23.7.3 General timing rules

Signal synchronization is performed as follows:

- All controller output signals change on the rising edge of the fmc_ker_ck clock.
- In Synchronous read and write modes, all output signals change on the rising edge of fmc_ker_ck clock. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADVL/ NADVH /NBLL/ Address valid outputs change on the falling edge of FMC_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC_CLK clock.

---

1. NBL[1:0] are also driven by AXI write strobes.
23.7.4 NOR flash/PSRAM controller asynchronous transactions

Asynchronous transactions on static memories (NOR flash memory, PSRAM, SRAM) are performed as follows:

- Signals are synchronized by the internal clock. This clock is not issued to the memory.
- The FMC always samples the data before deasserting the Chip Select signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns)
- If the Extended mode is enabled (EXTMOD bit is set in the FMC_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the Extended mode is disabled (EXTMOD bit is reset in the FMC_BCRx register), the FMC can operate in Mode1 or Mode2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01 in the FMC_BCRx register)
  - Mode 2 is the default mode when NOR memory type is selected (MTYP = 0x10 in the FMC_BCRx register).

Mode 1 - SRAM/PSRAM (CRAM)

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC_BCRx, and FMC_BTRx/FMC_BWTRx registers.

Figure 164. Mode 1 read access waveforms
The fmc_ker_ck cycle at the end of the write transaction helps guarantee the address and data hold time after the NWE rising edge. Due to the presence of this fmc_ker_ck cycle, the DATAST value must be greater than zero (DATAST > 0).

WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCWAIT bit has to be set in FMC_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 fmc_ker_ck cycles before the end of the memory transaction. The following cases must be considered:

1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:
   
   \[ \text{DATAST} \geq (4 \times \text{fmc_ker_ck}) + \text{max_wait_assertion_time} \]

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):
   
   if
   
   \[ \text{max_wait_assertion_time} > \text{address_phase} + \text{hold_phase} \]
   
   then:
   
   \[ \text{DATAST} \geq (4 \times \text{fmc_ker_ck}) + (\text{max_wait_assertion_time} - \text{address_phase} - \text{hold_phase}) \]

   otherwise
   
   \[ \text{DATAST} \geq (4 \times \text{fmc_ker_ck}) \]

   where max_wait Assertion time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

*Figure 177* and *Figure 178* show the number of fmc_ker_ck clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).
Figure 177. Asynchronous wait during a read access waveforms

1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

Figure 178. Asynchronous wait during a write access waveforms

1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.
23.7.5 **Synchronous transactions**

The memory clock, FMC_CLK, is a sub-multiple of fmc_ker_ck. It depends on the value of CLKDIV and the MWID/AXI data size, following the formula given below:

\[
\text{FMC_CLK divider ratio} = \max(\text{CLKDIV} + 1, \text{MWID}(\text{AXI data size}))
\]

If MWID is 16 or 8-bit, the FMC_CLK divider ratio is always defined by the programmed CLKDIV value.

If MWID is 32-bit, the FMC_CLK divider ratio depends also on AXI data size.

Example:
- If CLKDIV=1, MWID = 32 bits, AXI data size=8 bits, FMC_CLK=fmc_ker_ck/4.
- If CLKDIV=1, MWID = 16 bits, AXI data size=8 bits, FMC_CLK=fmc_ker_ck/2.

NOR flash memories specify a minimum time from NADV assertion to FMC_CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

For some PSRAM memories which must be configured to Synchronous mode, during the BCR register writing, the memory attribute space must be configured to device or strongly-ordered. Once PSRAM BCR register is configured, the memory attribute of PSRAM address space can be programmed to cacheable.

**Data latency versus NOR memory latency**

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR flash configuration register. The FMC does not include the clock cycle when NADV is low in the data latency count.

**Caution:** Some NOR flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR flash latency and the FMC DATLAT parameter can be either:
- NOR flash latency = (DATLAT + 2) FMC_CLK clock cycles
- or NOR flash latency = (DATLAT + 3) FMC_CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.
**Single-burst transfer**

When the selected bank is configured in Burst mode for synchronous accesses, if for example a single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AXI transfer is 16 bits), or length 2 (if the AXI transfer is 32 bits) and deassert the Chip Select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

**Cross boundary page for Cellular RAM 1.5**

Cellular RAM 1.5 does not allow burst access to cross the page boundary. The FMC allows to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC_BCR1 register following the memory page size.

**Wait management**

For synchronous NOR flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) FMC_CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the Chip Select and output enable signals valid. It does not consider the data as valid.

In Burst mode, there are two timing configurations for the NOR flash NWAIT signal:

- The flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The flash memory asserts the NWAIT signal during the wait state

The FMC supports both NOR flash wait state configurations, for each Chip Select, thanks to the WAITCFG bit in the FMC_BCRx registers (x = 0..3).
1. Byte lane outputs (NBL) are not shown; for NOR access, they are held high, and, for PSRAM (CRAM) access, they are held low.

</tbody>
</table>
Bit 20 CCLKEN: Continuous Clock Enable
This bit enables the FMC_CLK clock output to external memory devices.
0: The FMC_CLK is only generated during the synchronous memory access (read/write transaction). The FMC_CLK clock ratio is specified by the programmed CLKDIV value in the FMC_BCRx register (default after reset).
1: The FMC_CLK is generated continuously during asynchronous and synchronous access. The FMC_CLK clock is activated when the CCLKEN is set.

Note: The CCLKEN bit of the FMC_BCR2..4 registers is don’t care. It is only enabled through the FMC_BCR1 register. Bank 1 must be configured in Synchronous mode to generate the FMC_CLK continuous clock.

If CCLKEN bit is set, the FMC_CLK clock ratio is specified by CLKDIV value in the FMC_BTR1 register. CLKDIV in FMC_BWTR1 is don’t care.

If the Synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC_BTR2..4 and FMC_BWTR2..4 registers for other banks has no effect.)

Bit 19 CBURSTR: Write burst enable
For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC_BCRx register.
0: Write operations are always performed in Asynchronous mode
1: Write operations are performed in Synchronous mode.

Bits 18:16 CPSIZE[2:0]: CRAM Page Size
These are used for Cellular RAM 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).
000: No burst split when crossing page boundary (default after reset).
001: 128 bytes
010: 256 bytes
100: 1024 bytes
Other configuration: reserved.

Bit 15 ASYNCHWAIT: Wait signal during asynchronous transfers
This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.
0: NWAIT signal is not taken in to account when running an asynchronous protocol (default after reset)
1: NWAIT signal is taken in to account when running an asynchronous protocol

Bit 14 EXTMOD: Extended mode enable.
This bit enables the FMC to program the write timings for asynchronous accesses inside the FMC_BWTR register, thus resulting in different timings for read and write operations.
0: values inside FMC_BWTR register are not taken into account (default after reset)
1: values inside FMC_BWTR register are taken into account

Note: When the Extended mode is disabled, the FMC can operate in Mode1 or Mode2 as follows:
- Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01)
- Mode 2 is the default mode when the NOR memory type is selected (MTYP = 0x10).
Bit 13  **WAITEN**: Wait enable bit  
This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in Synchronous mode.  
0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed flash latency period)  
1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset)  

Bit 12  **WREN**: Write enable bit  
This bit indicates whether write operations are enabled/disabled in the bank by the FMC:  
0: Write operations are disabled in the bank by the FMC, an AXI slave error is reported  
1: Write operations are enabled for the bank by the FMC (default after reset).  

Bit 11  **WAITCFG**: Wait timing configuration  
The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in Synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:  
0: NWAIT signal is active one data cycle before wait state (default after reset)  
1: NWAIT signal is active during wait state (not used for PSRAM).  

Bit 10  Reserved, must be kept at reset value.  

Bit 9  **WAITPOL**: Wait signal polarity bit  
This bit defines the polarity of the wait signal from memory used for either in Synchronous or Asynchronous mode:  
0: NWAIT active low (default after reset)  
1: NWAIT active high.  

Bit 8  **BURSTEN**: Burst enable bit  
This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode:  
0: Burst mode disabled (default after reset). Read accesses are performed in Asynchronous mode  
1: Burst mode enable. Read accesses are performed in Synchronous mode.  

Bit 7  Reserved, must be kept at reset value.  

Bit 6  **FACCEN**: Flash access enable  
This bit enables NOR flash memory access operations.  
0: Corresponding NOR flash memory access is disabled  
1: Corresponding NOR flash memory access is enabled (default after reset)  

Bits 5:4  **MWID[1:0]**: Memory data bus width  
Defines the external memory device width, valid for all type of memories.  
00: 8 bits  
01: 16 bits (default after reset)  
10: 32 bits  
11: reserved
Bits 3:2 **MTYP[1:0]: Memory type**

These bits define the type of external memory attached to the corresponding memory bank:
- 00: SRAM (default after reset for Bank 2...4)
- 01: PSRAM (CRAM)
- 10: NOR flash/OneNAND flash (default after reset for Bank 1)
- 11: reserved

Bit 1 **MUXEN: Address/data multiplexing enable bit**

When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:
- 0: Address/Data non-multiplexed
- 1: Address/Data multiplexed on databus (default after reset)

Bit 0 **MBKEN: Memory bank enable bit**

This bit enables the memory bank. After reset Bank1 is enabled, all others are disabled. Accessing a disabled bank causes an ERROR on AXI bus.
- 0: Corresponding memory bank is disabled
- 1: Corresponding memory bank is enabled
SRAM/NOR-flash chip-select timing registers for bank x (FMC_BTRx)

Address offset: 0x04 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR flash memories. If the EXTMOD bit is set in the FMC_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC_BWTRx registers).

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ACCMOD[1:0]:** Access mode

These bits specify the Asynchronous access modes as shown in the timing diagrams. They are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

00: access mode A
01: access mode B
10: access mode C
11: access mode D

Bits 27:24 **DATLAT[3:0]:** (see note below bit descriptions): Data latency for synchronous memory

For synchronous access with read/write Burst mode enabled (BURSTEN / CBURSTRW bits set), these bits define the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:

This timing parameter is not expressed in fmc_ker_ck periods, but in FMC_CLK periods.

For asynchronous access, this value is don't care.

0000: Data latency of 2 FMC_CLK clock cycles for first burst access
1111: Data latency of 17 FMC_CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]:** Clock divide ratio (for FMC_CLK signal)

These bits define the period of FMC_CLK clock output signal, expressed in number of fmc_ker_ck cycles:

0000: FMC_CLK period = 1 x fmc_ker_ck period
0001: FMC_CLK period = 2 x fmc_ker_ck periods
0010: FMC_CLK period = 3 x fmc_ker_ck periods
1111: FMC_CLK period = 16 x fmc_ker_ck periods (default value after reset)

In asynchronous NOR flash, SRAM or PSRAM accesses, this value is don't care.

*Note: Refer to Section 23.7.5: Synchronous transactions for FMC_CLK divider ratio formula*
Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write-to-read (and read-to-write) transaction. This delay allows to match the minimum time between consecutive transactions ($t_{EHEL}$ from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access ($t_{EHQZ}$). The programmed bus turnaround delay is inserted between an asynchronous read (muxed or mode D) or write transaction and any other asynchronous/synchronous read or write to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different except for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for muxed and D modes.
- There is a bus turnaround delay of 1 FMC clock cycle between:
  - Two consecutive asynchronous read transfers to the same static memory bank except for muxed and D modes.
  - An asynchronous read to an asynchronous or synchronous write to any static bank or dynamic bank except for muxed and D modes.
  - An asynchronous (modes 1, 2, A, B or C) read and a read from another static bank.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to the same bank.
  - A synchronous write (burst or single) access and an asynchronous write or read transfer to or from static memory bank (the bank can be the same or different for the case of read).
  - Two consecutive synchronous reads (burst or single) followed by any synchronous/asynchronous read or write from/to another static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to different static bank.
  - A synchronous write (burst or single) access and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 fmc_ker_ck clock cycle added

... 
1111: BUSTURN phase duration = 15 x fmc_ker_ck clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]**: Data-phase duration

These bits are written by software to define the duration of the data phase (refer to Figure 164 to Figure 176), used in asynchronous accesses:

0000 0000: Reserved
0000 0001: DATAST phase duration = 1 x fmc_ker_ck clock cycles
0000 0010: DATAST phase duration = 2 x fmc_ker_ck clock cycles

... 
1111 1111: DATAST phase duration = 255 x fmc_ker_ck clock cycles (default value after reset)

For each memory type and access mode data-phase duration, refer to the respective figure (Figure 164 to Figure 176).

Example: Mode1, write access, DATAST = 1: Data-phase duration = DATAST+1 = 1 x fmc_ker_ck clock cycles.

Note: In synchronous accesses, this value is don’t care.
Bits 7:4 ADDHLD[3:0]: Address-hold phase duration
These bits are written by software to define the duration of the address hold phase (refer to Figure 164 to Figure 176), used in mode D or multiplexed accesses:
- 0000: Reserved
- 0001: ADDHLD phase duration = 1 × fmc_ker_ck clock cycle
- 0010: ADDHLD phase duration = 2 × fmc_ker_ck clock cycle
  ... 
- 1111: ADDHLD phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)
For each access mode address-hold phase duration, refer to the respective figure (Figure 164 to Figure 176).

Note: In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.

Bits 3:0 ADDSET[3:0]: Address setup phase duration
These bits are written by software to define the duration of the address setup phase (refer to Figure 164 to Figure 176), used in SRAMs, ROMs and asynchronous NOR flash:
- 0000: ADDSET phase duration = 0 × fmc_ker_ck clock cycle
  ... 
- 1111: ADDSET phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)
For each access mode address setup phase duration, refer to the respective figure (refer to Figure 164 to Figure 176).

Note: In synchronous accesses, this value is don't care.
In Muxed mode or mode D, the minimum value for ADDSET is 1.
In mode 1 and PSRAM memory, the minimum value for ADDSET is 1.

Note: PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to extend the latency as needed.

On PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.

This method can be used also with the latest generation of synchronous flash memories that issue the NWAIT signal, unlike older flash memories (check the datasheet of the specific flash memory being used).
SRAM/NOR-flash write timing registers for bank x (FMC_BWTRx)

Address offset: 0x104 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR flash memories. When the EXTMOD bit is set in the FMC_BCRx register, then this register is active for write access.

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ACCMOD[1:0]**: Access mode.

These bits specify the asynchronous access modes as shown in the next timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

- 00: access mode A
- 01: access mode B
- 10: access mode C
- 11: access mode D

Bits 27:20 Reserved, must be kept at reset value.

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write transaction to match the minimum time between consecutive transactions (tEHEL from ENx high to ENx low):

(BUSTURN + 1) fmc_ker_ck period ≥ tEHELmin

The programmed bus turnaround delay is inserted between an asynchronous write transfer and any other asynchronous/synchronous read or write transfer to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different except for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for muxed and D modes.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to the same bank.
  - A synchronous write (burst or single) transfer and an asynchronous write or read transfer to or from static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to different static bank.
  - A synchronous write (burst or single) transfer and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 fmc_ker_ck clock cycle added

... 

1111: BUSTURN phase duration = 15 fmc_ker_ck clock cycles added (default value after reset)
Bits 15:8 DATAST[7:0]: Data-phase duration.
These bits are written by software to define the duration of the data phase (refer to Figure 164 to Figure 176), used in asynchronous SRAM, PSRAM and NOR flash memory accesses:
- 0000 0000: Reserved
- 0000 0001: DATAST phase duration = 1 × fmc_ker_ck clock cycles
- 0000 0010: DATAST phase duration = 2 × fmc_ker_ck clock cycles
- ... 1111 1111: DATAST phase duration = 255 × fmc_ker_ck clock cycles (default value after reset)

Bits 7:4 ADDHLD[3:0]: Address-hold phase duration.
These bits are written by software to define the duration of the address hold phase (refer to Figure 164 to Figure 176), used in asynchronous multiplexed accesses:
- 0000: Reserved
- 0001: ADDHLD phase duration = 1 × fmc_ker_ck clock cycle
- 0010: ADDHLD phase duration = 2 × fmc_ker_ck clock cycle
- ... 1111: ADDHLD phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)

Note: In synchronous NOR flash accesses, this value is not used, the address hold phase is always 1 flash clock period duration.

Bits 3:0 ADDSET[3:0]: Address setup phase duration.
These bits are written by software to define the duration of the address setup phase in fmc_ker_ck cycles (refer to Figure 164 to Figure 176), used in asynchronous accesses:
- 0000: ADDSET phase duration = 0 × fmc_ker_ck clock cycle
- ... 1111: ADDSET phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)

Note: In synchronous accesses, this value is not used, the address setup phase is always 1 flash clock period duration. In muxed mode, the minimum ADDSET value is 1.
23.8 NAND flash controller

The FMC generates the appropriate signal timings to drive 8- and 16-bit NAND flash memories.

The NAND bank is configured through dedicated registers (Section 23.8.7). The programmable memory parameters include access timings (shown in Table 201) and ECC configuration.

### Table 201. Programmable NAND flash access parameters

The NAND flash memory bank is managed through a set of registers:

- Control register: FMC_PCR
- Interrupt status register: FMC_SR
- ECC register: FMC_ECCR
- Timing register for Common memory space: FMC_PMEM
- Timing register for Attribute memory space: FMC_PATT

Each timing configuration register contains three parameters used to define the number of fmc_ker_ck cycles for the three phases of any NAND flash access, plus one parameter that defines the timing to start driving the data bus when a write access is performed. Figure 182 shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.

23.8.4 NAND flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND flash memory device are driven by address signals from the FMC. This means that to send a command or an address to the NAND flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC_PCR and FMC_PMEM (and for some devices, FMC_PATT, see Section 23.8.5: NAND flash prewait feature) registers according to the characteristics of the NAND flash memory (PWID bits for the data bus width of the NAND flash memory, PWAITEN = 0 or 1 as needed, see Section 23.6.2: NAND flash memory address mapping for timing configuration).

2. The CPU performs a byte write to the common memory space, with data byte equal to one flash command byte (for example 0x00 for Samsung NAND flash devices). The LE input of the NAND flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.

3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND flash memories) in the common memory or attribute space. The ALE input of the NAND flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used...
to implement the prewait functionality needed by some NAND flash memories (see details in Section 23.8.5: NAND flash prewait feature).

4. The controller waits for the NAND flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).

5. The CPU can then perform byte read operations from the common memory space to read the NAND flash page (data field + Spare field) byte by byte.

6. The next NAND flash page can be read without any CPU command or address write operation. This can be done in three different ways:
   – by simply performing the operation described in step 5
   – a new random address can be accessed by restarting the operation at step 3
   – a new command can be sent to the NAND flash device by restarting at step 2

### 23.8.5 NAND flash prewait feature

Some NAND flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see Figure 183).

**Figure 183. Access to non ‘CE don’t care’ NAND-flash**

1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7–A0 at address 0x7002 0000.
3. CPU wrote byte A16–A9 at address 0x7002 0000.
4. CPU wrote byte A24–A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x8802 0000: FMC performs a write access using FMC_PATT2 timing definition, where ATTHOLD ≥ 7 (providing that (7+1) × fmc_ker_ck = 112 ns > tWB max). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND flash memories where NCE is not don’t care).
When this function is required, it can be performed by programming the MEMHOLD value to meet the t\textsubscript{WB} timing. However, any CPU read access to NAND flash memory has a hold delay of (MEMHOLD + 1) fmc\textsubscript{ker} ck cycles, and any CPU write access has a hold delay of (MEMHOLD) fmc\textsubscript{ker} ck cycles that is inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the t\textsubscript{WB} timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND flash read and write accesses, except when writing the last address byte to the NAND flash device, where the CPU must write to the attribute memory space.

### 23.8.6 Computation of the error correction code (ECC) in NAND flash memory

The FMC includes an error correction code computation hardware block. It reduces the host CPU workload when processing the ECC by software. The ECC block is associated with NAND bank.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1 024, 2 048, 4 096 or 8 192 bytes read or written from/to the NAND flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND flash data bus and read/write signals (NCE and NWE) each time the NAND flash memory bank is active.

The ECC operates as follows:
- When accessing NAND flash bank, the data present on the D\textsubscript{15:0} bus is latched and used for ECC computation.
- When accessing any other address in NAND flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND flash memory by the host CPU, the FMC\_ECCR registers must be read to retrieve the computed value. Once read, they should be cleared by resetting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to one in the FMC\_PCR registers.

Execute below the sequence to perform an ECC computation:
1. Enable the ECCEN bit in the FMC\_PCR register.
2. Write data to the NAND flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Wait until the ECC code is ready (FIFO empty).
4. Read the ECC value available in the FMC\_ECCR register and store it in a variable.
5. Clear the ECCEN bit and then enable it in the FMC\_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
6. Read the new ECC value available in the FMC\_ECCR register.
7. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.
### NAND flash controller registers

FIFO status and interrupt register (FMC_SR)

Address offset: 0x84

Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data.

This is used to quickly write to the FIFO and free the AXI bus for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

</table>
Attribute memory space timing registers (FMC_PATT)

Address offset: 0x8C

Reset value: 0xFCFC FCFC

The FMC_PATT read/write register contains the timing information for NAND flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to Section 23.8.5: NAND flash prewait feature).

### Bits 15:8 MEMWAIT[7:0]: Common memory wait time
These bits define the minimum number of fmc_ker_ck (+1) clock cycles to assert the command (NWE, NOE), for NAND flash read or write access to common memory space. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of fmc_ker_ck:

- 0000 0000: reserved
- 0000 0001: x fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)
- 1111 1110: 255 x fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)
- 1111 1111: reserved.

### Bits 7:0 MEMSET[7:0]: Common memory x setup time
These bits define the number of fmc_ker_ck clock cycles to set up the address before the command assertion (NWE, NOE), for NAND flash read or write access to common memory space:

- 0000 0000: fmc_ker_ck cycles
- 1111 1110: 255 x fmc_ker_ck cycles
- 1111 1111: reserved

### Bits 31:24 ATTHIZ[7:0]: Attribute memory data bus Hi-Z time
These bits define the number of fmc_ker_ck clock cycles during which the data bus is kept in Hi-Z after the start of a NAND flash write access to attribute memory space on socket. Only valid for write transaction:

- 0000 0000: 0 x fmc_ker_ck cycle
- 1111 1110: 254 x fmc_ker_ck cycles
- 1111 1111: reserved.

### Bits 23:16 ATTHOLD[7:0]: Attribute memory hold time
These bits define the number of fmc_ker_ck clock cycles during which the address is held (and data for write access) after the command deassertion (NWE, NOE), for NAND flash read or write access to attribute memory space:

- 0000 0000: reserved
- 0000 0001: 1 x fmc_ker_ck cycle
- 1111 1110: 254 x fmc_ker_ck cycles
- 1111 1111: reserved.
Bits 15:8 **ATTWAIT[7:0]**: Attribute memory wait time

These bits define the minimum number of \( \times \text{fmc}_\text{ker}_\text{ck} \) (+1) clock cycles to assert the command (NWE, NOE), for NAND flash read or write access to attribute memory space. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of \( \text{fmc}_\text{ker}_\text{ck} \):

- 0000 0000: reserved
- 0000 0001: 2 \( \times \text{fmc}_\text{ker}_\text{ck} \) cycles (+ wait cycle introduced by deassertion of NWAIT)
- 1111 1110: 255 \( \times \text{fmc}_\text{ker}_\text{ck} \) cycles (+ wait cycle introduced by deasserting NWAIT)
- 1111 1111: reserved.

Bits 7:0 **ATTSET[7:0]**: Attribute memory setup time

These bits define the number of \( \times \text{fmc}_\text{ker}_\text{ck} \) (+1) clock cycles to set up address before the command assertion (NWE, NOE), for NAND flash read or write access to attribute memory space:

- 0000 0000: 1 \( \times \text{fmc}_\text{ker}_\text{ck} \) cycle
- 1111 1110: 255 \( \times \text{fmc}_\text{ker}_\text{ck} \) cycles
- 1111 1111: reserved.
ECC result registers (FMC_ECCR)

Address offset: 0x94
Reset value: 0x0000 0000

This register contain the current error correction code value computed by the ECC computation modules of the FMC NAND controller. When the CPU reads/writes the data from a NAND flash memory page at the correct address (refer to Section 23.8.6: Computation of the error correction code (ECC) in NAND flash memory), the data read/written from/to the NAND flash memory are processed automatically by the ECC computation module. When X bytes have been read (according to the ECCPS field in the FMC_PCR registers), the CPU must read the computed ECC value from the FMC_ECC registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC_ECC register should be cleared after being read by setting the ECCEN bit to '0'. To compute a new data block, the ECCEN bit must be set to '1'.

23.9 SDRAM controller

23.9.1 SDRAM controller main features

The main features of the SDRAM controller are the following:

- Two SDRAM banks with independent configuration
- 8-bit, 16-bit, 32-bit data bus width
- 13-bits Address Row, 11-bits Address Column, 4 internal banks: 4x16Mx32bit (256 MB), 4x16Mx16bit (128 MB), 4x16Mx8bit (64 MB)
- Word, half-word, byte access
- SDRAM clock can be fmc_ker_ck/2 or fmc_ker_ck/3
- Automatic row and bank boundary management
- Multibank ping-pong access
- Programmable timing parameters
- Automatic Refresh operation with programmable Refresh rate
- Self-refresh mode
- Power-down mode
- SDRAM power-up initialization by software
- CAS latency of 1,2,3
- Cacheable Read FIFO with depth of 6 lines x32-bit (6 x14-bit address tag)

23.9.2 SDRAM External memory interface signals

At startup, the SDRAM I/O pins used to interface the FMC SDRAM controller with the external SDRAM devices must configured by the user application. The SDRAM controller I/O pins which are not used by the application, can be used for other purposes.

23.9.3 SDRAM controller functional description

All SDRAM controller outputs (signals, address and data) change on the falling edge of the memory clock (FMC_SDCLK).

SDRAM initialization

The initialization sequence is managed by software. If the two banks are used, the initialization sequence must be generated simultaneously to Bank 1 and Bank 2 by setting the Target Bank bits CTB1 and CTB2 in the FMC_SDCMR register:

1. Program the memory device features into the FMC_SDCRx register. The SDRAM clock frequency, RBURST and RPIPE must be programmed in the FMC_SDCR1 register.
2. Program the memory device timing into the FMC_SDTRx register. The TRP and TRC timings must be programmed in the FMC_SDTR1 register.
3. Set MODE bits to ‘001’ and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to start delivering the clock to the memory (SDCKE is driven high).
4. Wait during the prescribed delay period. Typical delay is around 100 μs (refer to the SDRAM datasheet for the required delay after power-up).
5. Set MODE bits to ‘010’ and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to issue a “Precharge All” command.
6. Set MODE bits to ‘011’, and configure the Target Bank bits (CTB1 and/or CTB2) as well as the number of consecutive Auto-refresh commands (NRFS) in the FMC_SDCMR register. Refer to the SDRAM datasheet for the number of Auto-refresh commands that should be issued. Typical number is 8.
7. Configure the MRD field, set the MODE bits to ‘100’, and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to issue a “Load Mode Register” command and program the SDRAM device. In particular the Burst Length (BL) has to be set to ‘1’) and the CAS latency has to be selected. If the Mode Register is not the same for both SDRAM banks, this step has to be repeated twice, once for each bank and the Target Bank bits set accordingly. For mobile SDRAM devices, the MRD field is also used to configure the extended mode register while issuing the Load Mode Register.
8. Program the refresh rate in the FMC_SDRTR register.

The refresh rate corresponds to the delay between refresh cycles. Its value must be adapted to SDRAM devices.

At this stage the SDRAM device is ready to accept commands. If a system reset occurs during an ongoing SDRAM access, the data bus might still be driven by the SDRAM device. Therefore the SDRAM device must be first reinitialized after reset before issuing any new access by the NOR flash/PSRAM/SRAM or NAND flash controller.

Note: If two SDRAM devices are connected to the FMC, all the accesses performed at the same time to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for SDRAM Bank 1 (TMRD and TRAS timings) in the FMC_SDTR1 register.
SDRAM controller write cycle

The SDRAM controller accepts single and burst write requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row for each bank to be able to perform consecutive write accesses to different banks (Multibank ping-pong access).

Before performing any write access, the SDRAM bank write protection must be disabled by clearing the WP bit in the FMC_SDCRx register.

The SDRAM controller always checks the next access.
- If the next access is in the same row or in another active row, the write operation is carried out,
- if the next access targets another row (not active), the SDRAM controller generates a precharge command, activates the new row and initiates a write command.
SDRAM controller read cycle

The SDRAM controller accepts single and burst read requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row in each bank to be able to perform consecutive read accesses in different banks (Multibank ping-pong access).

The FMC SDRAM controller features a Cacheable read FIFO (6 lines x 32 bits). It is used to store data read in advance during the CAS latency period (up to 3 memory clock cycles, programmed FMC_SDCRx) and during the RPIPE delay when set to 2xfmc_ker_ck clock cycles as configured in FMC_SDCR1) following this formula: CAS Latency + 1 + (RPIPE DIV2). The RBURST bit must be set in the FMC_SDCR1 register to anticipate the next read access.

Examples:
- CAS=3, RPIPE= 2xfmc_ker_ck. In this case, 5 data (not committed) are stored in the FIFO (4 data during CAS latency and 1 data during RPIPE delay)
- CAS=3, RPIPE= 1xfmc_ker_ck. In this case, 4 data (not committed) are stored in the FIFO (4 data during CAS latency)

The read FIFO features a 14-bit address tag to each line to identify its content: 11 bits for the column address, 2 bits to select the internal bank and the active row, and 1 bit to select the SDRAM device.

When the end of the row is reached in advance during an burst read transaction, the data read in advance (not committed) are not stored in the read FIFO. For single read access, data are correctly stored in the FIFO.
Each time a read request occurs, the SDRAM controller checks:

- If the address matches one of the address tags, data are directly read from the FIFO and the corresponding address tag/line content is cleared and the remaining data in the FIFO are compacted to avoid empty lines.
- Otherwise, a new read command is issued to the memory and the FIFO is updated with new data. If the FIFO is full, the older data are lost.

**Figure 186. Logic diagram of Read access with RBURST bit set (CAS=2, RPIPE=0)**

During a write access or a Precharge command, the read FIFO is flushed and ready to be filled with new data.

After the first read request, if the current access was not performed to a row boundary, the SDRAM controller anticipates the next read access during the CAS latency period and the RPIPE delay (if configured). This is done by incrementing the memory address. The following condition must be met:

- RBURST control bit should be set to ‘1’ in the FMC_SDCR1 register.
The address management depends on the next AXI request:

- Next request is sequential (Burst access)
  
  In this case, the SDRAM controller increments the address.

- Next request is not sequential
  
  - If the new read request targets the same row or another active row, the new address is passed to the memory and the master is stalled for the CAS latency period, waiting for the new data from memory.
  
  - If the new read request does not target an active row, the SDRAM controller generates a Precharge command, activates the new row, and initiates a read command.

If the RBURST is reset, the read FIFO is not used.

**Row and bank boundary management**

When a read or write access crosses a row boundary, if the next read or write access is sequential and the current access was performed to a row boundary, the SDRAM controller executes the following operations:

1. Precharge of the active row,
2. Activation of the new row
3. Start of a read/write command.

At a row boundary, the automatic activation of the next row is supported for all columns and data bus width configurations.

If necessary, the SDRAM controller inserts additional clock cycles between the following commands:

- Between Precharge and Active commands to match TRP parameter (only if the next access is in a different row in the same bank),
- Between Active and Read commands to match the TRCD parameter.

These parameters are defined into the FMC_SDTRx register.

