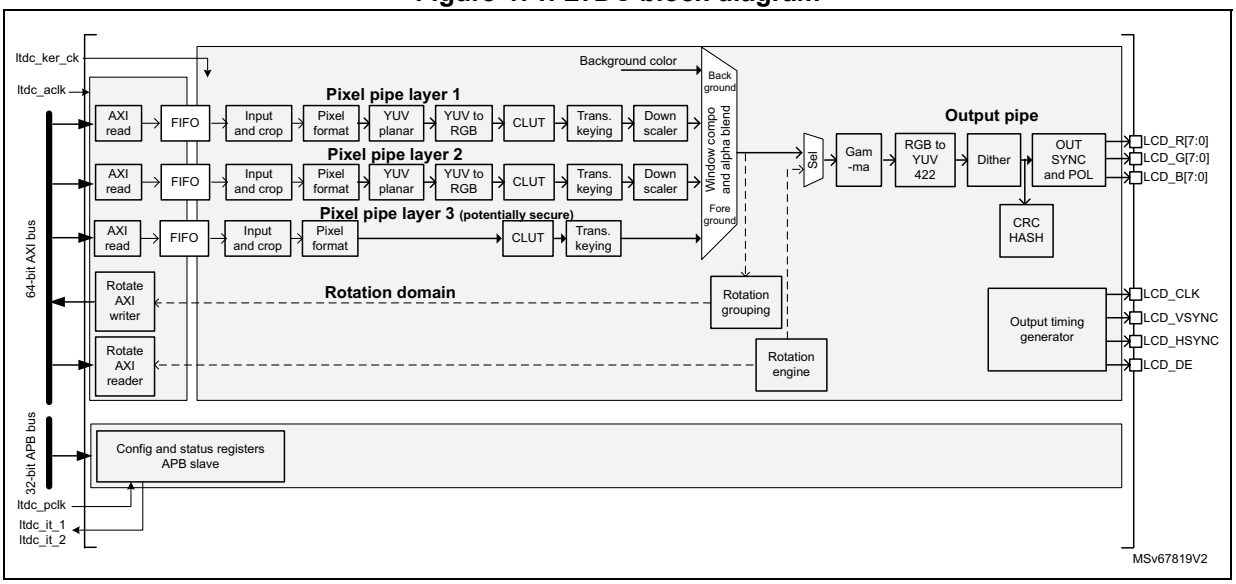
53.2 LTDC main features

- 3 input layers blended together to compose the display
- Cropping of layers from any input size and location
- Multiple input pixel formats:
  - Predefined ARGB formats: ARGB8888, ABGR8888, RGBA8888, BGRA8888, RGB565, BGR565, and RGB888packed
  - Flexible ARGB, allowing any width and location for A,R,G, and B components
  - Predefined YUV formats: YUV422-1L (FourCC: YUYV, Interleaved), YUV420-2L (FourCC: NV12, semi planar), YUV420-3L (FourCC: Yxx I420, full planar) with some flexibility on the component sequence
- Color look-up table (CLUT) up to 256 colors (256 x 24 bits) per layer
- Color transparency keying
- Upscaler (horizontal and vertical) with bilinear filtering, up to 8 x 8 with decimal ratios
- Composition with flexible window position and size versus output display
- Blending with flexible layer order and alpha value (per pixel or constant)
- Background underlying color
- Rotation of the composition output allowing 90 ,180 or 270 degrees
- Gamma with non-linear configurable table
- Dithering for output with less bits per component (pseudo-random on 2 bits)
- Polarity inversion for HSync, VSync, DataEnable outputs, and clock via the I/O
- Output as RGB888 24 bpp or YUV422 16 bpp (interleaved)
- Secure layer (using layer3) capability, with grouped regs and additional interrupt set
- Interrupts based on 7 different events, controlled by two independent register sets
- AXI master interface with long efficient bursts (64 or 128 bytes)

Note: The above mentioned FourCC pixel formats are described at www.fourcc.org.

53.3 LTDC implementation

The LTDC has been implemented with the following settings:



- Maximum pixel rate: 312 Mpixel/s, enough for a DSI with 4DL @ 2.5 Gbps/lane
- AXI bandwidth: an average of 4 bytes per AXI cycle (1.6 Gbyte/s if 400 MHz)
- Maximum memory latency: 2 µs resilient (for 1080p60, thus 150 Mpixel/s)

These settings depend on the configured frequencies of the AXI and pixel clocks.

53.4 LTDC functional description

53.4.1 LTDC block diagram

Figure 471. LTDC block diagram

Blocks shown in the above figure are the following:

- AXI read/write: AXI DMA engines, exposing a final single read/write AXI interface
- FIFO: per-layer FIFO, sized to support large memory latencies
- Input and crop: crops any input window size from the input buffer
- Pixel format: pixel format converter, that extract 32-bit words into ARGB pixels
- YUV-to-RGB: YUV-Planar handling and YCbCr-to-RGB color conversion
- CLUT: color look-up table (256 entries) to allow indexed colors
- Transp. keying: extracts one color to define it as transparent
- Upscaler: upscaler with bilinear filtering, with decimal ratios
- Alpha blender: blending with configurable layer level and a background color
- Rotation: implemented by writing and reading a temporary full-frame outside
- Gamma: gamma correction, with 8-segment interpolations
- Dithering: reduces component dynamic, with pseudo-random smoothing
- RGB-to-YUV: output conversion to YCbCr, to support low-bitrate YUV422 links
- LCD-OUT: output pixel interface, with Clk, VSync, HSync, DE, RGB888
- CRC hash: CRC computation, per frame, to sign each frame and help debug
- Timing generator: handles the HSync/VSync timings and blanking
- APB registers (control, status, interrupts): accessed by APB

These operators and their configuration are described from *Section 53.5.1* to *Section 53.5.22*.

53.4.2 LTDC pins and internal signals

Table 497. LTDC pins

Pin name	Pin type	Description
FRAME_TRIGGER	Input	Frame trigger input, from the DSI wrapper
LCD_CLK	Output	Clock output
LCD_HSYNC		Horizontal synchronization
LCD_VSYNC		Vertical synchronization
LCD_DE		Not data enable
LCD_R[7:0]		8-bit Red data (or U/V component, if output is YUV422)
LCD_G[7:0]		8-bit Green data (or Y component if output is YUV422)
LCD_B[7:0]		8-bit Blue data

The LTDC pins must be configured by the user application. The unused pins can be used for other purposes.

Using less pins than the default 24 bpp

The LTDC outputs the pixels on 24 pins by default (RGB888). The user can however connect the display panel using less wires, for instance 16 wires (if RGB565) or 18 wires (RGB666). If so, R (resp. G, B) wires must be connected to the MSB of the LTDC R (resp. G, B) output pins (see *Section 53.4.2*).

Example: LTDC interfacing with a RGB565 16-bit display panel. Display panel R[4:0], G[5:0] and B[4:0] wires and input pins must be connected to LTDC_R[7:3], LCD_G[7:2], and LCD_B[7:3] output pins.

53.4.3 LTDC reset and clocks

The LTDC uses the following clock domains:

- **AXI clock domain** (see ck_icn_m_ltdc in *Section 21: Reset and clock control (RCC)*)
  This domain contains the LTDC AXI master interface for data transfer from the memories to the layer FIFO and the frame buffer configuration register.
- **APB clock domain** (see ck_icn_p_ltdc in *Section 21: Reset and clock control (RCC)*)
  This domain contains the global configuration registers and the interrupt register.
- **Pixel clock domain** (see *Section 52: Display subsystem*)
  This domain contains the pixel data generation, the layer configuration register as well as the LTDC interface signal generator. The LCD_CLK output must be configured following the panel, serial controller (DSI, LVDS), or bridge (HDMI) requirements.

Note: For normal operation, all clocks must be provided to allow clock domain crossing for read and write operations.

The following table lists the clock domains used to store the register values.

Table 498. Clock domain for each register

LTDC register	Clock domain
LTDC_IDR	APB clock
LTDC_LCR	
LTDC_SSCR	Pixel clock
LTDC_BPCR	AXI + pixel clock
LTDC_AWCR	
LTDC_TWCR	
LTDC_GCR	
LTDC_GC1R	APB clock
LTDC_GC2R	
LTDC_SRCR	
LTDC_GCCR	Pixel clock

LTDC_LxCFBLNR	
LTDC_LxAFBA0R	
LTDC_LxAFBA1R	
LTDC_LxAFBLR	
LTDC_LxAFBLNR	
LTDC_LxCLUTWR	Pixel clock
LTDC_LxSISR	
LTDC_LxSOSR	
LTDC_LxSVSFR	
LTDC_LxSVSPR	
LTDC_LxSHSFR	
LTDC_LxSHSPR	
LTDC_LxCYR0R	
LTDC_LxCYR1R	
LTDC_LxFPF0R	
LTDC_LxFPR1R	

While accessing LTDC registers, the APB bus is stalled during the access for a given time period detailed in the following table.

Table 499. LTDC register access and updated durations

Access type	AXI register clock domain	APB register clock domain	Pixel register clock domain
Read	7 x ltdc_pclk + 5 x ltdc_aclk	7 x ltdc_pclk	7 x ltdc_pclk + 5 x ltdc_ker_clk
Write	6 x ltdc_pclk + 5 x ltdc_aclk	6 x ltdc_pclk	6 x ltdc_pclk + 5 x ltdc_ker_clk

The LTDC can be reset by setting the corresponding bit in the RCC, that resets the three clock domains.

53.5 LTDC configuration parameters

The LTDC configuration parameters are sequenced following the pixel flow as shown in *Figure 471*, starting at the input (AXI master that reads pixels) and ending at the pixel output.

Common controls (such as interrupts) are listed at the end.

53.5.1 AXI master

The AXI master busses perform the accesses to the memory and are driven by the internal logic. FIFOs allocated in the LTDC for the different streams (3 layers, rotation write and read) are fairly large to cope with reasonably long external memory latencies.

The LDTC generates long burst (128-byte) for higher external memory efficiency.
For more granularity, it is possible to decrease the max burst size to 64 bytes, but it is not recommended.

Parameter in LTDC_LxBLCR

BL: burst length, in 64-bit words, with a default 0 for max size

Default configuration

The default AXI burst length is set at its maximum value after reset, with BL = 0.

53.5.2 Input layer definition and cropping

The LTDC supports three layers. Each layer is defined by:

- Its base-address in the memory

  If the buffer is YUV semi-planar or full-planar, there are respectively two and three base-addresses. The first buffer is called main and stores the luminance data, while the other buffers are called auxiliary and store the chrominance data.
- A dimension in the memory
  - Width defined as its pitch (or address jump or stride): amount of bytes between the start of one line and the start of the next line
  - Height that does not need to be defined
- A dimension of the pixel rectangle that is cropped and read from the memory

  - Top-left start position: set by the base-address at exactly the byte where the top-left pixel is located
  - Width, number of bytes per line to read
    - If too few bytes versus required, a FIFO underrun interrupt is generated(FUWIF).
    - If too many bytes versus required, the useless data are discarded.
  - Height, number of lines per frame to read

Note: The pitch and number of bytes per line can be different if a sub-part of a frame is cropped to be displayed. If the full frame is displayed, the pitch and number of lines are the same.

Parameters

- LEN in LTDC_LxCR: activates this layer.
- CFBADD in LTDC_LxCFBAR: main base address, for ARGB or Y buffer
- CFBLL in LTDC_LxCFBLR: main number of bytes per line
- CFBP in LTDC_LxCFBLR: pitch between two consecutive lines of the main buffer
- CFBLNBR in LTDC_LxCFBLNR: main number of lines per frame

Specifically for multi-planar-capable layers, the following additional registers have to be configured (only required for YUV420 semi-planar and full-planar pixel formats):

- AFBADD0 in LTDC_LxAFBA0R: auxiliary address 0, for UV if semi-planar or for V if full-planar
- AFBADD1 in LTDC_LxAFBA1R: auxiliary address 1, for U if full-planar
- AFBLL in LTDC_LxAFBLR: auxiliary 0 and 1, number of bytes per line
- AFBP in LTDC_LxAFBLR: pitch for the auxiliary 0 and 1 buffers
- AFBLNBR in LTDC_LxAFBLNR: auxiliary 0 and 1 number of lines per frame

Configuration examples

- A frame buffer having the format RGB565 (2 bytes per pixel) and a width of 256 pixels (total number of bytes per line is 256 * 2 = 512), where pitch = line length requires a value of 0x02000207 to be written into this register.
- A frame buffer having the format RGB888 (3 bytes per pixel) and a width of 320 pixels (total number of bytes per line is 320 * 3 = 960), where pitch = line length requires a value of 0x03C003C7 to be written into this register.
- A frame buffer having the format CbCr (2 bytes per pixel) and a width of 256 pixels (total number of bytes per line is 256 * 2 = 512), where pitch = line length requires a value of 0x02000207 to be written into this register.
- A frame buffer having the format Cb (1 byte per pixel) and a width of 320 pixels (total number of bytes per line is 320 * 1 = 320), where pitch = line length requires a value of 0x01400147 to be written into this register.

53.5.3 Input pixel format

The LTDC reads the pixel data from memory buffers and maps it onto the internal LTDC format that is based on the definition of the input pixel format, defined per layer.

The pixel formats are grouped as follows:

- **Predefined ARGB formats:**

  ARGB8888, ABGR8888, RGBA8888, BGRA8888, RGB565, BGR565, and RGB888pack
- **Flexible ARGB format:**

  Allows a configurable width and location of each A,R,G, and B component and is used to extend the above list to any multi-component pixel format except to coplanar ARGB.
- **YUV formats:**

  Used to read YUV with a 422 coplanar, 420 semi-planar, or 420 full-planar format, and to convert the YUV color into RGB.

  The YUV option is not available for the layer 3.

Note: The LTDC hardware pipeline uses 8 bits per component: when reading and mapping a pixel format, with less than 8 bits per component. That component is extended to 8 bits by stuffing the LSB, that are recopied from its MSB. This applies mostly on RGB565.

For instance, a component on 5 bits (named: 43210) results in the following 8 bits mapped into the pipe: 43210432. A 3-bit input (named 210) results in 21021021.

Parameter when using the predefined ARGB formats

- PF in LTDC_LxPFCR: 0 to 6 to select one of the seven predefined pixel formats

Parameters when using the flexible ARGB formats

- PR in LTDC_LxPFCR: seven to activate the flexible pixel format type
- PSIZE in LTDC_LxFPF1R: defines the amount of bytes per pixel (typically 1,2,3, or 4)
- APOS/RPOS in LTDC_LxFPF0R: defines the Alpha/Red location inside a 32-bit word
- BPOS/GPOS in LTDC_LxFPF1R: defines the Blue/Green location inside a 32-bit word
- ALEN/RLEN in LTDC_LxFPF0R: defines the amount of bits for Alpha/Red components
- BLEN/GLEN in LTDC_LxFPF1R: defines the amount of bits for Blue/Green components

  Examples:

  An RGB565 pixel format is defined as follows:
  - Alpha: APOS = 0, ALEN = 0
  - Red: RPOS= 11, RLEN = 5
  - Green: GPOS = 5, GLEN = 6
  - Blue: BPOS = 0, BLEN = 5

  The BGRA8888 32 bpp pixel format is set as follows (default reset values of LTDC_LxFPF0R and LTDC_LxFPF1R):
  - Alpha: APOS = 0, ALEN = 8
  - Red: RPOS= 8, RLEN = 8
  - Green: GPOS = 16, GLEN = 8
  - Blue: BPOS = 24, BLEN = 8

Parameters when using the YUV formats

The YUV pixel format is defined and detailed in *Section 53.5.4: YUV planar* and supersedes any setting here.

The following table describes the memory mapping of the predefined ARGB pixel format.

Table 500. Pixel data mapping versus color format

ARGB8888 (PF = 000)			
@+3 A_x[7:0]	@+2 R_x[7:0]	@+1 G_x[7:0]	@ B_x[7:0]
@+7 A_{x+1}[7:0]	@+6 R_{x+1}[7:0]	@+5 G_{x+1}[7:0]	@+4 B_{x+1}[7:0]
ABGR8888 (PF = 001)			
@+3 A_x[7:0]	@+2 B_x[7:0]	@+1 G_x[7:0]	@ R_x[7:0]
@+7 A_{x+1}[7:0]	@+6 B_{x+1}[7:0]	@+5 G_{x+1}[7:0]	@+4 R_{x+1}[7:0]
RGBA8888 (PF = 010)			
@+3 R_x[7:0]	@+2 G_x[7:0]	@+1 B_x[7:0]	@ A_x[7:0]
@+7 R_{x+1}[7:0]	@+6 G_{x+1}[7:0]	@+5 B_{x+1}[7:0]	@+4 A_{x+1}[7:0]
BGRA8888 (PF = 011)			
@+3 B_x[7:0]	@+2 G_x[7:0]	@+1 R_x[7:0]	@ A_x[7:0]
@+7 B_{x+1}[7:0]	@+6 G_{x+1}[7:0]	@+5 R_{x+1}[7:0]	@+4 A_{x+1}[7:0]
RGB565 (PF = 100)			
@+3 R_{x+1}[4:0] G_{x+1}[5:3]	@+2 G_{x+1}[2:0] B_{x+1}[4:0]	@+1 R_x[4:0] G_x[5:3]	@ G_x[2:0] B_x[4:0]
@+7 R_{x+3}[4:0] G_{x+3}[5:3]	@+6 G_{x+3}[2:0] B_{x+3}[4:0]	@+5 R_{x+2}[4:0] G_{x+2}[5:3]	@+4 G_{x+2}[2:0] B_{x+2}[4:0]
BGR565 (PF = 101)			
@+3 B_{x+1}[4:0] G_{x+1}[5:3]	@+2 G_{x+1}[2:0] R_{x+1}[4:0]	@+1 B_x[4:0] G_x[5:3]	@ G_x[2:0] R_x[4:0]
@+7 B_{x+3}[4:0] G_{x+3}[5:3]	@+6 G_{x+3}[2:0] R_{x+3}[4:0]	@+5 B_{x+2}[4:0] G_{x+2}[5:3]	@+4 G_{x+2}[2:0] R_{x+2}[4:0]
RGB888 (PF = 110)			
@+3 B_{x+1}[7:0]	@+2 R_x[7:0]	@+1 G_x[7:0]	@ B_x[7:0]
@+7 G_{x+2}[7:0]	@+6 B_{x+2}[7:0]	@+5 R_{x+1}[7:0]	@+4 G_{x+1}[7:0]
The flexible format (PF = 111), not represented here, allows any above mapping.			

53.5.4 YUV planar

This operator handles the YUV planar formats, reading data from potentially several distinct buffers (Y versus Cb versus Cr) into a single pixel information. The feature is available for layer 1 and layer 2. It is not available for layer 3.

The LTDC supports the following planar formats:

- YUV422 coplanar (one buffer)
- YUV420 semi-planar (two buffers)
- YUV420 full-planar (three buffers)

Following its configuration, the LTDC reads the relevant luminance and chrominance buffers, upscales the chrominance components required to reach YUV444 pixels, and converts the color from YUV to RGB as described in *Section 53.5.5*.

The LTDC allows swapping the memory locations of the Y and Cb/Cr data and of the Cb and Cr data. It also allows inverting the endianness of the Y data. This extends the amount of supported pixel format variants.

Parameters

Pixel format parameters are stored in LTDC_LxPCR:

- YCEN: activates the YUV mode (both the planar extraction and color conversion).
- YCM: selects the input scheme (422 for coplanar, 420 for semi-planar, 420 for full-planar).
- YF: defines if either Y or Cb/Cr is provided first (from LSB).
- CBF: defines if either Cb or Cr is provided first (from LSB).
- OF: defines if either odd or even Y is provided first (from LSB).

When using a semi-planar or full-planar buffer, some additional base-address must be configured for auxiliary (chrominance) buffers, as well as the pitch of these buffers (see *Section 53.5.2*).

Configuration examples

Settings of OF, CBF, YF bits for a YCbCr 422 pixel format:

- OF = 0, CBF = 0, YF = 0 define the buffer word to containWord[31:0] = Y1-Cb-Y0-Cr.
- OF = 1, CBF = 0, YF = 0 define the buffer word to contain Word[31:0] = Y0-Cb-Y1-Cr.
- OF = 0, CBF = 1, YF = 0 define the buffer word to contain Word[31:0] = Y0-Cr-Y1-Cb.
- OF = 0, CBF = 0, YF = 1 define the buffer word to contain Word[31:0] = Cb-Y1-Cr-Y0.
- OF = 1, CBF = 1, YF = 1 define the buffer word to contain Word[31:0] = Cr-Y0-Cb-Y1.

  These settings are also valid for YCbCr 420 pixel formats.

53.5.5 YUV-to-RGB color conversion

This operator handles the YUV-to-RGB color conversion of the YUV planar pixels. Like the above operator, it is only available for layer 1 and layer 2. The color conversion is activated automatically, simultaneously with the YUV planar handling.

The color conversion is based on a semi-flexible 3x3 matrix multiplication:

- It is restricted to YUV-to-RGB conversion due to some frozen coefficients (see next).

- It handles the most used YUV references (ITU-R BT.601 and ITU-R BT.709) thanks to some configurable coefficients.
- It supports the full versus reduced dynamic of the input pixel (luminance defined either in 0 to 255, or in 16 to 235), by extending a potential reduced-range input to a full range.

Parameters

- YCEN in LTDC_LxPCR: activates the color conversion, same bit as for planar.
- YREN in LTDC_LxPCR: if active, extends a reduced range to a full range.
- CR2R in LTDC_LxCYR0R: matrix coefficient from Cr to Red
- CB2B in LTDC_LxCYR0R: matrix coefficient from Cb to Blue
- CR2G in LTDC_LxCYR0R: matrix coefficient from Cr to Green
- CB2G in LTDC_LxCYR0R: matrix coefficient from Cb to Green

The full matrix computation, to convert from YCbCr to RGB, is defined as the following:

$$\begin{pmatrix} R \\ G \\ B \end{pmatrix} = \begin{pmatrix} CR2R & 256 & 0 \\ -CR2G & 256 & -CB2G \\ 0 & 256 & CB2B \end{pmatrix} \times \begin{pmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{pmatrix}$$

The CR2R, CB2B, CR2G, and CB2G coefficients are defined on 10 bits unsigned: as the operator works with 8-bit components, the coefficients are thus equivalent, in fixed-point, to 2-bit integer and 8-bit decimals.

The CR2G and CB2G coefficients are configured as unsigned positive, but are set negative in the hardware computation, as shown in the above matrix where a “-” is mentioned.

When the luminance scaling is active (YREN = 1, thus where the YCbCr input is assumed in the range of 16 to 235/240, and RGB in 0 to 255), then the Y input value is first scaled in hardware to Y’ = 255/219 * (Y - 16). That first result is then inserted as input to the above matrix multiplication.

Configuration examples

To read an ITU-R BT.601 layer and to convert its YCbCr (assuming a default reduced dynamic in 16 to 235/240) to RGB (with full dynamic in 0 to 255), the recommended coefficients are:

- YCEN = 1: to activate the conversion
- YREN = 1: to select the reduced dynamic range
- CR2R = 409: specific coefficient set for ITU-R BT.601
- CR2G = 208
- CB2G = 100
- CB2B = 516

To read an ITU-R BT.709 layer and to convert its YCbCr (assuming a default reduced dynamic in 16 to 235/240) to RGB (with full dynamic in 0 to 255), the recommended values to configure coefficients are:

- YCEN = 1: to activate the conversion
- YREN = 1: to select the reduced dynamic range
- CR2R = 459: specific following coefficient set is for ITU-R BT.709
- CR2G = 136
- CB2G = 55
- CB2B = 541

53.5.6 Horizontal or vertical mirroring

The LTDC can mirror horizontally or vertically its input layers, thus to read them from right to left, and/or from bottom to top.

It applies on both coplanar (ARGB, YUV422) and multi-planar (YUV420) pixel formats.

Parameters for horizontal mirroring

To mirror a layer horizontally, the LTDC must be configured to extract the pixels from right to left (backward), and to set the layer base-address at the right-end of the line.

The configuration bitfields are the following:

- HMEN in LTDC_LxCR: activates the horizontal mirroring.
- CFBADD in LTDC_LxCFBAR = base + (width - 1) (increase for horizontal mirror)
- AFBADD0LTDC_LxAFBA0R = base + (width - 1)
- AFBADD1 in LTDC_LxAFBA1R = base + (width - 1)

Parameters for vertical mirroring

To mirror a layer vertically, the LTDC must be configured to start reading this layer from the bottom, and line per line, to come upward. The layer base-address must be set to the start of the bottom line, and a negative line-per-line pitch must be provided.

The configuration bitfields for the base-address are (all to be set at bottom line start):

- CFBADD in LTDC_LxCFBAR: main base-address
- AFBADD0 in LTDC_LxAFBA0R: auxiliary address 0
- AFBADD1 in LTDC_LxAFBA1R: auxiliary address 1
- CFBADD in LTDC_LxCFBAR = base + (lines - 1) * pitch (increase for vertical mirror)
- AFBADD0 in LTDC_LxAFBA0R = base + (lines - 1) * pitch
- AFBADD1 in LTDC_LxAFBA1R. = base + (lines - 1) * pitch

The configuration bitfields for the pitch are (all to be set with a negative pitch):

- CFBP in LTDC_LxCFBLR: -pitch (negative line pitch for vertical mirror)
- AFBP in LTDC_LxAFBLR: - pitch

53.5.7 Default layer color

Every layer has a default color in the format ARGB8888, that is used outside the defined layer window or when a layer is disabled. This default color can be configured as active or absent.

Parameters

The default layer color parameters are:

- DCBEN in LTDC_LxCR: default color activation
- DCALPHA in LTDC_LxDCCR: default Alpha transparency setting
- DCRED in LTDC_LxDCCR: default Red component
- DCGREEN in LTDC_LxDCCR: default Green component
- DCBLUE in LTDC_LxDCCR: default Blue component

Default configuration

By default, and after reset, the default layer color is inactive (DCBEN = 0 and DCALPHA = 0.

Note: The blending of a layer is always performed even when a layer is disabled. To avoid displaying the default color when a layer is disabled, the default Alpha must be set to null (DCALPHA = 0), or the whole default color must be disabled (with DCBEN).

53.5.8 Color look-up table (CLUT)

The LTDC supports frame buffers with each pixel defined as an index to a color table, allowing a display with a set of 256 colors, but stored in memory with only 8 bpp.

The CLUT defines 256 colors and must be indexed with a maximum 8-bit pixel format (typically L8 or AL44). Such format can be extracted using the flexible RGB approach described in *Section 53.5.3*.

The CLUT table is differentiated for each layer. It must be initialized with one RGB888 value per color index, with the color index corresponding to the CLUT address:

- For L8, the CLUT must be loaded with 256 colors.
- For AL44, the CLUT must be only loaded with 16 colors. Each color address is defined by replicating the 4-bit L channel to 8 bits as follows:
  - Color L4 = 0: looks out its RGB888 from index = 0x00.
  - Color L4 = 1: looks out its RGB888 from index = 0x11.
  - Color L4 = 2: looks out its RGB888 from index = 0x22.
  - ...
  - Color L4 = 15: looks out its RGB888 from index = 0xFF.
- For ARGB, the Blue component is used as the CLUT index.

Parameters

The RGB888 values and color indices are configured through the following bitfields in LTDC_LxCLUTWR:

- CLUTADD defines the color index to update.
- RED defines the 8-bit Red component of that color index.
- GREEN defines the 8-bit Green component of that color index.

- BLUE defines the 8-bit Blue component of that color index.

53.5.9 Transparency color keying

Pixels can be defined as transparent using a color key. If the pixel RGB components equals the defined RGB color key, that pixel is considered transparent and its Alpha channel is forced null.

A pixel forced to transparent is transparent when proceeding to the later blending phase, and shows the pixel of the underlying layer.

The color key is defined as an RGB888 value, that is compared with the flowing pixel after some processing in the input format operator (where LSBs are stuffed by replication) and CLUT processing. The constant color keying parameters must take these previous processing into account.

Parameters

The color keying parameters are the following:

- CKEN in LTDC_LxCR enables the color keying.
- CKRED in LTDC_LxCKCR defines the 8-bit Red color key.
- CKGREEN in LTDC_LxCKCR defines the 8-bit Green color key.
- CKBLUE in LTDC_LxCKCR defines the 8-bit Blue color key.

Configuration example

A mid-yellow color (50 % Red + 50 % Green) is used as the transparent color key. The color keying parameters take it into account as follows:

- ARGB8888 input: The mid-yellow input is 0x808000. Set LTDC_LxCKCR = 0x808000.
- RGB565 input: The mid-yellow input is 0x8400. Set LTDC_LxCKCR = 0x848200 (due to the replication of input MSB onto the missing LSB).
- CLUT input for L8, AL88 or AL44: Set one of the palette entry to the mid-yellow color 0x808000 and set LTDC_LxCKCR = 0x808000.

53.5.10 Upscaler

Layer 1 and layer 2 can be upscaled using a bilinear filter with decimal ratios. Vertical and horizontal ratios can be differentiated.

The filter is based on a bilinear filter, that provides very good results for upscale ratios from 1x to 2x, but may provide aliasing artifacts for higher ratios.

Parameters

The upscaler parameters are the following:

- SCEN in LTDC_LxCR enables the upscale.
- SIH (SIV) in LTDC_LxSISR: input width (height)
- SOH (SOV) in LTDC_LxSOSR: output width (height)
- LTDC_LxSHSFR and LTDC_LxSHSPR: horizontal ratio and phase
- LTDC_LxSVSFR and LTDC_LxSVSPR: vertical ratio and phase

The ratio is given as the input size/output size with a 16-bit fixed-point decimal. The phase is given as the start proportion of the first pixel, with a 12-bit fixed-point decimal.

Example:

To upscale from a 720p frame (1280x720 pixels) to a 1080p frame (1920x1080 pixels), the following configuration is needed:

- SCEN in LTDC_LxCR = 1 enables the upscale.
- SIH in LTDC_LxSISR = 1280: input width
- SIV in LTDC_LxSISR = 720: input height
- SOH in LTDC_LxSOSR = 1920: output width
- SOV in LTDC_LxSOSR = 1080: output height
- SHF in LTDC_LxSHSFR = 65536 * 1280 / 1920 = 43691: horizontal scaling factor
- SVF in LTDC_LxSVSFR = 65536 * 720 / 1080 = 43691: vertical scaling factor
- SHP in LTDC_LxSHSPR: horizontal phase
- SVP in LTDC_LxSVSPR: vertical phase

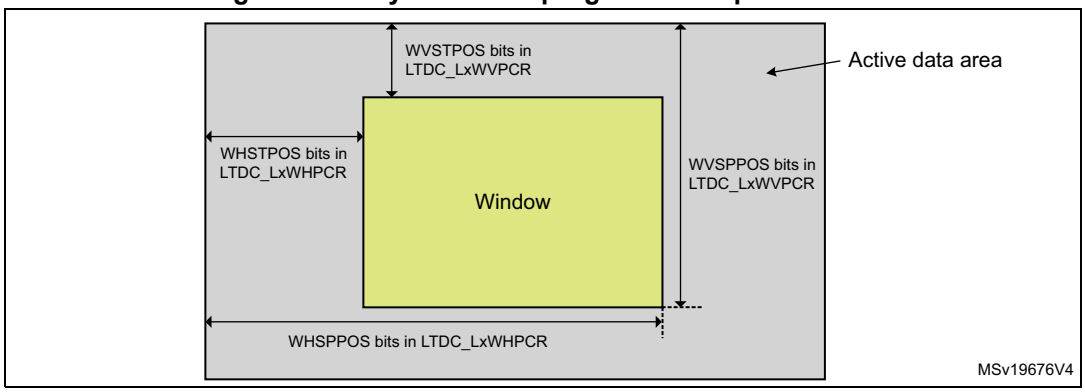
Phase can be kept by default at 0, to start the upscaled layer with the left-most top-most as a native pixel (recopy from the input)

53.5.11 Display composition - windowing

When performing the display composition, every layer (after a potential upscale) can be cropped and positioned into the active display area. The window position and size are configured by defining its top-left and bottom-right corners.

Note: The locations are defined versus the internal timing generator that must take into account the potential synchronization header, the back porch size and the chosen active pixel area (as shown in Figure 472).

The mapping between the input layer and the visible window is performed as follows:



- The most top-left pixels of the input layer are mapped to the top-left of the visible window of this layer.
- If the visible window is smaller (less wide, less high) than the input layer, then the exceeding input pixels are automatically discarded from the pipe.

Parameters:

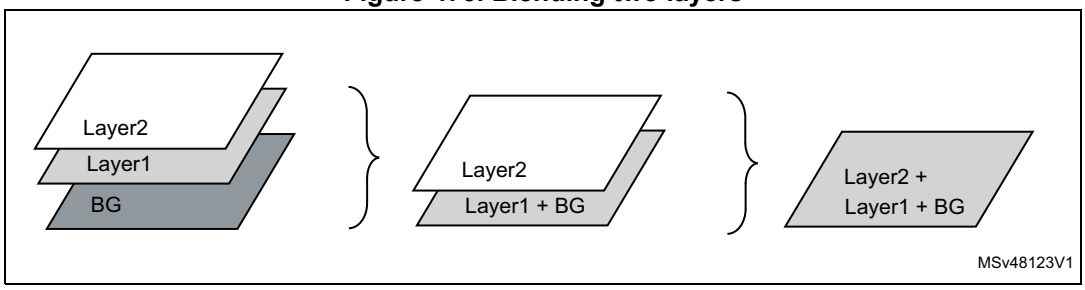
The following parameters are defined versus the top-left of the synchronization:

- WHSTPOS in LTDC_LxWHPCR: first (left) visible pixel of the layer
- WHSPPOS in LTDC_LxWHPCR: last (right) visible pixel of the layer
- WVSTPOS in LTDC_LxWVPCR: first (top) visible line of the layer
- WVSPPOS in LTDC_LxWVPCR: last (bottom) visible line of the layer

Figure 472. Layer window programmable parameters

Configuration examples

- LTDC_BPCR is configured to 0x000E0005 (AHBP[11:0] is 0xE), and LTDC_AWCR is configured to 0x028E01E5 (AAW[11:0] is 0x28E). To configure the horizontal position of a window size of 630x460, with horizontal start offset of 5 pixels in the active data area:
  - Layer window first pixel: WHSTPOS[11:0] must be programmed to 0x14 (0xE + 1 + 0x5).
  - Layer window last pixel: WHSPPOS[11:0] must be programmed to 0x28A.
- LTDC_BPCR is configured to 0x000E0005 (AVBP[11:0] is 0x5) and LTDC_AWCR is configured to 0x028E01E5 (AAH[11:0] is 0x1E5). To configure the vertical position of a window size of 630x460, with vertical start offset of eight lines in the active data area:
  - Layer window, first line: WVSTPOS[11:0] must be programmed to 0xE (0x5 + 1 + 0x8).
  - Layer window last line: WVSTPOS[11:0] must be programmed to 0x1DA.



53.5.12 Display composition - blending

The Alpha blending stage is used to blend together the 3 input layers, on top of a background color.

It is possible to select the sequence of the layers (foreground, middle, and background), to apply a global multiplicative Alpha per-layer, and to define an underlying background color.

The blending computation is performed from back to front, sequentially, as shown the following figure, with only two layers for the example instead of three.

Figure 473. Blending two layers

The general formula for a 2-to-1 blending is CR = (BF1 x C1) + (BF2 x C2) where:

- CR: resulting blended color
- BF1: blending-factor of current layer
- C1: layer-color of the current layer
- BF2: blend-factor of underlying pixels
- C2: layer-color of the underlying pixels

Both blending factor, BF1 and BF2, can be defined as one of the following:

- Pure per-pixel Alpha value
- Mix of per-pixel Alpha and a global per-layer Alpha (the mix is multiplicative)

Parameters

- CONSTA in LTDC_LxCACR: global multiplicative Alpha value of the current layer
- BOR in LTDC_LxBFCR: blending order of the current layer
- BF1 in LTDC_LxBFCR: blending factor for the current layer
- BF2 in LTDC_LxBFCR: blending factor for the underlying layer

The background color is defined by the following bitfields in LTDC_BCCR:

- BCRED: background Red component
- BCGREEN: background Green component
- BCBLUE: background Blue component

Note: For secure purposes, in case of an inconsistent configuration, the blending order falls back to a fixed order, with the layer 3 on the foreground, the layer 2 in middle, and layer 1 in background, followed by the underlying background color.

The inconsistent fallback is setup to protect a potential secure layer: If a secure software configures the secure layer3 to be on the foreground, and a malware tries to place that another layer on the foreground, the inconsistency is detected, and the secure layer is automatically forced on the foreground, guaranteeing that it is visible.

Configuration example

Only layer 1 is enabled, BF1 configured to constant alpha. BF2 configured to 1 - constant alpha. The constant alpha programmed in LTDC_LxCACR is 240 (0xF0). Thus, the constant alpha value is 240 / 255 = 0.94. C: current layer color is 128. Cs: background color is 48. Layer 1 is blended with the background color.
BC = constant alpha x C + (1 - constant alpha) x Cs = 0.94 x 128 + (1 - 0.94) x 48 = 123.

Default configuration

All active layers can be made visible and blended by keeping the following configuration values after reset:

- CONSTA: keep as reset CONSTA = 255.
- BOR: keep as reset BOR (layer) = LayerID-1.
- BF1: keep as reset BF1 = 6 for default mixed Alpha.
- BF12: keep as reset BF2 = 7 for default mixed 1-Alpha.
- Background color: keep as reset (black), although any color is ok.

53.5.13 Rotation

The LTDC can rotate the blended result, by writing the full-blended frame in the external memory, reading it back and displaying it. The write-out occurs with virtual horizontal raster-scan lines, while the read-back-in occurs with virtual vertical raster-scan lines. An internal complex logic optimizes the burst length and external memory page opening.

The LTDC temporarily reads the input layers, blends them, and stores the blended result into the rotation buffer in the external memory. In parallel, the LTDC reads the previously blended and rotated buffer from the external memory, and sends it to the display panel, with the following consequences:

- When the rotation is active, there is a one-frame delay between a read of the input layers, and their display.
- When the rotation is activated during the very first frame, there is no rotated frame available yet, and there is not any more non-rotated frame available: during one frame, the LTDC displays a default flat-color frame that can be configured.
- Two rotation buffers are used in ping-pong: one buffer to write-in new blended pixels, and a second buffer to read-out pixels to be displayed. The LTDC requires to configure two base-address buffers.

The size to allocate for each of the two rotation buffers can be simply computed from width and height of the composed display, storing RGB888 pixels.

Note: The composed display width becomes, after rotation, the height of the display panel. The composed display height becomes, after rotation, the width of the display panel.

Due to some implementation constrain, the composed width must be rounded up, per 10 pixel, and added an overhead of 1/15th. The hardware also works internally with a double-line concept. It results in the following computations, used for the configuration: (with width and height being defined before rotation, at the composition level):

- Rotation buffer pitch: [(width + 9) / 10] x 64
- Rotation buffer height: [(height + 1) / 2]
- Buffer 0 volume: [(width + 9) / 10] x 64 x [(height +1) / 2]

Activating the rotation performs an axial symmetry across the diagonal going to the bottom-right. To perform a clean rotation, this rotation must be combined with either an horizontal mirroring (for a clockwise rotation) ,or a vertical mirroring (for an anti-clockwise rotation).

Parameters

The pure rotation parameters are the following:

- ROTEN in LTDC_GCR: rotation enable
- ADDR in LTDC_RB0AR.: base-address of rotation framebuffer 0
- ADDR in LTDC_RB1AR: base-address of rotation framebuffer 1
- PITCH in LTDC_RBPR: line pitch of the rotation framebuffer 0 and 1 (see next)
- RIFRED in LTDC_RIFCR: Red component for the first frame after activating rotation
- RIFGREEN in LTDC_RIFCR: Green component for the first frame after activation
- RIFBLUE in LTDC_RIFCR: Blue component for the first frame after activating rotation

Example 1 - Clockwise 90° rotation

Assuming a portrait buffer (with horizontal raster-scan) to display on a display panel (initially landscape with a horizontal raster) that has been turned in a portrait orientation, after a clockwise rotation, thus with its first raster-scan line starting on top-right, going down.

The configuration requires a rotation and a horizontal mirroring:

- ROTEN = 1 (rotation enable) in LTDC_GCR.
- HMEN = 1 (horizontal mirror enable, per layer) in LTDC_LxCR.
- CFBADD = base + (width - 1) (increase for horizontal mirror) in LTDC_LxCFBAR.
- AFBADD0 = base + (width-1) in LTDC_LxAFBA0R.
- AFBADD1 = base + (width-1) in LTDC_LxAFBA1R.

Example 2 - Anti-clockwise 90° rotation

Assuming a portrait buffer (with horizontal raster scan) to display on a display panel (initially landscape with a horizontal raster) that has been turned in a portrait orientation, after an anti-clockwise rotation, thus with its first raster scan line starting on bottom-left, going up.

The configuration requires a rotation and a vertical mirroring:

- ROTEN = 1 (rotation enable) in LTDC_GCR.
- CFBADD = base + (lines - 1) * pitch (increase for vertical mirror) in LTDC_LxCFBAR.
- AFBADD0 = base + (lines - 1) * pitch in LTDC_LxAFBA0R.
- AFBADD1 = base + (lines - 1) * pitch in LTDC_LxAFBA1R.
- CFBP = - pitch in LTDC_LxCFBLR.
- AFBP = - pitch in LTDC_LxAFBLR.

Example 3 - Anti-clockwise 180° rotation

A rotation of 180 degrees if performed by combining a horizontal mirror and a vertical mirror, but without activating the here-described rotation feature. More details about mirroring can be found in *Section 53.5.6*.

Example 4 - Rotation-pitch configuration

Assume a typical 1080p60 panel, with a horizontal raster-scan when oriented in landscape (like a usual TV), and specifically hanged vertically (in portrait orientation), with thus a vertical raster:

- The content to be generated (by a GPU or any) in the input layers has a width of 1080 pixels, and a height of 1920 lines. The input layer aspect ratios to configure in the LTDC with: W x H = 1080 x 1920.
- The display itself has a raster width of 1920 pixels and a raster height of 1080 lines. A display synchro to configure in the LTDC with: W x H = 1920 x 1080.
- PITCH = (1080 + 9)/10 x 64 = 6912 bytes
- The rotated buffer sizes are:
  [(1920 + 1) / 2] * [(1080 + 9) / 10] * 64 = 6480 Kbytes each.

The intermediate color must be selected to be an average of colors used in the display, so that the user does not notice presence of that frame during the typical 16 ms of its display duration.

Default configuration

The rotation is disabled with the default configuration after reset, with REN = 0.

53.5.14 Gamma correction

The gamma correction is a non-linear operator that adapts the pixel to the non-linear display, using a compensating pre-distortion. The R, G, B components can be independently adapted, using a configurable non-linear transformation.

The non-linear transformation is implemented in the LTDC as eight independent linearly-interpolated segments: the desired non-linear transformation must thus be mapped onto the eight segments, and the shape of the eight segments configured in LTDC registers.

Parameters

- GAMEN in LTDC_GCR: activation of the gamma operator
- ADDR in LTDC_GCCR: table configuration, index (among 256) to write-in
- COMP in LTDC_GCCR: table configuration, 8-bit component to write-in
- REN in LTDC_GCCR: table configuration, active to write into the Red table
- GEN in LTDC_GCCR: table configuration, active to write into the Green table
- BEN in LTDC_GCCR: table configuration, active to write into the Blue table

Note: As the gamma correction works with eight interpolated segments. The only table indices to write-in are located at index: 0, 32, 64, 96,...,224, 255. The value to provide for index 255 contains the value for the pseudo-index 256.

Example configuration

The gamma correction is recommended to be set to pre-compensate the pixels with a gamma exponent of 2.2: Red, Green, and Blue components are compensated the same way by the Gamma. The configuration of Red, Green, and Blue tables is then usually the same.

Default configuration

The gamma correction is disabled with the default configuration after reset, with GAMEN = 0.

53.5.15 YUV output conversion

The default RGB888 24 bpp output can be converted to a YUV422 16 bpp output (coplanar), in order to reduce the bitrate or the interface width, if necessary.

The operator can convert the RGB to YUV with either ITU-R BT.601 versus BT.709 reference, and filter down the chrominance, to output the pixels as a YUV422 interface.

When the conversion is enabled, the Y is output on the LCD_G (green bits) and the Cb/Cr are output on the LCD_R (red bits).

Parameters in LTDC_EDCR

- OCYEN: activates the output conversion to YUV422.
- OCSEL: selects between a color conversion to ITU-R BT.601 versus to BT.709.
- OCYCO: defines whether Cb or Cr is output first.

The configuration must follow what is expected by the external display panel.

Default configuration

The YUV output conversion is disabled with the default configuration after reset, with OCYEN = 0, allowing a default RGB888 to be output.

53.5.16 Dithering

The dithering operator allows a clean conversion of the RGB888 output into a reduced pixel format, like RGB565 or RGB666, and so avoiding the usual artifact of flat area that occurs when no dithering is available.

The dithering is based on a LFSR (polynomial generating random) and adds pseudo-random noise on the LSB of each of the displayed component (bit 2 in case of an RGB666), and makes that the average of the local pixels represents the information content of the full 8-component value.

Parameters in LTDC_GCR

- DEN: dithering enable
- DRW: bit-id of LSB of the displayed Red component (among 8 bits)
- DGW: bit-id of LSB of the displayed Green component (among 8 bits)
- DBW: bit-id of LSB of the displayed Blue component (among 8 bits)

Example

To dither from RGB888 to RGB565 (assuming a RGB565 display panel):

- The LTDC outputs the Red component on pins LCD_R[7:0].
- The display panel probes the five MSB bits LCD_R[7:3].
- The red bit to dither, using its two following LSB as decimals, is the bit 3.
- DRW must be configured to 3.
- DGW = 2 and DBW = 3.

Similarly, a dithering to RGB666 requires DRW = DGW = DBW = 2.

Default configuration

The dithering is disabled with the default configuration after reset, with DEN = 0, allowing a default RGB888 to be output.

53.5.17 CRC hashing

The CRC operator allows a 16-bit signature to be extracted for each frame, by hashing the R,G,B components of all the frame pixels.

The computed CRC can be read in LTDC_CCRCR.

An expected CRC value can be configured: if the computed CRC does not match the expected CRC, the CRC interrupt is triggered. It allows a system test, letting the LTDC run for hours, and be warned only if a failed frame occurs.