Refer to *Figure 184* and *Figure 185* for read and burst write access crossing a row boundary.
Figure 187. Read access crossing row boundary

Figure 188. Write access crossing row boundary
If the next access is sequential and the current access crosses a bank boundary, the SDRAM controller activates the first row in the next bank and initiates a new read/write command. Two cases are possible:

- If the current bank is not the last one, the active row in the new bank must be precharged. At a bank boundary, the automatic activation of the next row is supported for all rows/columns and data bus width configuration.
- If the current bank is the last one, the automatic activation of the next row is supported only when addressing 13-bit rows, 11-bit columns, 4 internal banks and 32-bit data bus SDRAM devices. Otherwise, the SDRAM address range is violated and an AXI slave error is generated.
- In case of 13-bit row address, 11-bit column address, 4 internal banks and bus width 32-bit SDRAM memories, at boundary bank, the SDRAM controller continues to read/write from the second SDRAM device (assuming it has been initialized):
  a) The SDRAM controller activates the first row (after precharging the active row, if there is already an active row in the first internal bank, and initiates a new read/write command.
  b) If the first row is already activated, the SDRAM controller just initiates a read/write command.

SDRAM controller refresh cycle

The Auto-refresh command is used to refresh the SDRAM device content. The SDRAM controller periodically issues auto-refresh commands. An internal counter is loaded with the COUNT value in the register FMC_SDRTR. This value defines the number of memory clock cycles between the refresh cycles (refresh rate). When this counter reaches zero, an internal pulse is generated.

If a memory access is ongoing, the auto-refresh request is delayed. However, if the memory access and the auto-refresh requests are generated simultaneously, the auto-refresh request takes precedence.

If the memory access occurs during an auto-refresh operation, the request is buffered and processed when the auto-refresh is complete.

If a new auto-refresh request occurs while the previous one was not served, the RE (Refresh Error) bit is set in the Status register. An Interrupt is generated if it has been enabled (REIE = ‘1’).

If SDRAM lines are not in idle state (not all row are closed), the SDRAM controller generates a PALL (Precharge ALL) command before the auto-refresh.

If the Auto-refresh command is generated by the FMC_SDCMR Command Mode register (Mode bits = ‘011’), a PALL command (Mode bits = ‘010’) must be issued first.
23.9.4 Low-power modes

Two low-power modes are available:

- **Self-refresh mode**
  The auto-refresh cycles are performed by the SDRAM device itself to retain data without external clocking.

- **Power-down mode**
  The auto-refresh cycles are performed by the SDRAM controller.

**Self-refresh mode**

This mode is selected by setting the MODE bits to ‘101’ and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register.

The SDRAM clock stops running after a TRAS delay and the internal refresh timer stops counting only if one of the following conditions is met:

- A Self-refresh command is issued to both devices
- One of the devices is not activated (SDRAM bank is not initialized).

Before entering Self-Refresh mode, the SDRAM controller automatically issues a PALL command.

If the Write data FIFO is not empty, all data are sent to the memory before activating the Self-refresh mode and the BUSY status flag remains set.

In Self-refresh mode, all SDRAM device inputs become don’t care except for SDCKE which remains low.

The SDRAM device must remain in Self-refresh mode for a minimum period of time of TRAS and can remain in Self-refresh mode for an indefinite period beyond that. To guarantee this minimum period, the BUSY status flag remains high after the Self-refresh activation during a TRAS delay.

As soon as an SDRAM device is selected, the SDRAM controller generates a sequence of commands to exit from Self-refresh mode. After the memory access, the selected device remains in Normal mode.

To exit from Self-refresh, the MODE bits must be set to ‘000’ (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC_SDCMR register.
Figure 189. Self-refresh mode

- **SDCLK**

  - PRECHARGE
  - NOP
  - AUTO REFRESH
  - NOP or COMMAND INHERIT
  - AUTO REFRESH
- **DOM/DOML/DOMU**
- **A0- A9 A11, A12**
- **A10**:
  - ALL BANKS
- **Data[31:0]**
  - Hi-Z

\[tRAS(\text{min})\]

Events:
- Precharge all active banks
- Enter Self-refresh mode
- Exit Self-refresh mode
- CLK stable prior to existing Self-refresh mode
- (restart refresh timebase)
Power-down mode

This mode is selected by setting the MODE bits to ‘110’ and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register.

If the Write data FIFO is not empty, all data are sent to the memory before activating the Power-down mode.

As soon as an SDRAM device is selected, the SDRAM controller exits from the Power-down mode. After the memory access, the selected SDRAM device remains in Normal mode.

During Power-down mode, all SDRAM device input and output buffers are deactivated except for the SDCKE which remains low.

The SDRAM device cannot remain in Power-down mode longer than the refresh period and cannot perform the Auto-refresh cycles by itself. Therefore, the SDRAM controller carries out the refresh operation by executing the operations below:

1. Exit from Power-down mode and drive the SDCKE high
2. Generate the PALL command only if a row was active during Power-down mode
3. Generate the auto-refresh command
4. Drive SDCKE low again to return to Power-down mode.

To exit from Power-down mode, the MODE bits must be set to ‘000’ (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC_SDCMR register.
23.9.5 SDRAM controller registers

SDRAM Control registers for SDRAM memory bank x (FMC_SDCRx)

Address offset: 0x140+ 0x4* (x − 1), (x = 1 to 2)

Reset value: 0x0000 02D0

This register contains the control parameters for each SDRAM memory bank

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:13 **RPIPE[1:0]**: Read pipe

These bits define the delay, in fmc_ker_ck clock cycles, for reading data after CAS latency.

00: No fmc_ker_ck clock cycle delay
01: One fmc_ker_ck clock cycle delay
10: Two fmc_ker_ck clock cycle delay
11: reserved.

*Note: The corresponding bits in the FMC_SDCR2 register is read only.*

Bit 12 **RBURST**: Burst read

This bit enables Burst read mode. The SDRAM controller anticipates the next read commands during the CAS latency and stores data in the Read FIFO.

0: single read requests are not managed as bursts
1: single read requests are always managed as bursts

*Note: The corresponding bit in the FMC_SDCR2 register is read only.*

Bits 11:10 **SDCLK[1:0]**: SDRAM clock configuration

These bits define the SDRAM clock period for both SDRAM banks and allow disabling the clock before changing the frequency. In this case the SDRAM must be re-initialized.

00: SDCLK clock disabled
01: Reserved
10: SDCLK period = 2 x fmc_ker_ck periods
11: SDCLK period = 3 x fmc_ker_ck periods

*Note: The corresponding bits in the FMC_SDCR2 register is read only.*

Bit 9 **WP**: Write protection

This bit enables Write mode access to the SDRAM bank.

0: Write accesses allowed
1: Write accesses ignored
Note: Before modifying the RBURST or RPIPE settings or disabling the SDCLK clock, the user must first send a PALL command to make sure ongoing operations are complete.

SDRAM Timing registers for SDRAM memory bank x (FMC_SDTRx)

Address offset: 0x148 + 0x4 * (x - 1), (x = 1 to 2)

Reset value: 0x0FFF FFFF

This register contains the timing parameters of each SDRAM bank

</table>

Bits 8:7  **CAS[1:0]:** CAS Latency
This bits sets the SDRAM CAS latency in number of memory clock cycles
00: reserved.
01: 1 cycle
10: 2 cycles
11: 3 cycles

Bit 6  **NB:** Number of internal banks
This bit sets the number of internal banks.
0: Two internal Banks
1: Four internal Banks

Bits 5:4  **MWID[1:0]:** Memory data bus width.
These bits define the memory device width.
00: 8 bits
01: 16 bits
10: 32 bits
11: reserved.

Bits 3:2  **NR[1:0]:** Number of row address bits
These bits define the number of bits of a row address.
00: 11 bit
01: 12 bits
10: 13 bits
11: reserved.

Bits 1:0  **NC[1:0]:** Number of column address bits
These bits define the number of bits of a column address.
00: 8 bits
01: 9 bits
10: 10 bits
11: 11 bits.
Bits 31:28  Reserved, must be kept at reset value.

Bits 27:24  TRCD[3:0]: Row to column delay
These bits define the delay between the Activate command and a Read/Write command in number of memory clock cycles.
0000: 1 cycle.
0001: 2 cycles
....
1111: 16 cycles

Bits 23:20  TRP[3:0]: Row precharge delay
These bits define the delay between a Precharge command and another command in number of memory clock cycles. The TRP timing is only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRP must be programmed with the timing of the slowest device.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles
Note: The corresponding bits in the FMC_SDTR2 register are don’t care.

Bits 19:16  TWR[3:0]: Recovery delay
These bits define the delay between a Write and a Precharge command in number of memory clock cycles.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles
Note: TWR must be programmed to match the write recovery time (tWR) defined in the SDRAM datasheet, and to guarantee that:
TWR ≥ TRAS - TRCD and TWR ≥ TRC - TRCD - TRP
Example: TRAS = 4 cycles, TRCD = 2 cycles. So, TWR ≥ 2 cycles. TWR must be programmed to 0x1.
If two SDRAM devices are used, the FMC_SDTR1 and FMC_SDTR2 must be programmed with the same TWR timing corresponding to the slowest SDRAM device.
If only one SDRAM device is used, the TWR timing must be kept at reset value (0xF) for the not used bank.

Bits 15:12  TRC[3:0]: Row cycle delay
These bits define the delay between the Refresh command and the Activate command, as well as the delay between two consecutive Refresh commands. It is expressed in number of memory clock cycles. The TRC timing is only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRC must be programmed with the timings of the slowest device.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles
Note: TRC must match the TRC and TRFC (Auto Refresh period) timings defined in the SDRAM device datasheet.
Note: The corresponding bits in the FMC_SDTR2 register are don’t care.
Bits 11:8 **TRAS[3:0]:** Self refresh time
These bits define the minimum Self-refresh period in number of memory clock cycles.
0000: 1 cycle  
0001: 2 cycles  
....  
1111: 16 cycles  

Bits 7:4 **TXSR[3:0]:** Exit Self-refresh delay
These bits define the delay from releasing the Self-refresh command to issuing the Activate command in number of memory clock cycles.
0000: 1 cycle  
0001: 2 cycles  
....  
1111: 16 cycles  

Note: If two SDRAM devices are used, the FMC_SDTR1 and FMC_SDTR2 must be programmed with the same TXSR timing corresponding to the slowest SDRAM device.

Bits 3:0 **TMRD[3:0]:** Load Mode Register to Active
These bits define the delay between a Load Mode Register command and an Active or Refresh command in number of memory clock cycles.
0000: 1 cycle  
0001: 2 cycles  
....  
1111: 16 cycles  

Note: If two SDRAM devices are connected, all the accesses performed simultaneously to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for Bank 1 (TMRD and TRAS timings) in the FMC_SDTR1 register.

The TRP and TRC timings are only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRP and TRC timings must be programmed with the timings of the slowest device.

**SDRAM Command mode register (FMC_SDCMR)**
Address offset: 0x150  
Reset value: 0x0000 0000  

This register contains the command issued when the SDRAM device is accessed. This register is used to initialize the SDRAM device, and to activate the Self-refresh and the Power-down modes. As soon as the MODE field is written, the command is issued only to one or to both SDRAM banks according to CTB1 and CTB2 command bits. This register is the same for both SDRAM banks.

Bits 31:23 Reserved, must be kept at reset value.
Flexible memory controller (FMC) RM0477

SDRAM refresh timer register (FMC_SDRTR)

Address offset: 0x154
Reset value: 0x0000 0000

This register sets the refresh rate in number of SDCLK clock cycles between the refresh cycles by configuring the Refresh Timer Count value.

\[
\text{Refresh rate} = (\text{COUNT} + 1) \times \text{SDRAM clock frequency}
\]

\[
\text{COUNT} = (\text{SDRAM refresh period} / \text{Number of rows}) - 20
\]
Below an example of refresh rate calculation:

\[
\text{Refresh rate} = \frac{64 \text{ ms}}{(8196 \text{ rows})} = 7.81 \mu s
\]

where 64 ms is the SDRAM refresh period.

\[7.81 \mu s \times 60 \text{ MHz} = 468.6\]

The refresh rate must be increased by 20 SDRAM clock cycles (as in the above example) to obtain a safe margin if an internal refresh request occurs when a read request has been accepted. It corresponds to a COUNT value of '0000111000000' (448).

This 13-bit field is loaded into a timer which is decremented using the SDRAM clock. This timer generates a refresh pulse when zero is reached. The COUNT value must be set at least to 41 SDRAM clock cycles.

As soon as the FMC_SDRTR register is programmed, the timer starts counting. If the value programmed in the register is '0', no refresh is carried out. This register must not be reprogrammed after the initialization procedure to avoid modifying the refresh rate.

Each time a refresh pulse is generated, this 13-bit COUNT field is reloaded into the counter.

If a memory access is in progress, the Auto-refresh request is delayed. However, if the memory access and Auto-refresh requests are generated simultaneously, the Auto-refresh takes precedence. If the memory access occurs during a refresh operation, the request is buffered to be processed when the refresh is complete.

This register is common to SDRAM bank 1 and bank 2.

### Register Description

</tr>
<tr>
<td>1: Refresh Error flag is cleared</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** The programmed COUNT value must not be equal to the sum of the following timings: TWR+TRP+TRC+TRCD+4 memory clock cycles.
SDRAM Status register (FMC_SDSR)

Address offset: 0x158
Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:3 **MODES2[1:0]**: Status Mode for Bank 2
These bits define the Status Mode of SDRAM Bank 2.
00: Normal Mode
01: Self-refresh mode
10: Power-down mode

Bits 2:1 **MODES1[1:0]**: Status Mode for Bank 1
These bits define the Status Mode of SDRAM Bank 1.
00: Normal Mode
01: Self-refresh mode
10: Power-down mode

Bit 0 **RE**: Refresh error flag
0: No refresh error has been detected
1: A refresh error has been detected
An interrupt is generated if REIE = 1 and RE = 1

Refer to Section 2.3 on page 149 for the register boundary addresses.
24 Extended-SPI interface (XSPI)

24.1 Introduction

The XSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- **indirect mode**: all the operations are performed using the XSPI registers to preset commands, addresses, data, and transfer parameters.
- **automatic status-polling mode**: the external memory status register is periodically read and an interrupt can be generated in case of flag setting. This feature is only available in regular-command protocol.
- **memory-mapped mode**: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The XSPI supports the following protocols with associated frame formats:

- the regular-command frame format with the command, address, alternate byte, dummy cycles, and data phase
- the HyperBus™ frame format

24.2 XSPI main features

- Functional modes: indirect, automatic status-polling, and memory-mapped
- Read and write support in memory-mapped mode
- Support for single, dual, quad, and octal communication
- Dual-memory configuration, where 8 bits can be sent/received simultaneously by accessing two quad or two octal memories in parallel
- XSPI mode accessing a single 16-bit memory
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- 8-, 16-, and 32-bit data accesses allowed
- DMA protocol support
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AXI interface with transaction acceptance limited to one: the interface accepts the next transfer on AXI bus only once the previous is completed on memory side.
- Dual chip select support (NCS1 and NCS2)

24.4 **XSPI functional description**

24.4.1 **XSPI block diagram**

The block diagrams provided below correspond to a single XSPI connected to the I/O ports. In case several XSPIs are connected to the I/O ports through the XSPIM I/O manager, refer to Section 25: XSPI I/O manager (XSPIM) for more details.

Figure 191. XSPI block diagram for 16-bit configuration

1. The configuration depends on the package (see the datasheet for more details).
1. The configuration depends on the package (see the datasheet for more details).
Figure 193. XSPI block diagram for octal configuration

(1) The Octo-SPI memory is connected to XSPIM_P1_IO[0:7] but it can also be connected to XSPIM_P1_IO[8:15].

(2) The configuration with NCS2 used corresponds to a semi-static management with two external memories hooked on the same XSPI bus. The software selects which memory is accessed.
Figure 194. XSPI block diagram in quad configuration

(1) The Quad-SPI memory is connected to XSPIM_P1_IO[0:3] but it can also be connected to XSPIM_P1_IO[4:7], XSPIM_P1_IO[8:11], or XSPIM_P1_IO[12:15].

(2) The configuration with NCS2 used corresponds to a semi-static management with two external memories hooked on the same XSPI bus. The software selects which memory is accessed.
24.4.2 XSPI pins and internal signals

</table>
24.4.3 Clock constraints

The XSPI AXI clock (xspi_aclk) has to be greater or equal than the XSPI kernel clock (xspi_ker_ck).

24.4.4 XSPI interface to memory modes

The XSPI supports the following protocols:
- regular-command protocol
- HyperBus protocol

The XSPI uses from 6 to 21 signals to interface with a memory, depending on the functional mode:
- NCS: chip-select (in the following sections, unless otherwise specified, NCS applies for NCS1 or NCS2. Only one of these two signals is active at a given moment in time).
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS0, DQS1: data strobe used only in regular-command protocol
- IO[3:0]: data bus LSB
- IO[7:4]:
  - data bus MSB used in dual-quad and octal configurations
  - data bus used as possible remap for quad-SPI mode
- IO[15:8]:
  - data bus MSB used in dual-quad, dual-octal and 16-bit configurations
  - data bus used as possible remap for octal-SPI mode
  - IO[15:12] and IO[11:8] can also be used as possible remap for quad-SPI mode

24.4.5 XSPI regular-command protocol

When in regular-command protocol, the XSPI communicates with the external device using commands. Each command can include the following phases:
- instruction phase
- address phase
- alternate-byte phase
- dummy-cycle phase
- data phase

Only the data phase uses 16 bits. Instruction, address, and alternate phases use only the eight LSB of the bus as for octal configuration.
Any of these phases can be configured to be skipped, but single-phase commands supported are only those with instruction phase.

The NCS falls before the start of each command and rises again after each command finishes.

In memory-mapped mode, both read and write operation are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

**Figure 196. SDR read command in 16-bit configuration**

![Diagram showing the SDR read command in 16-bit configuration]

1. Data (such as D0, D1, D2) are sent in 16-bit configuration mode over IO[15:0]. Only the command and address are sent over IO[7:0] as for octal mode.

The specific regular-command protocol features are configured through the registers in the 0x0100-0x01FC offset range.

**Instruction phase**

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured in ISIZE[1:0] of XSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of XSPI_IR.

The instruction phase can optionally send:
- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode, or in 16-bit SPI mode)

This can be configured using IMODE[2:0] of XSPI_CCR.

The instruction can be sent in DTR (double-transfer rate) mode on each rising and falling edge of the clock, by setting IDTR in XSPI_CCR.

When IMODE[2:0] = 000 in XSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

When in memory-mapped mode, the instruction used for the write operation is specified in XSPI_WIR and the instruction format is specified in XSPI_WCCR. The instruction used for the read operation and the instruction format are specified in XSPI_IR and XSPI_CCR.

**Address phase**

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured in ADSIZE[1:0] of XSPI_CCR.
In indirect and automatic status-polling modes, the address bytes to be sent are specified in ADDRESS[31:0] of XSPI_AR. In memory-mapped mode, the address is given directly via the AXI (from any master in the system).

The address phase can send:
- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode, or in 16-bit SPI mode)

This can be configured using ADMODE[2:0] of XSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR in XSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In memory-mapped mode, the address format for the write operation is specified in XSPI_WCCR. The address format for the read operation is specified in XSPI_CCR.

---

**Warning:** Some memory specifications consider that each address corresponds to a 16-bit value. XSPI considers that each address corresponds to an 8-bit value. So the software needs to multiple the address by two when accessing the memory registers.

---

**Alternate-byte phase**

In the alternate-bytes phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured in ABSIZE[1:0] of XSPI_CCR. The bytes to be sent are specified in XSPI_ABR.

The alternate-byte phase can send:
- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode, or in 16-bit SPI mode)

This can be configured using ABMODE[2:0] of XSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR of XSPI_CCR.

When ABMODE[2:0] = 000, the alternate-bytes phase is skipped and the command sequence proceeds directly to the next phase, if any.

Only a single nibble may need to be sent during the alternate-byte phase rather than a full byte, such as when the dual-SPI mode is used and only two cycles are used for the alternate bytes.
In this case, the firmware can use the quad-SPI mode (ABMODE[2:0] = 011), and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in XSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 5:4 of ALTERNATE[31:0], while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In memory-mapped mode, the alternate bytes used for the write operation are specified in XSPI_WABR, and the alternate byte format is specified in XSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in XSPI_ABR and XSPI_CCR.

**Dummy-cycle phase (memory latency)**

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when the higher clock frequencies are used. The number of cycles given during this phase is specified in DCYC[4:0] of XSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual-, quad-, octal-, or 16-bit SPI mode, to receive data from the external device.

In memory-mapped mode, the dummy cycles for the write operations are specified in XSPI_WTCR. The dummy cycles for the read operation are specified in XSPI_TCR.

**Data phase**

During the data phase, any number of bytes can be sent to or received from the external device.

In indirect mode, the number of bytes to be sent/received is specified in XSPI_DLR. In this mode, the data to be sent to the external device must be written to XSPI_DR. In indirect-read mode, the data received from the external device is obtained by reading XSPI_DR.

In automatic status-polling mode, the number of bytes to be received is specified in XSPI_DLR, and the data received from the external device can be obtained by reading XSPI_DR.

In memory-mapped mode, the data read or written, is sent or received directly over the AXI to the Cortex core or to a DMA.

The data phase can send/receive:
- 1 bit at a time (over IO0/IO1 (SO/SI respectively) in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)
- 16 bits at a time (over IO0 to IO15 in 16-bit SPI mode)

This can be configured using DMODE[2:0] of XSPI_CCR.
The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR of XSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in indirect-write mode.

In memory-mapped mode, the data format for the write operation is specified in XSPI_WCCR. The data format for the read operation is specified in XSPI_CCR.

**DQS use**

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.

The DQS management can be enabled by setting DQSE of XSPI_CCR.

**24.4.6 XSPI regular-command protocol signal interface**

**Single-SPI mode**

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (Single-SPI Output) (whose I/Os are shared with IO0). The data received from the external device arrives via SI (Single-SPI Input) (whose I/Os are shared with IO1).

Compared to the SPI legacy mode, IO/SO and I1/SI are respectively equivalent to MOSI and MISO, having the XSPI generating the clock.

The different phases can each be configured separately to use this single-bit mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in single-SPI mode:
- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0 (to deactivate the “write protect” function).
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO15 are in output mode and forced to 0.
This is the case even for the dummy phase if DMODE[2:0] = 001.

**Dual-SPI mode**

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals. The different phases can each be configured separately to use dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in dual-SPI mode:
- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO15 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 010, IO0/IO1 are always high-impedance.

**Quad-SPI mode**

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals. The different phases can each be configured separately to use the quad-SPI mode by setting to 011 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in quad-SPI mode:
- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO15 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 011, IO0 to IO3 are all high-impedance.

**Octal-SPI mode**

In regular octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals. The different phases can each be configured separately to use the octal-SPI mode by setting to 100 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase that is configured in octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 100, IO[0:7] are all high-impedance.

**XSPI mode**

In XSPI mode, the 16 bits are sent/received simultaneously over the IO[0:15] signals during the data phase.
The following phases must be configured separately to use the XSPI mode:

1. Set to 100 the IMODE, ADMODE, and ABMODE fields (in XSPI_CCR and XSPI_WCCR).
2. Set to 101 the DMODE fields (in XSPI_CCR and XSPI_WCCR).

In each phase that is configured in XSPI mode, IO[0:15] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 101, IO[0:15] are all high-impedance.

IO[8:15] are used only in XSPI mode. If none of the phases are configured to use this mode, then the pins corresponding to IO[8:15] can be used for other functions, even while the XSPI is active.

**Single-data rate (SDR) mode**

By default, all the phases operate in single-data rate (SDR) mode.

In SDR mode, when the XSPI drives the IO0/SO and IO1 to IO15 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the XSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in XSPI_TCR), the signals are sampled using the following (rising) edge of CLK.

**Double-transfer rate (DTR) mode**

Each of the instruction, address, alternate-byte, and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in XSPI_CCR.

In memory-mapped mode, the DTR mode for each phase of the write operations is specified in XSPI_WCCR. The DTR mode for each phase of the read operations is specified in XSPI_CCR.

In DTR mode, when the XSPI drives the IO0/SO and IO1 to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

In DTR mode, when the XSPI drives the IO0 to IO15 signals in the data phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the XSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in XSPI_CCR, the software must clear SSHIFT in XSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).
Dual-quad configuration

When \( \text{DMM} = 1 \) in \( \text{XSPI\_CR} \), the XSPI is in dual-memory configuration: if \( \text{DMODE} = 011 \), two external quad-SPI devices (device A and device B) are used in order to send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.

The dual-quad configuration can be used in conjunction with the single-SPI, dual-SPI, and quad-SPI modes, as well as with either SDR or DTR mode.

The device size, as specified in \( \text{DEVSIZE}[4:0] \) of \( \text{XSPI\_DCR1} \), must reflect the total external device capacity that is the double of the size of one individual component.

If address \( X \) is even, then the byte that the XSPI gives for address \( X \) is the byte at the address \( X/2 \) of device A, and the byte that the XSPI gives for address \( X + 1 \) is the byte at the address \( X/2 \) of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the XSPI must be configured with a data length of 2 bytes (16 bits), and the XSPI receives one byte from each device.

If each device gives a status of 16 bits, then the XSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The forth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of \( \text{DL}[31:0] \) in \( \text{XSPI\_DLR} \) is stuck at 1 when \( \text{DMM} = 1 \).

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AI0x and the BI0x buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.
Dual-octal configuration

When DMM = 1 in XSPI_CCR, the XSPI is in dual-memory configuration: when DMODE = 100, two external octal-SPI devices (device A and device B) are used in order to receive 32 bits in DTR mode every cycle, effectively doubling the throughput as well as the capacity.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO7 signals.

The dual-octal configuration can be used in DTR mode exclusively in conjunction with the single-SPI, dual-SPI, quad-SPI and octal-SPI modes.

The device size, as specified in DEVSIZE[4:0] of XSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the XSPI gives for address X is the byte at the address X/2 of device A, and the byte that the XSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-octal DTR mode, twice as many bytes must be read compared to the same read in regular DTR mode: if each device gives twice eight valid bits after the instruction for fetching the status register, then the XSPI must be configured with a data length of 4 bytes. The LSB is the LSB of device A, and the third byte is the LSB of device B.

If each device gives a status of 16 bits, then the XSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-octal DTR mode. In such case, the order of retrieved status bits is as follows:
- first byte: LSB of device A
- second byte: second byte of device A
- third byte: LSB of device B
- fourth byte: second byte of device B

In indirect mode using DTR mode, a number of bytes multiple of four must always be accessed in XSPI mode. For this reason, bit 0 and bit 1 of the DL[31:0] bitfield in XSPI_DLR are stuck at 0 when DMODE[2:0] = 101.

In dual-octal configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycles phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

Note: The variable latency is not supported in dual-octal configuration.

XSPI mode

When DMODE[2:0] = 0b101 in XSPI_CCR, the XSPI is in single 16-bit-memory configuration: when DMODE[2:0] = 0b101 with DMM value ignored in that case. A single external XSPI device is used in order to send/receive 16 bits (or 32 bits in DTR mode) every cycle, effectively doubling the throughput.

The device provides/receives two separate DQS signals: DQS0 for the eight LSBs and DQS1 for the eight MSBs.
The XSPI mode can be used in conjunction with the single-SPI, dual-SPI, quad-SPI and octal-SPI modes, as well as with either the SDR or the DTR mode.

The device size, as specified in DEVSIZE[4:0] of XSPI_DCR1, must reflect the total external device capacity.

In SDR mode, a number of bytes multiple of two must always be accessed in XSPI mode. For this reason, bit 0 of DL[31:0] in XSPI_DLR is stuck at 0 when DMODE = 101.

In DTR mode, a number of bytes multiple of four must always be accessed in XSPI mode. For this reason, bit 0 and 1 of DL[31:0] in XSPI_DLR are stuck at 0 when DMODE = 101.

### 24.4.7 HyperBus protocol

The XSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins in 8-bit data mode, or 19 to 20 pins in 16-bit data mode depending on the operating voltage:

- IO[7:0] as bidirectional data bus for 8-bit data mode and IO[15:0] as bidirectional data bus for 16-bit data mode
- DQS for read and write data strobe and latency insertion
- NCS
- CLK
- NCLK for 1.8 V operations (to support this mode, the device must be powered with 1.8 V)

The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:

- command/address phase
- data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.

---

**Figure 200. Example of HyperBus read operation (8-bit data mode)**

- NCS
- CLK
- DQS0
- IO[7:0]
- Dout A
- Dout B
- Dout[11:0]
- Dout[11:0]
- Memory drives IO[7:0] and DQS0
- Host drives IO[7:0] and memory drives DQS0
- Command-Address
- Latency count
- High = 2x Latency count
- Low = 1x Latency count

Note: DQS0 and data are edge aligned.
The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

**Command/address phase**

During this initial phase, the XSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

<table>
<thead>
<tr>
<th>CA bit</th>
<th>Bit name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>47</td>
<td>R/W#</td>
<td>Identifies the transaction as a read or a write</td>
</tr>
<tr>
<td>46</td>
<td>Address space</td>
<td>Indicates if the transaction accesses the memory or the register space</td>
</tr>
<tr>
<td>45</td>
<td>Burst type</td>
<td>Indicates if the burst is linear or wrapped</td>
</tr>
<tr>
<td>44-16</td>
<td>Row and upper column address</td>
<td>Selects the row and the upper column addresses</td>
</tr>
<tr>
<td>15-3</td>
<td>Reserved</td>
<td>-</td>
</tr>
<tr>
<td>2-0</td>
<td>Lower column address</td>
<td>Selects the starting 16-bit word within the half page</td>
</tr>
</tbody>
</table>

The address space is configured through the memory type MTYP[2:0] of XSPI_DCR1. The total size of the device must be considered through DEVSIZE[4:0] of XSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

---

**Warning:** Some memory specifications consider that each address corresponds to a 16-bit value. The XSPI considers that each address corresponds to an 8-bit value. So, the software needs to multiple the address by two when accessing the memory registers.

---

**Read/write operation with initial latency**

The HyperBus read and write operations need to respect two timings:

- **tRWR**: minimal read/write recovery time for the device (defined by TRWR[7:0] in XSPI_HLCR)
- **tACC**: access time for the device (defined in TACC[7:0] of XSPI_HLCR) according to the memory latency

During the read operation, the DQS0/1 is used by the device, in two ways (see Figure 200):

- during the command/address phase, to request an additional latency
- during the data phase, for data strobing
During the write operation, the DQS0/1 is used:
- by the device, during the command/address phase, to request an additional latency.
- by the XSPI, during the data phase, for write data masking.

**Figure 201. HyperBus write operation with initial latency (8-bit data mode)**

Read/write operation with additional latency

If the device needs an additional latency (during refresh period of an SDRAM for example), DQS0/1 must be tied to one during one of the DQS signals, during the command/address phase.

An additional $t_{\text{ACC}}$ duration is added by the XSPI to meet the device request.

**Figure 202. HyperBus read operation with additional latency (8-bit data mode)**
Fixed latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.

The latency can be forced to 2 x t_{ACC} by setting LM of XSPI_HLCR.

In this XSPI latency mode, the state of the DQS signal is not taken into account by the XSPI and an additional latency is always added leading to a fixed 2 x t_{ACC} latency time.

Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in XSPI_HLCR.
Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the \( t_{ACC} \) time.

**Figure 205. HyperBus read operation page crossing with latency (8-bit data mode)**

16-bit data transfer using HyperBus

In HyperBus protocol, the XSPI supports a dual-octal configuration (16-bit data transfers) when \( DMM = 1 \) in XSPI\_CR: one octal HyperBus memory is connected to IO0-IO7 and another is connected to IO8-IO15. These memories share all signals except DQS that are dedicated.

For 16-bit data transfers, \( DMODE[2:0] \) must be to equal to 101. Any other value in \( DMODE[2:0] \) correspond to 8-bit data transfer (quad-, dual-, and single-bit data transfer do not exist in HyperBus protocol). Command-address phase is always using 8 bits in HyperBus protocol (from IO8-IO15). Only the data is on 16-bit for write or read operations accessing the memory space (from IO0-IO15) as shown for instance in **Figure 206**. For the memory register accesses, the data is on 8-bit (from IO0 to IO7, IO8 to IO15 being not used but driven by the controller) as shown in **Figure 204**.

The behavior of the interface at protocol-level is exactly the same as for HyperBus octal configuration, as described above, except that the variable latency is not supported in dual-octal HyperBus configuration. LM in XSPI\_HLCR must be set.
24.4.8 Specific features

The XSPI supports some specific features, such as:
- wrap support
- NCS boundary and refresh
- communication regulation

Wrap support

The XSPI supports an hybrid wrap as defined by the HyperBus protocol. A hybrid wrap is also supported in the regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in XSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 8 bytes. Wrapped reads are supported for both HyperBus and regular-command protocols. To enable wrapped-read accesses, the dedicated registers XSPI_WPxxx must be programmed according to the wrapped-read access characteristics. The dedicated XSPI_WPxxx registers apply for both HyperBus and regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

Note: Hybrid wrap requires that the nonwrapped registers (XSPI_CCR, XSPI_TCR, XSPI_IR) are set according to the memory configuration to satisfy its correct data prefetch (initiated after the wrap command).

The wrap operation cannot be interrupted by a refresh. The refresh event is only considered after the wrap completion.
NCS boundary and refresh

Two processes can be activated to regulate the XSPI transactions:

- NCS boundary
- refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with is configured in CSBOUND[4:0] of XSPI_DCR3 and it is equal to $2^{\text{CSBOUND}}$.

As an example, if CSBOUND[4:0] = 0x4, the boundary is set to $2^4 = 16$ bytes. As a consequence, the NCS is released each time that the LSB address is equal to 0xF, and each time that a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled. A minimum value of three is recommended.

The NCS boundary feature cannot be used for flash memory devices in write mode since a command is necessary to program another page of the flash memory.

The refresh feature limits the duration of the transactions to the value programmed in REFRESH[31:0] of XSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command, address, alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

Communication regulation

The communication regulation feature is useful in case two or more XSPIs share access to the same I/O port through an I/O manager. This feature limits the maximum length of a transaction to the value programmed in MAXTRAN[7:0] of XSPI_DCR3.

If the number of clock cycles of XSPI1 for example reach the MAXTRAN + 1 value, and if the second interface connected to the I/O manager requests an access, the NCS is released, and a new transaction is issued. If the second interface connected to the I/O manager does not request an access, the transaction is not stopped, and the NCS is not released.

If MAXTRAN[7:0] = 0, no limitation occurs.

The MAXTRAN[7:0] value must be greater than the minimal transaction size in terms of number of cycles including the command, address, alternate, and dummy phases.

Note: The communication regulation feature cannot be used in write mode for the flash memory devices that require extra command to reenable the write operation after the NCS is active again.

If NCS boundary, refresh and communication regulation are enabled at the same time, the NCS is released on the first condition met.

Restarting after an interrupted transfer

When a read or write operation is interrupted by a timeout, the XSPI interface, as soon as possible after getting back the port ownership, re-issues the initial command sequence together with the address following the last address actually accessed before interruption. The transfer initially set goes on and ends seamlessly.
24.4.9  XSPI operating modes introduction

The XSPI has the following operating modes regardless of the low-level protocol used (either regular-command or HyperBus):
- indirect mode (read or write)
- automatic status-polling mode (only in regular-command protocol)
- memory-mapped mode

24.4.10  XSPI indirect mode

In indirect mode, the commands are started by writing to the XSPI registers, and the data is transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 00 in XSPI_CR, the XSPI is in indirect-write mode: bytes are sent to the external device during the data phase. Data are provided by writing to XSPI_DR.

When FMODE[1:0] = 01, the XSPI is in indirect-read mode: bytes are received from the external device during the data phase. Data are recovered by reading XSPI_DR.

In indirect mode, when the XSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

Note: The XSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.

The number of bytes to be read/written is specified in XSPI_DLR:
- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the XSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in XSPI_CCR.
- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the XSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, TCF bit is set in XSPI_SR and an interrupt is generated if TCIE = 1 in XSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in XSPI_DCR1.

Triggering the start of a transfer in regular-command protocol

Depending on the XSPI configuration, there are three different ways to trigger the start of a transfer in indirect mode when using regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in indirect mode, a transfer starts when one of the following sequence of events occurs:
- if no address is necessary (ADMODE[2:0] = 000) and if no data needs to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in XSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data needs to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in XSPI_AR
• if data needs to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in XSPI_DR

A write to XSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in XSPI_SR.

**Triggering the start of a transfer in HyperBus protocol**

Depending on the XSPI configuration, there are different ways to trigger the start of a command in indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (XSPI_AR) with ADMODE[2:0] ≠ 000 in indirect read mode (FMODE[1:0] = 01)
- when a write is performed to DATA[31:0] (XSPI_DR) in indirect-write mode (when FMODE = 00)
- when a (dummy) write is performed to INSTRUCTION[31:0] (XSPI_IR) for indirect read mode (with ADMODE[2:0] = 000 and FMODE = 01)

As soon as a transfer is started, the BUSY bit (XSPI_SR[5]) is automatically set.

**FIFO and data management**

Data in indirect mode pass through a 64-byte FIFO that is internal to the XSPI. FLEVEL in XSPI_SR indicates how many bytes are currently being held in the FIFO.

In indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in the XSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to the XSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

In indirect-read mode, when the FIFO becomes full, the XSPI temporarily stops reading bytes from the external device to avoid an overrun. Note that the reading of the external device does not restart until 4 bytes become vacant in the FIFO (when FLEVEL ≤ (FIFO_size - 4)). Thus, when FTHRES ≥ (FIFO_size - 3), the application must be sure to read enough bytes to assure that the XSPI starts retrieving data from the external device again. Otherwise, the FTF flag stays at 0 as long as FLEVEL < FTHRES.
The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

24.4.11 XSPI automatic status-polling mode

In automatic status-polling mode, the XSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.

The automatic status-polling mode must be used only in regular-command protocol. For HyperBus protocol, it is not exploitable since the read status register into the HyperFlash memory must be performed in two steps (a write operation followed by a read operation).

The access to the device begins in the same manner as in indirect-read mode. BUSY in XSPI_SR goes high at this point, and stays high even between the periodic accesses.

The content of MASK[31:0] in XSPI_PSMAR is used to mask the data from the external device in automatic status-polling mode:
- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in XSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in XSPI_CR, the AND-match mode is activated: SMF is set in XSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in XSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in XSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the XSPI is disabled (EN = 0).

XSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in XSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In automatic status-polling mode, variable latency is not supported. As a consequence, the memory must be configured in fixed latency.

24.4.12 XSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

**Note:** No more than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256-Mbyte range, then an AXI error is given. The effect of this error depends on the AXI master that attempted the access:
- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated, and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.
A support for execute in place (XIP) operation is implemented, where the XSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations end up quickly since their results were prefetched.

By default, the XSPI never stops its prefetch operation, it either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time.

Since external devices tend to consume more when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in XSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in XSPI_LPTR, when x cycles have elapsed without an access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

### 24.4.13 XSPI configuration introduction

The XSPI configuration is done in three steps:

1. XSPI system configuration
2. XSPI device configuration
3. XSPI mode configuration

### 24.4.14 XSPI system configuration

The XSPI is configured using XSPI_CR. The user must program:

- the functional mode with FMODE[1:0]
- the automatic status-polling mode behavior if needed with PMM and APMS
- the FIFO level with FTHRES
- DMA use with DMAEN
- the timeout counter use with TCEN
- the dual-memory configuration, if needed, with DMM

In case of an interrupt use, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in XSPI_LPTR.

The DMA channel must not be enabled during the XSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and XSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

### 24.4.15 XSPI device configuration

The parameters related to the external device targeted are configured through XSPI_DCR1 and XSPI_DCR2. The user must program:

- the device size with DEVSIZE[4:0]
- the chip-select minimum high time with CSHT[5:0]
the device frequency with PRESCALER[7:0]

DEVSIZE[4:0] defines the size of external memory using the following formula:

Number of bytes in the device = \(2^{(DEVSIZE+1)}\)

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

If DMM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

When the XSPI executes two commands, one immediately after the other, it raises the NCS high between the two commands, at least one CLK cycle by default.

If the external device requires more time between commands, CSHT[5:0] can be used to specify the minimum number of CLK cycles (up to 64) for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

In HyperBus protocol, the device timing (tACC and tRWR) and the Latency mode must be configured in XSPI_HLCR.

**Memory types**

External memory providers may present some architecture and slight data formatting differences between them. The bitfield MTYP[2:0] into the XSPI_CR register allows targeting the right controller configuration depending on the associated memory type selected in the application. This is the responsibility of the software developer to align the controller configuration to fit with the targeted memory type.

The memory types are grouped in a such way:

- D0/D1 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 000. For instance, Micron is using such data ordering. In this configuration, the DQS is sent with a polarity inverted respect to the clock polarity.

- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 001. For instance, Macronix is using this reverse data ordering in its Octaflash portfolio (this configuration is not adapted to its OctaRAM™ memories). DQS is keeping the same polarity as the clock when reading data from the
memory. Refer to Figure 197: DTR read in octal-SPI mode with DQS (Macronix mode) example.

- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 011 with specific address phase built with row and column to fit with Macronix OctaRAM™ memories requirement (refer to Table 212: OctaRAM command address bit assignment (based on 64 Mb OctaRAM)). This is the controller which translates internally the targeted address provided by the software in row/column address formatting to sent to the memory. DQS is keeping the same polarity as the clock when reading data from the memory.

Figure 208. OctaRAM read operation with reverse data ordering D1/D0

1. Example of 64 Mb OctaRAM address assignment:
   Row Address [RA12:RA0]: 8K. Column address [CA9:CA0]: 1K. 64 Mb density = 8K x 1K x 8 bits
2. Column address A0 must be always 0.

- HyperBus memories need to be selected when targeted by the application. The configuration to set depends on the access type:
  - HyperBus memory mode: The protocol follows the HyperBus specification. MTYP[2:0] = 100 is the configuration to use to access the memory space.
  - HyperBus register mode (addressing register space): the memory-mapped accesses in this mode must be noncacheable, or the indirect read/write modes
must be used. The configuration to be set for this particular register space access
is MTYP[2:0] = 101.

- The software must configure MTYP[2:0] = 110 when the memory targeted comes from
APmemory and DMODE[2:0] = 101 to fit with the memory provider requirements
concerning the address formatting.
- Standard mode. It is the mode to use whenever the targeted memory is not
  corresponding to any others configurations described in this section. MTYP[2:0] = 010
for this standard mode.

24.4.16 XSPI regular-command mode configuration

Indirect mode configuration

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the
external device. When FMODE[1:0] = 01, the indirect-read mode is selected and data can
be read from the external device.

When the XSPI is used in indirect mode, the frames are constructed in the following way:
1. Specify a number of data bytes to read or write in XSPI_DLR.
2. Specify the frame timing in XSPI_TCR.
3. Specify the frame format in XSPI_CCR.
4. Specify the instruction in XSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in
   XSPI_ABR.
6. Specify the targeted address in XSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through XSPI_DR (if no DMA usage).

If neither the address register (XSPI_AR) nor the data register (XSPI_DR) need to be
updated for a particular command, then the command sequence starts as soon as XSPI_IR
is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just
ADMODE[2:0] = 000 when in indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to
be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as
soon as the address is updated with a write to XSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the
communication start is triggered by a write in the FIFO through XSPI_DR.

Automatic status-polling mode configuration

The automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the
programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in
XSPI_DLR, it is ignored, and only 4 bytes are read. The periodicity is specified in XSPI_PIR.

Once the status data has been retrieved, the following can be processed:
- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.
The received value can be masked with the value stored in XSPI_PSMKR, and can be ORed or ANDed with the value stored in XSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The XSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in XSPI_DR.

When the XSPI is used in automatic status-polling mode, the frames are constructed in the following way:
1. Specify the input mask in XSPI_PSMKR.
2. Specify the comparison value in XSPI_PSMAR.
3. Specify the read period in XSPI_PIR.
4. Specify a number of data bytes to read in XSPI_DLR.
5. Specify the frame timing in XSPI_TCR.
6. Specify the frame format in XSPI_CCR.
7. Specify the instruction in XSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR.
9. Specify the optional targeted address in XSPI_AR.

If the address register (XSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as XSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to XSPI_AR.

Memory-mapped mode configuration

In memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled. The indirect-write mode fulfills this operation, possibly in conjunction with the automatic status-polling mode.

Memory-mapped mode is entered by setting FMODE[1:0] = 11 in XSPI_CR.

The programmed instruction and frame are sent when an AXI master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to XSPI_DR in this mode returns zero.

The data length register (XSPI_DLR) has no meaning in memory-mapped mode.

When the XSPI is used in memory-mapped mode, the frames are constructed in the following way:
1. Specify the frame timing in XSPI_TCR for read operation.
2. Specify the frame format in XSPI_CCR for read operation.
3. Specify the instruction in XSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR for read operation.
5. Specify the frame timing in XSPI_WTCR for write operation.
6. Specify the frame format in XSPI_WCCR for write operation.
7. Specify the instruction in XSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in XSPI_WABR for write operation.

All the configuration operations must be completed (ensured by checking BUSY = 0) before the first access to the memory area: any register write operation when BUSY = 1 have no effect and is not signaled with an error response. On the first access, the XSPI becomes busy, and no further configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

Memory-mapped write operations are not supported without write strobe.

**XSPI delayed data sampling when no DQS is used**

By default, when no DQS is used, the XSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in XSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

**XSPI delayed data sampling when DQS is used**

When external DQS is used as a sampling clock, it is shifted precisely by one quarter of the SPI clock cycle, for all frequencies above freq_min, to compensate the data propagation delay in the “high-speed interface” when the product embeds one.

### 24.4.17 XSPI HyperBus protocol configuration

**Indirect mode configuration (HyperBus)**

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected where data can be read from the external device. ADMODE must be configured with a value different from 000 (for instance ADMODE = 100).

When the XSPI is used in indirect mode, the frames are constructed in the following way:
1. Specify a number of data bytes to read or write in XSPI_DLR.
2. Specify the targeted address in XSPI_AR.
3. Enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through XSPI_DR (if no DMA usage).

In indirect-read mode, the command sequence starts as soon as the address is updated with a write to XSPI_AR.

In indirect-write mode, the communication start is triggered by a write in the FIFO through XSPI_DR.
Memory-mapped mode configuration (HyperBus)

In memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

The memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AXI master is accessing the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to XSPI_DR in this mode returns zero.

The data length register (XSPI_DLR) has no meaning in memory-mapped mode.

All the configuration operation must be completed before the first access to the memory area. On the first access, the XSPI becomes busy, and no configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

24.4.18 XSPI error management

The following errors set the TEF flag in XSPI_SR and generates an interrupt if enabled (TEIE = 1 in XSPI_CR):

- in indirect or automatic status-polling mode, when a wrong address has been programmed in XSPI_AR (according to the device size defined by DEVSIZE[4:0]).
- in indirect mode, if the address plus the data length exceed the device size. TEF is set as soon as the access is triggered.

In memory-mapped mode, the XSPI generates an AXI slave error in the following situations:

- The memory-mapped mode is disabled and an AXI read or write request occurs.
- Read or write address exceeds the size of the external memory.
- Abort is received while a read or write burst is ongoing when the abort condition is present at the moment of transfer phases preceding the data phase (In incremental or wrap burst type modes). To avoid the error, refer to Section 24.4.20: XSPI BUSY and ABORT.
- The XSPI is disabled while a read or write burst is requested.
- A write wrap burst is received.
- A write request is received while DQSE = 0 in XSPI_WCCR in octal DTR mode, in dual-memory configuration, in hyperbus mode or 16-bit mode.
- A read or write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means AXI Bus transfer size (ARSIZE) is different from 8 bytes (only for memory-mapped mode).
- Bit DMM is set in XSPI_CR (dual-memory configuration) and 16-bit mode is set.

24.4.19 XSPI high-speed interface and calibration

To reach higher frequencies, a dedicated high-speed interface is inserted between the XSPI (or the I/O manager in case the product embeds one), and the I/O pads.
The following is valid for all data bus sizes 1, 2, 4, 8 or 16 bits.

The high-speed interface block embeds resynchronization registers that are clocked by delayed clock created from a DLL (delay locked loop) also located in the high-speed interface. The high-speed interface features are controlled by registers located in the XSPI.

The purpose of resynchronization is primary to shift data or data strobe by one quarter of octal bus clock period, with a correct timing accuracy. DLL must be calibrated versus this clock period.

The calibration process is automatically enabled when one of the three conditions below is met:

- The XSPI exits reset state.
- A value is written in PRESCALER[7:0] of XSPI_DCR2.
- A value is written in XSPI_CCR.

The calibration process starts when the two following conditions are both met:

- The calibration has been enabled by one of the three conditions above.
- An action that sets BUSY = 1 is performed. For example the first transfer to memory after calibration is enabled. When the calibration is completed, BUSY returns to 0.

In case a periodic recalibration is needed (for example to take in account possible variations in temperature or power supply on a long duration), this recalibration must be triggered by writing periodically in PRESCALER[7:0] of XSPI_DCR2, while BUSY = 0.

Once the calibration is completed, the value of the SPI bus clock period, expressed in number of unitary delay, is available to user in COARSE[5:0] and FINE[6:0] of XSPI_CALFCR.

After auto-calibration, XSPI_CALSOR and XSPI_CALSIR are automatically loaded with the same value that corresponds to the delay for a quarter cycle.

The automatic calibration is not executed if at least one of both registers XSPI_CALSOR/XSPI_CALSIR is written between the last write operation on XSPI_DCR2 or XSPI_CCR and the next transfer start. In such case, the calibration values must be set by the software code into XSPI_CALSOR and XSPI_CALSIR registers. It may improve the flash programming time without relaunching the automatic calibration processing between two programming pages.

When the memory is not supporting DQS (DQSE = 0), the automatic calibration is not used in reception. The DLL Master is used instead for delaying the feedback clock (XSPI_CALMR). This delay needs to be adjusted by the application itself, using a software sequence that determines which delay is optimal to guarantee the correct read operations.

When the clock is divided in DTR transmission mode, the quarter cycle delays on DQS/data are not inserted by the DLLs themselves, but by internal flops design scheme. In SDR transmission mode, the DLLs are not used and this, whatever the clock prescaler value.

In case of DTR mode and prescaler bypassed (PRESCALER[7:0] = 0), the kernel clock provided to interface must have a 50 % duty-cycle.

When using the high-speed-interface, the system clock (AXI clock) must be at least as fast as the SPI clock.
24.4.20 XSPI BUSY and ABORT

Once the XSPI starts an operation with the external device, BUSY is automatically set in XSPI_SR.

In indirect mode, BUSY is reset once the XSPI has completed the requested command sequence and the FIFO is empty.

In automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on an abort.

Any operation can be aborted by setting ABORT in XSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers, otherwise, an error may be triggered and the data can be discarded. When DMA is enabled to handle the data read or write operations in XSPI_DR, it is recommended to disable the DMA channel before aborting the XSPI.

*Note:* Some devices may misbehave if a write operation to a status register is aborted.

24.4.21 XSPI reconfiguration or deactivation

Before any XSPI reconfiguration, the software must ensure that all the transactions are completed:

- After a memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a memory-mapped read, the software must perform a synchronization barrier then an abort.

24.4.22 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 (clock mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

*Figure 209. NCS when CKMODE = 0 (T = CLK period)*
When CKMODE = 1 (clock mode 3: CLK goes high when no operation is in progress) and when in SDR mode, NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

**Figure 210. NCS when CKMODE = 1 in SDR mode (T = CLK period)**

When the CKMODE = 1 (clock mode 3) and DDTR = 1 (data DTR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge (see the figure below). Because the DTR operations must finish with a falling edge, the CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

**Figure 211. NCS when CKMODE = 1 in DTR mode (T = CLK period)**

When the FIFO stays full during a read operation, or if the FIFO stays empty during a write operation, the operation stalls and CLK stays low until the software services the FIFO. If an abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later (see the figure below).

**Figure 212. NCS when CKMODE =1 with an abort (T = CLK period)**

In dual-memory configuration, the NCS2 behaves exactly the same as the NCS1. The quad-SPI/octal-SPI memory 2 can then use the NCS1, and the NCS2 pin can be used for other functions.
24.4.23 Software-controlled dual-memory support

One XSPI instance is able to control the generation of the two chip-select signals (NCS1 and NCS2). This allows two external memories to be connected to the same I/O port driven by the XSPI.

The XSPI generates one NCS signal and the user defines how the NCS is directed to NCS1 or NCS2, by setting the CSSEL bit in XSPI_CR. Intended operation is semistatic commutation, such as starting an application reading an external flash memory and then, for the rest of the application, use an external SRAM connected to the same I/O bus. From a memory-map point of view, these two memories are located in the same address range.

![Example of software-controller dual-memory support](image)

24.5 Address alignment and data number

The following table summarizes the effect of the address alignment and programmed data number depending on the use case.

</tbody>
</table>

1. To be respected by the software.
2. IND = indirect mode.
3. MM = memory-mapped mode.
4. Extra data at transfer start.
5. Extra data at transfer end.
6. WDM = write data mask.

7. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 2 aligned in DTR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.

8. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 4 aligned in DTR mode or modulo 2 in SDR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.

9. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 4 aligned in DTR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.

### 24.6 XSPI interrupts

An interrupt can be produced on the following events:
- timeout
- status match
- FIFO threshold
- transfer complete
- transfer error

Separate interrupt enable bits are available to provide more flexibility.

### 24.7 XSPI registers

#### 24.7.1 XSPI control register (XSPI_CR)

Address offset: 0x0000
Reset value: 0x00000 0000
Bits 31:30 **MSEL[1:0]: Flash select**  
These bits select the memory to be addressed in single-, dual-, quad-, or octal-SPI mode in single-memory configuration (when DMM = 0).  
- when in quad-SPI mode:  
  00: Data exchanged over IO[3:0]  
  01: Data exchanged over IO[7:4]  
  10: Data exchanged over IO[11:8]  
  11: Data exchanged over IO[15:12]  
- when in octal-SPI mode or dual-quad configuration:  
  0x: Data exchanged over IO[7:0]  
  1x: Data exchanged over IO[15:8]  
These bits are ignored when in dual-octal configuration (data on 8 bits and DMM = 1) or 16-bit configuration (data exchanged over IO[15:0]).  
*Note: Bit 30 is mirrored in bit 7. This bitfield can be modified only when BUSY = 0.*

Bits 29:28 **FMODE[1:0]: Functional mode**  
This bitfield defines the XSPI functional mode of operation.  
00: Indirect-write mode  
01: Indirect-read mode  
10: Automatic status-polling mode (relevant in regular-command protocol only)  
11: Memory-mapped mode  
If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value.  
*Note: This bitfield can be modified only when BUSY = 0.*

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **CSSEL: chip select selection**  
This bit indicates if the XSPI must activate NCS1 or NCS2.  
0: NCS1 active  
1: NCS2 active  
*Note: This bit can be modified only when BUSY = 0.*

Bit 23 **PMM: Polling match mode**  
This bit indicates which method must be used to determine a match during the automatic status-polling mode.  
0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.  
1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.  
*Note: This bit can be modified only when BUSY = 0.*

Bit 22 **APMS: Automatic status-polling mode stop**  
This bit determines if the automatic status-polling mode is stopped after a match.  
0: Automatic status-polling mode is stopped only by abort or by disabling the XSPI.  
1: Automatic status-polling mode stops as soon as there is a match.  
*Note: This bit can be modified only when BUSY = 0.*

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE: Timeout interrupt enable**  
This bit enables the timeout interrupt.  
0: Interrupt disabled  
1: Interrupt enabled
Bit 19  **SMIE**: Status match interrupt enable
This bit enables the status match interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 18  **FTIE**: FIFO threshold interrupt enable
This bit enables the FIFO threshold interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 17  **TCIE**: Transfer complete interrupt enable
This bit enables the transfer complete interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 16  **TEIE**: Transfer error interrupt enable
This bit enables the transfer error interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bits 15:14  Reserved, must be kept at reset value.

Bits 13:8  **FTHRES[5:0]**: FIFO threshold level
This bitfield defines, in indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag FTF in XSPI_SR, to be set.
000000: FTF is set if there are one or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in indirect-read mode.
000001: FTF is set if there are two or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in indirect-read mode.
...
111111: FTF is set if there are 64 free bytes available to be written to in the FIFO in indirect-write mode, or if there are 64 valid bytes can be read from the FIFO in indirect-read mode.

*Note: If DMAEN = 1, the DMA controller for the corresponding channel must be disabled before changing the FTHRES[5:0] value.*

Bit 7  Reserved, must be kept at reset value.

Bit 6  **DMM**: Dual-memory configuration
This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity.
0: Dual-memory configuration disabled
1: Dual-memory configuration enabled

*Note: This bit can be modified only when BUSY = 0.*

Bits 5:4  Reserved, must be kept at reset value.

Bit 3  **TCEN**: Timeout counter enable
This bit is valid only when the memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.
0: The timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in memory-mapped mode.
1: The timeout counter is enabled, and thus the chip-select is released in the memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.

*Note: This bit can be modified only when BUSY = 0.*
24.7.2 XSPI device configuration register 1 (XSPI_DCR1)

Address offset: 0x008
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

</tr>
</tbody>
</table>

Bits 31:27 Reserved, must be kept at reset value.
Bits 26:24 **MTYP[2:0]:** Memory type

This bitfield indicates the type of memory to be supported.

- 000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes. In this mode, DQS signal polarity is inverted with respect to the memory clock signal. This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron.
- 010: Standard mode
- 011: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes with dedicated address mapping (address is built with row and column to fit with Macronix requirements).
- 100: HyperBus memory mode, the protocol follows the HyperBus specification.
- 101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be noncacheable, or indirect read/write modes must be used.
- 110: AP memory mode. If DMODE = 101, there is a special hardware operation on address word from the bit 10 and above to fit the provider requirement (shift operation on the left from the address bit 10, keeping this last at 0).
- Others: Reserved

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **DEVSIZE[4:0]:** Device size

This bitfield defines the size of the external device using the following formula:

Number of bytes in device = 2^{DEVSIZE+1}.

DEVSIZE + 1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 Gbytes (addressed using 32-bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

In regular-command protocol, if DMM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **CSHT[5:0]:** Chip-select high time

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.

- 0x0: NCS stays high for at least 1 cycle between external device commands.
- 0x1: NCS stays high for at least 2 cycles between external device commands.
- ...
- 0x3F: NCS stays high for at least 64 cycles between external device commands.

Bits 7:2 Reserved, must be kept at reset value.

**Bit 1 **FRCK:** Free running clock

This bit configures the free running clock.

- 0: CLK is not free running.
- 1: CLK is free running (always provided).

**Bit 0 **CKMODE:** Clock mode 0/mode 3

This bit indicates the level taken by the CLK between commands (when NCS = 1).

- 0: CLK must stay low while NCS is high (chip-select released), referred to as clock mode 0.
- 1: CLK must stay high while NCS is high (chip-select released), referred to as clock mode 3.
24.7.3  XSPI device configuration register 2 (XSPI_DCR2)

Address offset: 0x00C
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:19  Reserved, must be kept at reset value.

Bits 18:16  WRAPSIZE[2:0]: Wrap size
This bitfield indicates the wrap size to which the memory is configured. For memories, which have a separate command for wrapped instructions, this bitfield indicates the wrap-size associated with the command held in XSPI_WPIR.
- 000: Wrapped reads are not supported by the memory.
- 010: External memory supports wrap size of 16 bytes.
- 011: External memory supports wrap size of 32 bytes.
- 100: External memory supports wrap size of 64 bytes.
- 101: External memory supports wrap size of 128 bytes.
- Others: Reserved

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  PRESCALER[7:0]: Clock prescaler
This bitfield defines the scaler factor for generating the CLK based on the kernel clock (value + 1).
- 0: $F_{CLK} = F_{KERNEL}$, kernel clock used directly as XSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the XSPI a kernel clock that has 50% duty-cycle.
- 1: $F_{CLK} = F_{KERNEL}/2$
- 2: $F_{CLK} = F_{KERNEL}/3$
- ... 
- 255: $F_{CLK} = F_{KERNEL}/256$
For odd clock division factors, the CLK duty cycle is not 50%. The clock signal remains low one cycle longer than it stays high.
Writing this bitfield automatically starts a new calibration of high-speed interface DLL at the start of next transfer, except in case XSPI_CALOSR or XSPI_CALISR have been written in the meantime. BUSY stays high during the whole calibration execution.
### 24.7.4 XSPI device configuration register 3 (XSPI_DCR3)

Address offset: 0x010  
Reset value: 0x0000 0000  
This register can be modified only when BUSY = 0.

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary  
This bitfield enables the transaction boundary feature. When active, a minimum value of three is recommended.  
The NCS is released on each boundary of $2^{CSBOUND}$ bytes.  
0: NCS boundary disabled  
Others: NCS boundary set to $2^{CSBOUND}$ bytes

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **MAXTRAN[7:0]**: Maximum transfer  
This bitfield enables the communication regulation feature.  
The NCS is released every MAXTRAN+1 clock cycles when the other XSPI request the access to the bus.  
0: Maximum communication disabled  
Others: Maximum communication is set to (MAXTRAN + 1) bytes.

### 24.7.5 XSPI device configuration register 4 (XSPI_DCR4)

**REFRESH[31:16]**  
**REFRESH[15:0]**
24.7.6  XSPI status register (XSPI_SR)

Address offset: 0x020
Reset value: 0x0000 0000

Bits 31:0  REFRESH[31:0]: Refresh rate
This bitfield enables the refresh rate feature. The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads. These two values can be extended with few clock cycles when refresh occurs during a byte transmission in single-, dual-, or quad-SPI mode, because the byte transmission must be completed.
0: Refresh disabled
Others: Maximum communication length is set to REFRESH + 1 clock cycles.

Bits 31:15  Reserved, must be kept at reset value.

Bits 14:8  FLEVEL[6:0]: FIFO level
This bitfield gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 64 when it is full. In automatic-status polling mode, FLEVEL is zero.

Bits 7:6  Reserved, must be kept at reset value.

Bit 5  BUSY: Busy
This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

Bit 4  TOF: Timeout flag
This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3  SMF: Status match flag
This bit is set in automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (XSPI_PSMAR).
It is cleared by writing 1 to CSMF.

Bit 2  FTF: FIFO threshold flag
In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete.
It is cleared automatically as soon as the threshold condition is no longer true.
In automatic status-polling mode this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1  TCF: Transfer complete flag
This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted. It is cleared by writing 1 to CTCF.

Bit 0  TEF: Transfer error flag
This bit is set in indirect mode when an invalid address is being accessed in indirect mode.
It is cleared by writing 1 to CTEF.
### 24.7.7 XSPI flag clear register (XSPI_FCR)

- Bits 31:5: Reserved, must be kept at reset value.
- Bit 4 **CTOF**: Clear timeout flag  
  Writing 1 clears the TOF flag in the XSPI_SR register.
- Bit 3 **CSMF**: Clear status match flag  
  Writing 1 clears the SMF flag in the XSPI_SR register.
- Bit 2: Reserved, must be kept at reset value.
- Bit 1 **CTCF**: Clear transfer complete flag  
  Writing 1 clears the TCF flag in the XSPI_SR register.
- Bit 0 **CTEF**: Clear transfer error flag  
  Writing 1 clears the TEF flag in the XSPI_SR register.

### 24.7.8 XSPI data length register (XSPI_DLR)

Address offset: 0x040  
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

*STI*
Bits 31:0  **DL[31:0]:** Data length
Number of data to be retrieved (value + 1) in indirect and automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for automatic status-polling mode.
All 1’s in indirect mode means undefined length, where XSPI continues until the end of the memory, as defined by DEVSIZE.
0x0000_0000: 1 byte is to be transferred.
0x0000_0001: 2 bytes are to be transferred.
0x0000_0002: 3 bytes are to be transferred.
0x0000_0003: 4 bytes are to be transferred.
... 0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.
0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.
0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F.
DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.
This bitfield has no effect when in memory-mapped mode.