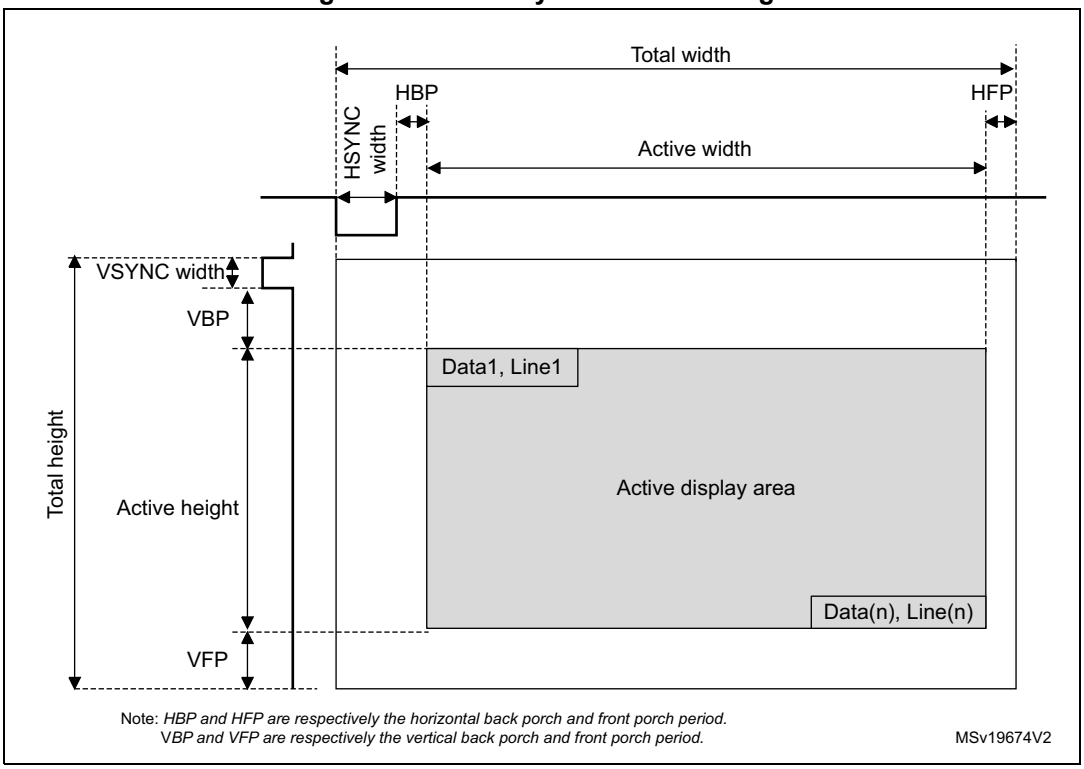
Parameters

- CRCEN in LTDC_GCR: activates the CRC computation
- ECRC in LTDC_ECRCR: expected 16-bit CRC value
- CCRC in LTDC_CCRCR: computed 16-bit CRC value

Default configuration

The CRC hashing is disabled with the default configuration after reset, with CRCEN = 0.

53.5.18 Display timing



This section describes the configuration of the display timings, so that the LTDC matches what is expected by the external display panel.

The configuration defines the horizontal and vertical duration of each of the following items:

- Synchronization period (HSYNC and VSYNC)
- Back porch (HBP, VBP)
- Active display (pixels that are visible on the screen)
- Front porch (HFP, VFP)

These timings are described in the following figure.

Figure 474. LTDC synchronous timings

Note: *HBP and HFP are respectively the horizontal back porch and front porch period.*
VBP and VFP are respectively the vertical back porch and front porch period.

MSv19674V2

As a result of these timings, the LTDC samples in pixels during the active display duration, and generates the output synchronization signals (HSYNC, VSYNC), the pixel data, and the data-enable signal.

Parameters

All the timings configured next are absolute timings, computed from the display start position, and not the relative increment (or width or height) of each area.

All these bitfields indicate the last pixel of each area, and hence are subtracted 1.

- **HSYNC and VSYNC width** (horizontal and vertical synchronization width) in LTDC_SSCR:
  - HSW = HSYNC width - 1
  - VSW = VSYNC width - 1
- **HBP and VBP** (last pixel/line of the horizontal and vertical synchronization back porch) in LTDC_BPCR:
  - AHBP = HSYNC width + HBP - 1
  - AVBP = VSYNC width + VBP - 1
- **Active width and active height** (last pixel/line of the active display area) in LTDC_AWCR:
  - AAW = HSYNC width + HBP + active width - 1
  - AAW = VSYNC width + VBP + active height - 1
- **Total display width** (last pixel/line of the total display timings) in LTDC_TWCR:
  - TOTALW = HSYNC width + HBP + active width + HFP - 1
  - TOTALH = VSYNC height + VBP + active height + VFP - 1

Note: When the LTDC is enabled, timings generated start at the position (X,Y) = (0,0), and generate immediately the first horizontal synchronization pixel in the vertical synchronization, followed by the back porch, then the active display area, and finally the front porch.

When the LTDC is disabled, the timing generator block is reset to X = total width - 1, Y = total height - 1. It holds the last pixel before the vertical synchronization phase and the FIFO are flushed. Therefore, only blanking data is output continuously.

Example of synchronous timing configuration

Assume the following display panel timings (to be extracted from panel datasheet):

- Horizontal and vertical synchronization width: 0xA pixels, 0x2 lines
- Horizontal and vertical back porch: 0x14 pixels, 0x2 lines
- Active width and active height (320x240): 0x140 pixels, 0x0F0 lines
- Horizontal and vertical front porch: 0xA pixels 0x4 lines

Bitfield values to configure become:

- HSW[11:0] = 0x9 (horizontal synchro -1) in LTDC_SSCR.
- VSH[11:0] = 0x1 (vertical synchro -1) in LTDC_SSCR.
- AHBP[11:0] = 0x1D (horizontal synchro + back porch -1) in LTDC_BPCR.
- AVBP[11:0] = 0x3 (vertical synchro + back porch -1) in LTDC_BPCR.
- AAW[11:0] = 0x15D (horizontal synchro + back porch + width -1) in LTDC_AWCR.
- AAH[11:0] = 0xF3 (vertical synchro + back porch + height -1) in LTDC_AWCR.
- TOTALW[11:0] = 0x167 (horizontal synchro + back porch + width + front porch -1) in LTDC_TWCR.

- TOTALH[11:0] = 0xF7 (vertical synchro + back porch + width + front porch -1) in LTDC_TWCR.

Default configuration

There is no default configuration to propose. As display timings depend on the specific display panel and its own required timings, all these parameters must be extracted from the display panel specification.

Note: The configuration of all the above is mandatory to have the LTDC driving correctly the external display panel.

53.5.19 Output interface polarity

The polarity of the control signals of the output interface includes the clock polarity, the vertical/horizontal synchronization, and the data-enable signal.

Parameters in LTDC_GCR

- PCPOL: polarity of the output clock
- VSPOL: polarity of the vertical synchronization
- HSPOL: polarity of the vertical synchronization
- DEPOL: polarity of the data enable

Default configuration

There is not default configuration, as the configuration of the polarity depends on the display panel specifications.

The following configuration can be used to have all items working with a positive polarity:

- PCPOL = 1 (rising-edge)
- VSPOL = 1 (active high)
- HSPOL = 1 (active high)
- DEPOL = 1 (active high)

53.5.20 Shadow registers

When activated, the LTDC is expected to display continuously data, frame after frame.

The user may want to modify some settings: for example, add a new layer, modify the layer window location, or update the displayed content by updating the pointer to the buffer that is displayed.

The LTDC provides shadow registers for most of its configuration registers to allow transitions to occur cleanly synchronized during the short vertical synchronization, when nothing is displayed: while the LTDC is busy working with a copy of its configuration registers to control the ongoing display (the active set), a new version of the registers can be progressively updated by software (the shadow set). When ready, and at the exact VSync event, the shadow set is copied into the active set, ready for the next frame.

Once the shadow set is fully updated, there are two ways to transfer it in the active set:

- Immediate copy: the copy occurs immediately.
- Delayed to next VSync: the copy occurs at the next VSync.

Note: In case of delayed copy, shadow registers must not be modified again before the reload has been done.

Reading from shadow registers returns the current active value. The new written value can only be read after the reload has taken place.

The impossibility to read a temporary value in a shadow register makes impossible to perform a read-modify-write to set/reset a single bit inside a shadow register.

A register reload interrupt can be generated if enabled in LTDC_IER or LTDC_IER2.

Shadowed registers

Non-layer registers

The non-layer registers (not prefixed with LTDC_Lx) are all non-shadowed. They contain static configurations dependent mostly on the attached display panel. They do not require update during an ongoing display.

Layer registers

The layer registers are prefixed with LTDC_Lx. Most are shadowed to support a clean frame-to-frame update. The following are not shadowed, either because their shadowing would be too costly or because they are not expected to require frequent or synchronized updates:

- LTDC_LxRCR reload control
- LTDC_LxCKCR color key (assumed static)
- LTDC_LxCLUTWR CLUT (indirect access, too costly to shadow)
- All upscaler LTDC_LxSIS/SOS/SVSFR/SHSFR (assumed static)
- LTDC_LxCYR0R/R1R YUV-to-RGB color conversion (assumed static)
- LTDC_LxFPF0R/LTDC_LxFPF1R flexible pixel format (assumed static)

Parameters

The centralized reload of the shadow register is controlled with bitfields in LTDC_SRCR:

- IMR: writing 1 triggers an immediate copy.
- VBR: writing 1 triggers a copy delayed at the next blanking.

A per-layer reload control is available with bitfields in LTDC_LxRCR:

- GRMSK delegates the per-layer reload to the central reload (above).
- IMR: writing 1 triggers an immediate copy for this layer.
- VBR: writing 1 triggers a copy delayed at the next blanking.

Default configuration

For the initial LTDC configuration, when the display is inactive, the IMR mode must be used to copy the initial configuration to the active set.

When the display is active, it is recommended to use VBR to update any parameters: the parameter transition occurs then from frame-to-frame, and not inside an ongoing frame. Applying an immediate change of the LTDC configuration within a frame results in an unpredictable behavior.

53.5.21 General control

The final and mandatory step, after all the above configurations, is to trigger the display. The LTDC has two working mode:

- Continuous mode: the LTDC continuously sends frames to the display.
- Single-frame mode: the LTDC sends a single frame after a trigger that can be:
  - Hardware-based, generated by the DSI-Host and wrapper logic
  - Software-based, generated by a software access to a register

Parameters in LTDC_GCR

- LTDCEN: general LTDC activation
- SFEN: moves from the continuous to the single-frame mode.
- SFEXEN: enables the external trigger, when in single-frame mode.
- SFSWTR: software trigger, when in single-frame mode

53.5.22 Provision for a secure layer

The LTDC allows a secure layer support, with the addition of a wrapper around the LTDC that secures the access to its registers (register-per-register), and secures the access of its AXI master to the layer and rotation framebuffers.

The layer 3 can be secured thanks to the measures described in the following sub-sections.

Configuration registers

The granularity between secure versus non-secure items is at register level:

- A secure register contains only to-be-secured bitfields.
- Non-secure bitfields are all in open-access registers.

It allows all registers to be segregated between secure ones (with an access only by secure software) and open ones (with an access by any non-secure software).

Interruptions

The interruption logic has been duplicated, with one secure interrupt logic (register and pin) reserved for secure software, and another open interrupt logic (second register set and second output pin) for non-secure software.

Blending

The blending order (foreground to background) is defined in per-layer register, so that the blending order of the secure layer3 can be securely defined as foreground. If some non-secure software defines an other layer (layer 1 or layer 2) in foreground, the integrated hardware consistency check reverses the blending order to a fixed one, forcing the secure layer to be in the foreground.

Rotation

The rotation configuration (activation, base-address of buffers) is located in specific registers, that can be secured too, if needed, by the LTDC wrapper.

CRC

The CRC that computes a signature of the displayed frame has its configuration located in specific registers that can be defined as secure, too.

53.6 LTDC interrupts

The LTDC provides various maskable interrupts, that are grouped into two global interrupt pins: one working interrupt pin, and one error interrupt pin.

These maskable interrupts and two global output pins are duplicated for the secure software usage, resulting in a duplicated set of registers (for masking) and a duplicated set of output pin. Hence a total of four interrupt output pins: global working, global error, secure global, secure global error.

The following working interrupts on which to synchronize software are ORed together as a global working interrupt:

- Line interrupt: generated when a configured line number is reached. Its position is Configured in LTDC_LIPCR.
- Register reload interrupt: generated when a shadow-register reload is performed during the vertical blanking period.

The following error interrupts warn about some internal processing errors, and are ORed together as a global error interrupt:

- FIFO underrun warning interrupt: generated when a pixel is requested from an empty layer FIFO.
- FIFO underrun error interrupt: generated when more pixels are requested from an empty layer FIFO.
- FIFO rotation interrupt: generated when a pixel is requested from an empty rotation FIFO.
- Transfer-error interrupt: generated when an AXI bus error occurs during data transfer.
- CRC-error interrupt: generated when the CRC computed and expected are different.

The LTDC also provides an observation mean, to retrieve X and Y positions of the currently displayed pixel.

Parameters

The following non-secure registers are used to handle the interrupts:

- LTDC_LIPCR: defines the line-number on which the line-number interrupt occurs.
- LTDC_IER demasking bit: setting each bit enables the corresponding interrupt.
- LTDC_ISR: event bit where to read if an event has occurred
- LTDC_ICR: clear bit where to write to clean an interrupt.
- LTDC_CPSR: location with X and Y of the current displayed pixel
- LTDC_FUTR: trigger from which a FIFO underrun warning becomes a FIFO underrun error, and is the amount of missed words of 64 bits

The duplicated secure registers are used to handle the interrupts (with same respective content as the non-secure ones): LTDC_LIPCR2, LTDC_IER2, LTDC_ISR2, LTDC_ICR2.

The following table lists the bitfields of the available interrupts, and shows the four pins on which these bitfields are directed:

- Non-secure registers drive ltdc_lo_xx interrupts. Secure registers drive ltdc_up_xx interrupts.
- Interrupts triggered by an error are suffixed with a xx_err_it. Interrupts triggered during a normal LTDC handling are suffixed with an _it only.

Table 501. LTDC interrupt requests

Registers	Interrupt event	Event bit	Enable control bit	Interrupt signal
Non-secure registers (IER, ISR, ICR)	Line number	LIF	LIE	ltdc_lo_li
	Register reload	RRIF	RRIE	ltdc_lo_li
	FIFO underrun warning	FUWIF	FUWIE	ltdc_lo_li
	FIFO underrun error	FUIF	FUIE	ltdc_lo_err_it
	FIFO underrun rotation error	FURIF	FURIE	ltdc_lo_err_it
	Bus transfer error	TERRIF	TERRIE	ltdc_lo_err_it
	CRC error	CRCIF	CRCIE	ltdc_lo_err_it
Secure registers (IER2, ISR2, ICR2)	Line number	LIF	LIE	ltdc_up_li
	Register reload	RRIF	RRIE	ltdc_up_li
	FIFO underrun warning	FUWIF	FUWIE	ltdc_up_li
	FIFO underrun error	FUIF	FUIE	ltdc_up_err_it
	FIFO underrun rotation error	FURIF	FURIE	ltdc_up_err_it
	Bus transfer error	TERRIF	TERRIE	ltdc_up_err_it
	CRC error	CRCIF	CRCIE	ltdc_up_err_it

53.7 LTDC programming procedure

The LTDC programming procedure consists to activate the clocks, to follow all the operator sequence (as listed in *Section 53.5*) from the beginning (AXI master) to the end (output interface polarity), and to configure the needed operators as described.

The minimum configuration that must be performed is the following:

1. Enable the LTDC clock in the RCC register:
   - APB slave: ck_icn_p_ltdc in the RCC
   - AXI master: ck_icn_m_ltdc in the RCC
   - Pixel clock that fits display panel requirements (resolution, blanking, frame rate)
2. Define the buffer of at least one input layer (see *Section 53.5.2*, with for example, layer base-address, size, or buffer pitch).
3. Define this layer pixel format (see *Section 53.5.3*). ARGB8888 can simply be used, depending on the stored buffer.
4. Define where this layer is inserted in the final display (see *Section 53.5.11*): typically the top-left and bottom-right corners of the display.

5. Define how this layer is blended in the final display (see *Section 53.5.12*).
6. Define timings of the display panel to drive (see *Section 53.5.18*).
7. Define polarity of the output signals (see *Section 53.5.19*).
8. Copy all above settings, once, using the immediate global reload (see *Section 53.5.20*).
9. Start the display by activating the main enable (see *Section 53.5.20*).

Note: Most layer registers are shadowed. Once a register is written, it must not be modified again before the reload has been done. A new write to the same register overrides the previous configuration if not yet reloaded. It is also not possible to read the temporary value of a shadowed register, which makes impossible to perform read-modify-write to set/reset a single bit inside a register.

53.8 LTDC registers

53.8.1 LTDC identification register (LTDC_IDR)

Address offset: 0x000

Reset value: 0x0004 0100

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **LNBR[7:0]**: Number of layers

53.8.3 LTDC synchronization size configuration register (LTDC_SSCR)

Address offset: 0x008

Reset value: 0x0000 0000

This register defines the number of horizontal synchronization pixels minus 1, and the number of vertical synchronization lines minus 1. Refer to *Figure 474* and *Section 53.5* for a configuration example.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	HSW[11:0]

Res.	Res.	Res.	Res.	VSH[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HSW[11:0]**: Horizontal synchronization width (in units of pixel clock period)
This bitfield defines the number of horizontal synchronization pixel minus 1.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **VSH[11:0]**: Vertical synchronization height (in units of horizontal scan line)
This bitfield defines the vertical synchronization height minus 1. It represents the number of horizontal synchronization lines.

53.8.4 LTDC back porch configuration register (LTDC_BPCR)

Address offset: 0x00C

Reset value: 0x0000 0000

This register defines the accumulated number of horizontal synchronization and back porch pixels minus 1 (HSYNC width + HBP - 1), and the accumulated number of vertical synchronization and back porch lines minus 1 (VSYNC height + VBP - 1).
Refer to *Figure 474* and *Section 53.5* for a configuration example.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	AHBP[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	AVBP[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **AHBP[11:0]**: Accumulated horizontal back porch (in units of pixel clock period)
This bitfield defines the accumulated horizontal back porch width that includes the horizontal synchronization and horizontal back porch pixels minus 1.
The horizontal back porch is the period between horizontal synchronization going inactive, and the start of the active display part of the next scan line.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **AVBP[11:0]:** Accumulated Vertical back porch (in units of horizontal scan line)
This bitfield defines the accumulated vertical back porch width that includes the vertical synchronization and vertical back porch lines minus 1.
The vertical back porch is the number of horizontal scan lines at a start of frame to the start of the first active scan line of the next frame.

53.8.5 LTDC active width configuration register (LTDC_AWCR)

Address offset: 0x010

Reset value: 0x0000 0000

This register defines the accumulated number of horizontal synchronization, back porch and active pixels minus 1 (HSYNC width + HBP + active width - 1), and the accumulated number of vertical synchronization, back porch lines and active lines minus 1 (VSYNC height + BVBP + active height - 1). Refer to *Figure 474* and *Section 53.5* for a configuration example.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	AAW[11:0]

Res.	Res.	Res.	Res.	AAH[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **AAW[11:0]**: Accumulated active width (in units of pixel clock period)
This bitfield defines the accumulated active width that includes the horizontal synchronization, horizontal back porch and active pixels minus 1. The active width is the number of pixels in active display area of the panel scan line.
Refer to device datasheet for the maximum active width supported following the maximum pixel clock.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **AAH[11:0]**: Accumulated active height (in units of horizontal scan line)
This bitfield defines the accumulated height that includes the vertical synchronization, vertical back porch and the active height lines minus 1. The active height is the number of active lines in the panel.
Refer to device datasheet for the maximum active height supported following the maximum pixel clock.

53.8.6 LTDC total width configuration register (LTDC_TWCR)

Address offset: 0x014

Reset value: 0x0000 0000

This register defines the accumulated number of horizontal synchronization, back porch, active and front porch pixels minus 1 (HSYNC width + HBP + active width + HFP - 1), and the accumulated number of vertical synchronization, back porch lines, active and front lines minus 1 (VSYNC height + BVBP + active height + VFP - 1). Refer to *Figure 474* and *Section 53.5* for a configuration example.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	TOTALW[11:0]

Res.	Res.	Res.	Res.	TOTALH[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **TOTALW[11:0]**: Total width (in units of pixel clock period)

This bitfield defines the accumulated total width that includes the horizontal synchronization, horizontal back porch, active width and horizontal front porch pixels minus 1.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **TOTALH[11:0]**: Total height (in units of horizontal scan line)

This bitfield defines the accumulated height that includes the vertical synchronization, vertical back porch, the active height and vertical front porch height lines minus 1.

53.8.7 LTDC global control register (LTDC_GCR)

Address offset: 0x018

Reset value: 0x0000 2220

This register defines the LTDC global configuration.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HSPOL	VSPOL	DEPOL	PCPOL	Res.	SFEXEN	SFSWTR	SFEN	Res.	Res.	Res.	Res.	CRCEN	Res.	Res.	DEN

Bit 31 **HSPOL**: Horizontal synchronization polarity

This bit is set and cleared by software.

0: Horizontal synchronization polarity is active low.

1: Horizontal synchronization polarity is active high.

Bit 30 **VSPOL**: Vertical synchronization polarity

This bit is set and cleared by software.

0: Vertical synchronization is active low.

1: Vertical synchronization is active high.

Bit 29 **DEPOL**: Blanking (no data/pixel) polarity

This bit is set and cleared by software.

0: Blanking (no data/pixel) polarity is active low.

1: Blanking (no data/pixel) polarity is active high.

Bit 28 **PCPOL**: Pixel clock polarity

This bit is set and cleared by software.

0: The pixel and sync data are generated at the rising-edge of the output LCD_CLK clock.

1: The pixel and sync data are generated at the falling-edge of the output LCD_CLK clock.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **SFEXEN**: Single-frame mode: external trigger enable
This bit is set and cleared by software.
0: External trigger disabled
1: External trigger enabled: a trigger on the external trigger generates one single frame.

Bit 25 **SFSWTR**: Single-frame mode software trigger
This bit is set by software and cleared by hardware.
0: No action
1: Triggers one frame

Bit 24 **SFEN**: Single-frame mode enable
This bit is set and cleared by software.
0: Single-frame disabled: a trigger (on SFSWTR or external) generates a continuous flow.
1: Single-frame enabled: a trigger (on SFSWTR or external) generates a single frame.

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **CRCEN**: CRC enable
This bit is set and cleared by software.
0: CRC disabled
1: CRC enabled

Bits 18:17 Reserved, must be kept at reset value.

Bit 16 **DEN**: Dither enable
This bit is set and cleared by software.
0: Dither disabled
1: Dither enabled

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **DRW[2:0]**: Dither red width
This bitfield returns the dither red bits.

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **DGW[2:0]**: Dither green width
This bitfield returns the dither green bits.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **DBW[2:0]**: Dither blue width
This bitfield returns the dither Blue bits.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **ROTEN**: Rotation enable
This bit is set and cleared by software.
0: Rotation disabled
1: Rotation enabled (for a pure visual rotation, the mirroring has to be activated)

Bit 1 **GAMEN**: Gamma correction enable
This bit is set and cleared by software.
0: Gamma correction disabled (pixels bypass the gamma operator)
1: Gamma correction enabled

Bit 0 **LTDCEN**: LTDC global enable
This bit is set and cleared by software.
0: LTDC disabled
1: LTDC enabled

53.8.8 LTDC global configuration 1 register (LTDC_GC1R)

Address offset: 0x01C

Reset value: 0x6BE4 D888

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 30 **CRMA**: Configuration reading mode ability

Bit 29 **STRA**: Status register ability

Bit 28 **DWP:** Dither width programmability

Bit 27 **SPP**: Sync polarity programmability

Bit 26 Reserved, must be kept at reset value.

Bit 25 **TP**: Timing programmability

Bit 24 **LNIP**: Line-IRQ: line position programmability

Bit 23 **BBA**: Background blending ability

Bit 22 **BCP**: Background color programmability (unique color blended as background)

Bit 21 **SHRA**: Shadow register ability

Bit 20 Reserved, must be kept at reset value.

Bits 19:17 **GCT[2:0]**: Gamma correction technique implemented
000: No gamma
001: Gamma with 256 samples
010: Gamma with 8 interpolated segments
Others: Reserved

Bit 16 Reserved, must be kept at reset value.

Bits 15:14 **DT[1:0]**: Dithering technique implemented
00: No dithering
01: Ordered 4x4 Bayer
10: Ordered 4x4 custom
11: Pseudo-random LFSR

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PRBA**: Precise blending ability

Bits 11:8 **WRCH[3:0]**: Width of red channel output

Bits 7:4 **WGCH[3:0]**: Width of green channel output

Bits 3:0 **WBCH[3:0]**: Width of blue channel output

53.8.9 LTDC global configuration 2 register (LTDC_GC2R)

Address offset: 0x020

Reset value: 0x0000 BF30

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **BOA:** Blending order ability
0: Blending order fixed
1: Blending order configurable

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CRCA:** CRC ability
0: CRC no computation available
1: CRC computation available

Bit 12 **SFA:** Single frame mode ability
0: Single frame not available
1: Single frame available

Bit 11 **SISA:** Second interrupt set ability
0: Second interrupt set not available
1: Second interrupt set available

Bit 10 **ROTA**: Rotation support ability

Bit 9 **AXIIDA**: AXIID ability

Bit 8 **OCA**: Output conversion ability (RGB to YCbCr)

Bit 7 **EDCA**: External display control ability

Bits 6:4 **BW[2:0]**: Bus width (log2 of number of bytes)
010: 32-bit bus
011: 64-bit bus
100: 128-bit bus
Others: Reserved

Bit 3 **DPA:** Secondary RGB output port ability

Bit 2 **DVA:** Dual-view ability

Bit 1 **STSA:** Slave timings synchronization ability

Bit 0 **BLA:** Background layer ability (pixels of background layer are read from memory)

53.8.10 LTDC shadow reload configuration register (LTDC_SRCR)

Address offset: 0x024

Reset value: 0x0000 0000

This register allows the reload, either immediately or during the vertical blanking period, of shadow register values to the active registers. Shadow registers are all layer x ones, except LTDC_L1CLUTWR and LTDC_L2CLUTWR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VBR	IMR
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **VBR**: Vertical blanking reload request

This bit is set by software and cleared only by hardware after reload (it cannot be cleared through register write once it is set).

0: No effect

1: The shadow registers are reloaded during the vertical blanking period (at the beginning of the first line after the active display area).

Bit 0 **IMR**: Immediate reload trigger

This bit is set by software and cleared only by hardware after reload.

0: No effect

1: The shadow registers are reloaded immediately.

53.8.11 LTDC gamma correction configuration register (LTDC_GCCR)

Address offset: 0x028

Reset value: 0x0000 0000

This register performs indirect access to the gamma correction R,G,B tables.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REN	GEN	BEN
													w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COMP[7:0]								ADDR[7:0]							
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **REN**: Write trigger to the red table

0: No action

1: COMP is written at ADDR in the red table.

Bit 17 **GEN**: Write trigger to the green table

0: No action

1: COMP is written at ADDR in the green table.

Bit 16 **BEN**: Write trigger to the blue table
0: No action
1: COMP is written at ADDR in the blue table.

Bits 15:8 **COMP[7:0]**: Color component to be written, in either (or all) the R,G,B tables

Bits 7:0 **ADDR[7:0]**: Address of the R,G,B table where the COMP component is written
When LTDC_GC1R.GCT=2, the gamma is implemented with eight interpolated segment. In that case, the valid ADDR addresses are: 0, 32, 64, 96, 128, 160, 192, 224, 255.
Note: For ADDR = 255, the gamma interpolation hardware considers that the address is 256.

53.8.12 LTDC background color configuration register (LTDC_BCCR)

Address offset: 0x02C

Reset value: 0x0000 0000

This register defines the background color (RGB888).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BCRED[7:0]

BCGREEN[7:0]								BCBLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **BCRED[7:0]**: Background color red value
This bitfield configures the background red value.

Bits 15:8 **BCGREEN[7:0]**: Background color green value
This bitfield configures the background green value.

Bits 7:0 **BCBLUE[7:0]**: Background color blue value
This bitfield configures the background blue value.

53.8.13 LTDC interrupt enable register (LTDC_IER)

Address offset: 0x034

Reset value: 0x0000 0000

This register determines which status flags generate an interrupt request, by setting the corresponding bit to 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	FURIE	CRCIE	FUIE	Res.	Res.	RRIE	TERRIE	FUWIE	LIE
							rw	rw	rw			rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **FURIE**: FIFO underrun at rotation interrupt enable
This bit is set and cleared by software.
0: FIFO underrun at rotation interrupt disabled
1: FIFO underrun at rotation interrupt enabled

Bit 7 **CRCIE**: CRC error interrupt enable
This bit is set and cleared by software.
0: CRC error disabled
1: CRC error interrupt enabled

Bit 6 **FUIE**: FIFO underrun interrupt enable
This bit is set and cleared by software.
0: FIFO underrun interrupt disabled
1: FIFO underrun Interrupt enabled

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **RRIE**: Register reload interrupt enable
This bit is set and cleared by software.
0: Register reload interrupt disabled
1: Register reload interrupt enabled

Bit 2 **TERRIE**: Transfer error interrupt enable
This bit is set and cleared by software.
0: Transfer error interrupt disabled
1: Transfer error interrupt enabled

Bit 1 **FUWIE**: FIFO underrun warning interrupt enable
This bit is set and cleared by software.
0: FIFO underrun interrupt disabled
1: FIFO underrun Interrupt enabled

Bit 0 **LIE**: Line interrupt enable
This bit is set and cleared by software.
0: line interrupt disabled
1: line interrupt enabled

53.8.14 LTDC interrupt status register (LTDC_ISR)

Address offset: 0x038

Reset value: 0x0000 0000

This register returns the interrupt status flag.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	FURIF	CRCIF	FUIF	Res.	Res.	RRIF	TERRIF	FUWIF	LIF
							r	r	r			r	r	r	r

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **FURIF**: FIFO underrun at rotation interrupt flag
0: No FIFO underrun at rotation interrupt generated
1: FIFO underrun at rotation interrupt generated

Bit 7 **CRCIF**: CRC error interrupt flag
0: No CRC error interrupt generated
1: CRC error interrupt generated when a bus error occurs

Bit 6 **FUIF**: FIFO underrun interrupt flag
0: No FIFO underrun interrupt generated
1: FIFO underrun interrupt generated, if one of the layer FIFOs is empty and many pixel data are read from the FIFO

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **RRIF**: Register reload interrupt flag
0: No register reload interrupt generated
1: Register reload interrupt generated when a vertical blanking reload occurs (and the first line after the active area is reached)

Bit 2 **TERRIF**: Transfer error interrupt flag
0: No transfer error interrupt generated
1: Transfer error interrupt generated when a bus error occurs

Bit 1 **FUWIF**: FIFO underrun warning interrupt flag
0: No FIFO underrun warning interrupt generated
1: FIFO underrun warning interrupt generated, if one of the layer FIFO is empty and pixel data is read from the FIFO

Bit 0 **LIF**: Line interrupt flag
0: No line interrupt generated
1: Line interrupt generated when a programmed line is reached

53.8.15 LTDC interrupt clear register (LTDC_ICR)

Address offset: 0x03C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

							w	w	w			w	w	w	w

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **CFURIF**: FIFO underrun at rotation interrupt flag clear
0: No effect
1: Clear FURIF flag in LTDC_ISR.

Bit 7 **CCRCIF**: CRC error interrupt flag clear
0: No effect
1: Clear CRCIF flag in LTDC_ISR.

Bit 6 **CFUIF**: FIFO underrun interrupt flag clear
0: No effect
1: Clear FUIF flag in LTDC_ISR.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **CRRIF**: Register reload interrupt flag clear
0: No effect
1: Clear RRIF flag in LTDC_ISR.

Bit 2 **CTERRIF**: Transfer error interrupt flag clear
0: No effect
1: Clear TERRIF flag in LTDC_ISR.

Bit 1 **CFUWIF**: FIFO underrun warning interrupt flag clear
0: No effect
1: Clear FUWIF flag in LTDC_ISR.

Bit 0 **CLIF**: Line-interrupt flag clear
0: No effect
1: Clear LIF flag in LTDC_ISR.

53.8.16 LTDC line interrupt position configuration register (LTDC_LIPCR)

Address offset: 0x040

Reset value: 0x0000 0000

This register defines the line interrupt position. The line value to be programmed depends on timing parameters (see *Figure 474*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	LIPOS[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **LIPOS[11:0]**: Line interrupt position
This bitfield configures the line interrupt position.

53.8.17 LTDC current position status register (LTDC_CPSR)

Address offset: 0x044

Reset value: 0x0000 0000

This register returns the X,Y position of the currently displayed pixel.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	CXPOS[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	CYPOS[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **CXPOS[11:0]**: Current X position

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **CYPOS[11:0]**: Current Y position

53.8.18 LTDC current display status register (LTDC_CDSR)

Address offset: 0x048

Reset value: 0x0000 0003

This register returns the status of the current display phase that is controlled by HSYNC, VSYNC, and horizontal/vertical data-enable signals.

Example: if the current display phase is the vertical synchronization, VSYNCS is active high. If the current display phase is the horizontal synchronization, HSYNCS is active high.

The returned status does not depend on the configured polarity in LTDC_GCR: it returns the current active display phase.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSYNCS	VSYNCS	HDES	VDES
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **HSYNCS**: Horizontal synchronization display status
0: Active low
1: Active high

Bit 2 **VSYNCS**: Vertical synchronization display status
0: Active low
1: Active high

Bit 1 **HDES**: Horizontal data enable display status
0: Active low
1: Active high

Bit 0 **VDES**: Vertical data enable display status
0: Active low
1: Active high

53.8.19 LTDC external display control register (LTDC_EDCR)

Address offset: 0x060

Reset value: 0x0000 0000

This register controls the external display interface.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	OCYCO	OCYSEL	OCYEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
				rw	rw	rw									
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **OCYCO**: Output conversion to YCbCr 422
This bit defines the chrominance order (whether Cb or Cr is output first).
0: Cb is output first (Y0Cb, then Y1Cr, Y2Cb and so on).
1: Cr is output first (Y0Cr, then Y1Cb, Y2Cr and so on).

Bit 26 **OCYSEL**: Output conversion to YCbCr 422
This bit selects the set of CCIR hard-wired coefficients (ITU-R BT.601 or 709).
0: Use ITU-R BT.601 set (for typically SDTV analog-like displays).
1: Use ITU-R BT.709 set (for typically HDTV digital-like displays).

Bit 25 **OCYEN**: Output conversion to YCbCr 422 enable
0: Conversion disabled
1: Conversion enabled

Bits 24:0 Reserved, must be kept at reset value.

53.8.20 LTDC interrupt enable register 2 (LTDC_IER2)

Address offset: 0x064

Reset value: 0x0000 0000

This register determines which status flags generate an interrupt request, by setting the corresponding bit to 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	FURIE	CRCIE	FUIE	Res.	Res.	RRIE	TERRIE	FUWIE	LIE
							rw	rw	rw			rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **FURIE**: FIFO underrun at rotation interrupt enable
This bit is set and cleared by software.
0: FIFO underrun at rotation interrupt disabled
1: FIFO underrun at rotation interrupt enabled

Bit 7 **CRCIE**: CRC error interrupt enable
This bit is set and cleared by software.
0: CRC error disabled
1: CRC error interrupt enabled

Bit 6 **FUIE**: FIFO underrun interrupt enable
This bit is set and cleared by software.
0: FIFO underrun interrupt disabled
1: FIFO underrun Interrupt enabled

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **RRIE**: Register reload interrupt enable
This bit is set and cleared by software.
0: Register reload interrupt disabled
1: Register reload interrupt enabled

Bit 2 **TERRIE**: Transfer error interrupt enable
This bit is set and cleared by software.
0: Transfer error interrupt disabled
1: Transfer error interrupt enabled

Bit 1 **FUWIE**: FIFO underrun warning interrupt enable
This bit is set and cleared by software.
0: FIFO underrun interrupt disabled
1: FIFO underrun Interrupt enabled

Bit 0 **LIE**: Line interrupt enable
This bit is set and cleared by software.
0: Line interrupt disabled
1: Line interrupt enabled

53.8.21 LTDC interrupt status register 2 (LTDC_ISR2)

Address offset: 0x068

Reset value: 0x0000 0000

This register returns the interrupt status flag.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	FURIF	CRCIF	FUIF	Res.	Res.	RRIF	TERRIF	FUWIF	LIF
							r	r	r			r	r	r	r

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **FURIF**: FIFO underrun at rotation interrupt flag
0: No FIFO underrun at rotation interrupt generated
1: FIFO underrun at rotation interrupt generated

Bit 7 **CRCIF**: CRC Error interrupt flag
0: No CRC error interrupt generated
1: CRC error interrupt generated when a bus error occurs

Bit 6 **FUIF**: FIFO underrun interrupt flag
0: No FIFO underrun interrupt generated.
1: FIFO underrun interrupt generated, if one of the layer FIFO is empty and many pixel data are read from the FIFO

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **RRIF**: Register reload interrupt flag
0: No register reload interrupt generated
1: Register reload interrupt generated when a vertical blanking reload occurs (and the first line after the active area is reached)

Bit 2 **TERRIF**: Transfer error interrupt flag
0: No transfer error interrupt generated
1: Transfer error interrupt generated when a bus error occurs

Bit 1 **FUWIF**: FIFO underrun warning interrupt flag
0: No FIFO underrun warning interrupt generated.
1: FIFO underrun warning interrupt generated, if one of the layer FIFO is empty and pixel data is read from the FIFO

Bit 0 **LIF**: Line interrupt flag
0: No line interrupt generated
1: Line interrupt generated when a programmed line is reached

53.8.22 LTDC interrupt clear register 2 (LTDC_ICR2)

Address offset: 0x06C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

							w	w	w			w	w	w	w

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **CFURIF**: Clear FIFO underrun at rotation interrupt flag
0: No effect
1: Clear the FURIF flag in LTDC_ISR2.

Bit 7 **CCRCIF**: Clear the CRC error interrupt flag
0: No effect
1: Clear the CRCIF flag in LTDC_ISR2.

Bit 6 **CFUIF**: Clear the FIFO underrun interrupt flag
0: No effect
1: Clear the FUIF flag in LTDC_ISR2.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **CRRIF**: Clear register reload interrupt flag
0: No effect
1: Clear the RRIF flag in LTDC_ISR2.

Bit 2 **CTERRIF**: Clear the transfer error interrupt flag
0: No effect
1: Clear the TERRIF flag in LTDC_ISR2.

Bit 1 **CFUWIF**: Clear the FIFO underrun warning interrupt flag
0: No effect
1: Clear the FUWIF flag in LTDC_ISR2.

Bit 0 **CLIF**: Clear the line interrupt flag
0: No effect
1: Clear the LIF flag in LTDC_ISR2.

53.8.23 LTDC line interrupt position configuration register 2 (LTDC_LIPCR2)

Address offset: 0x070

Reset value: 0x0000 0000

This register defines the line interrupt position. The line value to be programmed depends on timing parameters (see *Figure 474*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **LIPOS[11:0]**: Line interrupt position

53.8.24 LTDC expected CRC register (LTDC_ECRCR)

Address offset: 0x078

Reset value: 0x0000 0000

This register is used to configure the expected CRC of a frame. If the computed CRC is not as expected, an interrupt CRCIF is generated.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

ECRC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ECRC[15:0]**: Expected CRC of frame

53.8.25 LTDC computed CRC register (LTDC_CCRCR)

Address offset: 0x07C

Reset value: 0x0000 0000

This register returns the computed CRC of a frame.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

CCRC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CCRC[15:0]**: Computed CRC of frame

53.8.26 LTDC rotation buffer 0 address register (LTDC_RB0AR)

Address offset: 0x080

Reset value: 0x0000 0000

This register defines the base address in the external memory of the buffer used to store the data after composition and before the rotation and output. There are two buffers used (0 and 1), used alternatively (in ping-pong). This register defines the buffer 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ADDR[31:0]**: Address of the rotation buffer 0

53.8.27 LTDC rotation buffer 1 address register (LTDC_RB1AR)

Address offset: 0x084

Reset value: 0x0000 0000

This register defines the base address in the external memory of the buffer used to store the data after composition and before the rotation and output. There are two buffers used (0 and 1), used alternatively (in ping-pong). This register defines the buffer 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

ADDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ADDR[31:0]**: Address of the rotation buffer 1

53.8.28 LTDC rotation buffer pitch register (LTDC_RBPR)

Address offset: 0x088

Reset value: 0x0000 0000

This register defines the pitch (line-to-line address increment) of the stored rotation buffer. The pitch is proportional to the composed display width (before rotation) and, (after rotation) proportional to the non-raster dimension of the display panel.

Example: A display panel with a composed width (before rotation) of 263 pixels requires a PITCH[11:0] value of [(263 + 9) / 10] * 32 = 27 * 32 = 864 bytes.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	PITCH[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **PITCH[11:0]**: Pitch in bytes of the rotation buffers 0 and 1

The pitch is configured with 32 bytes per 10 started pixels, of the width of the composed buffer. PITCH = (width + 9) / 10 32 bytes.

53.8.29 LTDC rotation intermediate frame color register (LTDC_RIFCR)

Address offset: 0x08C

Reset value: 0x0000 0000

This register defines the color that is displayed full-screen during one frame, when switching from normal to rotation mode (as there is a one-frame delay inserted, that must be filled)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **RIFRED[7:0]**: Red component of the rotation intermediate frame

Bits 15:8 **RIFGREEN[7:0]**: Green component of the rotation intermediate frame

Bits 7:0 **RIFBLUE[7:0]**: Blue component of the rotation intermediate frame

53.8.30 LTDC FIFO underrun threshold register (LTDC_FUTR)

Address offset: 0x090

Reset value: 0x0000 0010

A default value for THRE[15:0] is 0x80, that represents 128 words of 64 bits, thus 256 pixels 32bpp or 1024 luminance of a YUV420 pixel.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 29 **RGBA8888**: Pixel format, ability for rgba8888

Bit 28 **BGRA888**: Pixel format, ability for bgra8888

Bit 27 **RGB565**: Pixel format, ability for rgb565

Bit 26 **BGR565**: Pixel format, ability for bgr565

Bit 25 **RGB888**: Pixel format, ability for rgb888

Bit 24 **FF**: Flexible pixel format, ability

Bit 23 **F11PC**: Blending factor 1, ability for 1.0 - (pixel_alpha * constant_alpha)

Bit 22 **F1PC**: Blending factor 1, ability for pixel_alpha * constant_alpha

Bit 21 **F11C**: Blending factor 1, ability for 1.0 - constant_alpha

Bit 20 **F1C**: Blending factor 1, ability for constant_alpha

Bit 19 **F11P**: Blending factor 1, ability for 1.0 - pixel_alpha

Bit 18 **F1P**: Blending factor 1, ability for pixel_alpha

Bit 17 **F10**: Blending factor 1,ability for 0.0

Bit 16 **F11**: Blending factor 1, ability for 1.0

Bit 15 **F21PC**: Blending factor 2, ability for 1.0 - (pixel_alpha * constant_alpha)

Bit 14 **F2PC**: Blending factor 2, ability for pixel_alpha * constant_alpha

Bit 13 **F21C**: Blending factor 2, ability for 1.0 - constant_alpha

Bit 12 **F2C**: Blending factor 2, ability for constant_alpha

Bit 11 **F21P**: Blending factor 2, ability for 1.0 - pixel_alpha

Bit 10 **F2P**: Blending factor 2, ability for pixel_alpha

Bit 9 **F20**: Blending factor 2, ability for 0.0

Bit 8 **F21**: Blending factor 2, ability for 1.0

Bit 7 **CKRA**: Color key replace ability

Bit 6 **CLUTA**: CLUT ability

Bit 5 **WINA**: Windowing ability

Bit 4 **DCP**: Default color programmability

Bit 3 **APA**: Alpha plane ability

Bit 2 **CFBPA**: Color frame buffer pitch ability

Bit 1 **CFBDA**: Color frame buffer duplication ability

Bit 0 **CKTA**: Color key transparency ability

53.8.32 LTDC layer x configuration 1 register (LTDC_LxC1R)

Address offset: 0x104 + 0x100 * (x - 1), (x = 1 to 3)

Reset value: 0x8000 0007, 0x8000 0007, 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GRMSK	VBR	IMR
													rw	rw	w

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **GRMSK**: Shadow reload control, global (centralized) reload masked
This bit is set and cleared by software.
0: Global reload masked for this layer (control from LTDC_SRCR disabled)
1: Global reload active for this layer (control from LTDC_SRCR enabled)

Bit 1 **VBR**: Vertical blanking reload request
This bit is set by software and cleared only by hardware after reload (it cannot be cleared through register write once it is set).
0: No effect
1: Shadow registers are reloaded during the vertical blanking period (at the beginning of the first line after the active display area).

Bit 0 **IMR**: Immediate reload trigger
This bit is set by software and cleared only by hardware after reload.
0: No effect
1: Shadow registers are reloaded immediately.

53.8.34 LTDC layer x control register (LTDC_LxCR)

Address offset: 0x10C + 0x100 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					rw	rw	rw				rw			rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **SCEN**: Scaler enable
This bit is set and cleared by software.
0: Scaler disabled
1: Scaler enabled

Bit 9 **DCBEN**: Default color blending enable
This bit is set and cleared by software.
0: Blending disabled
1: Blending enabled

Bit 8 **HMEN**: Horizontal mirroring enable
This bit is set and cleared by software.
0: Mirror disabled
1: Mirror enabled (if so, the color frame buffer start address has to be set to the last byte of the first line, so for instance: if line is 100 pixels, 24 bpp, then address is set to 299)

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **CLUTEN**: Color look-up table enable
This bit is set and cleared by software.
0: Color look-up table disabled
1: Color look-up table enabled
The CLUT is only meaningful for L8, AL44 and AL88 pixel format.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **CKEN**: Color keying enable
This bit is set and cleared by software.
0: Color keying disabled
1: Color keying enabled: if RGB matches, then the ARGB are set to 0.

Bit 0 **LEN**: Layer enable
This bit is used to enable/disable the presence of this whole layer. it is set and cleared by software.
0: Layer disabled
1: Layer enabled

53.8.35 LTDC layer x window horizontal position configuration register (LTDC_LxWHPCR)

Address offset: 0x110 + 0x100 * (x -1), (x = 1 to 3)

Reset value: 0x0000 0000

This register defines the horizontal position (first and last pixel) of the window of layer 1/3.

The first visible pixel of a line is the programmed value of AHBP[11:0] + 1 in LTDC_BPCR.

The last visible pixel of a line is the programmed value of AAW[11:0] in LTDC_AWCR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	WHSTPOS[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **WHSPPOS[11:0]**: Window horizontal stop position
This bitfield configures the last visible pixel of a line of the layer window.
WHSPPOS[11:0] must be ≥ AHBP[11:0] bits + 1 (programmed in LTDC_BPCR).

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **WHSTPOS[11:0]**: Window horizontal start position
This bitfield configures the first visible pixel of a line of the layer window.
WHSTPOS[11:0] must be ≤ AAW[11:0] bits (programmed in LTDC_AWCR).

53.8.36 LTDC layer x window vertical position configuration register (LTDC_LxWVPCR)

Address offset: 0x114 + 0x100 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

This register defines the vertical position (first and last line) of the layer 1 or 2 window.

The first visible line of a frame is the programmed value of AVBP[11:0] + 1 in LTDC_BPCR.

The last visible line of a frame is the programmed value of AAH[11:0] in LTDC_AWCR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **WVSPPOS[11:0]**: Window vertical stop position
This bitfield configures the last visible line of the layer window.
WVSPPOS[11:0] must be ≥ AVBP[11:0] + 1 (programmed in LTDC_BPCR).

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **WVSTPOS[11:0]**: Window vertical start position
This bitfield configures the first visible line of the layer window.
WVSTPOS[11:0] must be ≤ AAH[11:0] (programmed in LTDC_AWCR).

53.8.37 LTDC layer x color keying configuration register (LTDC_LxCKCR)

Address offset: 0x118 + 0x100 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

This register defines the color key value (RGB), that is used by the color keying.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **CKRED[7:0]**: Color key red value

Bits 15:8 **CKGREEN[7:0]**: Color key green value

Bits 7:0 **CKBLUE[7:0]**: Color key blue value

53.8.38 LTDC layer x pixel format configuration register (LTDC_LxPFCR)

Address offset: 0x11C + 0x100 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

This register defines the pixel format that is used for the stored data in the frame buffer of a layer. The pixel data is read from the frame buffer and then transformed to the internal format 8888 (ARGB). When components are provided with less than 8 bits per component, they get expanded to 8 bits by replication of their MSB onto their LSB.

When the Alpha value is not defined in the input pixel format, Alpha is assumed for farther needs to be equal to 255 (opaque layer).

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PF[2:0]		
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **PF[2:0]**: Pixel format

This bitfield configures the pixel format.
000: ARGB8888 (32 bpp)
001: ABGR8888 (32 bpp)
010: RGBA8888 (32 bpp)
011: BGRA8888 (32 bpp)
100: RGB565 (16 bpp, A = 255)
101: BGR565 (16 bpp, A = 255)
110: RGB888 (24 bpp packed, A = 255)
111: Flexible pixel format selected (see *Section 53.8.60* and *Section 53.8.61*)

53.8.39 LTDC layer x constant alpha configuration register (LTDC_LxCACR)

Address offset: 0x120 + 0x100 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 00FF

This register defines the constant alpha value (divided by 255 by hardware), that is used in the alpha blending (see LTDC_LxBFCR).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CONSTA[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **CONSTA[7:0]**: Constant alpha

This bitfield configures the constant alpha used for blending. The constant alpha is divided by 255 by hardware.

Example: if the programmed constant alpha is 0xFF, the floating alpha value is 255 / 255 = 1.

53.8.40 LTDC layer x default color configuration register (LTDC_LxDCCR)

Address offset: 0x124 + 0x100 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

This register defines the default color of a layer in the format ARGB. The default color is used outside the defined layer window or when a layer is disabled. The reset value of 0x00000000 defines a transparent black color.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DCALPHA[7:0]								DCRED[7:0]

DCGREEN[7:0]								DCBLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **DCALPHA[7:0]**: Default color alpha

This bitfield configures the default alpha value.

Bits 23:16 **DCRED[7:0]**: Default color red

This bitfield configures the default red value.

Bits 15:8 **DCGREEN[7:0]**: Default color green

This bitfield configures the default green value.

Bits 7:0 **DCBLUE[7:0]**: Default color blue

This bitfield configures the default blue value.

53.8.41 LTDC layer x blending factors configuration register (LTDC_LxBFCR)

Address offset: 0x128 + 0x100 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0607, 0x0001 0607, 0x0002 0607

This register defines the blending order, and the factors BF1 and BF2. The constant alpha value is the programmed value in LTDC_LxCACR, divided by 255 by hardware.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BOR[2:0]

Res.	Res.	Res.	Res.	Res.	BF1[2:0]			Res.	Res.	Res.	Res.	Res.	BF2[2:0]		
					rw	rw	rw						rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **BOR[2:0]**: Blending order
This bitfield selects the blending order, BOR:
000: For the most background layer (usually hidden behind others)
111: For the most foreground layer (always visible, never hidden by any other)
The BOR value is limited to the max amount of layers, minus 1. For instance, if the LTDC supports three layers (layer 1/2/3), then the BOR can be configured with only the following values: 000, 001, 010.
In case of inconsistency, like two layers sharing same BOR, the blending engine reverses to BOR[layerID] = layerID - 1, so that layer 3 gets in foreground and layer 1 is in background.
Usually, the default configuration is the following one:
BOR(layer 1) = 000
BOR(layer 2) = 001
BOR(layer 3) = 010

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **BF1[2:0]**: Default factor 1
This bitfield selects the blending factor F1.
100: Constant alpha
110: Pixel alpha x constant alpha
Others: Reserved

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **BF2[2:0]**: Blending factor 2
This bitfield selects the blending factor F2.
101: 1 - constant alpha
111: 1 - (pixel alpha x constant alpha)
Others: Reserved

53.8.42 LTDC layer x burst length configuration register (LTDC_LxBLCR)

Address offset: 0x12C + 0x100 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

This register defines the length of the bursts requested by layer x.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BL[4:0]				
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **BL[4:0]**: Burst length
0x00: maximum burst length (16 words 64 bits, thus 128 Bytes)
0x01: 1 word (of 64 bits) per burst
0x10: 16 words (of 64 bits) per burst
Others: Reserved

53.8.43 LTDC layer x planar configuration register (LTDC_LxPCR)

Address offset: 0x130 + 0x100 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines, for layer x, the configuration when accessing planar or semi-planar buffers.

Res.	Res.	Res.	Res.	Res.	Res.	YREN	OF	CBF	YF	YCM[1:0]		YCEN	Res.	Res.	Res.
						rw	rw	rw	rw	rw	rw	rw			

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **YREN**: Y rescale enable for the color dynamic range
When enabled, incoming Y values in range 16 to 235, are re-scaled to range 0 to 255.
0: Rescaling disabled (input component thus assumed provided in 0 to 255)
1: Rescaling enabled (input component thus assumed provided in 16 to 235).

Bit 8 **OF**: Odd pixel first
This bit defines if the byte 0 of a word (in LSB) contains the odd pixel.
0: Odd pixel disabled (thus even pixel on byte 0)
1: Odd pixel enabled (thus odd pixel on byte 0)

Bit 7 **CBF**: Cb component first
This bit defines if the byte 0 and 1 of a word (in LSB) contains the Cb component. The setting impacts only for interleaved and semi-planar modes, as it has no meaning in full-planar mode.
0: Cb disabled (thus Cr component is on byte 0 and 1)
1: Cb enabled (thus Cb component is on byte 0 and 1)

Bit 6 **YF**: Y component first
This bit defines if the byte 0 of a word (in LSB) contains the Y component.
0: Y component disabled (thus Cr or Cb component is on byte 0)
1: Y component enabled (thus Y component is on byte 0)

Bits 5:4 **YCM[1:0]**: YCbCr conversion mode
This bitfield defines the type of input that is considered and converted to a YCbCr 444.
00: Interleaved 422 (Cb and Cr component are replicated horizontally for pixels P and P+1)
01: Semi-Planar 420: (Cb and Cr component are replicated horizontally and vertically.The layer main configuration defines the access to the Y buffer, and auxiliary registers define the access to the Cb and Cr buffers).
10: Full-Planar 420: (Cb and Cr component are replicated horizontally and vertically. The layer main configuration defines the access to the Y buffer, and auxiliary registers define the access to the Cb and Cr buffers).
11: Reserved

Bit 3 **YCEN**: YCbCr-to-RGB conversion enable
0: Conversion disabled
1: YCbCr conversion enabled, using the YCM setting above

Bits 2:0 Reserved, must be kept at reset value.

53.8.44 LTDC layer x color frame buffer address register (LTDC_LxCFBAR)

Address offset: 0x134 + 0x100 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

This register defines the color frame buffer start address, which has to point to the address where the pixel data of the top-left pixel of a layer is stored in the frame buffer.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CFBADD[31:0]**: Color frame buffer start address

This bitfield defines the color frame buffer start address.

53.8.45 LTDC layer x color frame buffer length register (LTDC_LxCFBLR)

Address offset: 0x138 + 0x100 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

This register defines the color frame buffer line length and pitch.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	CFBP[14:0]

Res.	Res.	CFBLL[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value. Upon reading, this bit returns the value of the bit 30.

Bits 30:16 **CFBP[14:0]**: Color frame buffer pitch in bytes

This bitfield defines the pitch that is the increment from the start of one line of pixels to the start of the next line in bytes.

Negative values (with MSB bit = 1) are allowed, to read the buffer from bottom to top, and thus to flip is vertically. When vertically flipped, as the address register must provide the address of the first line to be read, the address register must point to the start of the bottom line of the buffer.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **CFBLL[13:0]**: Color frame buffer line length

This bitfield defines the length of one line of pixels in bytes + 7.

The line length is computed as follows: active high width * number of bytes per pixel + 7.

53.8.46 LTDC layer x color frame buffer line number register (LTDC_LxCFBLNR)

Address offset: 0x13C + 0x100 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

This register defines the number of lines in the color frame buffer. The number of lines and line-length settings define how much data are fetched per frame for every layer. If it is configured to less bytes than required, a FIFO underrun interrupt is generated if enabled. The start address and pitch settings define the correct start of every line in memory.

				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **CFBLNBR[11:0]**: Frame buffer line number

This bitfield defines the number of lines in the frame buffer that corresponds to the active high width.

53.8.47 LTDC layer x auxiliary frame buffer address 0 register (LTDC_LxAFBA0R)

Address offset: 0x140 + 0x100 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the start address for the auxiliary 0 frame buffer. It has to point to the address where the pixel data of the top left pixel of a layer is stored in the frame buffer. The auxiliary 0 and 1 frame buffers are for YCbCr semi-planar or full-planar pixel formats: the color frame buffer is used to store the Y components, while the auxiliary buffers 0 and 1 are used to store the other one (for semi-planar) or two (for full-planar) planes of components.

Bits 31:0 **AFBADD0[31:0]**: Frame buffer start address

53.8.48 LTDC layer x auxiliary frame buffer address 1 register (LTDC_LxAFBA1R)

Address offset: 0x144 + 0x100 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the start address for the auxiliary 0 frame buffer. It has to point to the address where the pixel data of the top left pixel of a layer is stored in the frame buffer (the auxiliary 0 and 1 frame buffers are for YCbCr semi-planar or full-planar pixel formats).

		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value. Upon reading, this bit returns the value of the bit 30.

Bits 30:16 **AFBP[14:0]**: Auxiliary frame buffer pitch in bytes

This bitfield defines the pitch that is the increment from the start of one line of pixels to the start of the next line in bytes.
Negative values (with MSB bit = 1) are allowed, to read the buffer from bottom to top, and thus to flip is vertically. When vertically flipped, as the address register must provide the address of the first line to be read, the address register must point to the start of the bottom line of the buffer.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **AFBLL[13:0]**: Auxiliary frame buffer line length

This bitfield defines the length of one line of pixels in bytes + 7.
The line length is computed as follows: active high width * number of bytes per pixel + 7.

53.8.50 LTDC layer x auxiliary frame buffer line number register (LTDC_LxAFBLNR)

Address offset: 0x14C + 0x100 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the number of lines in the auxiliary 0 and 1 frame buffers (the auxiliary 0 and 1 frame buffers are for YCbCr semi-planar or full-planar pixel formats). The number of lines and line length settings define how much data is fetched per frame for every layer. If it is configured to less bytes than required, a FIFO underrun interrupt is generated if enabled. The start address and pitch settings define the correct start of every line in memory.

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **AFBLNBR[11:0]**: Auxiliary frame buffer line number
This bitfield defines the number of lines in the frame buffer that corresponds to the active high width.

53.8.51 LTDC layer x CLUT write register (LTDC_LxCLUTWR)

Address offset: 0x150 + 0x100 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

This register defines the CLUT address and the RGB value. The CLUT write register must only be configured during blanking period or if the layer is disabled. The CLUT can be enabled or disabled in LTDC_LxCR. The CLUT is only meaningful for L8, AL44, and AL88 pixel format.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:24 **CLUTADD[7:0]**: CLUT address
This bitfield configures the CLUT address (color position within the CLUT) of each RGB value.

Bits 23:16 **RED[7:0]**: Red value
This bitfield configures the red value.

Bits 15:8 **GREEN[7:0]**: Green value
This bitfield configures the green value.

Bits 7:0 **BLUE[7:0]**: Blue value
This bitfield configures the blue value.

53.8.52 LTDC layer x scaler input size register (LTDC_LxSISR)

Address offset: 0x154 + 0x100 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the scaler input size (width and height).

Refer to *Section 2.4* for the register boundary addresses.

54 LVDS display interface transmitter (LVDS)

54.1 Introduction

The LVDS display interface transmitter (LVDS) handles the LVDS protocol: it maps the pixels received from the upstream Pixel-DMA (LTDC) onto the LVDS PHY (LVDS PHY).

It is regroups three sub blocks:

- LVDS host: handles the LVDS protocol (FPD / OpenLDI)
  (maps its input pixels onto the data lanes of the PHY)
- LVDS PHY: parallelize the data and drives the LVDS data lanes
- LVDS wrapper: handles top-level settings

54.2 LVDS main features

The LVDS host supports the following high-level features:

- FPD-Link-I and OpenLDI (v0.95) protocols
- Single-Link or Dual-Link operation
- Single-Display or Double-Display (with the same content duplicated on both)
- Flexible Bit-Mapping, including JEIDA and VESA
- RGB888 or RGB666 output
- Synchronous design, with one input pixel per clock cycle
- No resolution limitation.

The LVDS PHY supports the following high-level features:

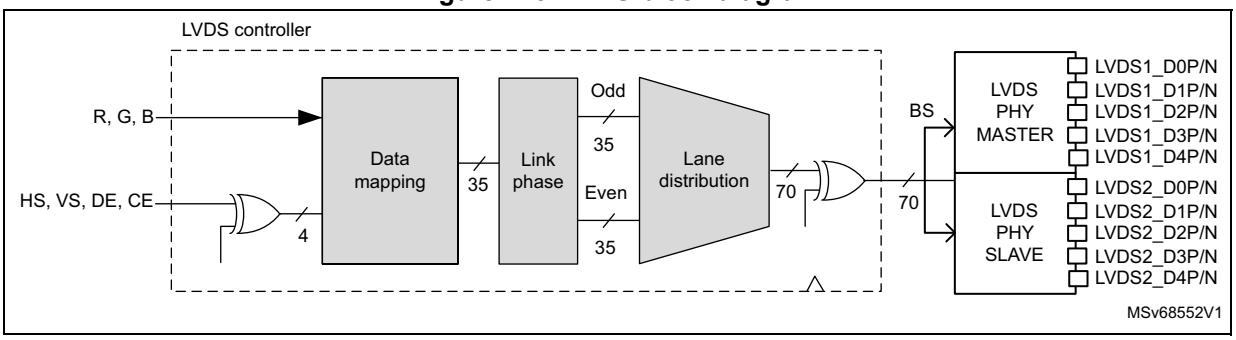
- FPD bitrate: 784 Mbps/lane (112 Mpixel/s/Link, 224 Mpixel/s if Dual Link)
- OpenLDI bitrate: 1100 Mbps/lane (157 Mpixel/s/Link, 314 Mpixel/s if Dual Link)

54.3 LVDS implementation

The LVDS host implementation is based on five sequential operators:

- Input polarity: to update the polarity of the input VS, HS, DE
  - Used to adapt to any polarity of the upstream LTDC.
- Data mapping: to map the input pixel onto the intermediate frame-word
  - Used to map JEIDA, VESA, or any other standards.
- Dual-Link Phase: to select between an even or odd phase
  - Used to adapt the inter-link phase to panel reqs, when a Dual-Link is used.
- Channel distribution: to adapt to RGB666 (3+1DataLanes) or RGB888 (4+1DL)
  - it adapts to the various panel expected input.
- Lane polarity: to update the differential polarity of the differential-lanes.
  - Used to adapt to PCB lane constraints by swapping the D+ vs D- lanes.

The LVDS is fully synchronous, which mandates a same pixel clock for the upstream LTDC and downstream LVDS PHY.



The LVDS PHY implementation is based on a duplicated PHY and an integrated PLL.

54.4 LVDS functional description

54.4.1 LVDS host block diagram

The following block diagram shows the five consecutive operating blocks of the LVDS: the input polarity, the data mapping, the link phase, the channel distribution, the lane polarity.

Figure 475. LVDS block diagram

54.4.2 LVDS pins and internal signals

The LVDS implements the following three interfaces:

- Pixel Input: RGB888 and its synchronization: VS, HS, DE
- Output data lanes: two links, with each five lanes (four data lanes + one clock lane)
- APB configuration interface

54.4.3 LVDS reset and clocks

The LVDS uses the following signals:

- clk_pix: pixel clock (and reset) for its datapath, from pixel input to the lane output
- pclk: APB clock (and reset) for its configuration interface

54.4.4 LVDS host input polarity functional block

The input polarity is used to update the polarity of the following signals, to suit the flat panel requirements:

- vertical sync pulse (VS)
- horizontal sync pulse (HS)
- data enable (DE)

Software configuration

If the input polarity (sent by the LTDC) and the output polarity (expected by the display panel) are different for the synchronization signals (VS, HS, CE), the LVDS can invert each polarity:

- vertical sync (VS) inversion: set bit LVDS_CR.VSPOL = 1
- horizontal sync (HS) inversion: set bit LVDS_CR.HSPOL = 1
- data enable (DE) inversion: set bit LVDS_CR.DEPOL = 1

The register is described in detail in *Section 54.5.1: LVDS configuration register (LVDS_CR)*.

Configuration example

The polarity of the LTDC is usually active high, and the polarity of the Display panel also active high. It means that no polarity would need to be inverted, which results in the following configuration for the input polarity functional block:

- LVDS_CR.VSPOL = 0
- LVDS_CR.HSPOL = 0
- LVDS_CR.DEPOL = 0

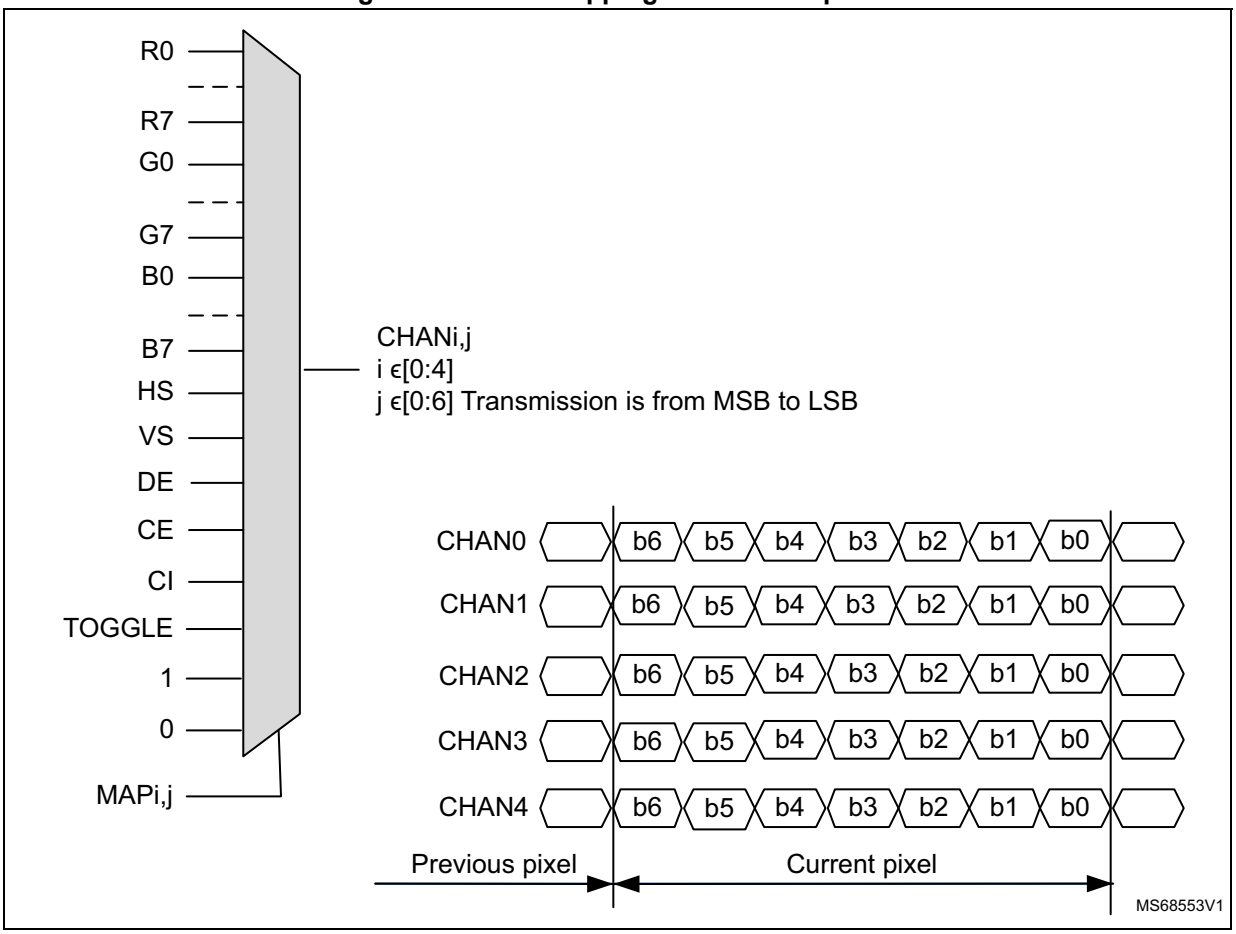
54.4.5 LVDS host data mapping functional block

The data mapping maps the input pixel bits onto an intermediate frame-word.

Standardization bodies and panel manufacturers have opted different data mapping when moving from 6-bit to 8-bit and later to 10-bit color depths. In order to maintain a maximum interoperability, the LVDS controller features a complete flexibility of how parallel input signals are mapped in the Data Lanes of the LVDS links.

Any of the input bits (RGB components, synchronization signals, ancillary data) can be mapped onto any of the 35 output bits (the 7 bits of an LVDS Frame, for each of the 5 potential data lanes).

Note: A Mux bank consisting of thirty-five 32-to-1 muxes is used for that purpose.



The LVDS can drive two links: the two links get the same data mapping configuration.

The output data lanes of the data mapping are named channels: the downstream lane distribution maps these channels onto the true output data lanes.

The input bits available for mapping are the following as shown in *Figure 476*:

- RGB888: R[7...0], G[7...0], B[7...0]
- Synchronization: VS, HS, DE
- Hardware bit: CE, forced to 0 in this device
- Software bit: CI, software defined bit, configured as a register bit
- Constants: 0 or 1, for programming the link clock as 1100011, or test patterns
- Pattern: TOGGLE, to extend the test pattern to 14 bits

Figure 476. Data mapping and its multiplexer

Software configuration

The content of each output bit (named j=b6 to b0) of each channel (named CHAN0 to CHAN4), similarly for the two Links (Link-1 and Link-2) can be configured using the MAP field, that selects between the input bits available (R0...R7, G0...G7, B0...B7, HS, VS, DE, CE, CI, TOGGLE, 1, 0).

- The MAP field and the exact correspondence with the input bits is detailed in LVDS_DMLCR0.
- The Link-1 and Link-2 use the same bit configuration and are thus not differentiated in the register configuration.
- The MAP description for each of the five channels are listed in five pair of registers, with the register suffix CR0 to CR4 for channels 0 to 4.
- The seven MAP fields (named MAP6 to MAP0) configure the output bits b6...b0. They are split among the two registers, LVDS_DMMCR0 and LVDS_DMLCR0.
  - By convention, the bit 6 is output first and bit 0 output last, for each pixel.

Configuration example

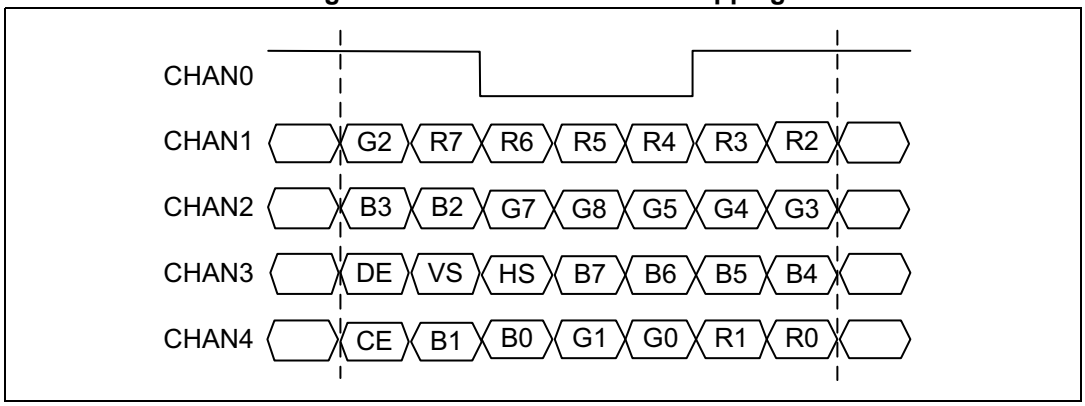
The LVDS Display Panels use typically only two types of bit-mapping, defined in the VESA and JEIDA sub-standards:

- The transmission of RGB666 requires three data lanes (+1 clock lane) while the transmission of RGB888 requires four data lanes (+1 clock lane).
- VESA groups on its three first lanes the LSB of the RGB components, which results in a different pattern for RGB666 and for RGB888.
- JEIDA groups on its three first lanes the MSB of the RGB components, which results in a same pattern for RGB666 and for RGB888:
  - the 6 MSB bits are transmitted onto a common three data lanes (+1 clock lane), which maps RGB666.
  - the additional bits for RGB888 are mapped into the additional 4th data lane.

The two following figures illustrates the above description, with the here-named bit R7,G7,B7 are the component MSB, while the R0,G0,B0 are the LSB.

Note that some panel specifications mention the MSB as R5,G5,B5, while the two LSB are called R7 and R6 (same for G and B), which can create some confusion.

Figure 477. LVDS JEIDA Data mapping



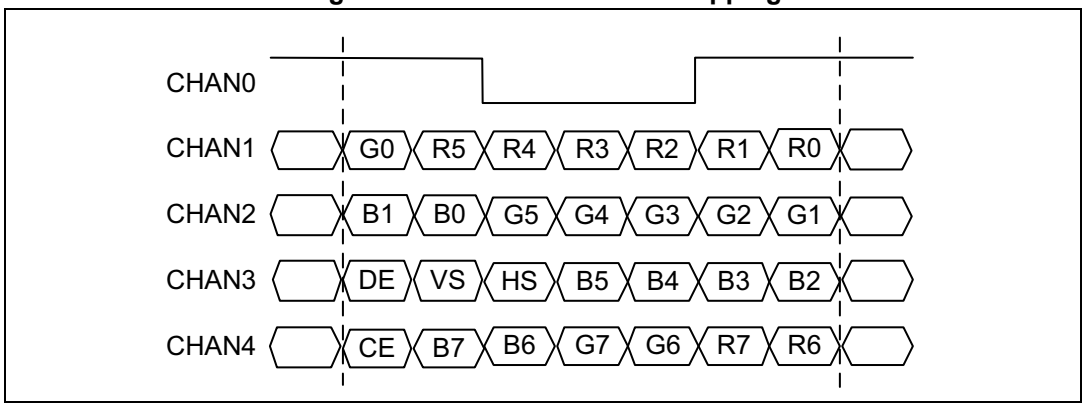


Figure 478. LVDS VESA data mapping

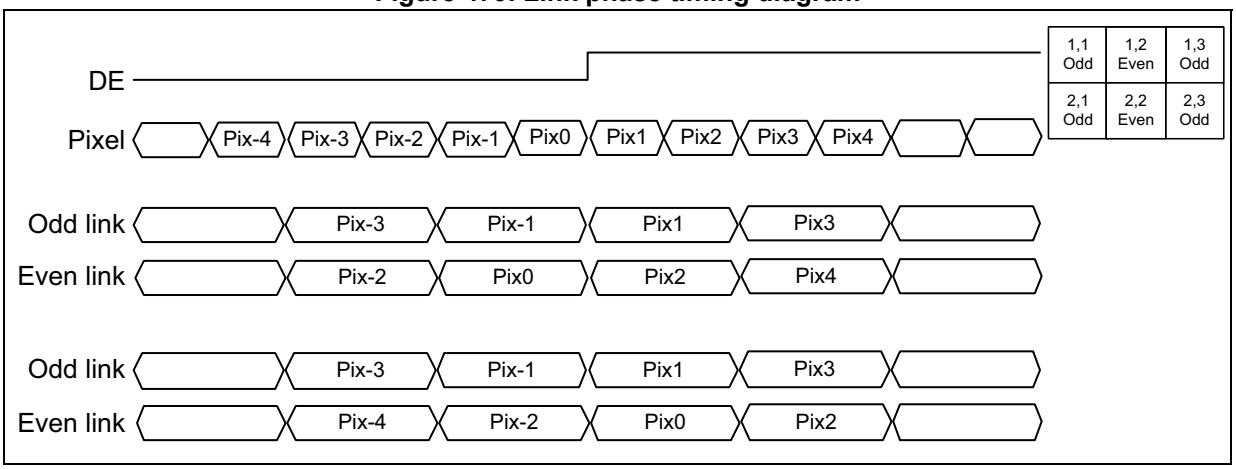
The configuration for the VESA-RGB666, VESA-RGB888, and JEIDA-RGB666/RGB888 is listed in the below table:

Table 503. LVDS Data mapping for VESA and JEIDA

Register	VESA-RGB666	VESA-RGB888	JEIDA-RGB666	JEIDA-RGB888
LVDS_DMLCR0	0x000FFFDE	0x000FFFDE	0x000FFFDE	0x000FFFDE
LVDS_DMMCR0	0x00007BDF	0x00007BDF	0x00007BDF	0x00007BDF
LVDS_DMLCR1	0x00029062	0x00018820	0x00029062	0x00029062
LVDS_DMMCR1	0x000028E6	0x000020A4	0x000028E6	0x000028E6
LVDS_DMLCR2	0x0007358B	0x00062D49	0x0007358B	0x0007358B
LVDS_DMMCR2	0x00004E4F	0x0000460D	0x00004E4F	0x00004E4F
LVDS_DMLCR3	0x000BDAB4	0x000AD272	0x000BDAB4	0x000BDAB4
LVDS_DMMCR3	0x00006B38	0x00006B38	0x00006B38	0x00006B38
LVDS_DMLCR4	0x000FFFFF	0x0007B8E6	0x000FFFFF	0x0004A020
LVDS_DMMCR4	0x00007FFF	0x00007EF6	0x00007FFF	0x00007E30

54.4.6 LVDS host link phase functional block



When the LVDS is configured in single-Link, the input pixels are transfered to the output links with the same rate and phase: one input pixels maps to one output pixel.

When the LVDS is configured to drive a dual-Link, the input pixel flow is split between two output Links, based on even and odd pixels, and creating an even and an odd link:

- The output pixel rate (per link) is half of the input pixel rate.
- The phase between the two links must be defined, which is the role of this functional block.

The first active pixel of each line, Pixel-1, is defined as odd. The next pixel, Pixel-2, is consequently defined as even. The link phase defines whether an odd pixel is carried over together with the next even pixel or together with the previous even pixel.

Figure 479. Link phase timing diagram

Software configuration

The dual-link phase setting is configured using LKPHA in LVDS_CR:

- 0: The first two pixels of a line are transmitted simultaneously.
- 1: The first pixel of a line is transmitted with the last of the previous line.

Note: When the LVDS works as single-link (and not dual-link), the same pixels are duplicated on both Links, so that the phase does not matter.

Configuration example

The typical configuration is to have the first two pixels transmitted simultaneously, thus with LVDS_CR.LKPHA = 0.

54.4.7 LVDS host channel distribution

The channel distribution maps the Channels created in the Data mapping onto the output data lanes.

The 12 possible input data for the multiplexer are respectively:

- the five odd channels (0-to-4) foreseen for the Odd Link in case of Dual-Links)
- the five even channels (0-to-4) (foreseen for the Even Link in case of Dual-Links)
- one bit from a 14- bit PRBS sequence
- constant 0, for non-used outputs

The five data lanes output to Link-1 are numbered as follows:

- Lane0: transmits by default the DataChannel0, for RGB888 or RGB666
- Lane1: transmits by default the DataChannel1, for RGB888 or RGB666
- Lane2: transmits by default the DataChannel2, for RGB888 or RGB666
- Lane3: transmits by default the DataChannel3, for RGB888 only
- Lane4: transmits by default the Clock

The five data lanes output to Link-2 are numbered similarly Lane0 to Lane4.

Software configuration

Three exclusive LVDS display configuration can be set here:

- single-display and single-link, which is the default configuration:
  - A single physical link is used.
  - The input flow is not split (as odd/even).
  - Channels 0...4 are assigned to Link-1 Lanes 0...4.
- single-display and dual-link, used for large displays:
  - Both physical links are used.
  - The input flow is split between the two Links, based on odd and even pixels.
  - Odd channels 4...0 are assigned to Link-1 Lanes 4...0.
  - Even channels 4...0 are assigned to Link-2 Lanes 4...0.

- double-display, used to duplicate a same content to two displays:
  - Both physical Links are used.
  - the input flow is not split (as odd/even).
  - Channels 4...0 are assigned to Link-1 Lanes 4...0.
  - Channels 4...0 (the same) are sent in parallel to Link-2 Lanes 4...0.

The configuration of the assignment of channels to lanes is done using LVDS_CDL1CR and LVDS_CDL2CR, using the following fields, with the field DISTR_i defining what gets into the Lane_i.

Configuration example

The default configuration is to assign the Clock to Lane 4, and the Data Channels to the Lanes 0 to 3:

- Single-Display and Single-Link:
  - LVDS_CR.LKMOD = 0 (Mode for a Single-Link)
  - LVDS_CDL1CR = 0x0000_4321 (Channels4...0 to Link-1: Lanes 3, 2, 1, 0, 4)
- Single-Display and Dual-Link:
  - LVDS_CR.LKMOD = 1 (Mode for a Dual-Link)
  - LVDS_CDL1CR = 0x0000_4321 (Odd Channels4...0 to Link-1: Lanes 3, 2, 1, 0, 4)
  - LVDS_CDL2CR = 0x0005_9876 (Even Channels4...0 to Link-2: Lanes 3, 2, 1, 0, 4)
- Double-Display:
  - LVDS_CDL1CR = 0x0000_4321 (Channels4...0 to Link-1: Lanes 3, 2, 1, 0, 4)
  - LVDS_CDL2CR = 0x0000_4321 (Channels4...0 to Link-2: Lanes 3, 2, 1, 0, 4)

54.4.8 LVDS host lane polarity functional block

The lane polarity allows to swap the D+ and D- lines of each differential output pair, in order to fix PCB layout issues.

Software configuration

It is configured using the LK1POL and LK2POL of the LVDS_CD.register.

Configuration example

The default configuration is to no invert the polarity of the bits, by setting a 0 in both LK1POL and LK2POL.

54.4.9 LVDS host PRBS Generator functional block

The PRBS generator is capable of four sequences common in measuring and testing equipment. The polynomials are defined in ITU-T standard O.150 as follows

- PRBS7: x 7 + x 6 + 1
- PRBS15: x15 + x14 + 1
- PRBS23: x23 + x18 + 1
- PRBS31: x31 + x28 + 1

A PRBS with a longer period generally produces a greater variety of data patterns that more thoroughly check the transmission system's performance.

Software configuration

The PRBS Polynomial is selected using LVDS_CDL2CR.PRBS. It is advised to use the most complex polynomial, PRBS31, which provides a longer random sequence.

The PRBS is transmitted outside by selecting it as a Channel, in the channel distribution operator, by selecting LVDS_CDLxCR.DISTRy = 0xA, for any Lane y of Link x.

Configuration example

LVDS_CDL2CR.PRBS = 3 for the longest sequence.

54.4.10 LVDS PHY functional block

The LVDS PHY serializes its 7-bit input words and drives them differentially out.

Software configuration

After initialization, each of the 5 DataLanes of each two link can be enabled using:

- Link 1 / Master: LVDS_PMCFGCR.MST_EN_DIG_DL[i] = 1 for DataLane 4...0
- Link 2 / Slave: LVDS_PSCFGCR.SLV_EN_DIG_DL[i] = 1 for DataLane 4...0

Configuration example

The LVDS PHY can be initialized with the following sequence, here for the Master PHY:

- Action 0: LVDS_PMXXX.YYY[4:0] = 1.

The LVDS PHY Slave is similarly configured as the LVDS PHY Master.

To slave the LVDS PHY Slave onto the LVDS PHY Master, the Slave must select the clock generated by the Master, with the following settings:

- Action 0: LVDS_PSXXX.YYY[4:0] = 1.
- Action 0: LVDS_PSXXX.YYY[4:0] = 1.

54.4.11 LVDS Wrapper functional block

The LVDS Wrapper is only used to select the LVDS PLL reference clock, between an RCC divided clock, or a clock provided directly by the local oscillator (HSE).

54.5 LVDS host registers

54.5.1 LVDS configuration register (LVDS_CR)

Address offset: 0x0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	LK2POL[4:0]					LK1POL[4:0]				
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LKPHA	LKMOD	CI	DEPOL	VSPOL	HSPOL	LVDSEN
									rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:21 **LK2POL[4:0]**: Link-2 output polarity, defined per output data/clock lane, from Lane-[4:0]
0x0: unchanged polarity
0x1: inverted polarity

Bits 20:16 **LK1POL[4:0]**: Link-1 output polarity, defined per output data/clock lane, from Lane-[4:0]
0x0: unchanged polarity
0x1: inverted polarity

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **LKPHA**: Link phase, for both links
0x0: Even pixel after odd pixel
0x1: Even pixel before odd pixel

Bit 5 **LKMOD**: Link mode, for both links, which impacts the clock used
0x0: Single-link mode (all pixels sent to both links)
0x1: Dual-link mode (pixels shared between two links: even pixels to one link, odd to the other)
The LVDS PHY generates a clock at double the pixel rate: in Single-link mode, the pixel generation is set at half the double-pixel-rate clock, while in Dual-link mode, the pixel generation is done at the double-pixel-rate, as each PHY receives half the pixel rate (see *Figure 469: Display subsystem clock diagram*).

Bit 4 **CI**: Control internal (software controlled bit, that can be inserted among output data)
0x0: a 1 and apos;b0 is inserted.
0x1: a 1 and apos;b1 is inserted.

Bit 3 **DEPOL**: Data enable polarity
0x0: unchanged polarity
0x1: inverted polarity

Bit 2 **VSPOL**: Vertical synchronization polarity
0x0: unchanged polarity
0x1: inverted polarity

Bit 1 **HSPOL**: Horizontal synchronization polarity
0x0: unchanged polarity
0x1: inverted polarity

Bit 0 **LVDSEN**: LVDS PHY enable
0x0: display inactive (no active pixel among the synchronization)
0x1: display active (active pixels among synchronization)

54.5.2 LVDS data mapping LSB configuration register 0 (LVDS_DMLCR0)

Address offset: 0x4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 Reserved, must be kept at reset value.

Bit 30 **MST_CM_USE_VM_VMID_DL3**: common mode of datalane3
When high, reference is mid voltage of the driver levels.

Bit 29 **MST_CM_USE_VDD_REF_DL3**: common mode of data lane3
When high, reference is derived from AVDD_IO voltage.

Bit 28 **MST_CM_EN_DL3**: Enable for current mode driver, data lane3

Bits 27:24 **MST_CM_AMP_CTRL_DL3[3:0]**: Amplitude control for current mode driver, data lane3

Bit 23 Reserved, must be kept at reset value.

Bit 22 **MST_CM_USE_VM_VMID_DL2**: common mode of data lane2
When high, reference is mid voltage of the driver levels.

Bit 21 **MST_CM_USE_VDD_REF_DL2**: common mode of data lane2
When high, reference is derived from AVDD_IO voltage.

Bit 20 **MST_CM_EN_DL2**: Enable for current mode driver, data lane2

Bits 19:16 **MST_CM_AMP_CTRL_DL2[3:0]**: Amplitude control for current mode driver, data lane2

Bit 15 Reserved, must be kept at reset value.

Bit 14 **MST_CM_USE_VM_VMID_DL1**: common mode of data lane1
When high, reference is mid voltage of the driver levels.

Bit 13 **MST_CM_USE_VDD_REF_DL1**: common mode of data lane1
When high, reference is derived from AVDD_IO voltage.

Bit 12 **MST_CM_EN_DL1**: Enable for current mode driver, data lane1

Bits 11:8 **MST_CM_AMP_CTRL_DL1[3:0]**: Amplitude control for current mode driver, data lane1

Bit 7 Reserved, must be kept at reset value.

Bit 6 **MST_CM_USE_VM_VMID_DL0**: common mode of data lane0
When high, reference is mid voltage of the driver levels.

Bit 5 **MST_CM_USE_VDD_REF_DL0**: common mode of datalane0
When high, reference is derived from AVDD_IO voltage.

Bit 4 **MST_CM_EN_DL0**: Enable for current mode driver, data lane0

Bits 3:0 **MST_CM_AMP_CTRL_DL0[3:0]**: Amplitude control for current mode driver, data lane0

											r				r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **MST_MON_BG_VOLT_FAULT**: Bandgap output voltage monitor fault
Indicates that a fault has occurred when high. This signal is latched in the LVDS PHY, so it is kept high until cleared by mst_mon_bg_volt_clear_fault_mst.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **MST_MON_BG_VOLT_PERMANENT_FAULT**: Bandgap output voltage monitor permanent fault
Indicates that a fault is occurring when high.
If mst_mon_bg_volt_fault_mst is high and mst_bg_volt_permanent_fault_mst is low, the fault was a glitch that has since faded.
If mst_mon_bg_volt_fault_mst is high and mst_bg_volt_permanent_fault_mst is high, the fault is still occurring.

54.6.24 LVDS PHY-Master monitor PLL LDO output voltage control register (LVDS_PMMPLOVCR)

Address offset: 0x105C

Reset value: 0x0000 0000

											rw				rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 **MST_MON_LDO_OK_UNMASK_TUNE[8:0]**: PLL LDO output voltage timing control for the monitor unmask after startup

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **MST_MON_LDO_OK_CLEAR_FAULT**: PLL LDO output voltage monitor clear fault
If set high, lvds_monitor_ldo_ok_fault_mst is cleared.
It has to be set low again in order to continue monitoring the PLL LDO output voltage

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **MST_MON_LDO_OK_FORCE_FAULT**: PLL LDO output voltage monitor force fault
If set high, force the lvds_monitor_ldo_ok_fault_mst and lvds_monitor_ldo_ok_permanent_fault_mst to indicate a fault.
This force is only removed once it goes low again

54.6.25 LVDS PHY-Master monitor PLL LDO output voltage status register (LVDS_PMMPLOVSR)

Address offset: 0x1060

Reset value: 0x0000 0000

											r				r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **SLV_MON_BG_CURR_FAULT**: Bandgap current monitor fault
Indicates that a fault has occurred when high.
This signal is latched in the LVDS PHY, so it is kept high until cleared by slv_mon_bg_curr_clear_fault_mst

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **SLV_MON_BG_CURR_PERMANENT_FAULT**: Bandgap current monitor permanent fault
Indicates that a fault is occurring when high.
If slv_mon_bg_curr_fault_mst is high and slv_bg_curr_permanent_fault_mst is low, the fault was a glitch that has since faded
If slv_mon_bg_curr_fault_mst is high and slv_bg_curr_permanent_fault_mst is high, the fault is still occurring

54.6.68 LVDS PHY-Slave monitor bandgap loop control register (LVDS_PSMBLCR)

Address offset: 0x114C

Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **SLV_MON_BG_LOOP_FAULT**: Bandgap loop monitor fault
Indicates that a fault has occurred when high.
This signal is latched in the LVDS PHY, so it is kept high until cleared by slv_mon_bg_loop_clear_fault_mst

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **SLV_MON_BG_LOOP_PERMANENT_FAULT**: Bandgap loop monitor permanent fault
Indicates that a fault is occurring when high.
If slv_mon_bg_loop_fault_mst is high and slv_bg_loop_permanent_fault_mst is low, the fault was a glitch that has since faded
If slv_mon_bg_loop_fault_mst is high and slv_bg_loop_permanent_fault_mst is high, the fault is still occurring

54.6.70 LVDS PHY-Slave monitor bandgap output voltage control register (LVDS_PSMBOVCR)

Address offset: 0x1154

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw				rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 **SLV_MON_BG_VOLT_UNMASK_TUNE[8:0]**: Bandgap output voltage timing control for the monitor unmask after startup

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **SLV_MON_BG_VOLT_CLEAR_FAULT**: Bandgap output voltage monitor clear fault
If set high, lvds_monitor_bg_volt_fault_mst is cleared.
It has to be set low again in order to continue monitoring the bandgap output voltage

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **SLV_MON_BG_VOLT_FORCE_FAULT**: Bandgap output voltage monitor force fault
If set high, force the lvds_monitor_bg_volt_fault_mst and lvds_monitor_bg_volt_permanent_fault_mst to indicate a fault.
This force is only removed once it goes low again

54.6.71 LVDS PHY-Slave monitor bandgap output voltage status register (LVDS_PSMBOVSR)

Address offset: 0x1158

Reset value: 0x0000 0000

			r				rw				rw		rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **SLV_PLL_BYPASS_START_DECT**: Bypass start DECT.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **SLV_PLL_DIVIDERS_ENABLE**: 0x0: Dividers disabled
1: Dividers enabled

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SLV_PLL_BYPASS**: 0x0: from VCO output
1: from external (lvds_pll_clk_bypass_2g2)

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SLV_PLL_TWG_ENABLE**: Triangular wave pattern used to modulate MDIV
0: Triangular wave generator powered down
1: Triangular wave generator enable (not recommended if integer N PLL mode is selected)

Bit 1 **SLV_PLL_SD_ENABLE**: sigma-delta enable
0: disable (Integer N PLL mode)
1: enable (fractional N PLL mode if SLV_PLL_twg_enable=0 , spread spectrum clocking if SLV_PLL_twg_enable=1)

Bit 0 **SLV_PLL_ENABLE**: 0x0: LVDS-PHY PLL Disable
0x1: LVDS-PHY PLL Enable

54.6.82 LVDS PHY-Slave PLL_MODE 2 control register (LVDS_PSPLLCR2)

Address offset: 0x11C4

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **PMATDL3[7:0]**: PHY-Master analog test data lane 3

Analog test mux control for mst_lvds_ana_test output, for data lane 3.
0x80: Current mode driver test current
0x40: Current mode driver test current
0x20: internal 1.2V reference
0x10: internal 0.775V reference
0x08: output of the LDO which sets VOL
0x04: output of the LDO which sets VOH
0x02: Feedback loop of the LDO which sets VOL
0x01: Output of the RX loopback
0x00: tristate

Bits 23:16 **PMATDL2[7:0]**: PHY-Master analog test data lane 2

Analog test mux control for mst_lvds_ana_test output, for data lane 2:
0x80: Current mode driver test current
0x40: Current mode driver test current
0x20: internal 1.2V reference
0x10: internal 0.775V reference
0x08: output of the LDO which sets VOL
0x04: output of the LDO which sets VOH
0x02: Feedback loop of the LDO which sets VOL
0x01: Output of the RX loopback
0x00: tristate

Bits 15:8 **PMATDL1[7:0]**: PHY-Master analog test data lane 1

Analog test mux control for mst_lvds_ana_test output, for data lane 1.
0x80: Current mode driver test current
0x40: Current mode driver test current
0x20: internal 1.2V reference
0x10: internal 0.775V reference
0x08: output of the LDO which sets VOL
0x04: output of the LDO which sets VOH
0x02: Feedback loop of the LDO which sets VOL
0x01: Output of the RX loopback
0x00: tristate

Bits 7:0 **PMATDL0[7:0]**: PHY-Master analog test data lane 0

Analog test mux control for mst_lvds_ana_test output, for data lane 0.
0x80: Current mode driver test current
0x40: Current mode driver test current
0x20: internal 1.2V reference
0x10: internal 0.775V reference
0x08: output of the LDO which sets VOL
0x04: output of the LDO which sets VOH
0x02: Feedback loop of the LDO which sets VOL
0x01: Output of the RX loopback
0x00: tristate

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **PMATPC[6:0]**: Phy-Master analog test PLL control

PLL master analog test miux control for mst_lvds_ana_test output.
0x40: vcp_sup (internal 1.4 V VCO LDO output)
0x20: vctrl (VCO control voltage number 1, expected value is 1.4 V-0.7 V)
0x10: vcap (VCO control voltage number 2, expected value is 1.4 V-0.7 V)
0x08: icp_test (Charge pump current replica, expected value is 5uA)
0x04: pll_lock (PLL lock indication, sets to DVDD_CORE when the PLL is powered up, 0 V otherwise)
0x02: ref_ok (PLL reference presence indication, sets to DVDD_CORE when the PLL is powered up and the reference, 0 V otherwise)
0x01: AVSS_IO
0x00: tristate

Bits 15:8 **PMATB[7:0]**: Phy-Master analog test bias

Bias analog test mux control for mst_lvds_ana_test output.
0x80: Local ground (0 V)
0x40: Local ground (0 V)
0x20: internal reference for the current generator block, 0.5 V
0x10: Local ground (0 V)
0x08: Bandgap diode (0.7 V)
0x04: 12.5 µA reference current, measured referred to ground
0x02: internal reference for the current generator block, 0.5 V
0x01: internal filtered AVDD_CORE
0x00: tristate

Bits 7:0 **PMATDL4[7:0]**: PHY-Master analog test data lane 4
Analog test mux control for mst_lvds_ana_test output, for data lane 4.
0x80: Current mode driver test current
0x40: Current mode driver test current
0x20: internal 1.2 V reference
0x10: internal 0.775 V reference
0x08: output of the LDO which sets VOL
0x04: output of the LDO which sets VOH
0x02: Feedback loop of the LDO which sets VOL
0x01: Output of the RX loopback
0x00: tristate

										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **PSDTPS**: Phy-Slave digital test PLL status

Bit 4 **PSDTDLS4**: Phy-Slave digital test data lane status 4

Bit 3 **PSDTDLS3**: Phy-Slave digital test data lane status 3

Bit 2 **PSDTDLS2**: Phy-Slave digital test data lane status 2

Bit 1 **PSDTDLS1**: Phy-Slave digital test data lane status 1

Bit 0 **PSDTDLS0**: Phy-Slave digital test data lane status 0

54.6.102 LVDS hardware configuration register (LVDS_HWCFGR)

Address offset: 0x1FF0

Reset value: 0x0000 0251

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	LINKS[3:0]				LANES[3:0]				TECHNO[3:0]			
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:8 **LINKS[3:0]**: amount of LVDS PHY links
0x0: information not defined
0x1: One LVDS LInk
0x2: Two LVDS links (used as either dual link or two independent links)

Bits 7:4 **LANES[3:0]**: amount of LVDS PHY Lanes (including the LVDS PHY clock lane) in one link
0x0: information not defined
0x4: 3 DataLanes + 1 ClockLane, which suits for RGB666
0x5: 4 DataLanes + 1 ClockLane, which suits for RGB888 (or backward RGB666)

Bits 3:0 **TECHNO[3:0]**: PHY technology (and version)
0x0: information not defined
0x1: 16FF (Cadence OpenLDI PHY spec v1.2)

54.6.103 LVDS version register (LVDS_VERR)

Address offset: 0x1FF4

Reset value: 0x0000 0020

55 DSI Host (DSI)

55.1 Introduction

Portions Copyright (c) Synopsys, Inc. All rights reserved. Used with permission.