24.7.9  **XSPI address register (XSPI_AR)**
Address offset: 0x048
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0 and FMODE ≠ 11.

</tr>
</tbody>
</table>

Bits 31:0  **ADDRESS[31:0]:** Address
Address to be sent to the external device. In HyperBus protocol, this bitfield must be even as this protocol is 16-bit word oriented. In dual-memory configuration, AR[0] is forced to 0.

**Caution:** Some memory specifications consider that each address corresponds to a 16-bit value. XSPI considers that each address corresponds to an 8-bit value. So the software needs to multiple the address by two when accessing the memory registers.
### 24.7.10 XSPI data register (XSPI_DR)

**Bits 31:0** `DATA[31:0]`: Data

Data to be sent/received to/from the external SPI device

In indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.

In indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.

In automatic status-polling mode, this register contains the last data read from the external device (without masking).

Word, half-word, and byte accesses to this register are supported. In indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes.

Similarly, in indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in indirect mode must be aligned to the bottom of this register: A byte read must read `DATA[7:0]` and a half-word read must read `DATA[15:0]`.

### 24.7.11 XSPI polling status mask register (XSPI_PSMKR)

Address offset: 0x080

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

**Bits 31:0** `MASK[31:0]`: Status mask

Mask to be applied to the status bytes received in automatic status-polling mode

For bit n:

0: Bit n of the data received in automatic status-polling mode is masked and its value is not considered in the matching logic.

1: Bit n of the data received in automatic status-polling mode is unmasked and its value is considered in the matching logic.
### 24.7.12 XSPI polling status match register (XSPI_PSMAR)

Address offset: 0x088  
Reset value: 0x0000 0000  
This register can be modified only when BUSY = 0.

### 24.7.14 XSPI communication configuration register (XSPI_CCR)

Address offset: 0x100  
Reset value: 0x0000 0000  
This register can be modified only when BUSY = 0.
Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
- 0: DQS disabled
- 1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
- 0: DTR mode disabled for the data phase
- 1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
- 000: No data
- 001: Data on a single line
- 010: Data on two lines
- 011: Data on four lines
- 100: Data on eight lines
- 101: Data on 16 lines
- Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
- 00: 8-bit alternate bytes
- 01: 16-bit alternate bytes
- 10: 24-bit alternate bytes
- 11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
- 0: DTR mode disabled for the alternate-byte phase
- 1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
- 000: No alternate bytes
- 001: Alternate bytes on a single line
- 010: Alternate bytes on two lines
- 011: Alternate bytes on four lines
- 100: Alternate bytes on eight lines
- Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
- 00: 8-bit address
- 01: 16-bit address
- 10: 24-bit address
- 11: 32-bit address
24.7.15 XSPI timing configuration register (XSPI_TCR)

Address offset: 0x108

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>Reserved, must be kept at reset value.</th>

</table>

Bit 11 **ADDTR**: Address double transfer rate

This bit sets the DTR mode for the address phase.

0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode

This bitfield defines the address phase mode of operation.

000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size

This bitfield defines the instruction size.

00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate

This bit sets the DTR mode for the instruction phase.

0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode

This bitfield defines the instruction phase mode of operation.

000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

Bit 31 Reserved, must be kept at reset value.
24.7.16 XSPI instruction register (XSPI_IR)

Address offset: 0x110
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

**TIMEOUT[15:0]**

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **TIMEOUT[15:0]:** Timeout period

After each access in memory-mapped mode, the XSPI prefetches the subsequent bytes and hold them in the FIFO.

This bitfield indicates how many CLK cycles the XSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

24.7.19  XSPI wrap communication configuration register (XSPI_WPCCR)

Address offset: 0x140
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

</tbody>
</table>

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSSHIFT**: Sample shift

- By default, the XSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
- This bit allows the data to be sampled later in order to consider the external signal delays.
- 0: No shift
- 1: 1/2 cycle shift
- The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1).

Bits 29:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles

- This bitfield defines the duration of the dummy phase according to the memory latency.
- In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).
24.7.21 **XSPI wrap instruction register (XSPI_WPIR)**

Address offset: 0x150  
Reset value: 0x0000 0000  
This register can be modified only when BUSY = 0.

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
- 0: DQS disabled
- 1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
- 0: DTR mode disabled for the data phase
- 1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
- 000: No data
- 001: Data on a single line
- 010: Data on two lines
- 011: Data on four lines
- 100: Data on eight lines
- 101: Data on 16 lines
- Others: Reserved

 Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size:
- 00: 8-bit alternate bytes
- 01: 16-bit alternate bytes
- 10: 24-bit alternate bytes
- 11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double-transfer rate
This bit sets the DTR mode for the alternate-byte phase.
- 0: DTR mode disabled for the alternate-byte phase
- 1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
- 000: No alternate bytes
- 001: Alternate bytes on a single line
- 010: Alternate bytes on two lines
- 011: Alternate bytes on four lines
- 100: Alternate bytes on eight lines

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  TRWR[7:0]: Read-write minimum recovery time
            Device Read-to-write/write-to-read minimum recovery time expressed in number of
            communication clock cycles

Bits 15:8  TACC[7:0]: Access time
            Device access time according to the memory latency, expressed in number of
            communication clock cycles

Bits 7:2  Reserved, must be kept at reset value.

Bit 1  WZL: Write zero latency
            This bit enables zero latency on write operations.
            0: Latency on write accesses
            1: No latency on write accesses

Bit 0  LM: Latency mode
            This bit selects the latency mode.
            0: Variable initial latency
            1: Fixed latency
            Note:  This bit must be set when using the dual-octal HyperBus configuration.

24.7.28  XSPI full-cycle calibration configuration (XSPI_CALFCR)

Address offset: 0x210
Reset value: 0x0000 0000

This read-only register gives the calibration code needed by the DLL master so that its delay is
equivalent to a full memory-clock cycle. The value of this register is updated every time that auto-calibration finishes.

Bits 23:16  COARSE[4:0]

Bits 15:8  FINE[6:0]
24.7.29 XSPI DLL master calibration configuration (XSPI_CALMR)

Address offset: 0x218
Reset value: 0x0000 0000

The DLL Master is used for delaying the feedback clock when reading without DQS.
The delay of the master DLL is determined by the value in this register.
This register can always be read by software and can be modified only when BUSY = 0.
This register never gets updated automatically by hardware.

<table>

24.7.30 XSPI DLL slave output calibration configuration (XSPI_CALSIR)

Address offset: 0x220
Reset value: 0x0000 0000

The DLL output slave is used to delay the output data in DDR mode for write operations. The delay of the output slave DLL is determined by the value in this register.

This register is updated automatically by hardware at the end of calibration (at the same moment that XSPI_CALFCR is updated).

If this register is written after the last write to XSPI_DCR2 or XSPI_CCR, then auto-calibration is not executed on the next transfer (auto-calibration is not performed for XSPI_CALSIR as well).

This register can always be read by software and can be modified only when BUSY = 0.

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **COARSE[4:0]**: Coarse calibration

The delay unitary value for this bitfield depends on product technology.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **FINE[6:0]**: Fine calibration

The delay unitary value for this bitfield depends on product technology.
24.7.31 XSPI DLL slave input calibration configuration (XSPI_CALSIR)

Address offset: 0x228
Reset value: 0x0000 0000

The DLL input slave is used to delay the DQS input for sampling the data when DQS is enabled for read operations. The delay of the input slave DLL is determined by the value in this register.

This register is updated automatically by hardware at the end of calibration (at the same moment that XSPI_CALFCR is updated).

If this register is written after the last write to XSPI_DCR2 or XSPI_CCR, then auto-calibration is not executed on the next transfer (auto-calibration is not performed for XSPI_CALSOR as well).

This register can always be read by software and can be modified only when BUSY = 0.

**XSPI I/O manager (XSPIM)**

### 25.1 Introduction

The XSPI I/O manager is a low-level interface, enabling an efficient XSPI pin assignment with a full I/O matrix (before alternate function map), and multiplex of single/dual/quad/octal/16-bit SPI interfaces over the same bus.

### 25.2 XSPIM main features

- Supports up to two single/dual/quad/octal/16-bit SPI interfaces
- Supports up to two ports for pin assignment
- Supports high-speed interfaces

### 25.3 XSPIM implementation

*Table 216* describes the XSPIM implementation.

<table>
<thead>
<tr>

25.4.3 XSPIM matrix

The XSPI I/O manager matrix allows the user to set a premapping of functions:
- XSPI1 mapped to Port 1, with XSPI2 mapped to Port 2 (direct mode)
- XSPI1 mapped to Port 2, with XSPI2 mapped to Port 1 (swapped mode)
- XSPI1 and XSPI2 both mapped to Port 1, with arbitration (multiplexed mode)
- XSPI1 and XSPI2 both mapped to Port 2, with arbitration (multiplexed mode)

Note: There is no possibility to use mixed combinations of signals (like NCS of XSPI1 with data of XSPI2).

When several I/O pins have the same configuration and are enabled at the same time, the result can be unpredictable.

In the default out-of-reset configuration, all the XSPI1 and XSPI2 signals are mapped, respectively, on Port 1 and on Port 2.

The configuration can be changed only when all XSPIs are disabled.
25.4.4 XSPIM multiplexed mode

When this mode is set, the XSPIs are time-multiplexed over the same bus. They get the ownership of the bus (in turn) through a request/acknowledge protocol with REQ/ACK signals.

The time-multiplexing is enabled by setting the MUXEN bit in the configuration register XSPIM_CR.

The fairness counter (MAXTRAN) of each XSPI can be used to manage the maximum duration for which a given XSPI takes the bus: this feature ensures the maximum bus access latency for the other XSPI(s). When one XSPI releases the bus, a round-robin arbitration phase occurs: when another XSPI requests the bus, it gets it.

When the multiplexed mode is enabled, either the fairness counter or the refresh timeout counter of both XSPI interfaces must be activated.

Each XSPI delivers one NCS signal together with a CSSEL control signal. The CSSEL signal selects which of the two outputs (NCS1, NCS2) is active. In multiplexed modes the active CCSEL signal is the one of the XSPI owning the bus. The default value of XSPI_CR.CSSEL is 0 for XSPI1 and 1 for XSPI2. Only XSPIn_IOs, XSPIn_DQS and XSPIn_CLK / XSPIn_NCLK are multiplexed.

When the multiplexed mode is used, only clock mode 0 is supported on the XSPIs.

Due to arbitration and bus sharing, the auto polling interval time of the XSPI, when used, can be increased.

**Minimum switching duration**

The minimum number of cycles needed to switch from an XSPI to another can be configured. This guarantees a latency between the falling edge of the REQ signal of the active XSPI (the active one releases the bus), and the rising edge of the ACK signal to the requesting XSPI (the bus is granted to the requesting one).

The duration is defined by the REQ2ACK_TIME field in the XSPIM_CR register.

25.5 Use cases description

The following table summarizes the use cases corresponding to IO manager modes.

</tbody>
</table>
25.5.1 XSPIs direct octal mode

This is the baseline mode: each XSPI drives independently the corresponding port and high-speed interface. There is no multiplexing.

The configuration selection signal selects the signals used for each high speed interface. These signals come from the XSPI_CR and XSPI_CALxxx register outputs.

Alternate function signals can be routed on NCS2 pins (they are not used for the XSPI bus), nclk clocks are requested in case of 1.8 V HyperBus memory type.

This mode is selected by default through bits XSPIM_CR[1:0].

25.5.2 XSPI direct 16-bit mode

This is the baseline mode, completely similar to XSPI octal direct mode, where each XSPI drives directly the corresponding port (XSPI1 connected to Port 1, XSPI2 connected to Port 2). Two DQS (1 per byte) are needed for each 16-bit port, when available.
25.5.3 **XSPI dual-octal mode**

This mode is equivalent to XSPI direct mode, but, for simplicity, only one XSPI interface is represented. Two external octal memories are accessed in parallel, similarly to the dual-quad mode implemented with octal interfaces.
25.5.4 XSPI swapped mode

This mode is similar to XSPI direct mode, but the ports are swapped, to help I/O mapping. The mode is selected by bits XSPIM.CR[1:0].

If XSPIM.CR[0] or XSPIM.CR[1] is toggled in application, XSPI DCR2 or XSPI.CCR must be written, so that the calibration of the high speed interface is launched according to the new XSPI using it.

**Note:** In swapped mode, the XSPI2 can be configured in 16-bit mode, and the XSPI1 can be configured in octal mode, to connect an external 16-bit memory on Port 1, and to connect in a concurrent way an octal external memory connected to Port 2 of the I/O manager.

**Figure 218. XSPI swapped (octal) mode**

25.5.5 Two XSPIs multiplexed mode to Port 1 accessing two external memories

If only one output port is used to access two memories, alternate function signals can be routed to pins corresponding to the other port. This mode is selected by bits XSPIM.CR[1:0].

The arbiter in IO manager selects XSPI1 or XSPI2 to own the octal-SPI bus according to the existing transfer requests and status of the two MAXTRAN fairness counters.

The external memories can be on separate chips, or embedded in a single multichip package. In this case, each memory requests a dedicated Chip select, selected according to the CSSEL control of the XSPI currently owning the bus.

The configuration signals of the high speed interface toggle when the corresponding XSPI is selected, because the timing characteristics of the two memories can be different.
25.5.6 Two XSPIs multiplexed mode to Port 2 accessing two external memories

This is similar to XSPI multiplexed mode to Port 1, but target is Port 2. This mode is selected by bits XSPIM_CR[2:1].
25.5.7 XSPI1 and XSPI2 drive a single external memory

This is similar to XSPIs multiplexed mode to Port 1, but in this case only one external memory is present. Both CSSEL controls must target the same NCS (NCS1 in Figure 221).

Figure 221. XSPI1 and XSPI2 drive a single external memory (octal mode)

This use case is valid even when Port 2 is used instead of Port 1, and also possible with XSPI1 and XSPI2 interfacing a 16-bit memory (connecting XSPIM_P1_DQS1 to the memory).

25.5.8 A single XSPI drives two external memories

This is a subset of direct mode and corresponds to semi-dynamic switching. There are two target memories, but the arbiter is not used. The software must set the XSPI1 chip selector (bit 24 of XSPI_CR register) each time the target memory changes.

The baseline use case boots on flash (memory1) and then switches to SRAM (memory2) for the rest of the application.
This use case is valid even when Port 2 is used instead of Port 1, and also with XSPI3 interfacing two 16-bit memories (connecting XSPIM_P1_DQS1 to the memory).
25.6 XSPIM registers

25.6.1 XSPIM control register (XSPIM_CR)

Address offset: 0x0000
Reset value: 0x0000 0000

| Bits 31:24 | Reserved, must be kept at reset value. |
| Bits 23:16 | **REQ2ACK_TIME[7:0]**: REQ to ACK time |
| In Multiplexed mode (MUXEN = 1), this field defines the time between two transactions. |
| The value is the number of XSPI clock cycles - 1 |
| Bits 15:7 | Reserved, must be kept at reset value. |
| Bit 6 | **CSSEL_OVR_O2**: Chip select selector override setting for XSPI2 |
| 0: the chip select signal from XSPI2 is sent to NCS1 |
| 1: the chip select signal from XSPI2 is sent to NCS2 |
| Bit 5 | **CSSEL_OVR_O1**: Chip select selector override setting for XSPI1 |
| 0: the chip select signal from XSPI1 is sent to NCS1 |
| 1: the chip select signal from XSPI1 is sent to NCS2 |
| Bit 4 | **CSSEL_OVR_EN**: Chip select selector override enable |
| 0: override not enabled |
| 1: CSSEL_OVR_O1 and CSSEL_OVR_O2 bit values overwrite the CSSEL signal values coming from XSPI1 and XSPI2 |
| Bits 3:2 | Reserved, must be kept at reset value. |
| Bit 1 | **MODE**: XSPI multiplexing mode |
| 0: if MUXEN = 0 direct mode, if MUXEN = 1 arbitration mode to output Port 1 |
| 1: if MUXEN = 0 swapped mode, if MUXEN = 1 arbitration mode to output Port 2 |
| Bit 0 | **MUXEN**: Multiplexed mode enable |
| This bit enables the multiplexing of the two XSPIs. |
| 0: No multiplexing, hence no arbitration |
| 1: XSPI1 and XSPI2 are multiplexed over the same bus |

Refer to *Section 2.3 on page 149* for the register boundary addresses.
26 Delay block (DLYB)

26.1 Introduction
The delay block (DLYB) is used to generate an output clock that is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an SDMMC interface.

The delay is voltage- and temperature-dependent, that may require the application to reconfigure and recenter the output clock phase with the receive data.

26.2 DLYB main features
The delay block has the following features:
- Input clock frequency ranging from 25 MHz to the maximum frequency supported by the communication interface (see datasheet)
- Up to 12 oversampling phases.

26.3 DLYB functional description
26.3.1 DLYB diagram
The delay block includes the following sub-blocks (shown in the figure below):
- register interface block providing AHB access to the DLYB registers
- delay line supporting the unit delays
- delay line length sampling
- output clock selection multiplexer

Figure 223. DLYB block diagram
26.3.2 DLYB pins and internal signals

Table 220 lists the DLYB internal signals.

</tr>
</tbody>
</table>

26.3.3 General description

The delay block is enabled by setting the DEN bit in the DLYB control register (DLYB_CR). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT[6:0] field in the DLYB configuration register (DLYB_CFGR).

Note: UNIT[6:0] can be programmed only when the output clock is disabled (SEN = 1).

When the delay block is enabled, the output clock phase is selected through the SEL[3:0] field in DLYB_CFGR register.

Note: SEL can be programmed only when the output clock is disabled (SEN = 1).

The output clock can be de-phased over one input clock period by configuring the delay line length to span one period. The delay line length can be configured by enabling the length sampler through the SEN bit, that gives access to the delay line length (LNG[11:0]) and length valid flag (LNGF) in DLYB_CFGR.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced. This allows a smaller unit delay providing higher resolution.

Once the delay line length is configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL[3:0]. The output clock is only available on the selected phase when SEN is set to 0.

The table below gives a summary of the delay block control.

Table 222. Delay block control

</tr>
</tbody>
</table>
26.3.4 Delay line length configuration procedure

LNG[11:0] is used to determine the delay line length with respect to the input clock period. The length must be configured so that one full input clock period is covered by the delay line length.

Note that despite the delay line has 12 unit delay elements, the following procedure description returns a length between 0 and 10, as the upper delay output value is used to ensure that the delay is calibrated over one full input clock cycle. Depending on the clock frequency and UNIT value, unit delay element 10 may also be truncated from the clock cycle length.

A clock input (free running clock) must be present during the whole tuning procedure.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to 1.
2. Enable the length sampling by setting SEN bit to 1.
3. Enable all delay cells by setting SEL[3:0] to 12.
4. For UNIT[6:0] = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT[6:0] value and wait till the length flag LNGF is set to 1.
   b) Read LNG[11:0].
      If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period: for N = 0 to 10, if LNG[N] = 1, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to 0.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced smaller than one input clock period. This allows a smaller unit delay, providing a higher resolution spanning a shorter time interval.

26.3.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:

---

### Table 222. Delay block control

<table>
<thead>
<tr>
<th>DEN</th>
<th>SEN</th>
<th>UNIT</th>
<th>SEL</th>
<th>LNG</th>
<th>LNGF</th>
<th>Output clock</th>
</tr>
</thead>
<tbody>

<td>1</td>
<td>0</td>
<td>Unit delay(1)</td>
<td>Output clock phase(2)</td>
<td>Don’t care</td>
<td>Don’t care</td>
<td>Enabled (= selected phase)</td>
</tr>
</tbody>
</table>

1. The unit delay can only be changed when SEN = 1.
2. The output clock phase can only be changed when SEN = 1.
Delay block (DLYB) RM0477

1. Disable the output clock and enable the access to the phase selection SEL[3:0] bits by setting SEN bit to 1.
2. Program SEL[3:0] with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to 0.

SDMMC use case:
The delay block is used in conjunction with SDMMC interface variable delay. For correct sampling point tuning the delay value must cover a whole SDMMC_CK clock period. After having tuned the delay line length the individual delays are used in the sampling point tuning to find the optimal sampling point.

26.4 DLYB registers

All registers can be accessed in word, half-word and byte access.

Bit 31 LNGF: Length valid flag
This flag indicates when the delay line length value contained in LNG[11:0] is valid after UNIT[6:0] bits changed.
0: Length value in LNG is not valid.
1: Length value in LNG is valid.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 LNG[11:0]: Delay line length value
These bits reflect the 12 unit delay values sampled at the rising edge of the input clock.
The value is only valid when LNGF = 1.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 UNIT[6:0]: Delay of a unit delay cell.
These bits can only be written when SEN = 1.
Unit delay = initial delay + UNIT[6:0] x delay step

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 SEL[3:0]: Phase for the output clock.
These bits can only be written when SEN = 1.
Output clock phase = input clock + SEL[3:0] x unit delay

Refer to Section 2.3 for the register boundary addresses.
27 Analog-to-digital converters (ADC1/2)

27.1 Introduction

This section describes the implementation of up to 2 ADCs:
- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).

Each ADC consists of a 12-bit successive approximation analog-to-digital converter.

Each ADC has up to 19 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 16-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows improving analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

27.2 ADC main features

- High-performance features
  - Up to 2 ADCs which can operate in dual mode:
    - ADC1 is connected to 17 external channels and to 2 internal channels
    - ADC2 is connected to 17 external channels and to 2 internal channels
  - 12, 10, 8 or 6-bit configurable resolution
  - ADC conversion time independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Manage single-ended or differential inputs
  - AHB slave bus interface to allow fast data handling
  - Self-calibration
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Up to 4 injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by DMA for regular channel conversions
  - Data can be routed to ADF interface for post processing
  - Four dedicated data registers for the injected channels
• Low-power features
  – Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  – Allows slow bus frequency application while keeping optimum ADC performance
  – Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (auto-delayed mode)

• Oversampler
  – 16-bit data register
  – Oversampling ratio adjustable from 2 to 256x
  – Programmable data shift up to 8 bits

• Data preconditioning
  – Offset compensation

• Analog input channels
  – External analog inputs (per ADC):
    Up to 6 fast channels from GPIO pads
    Up to 11 slow channels from GPIO pads
  – 1 channel for the internal temperature sensor (VSENSE)
  – 1 channel for the internal reference voltage (VREFINT)
  – 1 channel for monitoring the external VBAT power supply pin
  – 1 channel for monitoring the internal VDDCORE supply

• Start-of-conversion can be initiated:
  – By software for both regular and injected conversions
  – By hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions

• Conversion modes
  – Each ADC can convert a single channel or can scan a sequence of channels
  – Single mode converts selected inputs once per trigger
  – Continuous mode converts selected inputs continuously
  – Discontinuous mode

• Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events

• 3 analog watchdogs per ADC
  – Watchdog can perform filtering to ignore out-of-range data

• ADC input range: $V_{SSA} \leq V_{IN} \leq V_{REF+}$

*Figure 224* shows the block diagram of one ADC.

27.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC clock is independent from the AHB bus clock.

The ADC input clock can be selected between two different clock sources (see Figure 225: ADC clock scheme):

1. The ADC clock can be a specific clock source (adc_ker_ck_input), independent and asynchronous with the AHB clock.
   Refer to section Reset and clock control (RCC) for more information on how to generate the ADC dedicated clock. To select this scheme, CKMODE[1:0] bits of ADC_CCR register must be set to 00.

2. The ADC clock can be derived from the AHB clock interface divided by a programmable factor of 1, 2 or 4. To select this scheme, CKMODE[1:0] bits of ADC_CCR must be different from 00. The programmable divider factor can be configured through to CKMODE[1:0] bits of ADC_CCR.
   The prescaling factor of 1 (CKMODE[1:0] = 01) can be used only if the AHB prescaler is set to 1 (HPRE[3:0] = 0xx in the RCC_CFGR register).

Option 1 has the advantage of achieving the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by the following ratio: 1, 2, 4, 6, 8, 12, 16, 32, 64, 128, 256, using the prescaler configured with bits PRESC[3:0] in the ADC_CCR register.

Option 2 has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

The clock is configured through CKMODE[1:0] bits must be compliant with the operating frequency specified in the device datasheet.
Clock ratio constraint between ADC clock and AHB clock

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock except if some injected channels are programmed. In this case, it is mandatory to respect the following ratio:

- $F_{\text{adc\_hclk}} \geq F_{\text{ADC}} / 4$ if the resolution of all channels are 12-bit or 10-bit
- $F_{\text{adc\_hclk}} \geq F_{\text{ADC}} / 3$ if there are some channels with resolutions equal to 8-bit (and none with lower resolutions)
- $F_{\text{adc\_hclk}} \geq F_{\text{ADC}} / 2$ if there are some channels with resolutions equal to 6-bit

Constraints between ADC clocks

When several ADC interfaces are used simultaneously, it is mandatory to use the same clock source from the RCC block without prescaler ratio for all ADC interfaces.
27.4.4 ADC connectivity

ADC inputs are connected to the external channels as well as internal sources as described below.

27.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

27.4.6 ADC Deep-power-down mode (DEEPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in Deep-power-down mode where its supply is internally switched off to reduce the leakage currents (the reset state of bit DEEPWD is 1 in the ADC_CR register).

To start ADC operations, it is first needed to exit Deep-power-down mode by setting bit DEEPWD = 0.

Then, it is mandatory to enable the ADC internal voltage regulator by setting the bit ADVREGEN = 1 into ADC_CR register. The software must wait for the startup time of the ADC voltage regulator \( T_{ADVREG\_STUP} \) before launching a calibration or enabling the ADC. This delay must be implemented by software.

For the startup time of the ADC voltage regulator, refer to device datasheet for \( T_{ADVREG\_STUP} \) parameter.

When ADC operations are complete, the ADC can be disabled (ADEN = 0). It is possible to save power by also disabling the ADC voltage regulator. This is done by writing bit ADVREGEN = 0.

Then, to save more power by reducing the leakage currents, it is also possible to re-enter in ADC Deep-power-down mode by setting bit DEEPWD = 1 into ADC_CR register. This is particularly interesting before entering Stop mode.

**Note:** *Writing DEEPWD = 1 automatically disables the ADC voltage regulator and bit ADVREGEN is automatically cleared.*

*When the internal voltage regulator is disabled (ADVREGEN = 0), the internal analog calibration is kept.*

In ADC Deep-power-down mode (DEEPWD = 1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or re-apply the calibration factor which was previously saved (refer to Section 27.4.8: Calibration (ADCAL, ADCALDIF, ADC_CALFACT)).
27.4.7 Single-ended and differential input channels

Channels can be configured to be either single-ended input or differential input by programming DIFSEL[i] bits in the ADC_DIFSEL register. This configuration must be written while the ADC is disabled (ADEN = 0). Note that the DIFSEL[i] bits corresponding to single-ended channels are always programmed at 0.

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage \( V_{\text{INP}[i]} \) (positive input) and \( V_{\text{REF}} \).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage \( V_{\text{INP}[i]} \) (positive input) and \( V_{\text{INN}[i]} \) (negative input).

The output data for the differential mode is an unsigned data. When \( V_{\text{INP}[i]} \) equals \( V_{\text{REF}} \), \( V_{\text{INN}[i]} \) equals \( V_{\text{REF}} \) and the output data is 0x000 (12-bit resolution mode). When \( V_{\text{INP}[i]} \) equals \( V_{\text{REF}} \), \( V_{\text{INN}[i]} \) equals \( V_{\text{REF}} \) and the output data is 0xFFF.

\[
\text{Converted value} = \frac{\text{ADC Full Scale}}{2} \times \left( 1 + \frac{V_{\text{INP}} - V_{\text{INN}}}{V_{\text{REF}}} \right)
\]

When ADC is configured as differential mode, both inputs should be biased at \((V_{\text{REF}})/2\) voltage.

The input signals are supposed to be differential (common mode voltage should be fixed).

Internal channels (such as \( V_{\text{REFINT}} \) and \( V_{\text{SENSE}} \)) are used in single-ended mode only.

For a complete description of how the input channels are connected for each ADC, refer to Section 27.4.4: ADC connectivity.

Caution: When configuring the channel “i” in differential input mode, its negative input voltage \( V_{\text{INN}[i]} \) is connected to another channel. As a consequence, this channel is no longer usable in single-ended mode or in differential mode and must never be configured to be converted. Some channels are shared between ADC1/ADC2: this can make the channel on the other ADC unusable. Only exception is interleaved mode for ADC master and the slave.

27.4.8 Calibration (ADCAL, ADCALDIFF, ADC_CALFACT)

Each ADC provides an automatic calibration procedure which drives all the calibration sequence including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor which is 7-bit wide and which is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

Calibration is preliminary to any ADC operation. It removes the offset error which may vary from chip to chip due to process or bandgap variation.

The calibration factor to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Write ADCALDIFF = 0 before launching a calibration which is applied for single-ended input conversions.
- Write ADCALDIFF = 1 before launching a calibration which is applied for differential input conversions.

The calibration is then initiated by software by setting bit ADCAL = 1. Calibration can only be initiated when the ADC is disabled (when ADEN = 0). ADCAL bit stays at 1 during all the
calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT_S[6:0] or CALFACT_D[6:0] of ADC_CALFACT register (depending on single-ended or differential input calibration).

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). However, if the ADC is disabled for extended periods, then it is recommended that a new calibration cycle is run before re-enabling the ADC.

The internal analog calibration is lost each time the power of the ADC is removed (example, when the product enters in Standby or VBAT mode). In this case, to avoid spending time recalibrating the ADC, it is possible to re-write the calibration factor into the ADC_CALFACT register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.

The calibration factor can be written if the ADC is enabled but not converting (ADEN = 1 and ADSTART = 0 and JADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when VREF+ voltage changed more than 10%.

Software procedure to calibrate the ADC

1. Ensure DEEPPWD = 0, ADVREGEN = 1 and that ADC voltage regulator startup time has elapsed.
2. Ensure that ADEN = 0.
3. Select the input mode for this calibration by setting ADCALDIF = 0 (single-ended input) or ADCALDIF = 1 (differential input).
4. Set ADCAL = 1.
5. Wait until ADCAL = 0.
6. The calibration factor can be read from ADC_CALFACT register.

Figure 228. ADC calibration
Software procedure to reinject a calibration factor into the ADC

1. Ensure ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT_S and CALFACT_D with the new calibration factors.
3. When a conversion is launched, the calibration factor is injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT_S for single-ended input channel or bits CALFACT_D for differential input channel.

Converting single-ended and differential analog inputs with a single ADC

If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF = 0 and one with ADCALDIF = 1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF = 0). This updates the register CALFACT_S[6:0].
3. Calibrate the ADC in differential input modes (with ADCALDIF = 1). This updates the register CALFACT_D[6:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential inputs channel (and vice-versa), the calibration is automatically injected into the analog ADC.
27.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure explained in Section 27.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)). Once DEEPPWD = 0 and ADVREGEN = 1, the ADC can be enabled and the ADC needs a stabilization time of $t_{\text{STAB}}$ before it starts converting accurately, as shown in Figure 231. Two control bits enable or disable the ADC:

- ADEN = 1 enables the ADC. The flag ADRDY is set once the ADC is ready for operation.
- ADDIS = 1 disables the ADC. ADEN and ADDIS are then automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversion can then start either by setting ADSTART = 1 (refer to Section 27.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)) or when an external trigger event occurs, if triggers are enabled.

Injected conversions start by setting JADSTART = 1 or when an external injected trigger event occurs, if injected triggers are enabled.

**Software procedure to enable the ADC**

1. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’.
2. Set ADEN = 1.
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done using the associated interrupt (setting ADRDYIE = 1).
4. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’ (optional).

**Caution:** ADEN bit cannot be set when ADCAL is set and during four ADC clock cycles after the ADCAL bit is cleared by hardware (end of the calibration).
Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to ensure that no conversion is ongoing. If required, stop any regular and injected conversion ongoing by setting ADSTP = 1 and JADSTP = 1 and then wait until ADSTP = 0 and JADSTP = 0.
2. Set ADDIS = 1.
3. If required by the application, wait until ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).

Figure 231. Enabling / disabling the ADC

27.4.10 Constraints when writing the ADC control bits

The software is allowed to write the RCC control bits to configure and enable the ADC clock (refer to RCC Section), the DIFSEL[i] control bits in the ADC_DIFSEL register and the control bits ADCAL and ADEN in the ADC_CR register, only if the ADC is disabled (ADEN must be equal to 0).

The software is then allowed to write the control bits ADSTART, JADSTART and ADDIS of the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

For all the other control bits of the ADC_CFGR, ADC_SMPRx, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy, ADC_OFCHRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if the ADC is enabled (ADEN = 1) and if there is no regular conversion ongoing (ADSTART must be equal to 0).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if the ADC is enabled (ADEN = 1) and if there is no injected conversion ongoing (JADSTART must be equal to 0).
- ADC_TRy registers can be modified when an analog-to-digital conversion is ongoing (refer to Section 27.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx) for details).

The software is allowed to write the ADSTP or JADSTP control bits of the ADC_CR register only if the ADC is enabled, possibly converting, and if there is no pending request to disable the ADC (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).
The software can write the register ADC_JSQR at any time, when the ADC is enabled (ADEN = 1). Refer to Section 27.7.16: ADC injected sequence register (ADC_JSQR) for additional details.

**Note:** There is no hardware protection to prevent these forbidden write accesses and ADC behavior may become in an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN = 0 as well as all the bits of ADC_CR register).

### 27.4.11 Channel selection (SQRx, JSQRx)

The ADC features up to 19 multiplexed channels per ADC, out of which:

- Up to 17 analog inputs coming from GPIO pads (ADC_INP/INN[i]) depending on the products, not all of them are available on GPIO pads.
- ADC is connected to 4 internal analog inputs:
  - the internal temperature sensor \((V_{\text{SENSE}})\)
  - the internal reference voltage \((V_{\text{REFINT}})\)
  - the \(V_{\text{BAT}}\) monitoring channel \((V_{\text{BAT}}/4)\)
  - the internal digital core voltage \((V_{\text{DDCORE}})\)

To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming bits VREFEN, VBATEN or TSEN in the ADC_CCR registers.

Refer to Table ADC interconnection in Section 27.4.2: ADC pins and internal signals for the connection of the above internal analog inputs to external ADC pins or internal signals.

The conversions can be organized in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADC1/2_INP/INN3, ADC1/2_INP/INN8, ADC1/2_INP/INN2, ADC1/2_INN/INP2, ADC1/2_INP/INN0, ADC1/2_INP/INN2, ADC1/2_INP/INN15.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.

- An **injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions can occur. For this, the ADC regular conversions must be first stopped by writing ADSTP = 1 (refer to Section 27.4.17: Stopping an ongoing conversion (ADSTP, JADSTP)).

The software is allowed to modify on-the-fly the ADC_JSQR register when JADSTART is set to 1 (injected conversions ongoing) only when the context queue is enabled (JQDIS = 0 in ADC_CFGR register). Refer to Section 27.4.21: Queue of context for injected conversions.
27.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time which is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 2.5 ADC clock cycles
- SMP = 001: 6.5 ADC clock cycles
- SMP = 010: 12.5 ADC clock cycles
- SMP = 011: 24.5 ADC clock cycles
- SMP = 100: 47.5 ADC clock cycles
- SMP = 101: 92.5 ADC clock cycles
- SMP = 110: 247.5 ADC clock cycles
- SMP = 111: 640.5 ADC clock cycles

The total conversion time is calculated as follows:

\[ T_{\text{CONV}} = \text{Sampling time} + 12.5 \text{ ADC clock cycles} \]

Example:

With \( F_{\text{adc, ker, ck}} = 30 \text{ MHz} \) and a sampling time of 2.5 ADC clock cycles:

\[ T_{\text{CONV}} = (2.5 + 12.5) \text{ ADC clock cycles} = 15 \text{ ADC clock cycles} = 500 \text{ ns} \]

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

Note: Depending on the ADC conversion mode, the real sampling time can vary compared to the SMP value programmed above, while the equivalent total conversion time \( T_{\text{CONV}} \) does not change:

- For the first conversion in scan or continuous mode and all the conversions in discontinuous mode, the real sampling time is 0.5 clock cycle less compared to the value configured above.
- For the second and subsequent conversions in scan or continuous mode, 0.5 cycle is added to the configured sampling time. This additional 0.5 clock cycle overlaps with the previous conversion cycle.

Constraints on the sampling time

For each channel, SMP[2:0] bits must be programmed to respect a minimum sampling time as specified in the ADC characteristics section of the datasheets.
Bulb sampling mode
When the BULB bit is set in ADC register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in ADC_SMPR1 register. The very first ADC conversion, after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The bulb mode is effective starting from the second conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

The bulb mode is neither compatible with the continuous conversion mode nor with the injected channel conversion.

When the BULB bit is set, it is not allowed to set SMPTRIG bit in ADC_CFGR2.

Sampling time control trigger mode
When the SMPTRIG bit is set, the sampling time programmed though SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected, each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion.

When a software trigger is selected, the software trigger is not the ADSTART bit in ADC_CR but the SWTRIG bit. SWTRIG bit has to be set to start the sampling period, and the SWTRIG bit has to be cleared to end the sampling period and start the conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is neither compatible with the continuous conversion mode, nor with the injected channel conversion.

When SMPTRIG bit is set, it is not allowed to set BULB bit.

I/O analog switch voltage booster
The resistance of the I/O analog switches increases when the $V_{DDA}$ voltage is too low. The sampling time must consequently be adapted accordingly (refer to the device datasheet for the corresponding electrical characteristics). This resistance can be minimized at low $V_{DDA}$
by enabling an internal voltage booster through BOOSTE bit or by selecting a VDD booster voltage (if VDD > 2.7 V) through the ADV_READY bit of the PWR_PMCR register.

**SMPLPLUS control bit**

The SMPLPLUS bit can be used to change the sampling time from 2.5 ADC clock cycles to 3.5 ADC clock cycles.

### 27.4.13 Single conversion mode (CONT = 0)

In single conversion mode, the ADC performs once all the conversions of the channels. This mode is started with the CONT bit at 0 by either:
- Setting the ADSTART bit in the ADC_CR register (for a regular channel)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel)
- External hardware trigger event (for a regular or injected channel)

Inside the regular sequence, after each conversion is complete:
- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:
- The converted data are stored into one of the four 16-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:
- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:
- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

*Note:* To convert a single channel, program a sequence with a length of 1.

### 27.4.14 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts each conversions of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:
- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set
After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

**Note:** To convert a single channel, program a sequence with a length of 1. It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to Auto-injection mode section.

### 27.4.15 Starting conversions (ADSTART, JADSTART)

Software starts ADC regular conversions by setting ADSTART = 1.

When ADSTART is set, the conversion starts:

- Immediately: if EXTEN = 0x0 (software trigger)
- At the next active edge of the selected regular hardware trigger: if EXTEN is not equal to 0x0

Software starts ADC injected conversions by setting JADSTART = 1.

When JADSTART is set, the conversion starts:

- Immediately, if JEXTEN = 0x0 (software trigger)
- At the next active edge of the selected injected hardware trigger: if JEXTEN is not equal to 0x0

**Note:** In auto-injection mode (JAUTO = 1), use ADSTART bit to start the regular conversions followed by the auto-injected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether any ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART = 0 and JADSTART = 0 are both true, indicating that the ADC is idle.

ADSTART is cleared by hardware:

- In single mode with software regular trigger (CONT = 0, EXTSEL = 0x0)
  - At any end of regular conversion sequence (EOS assertion) or at any end of subgroup processing if DISCEN = 1
- In all cases (CONT = x, EXTSEL = x)
  - After execution of the ADSTP procedure asserted by the software.

**Note:** In continuous mode (CONT = 1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT = 0 and EXTSEL ≠ 0x00), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.
JADSTART is cleared by hardware:

- In single mode with software injected trigger (JEXTSEL = 0x0)
  - At any end of injected conversion sequence (JEOS assertion) or at any end of subgroup processing if JDISCEN = 1
- In all cases (JEXTSEL = x)
  - After execution of the JADSTP procedure asserted by the software.

Note: When the software trigger is selected, ADSTART bit should not be set if the EOC flag is still high.

27.4.16 ADC timing

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

\[
T_{CONV} = T_{SMPL} + T_{SAR} = [2.5 \text{ min} + 12.5 \text{ 12bit}] \times T_{ADC\_CLK}
\]

\[
T_{CONV} = T_{SMPL} + T_{SAR} = 83.33 \text{ ns min} + 416.67 \text{ ns 12bit} = 500.0 \text{ ns (for F}_{ADC\_CLK} = 30 \text{ MHz)}
\]

Figure 233. Analog-to-digital conversion time

1. \(T_{SMPL}\) depends on SMP[2:0].
2. \(T_{SAR}\) depends on RES[2:0].
27.4.17 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP = 1 and injected conversions ongoing by setting JADSTP = 1.

Stopping conversions resets the ongoing ADC operation. Then the ADC can be reconfigured (ex: changing the channel selection or the trigger) ready for a new operation.

Note that it is possible to stop injected conversions while regular conversions are still operating and vice-versa. This allows, for instance, re-configuration of the injected conversion sequence and triggers while regular conversions are still operating (and vice-versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC would restart a new sequence).

Once this procedure is complete, bits ADSTP/ADSTART (in case of regular conversion), or JADSTP/JADSTART (in case of injected conversion) are cleared by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

Note: In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

Figure 234. Stopping ongoing regular conversions
27.4.18 Conversion on external trigger and trigger polarity
(EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (such as timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

When the Injected Queue is enabled (bit JQDIS = 0), injected software triggers are not possible.

The regular trigger selection is effective once software has set bit ADSTART = 1 and the injected trigger selection is effective once software has set bit JADSTART = 1.

Any hardware triggers which occur while a conversion is ongoing are ignored.
- If bit ADSTART = 0, any regular hardware triggers which occur are ignored.
- If bit JADSTART = 0, any injected hardware triggers which occur are ignored.

Table 230 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

### Table 230. Configuring the trigger polarity for regular external triggers

<table>
<thead>
<tr>
<th>EXTEN[1:0]</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Hardware Trigger detection disabled, software trigger detection enabled</td>
</tr>
<tr>
<td>01</td>
<td>Hardware Trigger with detection on the rising edge</td>
</tr>
<tr>
<td>10</td>
<td>Hardware Trigger with detection on the falling edge</td>
</tr>
<tr>
<td>11</td>
<td>Hardware Trigger with detection on both the rising and falling edges</td>
</tr>
</tbody>
</table>

**Note:** The polarity of the regular trigger cannot be changed on-the-fly.
The polarity of the injected trigger can be anticipated and changed on-the-fly when the queue is enabled (JQDIS = 0). Refer to Section 27.4.21: Queue of context for injected conversions.

The EXTSEL and JEXTSEL control bits select which out of 32 possible events can trigger conversion for the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.

Note: The regular trigger selection cannot be changed on-the-fly. The injected trigger selection can be anticipated and changed on-the-fly. Refer to Section 27.4.21: Queue of context for injected conversions on page 1106.

### Figure 236. Triggers shared between ADC master and slave
Refer to Table ADC interconnection in Section 27.4.2: ADC pins and internal signals for the list of all the external triggers that can be used for regular conversion.

27.4.19 Injected channel management

Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC_CFGR register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.

2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once).

3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.

4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. Figure 237 shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 30 ADC clock cycles (that is two conversions with a sampling time of 2.5 clock periods), the minimum interval between triggers must be 31 ADC clock cycles.

Auto-injection mode

If the JAUTO bit in the ADC_CFGR register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the auto-injected and discontinuous modes simultaneously.

When the DMA is used for exporting regular sequencer’s data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence is stopped upon DMA Transfer Complete event.
27.4.20 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR register.

It is used to convert a short sequence (subgroup) of n conversions \((n \leq 8)\) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of \(n\) is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR register.

When an external trigger occurs, it starts the next \(n\) conversions selected in the ADC_SQRy registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:
- DISCEN = 1, n = 3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ...

- DISCEN = 0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.
Analog-to-digital converters (ADC1/2) RM0477

Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example:
- JDISCEN = 1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

27.4.21 Queue of context for injected conversions

A queue of context is implemented to anticipate up to 2 contexts for the next injected sequence of conversions. JQDIS bit of ADC_CFGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:
- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL bits in ADC_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in ADC_JSQR register)
All the parameters of the context are defined into a single register ADC_JSQR and this register implements a queue of 2 buffers, allowing the bufferization of up to 2 sets of parameters:

- The JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written into the JSQR register is stored into the Queue of context.
- At the beginning, the Queue is empty and the first write access into the JSQR register immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the Queue is consumed and the context changes according to the next JSQR parameters stored in the Queue. This new context is applied for the next injected sequence of conversions.
- A Queue overflow occurs when writing into register JSQR while the Queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.
- Two possible behaviors are possible when the Queue becomes empty, depending on the value of the control bit JQM of register ADC_CFGR:
  - If JQM = 0, the Queue is empty just after enabling the ADC, but then it can never be empty during run operations: the Queue always maintains the last active context and any further valid start of injected sequence is served according to the last active context.
  - If JQM = 1, the Queue can be empty after the end of an injected sequence or if the Queue is flushed. When this occurs, there is no more context in the queue and hardware triggers are disabled. Therefore, any further hardware injected triggers are ignored until the software re-writes a new injected context into JSQR register.
- Reading JSQR register returns the current JSQR context which is active at that moment. When the JSQR context is empty, JSQR is read as 0x0000.
- The Queue is flushed when stopping injected conversions by setting JADSTP = 1 or when disabling the ADC by setting ADDIS = 1:
  - If JQM = 0, the Queue is maintained with the last active context.
  - If JQM = 1, the Queue becomes empty and triggers are ignored.

Note: When configured in discontinuous mode (bit JDISCEN = 1), only the last trigger of the injected sequence changes the context and consumes the Queue. The 1st trigger only consumes the queue but others are still valid triggers as shown by the discontinuous mode example below (length = 3 for both contexts):

- 1st trigger, discontinuous. Sequence 1: context 1 consumed, 1st conversion carried out
- 2nd trigger, disc. Sequence 1: 2nd conversion.
- 3rd trigger, discontinuous. Sequence 1: 3rd conversion.
- 4th trigger, discontinuous. Sequence 2: context 2 consumed, 1st conversion carried out.
- 5th trigger, discontinuous. Sequence 2: 2nd conversion.
- 6th trigger, discontinuous. Sequence 2: 3rd conversion.
Behavior when changing the trigger or sequence context

*Figure 238* and *Figure 239* show the behavior of the context Queue when changing the sequence or the triggers.

**Figure 238. Example of JSQR queue of context (sequence change)**

1. Parameters:
   - P1: sequence of 3 conversions, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 4 conversions, hardware trigger 1

**Figure 239. Example of JSQR queue of context (trigger change)**

1. Parameters:
   - P1: sequence of 2 conversions, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 2
   - P3: sequence of 4 conversions, hardware trigger 1
Queue of context: Behavior when a queue overflow occurs

The Figure 240 and Figure 241 show the behavior of the context Queue if an overflow occurs before or during a conversion.

**Figure 240. Example of JSQR queue of context with overflow before conversion**

1. Parameters:
   - P1: sequence of 2 conversions, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 2
   - P3: sequence of 3 conversions, hardware trigger 1
   - P4: sequence of 4 conversions, hardware trigger 1

**Figure 241. Example of JSQR queue of context with overflow during conversion**

1. Parameters:
   - P1: sequence of 2 conversions, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 2
   - P3: sequence of 3 conversions, hardware trigger 1
   - P4: sequence of 4 conversions, hardware trigger 1
It is recommended to manage the queue overflows as described below:

- After each P context write into JSQR register, flag JQOVF shows if the write has been ignored or not (an interrupt can be generated).
- Avoid Queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

**Queue of context: Behavior when the queue becomes empty**

*Figure 242* and *Figure 243* show the behavior of the context Queue when the Queue becomes empty in both cases JQM = 0 or 1.

**Figure 242. Example of JSQR queue of context with empty queue (case JQM = 0)**

1. Parameters:
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1

   **Note:** When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.
Figure 243. Example of JSQR queue of context with empty queue (JQM = 1)

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Flush the queue of context

The figures below show the behavior of the context Queue in various situations when the queue is flushed.

Figure 244. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion.

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Figure 245. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion and a new trigger occurs

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Figure 246. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs outside an ongoing conversion

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Queue of context: Starting the ADC with an empty queue

The following procedure must be followed to start ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when JQM bit is reset:

5. Write a dummy JSQR with JEXTEN not equal to 0 (otherwise triggering a software conversion)
6. Set JADSTART
7. Set JADSTP
8. Wait until JADSTART is reset
9. Set JADSTART.

Disabling the queue

It is possible to disable the queue by setting bit JQDIS = 1 into the ADC_CFGR register.

27.4.22 Programmable resolution (RES) - fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the control bits RES[1:0]. Figure 254, Figure 255, Figure 256 and Figure 257 show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to Table 232.
### 27.4.23 End of conversion, end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy register. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

### 27.4.24 End of conversion sequence (EOS, JEOS)

The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.

27.4.26 Data management

Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 16 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 16 bits wide.

The ALIGN bit in the ADC_CFGR register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in Figure 254, Figure 255, Figure 256 and Figure 257.

Special case: when left-aligned, the data are aligned on a half-word basis except when the resolution is set to 6-bit. In that case, the data are aligned on a byte basis as shown in Figure 256 and Figure 257.

Note: Left-alignment is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the ALIGN bit value is ignored and the ADC only provides right-aligned data.

Offset

An offset \( y \) \( (y = 1, 2, 3, 4) \) can be applied to a channel by setting the bit OFFSET_EN = 1 into ADC_OFRy register. The channel to which the offset is to be applied is programmed into the bits OFFSET_CH[4:0] of ADC_OFRy register. In this case, the converted value is decreased by the user-defined offset written in the bits OFFSET[11:0]. The result may be a negative value so the read data is signed and the SEXT bit represents the extended sign value.

Note: Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSET_EN bit in ADC_OFRy register is ignored (considered as reset).

Table 235 describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

<table>

Offset compensation

When SATEN bit is set in ADC_OFRy register during offset operation, data are unsigned. All the offset data saturate at 0x000 (in 12-bit mode). When OFFSETPOS bit is set, the offset direction is positive and the data saturate at 0xFFF (in 12-bit mode). In 8-bit mode, data saturate at 0x00 and 0xFF, respectively.

The analog watchdog comparison is performed before the offset compensation.

ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) notifies when the regular converted data has not been read (by the CPU or the DMA) before ADC_DR FIFO (three stages) is overflowed.

The OVR flag is set when a new conversion completes while ADC_CR register FIFO was full. An interrupt is generated if OVRIE bit is set to 1.

When an overrun condition occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting ADSTP to 1. Since ADC_DR FIFO features three stages, up to three data are stored in the FIFO.

OVR flag is cleared by software by writing 1 to it.

It is possible to configure if data is preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- OVRMOD = 0: The overrun event preserves the data register from being overwritten: the old data is maintained up to ADC_DR FIFO depth (three stages) and the new conversion is discarded and lost. In this mode, ADC_DR FIFO is disabled. If the FIFO is full, any further conversion is performed but the resulting data is also discarded. EOC
is cleared by reading ADC_DR register. However, the FIFO can still contain previously converted data.

- **OVRMOD = 1**: The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, any further conversions is performed normally and the ADC_DR register always contains the latest converted data.

Indicative timings
Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD must be configured to 0 to manage overrun events or FIFO overflow as an error.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and OVR flag should be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMAEN bit set to 1 in the ADC_CFGR register in single ADC mode or MDMA different from 0b00 in dual ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.
Despite this, if an overrun occurs (OVR = 1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to Section: ADC overrun (OVR, OVRMOD)).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMACFG of the ADC_CFGR register in single ADC mode, or with bit DMACFG of the ADC_CCR register in dual ADC mode:

- DMA one shot mode (DMACFG = 0)
  This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMACFG = 1)
  This mode is suitable when programming the DMA in circular mode.

### DMA one shot mode (DMACFG = 0)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when a transfer complete interrupt occurs - refer to DMA section) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.

### DMA circular mode (DMACFG = 1)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

#### 27.4.27 Managing conversions using the ADF

The ADC conversion results can be transferred directly to the audio digital filter (ADF).

In this case, the ADFCFG bit must be set to 1 and DMAEN bit must be cleared to 0.

The ADC transfers all the 16 bits of the regular data register to the ADF and resets the EOC flag once the transfer is complete.

The data format must be 16-bit signed:

- \( \text{ADC\_DR}[15:12] = \text{sign extended} \)
- \( \text{ADC\_DR}[11] = \text{sign} \)
- \( \text{ADC\_DR}[11:0] = \text{data} \)
To obtain 16-bit signed format in 12-bit ADC mode, the software needs to configure the OFFSET[11:0] to 0x800 after having set OFFSET_EN to 1.

Only right aligned data format is available for the ADF interface (see Figure 255: Right alignment (offset enabled, signed value)).

27.4.28 Dynamic low-power features

Auto-delayed conversion mode (AUTDLY)

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

When AUTDLY = 1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADC_DR register has been read or if the EOC bit has been cleared (see Figure 260).
- For an injected conversion: when the JEOS bit has been cleared (see Figure 261).

This is a way to automatically adapt the speed of the ADC to the speed of the system which reads the data.

The delay is inserted after each regular conversion (whatever DISCEN = 0 or 1) and after each sequence of injected conversions (whatever JDISCEN = 0 or 1).

Note: There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

Note: This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to restart a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see Figure 261).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see Figure 263).

The behavior is slightly different in auto-injected mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see Figure 264).
To stop a conversion in continuous auto-injection mode combined with autodelay mode (JAUTO = 1, CONT = 1 and AUTDLY = 1), follow the following procedure:

1. Wait until JEOS = 1 (no more conversions are restarted)
2. Clear JEOS,
3. Set ADSTP = 1
4. Read the regular data.

If this procedure is not respected, a new regular sequence can restart if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

27.4.29 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

**Figure 265. Analog watchdog guarded area**

AWDx flag and interrupt

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDxIE in the ADC_IER register (x = 1,2,3).

AWDx (x = 1,2,3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

**Description of analog watchdog 1**

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR register. This watchdog monitors whether either one selected channel or all enabled channels\(^1\) remain within a configured voltage range (window).

**Table 234** shows how the ADC_CFGR registers should be configured to enable the analog watchdog on one or more channels.

</table>

1. Selected by the AWD1CH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.
These thresholds are programmed in bits HT1[11:0] and LT1[11:0] of the ADC_TR1 register for the analog watchdog 1. When converting data with a resolution of less than 12 bits (according to bits RES[1:0]), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned) before the offset compensation stage. 

Table 235 describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

**Analog watchdog filter for watchdog 1**

When an ADC is configured with only one input channel (selecting several channels in scan mode not allowed), a valid ADC conversion data interval can be configured through the ADC_TR1 register:

- When converted data belong to the interval defined in ADC_TR1, a DMA request is generated.
- Otherwise, no DMA request is issued. RDATA register is updated at each conversion. If data are out-of-range a number of times higher than the value specified in AWDFILT bit of ADC_TR1, the AWDx flag is set and the corresponding interrupt is issued.

**Description of analog watchdog 2 and 3**

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDxCH[18:0] (x = 2,3).

The corresponding watchdog is enabled when any bit of AWDxCH[18:0] (x = 2,3) is set.

They are limited to a resolution of 8 bits and only the 8 MSBs of the thresholds can be programmed into HTx[7:0] and LTx[7:0]. Table 236 describes how the comparison is performed for all the possible resolutions.
ADCy_AWDx_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADCy_AWDx_OUT (y = ADC number, x = watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADCy_AWDx_OUT signal as ETR.

ADCy_AWDx_OUT is activated when the associated analog watchdog is enabled:
- ADCy_AWDx_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADCy_AWDx_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADCy_AWDx_OUT is also reset when disabling the ADC (when setting ADDIS = 1). Note that stopping regular or injected conversions (setting ADSTP = 1 or JADSTP = 1) has no influence on the generation of ADCy_AWDx_OUT.

Note: AWDx flag is set by hardware and reset by software: AWDx flag has no influence on the generation of ADCy_AWDx_OUT (ex: ADCy_AWDx_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

Figure 266. ADCy_AWDx_OUT signal generation (on all regular channels)
**Figure 267. ADCY_AWDx_OUT signal generation (AWDx flag not cleared by software)**

- Converting regular channels 1,2,3,4,5,6,7
- Regular channels 1,2,3,4,5,6,7 are all guarded

**Figure 268. ADCY_AWDx_OUT signal generation (on a single regular channel)**

- Converting regular channels 1 and 2
- Only channel 1 is guarded

**Figure 269. ADCY_AWDx_OUT signal generation (on all injected channels)**

- Converting the injected channels 1, 2, 3, 4
- All injected channels 1, 2, 3, 4 are guarded
Analog watchdog threshold control

LTx[11:0] and HTx[11:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTx[11:0] and HTx[11:0] are updated during the ADC conversion of the ADC guarded channel, the watchdog function is masked for this conversion. This masking is removed at the next start of conversion, resulting in analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new interval, no interrupt and AWDx_OUT signal are issued. The Interrupt and the AWD generation only happen at the end of the conversion which started after the threshold update. If AWD_xOUT is already asserted, programming the new thresholds does not deassert the AWDx_OUT signal.

Analog watchdog with offset compensation

When the offset compensation is enabled, the analog watchdog compares the threshold before the data compensation.

27.4.30 Oversampler

The oversampling unit performs data pre-processing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 16-bit.

It provides a result with the following form, where N and M can be adjusted:

\[
\text{Result} = \frac{1}{M} \sum_{n = 0}^{n - N - 1} \text{Conversion}(t_n)
\]

It allows to perform by hardware the following functions: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OVFS[2:0] bits in the ADC_CFGR2 register, and can range from 2x to 256x. The division coefficient M consists of a right bit shift up to 8 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 20 bits (256x 12-bit results), which is first shifted right. It is then truncated to the 16 least significant bits, rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred into the ADC_DR data register.

Note: If the intermediary result after the shifting exceeds 16-bit, the result is truncated as is, without saturation.
Figure 270. 20-bit to 16-bit result truncation

![Diagram showing 20-bit to 16-bit result truncation process]

Figure 271 gives a numerical example of the processing, from a raw 20-bit accumulated data to the final 16-bit result.

Figure 271. Numerical example with 5-bit shift and rounding

![Diagram showing numerical example with 5-bit shift and rounding]

Table 237 gives the data format for the various N and M combinations, for a raw conversion data equal to 0xFFF.

Table 237. Maximum output results versus N and M (gray cells indicate truncation)

</table>

There are no changes for conversion timings in oversampled mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N
Analog-to-digital converters (ADC1/2) RM0477

conversions, with an equivalent delay equal to $N \times T_{\text{CONV}} = N \times (t_{\text{SMPL}} + t_{\text{SAR}})$. The flags are set as follow:

- The end of the sampling phase (EOSMP) is set after each sampling phase
- The end of conversion (EOC) occurs once every $N$ conversions, when the oversampled result is available
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (that is after $N \times$ sequence length conversions total)

**ADC operating modes supported when oversampling (single ADC mode)**

In oversampling mode, most of the ADC operating modes are maintained:

- Single or continuous conversion modes
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits in ADC_CFGR register) are accumulated, truncated, rounded and shifted in the same way as 12-bit conversions are

**Note:** The alignment mode is not available when working with oversampled data. The ALIGN bit in ADC_CFGR is ignored and the data are always provided right-aligned.

**Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSET_EN bit in ADC_OFRy register is ignored (considered as reset).**

**Analog watchdog**

The analog watchdog functionality is maintained, with the following difference:

- The RES[1:0] bits are ignored, the comparison is always done by using the full 12-bit values HT1[11:0] and LT1[11:0] for AWD1, and the 8-MSB value of HT2/HT3[7:0] and LT2/LT3[7:0] for AWD2 and AWD3.
- The comparison is done on the most significant 12-bit of the 16-bit oversampled results ADC_DR[15:4] for AWD1, and ADC_DR[15:8] for AWD2 and ADW3

**Note:** Care must be taken when using high shifting values, this reduces the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HTx[7:0] / LTx[7:0] (AWD1/2/3), with HT1[11:8] and LT1[11:8] kept reset (AWD1 only).

**Triggered mode**

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TROVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

The Figure 272 below shows how conversions are started in response to triggers during discontinuous mode.
If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

Figure 272. Triggered regular oversampling mode (TROVS bit = 1)

Injected and regular sequencer management when oversampling

In oversampling mode, it is possible to have differentiated behavior for injected and regular sequencers. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

Oversampling regular channels only

The regular oversampling mode bit ROVSM defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- In continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is complete whatever the injection frequency (providing at least one regular conversion can be completed between triggers);
- In resumed mode, the accumulation restarts from 0 (previous conversions results are ignored). This mode allows to guarantee that all data used for oversampling were converted back-to-back within a single timeslot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be completed and the regular sequencer is blocked.

The Figure 273 gives examples for a 4x oversampling ratio.
**Oversampling Injected channels only**

The Injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.
Oversampling regular and Injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as represented on Figure 274 below.

Figure 274. Regular and injected oversampling modes used simultaneously

![Diagram showing regular and injected oversampling modes used simultaneously.](MS34457V2)

Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (resumed mode is forced). The JOVSE bit must be reset. The behavior is represented on Figure 275 below.

Figure 275. Triggered regular oversampling with injection

![Diagram showing triggered regular oversampling with injection.](MS34458V4)
Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1, other combinations are not supported. The ROVSM bit is ignored in auto-injected mode. The Figure 276 below shows how the conversions are sequenced.

Figure 276. Oversampling in auto-injected mode

![Diagram showing oversampling in auto-injected mode]

It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as following: JAUTO = 1, DISCEN = 0, JDISCEN = 0, ROVSE = 1, JOVSE = 1 and TROVSE = 1.

Dual ADC modes supported when oversampling

It is possible to have oversampling enabled when working in dual ADC configuration, for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).

Combined modes summary

The Table 238 below summarizes all combinations, including modes not supported.

27.4.31 Dual ADC modes

Dual ADC modes can be used in devices with two ADCs or more (see Figure 277).

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADCx master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADC_CCR register.

Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + regular simultaneous mode
- Regular simultaneous mode + alternate trigger mode
- Injected simultaneous mode + interleaved mode

In dual ADC mode (when bits DUAL[4:0] in ADC_CCR register are not equal to zero), the bits CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JQM, JAUTO of the ADC_CFGR register are shared between the master and slave ADC: the bits in the slave ADC are always equal to the corresponding bits of the master ADC.

To start a conversion in dual mode, the user must program the bits EXTEN, EXTSEL, JEXTEN, JEXTSEL of the master ADC only, to configure a software or hardware trigger, and a regular or injected trigger. (the bits EXTEN[1:0] and JEXTEN[1:0] of the slave ADC are don’t care).

In regular simultaneous or interleaved modes: once the user sets bit ADSTART or bit ADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit ADSTART or bit ADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes: once the user sets bit JADSTART or bit JADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit JADSTART or bit JADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADC_CDR). The status bits can be also read in parallel by reading the dual-mode status register (ADC_CSR).
1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.
2. The ADC common data register (ADC_CDR) contains both the master and slave ADC regular converted data.

---

*MSv36025V2*
**Injected simultaneous mode**

This mode is selected by programming bits DUAL[4:0] = 00101

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL bits in the ADC_JSQR register).