The display serial interface (DSI) is part of a group of communication protocols defined by the MIPI® Alliance.

The MIPI® DSI Host controller is a digital core that implements all protocol functions defined in the MIPI® DSI specification. It provides an interface between the system and the MIPI® D-PHY, allowing the user to communicate with a DSI-compliant display.

55.2 Standard and references

  v1.1 - 7 November 2011

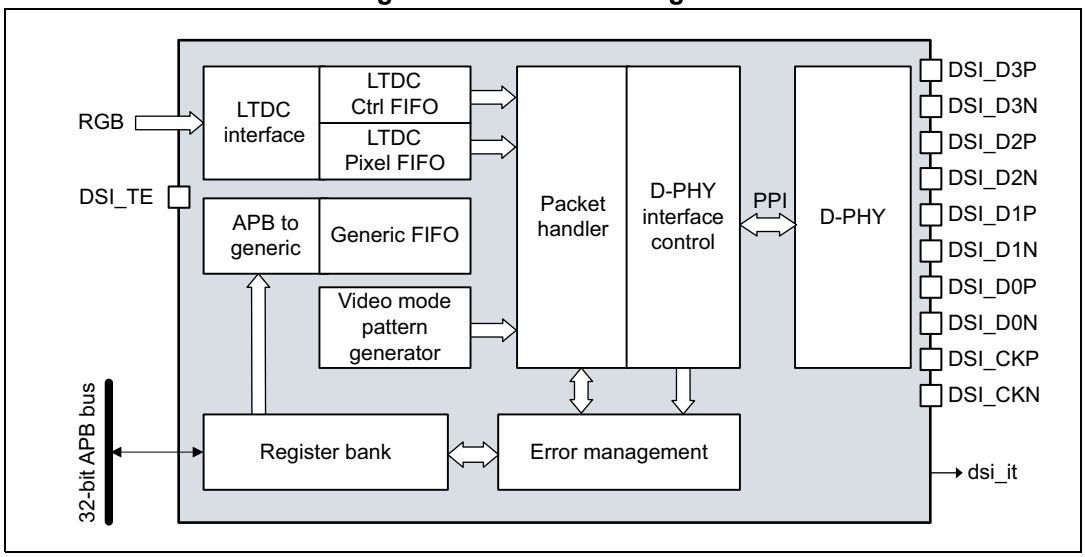
55.3 DSI Host main features

- Compliant with MIPI® Alliance standards (see *Section 55.2: Standard and references*)
- Interface with MIPI® D-PHY
- Supports all commands defined in the MIPI® Alliance specification for DCS:
  - Transmission of all command mode packets through the APB interface
  - Transmission of commands in low-power and high-speed during video mode
- Supports up to four D-PHY data lanes
- Bidirectional communication and escape mode support through data lane 0
- Supports non-continuous clock in D-PHY clock lane for additional power saving
- Supports ultra low-power mode with PLL disabled
- ECC and checksum capabilities
- Support for end of transmission packet (EoTp)
- Fault recovery schemes
- 3D transmission support

- Configurable selection of system interfaces:
  - AMBA APB for control and optional support for generic and DCS commands
  - Video mode interface through LTDC
  - Adapted command mode interface through LTDC
  - Independently programmable virtual channel ID in video mode, adapted command mode, and APB slave
- Video mode interfaces:
  - LTDC interface color coding mappings into 24-bit interface:
    - 16-bit RGB, configurations 1, 2, and 3
    - 18-bit RGB, configurations 1 and 2
    - 24-bit RGB
  - Programmable polarity of all LTDC interface signals
  - Extended resolutions beyond the DPI standard maximum resolution of 800x480 pixels:
  - Maximum resolution is limited by available DSI physical link bandwidth:
    - Number of lanes: 4
    - Maximum speed per lane: 2.5 Gbit/s
    - See examples in *Section 55.4.3: Supported resolutions and frame rates*
- Adapted interface features:
  - Support for sending large amounts of data through the *memory_write_start* (WMS) and *memory_write_continue* (WMC) DCS commands
  - LTDC interface color coding mappings into 24-bit interface:
    - 16-bit RGB, configurations 1, 2, and 3
    - 18-bit RGB, configurations 1 and 2
    - 24-bit RGB
- Video mode pattern generator:
  - Vertical and horizontal color bar generation without LTDC stimuli
  - BER pattern without LTDC stimuli

55.4 DSI Host functional description

55.4.1 General description



The MIPI® DSI Host includes dedicated video interfaces internally connected to the LTDC and a generic APB interface that can be used to transmit information to the display. More in detail:

- LTDC interface:
  - Used to transmit information in video mode, in which the transfers from the host processor to the peripheral take the form of a real-time pixel stream (DPI).
  - Through a customized mode, this interface can be used to transmit information in full bandwidth in the adapted command mode (DBI).
- APB slave interface: allows the transmission of generic information in command mode, and follows a proprietary register interface. This interface can operate concurrently with either LTDC interface, in video mode or adapted command mode.

- Video mode pattern generator: allows the transmission of horizontal/vertical color bar and D-PHY BER testing pattern without any kind of stimuli.

The block diagram is shown in *Figure 480*.

Figure 480. DSI block diagram

55.4.2 DSI pins and internal signals

Table 505 and *Table 506* list, respectively, the DSI pins (alternate functions) and the internal input/output signals.

Table 505. DSI pins

Signal name	Signal type	Description
DSI_D0P/D0N	Input/Output	Differential Data lane 0
DSI_D1P/D1N	Output	Differential Data lane 1
DSI_D2P/D2N	Output	Differential Data lane 2
DSI_D3P/D3N	Output	Differential Data lane 3
DSI_CKP/CKN	Output	Differential clock
DSI_TE	Input	DSI tearing effect pin

Table 506. DSI internal input/output signals

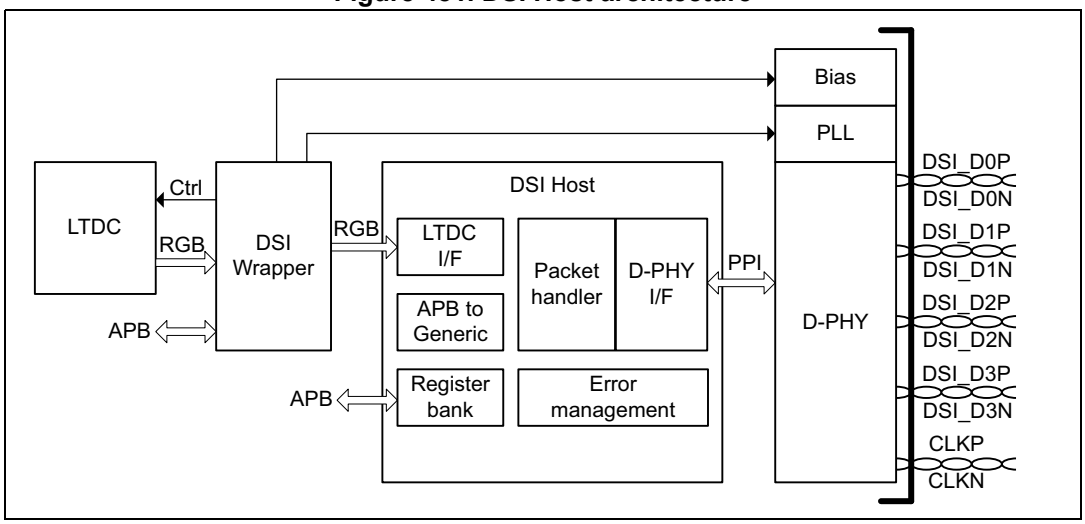
Signal name	Signal type	Description
dsi_it	Output	DSI global interrupt
dsi_wkup		DSI wake-up event
dsi_te_trg		DSI tearing effect for MDMA
dsi_eor_trg		DSI end-of-refresh for MDMA

Table 506. DSI internal input/output signals (continued)

Signal name	Signal type	Description
blclk_ck	Input	Byte lane clock
rxclkesc_ck		Escape clock
hse_ck		HSE clock used for DSI PLL
dsi_phy_ck		APB clock

55.4.3 Supported resolutions and frame rates

The DSI specification does not define supported standard resolutions or frame rates. Display resolution, blanking periods, synchronization events duration, frame rates, and pixel color depth play a fundamental role for the required bandwidth. In addition, other link related attributes can influence the ability of the link to support a DSI-specific device, namely display input buffering capabilities, video transmission mode (burst or non-burst), bus turn-around (BTA) time, concurrent command mode traffic in a video mode transmission, or display device specifics. All these variables make it difficult to define a standard procedure to estimate the minimum lane rate and the minimum number of lanes that support a specific display device.



The basic assumptions for estimates are:

- clock lane frequency is 1250 MHz, resulting in a bandwidth of 2.5 Gbit/s for each data lane
- the display must be capable of buffering the pixel data at the speed at which it is delivered in the DSI link
- no significant control traffic is present on the link when the pixel data is being transmitted.

55.4.4 System level architecture

Figure 481 shows the architecture of the DSI Host.

Figure 481. DSI Host architecture

The different parts have the following functions:

- The DSI Wrapper ensures the interfacing between the LTDC and the DSI Host kernel. It can adapt the color mode and the signal polarity, and manages the tearing effect (TE) for automatic frame buffer update in adapted command mode. The DSI Wrapper also controls the DSI regulator, the DSI PLL, and specific functions of the MIPI® D-PHY.
- The LTDC interface captures the data and control signals from the LTDC, and conveys them to a FIFO for video control signals and to another one for the pixel data. The data are then used to build one of the following:
  - Video packets, when in video mode (see *Section 55.5*)
  - The *memory_write_start* and *memory_write_continue* DCS commands, when in adapted command mode (see *Section 55.6*)
- The register bank is accessible through a standard AMBA-APB slave interface, providing access to the DSI Host registers for configuration and control. There is also a fully programmable interrupt generator to inform the system about certain events.
- The PHY interface control is responsible for managing the D-PHY interface. It acknowledges the current operation and enables low-power transmission/reception or a high-speed transmission. It also performs data splitting between available D-PHY lanes for high-speed transmission.
- The packet handler schedules the activities inside the link. It performs several functions based on the interfaces that are currently operational and the video transmission mode that is used (burst mode or non-burst mode with sync pulses or sync events). It builds long or short packet generating correspondent ECC and CRC codes. This block also performs the following functions:
  - packet reception
  - validation of packet header by checking the ECC
  - header correction and notification for single-bit errors
  - termination of reception
  - multiple header error notification
  - depending on the virtual channel of the incoming packet, the handler routes the output data to the respective port.
- The APB-to-generic block bridges the APB operations into FIFOs holding the generic commands. The block interfaces with the following FIFOS:
  - Command FIFO
  - Write payload FIFO
  - Read payload FIFO
- The error management notifies and monitors the error conditions on the DSI link. It controls the timers used to determine if a timeout condition occurred, performing an internal soft reset, and triggering an interruption notification.

55.5 Functional description: video mode on LTDC interface

The LTDC interface captures the data and control signals and conveys them to the FIFO interfaces that transmit them to the DSI link.

Two different streams of data are present at the interface, namely video control signals and pixel data. Depending on the interface color coding, the pixel data is disposed differently throughout the LTDC bus.

Interface pixel color coding is summarized in *Table 507*.

Table 507. Location of color components in the LTDC interface

Location	16-bit			18-bit		24-bit

D0	B[0]	B[0]	-	B[0]	B[0]	B[0]

The LTDC interface can be configured to increase flexibility and promote correct use of this interface for several systems. The following configuration options are available:

- Polarity control: all the control signals are programmable to change the polarity depending on the LTDC configuration.
- After the core reset, the DSI Host waits for the first VSYNC active transition to start signal sampling (including pixel data), thus avoiding starting the transmission of the image data in the middle of a frame.
- If interface pixel color coding is 18 bits and the 18-bit loosely packed stream is disabled, the number of pixels programmed in the VPSIZE field must be a multiple of four. This means that in this mode, the two LSBs in the configuration are always

inferred as 0. The specification states that in this mode the pixel line size must be a multiple of four.

- To avoid FIFO underflows and overflows, it is assumed that the LTDC receives the configured number of pixels at all times.
- To keep the memory organized with respect to the packet scheduling, the number of pixels per packet parameter is used to separate the memory space of different video packets.

For SHTDN and COLM sampling and transmission, the video streaming from the LTDC must be active: if the LTDC is not actively generating the video signals like VSYNC and HSYNC, these signals are not transmitted through the DSI link. Because of such constraints and for commands to be correctly transmitted, the first VSYNC active pulse must occur for the command sampling and transmission. When shutting down the display, it is necessary for keep the LTDC active for one frame after the command has been issued. This ensures that the commands are correctly transmitted before actually disabling the video generation at the LTDC interface.

The SHTDN and COLM values can be programmed in the DSI Wrapper control register (DSI_WCR).

For all of the data types, one entire pixel is received per each clock cycle. The number of pixels of the payload is restricted to a multiple of a value, as shown in *Table 508*.

Table 508. Multiplicity of the payload size in pixels, for each data type

Value	Data types
1	16-bit 18-bit loosely packed 24-bit
2	Loosely packed pixel stream
4	18-bit non-loosely packed

55.5.1 Video transmission mode

There are different video transmission modes, namely:

- Burst mode
- Non-burst mode
  - Non-burst mode with sync pulse
  - Non-burst mode with sync event

Burst mode

In this mode, the entire active pixel line is buffered into a FIFO, and transmitted in a single packet, without interruptions. This transmission mode requires that the DPI pixel FIFO has the capacity to store a full line of active pixel data inside it. This mode is optimally used when the difference between pixel required bandwidth and DSI link bandwidth is significant. It enables the DSI Host to dispatch quickly the entire active video line in a single burst of data, and then return to low-power mode.

Non-burst mode

In this mode, the processor uses the partitioning properties of the DSI Host to divide the video line transmission into several DSI packets. This is done to match the pixel required bandwidth with the DSI link bandwidth. With this mode, the controller configuration does not require a full line of pixel data to be stored inside the LTDC interface pixel FIFO. It requires only the content of one video packet.

Guidelines for selecting the burst or non-burst mode

Selecting the burst and non-burst mode is mainly dependent on the system configuration and the device requirements. Choose the video transmission mode that suits the application scenario. The burst mode is more beneficial because it increases the probability of the link spending more time in the low-power mode, decreasing power consumption. The following conditions must be met to get the maximum benefits from the burst mode of operation:

- The DSI Host core must have sufficient pixel memory to store an entire pixel line to avoid the overflow of the internal FIFOs.
- The display device must support the reception of a full pixel line in a single packet burst, to avoid the overflow on the reception buffer.
- The DSI output bandwidth must be higher than the LTDC interface input bandwidth in a relation that enables the link to go to low-power once per line.

If the system cannot meet these requirements, it is likely that pixel data are lost, causing the malfunctioning of the display while using the burst mode. These errors are related to the capabilities of the system to store the temporary pixel data.

If all the conditions for using the burst mode cannot be met, use the non-burst mode to avoid errors. The non-burst mode provides a better matching of rates for pixel transmission, enabling:

- only a certain number of pixels to be stored in the memory and not requiring a full pixel line (lesser LTDC interface RAM requirements in the DSI Host)
- operation with devices that support only a small amount of pixel buffering (less than a full pixel line).

The DSI non-burst mode must be configured so that the DSI output pixel ratio matches with the LTDC interface input pixel ratio, reducing the memory requirements on host and/or device side. This is achieved by dividing a line into several pixel chunks, and optionally interleaving them with null packets.

The following equations show how the DSI Host core transmission parameters must be programmed in non-burst mode to match the DSI link pixel output ratio (left hand side) and LTDC interface pixel input (right hand side).

When the null packets are enabled:

lanebyteclkperiod * NUMC (VPSIZE * bytes_per_pixel + 12 + NPSIZE) / number_of_lanes

= pixels_per_line * LTDC_Clock_period

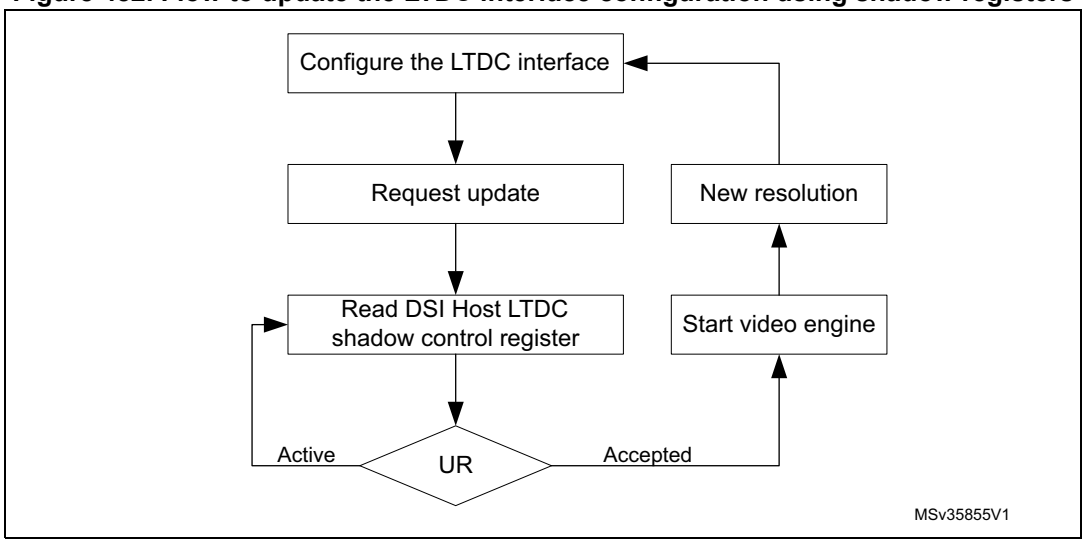
When the null packets are disabled:

lanebyteclkperiod * NUMC (VPSIZE * bytes_per_pixel + 6) / number_of_lanes

= pixels_per_line * LTDC_Clock_period

55.5.2 Updating the LTDC interface configuration in video mode

It is possible to update the LTDC interface configuration on the fly without impacting the current frame. This is done with the help of shadow registers: the DSI Host video shadow control register (DSI_VSCR) does it.



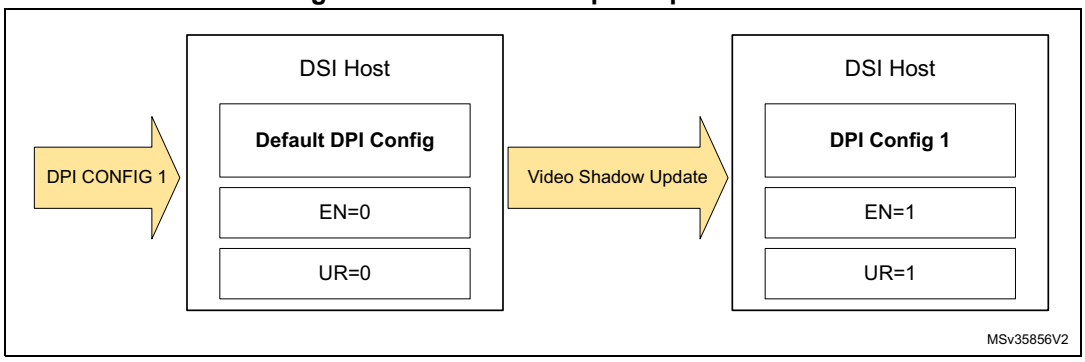
The new configuration is only used when the system requests for it. To update the video configuration during the transmission of a video frame, the configuration of that frame must be stored in the auxiliary registers. This way, the new frame configurations can be set through the APB interface without corrupting the current frame.

By default, this feature is disabled. To enable this feature, set the enable (EN) bit of the DSI Host video shadow control register (DSI_VSCR) to 1.

When this feature is enabled, the system supplies the configuration stored in the auxiliary registers.

Figure 482 shows the steps needed to update the LTDC interface configuration.

Figure 482. Flow to update the LTDC interface configuration using shadow registers

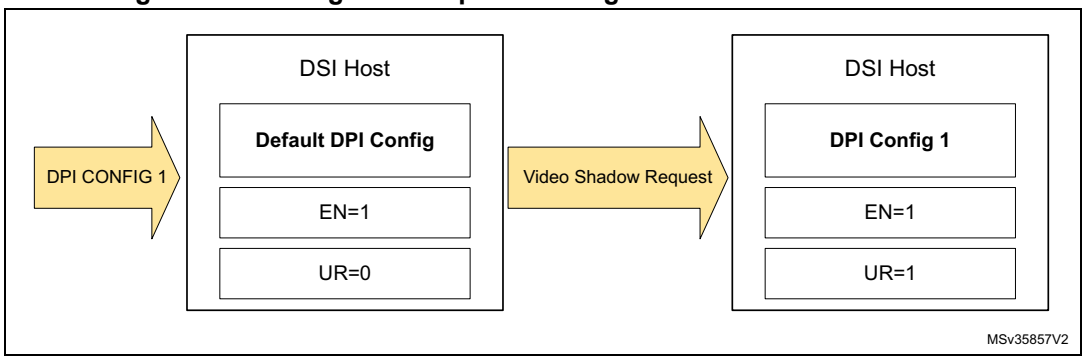


Immediate update

When the shadow register feature is active, the auxiliary registers require the LTDC configuration before the video engine starts. This means that, after a reset, update register (UR) bit is immediately granted.

When an immediately update the active registers without reset is required (see *Figure 483*), ensure that the enable (EN) and update register (UR) bits of the DSI Host video shadow control register (DSI_VSCR) are set to 0.

Figure 483. Immediate update procedure



Updating the configuration during the transmission of a frame using APB

To update the LTDC interface configuration, follow the steps shown in *Figure 484*:

1. Ensure that the enable (EN) bit of the DSI Host video shadow control register (DSI_VSCR) register is set to 1.
2. Set the update register (UR) bit of the DSI_VSCR register to 1.
3. Monitor the update register (UR) bit. This bit is set to 0 when the update is complete.

Figure 484. Configuration update during the transmission of a frame

Requesting a configuration update

It is possible to request the LTDC interface configuration update at any part of the frame. The DSI Host waits until the end of the frame to change the configuration. However, avoid sending the update request during the first line of the frame because the data must propagate between clock domains.

55.6 Functional description: adapted command mode on LTDC interface

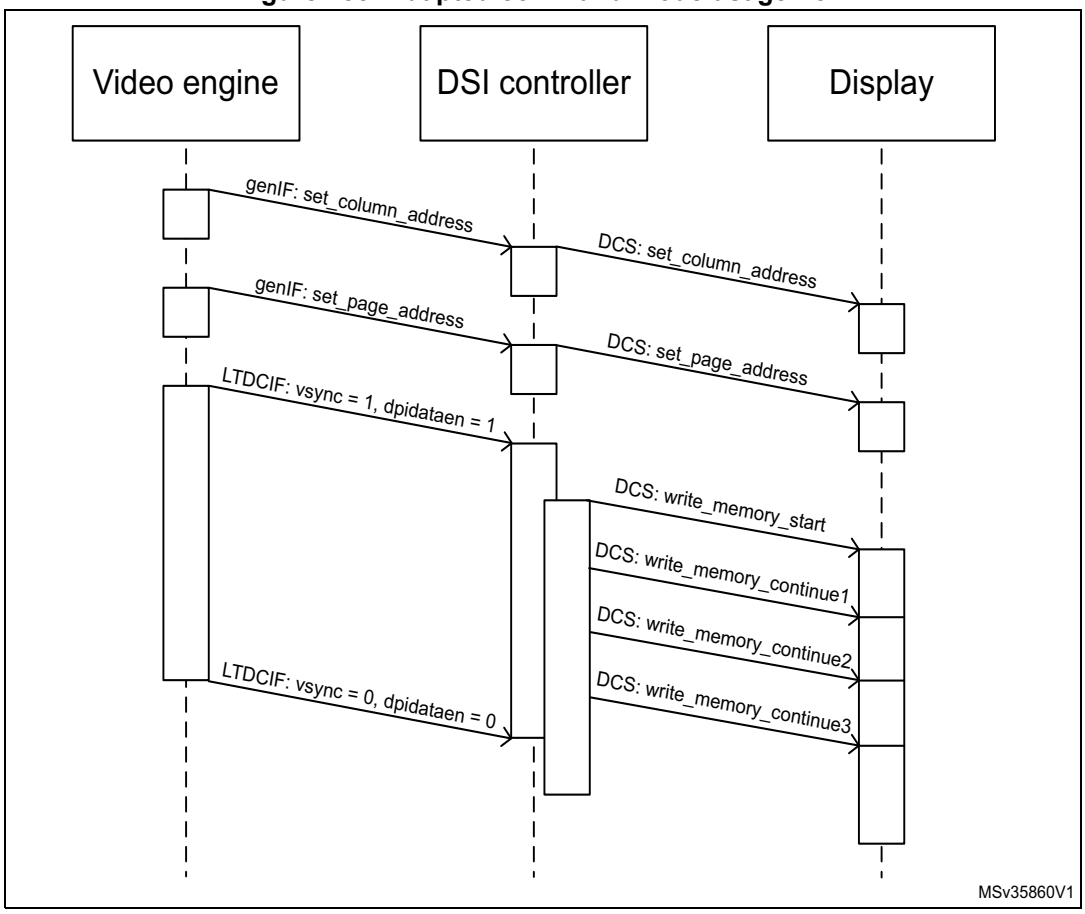
The adapted command mode, enables the system to input a stream of pixel from the LTDC that is conveyed by DSI Host using the command mode transmission (using the DCS packets). The adapted command mode also supports pixel input control rate signaling and tearing effect report mechanism.

The adapted command mode makes it possible to send large amounts of data through the *memory_write_start* (WMS) and *memory_write_continue* (WMC) DCS commands. It helps in delivering a wider data bandwidth for the memory write operations sent in command

mode to MIPI® displays, and to refresh large areas of pixels in high resolution displays. If additional commands (such as display configuration and read back), and tearing effect initialization must be transferred, then the APB slave generic interface must be used to complement the adapted command mode functionality.

Adapted command mode of operation supports 16 bpp, 18 bpp, and 24 bpp RGB.

To transmit the image data in adapted command mode:



- Set command mode (CMDM) bit of the DSI Host mode configuration register (DSI_MCR) to 1.
- Set DSI mode (DSIM) bit in the DSI Wrapper configuration register (DSI_WCFGR) to 1.

To transmit the image data, follow these steps:

- Define the image area to be refreshed, by using the *set_column_address* and *set_page_address* DCS commands. The image area must be defined only once, it remains effective until different values are defined.
- Define the pixel color coding to be used with the color coding (COLC) field in the DSI Host LTDC color coding register (DSI_LCOLCR).
- Define the virtual channel ID of the LTDC interface generated packets using the virtual channel ID (VCID) field in the DSI Host LTDC VCID register (DSI_LVCIDR). These also need to be defined only once.
- Start transmitting the data from the LTDC setting the LTDC enable (LTDCEN) bit of the DSI_WCR register.

Figure 485 shows the adapted command mode usage flow.

Figure 485. Adapted command mode usage flow

When the command mode (CMDM) bit of the DSI Host mode configuration register (DSI_CFGR) is set to 1, the LTDC interface assumes the behavior corresponding to the adapted command mode.

In this mode, the host processor can use the LTDC interface to transmit a continuous stream of pixels to be written in the local frame buffer of the peripheral. It uses a pixel input bus to receive the pixels, and controls the flow automatically to limit the stream of continuous pixels. When the first pixel is received, the current value of the command size (CMDSIZE) field of the DSI Host LTDC command configuration register (DSI_LCCR), is shadowed to the internal interface function. The interface increments a counter on every valid pixel that is fed through the interface. When this pixel counter reaches command size (CMDSIZE), a command is written into the command FIFO, and the packet is ready to be transmitted through the DSI link.

If the last pixel arrives before the counter reaches the shadowed command size value (CMDSIZE), a WMS command is issued to the command FIFO, with word count (WC) set to the number of bytes corresponding to the counter value. If more than CMDSIZE pixels are received (shadowed value), a WMS command is sent to the command FIFO, with WC set to the number of bytes corresponding to CMDSIZE, and the counter restarts.

After the first WMS command has been written to the FIFO, the circuit behaves in a similar way, but issues WMC commands instead of WMS commands. The process is repeated until

the last pixel of the image is received. The core automatically sends a new packet when the last pixel of the image is received, falls, or command size (CMDSIZE) limit is reached.

Synchronization with the LTDC

The DSI Wrapper performs the synchronization of the transfer process by:

- controlling the start/halt of the LTDC
- making the data flow control between LTDC and DSI Host.

Before using the DSI command mode, set bit LTDC_GCR in the DSI_SFEN and in the DSISFEXEN registers.

The transfer to refresh the display frame buffer can be triggered: manually, setting the LTDC enable (LTDCEN) bit of the DSI Wrapper control register (DSI_WCR) or the DSI Wrapper control register bits (DSI_WCRB), depending upon the security access on each, or automatically (when a tearing effect (TEIF) event occurs, an automatic refresh (AR) is enabled).

The selection between manual and automatic mode is done through the automatic refresh (AR) bit of the DSI Wrapper configuration register (DSI_WCFGR). In automatic refresh mode, the LTDC enable (LTDCEN) bit of the DSI Wrapper control register (DSI_WCR) is set automatically by a tearing effect (TEIF) event.

Once the transfer of one frame is done (in manual or automatic refresh mode), the DSI Wrapper halts the TFT display controller (LTDC) resetting the LTDC enable (LTDCEN) bit of the DSI Wrapper control register (DSI_WCR). Then it sets the end of refresh interrupt flag (ERIF) flag of the DSI Wrapper status register (DSI_WSR). If the end of refresh interrupt enable (ERIE) bit of the DSI Wrapper configuration register (DSI_WCFGR) is set, an interrupt is generated.

The end of refresh interrupt flag (ERIF) flag of the DSI Wrapper status register (DSI_WSR) can be reset by setting the clear end of refresh interrupt flag (CERIF) bit of the DSI Wrapper clear interrupt flag register (DSI_WCIFR).

The halting of the TFT display controller (LTDC) by the DSI Wrapper is done synchronously on a rising edge or a falling edge of VSync, according to the VSync polarity (VSPOL) bit of the DSI Wrapper configuration register (DSI_WCFGR).

Support of tearing effect

The DSI specification supports tearing effect function in command mode displays. It enables the Host processor to receive timing accurate information about where the display peripheral is in the process of reading the content of its frame buffer.

The tearing effect can be managed through:

- a separate pin, not covered in the DSI specification
- the DSI tearing effect functionality: a *set_tear_on* DCS command must be issued through the APB interface using the generic interface registers.

Tearing effect through a GPIO

When the tearing effect source (TESRC) bit of the DSI Wrapper configuration register (DSI_WCFGR) is set, the tearing effect is signaled through a GPIO.

The polarity of the input signal can be configured by the tearing effect polarity (TEPOL) bit of the DSI Wrapper configuration register (DSI_WCFGR).

When the programmed edge is detected, the tearing effect interrupt flag (TEIF) bit of the DSI Wrapper interrupt and status register (DSI_WISR) is set.

If the tearing effect interrupt enable (TEIE) bit of the DSI Wrapper interrupt enable register (DSI_WIER) is set, an interrupt is generated.

Tearing effect through DSI link

When the TESRC bit of the DSI Wrapper configuration register (DSI_WCFGR) is reset, the tearing effect is managed through the DSI link:

The DSI Host performs a double bus turn-around (BTA) after sending the *set_tear_on* command granting the ownership of the link to the DSI display. The display holds the ownership of the bus until the tear event occurs, which is indicated to the DSI Host by a D-PHY trigger event. The DSI Host then decodes the trigger and reports the event setting the tearing effect interrupt flag (TEIF) bit of the DSI Wrapper interrupt and status register (DSI_WISR).

If the tearing effect interrupt enable (TEIE) bit of the DSI Wrapper interrupt enable register (DSI_WIER) is set, an interrupt is generated.

To use this function, it is necessary to issue a *set_tear_on* command after the update of the display using the WMS and WMC DCS commands. This procedure halts the DSI link until the display is ready to receive a new frame update.

The DSI Host does not automatically generate the tearing effect request (double BTA) after a WMS/WMC sequence for flexibility purposes, so several regions of the display can be updated improving DSI bandwidth usage. Tearing effect request must always be triggered by a *set_tear_on* command in the DSI Host implementation.

Configure the following registers to activate the tearing effect:

- DSI Host command mode configuration register (DSI_CMCR): TEARE
- DSI Host protocol configuration register (DSI_PCR): BTAE.

55.7 Functional description: APB slave generic interface

The APB slave interface allows the transmission of generic information in command mode, and follows a proprietary register interface. Commands sent through this interface are not constrained to comply with the DCS specification, and can include generic commands described in the DSI specification as manufacturer-specific.

The DSI Host supports the transmission of write and read command mode packets as described in the DSI specification. These packets are built using the APB register access. The DSI Host generic payload data register (DSI_GPDR) has two distinct functions based on the operation. Writing to this register sends the data as payload when sending a command mode packet. Reading this register returns the payload of a read back operation. The DSI Host generic header configuration register (DSI_GHCR) contains the command mode packet header type and header data. Writing to this register triggers the packet transmission. For a long command mode packet, the packet payload must be written in advance in the DSI Host generic payload data register (DSI_GPDR).

The valid packets that can be transmitted through the generic interface are the following:

- Generic write short packet 0 parameters
- Generic write short packet 1 parameters
- Generic write short packet 2 parameters
- Generic read short packet 0 parameters
- Generic read short packet 1 parameters
- Generic read short packet 2 parameters
- Maximum read packet configuration
- Generic long write packet
- DCS write short packet 0 parameters
- DCS write short packet 1 parameters
- DCS read short packet 0 parameters
- DCS write long packet.

A set of bits in the DSI Host generic packet status register (DSI_GPSR) reports the status of the FIFO associated with APB interface support.

Generic interface packets are always transported using one of the DSI transmission modes, i.e. video mode or command mode. If neither of these modes is selected, the packets are not transmitted through the link, and the related FIFO eventually becomes overflown.

55.7.1 Packet transmission using the generic interface

The transfer of packets through the APB bus is based on the following conditions:

- The APB protocol defines that each of the write and read procedures take two clock cycles. This means that the maximum input data rate through the APB interface is always half the speed of the APB clock.
- The data input bus has a maximum width of 32 bits. This allows for a relation to be defined between the input APB clock frequency and the maximum bit rate achievable by the APB interface.
- The DSI link pixel bit rate when using solely APB is (APB clock frequency) * 16 Mbit/s.
- When using only the APB interface, the theoretical DSI link maximum bit rate can be expressed as DSI link maximum bit rate = APB clock frequency (in MHz) * 32 / 2 Mbit/s. In this formula the number 32 represents the APB data bus width, and the division by two is present because each APB write procedure takes two clock cycles to be executed.
- The bandwidth is dependent on the APB clock frequency; the available bandwidth increases with the clock frequency.

To drive the APB interface to achieve high bandwidth command mode traffic transported by the DSI link, the DSI Host must operate only in command mode, and the APB interface must be the only data source in use. Thus, the APB interface has the whole bandwidth of the DSI link and does not share it with any another input interface source.

The memory write commands require maximum throughput from the APB interface, because they contain the most amount of data conveyed by the DSI link. While writing the packet information, first write the payload of a given packet into the payload FIFO using the DSI Host generic payload data register (DSI_GPDR). When the payload data is for the command parameters, place the first byte to be transmitted in the least significant byte position of the APB data bus.

After writing the payload, write the packet header into the command FIFO. For more information about the packet header organization on the 32-bit APB data bus, so that it is correctly stored inside the command FIFO.

When the payload data is for a memory write command, it contains pixel information and it must follow the pixel to byte conversion organization referred in the Annexe A of the DCS specification.

Figures *486* to *490* show how the pixel data must be organized in the APB data write bus.

The memory write commands are conveyed in DCS long packets, encapsulated in a DSI packet. The DSI specifies that the DCS command must be present in the first payload byte of the packet. This is also included in the diagrams. In figures *486* to *490*, the *write memory* command can be replaced by the DCS command *write memory Start* and *write memory Continue*.

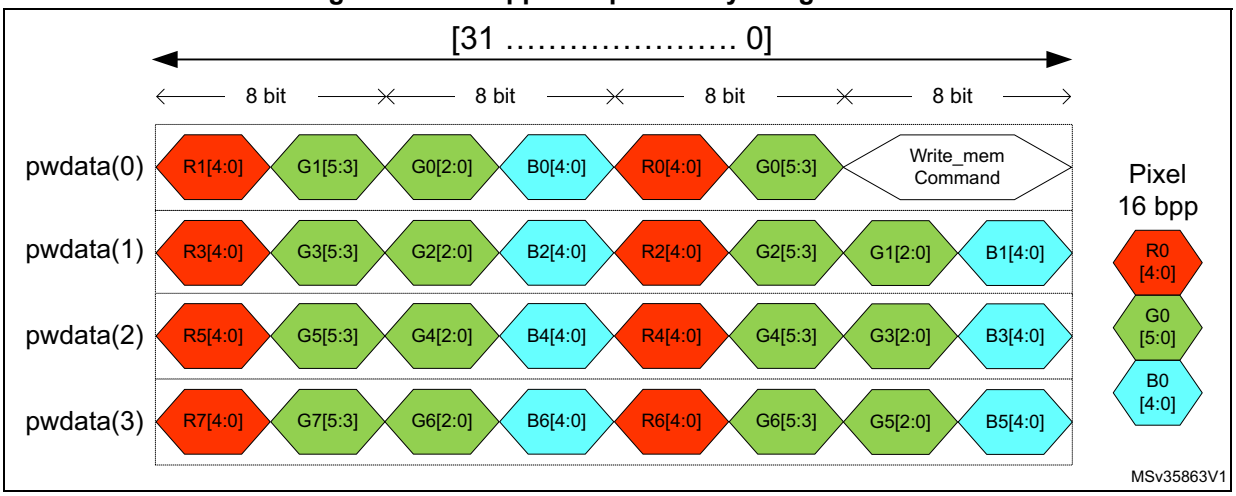

Figure 489. 12 bpp APB pixel to byte organization

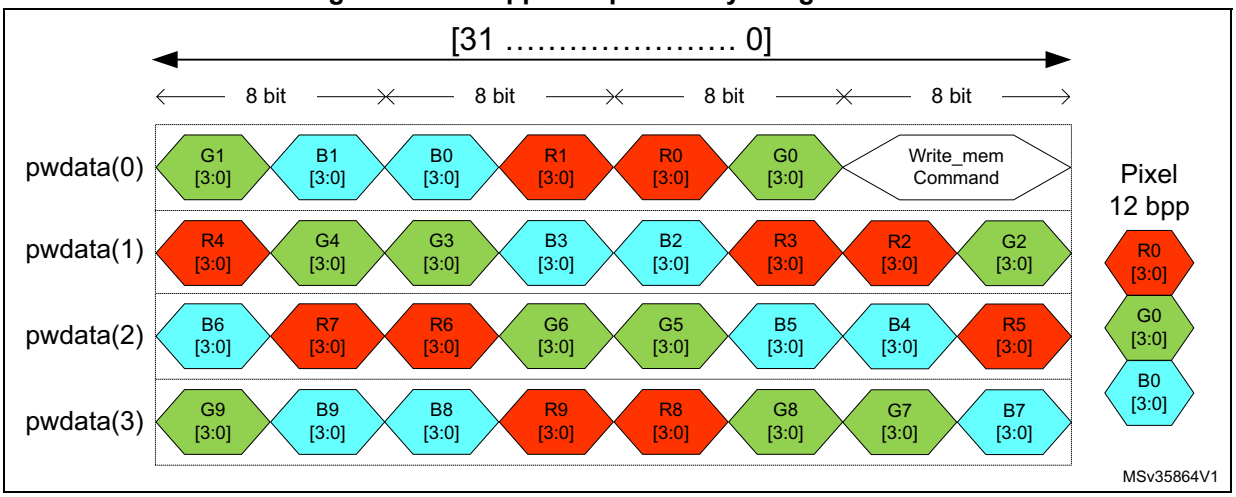

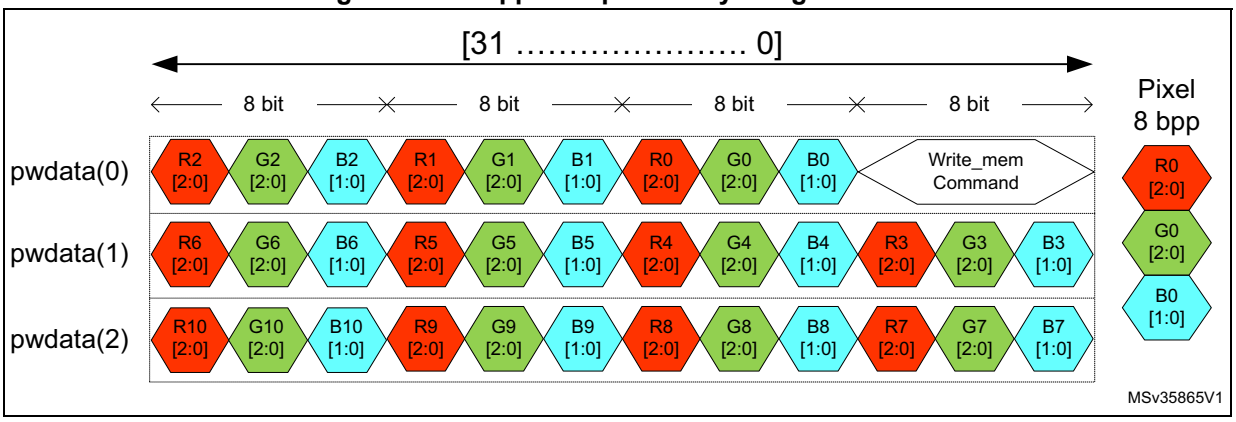

Figure 490. 8 bpp APB pixel to byte organization

55.8 Functional description: timeout counters

The DSI Host includes counters to manage timeout during the various communication phases. The duration of each timeout can be configured by the six timeout counter configuration registers (DSI_TCCR0...5).

There are two types of counters:

- contention error detection timeout counters (*Section 55.8.1*)
- peripheral response timeout counters (*Section 55.8.2*).

55.8.1 Contention error detection timeout counters

The DSI Host implements a set of counters and conditions to notify the errors. It features a set of registers to control the timers used to determine if a timeout has occurred, and also contains a set of interruption status registers that are cleared upon a read operation (detailed in *Table 509*). Optionally, these registers also trigger an interrupt signal that can be used by the system to be activated when an error occurs within the DSI connection.

Table 509. Contention detection timeout counters configuration

Timeout counter	Value register	Value field	Flag register	Flag field
High-speed transmission	DSI_TCCR0	TOHSTX	DSI_ISR1	TOHSTX
Low-power reception	DSI_TCCR0	TOLPRX	DSI_ISR1	TOLPRX

Time units for these 16-bit counters are configured in cycles defined in the timeout clock division (TOCKDIV) field in the DSI Host clock control register (DSI_CCR).

The value written to the timeout clock division (TOCKDIV) field in the DSI Host clock control register (DSI_CCR) defines the time unit for the timeout limits using the lane byte clock as input.

This mechanism increases the range to define these limits.

High-speed transmission contention detection

The timeout duration is configured in the high-speed transmission timeout count (HSTX_TOCNT) field of the DSI Host timeout counter configuration register 1 (DSI_TCCR0). A 16-bit counter measures the time during which the high-speed mode is active.

If that counter reaches the value defined by the high-speed transmission timeout count (HSTX_TOCNT) field of the DSI Host timeout counter configuration register 1 (DSI_TCCR0), the timeout high-speed transmission (TOHSTX) bit in the DSI Host interrupt and status register 1 (DSI_ISR1) is asserted and an internal soft reset is generated to the DSI Host.