**Note:** Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master injected sequence is equal to the duration of the slave injected one (like in Figure 278), it is possible for the software to enable only one of the two JEOS interrupt (ex: master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

**Figure 278. Injected simultaneous mode on 4 channels: dual ADC mode**

If JDISCEN = 1, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the
ongoing regular sequence and the associated delay phases are ignored. There is the same behavior for regular sequences occurring on the slave ADC.

Regular simultaneous mode with independent injected

This mode is selected by programming bits DUAL[4:0] = 00110.

This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL bits in the ADC_CFGR register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on master or on the slave) aborts the current simultaneous conversions, which are restarted once the injected conversion is completed.

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Software is notified by interrupts when it can read the data:

- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the slave ADC.
- If the duration of the master regular sequence is equal to the duration of the slave one (like in Figure 279), it is possible for the software to enable only one of the two EOC interrupt (ex: master EOC) and read both converted data from the Common Data register (ADC_CDR).

It is also possible to read the regular data using the DMA. Two methods are possible:

- Using two DMA channels (one for the master and one for the slave). In this case bits MDMA[1:0] must be kept cleared.
  - Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  - Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.

- Using MDMA mode, which leaves one DMA channel free for other uses:
  - Configure MDMA[1:0] = 0b10 or 0b11 (depending on resolution).
  - A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADC_CDR)
  - A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADC_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADC_CDR register.
  - Both EOC flags are cleared when the DMA reads the ADC_CDR register.

Note: In MDMA mode (MDMA[1:0] = 0b10 or 0b11), the user must program the same number of conversions in the master’s sequence as in the slave’s sequence. Otherwise, the remaining conversions does not generate a DMA request.
If DISCEN = 1 then each “n” simultaneous conversions of the regular sequence require a regular trigger event to occur (“n” is defined by DISCNUM).

This mode can be combined with AUTDLY mode:

- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence is started only if the common data register, ADC_CDR (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADC_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

It is possible to use the DMA to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multiple-DMA mode is used: bits MDMA must be set to 0b10 or 0b11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:

- The number of conversions in the master’s sequence is equal to the number of conversions in the slave’s.
- For each simultaneous conversions of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert and the sampling time and the resolution of each channels.

Note: This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

**Interleaved mode with independent injected**

This mode is selected by programming bits DUAL[4:0] = 00111.

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately.
- The slave ADC starts after a delay of several-ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay which separates two conversions in interleaved mode is configured in the DELAY bits in the ADC_CCR register. This delay starts counting one half cycle after the end of the sampling phase of the master conversion. This way, an ADC cannot start a
conversion if the complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.
- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

Note: It is possible to enable only the EOC interrupt of the slave and read the common data register (ADC_CDR). But in this case, the user must ensure that the duration of the conversions are compatible to ensure that inside the sequence, a master conversion is always followed by a slave conversion before a new master conversion restarts. It is recommended to use the MDMA mode.

It is also possible to have the regular data transferred by DMA. In this case, individual DMA requests on each ADC cannot be used and it is mandatory to use the MDMA mode, as following:

- Configure MDMA[1:0] = 0b10 or 0b11 (depending on resolution).
- A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADC_CDR).
- A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADC_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADC_CCR register.
- Both EOC flags are cleared when the DMA reads the ADC_CCR register.

**Figure 280. Interleaved mode on one channel in continuous conversion mode: dual ADC mode**
If DISCEN = 1, each "n" simultaneous conversions ("n" is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In this mode, injected conversions are supported. When injection is done (either on master or on slave), both the master and the slave regular conversions are aborted and the sequence is restarted from the master (see Figure 282 below).

**Alternate trigger mode**

This mode is selected by programming bits DUAL[4:0] = 01001.

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN must not be 0x0.
Injected discontinuous mode disabled (JDISCEN = 0 for both ADC)

1. When the 1st trigger occurs, all injected master ADC channels in the group are converted.
2. When the 2nd trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.

Figure 283. Alternate trigger: injected group of each ADC

Note: Regular conversions can be enabled on one or all ADCs. In this case the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between 2 trigger events must be greater than or equal to 1 ADC clock period. The minimum time interval between 2 trigger events that start conversions on the same ADC is the same as in the single ADC mode.
Injected discontinuous mode enabled (JDISCEN = 1 for both ADC)

If the injected discontinuous mode is enabled for both master and slave ADCs:

- When the 1st trigger occurs, the first injected channel of the master ADC is converted.
- When the 2nd trigger occurs, the first injected channel of the slave ADC is converted.
- And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversions.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts.

Figure 284. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode

Combined regular/injected simultaneous mode

This mode is selected by programming bits DUAL[4:0] = 00001.

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

*Note:* In combined regular/injected simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Combined regular simultaneous + alternate trigger mode

This mode is selected by programming bits DUAL[4:0] = 00010.

It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. Figure 285 shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.
Note: In combined regular simultaneous + alternate trigger mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Figure 285. Alternate + regular simultaneous

If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. Figure 286 shows the behavior in this case (note that the 6th trigger is ignored because the associated alternate conversion is not complete).

Figure 286. Case of trigger occurring during injected conversion

Combined injected simultaneous plus interleaved

This mode is selected by programming bits DUAL[4:0] = 00011

It is possible to interrupt an interleaved conversion with a simultaneous injected event.

In this case the interleaved conversion is interrupted immediately and the simultaneous injected conversion starts. At the end of the injected sequence the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master’s one. Figure 287, Figure 288 and Figure 289 show the behavior using an example.

Caution: In this mode, it is mandatory to use the Common Data Register to read the regular data with a single read access. On the contrary, master-slave data coherency is not guaranteed.
Figure 287. Interleaved single channel CH0 with injected sequence CH11, CH12

Figure 288. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 1: Master interrupted first

Figure 289. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 2: Slave interrupted first
DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to Figure 290: DMA Requests in regular simultaneous mode when MDMA = 0b00).

Figure 290. DMA Requests in regular simultaneous mode when MDMA = 0b00

In simultaneous regular and interleaved modes, it is also possible to save one DMA channel and transfer both data using a single DMA channel. For this MDMA bits must be configured in the ADC_CCR register:

- **MDMA = 0b10**: A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADC_CDR contains the two half-words representing two ADC-converted data items. The slave ADC data take the upper half-word and the master ADC data take the lower half-word.

  This mode is used in interleaved mode and in regular simultaneous mode when resolution is 10-bit or 12-bit.

**Example:**

Interleaved dual mode: a DMA request is generated each time 2 data items are available:

1st DMA request: \( \text{ADC}_{-}\text{CDR}[31:0] = \text{SLV}_{-}\text{ADC}_{-}\text{DR}[15:0] \mid \text{MST}_{-}\text{ADC}_{-}\text{DR}[15:0] \)

2nd DMA request: \( \text{ADC}_{-}\text{CDR}[31:0] = \text{SLV}_{-}\text{ADC}_{-}\text{DR}[15:0] \mid \text{MST}_{-}\text{ADC}_{-}\text{DR}[15:0] \)
Figure 291. DMA requests in regular simultaneous mode when MDMA = 0b10

Configuration where each sequence contains only one conversion

Figure 292. DMA requests in interleaved mode when MDMA = 0b10

Configuration where each sequence contains only one conversion
When using MDMA mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion is available.

- **MDMA = 0b11**: This mode is similar to the MDMA = 0b10. The only differences are that on each DMA request (two data items are available), two bytes representing two ADC converted data items are transferred as a half-word.
  
  This mode is used in interleaved and regular simultaneous mode when resolution is 6-bit or when resolution is 8-bit and data is not signed (offsets must be disabled for all the involved channels).

**Example:**

Interleaved dual mode: a DMA request is generated each time 2 data items are available:

1st DMA request: \( \text{ADC}_\text{CDR}[15:0] = \text{SLV}_\text{ADC}_\text{DR}[7:0] | \text{MST}_\text{ADC}_\text{DR}[7:0] \)

2nd DMA request: \( \text{ADC}_\text{CDR}[15:0] = \text{SLV}_\text{ADC}_\text{DR}[7:0] | \text{MST}_\text{ADC}_\text{DR}[7:0] \)

**Overrun detection**

In dual ADC mode (when `DUAL[4:0]` is not equal to b00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the MDMA configuration). It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

**DMA one shot mode/ DMA circular mode when MDMA mode is selected**

When MDMA mode is selected (0b10 or 0b11), bit DMACFG of the ADC_CCR register must also be configured to select between DMA one shot mode and circular mode, as explained in section *Section : Managing conversions using the DMA* (bits DMACFG of master and slave ADC_CFGR are not relevant).

**Stopping the conversions in dual ADC modes**

The user must set the control bits ADSTP/JADSTP of the master ADC to stop the conversions of both ADC in dual ADC mode. The other ADSTP control bit of the slave ADC has no effect in dual ADC mode.

Once both ADC are effectively stopped, the bits ADSTART/JADSTART of the master and slave ADCs are both cleared by hardware.

### 27.4.32 Temperature sensor

The temperature sensor can be used to measure the junction temperature \((T_j)\) of the device.

The temperature sensor is internally connected to the ADC input channels which are used to convert the sensor output voltage to a digital value (see *Table: ADC interconnection* in *Section 27.4.2: ADC pins and internal signals* for more details). When not in use, the sensor can be put in power down mode. It support the temperature range –40 to 125 °C.

*Figure 293* shows the block diagram of connections between the temperature sensor and the ADC.

The temperature sensor output voltage changes linearly with temperature. The offset of this line varies from chip to chip due to process variation (up to 45 °C from one chip to another).
The uncalibrated internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. To improve the accuracy of the temperature sensor measurement, calibration values are stored in system memory for each device by ST during production.

During the manufacturing process, the calibration data of the temperature sensor and the internal voltage reference are stored in the system memory area. The user application can then read them and use them to improve the accuracy of the temperature sensor or the internal reference (refer to the datasheet for additional information).

The temperature sensor is internally connected to the ADC input channel which is used to convert the sensor’s output voltage to a digital value. Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal temperature sensor.

When not in use, the sensor can be put in power-down mode. *Figure 293* shows the block diagram of the temperature sensor.

**Figure 293. Temperature sensor channel block diagram**

---

**Reading the temperature**

To use the sensor:

1. Select the ADC input channels that is connected to \( V_{\text{SENSE}} \).
2. Program with the appropriate sampling time (refer to electrical characteristics section of the device datasheet).
3. Set the bit in the ADC_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting \( V_{\text{SENSE}} \) data in the ADC data register.
6. Calculate the actual temperature using the following formula:
where:
- TS_CAL2 is the temperature sensor calibration value acquired at TS_CAL2_TEMP.
- TS_CAL1 is the temperature sensor calibration value acquired at TS_CAL1_TEMP.
- TS_DATA is the actual temperature sensor output value converted by ADC.

Refer to the device datasheet for more information about TS_CAL1 and TS_CAL2 calibration points.

Note: The sensor has a startup time after waking from power-down mode before it can output VSENSE at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and bits should be set at the same time.

27.4.33 VBAT supply monitoring

The VBATEN bit in the ADC_CCR register is used to switch to the battery voltage. As the VBAT voltage could be higher than VDDA, to ensure the correct operation of the ADC, the VBAT pin is internally connected to a bridge divider by 4. This bridge is automatically enabled when VBATEN is set, to connect VBAT/4 to the ADC input channels (see Table: ADC interconnection in Section 27.4.2: ADC pins and internal signals for more details). As a consequence, the converted digital value is one third of the VBAT voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the VBAT/4 voltage.

Figure 294 shows the block diagram of the VBAT sensing feature.
1. The VBATEN bit must be set to enable the conversion of internal channel for VBAT/4.

### 27.4.34 Monitoring the internal voltage reference

It is possible to monitor the internal voltage reference (VREFINT) to have a reference point for evaluating the ADC VREF+ voltage level.

Refer to Table: ADC interconnection in Section 27.4.2: ADC pins and internal signals for details on the ADC input channels to which the internal voltage reference is internally connected.

Refer to the electrical characteristics section of the product datasheet for the sampling time value to be applied when converting the internal voltage reference voltage.

*Figure 295* shows the block diagram of the VREFINT sensing feature.

1. The VREFEN bit into ADC_CCR register must be set to enable the conversion of internal channels (VREFINT).
Calculating the actual $V_{REF+}$ voltage using the internal reference voltage

$V_{REF+}$ voltage may be subject to variations or not precisely known. The embedded internal reference voltage $V_{REFINT}$ and its calibration data acquired by the ADC during the manufacturing process at $V_{REF+_charac}$ can be used to evaluate the actual $V_{REF+}$ voltage level.

The following formula gives the actual $V_{REF+}$ voltage supplying the device:

$$V_{REF+} = \frac{V_{REF+_Charac} \times V_{REFINT_CAL}}{V_{REFINT_Data}}$$

Where:
- $V_{REF+_Charac}$ is the value of $V_{REF+}$ voltage characterized at $V_{REFINT}$ during the manufacturing process. It is specified in the device datasheet.
- $V_{REFINT_CAL}$ is the $V_{REFINT}$ calibration value
- $V_{REFINT_Data}$ is the actual $V_{REFINT}$ output value converted by ADC

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between $V_{REF+}$ and the voltage applied on the converted channel.

For applications where $V_{REF+}$ value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from $V_{REF+}$:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL\_SCALE} \times ADC\_DATA$$

By replacing $V_{REF+}$ by the formula provided above, the absolute voltage value is given by the following formula

$$V_{CHANNELx} = \frac{V_{REF+_Charac} \times V_{REFINT_CAL} \times ADC\_DATA}{V_{REFINT_Data} \times FULL\_SCALE}$$

Where:
- $V_{REF+_Charac}$ is the value of $V_{REF+}$ voltage characterized at $V_{REFINT}$ during the manufacturing process.
- $V_{REFINT_CAL}$ is the $V_{REFINT}$ calibration value
- $ADC\_DATA$ is the value measured by the ADC on channel x (right-aligned)
- $V_{REFINT_Data}$ is the actual $V_{REFINT}$ output value converted by the ADC
- $FULL\_SCALE$ is the maximum digital value of the ADC output. For example with 12-bit resolution, it is $2^{12} - 1 = 4095$ or with 8-bit resolution, $2^8 - 1 = 255$.

Note: If ADC measurements are done using an output format other than 12-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

27.4.35 Monitoring the supply voltage

ADC2 is connected to the internal supply voltage. To use the ADC to measure this voltage, enable the connection through ADC option register.
27.5 **ADC in low-power modes**

Table 239. Effect of low-power modes on the ADC

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. DMA requests are functional. ADC interrupts cause the device to exit from Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The ADC peripheral is not operational. Prior to entering this mode, it is recommended to disable the ADC.</td>
</tr>
<tr>
<td>Standby</td>
<td>The ADC peripheral is powered down and must be reinitialized after exiting from Standby mode.</td>
</tr>
</tbody>
</table>

27.6 **ADC interrupts**

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (flag OVR)
- When the injected sequence context queue overflows (flag JQOVF)

Separate interrupt enable bits are available for flexibility.

---

![ST Logo](RM0477 Rev 6 1161/3791)
Bit 5  **JEOC**: Injected channel end of conversion flag  
This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register.  
0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)  
1: Injected channel conversion complete  

Bit 4  **OVR**: ADC overrun  
This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.  
0: No overrun occurred (or the flag event was already acknowledged and cleared by software)  
1: Overrun has occurred  

Bit 3  **EOS**: End of regular sequence flag  
This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.  
0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)  
1: Regular Conversions sequence complete  

Bit 2  **EOC**: End of conversion flag  
This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.  
0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)  
1: Regular channel conversion complete  

Bit 1  **EOSMP**: End of sampling flag  
This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.  
0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)  
1: End of sampling phase reached  

Bit 0  **ADRDY**: ADC ready  
This bit is set by hardware after the ADC has been enabled (ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests. It is cleared by software writing 1 to it.  
0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)  
1: ADC is ready to start conversion

Bits 31:11 Reserved, must be kept at reset value.

- **Bit 10 JQOVFIE**: Injected context queue overflow interrupt enable  
  - This bit is set and cleared by software to enable/disable the Injected Context Queue Overflow interrupt.  
  - 0: Injected Context Queue Overflow interrupt disabled  
  - 1: Injected Context Queue Overflow interrupt enabled. An interrupt is generated when the JQOVF bit is set.  
  
  **Note**: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

- **Bit 9 AWD3IE**: Analog watchdog 3 interrupt enable  
  - This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.  
  - 0: Analog watchdog 3 interrupt disabled  
  - 1: Analog watchdog 3 interrupt enabled  
  
  **Note**: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

- **Bit 8 AWD2IE**: Analog watchdog 2 interrupt enable  
  - This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.  
  - 0: Analog watchdog 2 interrupt disabled  
  - 1: Analog watchdog 2 interrupt enabled  
  
  **Note**: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

- **Bit 7 AWD1IE**: Analog watchdog 1 interrupt enable  
  - This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.  
  - 0: Analog watchdog 1 interrupt disabled  
  - 1: Analog watchdog 1 interrupt enabled  
  
  **Note**: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

- **Bit 6 JEOSIE**: End of injected sequence of conversions interrupt enable  
  - This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.  
  - 0: JEOS interrupt disabled  
  - 1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.  
  
  **Note**: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).
Bit 5  **JEOCIE**: End of injected conversion interrupt enable
   This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.
   0: JEOC interrupt disabled.
   1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.
   Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 4  **OVRIE**: Overrun interrupt enable
   This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.
   0: Overrun interrupt disabled
   1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.
   Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 3  **EOSIE**: End of regular sequence of conversions interrupt enable
   This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.
   0: EOS interrupt disabled
   1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.
   Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 2  **EOCIE**: End of regular conversion interrupt enable
   This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.
   0: EOC interrupt disabled
   1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.
   Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 1  **EOSMPIE**: End of sampling flag interrupt enable for regular conversions
   This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.
   0: EOSMP interrupt disabled.
   1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.
   Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 0  **ADRDYIE**: ADC ready interrupt enable
   This bit is set and cleared by software to enable/disable the ADC Ready interrupt.
   0: ADRDY interrupt disabled
   1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.
   Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

| 18|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 17|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 16|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

#### Bit 31 ADCAL: ADC calibration

This bit is set by software to start the calibration of the ADC. Program first the bit ADCALDIF to determine if this calibration applies for single-ended or Differential inputs mode.

It is cleared by hardware after calibration is complete.

- 0: Calibration complete
- 1: Write 1 to calibrate the ADC. Read at 1 means that a calibration is in progress.

**Note:** The software is allowed to launch a calibration by setting ADCAL only when ADEN = 0.

The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).

#### Bit 30 ADCALDIF: Differential mode for calibration

This bit is set and cleared by software to configure the single-ended or Differential inputs mode for the calibration.

- 0: Writing ADCAL launches a calibration in single-ended inputs mode.
- 1: Writing ADCAL launches a calibration in Differential inputs mode.

**Note:** The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

#### Bit 29 DEEPPWD: Deep-power-down enable

This bit is set and cleared by software to put the ADC in Deep-power-down mode.

- 0: ADC not in Deep-power down
- 1: ADC in Deep-power-down (default reset state)

**Note:** The software is allowed to write this bit only when the ADC is disabled (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).
Bit 28 **ADVREGEN**: ADC voltage regulator enable

This bit is set by software to enable the ADC voltage regulator.

Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.

0: ADC Voltage regulator disabled
1: ADC Voltage regulator enabled.

For more details about the ADC voltage regulator enable and disable sequences, refer to Section 27.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).

The software can program this bit field only when the ADC is disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 27:6 Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

0: No ADC stop injected conversion command ongoing
1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

**Note:** The software is allowed to set JADSTP only when JADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC)

In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)

Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

0: No ADC stop regular conversion command ongoing
1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

**Note:** The software is allowed to set ADSTP only when ADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)
Bit 3  **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN, a conversion immediately starts (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode when software trigger is selected (JEXTSEL = 0x0): at the assertion of the End of Injected Conversion Sequence (JEOS) flag.
- in all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.
1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

**Note:** The software is allowed to set JADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared).
Bit 2  **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN, a conversion immediately starts (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode when software trigger is selected (EXTSEL = 0x0): at the assertion of the End of Regular Conversion Sequence (EOS) flag.
- in all cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.
1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

*Note:* The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC)

In auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1  **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

*Note:* The software is allowed to set ADDIS only when ADEN = 1 and both ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0  **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

*Note:* The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)
### 27.7.4 ADC configuration register (ADC_CFGR)

</tr>
</tbody>
</table>
Bit 24  **JAWD1EN**: Analog watchdog 1 enable on injected channels
This bit is set and cleared by software
0: Analog watchdog 1 disabled on injected channels
1: Analog watchdog 1 enabled on injected channels

*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

Bit 23  **AWD1EN**: Analog watchdog 1 enable on regular channels
This bit is set and cleared by software
0: Analog watchdog 1 disabled on regular channels
1: Analog watchdog 1 enabled on regular channels

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 22  **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels
This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels
0: Analog watchdog 1 enabled on all channels
1: Analog watchdog 1 enabled on a single channel

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 21  **JQM**: JSQR queue mode
This bit is set and cleared by software.
It defines how an empty Queue is managed.
0: JSQR mode 0: The Queue is never empty and maintains the last written configuration into JSQR.
1: JSQR mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.

Refer to *Section 27.4.21: Queue of context for injected conversions* for more information.

*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit JQM of the slave ADC is no more writable and its content is equal to the bit JQM of the master ADC.

Bit 20  **JDISCEN**: Discontinuous mode on injected channels
This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.
0: Discontinuous mode on injected channels disabled
1: Discontinuous mode on injected channels enabled

*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

When dual mode is enabled (bits DUAL of ADC_CCR register are not equal to zero), the bit JDISCEN of the slave ADC is no more writable and its content is equal to the bit JDISCEN of the master ADC.
Bits 19:17 **DISCNUM[2:0]**: Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

- 000: 1 channel
- 001: 2 channels
- ...
- 111: 8 channels

**Note:** The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bits DISCNUM[2:0] of the slave ADC are no more writable and their content is equal to the bits DISCNUM[2:0] of the master ADC.

Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable discontinuous mode for regular channels.

- 0: Discontinuous mode for regular channels disabled
- 1: Discontinuous mode for regular channels enabled

**Note:** It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit DISCEN of the slave ADC is no more writable and its content is equal to the bit DISCEN of the master ADC.

Bit 15 **ALIGN**: Data alignment

This bit is set and cleared by software to select right or left alignment. Refer to Section: Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN).

- 0: Right alignment
- 1: Left alignment

**Note:** The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode.

- 0: Auto-delayed conversion mode off
- 1: Auto-delayed conversion mode on

**Note:** The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit AUTDLY of the slave ADC is no more writable and its content is equal to the bit AUTDLY of the master ADC.
Bit 13 CONT: Single / continuous conversion mode for regular conversions
This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.
0: Single conversion mode
1: Continuous conversion mode
Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.
The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).
When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit CONT of the slave ADC is no more writable and its content is equal to the bit CONT of the master ADC.

Bit 12 OVRMOD: Overrun mode
This bit is set and cleared by software and configure the way data overrun is managed.
0: ADC_DR register is preserved with the old data when an overrun is detected.
1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.
Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 11:10 EXTEN[1:0]: External trigger enable and polarity selection for regular channels
These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.
00: Hardware trigger detection disabled (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 9:5 EXTSEL[4:0]: External trigger selection for regular group
These bits select the external event used to trigger the start of conversion of a regular group:
00000: adc_ext_trg0
00001: adc_ext_trg1
00010: adc_ext_trg2
00011: adc_ext_trg3
00100: adc_ext_trg4
00101: adc_ext_trg5
00110: adc_ext_trg6
00111: adc_ext_trg7
...
11111: adc_ext_trg31
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 4:3 RES[1:0]: Data resolution
These bits are written by software to select the resolution of the conversion.
00: 12-bit
01: 10-bit
10: 8-bit
11: 6-bit
Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
Bit 2  **ADFCFG**: ADF mode configuration
This bit is set and cleared by software to enable the ADF mode. It is effective only when DMAEN = 0.
0: ADF mode disabled
1: ADF mode enabled
Note: To make sure no conversion is ongoing, the software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0.

Bit 1  **DMACFG**: Direct memory access configuration
This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN = 1.
0: DMA One Shot mode selected
1: DMA Circular mode selected
For more details, refer to **Section : Managing conversions using the DMA**
Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
In dual-ADC modes, this bit is not relevant and replaced by control bit DMACFG of the ADC_CCR register.

Bit 0  **DMAEN**: Direct memory access enable
This bit is set and cleared by software to enable the generation of DMA requests. This allows to use the DMA to manage automatically the converted data. For more details, refer to **Section : Managing conversions using the DMA**.
0: DMA disabled
1: DMA enabled
Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
In dual-ADC modes, this bit is not relevant and replaced by control bits MDMA[1:0] of the ADC_CCR register.

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **SMPTRG**: Sampling time control trigger mode
   This bit is set and cleared by software to enable the sampling time control trigger mode.
   0: Sampling time control trigger mode disabled
   1: Sampling time control trigger mode enabled
   The sampling time starts on the trigger rising edge, and the conversion on the trigger falling edge.
   EXTEN bit should be set to 01. BULB bit must not be set when the SMPTRG bit is set.
   When EXTEN bit is set to 00, set SWTRIG to start the sampling and clear SWTRIG bit to start the conversion.
   *Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 26 **BULB**: Bulb sampling mode
   This bit is set and cleared by software to enable the bulb sampling mode.
   0: Bulb sampling mode disabled
   1: Bulb sampling mode enabled. The sampling period starts just after the previous end of conversion.
   SAMPTRG bit must not be set when the BULB bit is set.
   The very first ADC conversion is performed with the sampling time specified in SMPx bits.
   *Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 25 **SWTRIG**: Software trigger bit for sampling time control trigger mode
   This bit is set and cleared by software to enable the bulb sampling mode.
   0: Software trigger starts the conversion for sampling time control trigger mode
   1: Software trigger starts the sampling for sampling time control trigger mode
   *Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 24:17 Reserved, must be kept at reset value.

Bits 16:11 Reserved, must be kept at reset value.

Bit 10 **ROVSM**: Regular oversampling mode
   This bit is set and cleared by software to select the regular oversampling mode.
   0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)
   1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)
   *Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 9 **TROVS**: Triggered Regular oversampling
   This bit is set and cleared by software to enable triggered oversampling
   0: All oversampled conversions for a channel are done consecutively following a trigger
   1: Each oversampled conversion for a channel needs a new trigger
   *Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*
Bits 8:5 **OVSS[3:0]:** Oversampling shift
This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.
- 0000: No shift
- 0001: Shift 1-bit
- 0010: Shift 2-bits
- 0011: Shift 3-bits
- 0100: Shift 4-bits
- 0101: Shift 5-bits
- 0110: Shift 6-bits
- 0111: Shift 7-bits
- 1000: Shift 8-bits
Other codes reserved
*Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 4:2 **OVSR[2:0]:** Oversampling ratio
This bitfield is set and cleared by software to define the oversampling ratio.
- 000: 2x
- 001: 4x
- 010: 8x
- 011: 16x
- 100: 32x
- 101: 64x
- 110: 128x
- 111: 256x
*Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 1 **JOVSE:** Injected oversampling Enable
This bit is set and cleared by software to enable injected oversampling.
- 0: Injected oversampling disabled
- 1: Injected oversampling enabled
*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)*

Bit 0 **ROVSE:** Regular oversampling Enable
This bit is set and cleared by software to enable regular oversampling.
- 0: Regular oversampling disabled
- 1: Regular oversampling enabled
*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)*

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:0 **SMPx[2:0]**: Channel x sampling time selection (x = 18 to 10)

These bits are written by software to select the sampling time individually for each channel. During sampling cycles, the channel selection bits must remain unchanged.

- 000: 2.5 ADC clock cycles
- 001: 6.5 ADC clock cycles
- 010: 12.5 ADC clock cycles
- 011: 24.5 ADC clock cycles
- 100: 47.5 ADC clock cycles
- 101: 92.5 ADC clock cycles
- 110: 247.5 ADC clock cycles
- 111: 640.5 ADC clock cycles

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing). Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.*

Bits 27:16 **HT1[11:0]**: Analog watchdog 1 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 1.

Refer to Section 27.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*
Bit 15  Reserved, must be kept at reset value.

Bits 14:12  **AWDFILT[2:0]**: Analog watchdog filtering parameter
            This bit is set and cleared by software.
            000: No filtering
            001: two consecutive detection generates an AWDx flag or an interrupt
            ...
            111: Eight consecutive detection generates an AWDx flag or an interrupt

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 11:0  **LT1[11:0]**: Analog watchdog 1 lower threshold
            These bits are written by software to define the lower threshold for the analog watchdog 1.
            Refer to Section 27.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

### 27.7.9  **ADC watchdog threshold register 2 (ADC_TR2)**

**HT2[7:0]**

**LT2[7:0]**

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **HT2[7:0]**: Analog watchdog 2 higher threshold
            These bits are written by software to define the higher threshold for the analog watchdog 2.
            Refer to Section 27.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **LT2[7:0]**: Analog watchdog 2 lower threshold
            These bits are written by software to define the lower threshold for the analog watchdog 2.
            Refer to Section 27.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*
27.7.10 ADC watchdog threshold register 3 (ADC_TR3)

Address offset: 0x28
Reset value: 0x00FF 0000

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **HT3[7:0]**: Analog watchdog 3 higher threshold
These bits are written by software to define the higher threshold for the analog watchdog 3.
Refer to Section 27.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **LT3[7:0]**: Analog watchdog 3 lower threshold
These bits are written by software to define the lower threshold for the analog watchdog 3.
This watchdog compares the 8-bit of LT3 with the 8 MSB of the converted data.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

27.7.11 ADC regular sequence register 1 (ADC_SQR1)

Address offset: 0x30
Reset value: 0x0000 0000

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]**: 4th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 4th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.
Bits 22:18 **SQ3[4:0]**: 3rd conversion in regular sequence
- These bits are written by software with the channel number (0 to 18) assigned as the 3rd in the regular conversion sequence.
- Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ2[4:0]**: 2nd conversion in regular sequence
- These bits are written by software with the channel number (0 to 18) assigned as the 2nd in the regular conversion sequence.
- Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ1[4:0]**: 1st conversion in regular sequence
- These bits are written by software with the channel number (0 to 18) assigned as the 1st in the regular conversion sequence.
- Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **L[3:0]**: Regular channel sequence length
- These bits are written by software to define the total number of conversions in the regular channel conversion sequence.
- 0000: 1 conversion
- 0001: 2 conversions
- ...
- 1111: 16 conversions
- Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

**Note:** Some channels are not connected physically and must not be selected for conversion.

### 27.7.12 ADC regular sequence register 2 (ADC_SQR2)

**Note:** The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).
Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]**: 9th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 9th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]**: 8th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 8th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]**: 7th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 7th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]**: 6th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 6th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ5[4:0]**: 5th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 5th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

*Note:* Some channels are not connected physically and must not be selected for conversion.

</table>
Bits 31:27  **JSQ4[4:0]**: 4th conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the 4th in the injected conversion sequence.
*Note:*  The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 26  Reserved, must be kept at reset value.

Bits 25:21  **JSQ3[4:0]**: 3rd conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the 3rd in the injected conversion sequence.
*Note:*  The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 20  Reserved, must be kept at reset value.

Bits 19:15  **JSQ2[4:0]**: 2nd conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the 2nd in the injected conversion sequence.
*Note:*  The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 14  Reserved, must be kept at reset value.

Bits 13:9  **JSQ1[4:0]**: 1st conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the 1st in the injected conversion sequence.
*Note:*  The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).
Bits 8:7 **JEXTEN[1:0]**: External trigger enable and polarity selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: If JQDIS = 0 (queue enabled), hardware and software trigger detection disabled. Otherwise, the queue is disabled as well as hardware trigger detection (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

**Note:** The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

If JQM = 1 and if the Queue of Context becomes empty, the software and hardware triggers of the injected sequence are both internally disabled (refer to Section 27.4.21: Queue of context for injected conversions)

Bits 6:2 **JEXTSEL[4:0]**: External Trigger Selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

00000: adc_jext_trg0

00001: adc_jext_trg1

00010: adc_jext_trg2

00011: adc_jext_trg3

00100: adc_jext_trg4

00101: adc_jext_trg5

00110: adc_jext_trg6

00111: adc_jext_trg7

... 

11111: adc_jext_trg31

**Note:** The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 1:0 **JL[1:0]**: Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

**Note:** The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

**Note:** Some channels are not connected physically and must not be selected for conversion.
27.7.17 ADC offset y register (ADC_OFRy)

Address offset: 0x60 + 0x04 * (y -1), (y = 1 to 4)

Bit 31 OFFSET_EN: Offset y enable
This bit is written by software to enable or disable the offset programmed into bits OFFSET[11:0].

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 30:26 OFFSET_CH[4:0]: Channel selection for the data offset y
These bits are written by software to define the channel to which the offset programmed into bits OFFSET[11:0] applies.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
Some channels are not connected physically and must not be selected for the data offset y.
If OFFSET_EN is set, it is not allowed to select the same channel for different ADC_OFRy registers.

Bit 25 SATEN: Saturation enable
This bit is set and cleared by software to enable the saturation at 0x000 and 0xFFF for the offset function.
0: No saturation control, offset result can be signed
1: Saturation enabled, offset result unsigned and saturated at 0x000 and 0xFFF

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
Bit 24 **OFFSETPOS**: Positive offset

This bit is set and cleared by software to enable the positive offset.

0: Negative offset
1: Positive offset

**Note:** The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 23:12 Reserved, must be kept at reset value.

Bits 11:0 **OFFSET[11:0]**: Data offset y for the channel programmed into bits OFFSET_CH[4:0]

These bits are written by software to define the offset to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset must be programmed in the bits OFFSET_CH[4:0]. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

**Note:** The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

If several offset (OFFSET) point to the same channel, only the offset with the lowest x value is considered for the subtraction.

Ex: if OFFSET1_CH[4:0] = 4 and OFFSET2_CH[4:0] = 4, this is OFFSET1[11:0] which is subtracted when converting channel 4.

### 27.7.18 ADC injected channel y data register (ADC_JDRy)

Address offset: 0x80 + 0x04 * (y - 1), (y = 1 to 4)

Reset value: 0x0000 0000

**Bits 31:19** Reserved, must be kept at reset value.  
**Bits 18:0** **AWD2CH[18:0]:** Analog watchdog 2 channel selection  
These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.  
AWD2CH[i] = 0: ADC analog input channel i is not monitored by AWD2  
AWD2CH[i] = 1: ADC analog input channel i is monitored by AWD2  
When AWD2CH[18:0] = 000..0, the analog Watchdog 2 is disabled  
Note: The channels selected by AWD2CH must be also selected into the SQRI or JSQRi registers.  
The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).  
Some channels are not connected physically and must not be selected for the analog watchdog.

</tr>
</tbody>
</table>

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:0 DIFSEL[18:0]: Differential mode for channels 18 to 0.

These bits are set and cleared by software. They allow to select if a channel is configured as single-ended or Differential mode.

DIFSEL[i] = 0: ADC analog input channel is configured in single-ended mode
DIFSEL[i] = 1: ADC analog input channel i is configured in Differential mode

Note: The DIFSEL bits corresponding to channels that are either connected to a single-ended I/O port or to an internal channel must be kept their reset value (single-ended input mode).
The software is allowed to write these bits only when the ADC is disabled (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).
27.7.22 ADC calibration factors (ADC_CALFACT)

Address offset: 0xB4
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address offset: 0xB4</th>

<tr>
<td>CALFACT_S[6:0]</td>
<td>rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 CALFACT_D[6:0]: Calibration Factors in differential mode
These bits are written by hardware or by software.
Once a differential inputs calibration is complete, they are updated by hardware with the calibration factors.
Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new differential calibration is launched.

Note: The software is allowed to write these bits only when ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 CALFACT_S[6:0]: Calibration Factors In single-ended mode
These bits are written by hardware or by software.
Once a single-ended inputs calibration is complete, they are updated by hardware with the calibration factors.
Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new single-ended calibration is launched.

Note: The software is allowed to write these bits only when ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

27.7.23 ADC option register (ADC_OR)

Address offset: 0xC8
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address offset: 0xC8</th>
<th>Reset value: 0x0000 0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 OP0: Output Polarity
These are written by hardware or by software.
These bits are used for selecting the output polarity of the ADC. The default value is 0, which means that the output is high when the analog input is high.

Note: The software is allowed to write these bits only when ADEN = 1 and ADSTART = 0 (ADC is enabled and no conversion is ongoing).
27.8 **ADC common registers**

These registers define the control and status registers common to master and slave ADCs:

### 27.8.1 ADC common status register (ADC_CSR)

Address offset: 0x300

Reset value: 0x0000 0000

This register provides an image of the status bits of the different ADC. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing 0 to it in the corresponding ADC_ISR register.

</table>
Bit 19  **EOS_SLV**: End of regular sequence flag of the slave ADC. This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 18  **EOC_SLV**: End of regular conversion of the slave ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 17  **EOSMP_SLV**: End of Sampling phase flag of the slave ADC
This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 16  **ADRDY_SLV**: Slave ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

Bits 15:11  Reserved, must be kept at reset value.

Bit 10  **JQOVF_MST**: Injected Context Queue Overflow flag of the master ADC
This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

Bit 9  **AWD3_MST**: Analog watchdog 3 flag of the master ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 8  **AWD2_MST**: Analog watchdog 2 flag of the master ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 7  **AWD1_MST**: Analog watchdog 1 flag of the master ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 6  **JEOS_MST**: End of injected sequence flag of the master ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 5  **JEOC_MST**: End of injected conversion flag of the master ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 4  **OVR_MST**: Overrun flag of the master ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 3  **EOS_MST**: End of regular sequence flag of the master ADC
This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 2  **EOC_MST**: End of regular conversion of the master ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 1  **EOSMP_MST**: End of Sampling phase flag of the master ADC
This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 0  **ADRDY_MST**: Master ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **VBATEN**: VBAT enable
This bit is set and cleared by software to control.
0: VBAT channel disabled
1: VBAT channel enabled

Bit 23 **TSEN**: VSENSE enable
This bit is set and cleared by software to control VSENSE.
0: Temperature sensor channel disabled
1: Temperature sensor channel enabled

Bit 22 **VREFEN**: VREFINT enable
This bit is set and cleared by software to enable/disable the VREFINT channel.
0: VREFINT channel disabled
1: VREFINT channel enabled

Bits 21:18 **PRESC[3:0]**: ADC prescaler
These bits are set and cleared by software to select the frequency of the clock to the ADC.
The clock is common for all the ADCs.
0000: input ADC clock not divided
0001: input ADC clock divided by 2
0010: input ADC clock divided by 4
0011: input ADC clock divided by 6
0100: input ADC clock divided by 8
0101: input ADC clock divided by 10
0110: input ADC clock divided by 12
0111: input ADC clock divided by 16
1000: input ADC clock divided by 32
1001: input ADC clock divided by 64
1010: input ADC clock divided by 128
1011: input ADC clock divided by 256
other: reserved

Note: The software is allowed to write these bits only when the ADC is disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0). The ADC prescaler value is applied only when CKMODE[1:0] = 0b00.
Bits 17:16 **CKMODE[1:0]**: ADC clock mode

These bits are set and cleared by software to define the ADC clock scheme (which is common to both master and slave ADCs):

- **00**: adc_ker_ck (x = 1/2) (Asynchronous clock mode), generated at product level (refer to Section 6: Reset and clock control (RCC))
- **01**: adc_hclk/1 (Synchronous clock mode). This configuration must be enabled only if the AHB clock prescaler is set to 1 (HPRE[3:0] = 0XXX in RCC_CFGR register) and if the system clock has a 50% duty cycle.
- **10**: adc_hclk/2 (Synchronous clock mode)
- **11**: adc_hclk/4 (Synchronous clock mode)

In all synchronous clock modes, there is no jitter in the delay from a timer trigger to the start of a conversion.

*Note:* The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 15:14 **MDMA[1:0]**: Direct memory access mode for dual ADC mode

This bitfield is set and cleared by software. Refer to the DMA controller section for more details.

- **00**: MDMA mode disabled
- **01**: Reserved
- **10**: MDMA mode enabled for 12 and 10-bit resolution
- **11**: MDMA mode enabled for 8 and 6-bit resolution

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 13 **DMACFG**: DMA configuration (for dual ADC mode)

This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN = 1.

- **0**: DMA One Shot mode selected
- **1**: DMA Circular mode selected

For more details, refer to Section : Managing conversions using the DMA

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 12 Reserved, must be kept at reset value.
Bits 11:8 **DELAY[3:0]**: Delay between 2 sampling phases

These bits are set and cleared by software. These bits are used in dual interleaved modes.
Refer to **Table 241** for the value of ADC resolution versus DELAY bits values.

*Note:* The software is allowed to write these bits only when the ADCs are disabled
(ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DUAL[4:0]**: Dual ADC mode selection

These bits are written by software to select the operating mode. 00000 corresponds to
independent mode. Values 00001 to 01001 correspond to dual mode, master and slave
ADCs working together.
00000: Independent mode
00001: Combined regular simultaneous + injected simultaneous mode
00010: Combined regular simultaneous + alternate trigger mode
00011: Combined interleaved mode + injected simultaneous mode
00100: Reserved
00101: Injected simultaneous mode only
00110: Regular simultaneous mode only
00111: Interleaved mode only
01001: Alternate trigger mode only
Others: Reserved, must not be used

*Note:* The software is allowed to write these bits only when the ADCs are disabled
(ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 31:16 **RDATA_SLV[15:0]**: Regular data of the slave ADC
In dual mode, these bits contain the regular data of the slave ADC. Refer to Section 27.4.31: Dual ADC modes.
The data alignment is applied as described in Section: Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN)

Bits 15:0 **RDATA_MST[15:0]**: Regular data of the master ADC.
In dual mode, these bits contain the regular data of the master ADC. Refer to Section 27.4.31: Dual ADC modes.
The data alignment is applied as described in Section: Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN)

In MDMA = 0b11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

Bits 31:0 **SID[31:0]**: Size Identification
   SID[31:8]: fixed code that characterizes the ADC_SiDR register. This field is always read at 0xA3C5DD.
   SID[7:0]: read-only numeric field that returns the address offset (in Kbytes) of the identification registers from the IP base address:
   - 0x01: 1 Kbytes address offset
   - 0x02: 2 Kbytes address offset
   - 0x04: 4 Kbytes address offset
   - 0x08: 8 Kbytes address offset
27.9 ADC register map

The following table summarizes the ADC registers.

### Table 242. ADC global register map

<table>
<thead>
<tr>
<th>Offset</th>
<th>Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x000 - 0x0B4</td>
<td>Master ADC1</td>
</tr>
<tr>
<td>0x0B8 - 0x0FC</td>
<td>Reserved</td>
</tr>
<tr>
<td>0x100 - 0x1B4</td>
<td>Slave ADC2</td>
</tr>
<tr>
<td>0x1B8 - 0x2FC</td>
<td>Reserved</td>
</tr>
<tr>
<td>0x300 - 0x30C</td>
<td>Master and slave ADCs common registers</td>
</tr>
</tbody>
</table>

### Table 243. ADC register map and reset values for each ADC (offset = 0x000 for master ADC, 0x100 for slave ADC)

<table>
<thead>
<tr>
<th>Offset</th>
<th>Register name</th>
<th>Reset value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00</td>
<td>ADC_ISR</td>
<td></td>
</tr>
<tr>
<td>0x04</td>
<td>ADC_IER</td>
<td></td>
</tr>
<tr>

Refer to Section 2.3 on page 149 for the register boundary addresses.
28 Digital temperature sensor (DTS)

28.1 Introduction

The device embeds a sensor that converts the temperature into a square wave which frequency is proportional to the temperature. The frequency is measured either with the PCLK or the LSE clock.

28.2 DTS main features

The temperature sensor block main features are the following:

- Start of measurement triggered by software or 4 hardware sources
- Programmable sampling time to increase temperature measurement precision
- Counter synchronized on LSE or PCLK clock
- Temperature watchdog on low and high threshold
- Interrupt generation when the temperature is lower or higher than predefined thresholds and at the end of measurement.
- Asynchronous wakeup signal generation when the temperature is higher/lower than a predefined threshold (LSE mode only)
- Quick measurement using LSE clock
28.3 DTS functional description

28.3.1 DTS block diagram

The temperature sensor block diagram is shown in Figure 296.

Figure 296. Temperature sensor functional block diagram

</tbody>
</table>
28.3.3 DTS block operation

The analog part of the temperature sensor outputs a frequency that is proportional to the absolute temperature (CLK_PTAT). The frequency measurement is based on the PCLK or the LSE clock.

Before each measurement, the temperature sensor performs a calibration of the frequency generation blocks.

28.3.4 Operating modes

Several operating modes can be selected by setting the REFCLK_SEL bit in Temperature sensor configuration register 1 (DTS_CFGR1):

- PCLK only (REFCLK_SEL = 0)
  The temperature sensor registers can be accessed. The interface can consequently be reconfigured and the measurement sequence is performed using PCLK clock

- PCLK and LSE (REFCLK_SEL = 1)
  The temperature sensor registers can be accessed. The interface can consequently be reconfigured and the measurement sequence is performed using the LSE clock.

- LSE only (REFCLK_SEL = 1) and PCLK OFF
  The registers cannot be accessed. The measurement can be performed using the LSE clock. This mode is used to exit from Sleep mode by using hardware triggers and the asynchronous interrupt line.

28.3.5 Calibration

The temperature sensor must run the calibration prior to any frequency measurement. The calibration is performed automatically when the temperature measurement is triggered except for quick measurement mode (Q_MEAS_OPT set to 1 in DTS_CFGR1).

28.3.6 Prescaler

When a calibration is ongoing, the counter clock must be slower than 1 MHz. This is achieved by the PCLK clock prescaler embedded in the temperature sensor.

During the temperature measurement period, the prescaler is bypassed.

- When PCLK is used as reference clock (REFCLK_SEL set to 0 in DTS_CFGR1), a prescaler is used. Its division ratio must be configured up to 127 (refer to the HSREF_CLK_DIV[6:0] register definition for the divider setting).

- When LSE is used as reference clock (REFCLK_SEL set to 1 in DTS_CFGR1), the timebase is equal to 2 LSE periods. In this case, no prescaler is used.
28.3.7 Temperature measurement principles

The analog part of temperature sensor outputs a signal (CLK_PTAT) which FM(T) frequency is temperature-dependent.

Either PCLK or LSE can be selected as reference clock (REF_CLK) through the REFCLK_SEL bit in DTS_CFG1.

The counting method depends on the REF_CLK frequency. This is due to the fact that two counters are implemented in the temperature sensor block:

- For low REF_CLK frequencies, a counting of FM(T) cycles is performed during one or several REF_CLK cycles.
- For high REF_CLK frequencies, a counting of REF_CLK cycles is performed during one or several FM(T) cycles.

This counter behavior is shown in Figure 297 and Figure 298.

**Figure 297. Method for low REF_CLK frequencies**

1. To increase the precision, FM(T) measurement can be done on several LSE periods.

**Figure 298. Method for high REF_CLK frequencies**

1. To increase the precision, PCLK measurement can be done on several FM(T) periods.

The counting result is stored in the DTS_DR register (see Temperature sensor data register (DTS_DR)).

Once the FM(T) frequency has been obtained, the corresponding temperature can be calculated by software using the following formula:

- When PCLK is used:

\[ T = T_0 + \left( \frac{F_{PCLK}}{\text{TS1_MFREQ} \times \text{TS1_SMP_TIME} - 100 \times \text{TS1_FMT0}} \right) \times \text{TS1_RAMP_COEFF} \]

where

- \( T_0 \) (factory calibration temperature) is equal to 30 °C.
- TS1_FMT0 is measured and stored in the DTS_T0VALR1 register. It is expressed in hundreds of Hertz.
TS1_RAMP_COEFF is measured during tests in factory and stored in DTS_RAMPVALR register. This value is expressed in Hz/°C.

- When the LSE clock is used

\[ T = T_0 + (F_{\text{LSE}} \cdot TS1_{\text{MFREQ}} \cdot TS1_{\text{SMP\_TIME}} - (100 \cdot TS1_{\text{FMT0}})) / TS1_{\text{RAMP\_COEFF}} \]

### 28.3.8 Sampling time

The sampling period can be increased to improve measurement accuracy. This is useful when the reference frequency (REF_CLK) is close to the FM(T) frequency. The default value is one REF_CLK cycle in LSE mode, and one FM(T) cycle in PCLK mode.

The sampling time is configured through TS1_SMP_TIME bits in DTS_CFGR1 register (see Table 246).

### 28.3.9 Quick measurement mode

If a high precision is not required, the calibration step included in each measurement sequence can be skipped by setting Q_MEAS_OPT to 1 in the DTS_CFGR1 register. This method must be used only when the LSE clock is selected as reference clock (LSREF_CLK set to 1). This mode can reduce the measurement time.
28.3.10 Trigger input

The temperature measurement can be triggered either by software or by an external event. The trigger source can be selected through TS1_INTRIG[3:0] bits in DTS_CFRG1.

</table>

Note: Hardware triggers are active only on the rising edge.

The temperature sensor can only capture a hardware trigger rising edge when TS1_RDY bit is set (see Section 28.3.11: On-off control and ready flag), otherwise the trigger is ignored. If a trigger source changes on-the-fly, the new trigger source signal should be low. If the new source signal is high, the temperature sensor detects a rising edge and starts the measurement sequence.

28.3.11 On-off control and ready flag

The DTS block can be enabled by setting TS1_EN bit in DTS_CFRG1 register. The TS1_RDY flag in the Temperature sensor status register (DTS_SR) indicate that the DTS block is ready for temperature measurement: when TS1_RDY bit is set to 1, the measurement can be started. Once a measurement has started, TS1_RDY bit is reset. New measurement requests are then ignored. Once the measurement is finished, TS1_RDY bit is set again to indicate the sensor is ready to start a new measurement.
28.3.12 Temperature measurement sequence

Start of measurement can be triggered by software or hardware.

Software trigger

The software trigger is selected when TS1_INTRIG_SEL[3:0] is set to '0000' in DTS_CFG1R.

If TS1_RDY is set to 1, writing TS1_START bit to 1 in DTS_CFG1R starts the measurement.
If TS1_RDY equals 0, the software trigger does not start until TS1_RDY is set.
If TS1_START bit is kept at 1 once the measurement is finished, then the TS1_RDY flag become 1 and the measurement restarts.

Hardware trigger

TS1_INTRIG_SEL[3:0] bits allow selecting one hardware trigger out of 4. If TS1_RDY is set to 1, a rising edge on the trigger signal starts the measurement. When TS1_RDY is 0, the rising edge is ignored.

Temperature measurement sequence

One measurement contains two steps: the calibration of the analog blocks and the measurement. The calibration automatically starts when the measurement is triggered (see Section 28.3.5: Calibration). The measurement period depends on the following DTS_CFG1R bits:

- the reference clock selected through REFCLK_SEL bit
- the divider ratio configured by HSREF_CLK_DIV bits
- the sampling time defined by TS1_SMP_TIME bits.

Figure 299. Temperature sensor sequence

</tr>
<tr>
<td>Stop</td>
<td>Only works in LSE mode. DTS interrupt cause the device to exit from Stop mode.</td>
</tr>
</tbody>
</table>

28.5 DTS interrupts

There are two ways to use the DTS block as an interrupt source. The DTS interrupt line can be connected to the EXTI controller (see *Section 28.5.3: Asynchronous wakeup*) or to the CPU NVIC (see *Section 28.5.2: Synchronous interrupt*).

28.5.1 Temperature window comparator

The DTS_ITR1 register allows defining the high and low threshold that are used for temperature comparison. If the temperature data is equal or higher than TS1_HITTHD, or equal or lower than TS1_LITTHD bit, an interrupt is generated and the corresponding flag, TS1_ITHF, TS1_LTHF, TS1_AITLF and TS1_AITHF, is set in the DTS_SR register (see *Section 28.6.6*).

28.5.2 Synchronous interrupt

A global interrupt output line is available on the DTS block. The interrupt can be generated at the end of measurement and/or when the measurement result is equal/higher or equal/lower than a predefined threshold (see *Section 28.5.1: Temperature window comparator*).

Three interrupt events can be select via 3 bits in DTS_ITENR register (see *Section 28.6.7*). All combinations of interrupts are allowed.

The TS1_ITEF, TS1_ITLF and TS1_ITHF flags in the DTS_SR register reflect the interrupt event. They can be reset with the correspond bits of the DTS_ICIFR register (see *Section 28.6.8*).

28.5.3 Asynchronous wakeup

The DTS block also provides an asynchronous interrupt line. It is used only when the LSE is selected as reference clock (REFCLK_SEL=1).

This line can generate a signal that wakes up the system from Sleep mode at the end of measurement and/or when the measurement result is equal/higher or equal/lower than a predefined threshold (see *Section 28.5.1: Temperature window comparator*).

Three asynchronous wakeup events can be selected via 3 bits in DTS_ITENR register. All combination of interrupts are allowed.
The TS1_AITEF, TS1_AITLF and TS1_AITHF flags in the DTS_SR register reflect the interrupt status. They can be reset with the correspond bits of the DTS_ICIFR register.

The following table shows the interrupt bits and their description.

<table>

### 28.6 DTS registers

The registers of this peripheral can only be accessed by-word (32-bit).

#### 28.6.1 Temperature sensor configuration register 1 (DTS_CFGR1)

DTS_CFGR1 is the configuration register for temperature sensor 1.

Address offset: 0x00
Reset value: 0x0000 0000
Bit 31  Reserved, must be kept at reset value.

Bits 30:24  **HSREF_CLK_DIV[6:0]**: High speed clock division ratio
   These bits are set and cleared by software. They can be used to define the division ratio for
   the main clock in order to obtain the internal frequency lower than 1 MHz required for the
   calibration. They are applicable only for calibration when PCLK is selected as reference
   clock (REFCLK_SEL=0).
   0000000: No divider
   0000001: No divider
   0000010: 1/2 division ratio
   ...
   1111111: 1/127 division ratio

Bits 23:22  Reserved, must be kept at reset value.

Bit 21  **Q_MEAS_OPT**: Quick measurement option bit
   This bit is set and cleared by software. It is used to increase the measurement speed by
   suppressing the calibration step. It is effective only when the LSE clock is used as reference
   clock (REFCLK_SEL=1).
   0: Measurement with calibration
   1: Measurement without calibration

Bit 20  **REFCLK_SEL**: Reference clock selection bit
   This bit is set and cleared by software. It indicates whether the reference clock is the high
   speed clock (PCLK) or the low speed clock (LSE).
   0: High speed reference clock (PCLK)
   1: Low speed reference clock (LSE)

Bits 19:16  **TS1_SMP_TIME[3:0]**: Sampling time for temperature sensor 1
   These bits allow increasing the sampling time to improve measurement precision.
   When the PCLK clock is selected as reference clock (REFCLK_SEL = 0), the measurement
   is performed at TS1_SMP_TIME period of CLK_PTAT.
   When the LSE is selected as reference clock (REFCLK_SEL = 1), the measurement is
   performed at TS1_SMP_TIME period of LSE.

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:8  **TS1_INTRIG_SEL[3:0]**: Input trigger selection bit for temperature sensor 1
   These bits are set and cleared by software. They select which input triggers a temperature
   measurement. Refer to *Section 28.3.10: Trigger input*.

Bits 7:5  Reserved, must be kept at reset value.

Bit 4  **TS1_START**: Start frequency measurement on temperature sensor 1
   This bit is set and cleared by software.
   0: No software trigger.
   1: Software trigger for a frequency measurement. (only if TS1 is ready).

Bits 3:1  Reserved, must be kept at reset value.

Bit 0  **TS1_EN**: Temperature sensor 1 enable bit
   This bit is set and cleared by software.
   0: Temperature sensor 1 disabled
   1: Temperature sensor 1 enabled

*Note:* Once enabled, the temperature sensor is active after a specific delay time. The
**TS1_RDY** flag is set when the sensor is ready.
28.6.2 Temperature sensor T0 value register 1 (DTS_T0VALR1)

DTS_T0VALR1 contains the value of the factory calibration temperature (T0) for temperature sensor 1. The reset value is factory trimmed.

Address offset: 0x08
Reset value: 0x000X XXXX

r r r r r r r r r r r r r r r r

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **TS1_RDY**: Temperature sensor 1 ready flag
- This bit is set and reset by hardware.
- It indicates that a measurement is ongoing.
  0: Temperature sensor 1 busy
  1: Temperature sensor 1 ready

Bits 14:7 Reserved, must be kept at reset value.

Bit 6 **TS1_AITHF**: Asynchronous interrupt flag for high threshold on temperature sensor 1
- This bit is set by hardware when the high threshold is reached.
- It is cleared by software by writing 1 to the TS1_CAITHF bit in the DTS_ICIFR register.
  0: High threshold not reached on temperature sensor 1
  1: High threshold reached on temperature sensor 1

*Note: This bit is active only when the TS1_AITHFEN bit is set*

Bit 5 **TS1_AITLF**: Asynchronous interrupt flag for low threshold on temperature sensor 1
- This bit is set by hardware when the low threshold is reached.
- It is cleared by software by writing 1 to the TS1_CAITLF bit in the DTS_ICIFR register.
  0: Low threshold not reached on temperature sensor 1
  1: Low threshold reached on temperature sensor 1

*Note: This bit is active only when the TS1_AITLFEN bit is set*

Bit 4 **TS1_AITEF**: Asynchronous interrupt flag for end of measure on temperature sensor 1
- This bit is set by hardware when a temperature measure is done.
- It is cleared by software by writing 1 to the TS1_CAITEF bit in the DTS_ICIFR register.
  0: End of measure not detected on temperature sensor 1
  1: End of measure detected on temperature sensor 1

*Note: This bit is active only when the TS1_AITEFEN bit is set*

Bit 3 Reserved, must be kept at reset value.
Bit 2 **TS1ITHF**: Interrupt flag for high threshold on temperature sensor 1, synchronized on PCLK.
   This bit is set by hardware when the high threshold is set and reached.
   It is cleared by software by writing 1 to the TS1_CITHF bit in the DTS_ICIFR register.
   0: High threshold not reached on temperature sensor 1
   1: High threshold reached on temperature sensor 1
   *Note: This bit is active only when the TS1ITHFEN bit is set*

Bit 1 **TS1ITLF**: Interrupt flag for low threshold on temperature sensor 1, synchronized on PCLK.
   This bit is set by hardware when the low threshold is set and reached.
   It is cleared by software by writing 1 to the TS1_CILTF bit in the DTS_ICIFR register.
   0: Low threshold not reached on temperature sensor 1
   1: Low threshold reached on temperature sensor 1
   *Note: This bit is active only when the TS1ITLFEN bit is set*

Bit 0 **TS1ITEF**: Interrupt flag for end of measurement on temperature sensor 1, synchronized on PCLK.
   This bit is set by hardware when a temperature measure is done.
   It is cleared by software by writing 1 to the TS2_CITEF bit in the DTS_ICIFR register.
   0: No end of measurement detected on temperature sensor 1
   1: End of measure detected on temperature sensor 1
   *Note: This bit is active only when the TS1ITEFEN bit is set*

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **TS1AITHEN**: Asynchronous interrupt enable flag on high threshold for temperature sensor 1.
   This bit is set and cleared by software.
   It enables the asynchronous interrupt when the temperature is above the high threshold
   (only when REFCLK_SEL = 1’b1)
   0: Asynchronous interrupt on high threshold disabled for temperature sensor 1
   1: Asynchronous interrupt on high threshold enabled for temperature sensor 1

Bit 5 **TS1AITLEN**: Asynchronous interrupt enable flag for low threshold on temperature sensor 1.
   This bit is set and cleared by software.
   It enables the asynchronous interrupt when the temperature is below the low threshold (only
   when REFCLK_SEL = 1)
   0: Asynchronous interrupt on low threshold disabled for temperature sensor 1
   1: Asynchronous interrupt on low threshold enabled for temperature sensor 1
Bit 4 **TS1_AITEEN**: Asynchronous interrupt enable flag for end of measurement on temperature sensor 1

This bit are set and cleared by software.
It enables the asynchronous interrupt for end of measurement (only when REFCLK_SEL = 1).
0: Asynchronous interrupt for end of measurement disabled on temperature sensor 1
1: Asynchronous interrupt for end of measurement enabled on temperature sensor 1

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TS1_ITHEN**: Interrupt enable flag for high threshold on temperature sensor 1, synchronized on PCLK.

This bit are set and cleared by software.
It enables the interrupt when the measure reaches or is above the high threshold.
0: Synchronous interrupt for high threshold disabled on temperature sensor 1
1: Synchronous interrupt for high threshold enabled on temperature sensor 1

Bit 1 **TS1_ITLEN**: Interrupt enable flag for low threshold on temperature sensor 1, synchronized on PCLK.

This bit are set and cleared by software.
It enables the synchronous interrupt when the measure reaches or is below the low threshold.
0: Synchronous interrupt for low threshold disabled on temperature sensor 1
1: Synchronous interrupt for low threshold enabled on temperature sensor 1

Bit 0 **TS1_ITEEN**: Interrupt enable flag for end of measurement on temperature sensor 1, synchronized on PCLK.

This bit are set and cleared by software.
It enables the synchronous interrupt for end of measurement.
0: Synchronous interrupt for end of measurement disabled on temperature sensor 1
1: Synchronous interrupt for end of measurement enabled on temperature sensor 1

### 28.6.8 Temperature sensor clear interrupt flag register (DTS_ICIFR)

DTS_ICIFR is the control register for the interrupt flags.

Address offset: 0x28
Reset value: 0x0000 0000

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **TS1_CAITHF**: Asynchronous interrupt clear flag for high threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_AITHF flag in the DTS_SR register.

Bit 5 **TS1_CAITLF**: Asynchronous interrupt clear flag for low threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_AITLF flag in the DTS_SR register.
Bit 4 **TS1_CAITEF**: Write once bit. Clear the asynchronous IT flag for End Of Measure for thermal sensor 1.

Writing 1 clears the TS1_AITEF flag of the DTS_SR register.

Bit 3 **Reserved**, must be kept at reset value.

Bit 2 **TS1_CITHF**: Interrupt clear flag for high threshold on temperature sensor 1

Writing this bit to 1 clears the TS1_IITHF flag in the DTS_SR register.

Bit 1 **TS1_CITLF**: Interrupt clear flag for low threshold on temperature sensor 1

Writing 1 to this bit clears the TS1_ITLF flag in the DTS_SR register.

Bit 0 **TS1_CITEF**: Interrupt clear flag for end of measurement on temperature sensor 1

Writing 1 to this bit clears the TS1_ITEF flag in the DTS_SR register.

### 28.6.9 Temperature sensor option register (DTS_OR)

The DTS_OR contains general-purpose option bits.

29 Voltage reference buffer (VREFBUF)

29.1 Introduction

The devices embed a voltage reference buffer which can be used as voltage reference for ADCs and also as voltage reference for external components through the VREF+ pin.

29.2 VREFBUF implementation

The table below describes the VREFBUF voltages typical values:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>VREFBUF0</td>
<td>2.5 V</td>
</tr>
<tr>
<td>VREFBUF1</td>
<td>2.048 V</td>
</tr>
<tr>
<td>VREFBUF2</td>
<td>1.8 V</td>
</tr>
</tbody>
</table>

Note: Refer to the product datasheet for more details.

29.3 VREFBUF functional description

The internal voltage reference buffer is an operational amplifier, with programmable gain. The amplifier input is connected to the internal voltage reference VREFINT. The VREFBUF supports three voltages\(^1\), which are configured with VRS bits in the VREFBUF_CSR register:

- VRS = 000: VREFBUF0 voltage selected.
- VRS = 001: VREFBUF1 voltage selected.
- VRS = 010: VREFBUF2 voltage selected.