If the timeout high-speed transmission interrupt enable (TOHSTXIE) bit of the DSI Host interrupt enable register 1 (DSI_IER1) is set, an interrupt is generated.

Low-power reception contention detection

The timeout is configured in the low-power reception timeout counter (LPRX_TOCNT) field of the DSI Host timeout counter configuration register 1 (DSI_TCCR1). A 16-bit counter measures the time during which the low-power reception is active.

If that counter reaches the value defined by the low-power reception timeout counter (LPRX_TOCNT) field of the DSI Host timeout counter configuration register 1 (DSI_TCCR0), the timeout low-power reception (TOLPRX) bit in the DSI Host interrupt and status register 1 (DSI_ISR1) is asserted and an internal soft reset is generated to the DSI Host.

If the timeout low-power reception interrupt enable (TOLPRXIE) bit of the DSI Host interrupt enable register 1 (DSI_IER1) is set, an interrupt is generated. Once the software gets notified by the interrupt, it must reset the D-PHY by de-asserting and asserting the Digital enable (DEN) bit of the DSI Host PHY control register (DSI_PCTLR).

55.8.2 Peripheral response timeout counters

A peripheral may not immediately respond correctly to some received packets. For example, a peripheral receives a read request, but due to its architecture cannot access the RAM for a while (for example the panel is being refreshed and takes some time to respond). In this case, set a timeout to ensure that the host waits long enough so that the device is

able to process the previous data before receiving the new data or responding correctly to new requests.

Table 510 lists the events belonging to various categories having an associated timeout for peripheral response.

Table 510. List of events of different categories of the PRESP_TO counter

Category	Event
Items implying a BTA PRESP_TO	Bus-turn-around
READ requests indicating a PRESP_TO (replicated for HS and LP)	(0x04) Generic read, no parameters short (0x14) Generic read, 1 parameter short (0x24) Generic read, 2 parameters short (0x06) DCS read, no parameters short
WRITE requests indicating a PRESP_TO (replicated for HS and LP)	(0x03) Generic short write, no parameters short (0x13) Generic short write, 1 parameter short (0x23) Generic short write, 2 parameters short (0x29) Generic long write long (0x05) DCS short write, no parameters short (0x15) DCS short write, 1 parameter short (0x39) DCS long write/write_LUT, command packet long (0x37) Set maximum return packet size

The DSI Host ensures that, on sending an event that triggers a timeout, the D-PHY switches to the Stop state and a counter starts running until it reaches the value of that timeout. The link remains in the LP-11 state and unused until the timeout ends, even if there are other events ready to be transmitted.

Figures *491* to *493* illustrate the flow of counting in the PRESP_TO counter for the three categories listed in *Table 510*.

Figure 491. Timing of PRESP_TO after a bus-turn-around

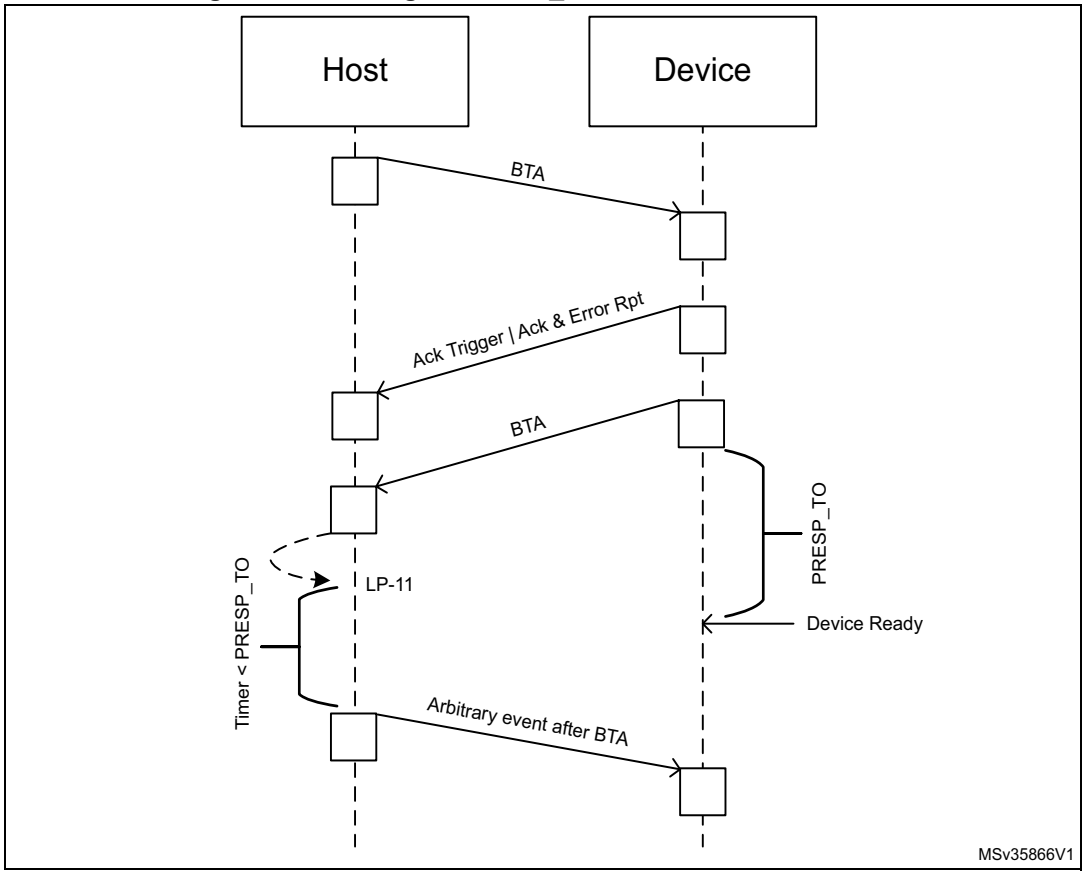

Figure 492. Timing of PRESP_TO after a read request (HS or LP)

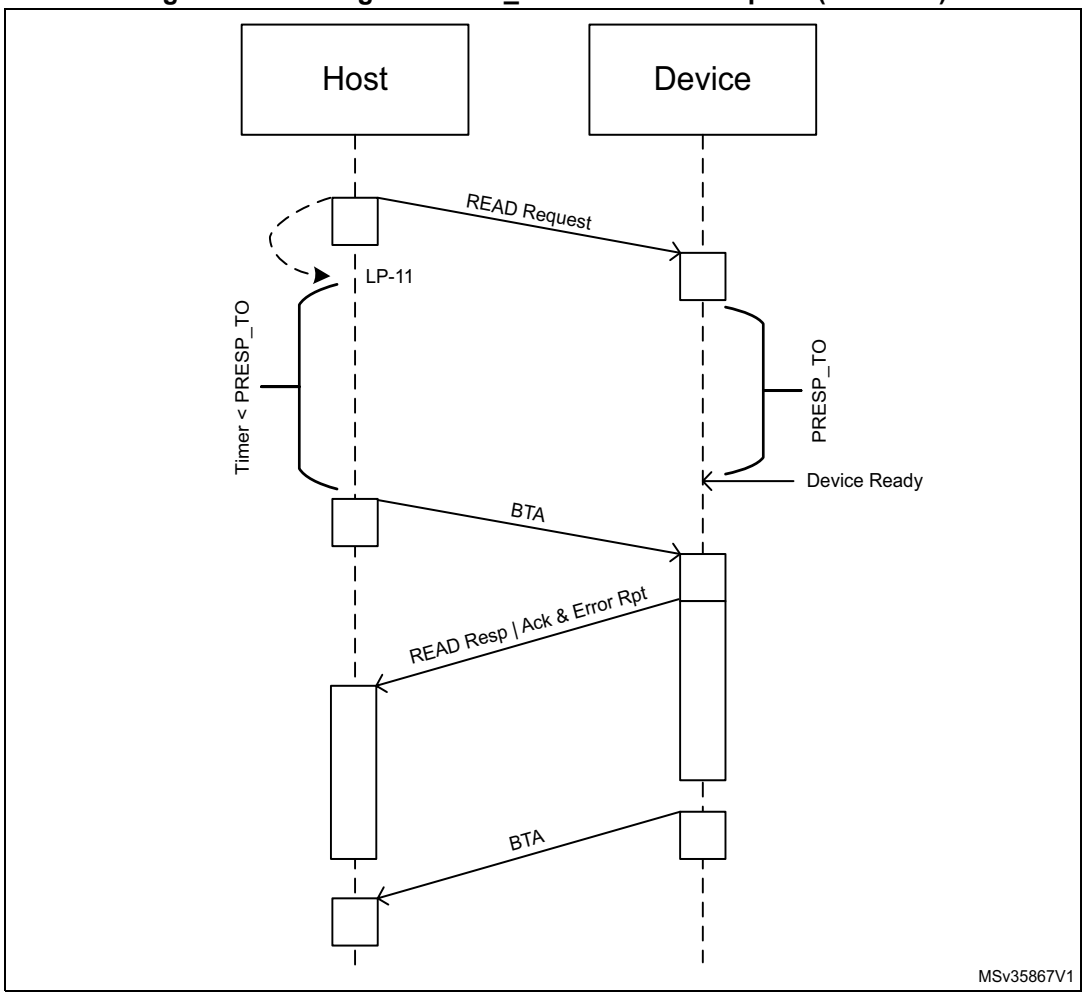

Figure 493. Timing of PRESP_TO after a write request (HS or LP)

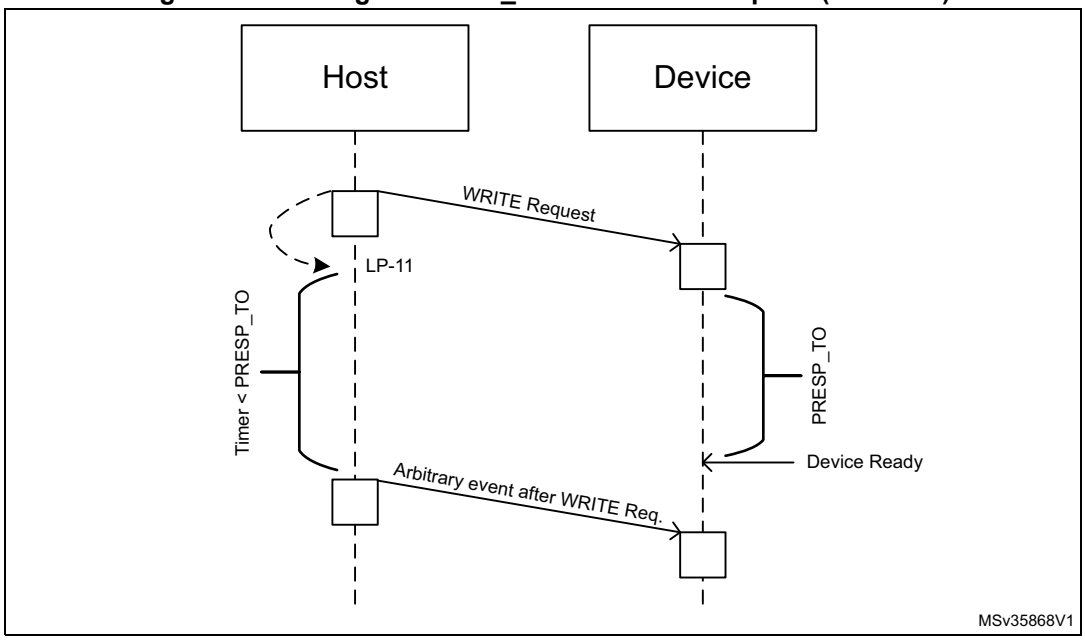

Table 511 describes the fields used for the configuration of the PRESP_TO counter.

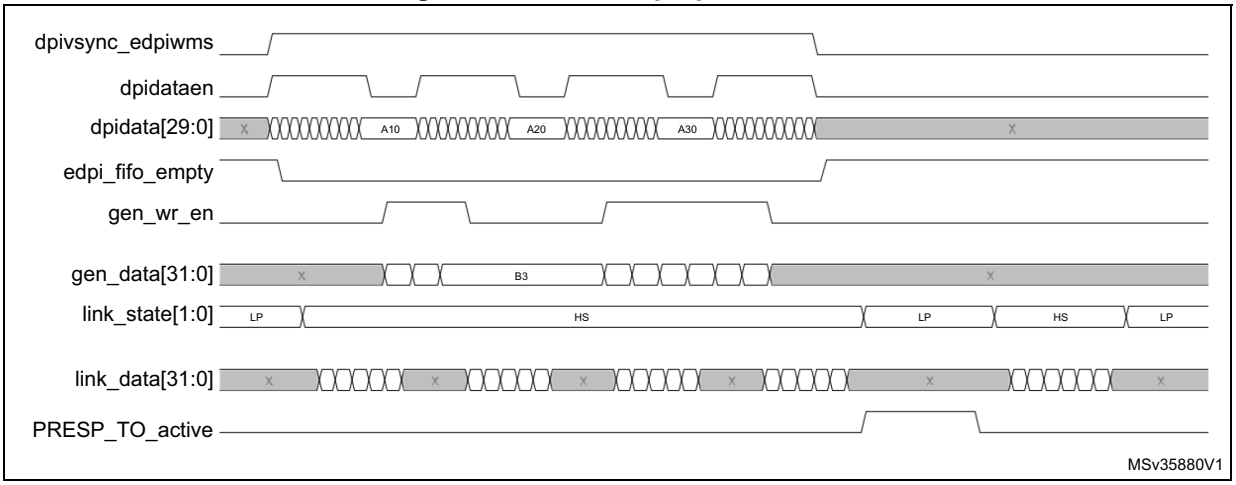
Table 511. PRESP_TO counter configuration

Description		Register	Field
Period for which the DSI Host keeps the link still	After sending a High-speed read operation	DSI_TCCR1	HSRD_TOCNT
	After sending a Low-power read operation	DSI_TCCR2	LPRD_TOCNT
	After completing a Bus-turn-around (BTA)	DSI_TCCR5	BTA_TOCNT
Period for which the DSI Host keeps the link inactive	After sending a High-speed write operation	DSI_TCCR3	HSWR_TOCNT
	After sending a Low-power write operation	DSI_TCCR4	LPWR_TOCNT

The values in these registers are measured in number of cycles of the lane byte clock. These registers are only used in command mode because in video mode, there is a rigid timing schedule to be met to keep the display properly refreshed and it must not be broken by these or any other timeouts. Setting a given timeout to 0 disables going into LP-11 state and timeout for events of that category.

The read and the write requests in high-speed mode are distinct from the read and the write requests in low-power mode. For example, if HSRD_TOCNT is set to zero and LPRD_TOCNT is set to a non-zero value, a generic read with no parameters does not activate the PRESP_TO counter in high-speed, but it activates the PRESP_TO in low-power.



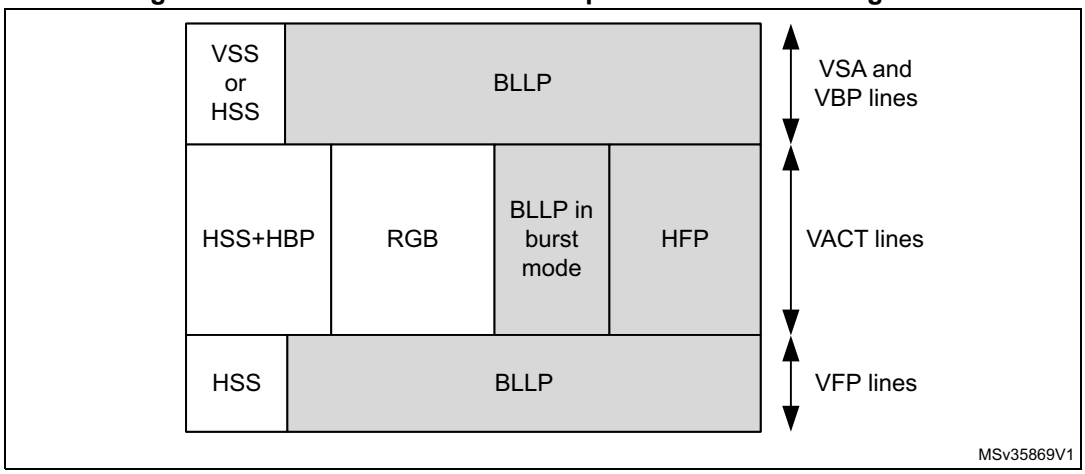
The DSI Host timeout counter configuration register 4 (DSI_TCCR3) includes a special Presp mode (PM) bit to change the normal behavior of PRESP_TO in Adaptive command

mode for high-speed write operation timeout. When set to 1, this bit allows the PRESP_TO from HSWR_TOCNT to be used only once, when both of the following conditions are met:

- the LTDC VSYNC signal rises and falls
- the packets originated from the LTDC interface in adapted command mode are transmitted and its FIFO is empty again.

In this scenario, non-adapted command mode requests are not sent to the D-PHY, even if there is traffic from the generic interface ready to be sent, returning them to the Stop state. When it happens, the PRESP_TO counter is activated and only when it is completed the DSI Host sends any other ready traffic, as illustrated in *Figure 494*.

Figure 494. Effect of prep mode at 1

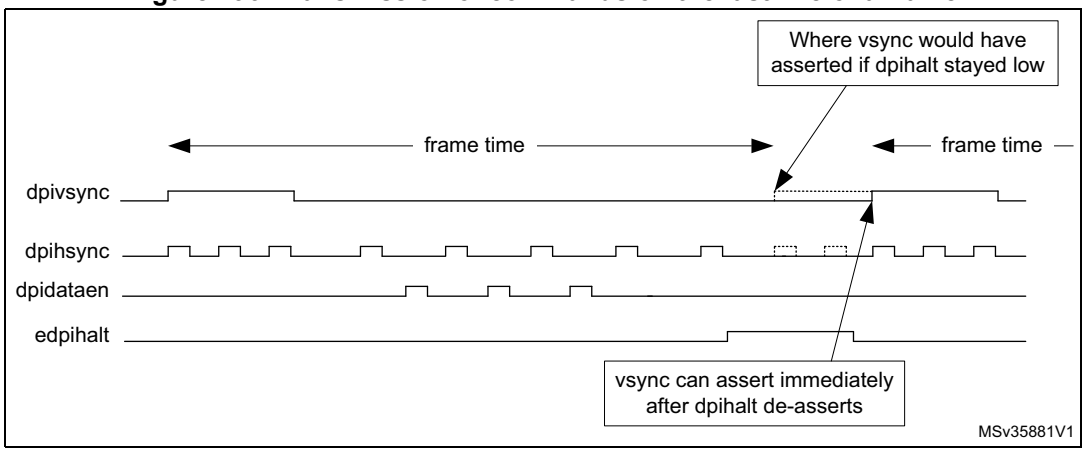


55.9 Functional description: transmission of commands

55.9.1 Transmission of commands in video mode

The DSI Host supports the transmission of commands, both in high-speed and low-power, while in video mode. The DSI Host uses blanking or low-power (BLLP) periods to transmit commands inserted through the APB generic interface. Those periods correspond to the gray areas of *Figure 495*.

Figure 495. Command transmission periods within the image area



Commands are transmitted in the blanking periods after the following packets/states:

- Vertical Sync Start (VSS) packets, if the video sync pulses are not enabled
- Horizontal sync end (HSE) packets, in the VSA, VBP, and VFP regions
- Horizontal sync Start (HSS) packets, if the video sync pulses are not enabled in the VSA, VBP, and VFP regions
- Horizontal active (HACT) state

Besides the areas corresponding to BLLP, large commands can also be sent during the last line of a frame. In this case, the line time for the video mode is violated and the edpihalt signal is set to request the DPI video timing signals to remain inactive. Only if a command does not fit into any BLLP area it is postponed to the last line, causing the violation of the line time for the video mode, as illustrated in *Figure 496*.

Figure 496. Transmission of commands on the last line of a frame

Only one command is transmitted per line, even in the case of the last line of a frame but one command is possible for each line.

There can be only one command sent in low-power per line. However, one low-power command is possible for each line. In high-speed, the DSI Host can send more than one command, as many as it determines to fit in the available time.

The DSI Host avoids sending commands in the last line because it is possible that the last line is shorter than the other ones. For instance, the line time (t_L) can be half a cycle longer

than the t_L on the LTDC interface, that is, each line in the frame taking half a cycle from time for the last line. This results in the last line being (½ cycle) x (number of lines -1) shorter than t_L.

The COLM and SHTDN bits of the DSI Wrapper control register (DSI_WCR) are also able to trigger the sending of command packets. The commands are:

- Color mode ON
- Color mode OFF
- Shut down peripheral
- Turn on peripheral

These commands are not sent in the VACT region. If the low-power command enable (LPCE) bit of the DSI Host video mode configuration register (DSI_VMCR) is set, these commands are sent in low-power mode.

In low-power mode, the largest packet size (LPSIZE) field of the DSI Host low-power mode configuration register (DSI_LPMCR) is used to determine if these commands can be transmitted. It is assumed that largest packet size (LPSIZE) is greater than or equal to four bytes (number of bytes in a short packet), because the DSI Host does not transmit these commands on the last line.

If the frame bus-turn-around acknowledge enable (FBTAAE) bit is set in the DSI Host low-power mode configuration register (DSI_LPMCR), a BTA is generated by DSI Host after the last line of a frame. This may coincide with a write command or a read command. In either case, the LTDC interface is halted until an acknowledge is received (control of the DSI bus is returned to the host).

55.9.2 Transmission of commands in low-power mode

DSI Host can be configured to send the low-power commands during the high-speed video mode transmission.

To enable this feature, set the Low Power command enable (LPCE) bit of the DSI Host video mode configuration register (DSI_VMCR) to 1. In this case, it is necessary to calculate the time available, in bytes, to transmit a command in low-power mode to horizontal front-porch (HFP), vertical sync active (VSA), vertical back-porch (VBP), and vertical front-porch (VFP) regions.

Bits 8 to 13 of the video mode configuration register (DSI_VMCR) register indicate if DSI Host can go to LP when in idle. If the low-power command enable (LPCE) bit is set and non-video packets are in queue, DSI Host ignores the low-power configuration and transmits low-power commands, even if it is not allowed to enter low-power mode in a specific region. After the low-power commands transmission, DSI Host remains in low-power until a sync event occurs.

For example, consider that the VFP is selected as high-speed region (LPVFPE = 1'b0) with LPCE set as a command to transmit in low-power in the VPF region. This command is transmitted in low-power, and the line stays in low-power mode until a new HSS arrives.

Calculating the time to transmit commands in LP mode in the VSA, VBP, and VFP regions

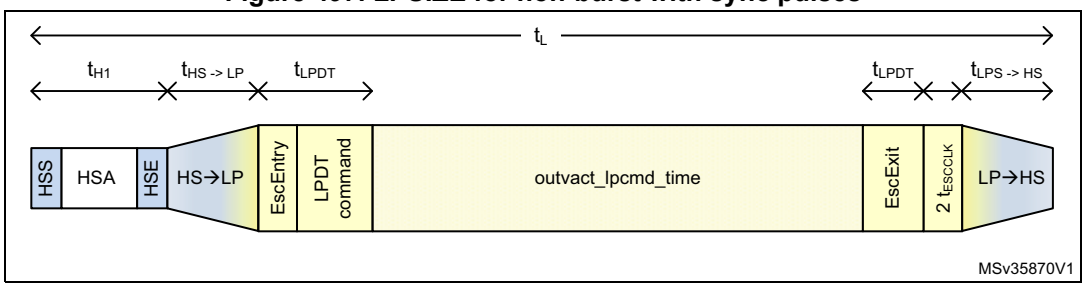
The largest packet size (LPSIZE) field of the DSI Host low-power mode configuration register (DSI_LPMCR) indicates the time available (in bytes) to transmit a command in

low-power mode (based on the escape clock) on a line during the VSA, VBP, and the VFP regions.

Calculation of largest packet size (LPSIZE) depends on the used video mode.

Figure 497 illustrates the timing intervals for the video mode in non-burst with sync pulses, while *Figure 498* refers to video mode in burst and non-burst with sync events.

Figure 497. LPSIZE for non-burst with sync pulses



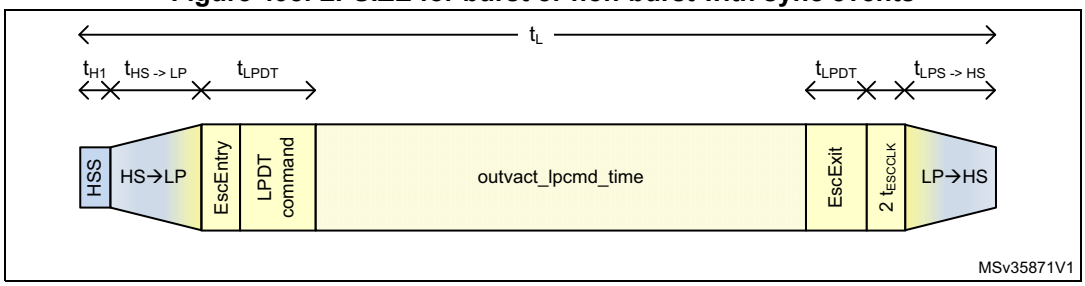


Figure 498. LPSIZE for burst or non-burst with sync events

This time is calculated as follows:

$LPSIZE = (t_L - (t_{H1} + t_{HS->LP} + t_{LPHS} + t_{LPDT} + 2\ t_{ESCCLK})) / (2 \times 8 \times t_{ESCCLK})$, where

- t_L = line time
- t_{H1} = time of the HSA pulse for sync pulses mode (*Figure 497*) or time to send the HSS packet, including EoTp (*Figure 498*)
- $t_{HS->LP}$ = time to enter the low-power mode
- $t_{LP->HS}$ = time to leave the low-power mode
- t_{LPDT} = D-PHY timing related with escape mode entry, LPDT command, and escape exit. According to the D-PHY specification, this value is always 11 bits in LP (or 22 TX escape clock cycles)
- t_{ESCCLK} = escape clock period as programmed in the TXECKDIV field of the DSI_CCR register
- t_{ESCCLK} = delay imposed by the DSI Host implementation.

In the above equation, division by eight is done to convert the available time to bytes. Division by two is done because one bit is transmitted every two escape clock cycles. The largest packet size (LPSIZE) field can be compared directly with the size of the command to be transmitted to determine if there is enough time to transmit the command. The maximum size of a command that can be transmitted in low-power mode is limited to 255 bytes by this field. You must program this register to a value greater than or equal to 4 bytes for the transmission of the DCTRL commands, such as shutdown and color in low-power mode.

Consider an example of a frame with 12.4 µs per line and assume an escape clock frequency of 20 MHz and a lane bit rate of 800 Mbits. In this case, it is possible to send 124 bits in escape mode (that is, 124 bit = 12.4 µs * 20 MHz / 2). Still, you need to take into consideration the D-PHY protocol and PHY timings.

The following assumptions are made:

- lane byte clock period is 10 ns (800 Mbits per lane)
- escape clock period is 50 ns (DSI_CCR.TXECKDIV = 5)
- video is transmitted in non-burst mode with sync pulses bounded by HSS and HSE packets
- DSI is configured for two lanes
- D-PHY takes 180 ns to transit from low-power to high-speed mode (DSI_DLTCR.LS2HS_TIME = 18)
- D-PHY takes 200 ns to transit from high-speed to low-power mode (DSI_DLTCR.HS2LP_TIME = 20)
- t_{HSA} = 420 ns.

In this example, a 13-byte command can be transmitted as follows:

LPSIZE = (12.4 µs - (420 ns + 180 ns +200 ns + (22 × 50 ns + 2 × 50 ns))) / (2 × 8 × 50 ns) = 13 bytes.

Calculating the time to transmit commands in low-power mode in HFP region

The VACT largest packet size (VLPSIZE) field of the DSI Host low-power mode configuration register (DSI_LPMCR) indicates the time available (in bytes) to transmit a command in low-power mode (based on the escape clock) in the vertical active (VACT) region.

To calculate the value of VACT largest packet size (VLPSIZE), consider the video mode being used. *Figure 499* shows the timing intervals for video mode in non-burst with sync pulses, *Figure 500* those for video mode in non-burst with sync events, and *Figure 501* refers to the burst video mode.

Figure 499. VLPSIZE for non-burst with sync pulses

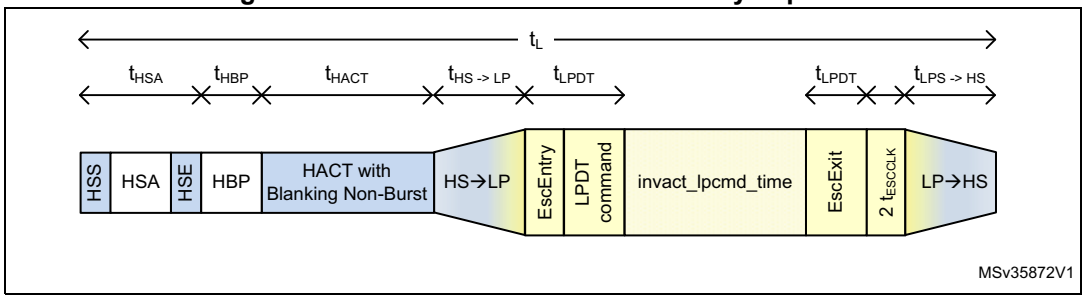

Figure 500. VLPSIZE for non-burst with sync events

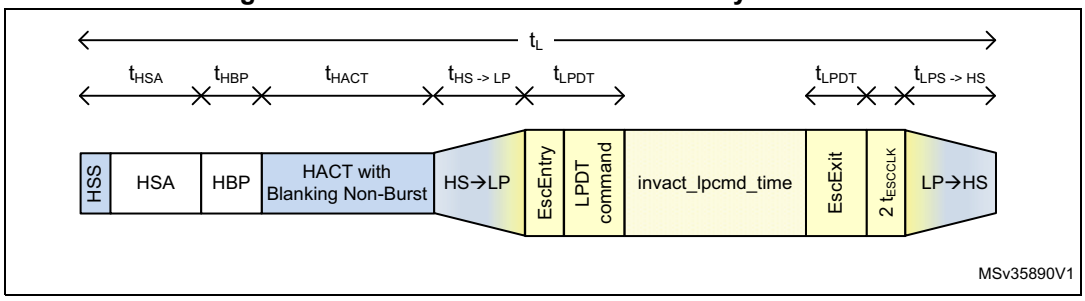

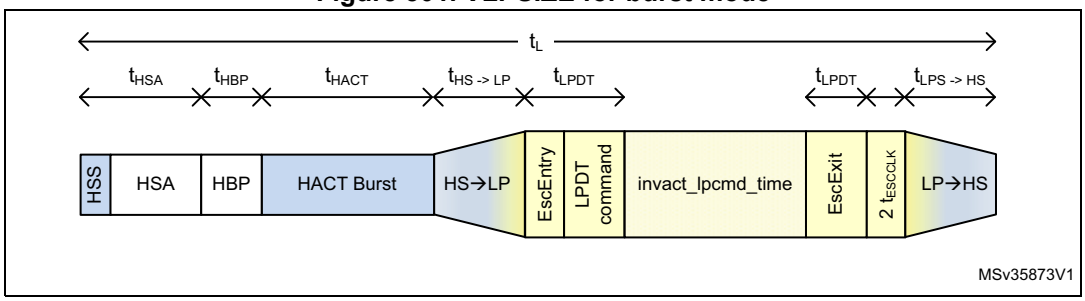

Figure 501. VLPSIZE for burst mode

This time is calculated as follows:

$VLPSIZE = (t_L - (t_{HSA} + t_{HBP} + t_{HACT} + t_{HS->LP} + t_{LP->HS} + t_{LPDT} + 2\ t_{ESCCLK})) / (2 \times 8 \times t_{ESCCLK})$

where

- t_L = line time
- t_{HSA} = time of the HSA pulse (DSI_VHSACR.HSA)
- t_{HBP} = time of horizontal back-porch (DSI_VHBPCR.HBP)
- t_{HACT} = time of video active. For burst mode, the video active is time compressed, and calculated as t_{HACT} = VPSIZE * Bytes_per_Pixel /Number_Lanes * $t_{Lane_byte_clk}$
- t_{ESCCLK} = escape clock period as programmed in TXECKDIV field of the DSI_CCR register.

The VLPSIZE field can be compared directly with the size of the command to be transmitted to determine if there is time to transmit the command.

Consider an example of a frame with 16.4 µs per line and assume an escape clock frequency of 20 MHz and a lane bit rate of 800 Mbits/s. In this case, it is possible to send 420 bits in escape mode (that is, 164 bits = 16.4 µs * 20 MHz / 2). Still, since it is the vertical active region of the frame, consider the HSA, HBP, and HACT timings apart from the D-PHY protocol and PHY timings. The following assumptions are made:

- number of active lanes is four
- lane byte clock period (lanebyteclkperiod) is 10 ns (800 Mbit/s per lane)
- escape clock period is 50 ns (DSI_CCR.TXECKDIV = 5)
- D-PHY takes 180 ns to pass from low-power to high-speed mode (DSI_DLTCR.LP2HS_TIME = 18)
- D-PHY takes 200 ns to pass from high-speed to low-power mode (DSI_DLTCR.HS2LP_TIME = 20)
- t_{HSA} = 420 ns

- t_{HBP} = 800 ns
- t_{HACT} = 12800 ns to send 1280 pixel at 24 bpp
- video is transmitted in non-burst mode
- DSI is configured for four lanes.

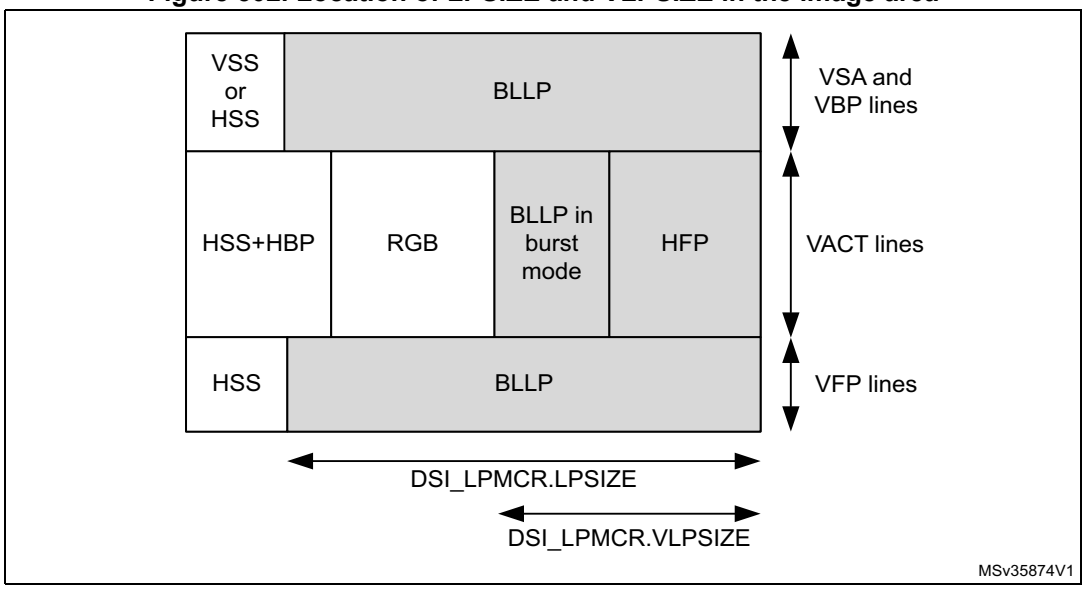
In this example, consider that video is sent in non-burst mode. The VLPSIZE is calculated as follows:

VLPSIZE = (16.4 µs -(420 ns + 800 ns + 12.8 µs + 180 ns +200 ns + (22 × 50 ns + 2 × 50 ns)) / (2 × 8 × 50 ns) = 1 byte

Only one byte can be transmitted in this period. A short packet (for example, generic short write) requires a minimum of four bytes. Therefore, in this example, commands are not sent in the VACT region.

If burst mode is enabled, more time is available to transmit the commands in the VACT region, because HACT is time compressed.

VLPSIZE = (16.4 µs - (420 ns + 800 ns + (1280 × 3 / 4 × 10 ns) + 180 ns + 200 ns + (22 × 50 ns + 2 × 50 ns) / (2 × 8 × 50 ns) = 5 bytes



For burst mode, the VLPSIZE is 5 bytes and then a 4-byte short packet can be sent.

Transmission of commands in different periods

The LPSIZE and VLPSIZE fields allow a simple comparison to determine if a command can be transmitted in any of the BLLP periods.

Figure 502 illustrates the meaning of VLPSIZE and LPSIZE, matching them with the shaded areas and the VACT region.

Figure 502. Location of LPSIZE and VLPSIZE in the image area

55.9.3 Transmission of commands in high-speed

If the LPCE bit of the DSI_VMCR register is 0, the commands are sent in high-speed in video mode. In this case, the DSI Host automatically determines the area where each command can be sent and no programming or calculation is required.

55.9.4 Read command transmission

The MRD_TIME field of the DSI_DLTCRDSI_DLTRCR register configures the maximum amount of time required to perform a read command in lane byte clock cycles, it is calculated as:

MRD_TIME = time to transmit the read command in low-power mode + time to enter and leave low-power mode + time to return the read data packet from the peripheral device.

The time to return the read data packet from the peripheral depends upon the number of bytes read and the peripheral escape clock frequency, and not upon the host escape clock. The MRD_TIME field is used in both high-speed and low-power mode to determine if there is time to complete a read command in a BLLP period.

In high-speed mode (LPCE = 0), MRD_TIME is calculated as follows:

MRD_TIME = ($t_{HS->LP}$ + $t_{LP->HS}$ + t_{read} + 2 x t_{BTA}) / lanebyteclkperiod

In low-power mode (LPCE = 1), MRD_TIME is calculated as follows:

MRD_TIME = ($t_{HS->LP}$ + $t_{LP->HS}$ + t_{LPDT} + t_{lprd} + t_{read} + 2 x t_{BTA}) / lanebyteclkperiod, where:

- $t_{HS->LP}$ = time to enter the low-power mode
- $t_{LP->HS}$ = time to leave the low-power mode
- t_{LPDT} = D-PHY timing related to escape mode entry, LPDT command, and escape mode exit (according to the D-PHY specification, this value is always 11 bits in LP, or 22 TX escape clock cycles)
- t_{lprd} = read command time in low-power mode (64 * TX esc clock)
- t_{read} = time to return the read data packet from the peripheral
- t_{BTA} = time to perform a bus-turn-around (D-PHY dependent).

Keep the maximum number of bytes read from the peripheral to a minimum, to have sufficient time available to issue the read commands in a line time. Ensure that MRD_TIME x lane byte clock period is less than LPSIZE x 16 x escape clock period of the host, otherwise the read commands are dispatched on the last line of a frame. If it is necessary to read a large number of parameters (> 16), increase MRD_TIME while the read command is executed. When the read has completed, decrease MRD_TIME.

If a read command is issued on the last line of a frame, the LTDC interface is halted, and stays halted until the read command is in progress. The video transmission must be stopped during this period.

55.9.5 Clock lane in low-power mode

To reduce the power consumption of the D-PHY, the DSI Host, when not transmitting in the high-speed mode, allows the clock lane to enter into the low-power mode. The controller automatically handles the clock lane transition from HS (clock lane active sending clock) to LP state without direct intervention by the software. This feature can be enabled by configuring the DPCC and the ACR bits of the DSI_CLCR register.

In the command mode, the DSI Host can place the clock lane in the low-power mode when it does not have any HS packets to transmit.

In the video mode (LTDC interface), the DSI Host controller uses its internal video and PHY timing configurations to determine if there is time available for the clock line to enter the low-power mode and not compromise the video data transmission of pixel data and sync events.

Along with a correct configuration of the video mode (see *Section 55.5*), the DSI Host needs to know the time required by the clock lane to go from high-speed to low-power mode, and vice-versa. The values required can be obtained from the D-PHY specification: program the DSI_CLTCR register with the following values:

- HS2LP_TIME = time from HS to LP in clock lane / byte clock period in HS (lanebyteclk)
- LP2HS_TIME = time from LP to HS in clock lane / byte clock period in HS (lanebyteclk)

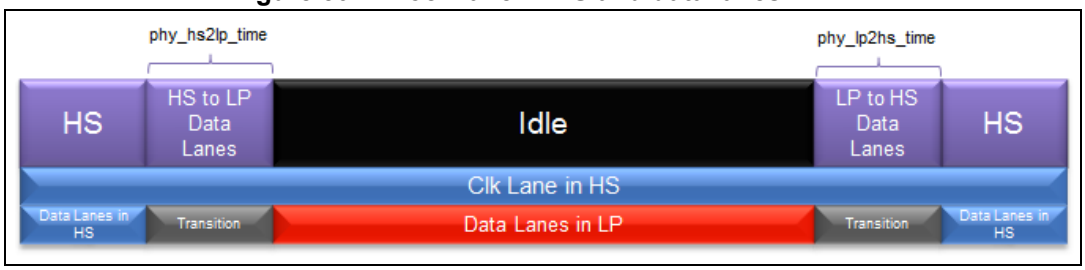
Based on the programmed values, the DSI Host calculates if there is enough time for the clock lane to enter the low-power mode during inactive regions of the video frame.

The DSI Host decides the best approach to follow regarding power saving out of the three possible scenarios:

- there is no enough time to go to the low-power mode. Therefore, blanking period is added as shown in *Figure 503*
- there is enough time for the data lanes to go to the low-power mode but not enough time for the clock lane to enter the low-power mode, see *Figure 504*.
- there is enough time for both data lanes and clock lane to go to the low-power mode, as in *Figure 505*.

Figure 503. Clock lane and data lane in HS

Figure 504. Clock lane in HS and data lanes in LP



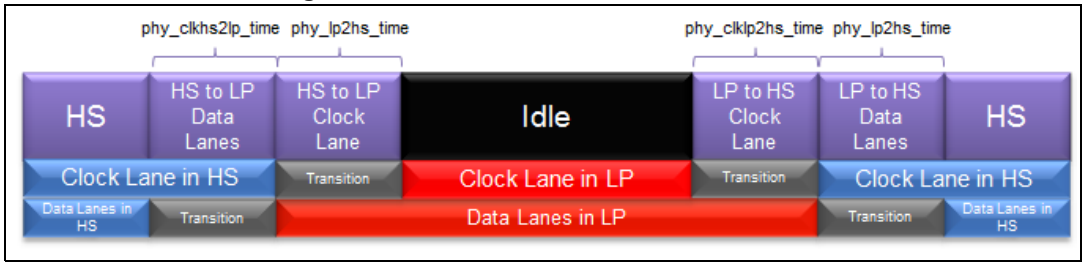


Figure 505. Clock lane and data lane in LP

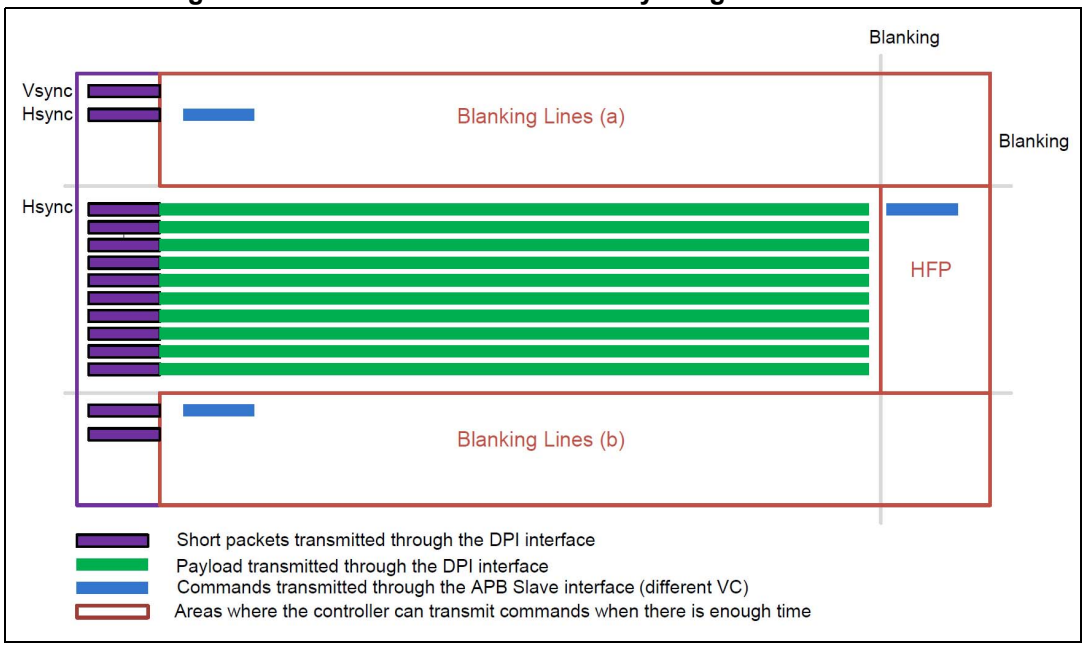

55.10 Functional description: virtual channels

The DSI Host supports choosing the virtual channel (VC) for use for each interface. Using multiple virtual channels, the system can address multiples displays at the same time, when each display has a different virtual channel identifier.

When the LTDC interface is configured for a particular virtual channel, it is possible to use the APB slave generic interface to issue commands while the video stream is transmitted. With this, it is possible to send the commands through the ongoing video stream, addressing different virtual channels, and thus enable the interface with multiple displays. During the video mode, the video stream transmission has the maximum priority. Therefore, the transmission of sideband packets such as those from the generic interface are only transported when there is time available within the video stream transmission. The DSI Host identifies the available time periods and uses them to transport the generic interface packets. *Figure 506* illustrates where the DSI Host inserts the packets from the APB generic interface within the video stream transmitted by the LTDC interface.

Figure 506. Command transmission by the generic interface

It is also possible to address multiple displays with only the generic interface, using different virtual channels. Because the generic interface is not restricted to any particular virtual channel through configuration, it is possible to issue the packets with different virtual channels. This enables the interface to time multiplex the packets to be provided to the displays with different virtual channels.

You can use the following configuration registers to select the virtual channel ID associated with transmissions over the LTDC and APB slave generic interfaces:

- DSI_LVCIDR.VCID field configures the virtual channel ID, indexed to the video mode packets using the LTDC interface.
- DSI_GHCR register configures the packet header (including the virtual channel ID to be used) for transmissions using APB slave generic interface.
- DSI_GVCIDR register configures the virtual channel ID of the read responses to store and return to the generic interface.

55.11 Functional description: video mode pattern generator

The video mode pattern generator allows the transmission of horizontal/vertical color bar and D-PHY BER testing pattern without any stimuli.

The frame requirements must be defined in video registers that are listed in *Table 512*.

Table 512. Frame requirement configuration registers

Register name	Description
DSI Host video mode configuration	Video mode configuration
DSI Host video packet configuration	Video packet size
DSI Host video chunks configuration	Number of chunks
DSI Host video null packet configuration	Null packet size
DSI Host video HSA configuration	Horizontal sync active time
DSI Host video HBP configuration	Horizontal back-porch time
DSI Host video line configuration	Line time
DSI Host video VSA configuration	Vertical sync active period
DSI Host video VBP configuration	Vertical back-porch period
DSI Host video VFP configuration	Vertical front-porch period
DSI Host video VA configuration	Vertical resolution

55.11.1 Color bar pattern

The color bar pattern comprises eight bars for white, yellow, cyan, green, magenta, red, blue, and black colors.

Each color width is calculated by dividing the line pixel size (vertical pattern) or the number of lines (horizontal pattern) by eight. In the vertical color bar mode (*Figure 507*), each single color bar has a width of the number of pixels in a line divided by eight. In case the number of pixels in a line is not divisible by eight, the last color (black) contains the remaining.

In the horizontal color bar mode (*Figure 508*), each color line has a color width of the number of lines in a frame divided by eight. In case the number of lines in a frame is not divisible by eight, the last color (black) contains the remaining lines.

Figure 507. Vertical color bar mode

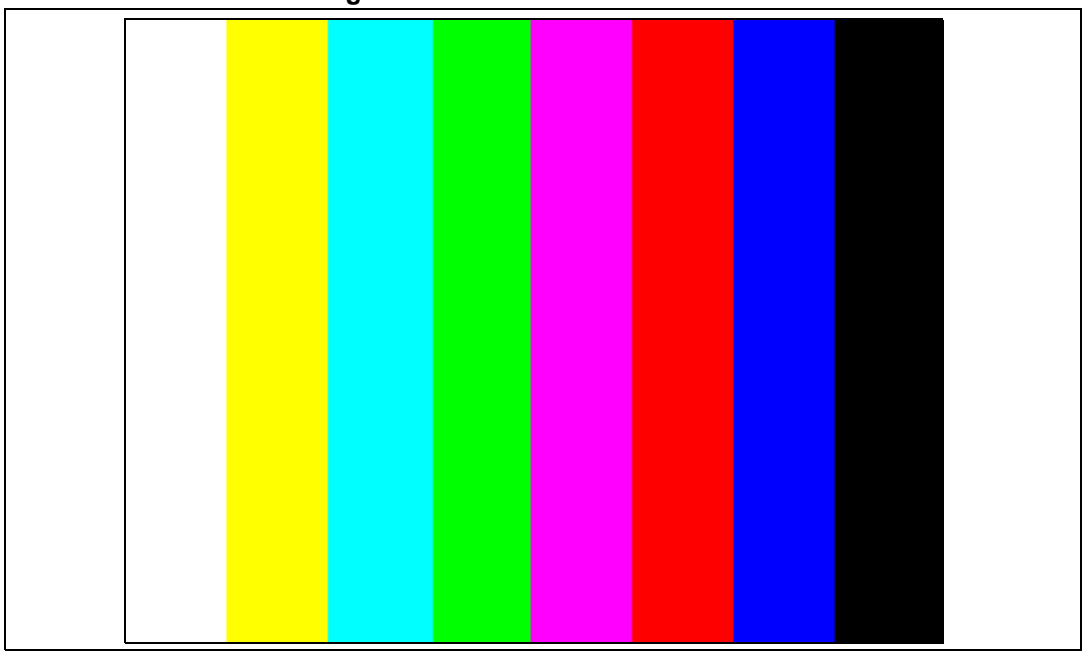

Figure 508. Horizontal color bar mode

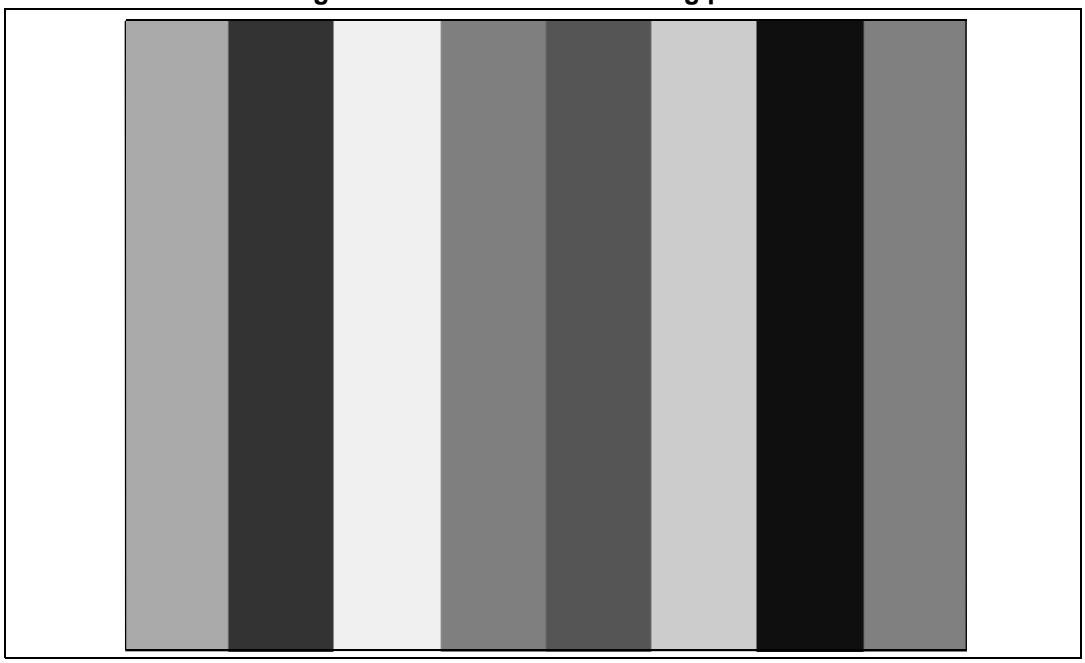
55.11.2 Color coding

Table 513 shows the RGB components used.

Table 513. RGB components

	White	Yellow	Cyan	Green	Magenta	Red	Blue	Black
R	High	High	Low	Low	High	High	Low	Low
G	High	High	High	High	Low	Low	Low	Low
B	High	Low	High	Low	High	Low	High	Low



55.11.3 BER testing pattern

The BER testing pattern simplifies conformance testing. This pattern tests the RX D-PHY capability to receive the data correctly. The following data patterns are required:

- X bytes of 0xAA (high-frequency pattern, inverted)
- X bytes of 0x33 (mid-frequency pattern)
- X bytes of 0xF0 (low-frequency pattern, inverted)
- X bytes of 0x7F (lone 0 pattern)
- X bytes of 0x55 (high-frequency pattern)
- X bytes of 0xCC (mid-frequency pattern, inverted)
- X bytes of 0x0F (low-frequency pattern)
- Y bytes of 0x80 (lone 1 pattern).

In most cases, Y is equal to X. However, depending on line length and the color coding used, Y may be different from X. With RGB888 color coding and horizontal resolution in multiples of eight, the pattern shown in *Figure 509* appears on the DSI display.

Figure 509. RGB888 BER testing pattern

55.11.4 Video mode pattern generator resolution

Depending upon orientation, BER mode, and color coding, the smallest resolutions accepted by the video mode pattern generator are:

- BER mode: 8x8
- horizontal color bar mode: 8x8
- vertical color bar mode: 8x8.

Vertical pattern

The width of each color bar is determined by the division of horizontal resolution (pixels) for eight test pattern colors. If the horizontal resolution is not divisible by eight, the last color (black) is extended to fill the resolution.

In the example in *Figure 510*, the horizontal resolution is 103.

Figure 510. Vertical pattern (103x15)

Horizontal pattern

The width of each color bar is determined by the division of the number of vertical resolution (lines) for eight test pattern colors. If the vertical resolution is not divisible by eight, the last color (black) is extended to fill the resolution, as shown in *Figure 511*.

Figure 511. Horizontal pattern (103x15)

55.12 Functional description: D-PHY management

The embedded MIPI® D-PHY is control directly by the DSI Host and is configured through the DSI Wrapper.

A dedicated PLL and a dedicated 1.2 V regulator are also embedded to supply the clock and the power supply to the DSI and D-PHY.

55.12.1 D-PHY configuration

The D-PHY configuration is carried out through the DSI Wrapper, thanks to the DSI_WPCRx registers.

55.12.2 Special D-PHY operations

The DSI Wrapper features some control bits to force the D-PHY in some particular state and/or behavior.

Forcing lane state

It is possible to force the data lane and/or the clock lane in TX Stop mode through the bits FTXSMDL and FTXSMCL of the DSI_WPCR0 register. Setting these bits causes the respective lane module to immediately jump in transmit control mode, and to begin transmitting a stop state (LP-11).

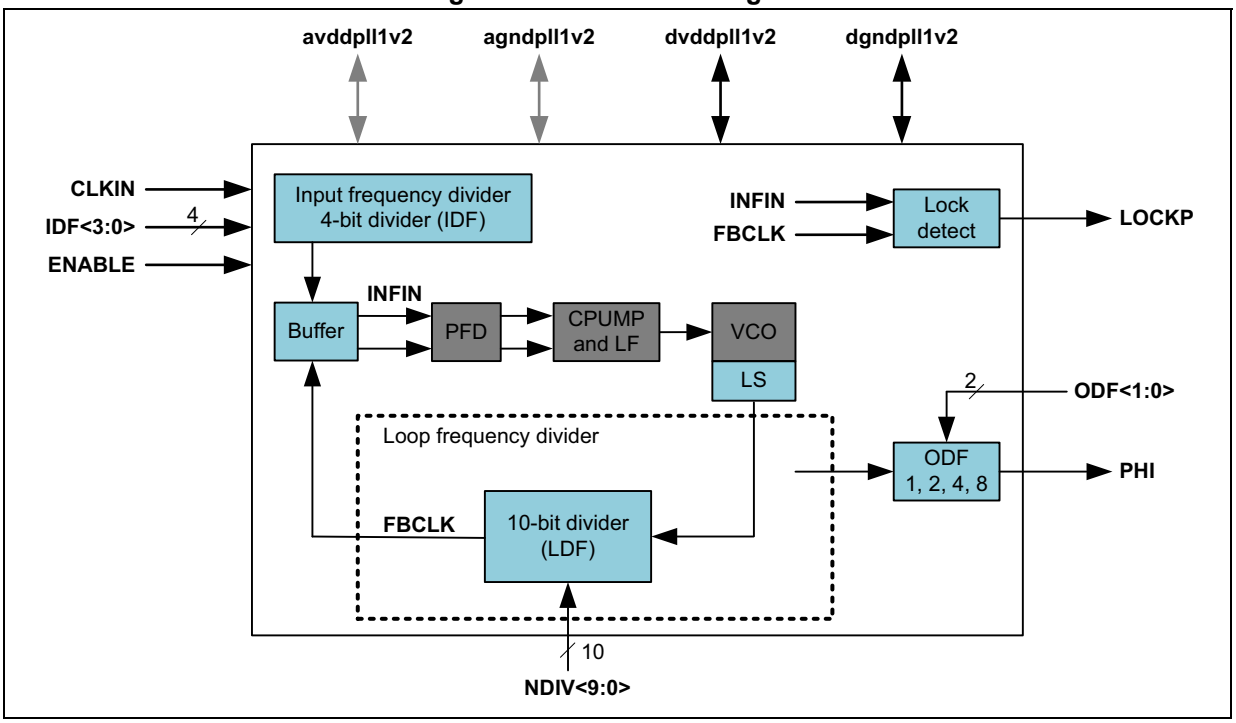
This feature can be used to go back in TX mode after a wrong BTA sequence.

Forcing low-power receiver in low-power mode

The FLPRXLPM bit of the DSI_WPCR1 register enables the low-power mode of the low power receiver (LPRX). When set, the LPRX operates in low-power mode all the time. When not set, the LPRX operates in low-power mode during ULPS only.

Disabling turn of data lane

When set, the TDDL bit of the DSI_WPCR0 register forces the data lane to remain in reception mode even if a bus-turn-around request (BTA) is received from the other side.



55.12.3 Special low-power D-PHY functions

The embedded D-PHY offers specific features to optimize consumption.

55.12.4 DSI PLL control

The dedicated DSI PLL is controlled through the DSI Wrapper, as shown in *Figure 512* (analog blocks and signals in gray, digital signals in black, digital blocks in light blue).

Figure 512. PLL block diagram

By default, the PLL output frequency is configured directly by the PHY, but it can be indirectly configured with shadow registers.

The following settings must be performed:

- bit RST can be used to reset the below settings (RST to be set, then reset)
- fields IDF, NDIV, ODF define the PLL VCO frequency
- field CCF defines the frequency used by the clock used for the PHY configuration (it is the clock defined in the RCC as ck_ker_dsi_phy).
- fields VCO, BIAS, GMP, INT, PROP define the associated regulation
- field SEL = 0x1 selects the PLL output to be the VCO
- field PSC = 1 selects the above settings
- bit UPD must then be used to commit the above settings, to be effectively used by the PLL logic (UPD to be set, then reset)
- bit PLLEN can then be set to globally enable the PLL.

The VCO frequency and the PLL output frequency are calculated as follows:

$$F_{VCO} = (CLK_{IN} / IDF) * NDIV,$$

$$PHI = F_{VCO} / ODF$$

where:

- CLK_{IN} (input reference clock) frequency is in the 17 to 27 MHz range (because it is shared with the configuration clock)
- NDIV (inloop division, = DSI_WRPCR0.NDIV + 2) ranges from 64 to 625
- IDF (input division factor, as DSI_WRPCR0.IDF + 1) ranges from 1 to 16
- INFIN (divided reference clock) ranges from 2 to 8 MHz
- F_{VCO} is in the 320 to 1250 MHz range

- ODF (output division factor) can be 2, 4, or 8 (division by 1 is not possible)
- F_{PHI} is in the 40 to 1250 MHz range

Note: The DSI-PHY uses a clock running at half the bitrate frequency. For instance, for a DSI transmission with 1 Gbps on the data lanes (500 MHz on the clock lane), the PLL must have the output of the PLL and PHI at 500 MHz. And, because the ODF divides by a minimum factor 2, the F_{VCO} must run at least at 1 GHz.

The regulation fields (VCO, BIAS, GMP, INT, PROP) are defined based on the targeted PHI frequency, according to *Table 514*.

Table 514. PLL regulation settings in function of the target frequency

PHI frequency range (MHz)	ODF field(1)	VCO field	BIAS field	GMP field	INT field	PROP field
1150-1250	00	0001	0010000	01	000000	001100

1. Cycles from txrequesthsclk are asserted until PHY starts driving high-speed clock signal in clock lane (toggling HS-0/HS-1).
2. Cycles from txrequesthsclk are de-asserted until PHY drives LP11 internally in clock lane.
3. Cycles from txrequesthsclk are asserted until payload data starts to be transmitted in the data lanes (if txrequestdatahs is asserted when ClockLane is already toggling).
4. Cycles from stopstate_n are asserted until PHY is ready to receive a new txrequestdatahs request. Because of internal synchronization, DataLane0 stopstate signal is asserted later than the other data lanes, so the 67 byteclk cycles minimum requirement for 2.5 Gbps can be taken in consideration only for the other enabled datalanes stopstate_n signals. This is not needed when single data/clock lane are used: the new request can be done immediately after txreadyhs_n de-assertion.

55.13 Functional description: interrupts and errors

The interrupts can be generated either by the DSI Host or by the DSI Wrapper.

All the interrupts are merged in one interrupt lane, going to the interrupt controller.

55.13.1 DSI Wrapper interrupts

An interrupt can be produced on the following events:

- tearing effect event
- end of refresh
- PLL locked
- PLL unlocked

Separate interrupt enable bits are available for flexibility.

Table 516. DSI Wrapper interrupt requests

Interrupt event	Event flag in DSI_WISR	Enable control bit in DSI_WIER
Tearing effect	TEIF	TEIE
End of refresh	ERIF	ERIE
PLL locked	PLLLIF	PLLLIE
PLL unlocked	PLLUIF	PLLUIE

55.13.2 DSI Host interrupts and errors

The DSI_ISR0 and DSI_ISR1 registers are associated with error condition reporting. These registers can trigger an interrupt to inform the system about the occurrence of errors.

The DSI Host has one interrupt line, set high when an error occurs in either the DSI_ISR0 or the DSI_ISR1 register.

The triggering of the interrupt can be masked by programming the mask registers DSI_IER0 and DSI_IER1. By default all errors are masked. When any bit of these registers is set to 1, it enables the interrupt for a specific error. The error bit is always set in the respective DSI_ISR register. The DSI_ISR0 and DSI_ISR1 registers are always cleared after a read operation. The interrupt line is cleared if all registers that caused the interrupt are read.

The interrupt force registers (DSI_FIR0 and DSI_FIR1) are used for test purposes: they allow triggering the interrupt events individually, without the need to activate the conditions that trigger the interrupt sources (it is extremely complex to generate the stimuli for that purpose). This feature also facilitates the development and testing of the software associated with the interrupt events. Setting any bit of these registers to 1 triggers the corresponding interrupt.

The light yellow boxes in *Figure 513* illustrate the location of some of the errors.

Figure 513. Error sources

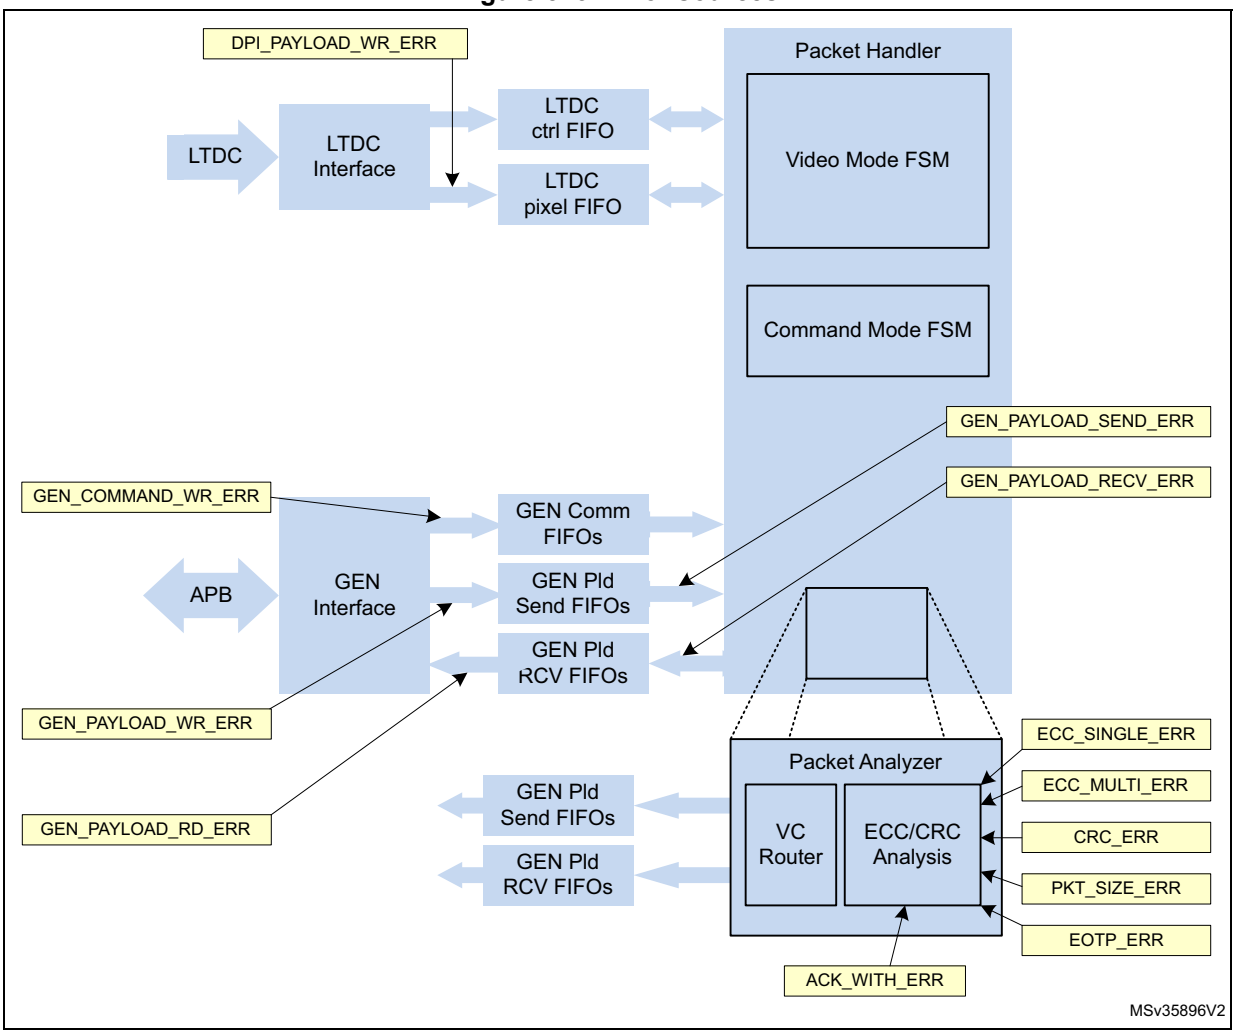

Table 517 explains the reasons that set off these interrupts and also explains how to recover from these interrupts.

Table 517. Error causes and recovery

DSI Host interrupt and status register	Bit	Name	Error cause	Recommended method to handle the error
0	20	PE4	The D-PHY reports the LP1 contention error. The D-PHY host detects the contention while trying to drive the line high.	Recover the D-PHY from contention. Reset the DSI Host and transmit the packets again. If this error is recurrent, carefully analyze the connectivity between the Host and the device.
0	19	PE3	D-PHY reports the LP0 contention error. The D-PHY Host detects the contention while trying to drive the line low.	Recover the D-PHY from contention. Reset the DSI Host and transmit the packets again. If this error is recurrent, carefully analyze the connectivity between the Host and the device.

Table 517. Error causes and recovery (continued)

DSI Host interrupt and status register	Bit	Name	Error cause	Recommended method to handle the error
0	18	PE2	The D-PHY reports the false control error. The D-PHY detects an incorrect line state sequence in lane 0 lines.	Device does not behave as expected, communication with the device is not properly established. This is an unrecoverable error. Reset the DSI Host and the D-PHY. If this error is recurrent, analyze the behavior of the device.
0	17	PE1	The D-PHY reports the LPDT error. The D-PHY detects that the LDPT did not match a multiple of 8 bits.	The data reception is not reliable. The D-PHY recovers but the received data from the device might not be reliable. It is recommended to reset the DSI Host and repeat the RX transmission.
0	16	PE0	The D-PHY reports the escape entry error. The D-PHY does not recognize the received escape entry code.	The D-PHY Host does not recognize the escape entry code. The transmission is ignored. The D-PHY Host recovers but the system must repeat the RX reception.
0	15	AE15	This error is directly retrieved from acknowledge with error packet. The device detected a protocol violation in the reception.	Refer to the display documentation. When this error is active, the device must have another read-back command that reports additional information about this error. Read the additional information and take appropriate actions.
0	14	AE14	The acknowledge with error packet contains this error. The device chooses to use this bit for error report.	Refer to the device documentation regarding possible reasons for this error and take appropriate actions.
0	13	AE13	The acknowledge with error packet contains this error. The device reports that the transmission length does not match the packet length.	Possible reason for this is multiple errors present in the packet header (more than 2), so the error detection fails and the device does not discard the packet. In this case, the packet header is corrupt and can cause decoding mismatches. Transmit the packets again. If this error is recurrent, carefully analyze the connectivity between the Host and the device.
0	12	AE12	The acknowledge with error packet contains this error. The device does not recognize the VC ID in at least one of the received packets.	Possible reason for this is multiple errors present in the packet header (more than 2), so the error detection fails and the device does not discard the packet. In this case, the packet header is corrupt and can cause decoding mismatches. Transmit the packets again. If this error is recurrent, carefully analyze the connectivity between the Host and the device.
0	11	AE11	The acknowledge with error packet contains this error. The device does not recognize the data type of at least one of the received packets.	Check the device capabilities. It is possible that there are some packets not supported by the device. Repeat the transmission.

Table 517. Error causes and recovery (continued)

DSI Host interrupt and status register	Bit	Name	Error cause	Recommended method to handle the error
0	10	AE10	The acknowledge with error packet contains this error. The device detects the CRC errors in at least one of the received packets.	Some of the long packets, transmitted after the last acknowledge request, might contain the CRC errors in the payload. If the payload content is critical, transmit the packets again. If this error is recurrent, carefully analyze the connectivity between the Host and the device.
0	9	AE9	The acknowledge with error packet contains this error. The device detects multi-bit ECC errors in at least one of the received packets.	The device does not interpret the packets transmitted after the last acknowledge request. If the packets are critical, transmit the packets again. If this error is recurrent, carefully analyze the connectivity between the Host and the device.
0	8	AE8	The acknowledge with error packet contains this error. The device detects and corrects the 1 bit ECC error in at least one of the received packets.	No action is required. The device acknowledges the packet. If this error is recurrent, analyze the signal integrity or the noise conditions of the link.
0	7	AE7	The acknowledge with error packet contains this error. The device detects the line Contention through LP0/LP1 detection.	This error might corrupt the low-power data reception and transmission. Ignore the packets and transmit them again. The device recovers automatically. If this error is recurrent, check the device capabilities and the connectivity between the Host and device. Refer to.section 7.2.1 of the DSI Specification 1.1.
0	6	AE6	The acknowledge with error packet contains this error. The device detects the false control error.	The device detects one of the following: – The LP-10 (LP request) is not followed by the remainder of a valid escape or turnaround sequence. – The LP-01 (HS request) is not followed by a bridge state (LP-00). The D-PHY communications are corrupted. This error is unrecoverable. Reset the DSI Host and the D-PHY. Refer to the section 7.1.6 of the DSI Specification 1.1.

Table 517. Error causes and recovery (continued)

DSI Host interrupt and status register	Bit	Name	Error cause	Recommended method to handle the error
0	5	AE5	The acknowledge with error packet contains this error. The display timeout counters for a HS reception and LP transmission expire.	It is possible that the Host and device timeout counters are not correctly configured. The device HS_TX timeout must be shorter than the Host HS_RX timeout. Host LP_RX timeout must be longer than the device LP_TX timeout. Check and confirm that the Host configuration is consistent with the device specifications. This error is automatically recovered, although there is no guarantee that all the packets in the transmission or reception are complete. For additional information about this error, see section 7.2.2 of the DSI Specification 1.1.
0	4	AE4	The acknowledge with error packet contains this error. The device reports that the LPDT is not aligned in an 8-bit boundary	There is no guarantee that the device properly receives the packets. Transmit the packets again. For additional information about this error, see section 7.1.5 of the DSI Specification.
0	3	AE3	The acknowledge with error packet contains this error. The device does not recognize the escape mode entry command.	The device does not recognize the escape mode entry code. Check the device capability. For additional information about this error, see section 7.1.4 of the DSI Specification. Repeat the transmission to the device.
0	2	AE2	The acknowledge with error packet contains this error. The device detects the HS transmission did not end in an 8-bit boundary when the EoT sequence is detected.	There is no guarantee that the device properly received the packets. Re-transmission must be performed. Transmit the packets again. For additional information about this error, see section 7.1.3 of the DSI Specification 1.1.
0	1	AE1	The acknowledge with error packet contains this error. The device detects that the SoT leader sequence is corrupted.	The device discards the incoming transmission. Re-transmission must be performed by the Host. For additional information about this error, see section 7.1.2 of the DSI Specification 1.1.
0	0	AE0	The acknowledge with error packet contains this error. The device reports that the SoT sequence is received with errors but synchronization can still be achieved.	The device is tolerant to single bit and some multi-bit errors in the SoT sequence, but the packet correctness is compromised. If the packet content was important, transmit the packets again. For additional information about this error, see section 7.1.1 of the DSI Specification 1.1.
1	19	PBUE	An underflow occurs in the LTDC payload buffer.	The LTDC frequency is too slow compared to the DSI bandwidth. Increase the LTDC frequency or decrease the DSI bandwidth.

Table 517. Error causes and recovery (continued)

DSI Host interrupt and status register	Bit	Name	Error cause	Recommended method to handle the error
1	12	GPRXE	An overflow occurs in the generic read FIFO.	The read FIFO size is not correctly dimensioned for the maximum read-back packet size. Configure the device to return the read data with a suitable size for the Host dimensioned FIFO. Data stored in the FIFO is corrupted. Reset the DSI Host and repeat the read procedure.
1	11	GPRDE	An underflow occurs in the generic read FIFO.	System does not wait for the read procedure to end and starts retrieving the data from the FIFO. The read data is requested before it is fully received. Data is corrupted. Reset the DSI Host and repeat the read procedure. Check that the read procedure is completed before reading the data through the APB interface.
1	10	GPTXE	An underflow occurs in the generic write payload FIFO.	The system writes the packet header before the respective packet payload is completely loaded into the payload FIFO. This error is unrecoverable, the transmitted packet is corrupted. Reset the DSI Host and repeat the write procedure.
1	9	GPWRE	An overflow occurs in the generic write payload FIFO.	The payload FIFO size is not correctly dimensioned to store the total payload of a long packet. Data stored in the FIFO is corrupted. Reset the DSI Host and repeat the write procedure.
1	8	GCWRE	An overflow occurs in the generic command FIFO.	The command FIFO size is not correctly dimensioned to store the total headers of a burst of packets. Data stored in the FIFO is corrupted. Reset the DSI Host and repeat the write procedure.
1	7	LPWRE	An overflow occurs in the DPI pixel payload FIFO.	The controller FIFO dimensions are not correctly set up for the operating resolution. Check the video mode configuration registers. They must be consistent with the LTDC video resolution. The pixel data sequence is corrupted. Reset the DSI Host and re-initiate the Video transmission.
1	6	EOTPE	Host receives a transmission that does not end with an end of transmission packet.	This error is not critical for the data integrity of the received packets. Check if the device supports the transmission of EoTp packets.

Table 517. Error causes and recovery (continued)

DSI Host interrupt and status register	Bit	Name	Error cause	Recommended method to handle the error
1	5	PSE	Host receives a transmission that does not end in the expected by boundaries.	The integrity of the received data cannot be guaranteed. Reset the DSI Host and repeat the read procedure.
1	4	CRCE	Host reports that a received long packet has a CRC error in its payload.	The received payload data is corrupted. Reset the DSI Host and repeat the read procedure. If this error is recurrent, check the DSI connectivity link for the noise levels.
1	3	ECCME	Host reports that a received packet contains multiple ECC errors.	The received packet is corrupted. The DSI Host ignores all the following packets. The DSI Host must repeat the read procedure.
1	2	ECCSE	Host reports that a received packet contains a single bit error.	This error is not critical because the DSI Host can correct the error and properly decode the packet. If this error is recurrent, check the DSI connectivity link for signal integrity and noise levels.
1	1	TOLPRX	Host reports that the configured timeout counter for the low-power reception has expired.	Once the configured timeout counter ends, the DSI Host automatically resets the controller side and recovers to normal operation. Packet transmissions happening during this event are lost. If this error is recurrent, check the timer configuration for any issue. This timer must be greater than the maximum low-power transmission generated by the device.
1	0	TOHSTX	Host reports that the configured timeout counter for the high-speed transmission has expired.	Once the configured timeout counter ends, the DSI Host automatically resets the controller side and recovers to normal operation. Packet transmissions happening during this event are lost. If this error is recurrent, check the timer configuration for any issue. This timer must be greater than the maximum high-speed transmission bursts generated by the Host.
DSI Wrapper	10	PLLUF	The PLL of the D-PHY has unlocked.	This error can be critical. The graphical subsystem must be reconfigured and restarted.

55.14 Programing procedure

To operate the DSI Host the user must be familiar with the MIPI® DSI specification. Every software programmable register is accessible through the APB interface.

55.14.1 Programing procedure overview

The programming procedure for video mode or adapted command mode must respect the following order:

1. Configure the RCC (refer to the RCC chapter)
   - Enable clock for DSI and LTDC
   - Configure LTDC PLL, turn it ON and wait for its lock
2. Optionally configure the GPIO (if tearing effect requires GPIO usage for example)
3. Optionally valid the ISR
4. Configure the LTDC (refer to the LTDC chapter)
   - Program the panel timings
   - Enable the relevant layers
5. Turn on the DSI bias
6. Configure the DSI PLL, turn it ON and wait for its lock as described in *Section 55.12.4*
7. Configure the D-PHY parameters in the DSI Host, DSI D_PHY and the DSI Wrapper to define D-PHY configuration and timing as detailed in *Section 55.14.2*
8. Configure the DSI Host timings as detailed in *Section 55.14.3*
9. Configure the DSI Host flow control and DBI interface as detailed in *Section 55.14.4*
10. Configure the DSI Host LTDC interface as detailed in *Section 55.14.5*
11. Configure the DSI Host for video mode as detailed in *Section 55.14.6* or adapted command mode as detailed in *Section 55.14.7*
12. Enable the D-PHY setting the DEN bit of the DSI_PCTLR
13. Enable the D-PHY clock lane setting the CKEN bit of the DSI_PCTLR
14. Enable the DSI Host setting the EN bit of the DSI_CR
15. Enable the DSI Wrapper setting the DSIEN bit of the DSI_WCR
16. Optionally send DCS commands through the APB generic interface to configure the display
17. Enable the LTDC in the LTDC
18. Start the LTDC flow through the DSI Wrapper (CR.LTDCEN = 1)

In video mode, the data streaming starts as soon as the LTDC is enabled.

In adapted command mode, the frame buffer update is launched as soon as the CR.LTDCEN bit is set.

55.14.2 Configuring the D-PHY parameters

The D-PHY requires a specific configuration prior starting any communications. The configuration parameters are stored either in the DSI Host or the DSI Wrapper.

Configuring the D-PHY parameters

The D-PHY must be configured to adjust:

- the slew rate for the clock lane through register DSI_DPCSRC
- the slew rate for the data lanes through DSI_DPDL0SRC and DSIDPDL1SRC
- the frequency band for the clock lane through DSI_DPCLBCR
- the frequency band for the data lanes through DSI_DPDL0BCR and DSI_DPBL1BCR

Configuring the D-PHY parameters in the DSI Host

The DSI Host stores the configuration of D-PHY timing parameters and number of lanes.

The following fields must be configured prior to any startup:

- Number of data lanes in the DSI_PCONFR register
- Automatic clock lane control (ACR) in the DSI_CLCR register
- Clock control (DPCC) in the DSI_CLCR register
- Time for LP/HS and HS/LP transitions for both clock lane and data lanes in DSI_CLTCR and DSI_DLTCR registers
- Stop wait time in the DSI_PCONFR register

55.14.3 Configuring the DSI Host timing

All the protocol timing must be configured in the DSI Host.

Clock divider configuration

Two clocks are generated internally

- Timeout clock
- TX escape clock.

The timeout clock is used as the timing unit in the configuration of HS to LP and LP to HS transition error. Its division factor is configured by the timeout clock division (TOCKDIV) field of the DSI Host clock control register (DSI_CCR).

The TX escape clock is used in low-power transmission. Its division factor is configured by the TX escape clock division (TXECKDIV) field of the DSI Host clock control register (DSI_CCR) relatively to the lanebyteclock. Its typical value must be around 20 MHz.

Timeout configuration

The timings for timeout management as described in *Section 55.8* are configured in the DSI Host timeout counter configuration registers (DSI_TCCR0 to DSI_TCCR5).

55.14.4 Configuring flow control and DBI interface

The flow control is configured thanks to the DSI Host protocol configuration register (DSI_PCR). The configuration parameters are the following

- CRC reception enable (CRCRXE bit)
- ECC reception enable (ECCRXE bit)
- BTA enable (BTAE bit)
- EoTp reception enable (ETRXE bit)
- EoTp transmission enable (ETTXE bit)

Their values depend on the protocol to be used for the communication with the DSI display.

The virtual channel ID used for the generic DBI interface must be configured by the virtual channel ID (VCID) field of the DSI Host generic VCID register (DSI_GVCIDR).

All the DCS command, depending on their type, can be transmitted or received either in high-speed or low-power. For each of them, a dedicated configuration bit must be programmed in the DSI Host command mode configuration register (DSI_CMCR).

Acknowledge request for packet or tearing effect event must also be configured in the DSI Host command mode configuration register (DSI_CMCR).

55.14.5 Configuring the DSI Host LTDC interface

As the DSI Host is interface to the system through the LTDC for video mode or adapted command mode, the DSI Wrapper perform a low level interfacing in between.

The parameter programmed into the DSI Wrapper must be aligned with the parameters programmed into the LTDC and the DSI Host.

The following fields must be configured:

- Virtual channel ID in the virtual channel ID (VCID) field of the DSI Host LTDC VCID register (DSI_LVCIDR).
- Color coding (COLC) field of the DSI Host LTDC color coding register (DSI_LCOLCR) and the color multiplexing (COLMUX) in the DSI Wrapper configuration register (DSI_WCFGR).
- If loose packets are used for 18-bit mode, the loosely packet enable (LPE) bit of the DSI Host LTDC color coding register (DSI_LCOLCR) must be set.
- The HSYNC polarity in the HSync polarity (HSP) bit of the DSI Host LTDC polarity configuration register (DSI_LPCR).
- The VSYNC polarity in the VSync polarity (VSP) bit of the DSI Host LTDC polarity configuration register (DSI_LPCR) and in the VSync polarity (VSPOL) bit of the DSI Wrapper configuration register (DSI_WCFGR).
- The DATA ENABLE polarity data enable polarity (DEP) bit of the DSI Host LTDC polarity configuration register (DSI_LPCR).

55.14.6 Configuring the video mode

The video mode configuration defines the behavior of the controller in low-power for command transmission, the type of video transmission (burst or non-burst mode) and the panel horizontal and vertical timing:

- Select the video transmission mode to define how the processor requires the video line to be transported through the DSI link.
  - Configure the low-power transitions in the DSI_VMCR to define the video periods, which are permitted to go to low-power if there is time available to do so.
  - Configure if the controller must request the peripheral acknowledge message at the end of frames (DSI_VMCR.FBTAAE).
  - Configure if commands are to be transmitted in low-power (DSI_VMCR.LPE).
- Select the video mode type
  - Burst mode:

    Configure the video mode type (DSI_VMCR.VMT) with value 2'b1x.

    Configure the video packet size (DSI_VPCR.VPSIZE) with the size of the active line period, measured in pixels.

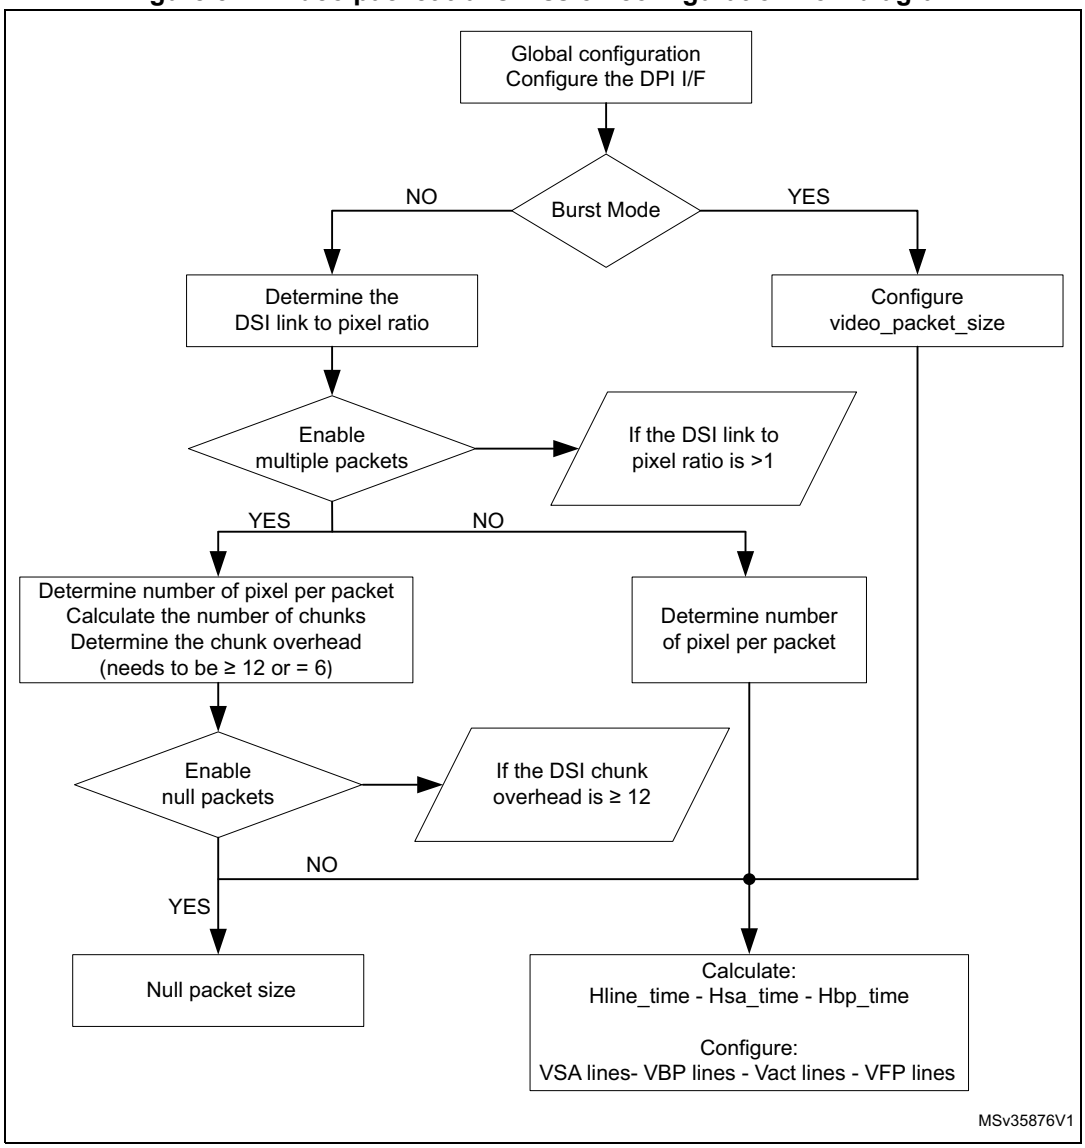
    The registers DSI_VCCR and DSI_VNPCR are ignored by the DSI Host.
  - Non-burst mode:

    Configure the video mode type (DSI_VMCR.VMT) with 2'b00 to enable the transmission of sync pulses or with 2'b01 to enable the transmission of sync events.

    Configure the video packet size (DSI_VPCR.VPSIZE) with the number of pixels to be transmitted in a single packet. Selecting this value depends on the available memory of the attached peripheral, if the data is first stored, or on the memory you want to select for the FIFO in DSI Host.

    Configure the number of chunks (DSI_VCCR.NUMC) with the number of packets to be transmitted per video line. The value of VPSIZE * NUMC is the number of pixels per line of video, except if NUMC is 0, which disables the multi-packets. If you set it to 1, there is still only one packet per line, but it can be part of a chunk, followed by a null packet.

    Configure the null packet size (DSI_VNPCR.NPSIZE) with the size of null packets to be inserted as part of the chunks. Setting it to 0 disables null packets.
- Define the video horizontal timing configuration as follows:
  - Configure the horizontal line time (DSI_VLCR.HLINE) with the time taken by an LTDC video line measured in cycles of lane byte clock (for a clock lane at 500 MHz the lane byte clock period is 8 ns). When the periods of LTDC clock and lane byte clock are not multiples, the value to program the DSI_VLCR.HLINE must be rounded. A timing mismatch is introduced between the lines due to the rounding of configuration values. If the DSI Host is configured not to go to low-power, this timing divergence accumulates on every line, introducing a significant amount of mismatch towards the end of the frame. The reason for this is that the DSI Host cannot re-synchronize on every new line because it transmits the blanking packets when the horizontal sync event occurs on the LTDC interface. However, the accumulated mismatch must become extinct on the last line of a frame, where, according to the DSI specification, the link must always return to low-power regaining synchronization, when a new frame starts on a vertical sync event. If the accumulated timing mismatch is greater than the time in low-power on the last



line, a malfunction occurs. This phenomenon can be avoided by configuring the DSI Host to go to low-power once per line.

  - Configure the horizontal sync duration (DSI_VHSACR.HSA) with the time taken by an LTDC horizontal sync active period measured in cycles of lane byte clock (normally a period of 8 ns).
  - Configure the horizontal back-porch duration (DSI_VHBPCR.HBP) with the time taken by the LTDC horizontal back-porch period measured in cycles of lane byte clock (normally a period of 8 ns). Special attention must be given to the calculation of this parameter.

- Define the vertical line configuration:
  - Configure the vertical sync duration (DSI_VVSACR.VSA) with the number of lines existing in the LTDC vertical sync active period.
  - Configure the vertical back-porch duration (DSI_VVBPCR.VBP) with the number of lines existing in the LTDC vertical back-porch period.
  - Configure the vertical front-porch duration (DSI_VVFPCR.VFP) with the number of lines existing in the LTDC vertical front-porch period.
  - Configure the vertical active duration (DSI_VVACR.VA) with the number of lines existing in the LTDC vertical active period.

Figure 514 illustrates the steps for configuring the DPI packet transmission.

Figure 514. Video packet transmission configuration flow diagram

Example of video configuration

The following is an example of video packet transmission configuration:

Video resolution:

- PCLK period = 50 ns
- HSA = 8 PCLK
- HBP = 8 PCLK
- HACT = 480 PCLK
- HFP = 24 PCLK
- VSA = 2 lines
- VBP = 2 lines
- VACT = 640 lines
- VFP = 4 lines

Configuration steps:

- Video transmission mode configuration:
  a) Configure the low-power transitions:
     DSI_VMCR[13:8] = 6'b111111, to enable LP in all video period.
  b) DSI_VMCR.FBTAAE = 1, for the DSI Host to request an acknowledge response message from the peripheral at the end of each frame.
- To use the burst mode, follow these steps:
  DSI_VMCR.VMT = 2'b1x
  DSI_VPCR.VPSIZE = 480
- Horizontal timing configuration:
  – DSI_VLCR.HLINE =
    (HSA + HBP + HACT + HFP) * (PCLK period / Clk lane byte period) =
    (8 + 8 + 480 + 24) * (50 / 8) = 3250
  – DSI_VHSACR.HSA = HSA * (PCLK period/Clk lane byte period) =
    8 * (50 / 8) = 50
  – DSI_VHBPCR.HBP = HBP * (PCLK period / Clk lane byte period) =
    8 * (50 / 8) = 50
- Vertical line configuration:
  – DSI_VVSACR.VSA = 2
  – DSI_VVBPCR.VBP = 2
  – DSI_VVFPCR.VFP = 4
  – DSI_VVACR.VA = 640

55.14.7 Configuring the adapted command mode

The adapted command mode requires the following parameters to be configured:

- Command size (CMDSIZE) field of the DSI Host LTDC command configuration register (DSI_LCCR) to define the maximum allowed size for a write memory command.
- The tearing effect source (TESRC) and optionally tearing effect polarity (TEPOL) bits of the DSI Wrapper configuration register (DSI_WCFGR).
- The automatic refresh (AR) bit of the DSI Wrapper configuration register (DSI_WCFGR) if the display must be updated automatically each time a tearing effect event is received.

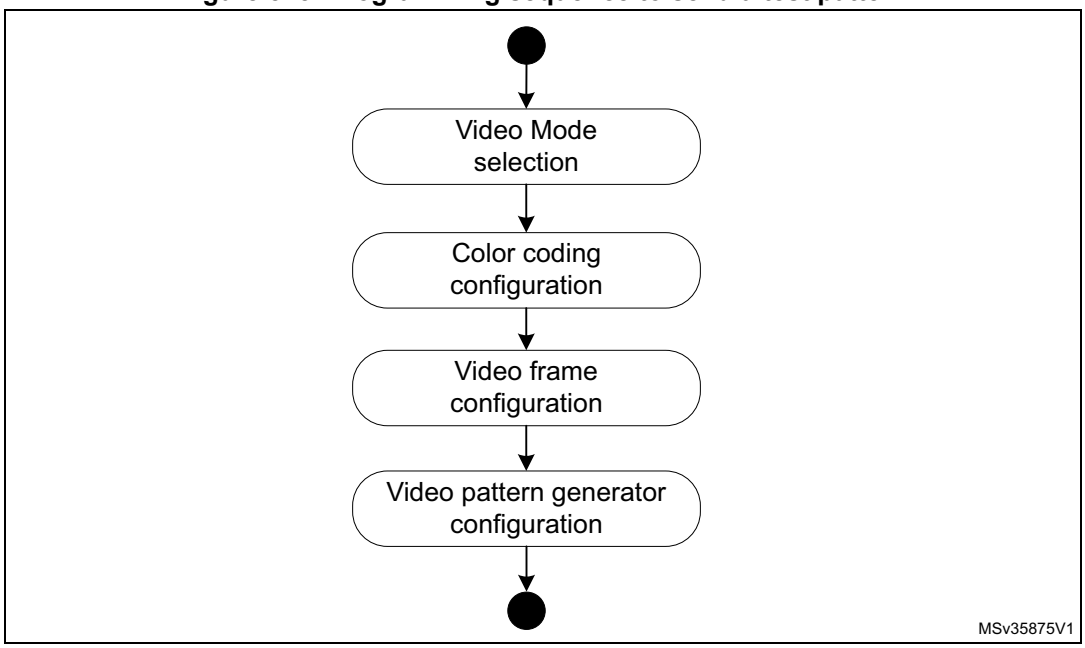
55.14.8 Configuring the video mode pattern generator

DSI Host can transmit a color bar pattern without horizontal/vertical color bar and D-PHY BER testing pattern without any kind of stimuli.

Figure 515 shows the programming sequence to send a test pattern:

1. Configure the DSI_MCR register to enable video mode. Configure the video mode type using DSI_VMCR.VMT.
2. Configure the DSI_LCOLCR register.
3. Configure the frame using registers shown in *Figure 516* (where the gray area indicates the transferred pixels).
4. Configure the pattern generation mode (DSI_VMCR.PGM) and the pattern orientation (DSI_VMCR.PGO), and enable them (DSI_VMCR.PGE).

Figure 515. Programming sequence to send a test pattern



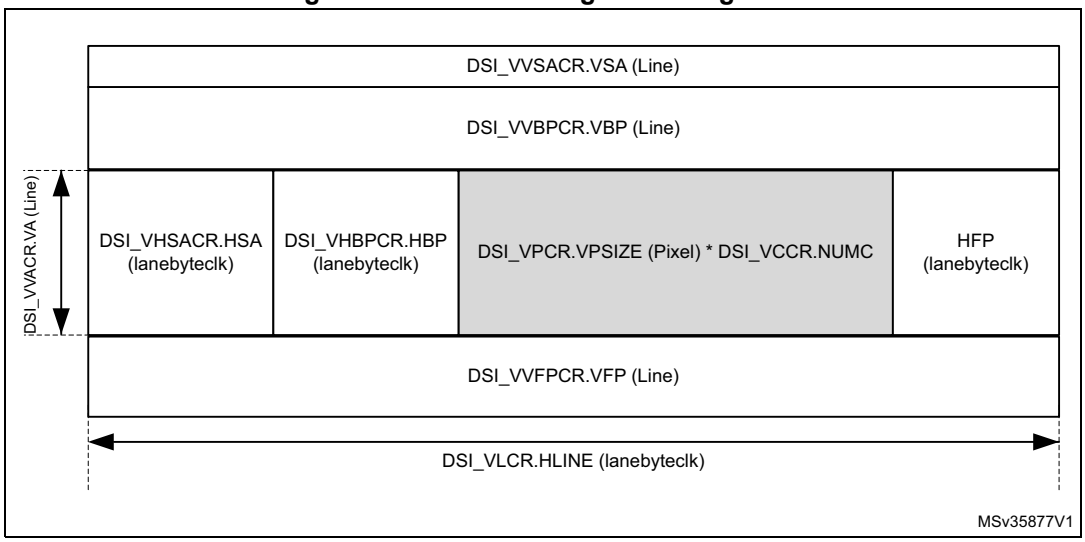


Figure 516. Frame configuration registers

Note: The number of pixels of payload is restricted to a multiple of a value provided in Table 508.

55.14.9 Managing ULPM

There are two ways to configure the software to enter and exit the ULPM:

- enter and exit the ULPM with the D-PHY PLL running (a faster process)
- enter and exit the ULPM with the D-PHY PLL turned off (a more efficient process in terms of power consumption).

Clock management for ULPM sequence

The ULPM management state machine is working on the lanebyteclock provided by the D-PHY.

Because the D-PHY is providing the lanebyteclock only when the clock lane is not in ULPM state, it is mandatory to switch the lanebyteclock source of the DSI Host before starting the ULPM mode entry sequence.

The lanebyteclock source is controlled by the RCC. It can be the lanebyteclock provided by the D-PHY (for all modes except ULPM), or a clock generated by the system PLL (for ULPM).

Flow to enter the ULPM

Implement the flow described in detail in the following procedure to enter the ULPM on both clock lane and data lanes:

1. Verify the initial status of the DSI Host:
   - DSI_PCTLR[2:1] = 2’h3
   - DSI_WRPCR2.PLLEN = 1’h1
   - DSI_PUCR[3:0] = 4'h0
   - DSI_PTTCR[3:0] = 4'h0
   - Verify that all active lanes are in Stop state and the D-PHY PLL is locked:

     One-lane configuration: DSI_PSR[6:4] = 3'h3 and DSI_PSR[1] = 1’h0 and DSI_WISR.PLLS = 1’h1

     Two-lanes configuration: DSI_PSR[8:4] = 5'h1B and DSI_PSR[1] = 1’h0 and DSI_WISR.PLLS = 1’h1
2. Switch the lanebyteclock source in the RCC from D-PHY to system PLL
3. Set DSI_PUCR[3:0] = 4'h5 to enter ULPM in the data and the clock lanes.
4. Wait until the D-PHY active lanes enter into ULPM:
   - One-lane configuration: DSI_PSR[6:1] = 6'h00
   - Two-lanes configuration: DSI_PSR[8:1] = 8'h00

   The DSI Host is now in ULPM.
5. Turn off the D-PHY PLL by setting DSI_WRPCR2.PLLEN = 1'b0

Flow to exit the ULPM

Implement the flow described in the following procedure to exit the ULPM on both clock lane and data lanes:

1. Verify that all active lanes are in ULPM:
   - One-lane configuration: DSI_PSR[6:1] = 6'h00
   - Two-lanes configuration: DSI_PSR[8:1] = 8'h00
2. Turn on the D-PHY PLL by setting DSI_WRPCR2.PLLEN = 1'b1.
3. Wait until D-PHY PLL locked
   - DSI_WISR.PLLS = 1'b1
4. Without de-asserting the ULPM request bits, assert the exit ULPM bits by setting DSI_PUCR[3:0] = 4'hF.
5. Wait until all active lanes exit ULPM:
   - One-lane configuration:

     DSI_PSR[5] = 1'b1

     DSI_PSR[3] = 1'b1
   - Two-lanes configuration:

     DSI_PSR[8] = 1'b1

     DSI_PSR[5] = 1'b1

     DSI_PSR[3] = 1'b1
6. Wait for 1 ms.
7. De-assert the ULPM requests and the ULPM exit bits by setting DSI_PUCR[3:0] = 4'h0.

8. Switch the lanbyteclock source in the RCC from system PLL to D-PHY
9. The DSI Host is now in Stop state and the D-PHY PLL is locked:
   – One-lane configuration:
   DSI_PSR[6:4] = 3'h3
   DSI_PSR[1] = 1'h0
   DSI_WRPCR2.PLLEN = 1'b1
   – Two-lanes configuration:
   DSI_PSR[8:4] = 5'h1B
   DSI_PSR[1] = 1'h0
   DSI_WRPCR2.PLLEN = 1'b1

55.15 DSI Host registers

55.15.1 DSI Host version register (DSI_VR)

Address offset: 0x0000

Reset value: 0x3134 312A

VERSION[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **VERSION[31:0]**: Version of the DSI Host
This read-only register contains the version of the DSI Host

55.15.2 DSI Host control register (DSI_CR)

Address offset: 0x0004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EN
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **EN**: Enable
This bit configures the DSI Host in either power-up mode or to reset.
0: DSI Host disabled (under reset)
1: DSI Host enabled

55.15.3 DSI Host clock control register (DSI_CCR)

Address offset: 0x0008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TOCKDIV[7:0]								TXECKDIV[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **TOCKDIV[7:0]**: Timeout clock division

This field indicates the division factor for the timeout clock used as the timing unit in the configuration of HS to LP and LP to HS transition error.

Bits 7:0 **TXECKDIV[7:0]**: TX escape clock division

This field indicates the division factor for the TX escape clock source (lanebyteclk). The values 0 and 1 stop the TX_ESC clock generation.

55.15.4 DSI Host LTDC VCID register (DSI_LVCIDR)

Address offset: 0x000C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VCID[1:0]	
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **VCID[1:0]**: Virtual channel ID

These bits configure the virtual channel ID for the LTDC interface traffic.

55.15.5 DSI Host LTDC color coding register (DSI_LCOLCR)

Address offset: 0x0010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	LPE	Res.	Res.	Res.	Res.	COLC[3:0]			
							rw					rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **LPE**: Loosely packet enable
Enables the loosely packed variant to 18-bit configuration
0: Loosely packet variant disabled
1: Loosely packet variant enabled

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **COLC[3:0]**: Color coding
This field configures the DPI color coding.
0000: 16-bit configuration 1
0001: 16-bit configuration 2
0010: 16-bit configuration 3
0011: 18-bit configuration 1
0100: 18-bit configuration 2
0101: 24-bit
Others: Reserved

55.15.6 DSI Host LTDC polarity configuration register (DSI_LPCR)

Address offset: 0x0014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSP	VSP	DEP
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **HSP**: HSYNC polarity
This bit configures the polarity of HSYNC pin.
0: HSYNC pin active high (default)
1: VSYNC pin active low

Bit 1 **VSP**: VSYNC polarity
This bit configures the polarity of VSYNC pin.
0: Shutdown pin active high (default)
1: Shutdown pin active low

Bit 0 **DEP**: Data enable polarity
This bit configures the polarity of data enable pin.
0: Data enable pin active high (default)
1: Data enable pin active low

55.15.7 DSI Host low-power mode configuration register (DSI_LPMCR)

Address offset: 0x0018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LPSIZE[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VLPSIZE[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **LPSIZE[7:0]**: Largest packet size

This field is used for the transmission of commands in low-power mode. It defines the size, in bytes, of the largest packet that can fit in a line during VSA, VBP and VFP regions.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **VLPSIZE[7:0]**: VACT largest packet size

This field is used for the transmission of commands in low-power mode. It defines the size, in bytes, of the largest packet that can fit in a line during VACT regions.

55.15.8 DSI Host protocol configuration register (DSI_PCR)

Address offset: 0x002C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CRCRXE	ECCRXE	BTAE	ETRXE	ETTXE
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CRCRXE**: CRC reception enable

Enables the CRC reception and error reporting.
0: CRC reception is disabled.
1: CRC reception is enabled.

Bit 3 **ECCRXE**: ECC reception enable

Enables the ECC reception, error correction and reporting.
0: ECC reception is disabled.
1: ECC reception is enabled.

Bit 2 **BTAE**: Bus-turn-around enable

Enables the bus-turn-around (BTA) request.
0: Bus-turn-around request is disabled.
1: Bus-turn-around request is enabled.

Bit 1 **ETRXE**: EoTp reception enable
Enables the EoTp reception.
0: EoTp reception is disabled.
1: EoTp reception is enabled.

Bit 0 **ETTXE**: EoTp transmission enable
Enables the EoTP transmission.
0: EoTp transmission is disabled.
1: EoTp transmission is enabled.

55.15.9 DSI Host generic VCID register (DSI_GVCIDR)

Address offset: 0x0030

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VCID[1:0]	
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **VCID[1:0]**: Virtual channel ID
This field indicates the generic interface read-back virtual channel identification.

55.15.10 DSI Host mode configuration register (DSI_MCR)

Address offset: 0x0034

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMDM
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **CMDM**: Command mode
This bit configures the DSI Host in either video or command mode.
0: DSI Host is configured in video mode.
1: DSI Host is configured in command mode.

55.15.11 DSI Host video mode configuration register (DSI_VMCR)

Address offset: 0x0038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	PGO	Res.	Res.	Res.	PGM	Res.	Res.	Res.	PGE
							rw				rw				rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LPCE	FBTAAE	LPHFPE	LPHBPE	LPVAE	LPVFPE	LPVBPE	LPVSAE	Res.	Res.	Res.	Res.	Res.	Res.	VMT[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **PGO**: Pattern generator orientation
This bit configures the color bar orientation.
0: Vertical color bars
1: Horizontal color bars

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **PGM**: Pattern generator mode
This bit configures the pattern generator mode.
0: Color bars (horizontal or vertical)
1: BER pattern (vertical only)

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **PGE**: Pattern generator enable
Enables the video mode pattern generator.
0: Pattern generator is disabled
1: Pattern generator is enabled

Bit 15 **LPCE**: Low-power command enable
Enables the command transmission only in low-power mode.
0: Command transmission in low-power mode is disabled
1: Command transmission in low-power mode is enabled

Bit 14 **FBTAAE**: Frame bus-turn-around acknowledge enable
Enables the request for an acknowledge response at the end of a frame.
0: Acknowledge response at the end of a frame is disabled
1: Acknowledge response at the end of a frame is enabled

Bit 13 **LPHFPE**: Low-power horizontal front-porch enable
Enables the return to low-power inside the horizontal front-porch (HFP) period when timing allows.
0: Return to low-power inside the HFP period is disabled
1: Return to low-power inside the HFP period is enabled

Bit 12 **LPHBPE**: Low-power horizontal back-porch enable
Enables the return to low-power inside the horizontal back-porch (HBP) period when timing allows.
0: Return to low-power inside the HBP period is disabled
1: Return to low-power inside the HBP period is enabled

Bit 11 **LPVAE**: Low-power vertical active enable
Enables to return to low-power inside the vertical active (VACT) period when timing allows.
0: Return to low-power inside the VACT is disabled
1: Return to low-power inside the VACT is enabled

Bit 10 **LPVFPE**: Low-power vertical front-porch enable
Enables to return to low-power inside the vertical front-porch (VFP) period when timing allows.
0: Return to low-power inside the VFP is disabled
1: Return to low-power inside the VFP is enabled

Bit 9 **LPVBPE**: Low-power vertical back-porch enable
Enables to return to low-power inside the vertical back-porch (VBP) period when timing allows.
0: Return to low-power inside the VBP is disabled
1: Return to low-power inside the VBP is enabled

Bit 8 **LPVSAE**: Low-power vertical sync active enable
Enables to return to low-power inside the vertical sync time (VSA) period when timing allows.
0: Return to low-power inside the VSA is disabled
1: Return to low-power inside the VSA is enabled

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **VMT[1:0]**: Video mode type
This field configures the video mode transmission type:
00: Non-burst with sync pulses
01: Non-burst with sync events
1x: Burst mode

55.15.12 DSI Host video packet configuration register (DSI_VPCR)

Address offset: 0x003C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	VPSIZE[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:0 **VPSIZE[13:0]**: Video packet size
This field configures the number of pixels in a single video packet.
For 18-bit not loosely packed data types this number must be a multiple of 4.
For YCbCr data types it must be a multiple of 2 as described in the DSI specification.

55.15.13 DSI Host video chunks configuration register (DSI_VCCR)

Address offset: 0x0040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	NUMC[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bits 12:0 **NUMC[12:0]**: Number of chunks

This register configures the number of chunks to be transmitted during a line period (a chunk consists of a video packet and a null packet).

If set to 0 or 1, the video line is transmitted in a single packet.

If set to 1, the packet is part of a chunk, so a null packet follows it if NPSIZE > 0. Otherwise, multiple chunks are used to transmit each video line.

55.15.14 DSI Host video null packet configuration register (DSI_VNPCR)

Address offset: 0x0044

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	NPSIZE[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bits 12:0 **NPSIZE[12:0]**: Null packet size

This field configures the number of bytes inside a null packet.

Setting to 0 disables the null packets.

55.15.15 DSI Host video HSA configuration register (DSI_VHSACR)

Address offset: 0x0048

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HSA[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **HSA[11:0]**: Horizontal synchronism active duration
This fields configures the horizontal synchronism active period in lane byte clock cycles.

55.15.16 DSI Host video HBP configuration register (DSI_VHBPCR)

Address offset: 0x004C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HBP[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **HBP[11:0]**: Horizontal back-porch duration
This fields configures the horizontal back-porch period in lane byte clock cycles.

55.15.17 DSI Host video line configuration register (DSI_VLCR)

Address offset: 0x0050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	HLINE[14:0]														
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **HLINE[14:0]**: Horizontal line duration
This fields configures the total of the horizontal line period (HSA+HBP+HACT+HFP) counted in lane byte clock cycles.

55.15.18 DSI Host video VSA configuration register (DSI_VVSACR)

Address offset: 0x0054

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	VSA[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **VSA[9:0]**: Vertical synchronism active duration

This fields configures the vertical synchronism active period measured in number of horizontal lines.

55.15.19 DSI Host video VBP configuration register (DSI_VVBPCR)

Address offset: 0x0058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	VBP[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **VBP[9:0]**: Vertical back-porch duration

This fields configures the vertical back-porch period measured in number of horizontal lines.

55.15.20 DSI Host video VFP configuration register (DSI_VVFPCR)

Address offset: 0x005C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	VFP[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **VFP[9:0]**: Vertical front-porch duration

This fields configures the vertical front-porch period measured in number of horizontal lines.

55.15.21 DSI Host video VA configuration register (DSI_VVACR)

Address offset: 0x0060

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	VA[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:0 **VA[13:0]**: Vertical active duration

This fields configures the vertical active period measured in number of horizontal lines.

55.15.22 DSI Host LTDC command configuration register (DSI_LCCR)

Address offset: 0x0064

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMDSIZE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CMDSIZE[15:0]**: Command size

This field configures the maximum allowed size for an LTDC write memory command, measured in pixels. Automatic partitioning of data obtained from LTDC is permanently enabled.

55.15.23 DSI Host command mode configuration register (DSI_CMCR)

Address offset: 0x0068

Reset value: 0x0000 0000

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **MRDPS**: Maximum read packet size
This bit configures the maximum read packet size command transmission type:
0: High-speed
1: Low-power

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **DLWTX**: DCS long write transmission
This bit configures the DCS long write packet command transmission type:
0: High-speed
1: Low-power

Bit 18 **DSR0TX**: DCS short read zero parameter transmission
This bit configures the DCS short read packet with zero parameter command transmission type:
0: High-speed
1: Low-power

Bit 17 **DSW1TX**: DCS short read one parameter transmission
This bit configures the DCS short read packet with one parameter command transmission type:
0: High-speed
1: Low-power

Bit 16 **DSW0TX**: DCS short write zero parameter transmission
This bit configures the DCS short write packet with zero parameter command transmission type:
0: High-speed
1: Low-power

Bit 15 Reserved, must be kept at reset value.

Bit 14 **GLWTX**: Generic long write transmission
This bit configures the generic long write packet command transmission type :
0: High-speed
1: Low-power

Bit 13 **GSR2TX**: Generic short read two parameters transmission
This bit configures the generic short read packet with two parameters command transmission type:
0: High-speed
1: Low-power

Bit 12 **GSR1TX**: Generic short read one parameters transmission
This bit configures the generic short read packet with one parameters command transmission type:
0: High-speed
1: Low-power

Bit 11 **GSR0TX**: Generic short read zero parameters transmission
This bit configures the generic short read packet with zero parameters command transmission type:
0: High-speed
1: Low-power

Bit 10 **GSW2TX**: Generic short write two parameters transmission
This bit configures the generic short write packet with two parameters command transmission type:
0: High-speed
1: Low-power

Bit 9 **GSW1TX**: Generic short write one parameters transmission
This bit configures the generic short write packet with one parameters command transmission type:
0: High-speed
1: Low-power

Bit 8 **GSW0TX**: Generic short write zero parameters transmission
This bit configures the generic short write packet with zero parameters command transmission type:
0: High-speed
1: Low-power

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **ARE**: Acknowledge request enable
Enables the acknowledge request after each packet transmission:
0: Acknowledge request is disabled
1: Acknowledge request is enabled

Bit 0 **TEARE**: Tearing effect acknowledge request enable
Enables the tearing effect acknowledge request:
0: Tearing effect acknowledge request is disabled
1: Tearing effect acknowledge request is enabled

55.15.24 DSI Host generic header configuration register (DSI_GHCR)

Address offset: 0x006C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WCMSB[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WCLSB[7:0]								VCID[1:0]		DT[5:0]					
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **WCMSB[7:0]**: WordCount MSB
This field configures the most significant byte of the header packet's word count for long packets, or data 1 for short packets.

Bits 15:8 **WCLSB[7:0]**: WordCount LSB
This field configures the less significant byte of the header packet word count for long packets, or data 0 for short packets.

Bits 7:6 **VCID[1:0]**: Channel
This field configures the virtual channel ID of the header packet.

Bits 5:0 **DT[5:0]**: Type
This field configures the packet data type of the header packet.

55.15.25 DSI Host generic payload data register (DSI_GPDR)

Address offset: 0x0070

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA4[7:0]								DATA3[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA2[7:0]								DATA1[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **DATA4[7:0]**: Payload byte 4
This field indicates byte 4 of the packet payload.

Bits 23:16 **DATA3[7:0]**: Payload byte 3
This field indicates byte 3 of the packet payload.

Bits 15:8 **DATA2[7:0]**: Payload byte 2
This field indicates byte 2 of the packet payload.

Bits 7:0 **DATA1[7:0]**: Payload byte 1
This field indicates byte 1 of the packet payload.

55.15.26 DSI Host generic packet status register (DSI_GPSR)

Address offset: 0x0074

Reset value: 0x0005 0015

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RCB	PRDFF	PRDFE	PWRFF	PWRFE	CMDFF	CMDFE
									r	r	r	r	r	r	r

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **RCB**: Read command busy
This bit is set when a read command is issued and cleared when the entire response is stored in the FIFO:
0: No read command ongoing
1: Read command ongoing

Bit 5 **PRDFF**: Payload read FIFO full
Indicates the full status of the generic read payload FIFO:
0: Read payload FIFO not full
1: Read payload FIFO full

Bit 4 **PRDFE**: Payload read FIFO empty
Indicates the empty status of the generic read payload FIFO:
0: Read payload FIFO not empty
1: Read payload FIFO empty

Bit 3 **PWRFF**: Payload write FIFO full
Indicates the full status of the generic write payload FIFO:
0: Write payload FIFO not full
1: Write payload FIFO full

Bit 2 **PWRFE**: Payload write FIFO empty
Indicates the empty status of the generic write payload FIFO:
0: Write payload FIFO not empty
1: Write payload FIFO empty

Bit 1 **CMDFF**: Command FIFO full
Indicates the full status of the generic command FIFO:
0: Write payload FIFO not full
1: Write payload FIFO full

Bit 0 **CMDFE**: Command FIFO empty
Indicates the empty status of the generic command FIFO:
0: Write payload FIFO not empty
1: Write payload FIFO empty

55.15.27 DSI Host timeout counter configuration register 0 (DSI_TCCR0)

Address offset: 0x0078

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HSTX_TOCNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LPRX_TOCNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **HSTX_TOCNT[15:0]**: High-speed transmission timeout counter
This field configures the timeout counter that triggers a high-speed transmission timeout contention detection (measured in TOCKDIV cycles).
If using the non-burst mode and there is no enough time to switch from high-speed to low-power and back in the period from one line data finishing to the next line sync start, the DSI link returns the low-power state once per frame, then configure the TOCKDIV and HSTX_TOCNT to be in accordance with:
HSTX_TOCNT * lanebyteclkperiod * TOCKDIV ≥ the time of one FRAME data transmission * (1 + 10%)
In burst mode, RGB pixel packets are time-compressed, leaving more time during a scan line. Therefore, if in burst mode and there is enough time to switch from high-speed to low-power and back in the period from one line data finishing to the next line sync start, the DSI link can return low-power mode and back in this time interval to save power. For this, configure the TOCKDIV and HSTX_TOCNT to be in accordance with:
HSTX_TOCNT * lanebyteclkperiod * TOCKDIV ≥ the time of one LINE data transmission * (1 + 10%)

Bits 15:0 **LPRX_TOCNT[15:0]**: Low-power reception timeout counter

This field configures the timeout counter that triggers a low-power reception timeout contention detection (measured in TOCKDIV cycles).

55.15.28 DSI Host timeout counter configuration register 1 (DSI_TCCR1)

Address offset: 0x007C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

HSRD_TOCNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HSRD_TOCNT[15:0]**: High-speed read timeout counter

This field sets a period for which the DSI Host keeps the link still, after sending a high-speed read operation. This period is measured in cycles of lanebyteclk. The counting starts when the D-PHY enters the Stop state and causes no interrupts.

55.15.29 DSI Host timeout counter configuration register 2 (DSI_TCCR2)

Address offset: 0x0080

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

LPRD_TOCNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LPRD_TOCNT[15:0]**: Low-power read timeout counter

This field sets a period for which the DSI Host keeps the link still, after sending a low-power read operation. This period is measured in cycles of lanebyteclk. The counting starts when the D-PHY enters the Stop state and causes no interrupts.

55.15.30 DSI Host timeout counter configuration register 3 (DSI_TCCR3)

Address offset: 0x0084

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	PM	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							rw								

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HSWR_TOCNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **PM**: Presp mode

When set to 1, this bit ensures that the peripheral response timeout caused by HSWR_TOCNT is used only once per LTDC frame in command mode, when both the following conditions are met:

– dpivsync_edpiwms has risen and fallen.

– Packets originated from LTDC in command mode have been transmitted and its FIFO is empty again.

In this scenario no non-LTDC command requests are sent to the D-PHY, even if there is traffic from generic interface ready to be sent, making it return to stop state. When it does so, PRESP_TO counter is activated and only when it finishes does the controller send any other traffic that is ready.

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:0 **HSWR_TOCNT[15:0]**: High-speed write timeout counter

This field sets a period for which the DSI Host keeps the link inactive after sending a high-speed write operation. This period is measured in cycles of lanebyteclk. The counting starts when the D-PHY enters the Stop state and causes no interrupts.

55.15.31 DSI Host timeout counter configuration register 4 (DSI_TCCR4)

Address offset: 0x0088

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BTA_TOCNT[15:0]**: Bus-turn-around timeout counter

This field sets a period for which the DSI Host keeps the link still, after completing a bus-turn-around. This period is measured in cycles of lanebyteclk. The counting starts when the D-PHY enters the Stop state and causes no interrupts.

55.15.33 DSI Host 3D configuration register (DSI_TDCR)

Address offset: 0x0090

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RF	SVS	F3D[1:0]		M3D[1:0]	
										rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **S3DC**: Send 3D control

When set, causes the next VSS packet to include 3D control payload in every VSS packet.

Bits 15:6 Reserved, must be kept at reset value.

Bit 5 **RF**: Right first

This bit defines the left or right order:

0: Left eye data is sent first, and then the right eye data is sent.

1: Right eye data is sent first, and then the left eye data is sent.

Bit 4 **SVS**: Second VSYNC

This field defines whether there is a second VSYNC pulse between left and right images, when 3D image format is frame-based:

0: No sync pulses between left and right data.

1: Sync pulse (HSYNC, VSYNC, blanking) between left and right data.

Bits 3:2 **F3D[1:0]**: 3D format
This field defines the 3D image format:
00: Line (alternating lines of left and right data)
01: Frame (alternating frames of left and right data)
10: Pixel (alternating pixels of left and right data)
11: Reserved

Bits 1:0 **M3D[1:0]**: 3D mode
This field defines the 3D mode on/off and display orientation:
00: 3D mode off (2D mode on)
01: 3D mode on, portrait orientation
10: 3D mode on, landscape orientation
11: Reserved

55.15.34 DSI Host clock lane configuration register (DSI_CLCR)

Address offset: 0x0094

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **ACR**: Automatic clock lane control
Enables the automatic mechanism to stop providing clock in the clock lane when time allows.
0: Automatic clock lane control disabled
1: Automatic clock lane control enabled

Bit 0 **DPCC**: D-PHY clock control
This bit controls the D-PHY clock state:
0: Clock lane is in low-power mode
1: Clock lane runs in high-speed mode

55.15.35 DSI Host clock lane timer configuration register (DSI_CLTCR)

Address offset: 0x0098

Reset value: 0x0000 0000

						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:16 **HS2LP_TIME[9:0]**: High-speed to low-power time

This field configures the maximum time that the D-PHY clock lane takes to go from high-speed to low-power transmission measured in lane byte clock cycles.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **LP2HS_TIME[9:0]**: Low-power to high-speed time

This field configures the maximum time that the D-PHY clock lane takes to go from low-power to high-speed transmission measured in lane byte clock cycles.

55.15.36 DSI Host data lane timer configuration register (DSI_DLTCR)

Address offset: 0x009C

Reset value: 0x0000 0000

												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **UCKEN**: ULPS clock enable
Enables the D-PHY PLL clock when in ULPS mode:
0: D-PHY clock lane module is disabled when in ULPS mode
1: D-PHY clock lane module is enabled when in ULPS mode

Bit 2 **CKEN**: Clock enable
Enables the D-PHY clock lane module:
0: D-PHY clock lane module is disabled
1: D-PHY clock lane module is enabled

Bit 1 **DEN**: Digital enable
When set to 0, this bit places the digital section of the D-PHY in the reset state
0: The digital section of the D-PHY is in the reset state
1: The digital section of the D-PHY is enabled

Bit 0 **PWEN**: Power enable
When set to 0, this bit places the complete D-PHY in the power-down state
0: The complete D-PHY is in the power-down state
1: The complete D-PHY is enabled

55.15.38 DSI Host PHY configuration register (DSI_PCONFR)

Address offset: 0x00A4

Reset value: 0x0000 0011

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **SW_TIME[7:0]**: Stop wait time
This field configures the minimum wait period to request a high-speed transmission after the Stop state.

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **NL[1:0]**: Number of lanes
This field configures the number of active data lanes:
00: One data lane (0)
01: Two data lanes (0 and 1)
10: Three data lanes (0, 1 and 2)
11: Four data lanes (0, 1, 2 and 3) - Reset value

55.15.39 DSI Host PHY ULPS control register (DSI_PUCR)

Address offset: 0x00A8

Reset value: 0x0000 0000

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **UEDL**: ULPS exit on data lane
ULPS mode exit on all active data lanes.
0: No exit request
1: Exit ULPS mode on all active data lane URDL

Bit 2 **URDL**: ULPS request on data lane
ULPS mode request on all active data lanes.
0: No ULPS request
1: Request ULPS mode on all active data lane UECL

Bit 1 **UECL**: ULPS exit on clock lane
ULPS mode exit on clock lane.
0: No exit request
1: Exit ULPS mode on clock lane

Bit 0 **URCL**: ULPS request on clock lane
ULPS mode request on clock lane.
0: No ULPS request
1: Request ULPS mode on clock lane

55.15.40 DSI Host PHY TX triggers configuration register (DSI_PTTCR)

Address offset: 0x00AC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TX_TRIG[3:0]			
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **TX_TRIG[3:0]**: Transmission trigger
Escape mode transmit trigger 0-3.
Only one bit of TX_TRIG is asserted at any given time.

55.15.41 DSI Host PHY status register (DSI_PSR)

Address offset: 0x00B0

Reset value: 0x0000 1528

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	UAN3	PSS3	UAN2	PSS2	UAN1	PSS1	RUE0	UAN0	PSS0	UANC	PSSC	PD	PL
			r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **UAN3**: ULPS active not lane 3
Indicates the status of ulpsactivenot1lane D-PHY signal.

Bit 11 **PSS3**: PHY stop state lane 3
Indicates the status of phystopstate1lane D-PHY signal.

Bit 10 **UAN2**: ULPS active not lane 2
Indicates the status of ulpsactivenot1lane D-PHY signal.

Bit 9 **PSS2**: PHY stop state lane 2
Indicates the status of phystopstate1lane D-PHY signal.

Bit 8 **UAN1**: ULPS active not lane 1
Indicates the status of ulpsactivenot1lane D-PHY signal.

Bit 7 **PSS1**: PHY stop state lane 1
Indicates the status of phystopstate1lane D-PHY signal.

Bit 6 **RUE0**: RX ULPS escape lane 0
Indicates the status of rxulpsesc0lane D-PHY signal.

Bit 5 **UAN0**: ULPS active not lane 0
Indicates the status of ulpsactivenot0lane D-PHY signal.

Bit 4 **PSS0**: PHY stop state lane 0
Indicates the status of phystopstate0lane D-PHY signal.

Bit 3 **UANC**: ULPS active not clock lane
Indicates the status of ulpsactivenotclklane D-PHY signal.

Bit 2 **PSSC**: PHY stop state clock lane
Indicates the status of phystopstateclklane D-PHY signal.

Bit 1 **PD**: PHY direction
Indicates the status of phydirection D-PHY signal.

Bit 0 **PL**: PHY direction
Indicates the status of rxulpsesc0lane D-PHY signal.

55.15.42 DSI Host PHY test control register 0 (DSI_PTCR0)

Address offset: 0x00B4

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TCKEN	TRSEN
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **TCKEN**: Test-interface clock enable for the TDI bus into the PHY:
0: D-PHY test clock is disabled
1: D-PHY test clock is enabled

Bit 0 **TRSEN**: Test-interface reset enable for the TDI bus into the D-PHY:
0: D-PHY test interface is available
1: D-PHY test interface is reset (reset value)

55.15.43 DSI Host PHY test control register 1 (DSI_PTCR1)

Address offset: 0x00B8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TWM
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TDO[7:0]								TDI[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **TWM**: Test write mode, selects the test write access performed to the D-PHY:
0: the data write operation is set on the rising edge of the test clock signal
1: the address write operation is set on the falling edge of the test clock signal

Bits 15:8 **TDO[7:0]**: Test data out
This field configures the TESTDOUT test bus sent to the D-PHY.

Bits 7:0 **TDI[7:0]**: Test data in
This field configures the TESTDIN bus returning from the D-PHY.

55.15.44 DSI Host interrupt and status register 0 (DSI_ISR0)

Address offset: 0x00BC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PE4	PE3	PE2	PE1	PE0
											r	r	r	r	r

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **PE4**: PHY error 4
Indicates the LP1 contention error ErrContentionLP1 from lane 0.

Bit 19 **PE3**: PHY error 3
Indicates the LP0 contention error ErrContentionLP0 from lane 0.

Bit 18 **PE2**: PHY error 2
Indicates the ErrControl error from lane 0.

Bit 17 **PE1**: PHY error 1
Indicates the ErrSyncEsc low-power transmission synchronization error from lane 0.

Bit 16 **PE0**: PHY error 0
Indicates the ErrEsc escape entry error from lane 0.

Bit 15 **AE15**: Acknowledge error 15
Retrieves the DSI protocol violation from the acknowledge error report.

Bit 14 **AE14**: Acknowledge error 14
Retrieves the reserved (specific to the device) from the acknowledge error report.

Bit 13 **AE13**: Acknowledge error 13
Retrieves the invalid transmission length from the acknowledge error report.

Bit 12 **AE12**: Acknowledge error 12
Retrieves the DSI VC ID Invalid from the acknowledge error report.

Bit 11 **AE11**: Acknowledge error 11
Retrieves the not recognized DSI data type from the acknowledge error report.

Bit 10 **AE10**: Acknowledge error 10
Retrieves the checksum error (long packet only) from the acknowledge error report.

Bit 9 **AE9**: Acknowledge error 9
Retrieves the ECC error, multi-bit (detected, not corrected) from the acknowledge error report.

Bit 8 **AE8**: Acknowledge error 8
Retrieves the ECC error, single-bit (detected and corrected) from the acknowledge error report.

Bit 7 **AE7**: Acknowledge error 7
Retrieves the reserved (specific to the device) from the acknowledge error report.

Bit 6 **AE6**: Acknowledge error 6
Retrieves the false control error from the acknowledge error report.

Bit 5 **AE5**: Acknowledge error 5
Retrieves the peripheral timeout error from the acknowledge error report.

Bit 4 **AE4**: Acknowledge error 4
Retrieves the LP transmit sync error from the acknowledge error report.

Bit 3 **AE3**: Acknowledge error 3
Retrieves the escape mode entry command error from the acknowledge error report.

Bit 2 **AE2**: Acknowledge error 2
Retrieves the EoT sync error from the acknowledge error report.

Bit 1 **AE1**: Acknowledge error 1
Retrieves the SoT sync error from the acknowledge error report.

Bit 0 **AE0**: Acknowledge error 0
Retrieves the SoT error from the acknowledge error report.

55.15.45 DSI Host interrupt and status register 1 (DSI_ISR1)

Address offset: 0x00C0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TEE	VMPUE	Res.	DICE	DROE
											r	r		r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DRUE	DDFFE	DCFFE	GPRXE	GPRDE	GPTXE	GPWRE	GCWRE	LPWRE	EOTPE	PSE	CRCE	ECCME	ECCSE	TOLPRX	TOHSTX
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **TEE**: Tear effect error
Indicates that tear_request has occurred, but tear effect is not active in DSI host and device.

Bit 19 **VMPUE**: Video mode underflow error
Indicates that an underflow has occurred when reading payload to build DSI packet for video mode.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **DICE**: DBI illegal command error
Indicates that an attempt to write an illegal command on the DBI interface is made and the controller is blocked by transmission.

Bit 16 **DROE**: DBI read overflow error
Indicates that during a DBI read back packet, the payload FIFO becomes full and the received data is corrupted.

Bit 15 **DRUE**: DCS read underflow error
Indicates that during a DCS read data, the payload FIFO goes empty and the data sent to the interface is corrupted.

Bit 14 **DDFFE**: DBI data FIFO full error
Indicates that the system tried to write the payload data through the DBI interface and the FIFO is full. Therefore, the command is not written.

Bit 13 **DCFFE**: DBI command FIFO full error
Indicates that the system tried to write a command through the DBI but the command FIFO is full. Therefore, the command is not written.

Bit 12 **GPRXE**: Generic payload receive error
Indicates that during a generic interface packet read back, the payload FIFO becomes full and the received data is corrupted.

Bit 11 **GPRDE**: Generic payload read error
Indicates that during a DCS read data, the payload FIFO becomes empty and the data sent to the interface is corrupted.

Bit 10 **GPTXE**: Generic payload transmit error
Indicates that during a generic interface packet build, the payload FIFO becomes empty and corrupt data is sent.

Bit 9 **GPWRE**: Generic payload write error
Indicates that the system tried to write a payload data through the generic interface and the FIFO is full. Therefore, the payload is not written.

Bit 8 **GCWRE**: Generic command write error
Indicates that the system tried to write a command through the generic interface and the FIFO is full. Therefore, the command is not written.

Bit 7 **LPWRE**: LTDC payload write error
Indicates that during a DPI pixel line storage, the payload FIFO becomes full and the data stored is corrupted.

Bit 6 **EOTPE**: EoTp error
Indicates that the EoTp packet is not received at the end of the incoming peripheral transmission.

Bit 5 **PSE**: Packet size error
Indicates that the packet size error is detected during the packet reception.

Bit 4 **CRCE**: CRC error
Indicates that the CRC error is detected in the received packet payload.

Bit 3 **ECCME**: ECC multi-bit error
Indicates that the ECC multiple error is detected in a received packet.

Bit 2 **ECCSE**: ECC single-bit error
Indicates that the ECC single error is detected and corrected in a received packet.

Bit 1 **TOLPRX**: Timeout low-power reception
Indicates that the low-power reception timeout counter reached the end and contention is detected.

Bit 0 **TOHSTX**: Timeout high-speed transmission
Indicates that the high-speed transmission timeout counter reached the end and contention is detected.

55.15.46 DSI Host interrupt enable register 0 (DSI_IER0)

Address offset: 0x00C4

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **PE4IE**: PHY error 4 interrupt enable
Enables the interrupt generation on PHY error 4.
0: Interrupt on PHY error 4 disabled
1: Interrupt on PHY error 4 enabled

Bit 19 **PE3IE**: PHY error 3 interrupt enable
Enables the interrupt generation on PHY error 4.
0: Interrupt on PHY error 3 disabled
1: Interrupt on PHY error 3 enabled

Bit 18 **PE2IE**: PHY error 2 interrupt enable
Enables the interrupt generation on PHY error 2.
0: Interrupt on PHY error 2 disabled
1: Interrupt on PHY error 2 enabled

Bit 17 **PE1IE**: PHY error 1 interrupt enable
Enables the interrupt generation on PHY error 1.
0: Interrupt on PHY error 1 disabled
1: Interrupt on PHY error 1 enabled

Bit 16 **PE0IE**: PHY error 0 interrupt enable
Enables the interrupt generation on PHY error 0.
0: Interrupt on PHY error 0 disabled
1: Interrupt on PHY error 0 enabled

Bit 15 **AE15IE**: Acknowledge error 15 interrupt enable
Enables the interrupt generation on acknowledge error 15.
0: Interrupt on acknowledge error 15 disabled
1: Interrupt on acknowledge error 15 enabled

Bit 14 **AE14IE**: Acknowledge error 14 interrupt enable
Enables the interrupt generation on acknowledge error 14.
0: Interrupt on acknowledge error 14 disabled
1: Interrupt on acknowledge error 14 enabled

Bit 13 **AE13IE**: Acknowledge error 13 interrupt enable
Enables the interrupt generation on acknowledge error 13.
0: Interrupt on acknowledge error 13 disabled
1: Interrupt on acknowledge error 13 enabled

Bit 12 **AE12IE**: Acknowledge error 12 interrupt enable
Enables the interrupt generation on acknowledge error 12.
0: Interrupt on acknowledge error 12 disabled
1: Interrupt on acknowledge error 12 enabled

Bit 11 **AE11IE**: Acknowledge error 11 interrupt enable
Enables the interrupt generation on acknowledge error 11.
0: Interrupt on acknowledge error 11 disabled
1: Interrupt on acknowledge error 11 enabled

Bit 10 **AE10IE**: Acknowledge error 10 interrupt enable
Enables the interrupt generation on acknowledge error 10.
0: Interrupt on acknowledge error 10 disabled
1: Interrupt on acknowledge error 10 enable.

Bit 9 **AE9IE**: Acknowledge error 9 interrupt enable
Enables the interrupt generation on acknowledge error 9.
0: Interrupt on acknowledge error 9 disabled
1: Interrupt on acknowledge error 9 enabled

Bit 8 **AE8IE**: Acknowledge error 8 interrupt enable
Enables the interrupt generation on acknowledge error 8.
0: Interrupt on acknowledge error 8 disabled
1: Interrupt on acknowledge error 8 enabled

Bit 7 **AE7IE**: Acknowledge error 7 interrupt enable
Enables the interrupt generation on acknowledge error 7.
0: Interrupt on acknowledge error 7 disabled
1: Interrupt on acknowledge error 7 enabled

Bit 6 **AE6IE**: Acknowledge error 6 interrupt enable
Enables the interrupt generation on acknowledge error 6.
0: Interrupt on acknowledge error 6 disabled
1: Interrupt on acknowledge error 6 enabled

Bit 5 **AE5IE**: Acknowledge error 5 interrupt enable
Enables the interrupt generation on acknowledge error 5.
0: Interrupt on acknowledge error 5 disabled
1: Interrupt on acknowledge error 5 enabled

Bit 4 **AE4IE**: Acknowledge error 4 interrupt enable
Enables the interrupt generation on acknowledge error 4.
0: Interrupt on acknowledge error 4 disabled
1: Interrupt on acknowledge error 4 enabled

Bit 3 **AE3IE**: Acknowledge error 3 interrupt enable
Enables the interrupt generation on acknowledge error 3.
0: Interrupt on acknowledge error 3 disabled
1: Interrupt on acknowledge error 3 enabled

Bit 2 **AE2IE**: Acknowledge error 2 interrupt enable
Enables the interrupt generation on acknowledge error 2.
0: Interrupt on acknowledge error 2 disabled
1: Interrupt on acknowledge error 2 enabled

Bit 1 **AE1IE**: Acknowledge error 1 interrupt enable
Enables the interrupt generation on acknowledge error 1.
0: Interrupt on acknowledge error 1 disabled
1: Interrupt on acknowledge error 1 enabled

Bit 0 **AE0IE**: Acknowledge error 0 interrupt enable
Enables the interrupt generation on acknowledge error 0.
0: Interrupt on acknowledge error 0 disabled
1: Interrupt on acknowledge error 0 enabled

55.15.47 DSI Host interrupt enable register 1 (DSI_IER1)

Address offset: 0x00C8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **TEIE**: Tear effect error interrupt enable
Enables the interrupt generation on tear effect error.
0: Interrupt disabled
1: Interrupt enabled

Bit 19 **VMPUIE**: Video mode underflow error interrupt enable
Enables the interrupt generation on video mode underflow error.
0: Interrupt disabled
1: Interrupt enabled

Bit 18 Reserved, must be kept at reset value.

Bit 17 **DICIE**: DBI illegal command error interrupt enable
Enables the interrupt generation on DBI illegal command error.
0: Interrupt disabled
1: Interrupt enabled

Bit 16 **DROIE**: DBI read overflow error interrupt enable
Enables the interrupt generation on DBI read overflow error.
0: Interrupt disabled
1: Interrupt enabled

Bit 15 **DRUIE**: DCS read underflow error interrupt enable
Enables the interrupt generation on DCS read underflow error.
0: Interrupt disabled
1: Interrupt enabled

Bit 14 **DDFFIE**: DBI data FIFO full error interrupt enable
Enables the interrupt generation on DBI data FIFO full error.
0: Interrupt disabled
1: Interrupt enabled

Bit 13 **DCFFIE**: DBI command FIFO full error interrupt enable
Enables the interrupt generation on DBI command FIFO full error.
0: Interrupt disabled
1: Interrupt enabled

Bit 12 **GPRXEIE**: Generic payload receive error interrupt enable
Enables the interrupt generation on generic payload receive error.
0: Interrupt disabled
1: Interrupt enabled

Bit 11 **GPRDEIE**: Generic payload read error interrupt enable
Enables the interrupt generation on generic payload read error.
0: Interrupt disabled
1: Interrupt enabled

Bit 10 **GPTXEIE**: Generic payload transmit error interrupt enable
Enables the interrupt generation on generic payload transmit error.
0: Interrupt disabled
1: Interrupt enabled

Bit 9 **GPWREIE**: Generic payload write error interrupt enable
Enables the interrupt generation on generic payload write error.
0: Interrupt disabled
1: Interrupt enabled

Bit 8 **GCWREIE**: Generic command write error interrupt enable
Enables the interrupt generation on generic command write error.
0: Interrupt disabled
1: Interrupt enabled

Bit 7 **LPWREIE**: LTDC payload write error interrupt enable
Enables the interrupt generation on LTDC payload write error.
0: Interrupt disabled
1: Interrupt enabled

Bit 6 **EOTPEIE**: EoTp error interrupt enable
Enables the interrupt generation on EoTp error.
0: Interrupt disabled
1: Interrupt enabled

Bit 5 **PSEIE**: Packet size error interrupt enable
Enables the interrupt generation on packet size error.
0: Interrupt disabled
1: Interrupt enabled

Bit 4 **CRCEIE**: CRC error interrupt enable
Enables the interrupt generation on CRC error.
0: Interrupt disabled
1: Interrupt enabled

Bit 3 **ECCMEIE**: ECC multi-bit error interrupt enable
Enables the interrupt generation on ECC multi-bit error.
0: Interrupt disabled
1: Interrupt enabled

Bit 2 **ECCSEIE**: ECC single-bit error interrupt enable
Enables the interrupt generation on ECC single-bit error.
0: Interrupt disabled
1: Interrupt enabled

Bit 1 **TOLPRXIE**: Timeout low-power reception interrupt enable
Enables the interrupt generation on timeout low-power reception.
0: Interrupt disabled
1: Interrupt enabled

Bit 0 **TOHSTXIE**: Timeout high-speed transmission interrupt enable
Enables the interrupt generation on timeout high-speed transmission .
0: Interrupt disabled
1: Interrupt enabled

55.15.48 DSI Host PHY calibration control register (DSI_PCCR)

Address offset: 0x00CC

Reset value: 0x0000 0000

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **FPE4**: Force PHY error 4
Writing 1 to this bit forces a PHY error 4.

Bit 19 **FPE3**: Force PHY error 3
Writing 1 to this bit forces a PHY error 3.

Bit 18 **FPE2**: Force PHY error 2
Writing 1 to this bit forces a PHY error 2.

Bit 17 **FPE1**: Force PHY error 1
Writing 1 to this bit forces a PHY error 1.

Bit 16 **FPE0**: Force PHY error 0
Writing 1 to this bit forces a PHY error 0.

Bit 15 **FAE15**: Force acknowledge error 15
Writing 1 to this bit forces an acknowledge error 15.

Bit 14 **FAE14**: Force acknowledge error 14
Writing 1 to this bit forces an acknowledge error 14.

Bit 13 **FAE13**: Force acknowledge error 13
Writing 1 to this bit forces an acknowledge error 13.

Bit 12 **FAE12**: Force acknowledge error 12
Writing 1 to this bit forces an acknowledge error 12.

Bit 11 **FAE11**: Force acknowledge error 11
Writing 1 to this bit forces an acknowledge error 11.

Bit 10 **FAE10**: Force acknowledge error 10
Writing 1 to this bit forces an acknowledge error 10.

Bit 9 **FAE9**: Force acknowledge error 9
Writing 1 to this bit forces an acknowledge error 9.

Bit 8 **FAE8**: Force acknowledge error 8
Writing 1 to this bit forces an acknowledge error 8.

Bit 7 **FAE7**: Force acknowledge error 7
Writing 1 to this bit forces an acknowledge error 7.

Bit 6 **FAE6**: Force acknowledge error 6
Writing 1 to this bit forces an acknowledge error 6.

Bit 5 **FAE5**: Force acknowledge error 5
Writing 1 to this bit forces an acknowledge error 5.

Bit 4 **FAE4**: Force acknowledge error 4
Writing 1 to this bit forces an acknowledge error 4.

Bit 3 **FAE3**: Force acknowledge error 3
Writing 1 to this bit forces an acknowledge error 3.

Bit 2 **FAE2**: Force acknowledge error 2
Writing 1 to this bit forces an acknowledge error 2.

Bit 1 **FAE1**: Force acknowledge error 1
Writing 1 to this bit forces an acknowledge error 1.

Bit 0 **FAE0**: Force acknowledge error 0
Writing 1 to this bit forces an acknowledge error 0.

55.15.50 DSI Host force interrupt register 1 (DSI_FIR1)

Address offset: 0x00DC

Reset value: 0x0000 0000

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **FGPRXE**: Force generic payload receive error
Writing 1 to this bit forces a generic payload receive error.

Bit 11 **FGPRDE**: Force generic payload read error
Writing 1 to this bit forces a generic payload read error.

Bit 10 **FGPTXE**: Force generic payload transmit error
Writing 1 to this bit forces a generic payload transmit error.

Bit 9 **FGPWRE**: Force generic payload write error
Writing 1 to this bit forces a generic payload write error.

Bit 8 **FGCWRE**: Force generic command write error
Writing 1 to this bit forces a generic command write error.

Bit 7 **FLPWRE**: Force LTDC payload write error
Writing 1 to this bit forces a LTDC payload write error.

Bit 6 **FEOTPE**: Force EoTp error
Writing 1 to this bit forces a EoTp error.

Bit 5 **FPSE**: Force packet size error
Writing 1 to this bit forces a packet size error.

Bit 4 **FCRCE**: Force CRC error
Writing 1 to this bit forces a CRC error.

Bit 3 **FECCME**: Force ECC multi-bit error
Writing 1 to this bit forces a ECC multi-bit error.

Bit 2 **FECCSE**: Force ECC single-bit error
Writing 1 to this bit forces a ECC single-bit error.

Bit 1 **FTOLPRX**: Force timeout low-power reception
Writing 1 to this bit forces a timeout low-power reception.

Bit 0 **FTOHSTX**: Force timeout high-speed transmission
Writing 1 to this bit forces a timeout high-speed transmission.

55.15.51 DSI Host data lane timer read configuration register (DSI_DLTRCR)

Address offset: 0x00F4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	MRD_TIME[14:0]														
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **MRD_TIME[14:0]**: Maximum read time

This field configures the maximum time required to perform a read command in lane byte clock cycles. This register can only be modified when no read command is in progress.

55.15.52 DSI Host video shadow control register (DSI_VSCR)

Address offset: 0x0100

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	UR	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EN
							rw								rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **UR**: Update register

When set to 1, the LTDC registers are copied to the auxiliary registers. After copying, this bit is auto cleared.

0: No update requested

1: Register update requested

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **EN**: Enable

When set to 1, DSI Host LTDC interface receives the active configuration from the auxiliary registers.

When this bit is set along with the UR bit, the auxiliary registers are automatically updated.

0: Register update is disabled

1: Register update is enabled

55.15.53 DSI Host LTDC current VCID register (DSI_LCVCIDR)

Address offset: 0x010C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VCID[1:0]	
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **VCID[1:0]**: Virtual channel ID

This field returns the virtual channel ID for the LTDC interface.

55.15.54 DSI Host LTDC current color coding register (DSI_LCCCR)

Address offset: 0x0110

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	LPE	Res.	Res.	Res.	Res.	COLC[3:0]			
							r					r	r	r	r

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **LPE**: Loosely packed enable

This bit returns the current state of the loosely packed variant to 18-bit configurations.
0: Loosely packed variant disabled
1: Loosely packed variant enabled

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **COLC[3:0]**: Color coding

This field returns the current LTDC interface color coding.
0000: 16-bit configuration 1
0001: 16-bit configuration 2
0010: 16-bit configuration 3
0011: 18-bit configuration 1
0100: 18-bit configuration 2
0101: 24-bit
0110 - 1111: reserved
If LTDC interface in command mode is chosen and currently works in the command mode (CMDM = 1), then 0110-1111: 24-bit

55.15.55 DSI Host low-power mode current configuration register (DSI_LPMCCR)

Address offset: 0x0118

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LPSIZE[7:0]							
								r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VLPSIZE[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **LPSIZE[7:0]**: Largest packet size

This field is returns the current size, in bytes, of the largest packet that can fit in a line during VSA, VBP and VFP regions, for the transmission of commands in low-power mode.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **VLPSIZE[7:0]**: VACT largest packet size

This field returns the current size, in bytes, of the largest packet that can fit in a line during VACT regions, for the transmission of commands in low-power mode.

55.15.56 DSI Host video mode current configuration register (DSI_VMCCR)

Address offset: 0x0138

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	LPCE	FBTAAE	LPHFE	LPHBPE	LPVAE	LPVFPE	LPVBPE	LPVSAE	VMT[1:0]	
						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **LPCE**: Low-power command enable

This bit returns the current command transmission state in low-power mode.

0: Command transmission in low-power mode is disabled.

1: Command transmission in low-power mode is enabled.

Bit 8 **FBTAAE**: Frame BTA acknowledge enable

This bit returns the current state of request for an acknowledge response at the end of a frame.

0: Acknowledge response at the end of a frame is disabled.

1: Acknowledge response at the end of a frame is enabled.

Bit 7 **LPHFE**: Low-power horizontal front-porch enable

This bit returns the current state of return to low-power inside the horizontal front-porch (HFP) period when timing allows.

0: Return to low-power inside the HFP period is disabled.

1: Return to low-power inside the HFP period is enabled.

Bit 6 **LPHBPE**: Low-power horizontal back-porch enable

This bit returns the current state of return to low-power inside the horizontal back-porch (HBP) period when timing allows.

0: Return to low-power inside the HBP period is disabled.

1: Return to low-power inside the HBP period is enabled.

Bit 5 **LPVAE**: Low-power vertical active enable

This bit returns the current state of return to low-power inside the vertical active (VACT) period when timing allows.

0: Return to low-power inside the VACT is disabled.

1: Return to low-power inside the VACT is enabled.

Bit 4 **LPVFPE**: Low-power vertical front-porch enable

This bit returns the current state of return to low-power inside the vertical front-porch (VFP) period when timing allows.

0: Return to low-power inside the VFP is disabled.

1: Return to low-power inside the VFP is enabled.

Bit 3 **LPVBPE**: Low-power vertical back-porch enable

This bit returns the current state of return to low-power inside the vertical back-porch (VBP) period when timing allows.

0: Return to low-power inside the VBP is disabled.

1: Return to low-power inside the VBP is enabled.

Bit 2 **LPVSAE**: Low-power vertical sync time enable

This bit returns the current state of return to low-power inside the vertical sync time (VSA) period when timing allows.

0: Return to low-power inside the VSA is disabled.

1: Return to low-power inside the VSA is enabled

Bits 1:0 **VMT[1:0]**: Video mode type

This field returns the current video mode transmission type:

00: Non-burst with sync pulses

01: Non-burst with sync events

1x: Burst mode

55.15.57 DSI Host video packet current configuration register (DSI_VPCCR)

Address offset: 0x013C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	VPSIZE[13:0]													
		r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:0 **VPSIZE[13:0]**: Video packet size
This field returns the number of pixels in a single video packet.

55.15.58 DSI Host video chunks current configuration register (DSI_VCCCR)

Address offset: 0x0140

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	NUMC[12:0]												
			r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:13 Reserved, must be kept at reset value.

Bits 12:0 **NUMC[12:0]**: Number of chunks
This field returns the number of chunks transmitted during a line period.

55.15.59 DSI Host video null packet current configuration register (DSI_VNPCCR)

Address offset: 0x0144

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	NPSIZE[12:0]												
			r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:13 Reserved, must be kept at reset value.

Bits 12:0 **NPSIZE[12:0]**: Null packet size
This field returns the number of bytes inside a null packet.

55.15.60 DSI Host video HSA current configuration register (DSI_VHSACCR)

Address offset: 0x0148

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HSA[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **HSA[11:0]**: Horizontal synchronism active duration

This fields returns the horizontal synchronism active period in lane byte clock cycles.

55.15.61 DSI Host video HBP current configuration register (DSI_VHBPCCR)

Address offset: 0x014C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HBP[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **HBP[11:0]**: Horizontal back-porch duration

This field returns the horizontal back-porch period in lane byte clock cycles.

55.15.62 DSI Host video line current configuration register (DSI_VLCCR)

Address offset: 0x0150

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	HLINE[14:0]														
	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 **HLINE[14:0]**: Horizontal line duration

This field returns the current total of the horizontal line period (HSA+HBP+HACT+HFP) counted in lane byte clock cycles.

55.15.63 DSI Host video VSA current configuration register (DSI_VVSACCR)

Address offset: 0x0154

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	VSA[9:0]									
						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **VSA[9:0]**: Vertical synchronism active duration

This field returns the current vertical synchronism active period measured in number of horizontal lines.

55.15.64 DSI Host video VBP current configuration register (DSI_VVBPCCR)

Address offset: 0x0158

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	VBP[9:0]									
						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **VBP[9:0]**: Vertical back-porch duration

This field returns the current vertical back-porch period measured in number of horizontal lines.

55.15.65 DSI Host video VFP current configuration register (DSI_VVFPCCR)

Address offset: 0x015C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	VFP[9:0]									
						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **VFP[9:0]**: Vertical front-porch duration

This field returns the current vertical front-porch period measured in number of horizontal lines.

55.15.66 DSI Host video VA current configuration register (DSI_VVACCR)

Address offset: 0x0160

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	VA[13:0]													
		r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:0 **VA[13:0]**: Vertical active duration

This field returns the current vertical active period measured in number of horizontal lines.

55.15.67 DSI Host 3D current configuration register (DSI_TDCCR)

Address offset: 0x0190

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	S3DC
															r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RF	SVS	F3D[1:0]		M3D[1:0]	
										r	r	r	r	r	r

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **S3DC**: Send 3D control

This bit returns the current state of 3D control Sending: when set, causes the next VSS packet to include 3D control payload in every VSS packet.

Bits 15:6 Reserved, must be kept at reset value.

Bit 5 **RF**: Right first

This bit returns the left or right order.

0: Left eye data is sent first, and then the right eye data is sent.

1: Right eye data is sent first, and then the left eye data is sent.

Bit 4 **SVS**: Second VSYNC

This bit returns whether there is a second VSYNC pulse between left and right images, when 3D Image format is frame-based.

0: No sync pulses between left and right data

1: Sync pulse (HSYNC, VSYNC, blanking) between left and right data

Bits 3:2 **F3D[1:0]**: 3D format

This field returns the 3D image format.

00: Line (alternating lines of left and right data)

01: Frame (alternating frames of left and right data)

10: Pixel (alternating pixels of left and right data)

11: Reserved

Bits 1:0 **M3D[1:0]**: 3D mode

This field returns the 3D mode on/off and display orientation.

00: 3D mode off (2D mode on)

01: 3D mode on, portrait orientation

10: 3D mode on, landscape orientation

11: Reserved

55.16 DSI Wrapper registers

55.16.1 DSI Wrapper configuration register (DSI_WCFGR)

Address offset: 0x0400

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VSPOL	AR	TEPOL	TESRC	COLMUX[2:0]			DSIM
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **VSPOL**: VSync polarity
This bit selects the VSync edge on which the LTDC is halted.
0: LTDC halted on a falling edge
1: LTDC halted on a rising edge
This bit can be changed only when DSI is stopped (DSI_WCR.DSIEN = 0 and DSI_CR.EN = 0).

Bit 6 **AR**: Automatic refresh
This bit selects the refresh mode in DBI mode.
0: Automatic refresh mode disabled
1: Automatic refresh mode enabled
This bit can be changed only when DSI Host is stopped (DSI_CR.EN = 0).

Bit 5 **TEPOL**: TE polarity
This bit selects the polarity of the external pin tearing effect (TE) source.
0: Rising edge.
1: Falling edge.
This bit can be changed only when DSI Host is stopped (DSI_CR.EN = 0).

Bit 4 **TESRC**: TE source
This bit selects the tearing effect (TE) source.
0: DSI Link
1: External pin
This bit can be changed only when DSI Host is stopped (DSI_CR.EN = 0).

Bits 3:1 **COLMUX[2:0]**: Color multiplexing
This bit selects the color multiplexing used by DSI Host.
000: 16-bit configuration 1
001: 16-bit configuration 2
010: 16-bit configuration 3
011: 18-bit configuration 1
100: 18-bit configuration 2
101: 24-bit
This field can be changed only when DSI is stopped (DSI_WCR.DSIEN = 0 and DSI_CR.EN = 0).

Bit 0 **DSIM**: DSI mode
This bit selects the mode for the video transmission.
0: Video mode
1: Adapted command mode
This bit can be changed only when DSI Host is stopped (DSI_CR.EN = 0).

55.16.2 DSI Wrapper control register (DSI_WCR)

Address offset: 0x0404

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DSIEN	LTDCEN	SHTDN	COLM
												rw	rs	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **DSIEN**: DSI enable
Enables the DSI Wrapper.
0: DSI disabled
1: DSI enabled

Bit 2 **LTDCEN**: LTDC enable
Enables the LTDC for a frame transfer in adapted command mode.
0: LTDC disabled
1: LTDC enabled

Bit 1 **SHTDN**: Shutdown
This bit controls the display shutdown in video mode.
0: Display ON
1: Display OFF. The DSI PHY is set in power-down, which allows to modify its static settings.

Bit 0 **COLM**: Color mode
This bit controls the display color mode in video mode.
0: Full color mode
1: Eight color mode

55.16.3 DSI Wrapper interrupt enable register (DSI_WIER)

Address offset: 0x0408

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	LAEIE	Res.	Res.	PLLUIE	PLLLIE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERIE	TEIE
		rw			rw	rw								rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **LAEIE**: LCD APB error interrupt flag
Enables the LCD APB error interrupt.
0: APB error interrupt disabled
1: APB error interrupt enabled

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **PLLUIE**: PLL unlock interrupt enable
Enables the PLL unlock interrupt.
0: PLL unlock interrupt disabled
1: PLL unlock interrupt enabled

Bit 9 **PLLLIE**: PLL lock interrupt enable
Enables the PLL lock interrupt.
0: PLL lock interrupt disabled
1: PLL lock interrupt enabled

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **ERIE**: End of refresh interrupt enable
Enables the end of refresh interrupt.
0: End of refresh interrupt disabled
1: End of refresh interrupt enabled

Bit 0 **TEIE**: Tearing effect interrupt enable
Enables the tearing effect interrupt.
0: Tearing effect interrupt disabled
1: Tearing effect interrupt enabled

55.16.4 DSI Wrapper interrupt and status register (DSI_WISR)

Address offset: 0x040C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	LAEIF	Res.	Res.	Res.	PLLUIF	PLLLIF	PLLLS	Res.	Res.	Res.	Res.	Res.	BUSY	ERIF	TEIF
	rw				r	r	r						r	r	r

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **LAEIF**: LCD APB error interrupt flag
This bit is set when an APB error occurs
0: No APB error occurred
1: APB error unlock event occurred

Bits 13:11 Reserved, must be kept at reset value.

Bit 10 **PLLUIF**: PLL unlock interrupt flag
This bit is set when the PLL becomes unlocked.
0: No PLL unlock event occurred
1: PLL unlock event occurred

Bit 9 **PLLLIF**: PLL lock interrupt flag
This bit is set when the PLL becomes locked.
0: No PLL lock event occurred
1: PLL lock event occurred

Bit 8 **PLLLS**: PLL lock status
This bit is set when the PLL is locked and cleared when it is unlocked.
0: PLL is unlocked.
1: PLL is locked.

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **BUSY**: Busy flag
This bit is set when the transfer of a frame in adapted command mode is ongoing.
0: No transfer on going
1: Transfer on going

Bit 1 **ERIF**: End of refresh interrupt flag
This bit is set when the transfer of a frame in adapted command mode is finished.
0: No end of refresh event occurred
1: End of refresh event occurred

Bit 0 **TEIF**: Tearing effect interrupt flag
This bit is set when a tearing effect event occurs.
0: No tearing effect event occurred
1: Tearing effect event occurred

55.16.5 DSI Wrapper interrupt flag clear register (DSI_WIFCR)

Address offset: 0x0410

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	CLAEIF	Res.	Res.	Res.	CPLLUIF	CPLLLIF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CERIF	CTEIF
	w				w	w								w	w

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **CLAEIF**: LCD APB error interrupt flag
Writing 1 clears the RRIF flag in the DSI_WSR register.

Bits 13:11 Reserved, must be kept at reset value.

Bit 10 **CPLLUIF**: Clear PLL unlock interrupt flag
Writing 1 clears the PLLUIF flag in the DSI_WSR register.

Bit 9 **CPLLLIF**: Clear PLL lock interrupt flag
Writing 1 clears the PLLLIF flag in the DSI_WSR register.

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **CERIF**: Clear end of refresh interrupt flag
Writing 1 clears the ERIF flag in the DSI_WSR register.

Bit 0 **CTEIF**: Clear tearing effect interrupt flag
Writing 1 clears the TEIF flag in the DSI_WSR register.

55.16.6 DSI Wrapper PHY configuration register 0 (DSI_WPCR0)

Address offset: 0x0418

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RXTRG[1:0]		Res.	Res.	FTXSMDL	TDDL
										rw	rw			rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 **RXTRG[1:0]**: Rx trigger escape selection
Writing 1 clears the RRIF flag in the DSI_WSR register.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **FTXSMDL**: Force to TX stop mode the data lanes
This bit forces the data lanes to Tx stop mode. It is used to initialize a lane module in Transmit mode. It causes the lane module to immediately jump to Tx control mode and to begin transmitting a Stop state (LP-11). It can be used to go back in Tx mode after a wrong BTA sequence.
0: No effect
1: Forces to Tx stop mode

Bit 0 **TDDL**: Turnaround disable data lanes
This bit forces the data lanes to remain in Rx mode even if it receives a bus turn around request form the other side.
0: No effect
1: Force data lanes in Rx mode after a BusTurnAround

55.16.7 DSI Wrapper PHY configuration register 1 (DSI_WPCR1)

Address offset: 0x0430

Reset value: 0x0000 0017

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DLD
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	HSFR[6:0]							Res.	Res.	CCF[5:0]					
	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **DLD**: Data lanes 0 direction:
0: Rx
1: Tx

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **HSFR[6:0]**: High speed frequency range in Tx mode. The values are given in *Table 515*,
This field must be set when the DPHY TX is in power-down, and must not change during operation.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **CCF[5:0]**: Configuration clock frequency:
Indicates the frequency of the clock used to configure the PHY and the PLL. It is computed as Value = Round((Frequency (in MHz) - 17) * 4). As an example, a 25.75 MHz reference clock requires SCCFG = (25.75 - 17) * 4 = 35.

55.16.8 DSI Wrapper regulator and PLL configuration register 0 (DSI_WRPCR0)

Address offset: 0x0434

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PSC
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	NDIV[9:0]										IDF[3:0]			
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **PSC**: PLL shadow control
Defines who controls the PLL frequency and regulator settings:
0: PHY test registers control the PLL
1: Wrapper controls the PLL (via registers DSI_WRPCR0/1/2). It is recommended to use the wrapper control, as the PHY test registers are reserved.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:4 **NDIV[9:0]**: PLL InLoop division ratio:
NDIV is active if DSI_WPCR0.PSC = 1’b0.
NDIV valid range is 10’h03E to 10’h26F (others are reserved).
The effective InLoop division ratio is equal to NDIV+2, thus from (d64 to d625).

Bits 3:0 **IDF[3:0]**: PLL input division ratio:
IDF is active if DSI_WPCR0.PSC = 1’b0, valid range is 4’h0 to 4’hF.
The effective input division is equal to IDF + 1, thus from (d1 to d16).

55.16.9 DSI Wrapper regulator and PLL configuration register 1 (DSI_WRPCR1)

Address offset: 0x0438

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	ODF[1:0]		VCO[3:0]				Res.	BIAS[6:0]						
		rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	INT[5:0]						GMP[1:0]		PROP[5:0]					
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ODF[1:0]**: Output division factor
This is the factor that divides the VCO, to provide the final output signal. ODF is active if DSI_WPCR0.PSC = 1’b0.
0: ratio 1/2 (cannot be divided by 1)
1: ratio 1/2
2: ratio 1/4
3: ratio 1/8

Bits 27:24 **VCO[3:0]**: VCO operating range
VCO is active if DSI_WPCR0.PSC = 1’b0. For VCO valid range see *Table 514*.

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **BIAS[6:0]**: Charge pump bias
BIAS is active if DSI_WPCR0.PSC = 1’b0. For BIAS valid range see *Table 514*.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **INT[5:0]**: Integral of charge pump
INT is active if DSI_WPCR0.PSC = 1’b0. For INT valid range see *Table 514*.

Bits 7:6 **GMP[1:0]**: Loop filter resistance
GMP is active if DSI_WPCR0.PSC = 1’b0. For GMP valid range see *Table 514*.

Bits 5:0 **PROP[5:0]**: Proportional charge pump
PROP is active if DSI_WPCR0.PSC = 1’b0. For PROP valid range see *Table 514*.

55.16.10 DSI Wrapper regulator and PLL configuration register 2 (DSI_WRPCR2)

Address offset: 0x043C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	PLLEN	Res.	Res.	Res.	Res.	Res.	Res.	SEL[1:0]	
							rw							rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **FPLLLOCK**: Force PLL lock signal
Writing 1 forces the PLL lock signal to high value.
0: No effect
1: Forces the PLL lock signal to high value.

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **CLR**: Clears the PLL shadow registers to their reset values
Writing 1 triggers a clear of the PLL shadow register to their reset values.
0: No effect
1: Clears the PLL shadow registers (field must be set, then reset)

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **UPD**: Update (copies) the PLL shadow registers to the effective PLL registers
Writing 1 triggers a copy of the PLL configured fields to the effective fields. The update must occur at least 10 cycles after the start of the reference clock.
0: No effect
1: Copies to the shadow registers (field must be set, then reset)

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **PLLEN**: PLL enable
Enables the D-PHY PLL:
0: PLL disabled
1: PLL enabled

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **SEL[1:0]**: Output selection for PLL Clock:
0: Clock stopped
1: Clock with four phases output by the PLL
2: Clock with four phases derived from the RCC clock ck_ker_dsiphy.
3: Reserved

55.16.11 DSI Wrapper regulator and PLL status register 0 (DSI_WRPSR0)

Address offset: 0x0440

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **PSC**: PLL shadow control
Defines who controls the PLL frequency and regulator settings:
0: PHY Test Registers control the PLL.
1: Wrapper controls the PLL (via registers DSI_WRPCR0/1/2)

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:4 **NDIV[9:0]**: Shadow value of PLL InLoop division ratio
NDIV is active if DSI_WPCR0.PSC = 1’b0, its valid range is 10’h03E to 10’h26F (others are reserved).
The effective InLoop division ratio is equal to NDIV + 2, thus from (d64 to d625)

Bits 3:0 **IDF[3:0]**: Shadow value of PLL input division ratio
IDF is active if DSI_WPCR0.PSC = 1’b0, its valid range is 4’h0 to 4’hF.
The effective input division is equal to NDIV+1, thus from (d1 to d16)

55.16.12 DSI Wrapper regulator and PLL status register 1 (DSI_WRPSR1)

Address offset: 0x0444

Reset value: 0x0000 0000

This is a status register, reflecting the status of the DSI_WRPCR1 register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	ODF[1:0]		VCO[3:0]				Res.	BIAS[6:0]

Res.	Res.	INT[5:0]						GMP[1:0]		PROP[5:0]					
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ODF[1:0]**: Output division factor
Factor that divides the VCO, to provide the final output signal, it is active if DSI_WPCR0.PSC = 1’b0.
0: ratio 1/1
1: ratio 1/2
2: ratio 1/4
3: ratio 1/8

Bits 27:24 **VCO[3:0]**: VCO operating range
VCO is active if DSI_WPCR0.PSC = 1’b0. VCO valid range provided by a table.

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **BIAS[6:0]**: Charge pump bias
BIAS is active if DSI_WPCR0.PSC = 1’b0. BIAS valid range is provided by a table.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **INT[5:0]**: Charge pump integral
INT is active if DSI_WPCR0.PSC = 1’b0. INT valid range is provided by a table.

Bits 7:6 **GMP[1:0]**: Charge pump integral
GMP is active if DSI_WPCR0.PSC = 1’b0. GMP valid range is provided by a table.

Bits 5:0 **PROP[5:0]**: Proportional charge pump
PROP is active if DSI_WPCR0.PSC = 1’b0. PROP valid range is provided by a table.

55.16.13 DSI Wrapper control register bis (DSI_WCRB)

Address offset: 0x0480

Reset value: 0x0000 0000

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **LINKS[3:0]**: Amount of DSI PHY links
0x0: Information is not provided
0x1: One DSI link is implemented
0x2: Two DSI links are implemented

Bits 19:16 **LANES[3:0]**: Amount of DSI DataLanes per Link (excluding the ClockLane)
0x0: Information is not provided
0x1: One DSI DataLane is implemented
0x2: Two DSI DataLanes are implemented
0x4: Four DSI DataLanes are implemented

Bits 15:4 **FIFOSIZE[11:0]**: FIFO size
This field returns size of the payload FIFO.

Bits 3:0 **TECHNO[3:0]**: Technology
This field returns the technology used
0x0: TECHNO information is not provided.
0x1: C40 / M40 PHY.
0x2: 16FF Synopsys PHY

55.16.15 DSI version register (DSI_VERR)

Address offset: 0x07F4

Reset value: 0x0000 0030

Refer to *Section 2.4 on page 228* for the register boundary addresses.

56 Video encoder (VENC)

56.1 VENC introduction

The video encoder (VENC) provides a hardware acceleration to encode a 1080p60 video stream in VP8 or H264 (= MPEG4_Part10/AVC).

The VENC also provides hardware acceleration to encode still images (JPEG) of up to 500 Mpixel/s.

The VENC implementation shares its large 128-Kbyte video RAM (VENCRAM) with the video decoder (see *Section 57: Video decoder (VDEC)*). Due to this sharing, VENC and VDEC have to run on a time-exclusive (frame) basis, hence they share the total 1080p60 performance.

When VENC and VDEC are both disabled, the VENCRAM is unused for video purposes, and is accessible by the system as a contiguous extension of the system SRAM.

56.2 VENC main features

The VENC supports the following features:

- Video encode:
  - codecs: H264 (MPEG4_Part10/AVC, baseline/Main/High up to 5.2), VP8
  - performance: 1080p60 for H264/VP8 (shared with the VDEC)
- Still-image encode:
  - codecs: JPEG (baseline interleaved)
  - performance: 500 Mpixel/s for JPEG (shared with the VDEC)
- VENCRAM:
  - size: 128 Kbytes
  - access: hardware handshake between VENC and VDEC, can be statically assigned to the system by SYSCFG settings

The VENC also provides the following features:

- Security via RIF:
  - The VENC is protected by a default slave and master control (RISUP and RIMU).
  - By default, the VENC works in non-protected mode.
  - The VENC can be set in protected mode, for instance to handle DRM tasks with a secure datapath. In such cases, the drivers must run in a protected process.
- Encode with multiple codecs on a same system:

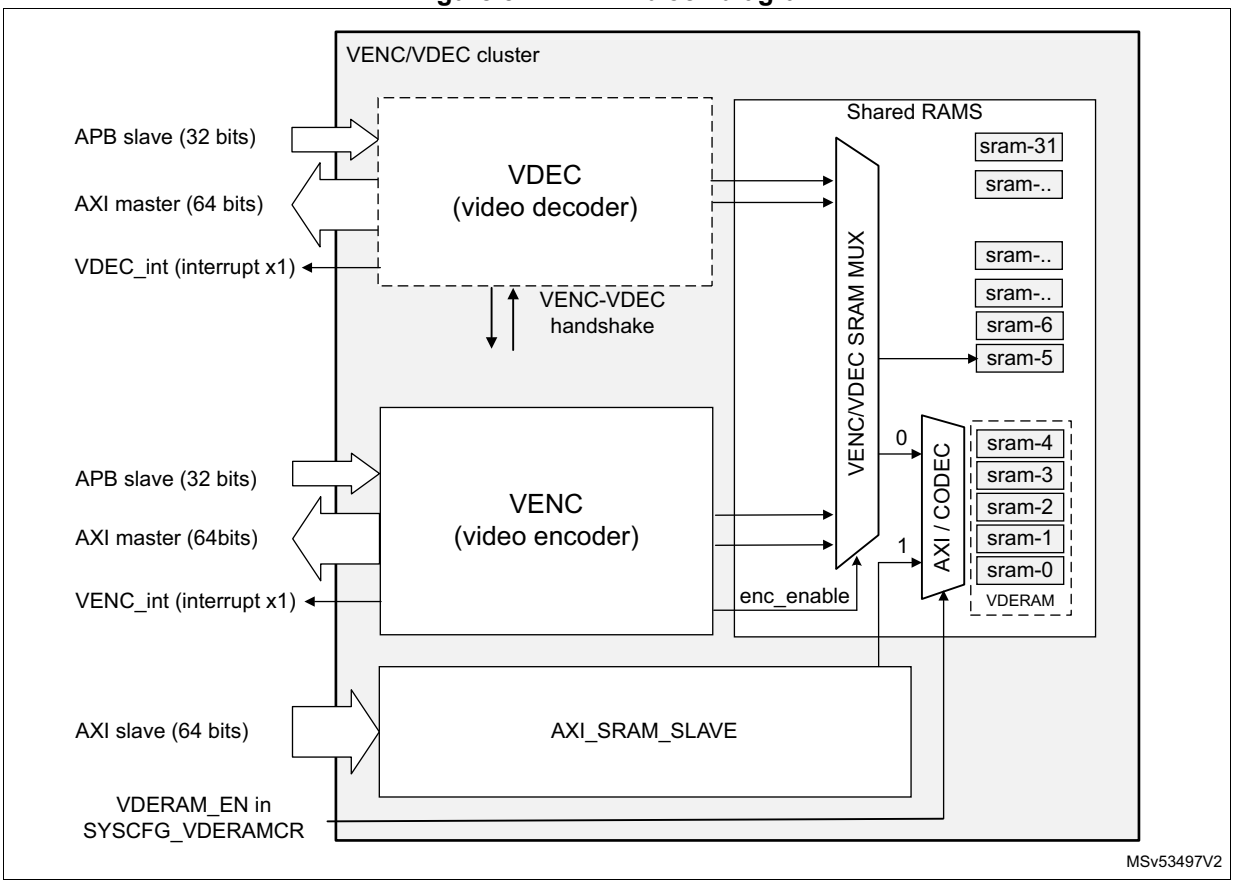
  The VENC can encode using different codecs on a same system: the VENC hardware processes the encode tasks sequentially, interleaved at frame level. Performances are shared across all the tasks.

56.3 VENC implementation

The VENC with a 600 MHz core clock supports up to 1080p60 video encode, or 500 Mpixel/s JPEG encode.

Since the VENC encoder is multi-instance, the input image can be changed at each encoding. The video format and resolution can thus be different for each instance.

The method for sharing the resource between several instances must be managed by software. This is to be done with locking mechanism, so that exclusive access to the VENC hardware is ensured for one instance at a time. The number of streams to be encoded this way is limited only by the external memory availability.



Note: Any use case with two (or more) simultaneous video encoding sessions must be tuned within the bandwidth limit of the system (especially memories accesses). Typical tunings are on pixel format, frame rate, and resolution.

56.4 VENC functional description

56.4.1 VENC block diagram

The following block diagram shows the VENC, the VENCRAM, and its interfaces.

Figure 517. VENC block diagram

56.4.2 VENC pins and internal signals

The VENC implements the following group of signals:

- APB Slave 32-bit bus: to configure the VENC and start its tasks.

- AXI Master 64-bit bus: for the VENC to fetch and store its needed data

  A 1080p60 video encode generates a bandwidth of 250 Mbyte/s to the buffer of its reference frame. An additional 90 Mbyte/s can be used to load the frame to encode.
- interrupts returned to the CPU interrupt controller

56.4.3 VENC reset and clocks

The VENC receives the following external signals:

- rstn_venc: to reset the whole VENC
- ck_icn_vid: to clock the AXI interconnect leading to the VENC
- ck_icn_s_venc: to clock the APB Slave to configure the VENC
- ck_icn_m_venc: to clock the AXI Master controlled by the VENC

56.4.4 VENC pre-processor

The VENC includes a pre-processor implemented at the input of the encoding pipe. This pre-processor allows on-the-fly processing of a frame that is read to be encoded, at no bandwidth cost.

The VENC pre-processor supports the following features:

- xRGB-to-YUV420 conversion: for direct encoding of an xRGB frame, for instance to store compressed the display output (that is usually in xRGB format)
- Cropping: for direct encoding of a specific region of interest
- Rotation90/270: for compensation of a rotated camera

Note: Any other feature is not supported.

The VENC pre-processor supports the following input pixel formats:

- YCbCr 4:2:0 planar (3 buffers)
- YCbCr 4:2:0 semi-planar (2 buffers)
- YCrCb 4:2:0 semi-planar (2 buffers)
- YCbYCr 4:2:2 interleaved (1 buffer)
- CbYCrY 4:2:2 interleaved (1 buffer)
- RGB444, BGR444 (16 bpp)
- RGB555, BGR555 (16 bpp)
- RGB565, BGR565 (16 bpp)
- RGB888, BGR888 (32 bpp)

56.4.5 VENC H264/VP8 encoder

The VENC supports the following features in H264/VP8 mode:

- Performance: 1080p60 (shared with the VDEC)
- Spec version: 12ISO/IEC 14496-10 / ITU-T Rec. H.264 (03/2010)
  - Baseline profile: levels 1 – 5.2
  - Main profile: levels 1 - 5.2
  - High profile: levels 1 – 5.2
- Profile: Baseline/Main/High, levels 1-52
- MVC supported

- Motion search: horizontal: ±126 pixels, vertical: ±30 pixels
- Output format: for VP8, VP8-bitstream, for H.264: byte unit stream or NAL unit stream
- Image size: 96x96 to 1920x1920 (by steps of 4 pixels)
- Bit rate: 10 Kbit/s to 40 Mbit/s
- Coding output: such as best matching motion vector, quality estimation (SAD)
- Bandwidth: optimized by buffering the luma search area in the SRAM
- Region of interest: two user definable rectangular areas with separate QP settings
- Region of intra: one user definable rectangular area coded as intra
- Cyclic intra refresh supported
- H264 ROI map: can define a different quantization delta for each macro-block, according to a table defined in the external DDR. A total of three quantization delta values can be selected in one picture.

Note: SVC is not supported.

56.4.6 VENC JPEG encoder

The VENC supports the following feature in JPEG mode:

- Performance: 500 Mpixel/s at 600 MHz
- Spec version: JPEG ISO/IEC 10918-1, ITU-T T.81
- Baseline process
- Huffman coding interleaved
- YUV420 supported internally
- Output format: JFIF file format 1.02, non-progressive JPEG 4:2:0
- Image size: 96x32 to 8176x8176 (by step of 4 pixels)
- Thumbnail insertion: RGB 8-bit, RGB 24-bit, JPEG compressed thumbnails
- User-defined quantization table: luma and chroma quantization tables
- Partial encoding: slice-by-slice according to the user defined restart interval
- ROI implemented by crop feature in pre-processor

The VENC shares its performance between video and JPEG encode: one task runs exclusively versus the other on a time-sharing basis.

56.4.7 VENC security

The VENC security is based on the RIF, with the following protections:

- protection of VENC register map (AHB slave) with a RISUP (see *Table 38: Indexes for non-RIF-aware peripherals (RISUP)*, the index for the VENC is 90).
- protection of VENC access to memory (AXI master) with a RIMU

The VENC RIMU by default inherits from its RISUP settings. More information can be found in *Section 9: Resource isolation framework security controller (RIFSC)*.

The security configuration is, by default, non-protected:

- It allows the default OS drivers to handle the VENC.
- AXI transactions are not protected, although they can be tagged with a CID specific for pixel buffers.
- The VENC can work in protected mode to allow secure data path (SDP) support with both the input flow and output bitstream being stored in protected buffers:
- The VENC AXI transaction becomes protected.
- The VENC APB configuration space becomes protected.
- The low-level software must work in protected mode to have access to the VENC registers.

56.4.8 VENC power-on sequence

The VENC power-on sequence is similar for all supported codecs, H264, VP8, or JPEG.

The RCC provides the needed master, slave, and core clocks. The software makes sure the VENC can access its VENCRAM, and lets the driver configure the VENC to start encoding.

The corresponding set up includes the following steps:

1. Set up security settings (see VENC index in *Table 38: Indexes for non-RIF-aware peripherals (RISUP)*).
   – The VENC is kept by default as non-protected.
2. Allocate the VENCRAM to the VENC and VDEC:
   – Clear VENCRAM_EN to 0 in SYSCFG_VENCRAMCR.
3. Set up the clock and reset (see *Section 21: Reset and clock control (RCC)*):
   – VENC core: ck_icn_vid to activate in the RCC (600 MHz typical)
   – VENC master: ck_icn_m_venc to activate in the RCC (600 MHz typical)
   – VENC slave: ck_icn_p_venc to activate in the RCC (200 MHz typical)
4. Handshaking between VENC and VDEC is done in hardware, and is hidden:
   a) The software just needs to request a frame encoding.
   b) When the shared SRAM becomes available (the VDEC has finished its task, or is simply disabled), the encoder task starts to run.
   c) After completion of the VENC task, the VENC interrupt is triggered to the software.

56.4.9 VENCRAM power-on sequence for AXI access

This section describes settings to access the shared VENCRAM with the AXI-Slave.
The RCC provides needed slave clocks, and makes sure the AXI Slave can access its VENCRAM, so that the system can start to use the SRAM.

The steps to set up this path are as follows:

1. Set up the security settings (see VENCRAM index in *Table 38: Indexes for non-RIF-aware peripherals (RISUP)*).
   – The VENCRAM can be set as protected or not-protected, depending on the system needs.
2. Allocate the VENCRAM to the CPU (the VENC and VDEC no longer work correctly).
   – Set VENCRAM to 1 in SYSCFG_VDERAMCR.
3. Setup the clock and reset (see *Section 21: Reset and clock control (RCC)*):
   – VENCRAM AXI: ck_icn_s_vderam to activate in the RCC (400 MHz typical).

56.5 VENC low power modes

The VENC has no voltage power modes.

56.6 VENC interrupts

The VENC can trigger a global interrupt (venc_gbl_int) that is referenced in the CPU interrupt handler as VENC.

56.7 VENC registers

SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Base address for reconstructed chroma (all format mode)

56.7.11 VENC base address for input picture luma register (VENC_SWREG11)

Address offset: 0x02C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Base address for input picture luma (all format mode)

56.7.12 VENC base address for input picture cb register (VENC_SWREG12)

Address offset: 0x030

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Base address for input picture cb (all format mode)

56.7.13 VENC base address for input picture cr register (VENC_SWREG13)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Base address for input picture cr (all format mode)

56.7.14 VENC encoder control register 0 (VENC_SWREG14)

Address offset: 0x038

Reset value: 0x0000 0000

This register is used to control data such as picture information or encoding mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Encoder control register 0 (such as picture information or encoding mode) (all format mode)

56.7.15 VENC encoder control register 1 (VENC_SWREG15)

Address offset: 0x03C

Reset value: 0x0000 0000

This register is used to control data such as preprocessing control, crop, rotate, or input format.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Encoder control register 1 (such as preprocessing control, crop, rotate, input format) (all format mode)

56.7.16 VENC encoder control register 2 (VENC_SWREG16)

Address offset: 0x040

Reset value: 0x0000 0000

This register controls the base address for second reference luma (H264 control).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Base address for second reference luma (H264 control) (all format mode)

56.7.17 VENC encoder control register 3 (VENC_SWREG17)

Address offset: 0x044

Reset value: 0x0000 0000

This register controls the base address for second reference chroma (H264 control).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Base address for second reference chroma (H264 control) (all format mode)

56.7.18 VENC encoder control register 4 (VENC_SWREG18)

Address offset: 0x048

Reset value: 0x0000 0000

This register controls the deblock filter mode (H264 control).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Encoder control register 4 (deblock filter mode, H264 control) (all format mode)

56.7.19 VENC encoder control register 5 (VENC_SWREG19)

Address offset: 0x04C

Reset value: 0x0000 0000

This register controls data such as input format or motion vector.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Encoder control register 5 (input format, motion vector etc) (all format mode)

56.7.20 VENC encoder control register 6 (VENC_SWREG20)

Address offset: 0x050

Reset value: 0x0000 0000

This register controls JPEG or VP8.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Control of data JPEG or VP8 (all format mode)

56.7.21 VENC encoder control register 7 (VENC_SWREG21)

Address offset: 0x054

Reset value: 0x0000 0000

This register controls data such as H264 or VP8.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**:Control of H264 or VP8 (all format mode)

56.7.22 VENC stream header remainder MSB bits register (VENC_SWREG22)

Address offset: 0x058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Stream header remainder bits MSB (MSB aligned) (all format mode)

56.7.23 VENC stream header remainder LSB bits register (VENC_SWREG23)

Address offset: 0x05C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Stream header remainder bits LSB (MSB aligned) (all format mode)

56.7.24 VENC stream buffer limit/output stream size register (VENC_SWREG24)

Address offset: 0x060

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Stream buffer limit (64-bit addresses)/output stream size (bits) (all format mode)

56.7.25 VENC encoder control register 8 (VENC_SWREG25)

Address offset: 0x064

Reset value: 0x0000 0000

This register controls the MAD control and QP sum output.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: Control of MAD control and QP sum output (all format mode)

56.7.26 VENC intra-slice bitmap/base address for VP8 counters register (VENC_SWREG26)

Address offset: 0x068

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: intra-slice bitmap/base address for VP8 counters for probability updates (all format mode)

56.7.27 VENC encoder control register 9 (VENC_SWREG27)

Address offset: 0x06C

Reset value: 0x0000 0000

This register controls H264 QP and VP8 QPY1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**:Control of H264 QP and VP8 QPY1 (all format mode)

56.7.28 VENC encoder control register 10 (VENC_SWREG28)

Address offset: 0x070

Reset value: 0x0000 0000

This register controls H264 checkpoint 1-2 and VP8 QPY1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: H264 checkpoint 1-2 and VP8 QPY1 (all format mode)

56.7.29 VENC encoder control register 11 (VENC_SWREG29)

Address offset: 0x074

Reset value: 0x0000 0000

This register controls H264 checkpoint 3-4 and VP8 QPY2.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: H.264 Checkpoint 3 -4 and VP8 QPY2 (all format mode)

56.7.30 VENC encoder control register 12 (VENC_SWREG30)

Address offset: 0x078

Reset value: 0x0000 0000

This register controls H264 checkpoint 5-6 and VP8 QPY2.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: H.264 checkpoint 5 -6 and VP8 QPY2 (all format mode)

56.7.31 VENC encoder control register 13 (VENC_SWREG31)

Address offset: 0x07C

Reset value: 0x0000 0000

This register controls H264 checkpoint 7-8 and VP8 QPCh.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: H.264 checkpoint 7 -8 and VP8 QPCh (all format mode)

56.7.32 VENC encoder control register 14 (VENC_SWREG32)

Address offset: 0x080

Reset value: 0x0000 0000

This register controls H264 checkpoint 8-10 and VP8 QPCh.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: H.264 Checkpoint 8 -10 / Encoder control register 14 (VP8 QPCh) (all format mode)

56.7.33 VENC encoder control register 15 (VENC_SWREG33)

Address offset: 0x084

Reset value: 0x0000 0000

This register controls H264 checkpoint 1-2 and mvRedfldx/VP8 QPY1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: H.264 Checkpoint word error 1-2 and mvRefIdx/VP8 QPY1 (all format mode)

56.7.34 VENC encoder control register 16 (VENC_SWREG34)

Address offset: 0x088

Reset value: 0x0000 0000

This register controls H264 checkpoint 3-4 and the second reference frame.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWREG_FIELD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SWREG_FIELD[31:0]**: H.264 checkpoint word error 3-4 and the second reference frame control (all format mode)

56.7.35 VENC H.264 checkpoint word error 5-6/encoder control register 17 (VENC_SWREG35)

Address offset: 0x08C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWREG_FIELD[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