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:
After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

### 29.4 VREFBUF trimming

The VREFBUF output voltage is factory-calibrated by ST. At reset, and each time the VRS setting is changed, the calibration data is automatically loaded to the TRIM register.

Optionally user can trim the output voltage by changing the TRIM register bits directly. In this case, the VRS setting has no more effect on the TRIM register until the device is reset.

### 29.5 VREFBUF registers

#### 29.5.1 VREFBUF control and status register (VREFBUF_CSR)

- The minimum VDDA voltage depends on VRS setting, refer to the product datasheet.
Bits 31:7  Reserved, must be kept at reset value.

Bits 6:4  **VRS[2:0]**: Voltage reference scale
These bits select the value generated by the voltage reference buffer.
- VRS = 000: VREFBUF0 voltage selected.
- VRS = 001: VREFBUF1 voltage selected.
- VRS = 010: VREFBUF2 voltage selected.
- Others: Reserved

*Note: Refer to the product datasheet for each VREFBUFx voltage setting value.*

The software can program this bitfield only when the VREFBUF is disabled (ENVR=0).

Bit 3  **VRR**: Voltage reference buffer ready
- 0: the voltage reference buffer output is not ready.
- 1: the voltage reference buffer output reached the requested level.

Bit 2  Reserved, must be kept at reset value.

Bit 1  **HIZ**: High impedance mode
This bit controls the analog switch to connect or not the VREF+ pin.
- 0: VREF+ pin is internally connected to the voltage reference buffer output.
- 1: VREF+ pin is high impedance.

Refer to [Table 252: VREF buffer modes](#) for the mode descriptions depending on ENVR bit configuration.

Bit 0  **ENVR**: Voltage reference buffer mode enable
This bit is used to enable the voltage reference buffer mode.
- 0: Internal voltage reference mode disable (external voltage reference mode).
- 1: Internal voltage reference mode (reference buffer enable or hold mode) enable.

Refer to Section 2.3 for the register boundary addresses.
30 Audio digital filter (ADF)

30.1 Introduction

The audio digital filter (ADF) is a high-performance module dedicated to the connection of external sigma-delta (ΣΔ) modulators. It is mainly targeted for the following applications:

- audio capture signals
- metering

The ADF features one digital serial interface (SITF0) and one digital filter (DFLT0) with flexible digital processing options in order to offer up to 24-bit final resolution.

The ADF serial interface supports several standards allowing the connection of various ΣΔ modulator sensors:

- SPI interface
- Manchester coded 1-wire interface
- PDM interface

The ADF converts an input data stream into clean decimated digital data words. This conversion is done thanks to low-pass digital filters and decimation blocks. In addition, it is possible to insert a high-pass filter.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter bypass, filter order, decimation ratio. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion and continuous modes. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A sound activity detector (SAD) is available for the detection of sounds or voice signals. The SAD is connected at the output of the DFLT0. Several parameters can be programmed in order to adjust properly the SAD to the sound environment. The SAD strongly reduces the power consumption by preventing the storage of samples into the system memory, as long as the observed signal does not match the programmed criteria.

The digital processing is performed using only the kernel clock. The ADF requests the bus interface clock (AHB clock) only when data must be transferred or when a specific event requests the attention of the system processor.

30.2 ADF main features

- AHB Interface
- 1 serial digital input:
  - configurable SPI interface to connect various digital sensors
  - configurable Manchester coded interface support
  - compatible with PDM interface to support digital microphones
- 2 common clocks input/output for ΣΔ modulators
- 1 flexible digital filter path including:
  - A MCIC filter configurable in Sinc⁴ or Sinc⁵ filter with an adjustable decimation ratio
  - A reshape filter to improve the out-of-band rejection and in-band ripple
- A high-pass filter to cancel the DC offset
- Gain control
- Saturation blocks

- Clock absence detector
- Sound activity detector
- 24-bit signed output data resolution
- Continuous or single conversion
- Possibility to delay the selected bitstream
- One trigger input
- Autonomous functionality in Stop modes
- DMA can be used to read the conversion data
- Interrupts services

The SITF0 input interface allows the connection of the external sensor to the digital filter via the bitstream matrix (BSMX). The SITF0 can be configured in the following modes:

- LF_MASTER SPI mode (low-frequency)
- normal SPI mode
- Manchester mode

The data from the serial interface is routed to the filter in order to perform the PDM to PCM conversion and the sound activity detection.

The serial interface is enabled by setting the SITFEN bit to 1. Once the interface is enabled, it receives serial data from the external $\Sigma\Delta$ modulator.

**Note:** Before enabling the serial interface, the user must insure that the adf_proc_ck is already enabled (see Section 30.4.5: Clock generator (CKGEN) for details).

The SITF0 is controlled via the ADF serial interface control register 0 (ADF_SITF0CR).

As shown in the Figure 302, ADF_CCK0 or ADF_CCK1 can be selected as clock source, in order to sample the incoming bitstream:

- If the serial interface is programmed in SPI mode, the selected clock source is a copy of the clock present on the ADF_CCK0 or ADF_CCK1 pin.
- If the serial interface is programmed in LF_MASTER SPI mode, the selected clock source is the clock directly provided by the CCKDIV to the ADF_CCK0 or ADF_CCK1 pin.

See Table 258 for additional information.
LF_MASTER and normal SPI modes

The LF_MASTER SPI mode is a special mode allowing the use of an adf_proc_ck clock frequency, only two times bigger than the sensor clock. This mode is dedicated to low-power use-cases, using low-speed sensors.

In LF_MASTER SPI mode, the ADF must provide the bitstream clock to the external sensors via ADF_CCK0 and ADF_CCK1 pins. The ADF receives the bitstream data via the serial data input ADF_SDI0.

For the SITF0, the application must select the same clock than the one provided to the external sensor (ADF_CCK0 or ADF_CCK1), in order to guarantee optimal timing performances. This selection is done via SCKSRC[1:0].

The normal SPI interface is a more flexible interface than the LF_MASTER SPI, but the adf_proc_ck frequency must be at least four times higher than the sensor clock.

The application can select ADF_CCK0 or ADF_CCK1 clock for the capture of the data received via the ADF_SDI0 pin.

The ADF can generate a clock to the sensors via ADF_CCK0 or ADF_CCK1 if needed.

For all SPI modes, the serial data is captured using the rising and the falling edge of the selected clock. The SITF0 always provides the following bitstreams:

- bitstream received using the bitstream clock falling edge (bs0_f)
- bitstream received using the bitstream clock rising edge (bs0_r)

According to the sensors connected, one of the two bitstreams may not be available.

The application can select the wanted stream via the BSMX matrix.
To properly synchronize/receive the data stream, the adf_proc_ck frequency must be adjusted according to the constraints listed in Table 259.

**Clock absence detection**

A no-clock-transition period may be detected when the serial interface works in normal SPI mode. This feature can be used to detect a clock failure in the SPI link.

The application can program a timeout value via the STH[4:0] bitfield of the SITF0. If the ADF does not detect clock transitions for a duration of STH[4:0] x T_{adf_proc_ck}, then the CKABF flag is set.

An interrupt can be generated if CKABIE is set to 1. The STH[4:0] bitfield is in the ADF serial interface control register 0 (ADF_SITF0CR).

When the serial interface is enabled, the CKABF flag remains to 1 until a first clock transition is detected.

To avoid spurious clock absence detection, the following sequence must be respected:

1. Configure the serial interface in normal SPI mode and enable it.
2. Clear the CKABF flag by writing CKABF bit to 1.
   - If no clock transition is detected on the serial interface, the hardware immediately sets the CKABF flag to 1.
3. Read the CKABF flag:
   - If CKABF = 1, go back to step 2.
   - If CKABF = 0, a clock has been detected. The CKABIE bit can be set to 1 if the application wants an interrupt on detection of a clock absence.

*Note: The clock absence detection feature is not available in the LF_MASTER SPI mode.*

**Manchester mode**

In Manchester coded format, the ADF receives data stream from the external sensor via the ADF_SDI0 pin only.

The ADF_CCK0 and ADF_CCK1 pins are not needed in this mode.
Decoded data and clock signals are recovered from serial stream after Manchester decoding. They are available on bs0_r. There are two possible settings of Manchester codings:

- signal rising edge decoded as 0 and signal falling edge decoded as 1
- signal rising edge decoded as 1 and signal falling edge decoded as 0

To decode the incoming Manchester stream, the user must program STH[4:0] in the ADF serial interface control register 0 (ADF_SITF0CR). The STH[4:0] bitfield is used by the SITF0 to estimate the Manchester symbol length and to detect a clock absence. An internal counter (MCNT) is restarted every time a transition is detected in the ADF_SDI0 input. It is used to detect short transitions, long transitions or clock absence. A long transition indicates that the data value changed. Figure 304 shows a case where the OVR is around height and STH[4:0] = 5.

The estimated Manchester symbol rate ($T_{SYM}$) must respect the following formula:

$$(STH + 1) \times T_{adf_proc_ck} < T_{SYM} < (2 \times STH \times T_{adf_proc_ck})$$

It is recommended to compute STH as follows:

$$STH[4:0] = \text{round}\left(\frac{(2 \times OVR) - 1}{3}\right)$$
where OVR represents the ratio between the adf_proc_ck frequency and the expected Manchester symbol frequency. OVR must be higher than five, and the adf_proc_ck clock must be adjusted according to the constraints listed in Table 259.

The clock absence flag CKABF is set to 1 when no transition is detected during more than 2 x STH[4:0] x Tadf_proc_ck, or when the SITF0 is not yet synchronized to the incoming Manchester stream. In addition, an interrupt can be generated if the bit CKABIE is set to 1.

When the serial interface is enabled, the ADF must first be synchronized to the incoming Manchester stream. The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (pink circle in the Figure 304) is detected.

The end of the synchronization phase can be checked by following the software sequence:

1. Clear the CKABF flag in the ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR) by writing CKABF bit to 1. If the serial interface is not yet synchronized the hardware immediately set the CKABF flag to 1.

2. Read the CKABF flag:
   - If CKABF= 1, go back to step 1.
   - If CKABF = 0, the Manchester interface is synchronized and provides valid data.

**Programming example**

In the following example, the ADF kernel clock frequency (Fadf_ker_ck) is 100 MHz and the received Manchester stream is at about 6 MHz (FSYMB):

1. Provide a valid adf_proc_ck to the SITF0.
   The adf_proc_ck frequency must be at least six times higher than the Manchester symbol frequency (means at least 36 MHz).
   PROCDIV is programmed to 1 to perform a division by two of the kernel clock. In that case, Fadf_proc_ck = 50 MHz (8.33 times higher than the Manchester symbol frequency).

2. Compute STH.
   OVR is given by: OVR = Fadf_proc_ck / FSYMB = 50 MHz / 6 MHz = 8.33.

   Then STH[4:0] = \( \lfloor \frac{(2 \times \text{round}(\frac{8.33}{3}) - 1)}{5} \rfloor \)

   The minimum allowed frequency for the Manchester stream is then:
   \( 1 / (2 \times \text{STH} \times T_{\text{adf_proc_ck}}) = 1 / (10 \times 20 \text{ ns}) = 5 \text{ MHz} \)

   The maximum allowed frequency for the Manchester stream is then:
   \( 1 / ((\text{STH}+1) \times T_{\text{adf_proc_ck}}) = 1 / (6 \times 20 \text{ ns}) = 8.33 \text{ MHz} \)

**30.4.4 ADC slave interface (ADCITF)**

The ADCs are not always connected to the ADF. Refer to Section 30.3 to check the situation for this product.

The ADF allows the connection of up to two ADCs to the filter path. For the filter, the DATSRC[1:0] bitfield in the ADF digital filter configuration register 0 (ADF_DFLT0CICR) allows the application to select data from the ADCs.
Warning: The ADF does not support receiving interleaved data from one of the ADCITF input.

30.4.5 Clock generator (CKGEN)

The RCC (reset and clock controller) provides the following clocks to the ADF:

- AHB clock (adf_hclk) used for the register interface
- kernel clock (adf_ker_ck) mainly used by all other parts of the circuit via the CKGEN

Those clocks are not supposed to be phase locked, so all signals crossing those clock domains are re-synchronized.

The clock generator (CKGEN) is responsible of the generation of the processing clock, and the clock provided to the ADF_CCK0 and ADF_CCK1 pins. All those clocks are generated from the adf_ker_ck.

The processing clock (adf_proc_ck) is used to run all the signal processing and to re-sample the incoming serial or parallel stream.

To adapt the kernel clock frequency provided by the RCC, the following dividers are available:

- PROCDIV[6:0] used to adapt the kernel clock frequency to the constraints of the parallel and serial interfaces, and to the processing blocks
- CCKDIV[3:0] used to adapt the frequency of the ADF_CCK0 and ADF_CCK1 clocks

PROCDIV[6:0] and CCKDIV[3:0] must be programmed when no clock is provided to the dividers (CKGDEN = 0).

The adf_proc_ck generation is controlled by CKGDEN.

In addition, the CKGMOD bit allows the application to define the way to trigger the CCKDIV divider:

- When CKGMOD = 0, the CCKDIV divider is started as soon as CKGDEN is set to 1.
- When CKGMOD = 1, the CCKDIV divider is started when CKGDEN is set to 1 and the programmed trigger condition occurred.

All the bits and fields controlling the CKGEN are in the Section 30.8.2: ADF clock generator control register (ADF_CKGCR).
The trigger logic for CKGEN is handled by the block TRG_CK. As shown in Figure 364, the CCKDIV divider can be triggered on the rising or falling edge of an external trigger source. When the proper trigger condition occurs, the cck_trg signal goes to high, allowing the CCKDIV divider to start. The TRG_CK logic is reset when CKGDEN is set to 0.

This feature can be helpful to synchronize the ADF_CCKy (y = 0,1) clock of several ADF instances, or to synchronize the clock generation to a timer event.

The application can control the activation of the ADF_CCK0 or ADF_CCK1 pin thanks to CCK0EN/CCK1EN and CCK0DIR/CCK1DIR bits:

- CCKyEN is used to enable the CCKDIV, and thus generates a clock for the external sensors.
- CCKyDIR is used to control the direction of the ADF_CCKy pin (input or output)

**Table 258. Control of the common clock generation**

<table>
<thead>

</tr>
</tbody>
</table>

1. The configuration with CCKyEN = 1 and CCKyDIR = 0 is not shown must be avoided (no interest).

**Note:** The adf_proc_ck must be enabled (by CKGDEN = 1) before enabling other blocks (such as SITF0 or DFLT0).

**CKGEN activation sequence example**

- Set CKGDEN to 0.
- Wait for CKGACTIVE = 0. If CKGDEN was previously enabled, this phase can take two periods of adf_hclk, and two periods of adf_proc_ck.
• Program PROCDIV[6:0], CKGMOD, CCKDIV[3:0], TRGSRC[3:0], TRGSENS, CCK1EN and CCK0EN.
• Set CKGDEN to 1.

When needed, at any moment, CCK[1:0]EN bitfield value can be changed without disabling the clock generator.

Clock frequency constraints

The table below shows the frequency constraints to receive and process properly the samples.

Note: The reshape filter (RSFLT) needs up to 24 cycles of adf_proc_ck clock to process one sample.

1. FADF_CCKy represents the frequency of clock received via ADF_CCKy, or generated via ADF_CCKy. FSYMB represents the frequency of the received symbol rate for Manchester mode.

30.4.6 Bitstream matrix (BSMX)

The BSMX receives the bitstreams from the serial interface SITF0 and provides the selected stream to the digital filter DFLT0.

As shown in the Figure 355, the SITF0 provides two bitstreams (bs0_r and bs0_f) to the BSMX.

The application to select the wanted stream via the ADF bitstream matrix control register 0 (ADF_BSMX0CR). This selection is intended to be static.
BSMX programming sequence example

The BSSEL[4:0] bitfield cannot be changed if the DFLT0 is enabled. The following steps are needed to change the value of BSMX:

- Set DFLTEN of DFLT0 to 0.
- Wait for BSMXACTIVE = 0.
- Program BSSEL[4:0].
- Set DFLTEN of DFLT0 to 1.

30.4.7 Digital filter processing (DFLT)

The digital filter processing includes the following sub-blocks:

- symbol remap (SBR)
- clock skipper delay (DLY)
- MCIC decimation filter that can be configured in Sinc⁴ or Sinc⁵
- gain control (SCALE)
- signal saturation (SAT)
- reshape filter (RSFLT)
- high-pass filter (HPF)
- receive RXFIFO
The figure below shows the filter path configuration according to CICMOD[2:0]. Several configuration bits are available to configure the digital filter to the application needs.

**Figure 307. DFLT overview**

**Symbol remap and source selection**

The symbol remap (SBR) converts the bitstream selected by the BSMX into data usable by the filter path. More especially:

- The high levels are converted into a 16-bit signed number + 1.
- The low levels are converted into a 16-bit signed number - 1.

The signal source of the digital filter can be selected via DATSRC[1:0] between the two following:

- data coming from the BSMX
- data coming from one of the ADC interfaces (ADCITF2 or 1)

**Programmable micro-delay control (DLY)**

The digital filter has a delay line that allows the timing adjustment of each stream with the resolution of the bitstream clock.

This feature is particularly helpful in the case of microphone beam forming applications where delays smaller than the final sampling rate must be applied to the incoming stream. This feature can be used when the ADF is synchronized with another MDF instance (if present in the product) for a beam forming application for example.

The delay is performed by discarding a given number of samples from the selected input stream, before samples enter into the CIC filter. This data discarding is done by skipping a given number of data strobe, preventing the CIC filter to take into account those data.

When the wanted amount of data strobe has been skipped, the next incoming samples are strobed normally.

The figure below shows an example on how to apply dynamically small delay to an incoming stream. For simplification, the CIC filter performs a decimation by height in this example. CIC1 represents the CIC included in the ADF and CIC0 represents a filter from another MDF instance (if present in the product).
The CIC of the ADF (CIC1) receives a command in order to skip three incoming samples. So the input samples named b10, b11 and b12 are not processed by CIC1. As a consequence, the output sample N+1 generated by CIC0 is built from input samples a[23:16] while the sample N+1 of CIC1 is built from input samples b[26:19].

Finally, the non-skipped data stream looks delayed by three bitstream periods.

**Note:** When the input data strobes are skipped, the decimation counter remains frozen. As a consequence, the samples delivered by the CIC1 are a bit delayed.

The following steps are needed to program the amount of bitstream clock periods to be skipped:

1. Wait for SKPBF equal to 0.
2. Write SKPDLY[6:0] to the wanted number of bitstream clock periods to be skipped. The SKPBF flag goes immediately to 1, indicating that the delay value entered into SKPDLY[6:0] is under process.
   - If the DFLT0 is not yet enabled (DFLTEN = 0), then the DLY logic waits for DFLTEN = 1. When the application sets DFLTEN to 1, the DLY logic starts to skip the amount of wanted data strobes.
   - If the DFLT0 is already enabled (DFLTEN = 1), then the DLY logic immediately starts to skip the amount of wanted data strobes.

When the ADF skipped the amount of wanted data strobes, then SKPBF goes back to 0.

3. If the application needs to skip more data strobes, then the operation must be restarted from step 1.

The effect of the delay performed with this mechanism is cumulative as long as the ADF is enabled. If the application performs a D1 delay followed by a D2 delay, then all other active filters are delayed by D1 + D2.

**Note:** If SKPDLY[6:0] is written when SKPBF = 1, the write operation is ignored.

### Cascaded-integrator-comb (CIC) filter

The CIC digital filters are an efficient implementation of low-pass filters, often used for decimation and interpolation. The CIC frequency response is equal to a Sinc\(^N\) function, this is why they are often called Sinc filters.
The Sinc\(^N\) digital filter embedded into the ADF can be configurable in Sinc\(^4\) or Sinc\(^5\), according to CICMOD:

- If CICMOD[2:0] = 4, Sinc\(^4\) is selected.
- If CICMOD[2:0] = 5, Sinc\(^5\) is selected.

The filters have the following transfer function:

\[
H(z) = \left(\frac{1 - z^{-D}}{1 - z^{-1}}\right)^N
\]

where \(N\) can be 4 or 5, and \(D\) is the decimation ratio. \(D\) is equal to MCICD+1.

**Figure 309. CIC4 and CIC5 frequency response with decimation ratio = 32 or 16**

**CIC output data size**

The size of samples delivered by the CIC (\(D_{\text{CIC}}\)), depends on the following parameters:

- CIC order (\(N\))
- CIC decimation ratio (\(D\))
- data size of the input stream (\(D_{\text{SIN}}\))

The CIC order and decimation ratio must be programmed in order to insure that the data size does not exceed the 26-bit CIC capability.

The following formula gives the output data size (\(D_{\text{CIC}}\)) according to the parameters above.
The decimation ratio can be adjusted from 2 to 512 for the CIC filter.

The table below gives some data output size in bits for some decimation values, when the data source is a full-scale signal coming from the serial interface or from a 12-bit ADC.

Note: $DS_{IN} = 1$ bit for a serial bitstream, but can be up to 16 bits when coming from the ADCITF.

**Table 260. Data size according to CIC order and CIC decimation values**

<table>
<thead>
<tr>

</tr>
<tr>
<td>64</td>
<td>25</td>
<td>-</td>
</tr>
<tr>
<td>76</td>
<td>26</td>
<td>-</td>
</tr>
</tbody>
</table>

Note: For a full-scale input signal, the decimation ratio must not exceed 76 for a Sinc$^4$ and 32 for a Sinc$^5$.

The LSB parts of the data provided by the CIC is not necessarily significant: it depends on the sensor performances and the ability of the CIC to reject the out-of-band noise.

The sample size at CIC output can be adjusted thanks to the SCALE block.

**Scaling (SCALE) and saturation (SAT)**

The SCALE block allows the application to adjust the amplitude of the signal provided by the CIC, by steps of 3 dB (± 0.5 dB).

The signal amplitude can be decreased by up to 8 bits (- 48.2 dB), and can be increased by up to 12 bits (+ 72.2 dB).
The gain is adjusted by the SCALE[5:0] bitfield in the **ADF digital filter configuration register 0 (ADF_DFLT0CICR)**.

SCALE[5:0] can be changed even if the DFLT0 is enabled. During the gain transition, the signal provided by the filter is disturbed.

Due to internal resynchronization, there is a delay of some cycles of adf_proc_ck clock between the moment where the application writes the new gain, and the moment where the gain is effectively applied to the samples. If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back SCALE[5:0] informs the application on the current gain value.

The table below shows the possible gain values.

</table>

The SAT blocks avoid having a wrap-around of the binary code when the code exceeds its maximal or minimal value.

The ADF performs saturation operations at the following levels:
- after the SCALE block (performed by the SAT block): The signal is saturated at 24 bits.
- inside the RSFLT, to insure a good filter behavior
- at the output of the HPF, to insure that the output signal does not exceed 24 bits

The SATF bit informs the application that a saturation occurred either after the SCALE, inside the RSFLT or after the HPF. In addition, an interrupt can be generated if SATIE is set to 1. As soon as a saturation is detected, the SATF flag is set to 1. It is up to the application to clear this flag in order to be able to detect a new saturation.

Those bits are in the **ADF DFLT0 interrupt enable register (ADF_DFLT0IER)** and **ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)**.

**Gain adjustment policy**

To get the best ADF performances, it is important to properly adjust the gain value via SCALE[5:0].
A usual way to adjust the gain is to select the SCALE[5:0] value that gives a final signal amplitude as close as possible to the 24-bit full-scale, for the maximum input signal.

A way to select the optimal gain is detailed below:

1. Check that, for the expected input signal, the data size into the CIC filter does not exceed 26 bits. This can be checked using this formula:

\[
\frac{\ln(\sin_{pp} \cdot D^N)}{\ln(2)} < 26
\]

where \( N \) represents the CIC order, \( D \) the decimation ratio and \( \sin_{pp} \) the maximum peak-to-peak amplitude of the input signal.

\( \sin_{pp} \) can take:
- a maximum peak-to-peak amplitude of 2 (± 1), for samples coming from SITF0
- A maximum peak-to-peak amplitude of 4095 (+ 2047, - 2048), for samples coming from a 12-bit ADC

**Example:** a Sinc^4 can be used with a decimation ratio of 96, if the maximum input signal does not exceed ± 0.35. Indeed:

\[
\frac{\ln(0.7 \cdot 96^4)}{\ln(2)} = -25.82 \text{ bits} < 26 \text{ bits}
\]
2. Adjust the SCALE value.

To select the most appropriate SCALE value, the user must check if the RSFLT is used or not. If the RSFLT is used, the data size at SCALE output must not exceed 22 bits, otherwise the data size can be up to 24 bits.

The SCALE value in dB must be selected using this formula:

\[
\text{SCALE}_{\text{dB}} < 20 \cdot \log_{10}\left( \frac{2^{\text{NB}}}{\text{SIN}_{\text{pp}} \cdot \text{D}^{N}} \right)
\]

where NB is equal to 22 if RSFLT is enabled, or 24 if RSFLT is bypassed. SCALE\text{dB} represents the gain value selected by SCALE[5:0].

Example: For a Sinc\(^4\) with a decimation ratio of 96 and a SIN\(_{pp}\) of 0.7.

- If the RSFLT is bypassed:

\[
20 \cdot \log_{10}\left( \frac{2^{24}}{0.7 \cdot 96^4} \right) = -11 \text{ dB}
\]

SCALE\text{dB} value must be lower than -11 dB, the closest lower value is -12 dB (SCALE[5:0] = 0x2C).

- If the RSFLT is enabled:

\[
20 \cdot \log_{10}\left( \frac{2^{22}}{0.7 \cdot 96^4} \right) = -23 \text{ dB}
\]

SCALE\text{dB} value must be lower than -23 dB, the closest lower value is -24.1 dB (SCALE[5:0] = 0x28).

If SCALE[5:0] is set to a higher value, then a saturation may occur. An event flag informs the user if a saturation occurred.

The table below proposes gain values for different filter configurations, when the data comes from the SITF0, according to the MCIC order, and the MCIC decimation ratio. This table is not exhaustive and considers a full-scale input signal (see Section 40.7.5: Total ADF gain for details).

Reshaping filter (RSFLT)

In addition to the CIC, the ADF offers a reshaping IIR filter mainly dedicated to the audio application, but also usable in other applications.

When the RSFLT is used, the sample size at its input must not exceed 22 bits.

The samples at the RSFLT output can be decimated by four or not according to the RSFLTDto bit in the ADF reshape filter configuration register 0 (ADF_DFLT0RSFR).

The RSFLT can be bypassed by setting RSFBYP to 1 in the ADF reshape filter configuration register 0 (ADF_DFLT0RSFR).

The table below shows which sampling rate must be provided to the RSFLT in order to process the most common audio streams.

The RSFLT cutoff frequency ($F_C$) depends on the sample rates at its input ($F_{RS}$), and is given by the following formula:

$$F_C = 0.111 \times F_{RS}$$

The figure below shows the frequency response of the reshape filter.

Figure 310. Reshape filter frequency response normalized (FRS / 2 = 1)

The RSFLT gain is close to 9.3 dB, so the output data size is a little bit lower than 24 bits for a 22-bit wide input signal.

The RSFLT takes 24 clock cycles of adf_proc_ck clock to process one sample at FRS. When the RSFLT is enabled, the application must insure that the adf_proc_ck is at least 24 times faster FRS.

The RSFLT generates an event (rfovr_evt) and sets the RFOVRF flag, if the RSFLT receives a new samples while the previous one is still under processing.

When RFOVRF is set, the samples provided by the RSFLT are invalid. The application must then stop the data acquisition and provides a faster adf_proc_ck clock to the RSFLT.

High-pass filter (HPF)

The high-pass filter suppresses the low-frequency content from the final output data stream in case of continuous conversion mode. The high-pass filter can be enabled or disabled via HPFBYP in the ADF reshape filter configuration register 0 (ADF_DFLT0RSFR).

The HPF is useful when there is parasitic low-frequency noise (or DC signal) in the input data source that must be removed from the final data.
The HPF is a first order IIR filter and the cut-off frequency can be selected via HPFC[1:0] in the ADF reshape filter configuration register 0 (ADF_DFLT0RSFR), among the following values:

- 0.000625 x FPCM
- 0.00125 x FPCM
- 0.00250 x FPCM
- 0.00950 x FPCM

The HPF output is saturated at 24 bits. The SATF flag is set if a sample is saturated.

### 30.4.8 Digital filter acquisition modes

The ADF offers the following modes to perform a data capture:

- asynchronous continuous acquisition mode
- asynchronous single-shot acquisition mode
- synchronous continuous acquisition mode
- synchronous single-shot acquisition mode
- window continuous acquisition mode

**Note:** To perform a data capture, the filter, the interface providing the data (SITF0 or ADCITF) and the CKGEN must be enabled. If needed, the ADF_CCK0 or ADF_CCK1 must be enabled as well.

The filter can be stopped immediately when DFLTEN is set to 0. This action resets the filter and flushes the RXFIFO. The DFLTACTIVE flag also goes back to 0 when the RXFIFO and the filter is reset.

The figure below shows a simplified view of the trigger logic available for each filter and for the clock generator.

**Figure 311. Trigger logic for DFLT and CKGEN**

A block common to all TRIG blocks performs the rising and falling edges detection and the re-synchronization of the input trigger to the adf_ker_ck clock domain. This implementation allows the application to use triggers with pulse width smaller than the adf_ker_ck period.

In synchronous modes, the TRIG block offers the possibility to select adf_trgi or TRGO bit as trigger sources. The TRGO bit is in the *ADF global control register (ADF_GCR)*.

The edge sensitivity can also be selected.

**Asynchronous continuous acquisition mode**

This mode allows the application to start a continuous acquisition by simply writing the DFLTEN bit to 1.

The asynchronous continuous acquisition mode is selected when ACQMOD[2:0] = 0.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN) so that the adf_proc_ck frequency is compatible with the targeted application (see examples in *Table 398*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 0.
4. Set to 1 the SITFEN bit of the serial data interface.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1, the acquisition sequence starts immediately.
The figure below shows a simplified example of the samples generated by the DFLT0.

**Figure 312. Asynchronous continuous mode (ACQMOD[2:0] = 0)**

![Diagram](Image)

**Note:** The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

### Asynchronous single-shot acquisition mode

This mode allows the application to start the acquisition of one sample by simply writing the DFLTEN bit to 1.

The asynchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 001.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the adf_proc_ck frequency is compatible with the targeted application (see examples in Table 398).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 001.
4. Set to 1 the SITFEN bit.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1, the filter provides one data to the RXFIFO and stops the acquisition.

To trigger a new acquisition, the application must:

1. Check that the previous acquisition is completed, by waiting that DFLTRUN = 0.
2. Set again DFLTEN to 1.

This sequence can be repeated every time a new data must be converted.

As shown in the Figure 366, every time DFLTEN is set to 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset, and the filter is ready to start a new conversion.
If DFLTEN is set to 0 while an acquisition is ongoing, the ongoing conversion is stopped (in the example, S3 is lost). This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Set DFLTEN to 0.

**Figure 313. Asynchronous single-shot mode (ACQMOD[2:0] = 001)**

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

**Synchronous continuous acquisition mode**

This mode allows the application to start a continuous acquisition by using one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The Synchronous continuous acquisition mode is selected when ACQMOD[2:0] = 010.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in Table 398).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 010.
4. Set to 1 the bit SITFEN.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. When the trigger condition is met, the filter starts the acquisition.
The TRGSENS bit allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). The first rising edge of the trigger signal is ignored because DFLTEN = 0. Then the next rising edge is taken into account and starts the acquisition. All other rising edges are ignored. The trigger logic is re-initialized when DFLTRUN goes back to 0.

**Figure 314. Synchronous continuous mode (ACQMOD[2:0] = 010)**

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

**Synchronous single-shot acquisition mode**

This mode allows the application to start a single acquisition by using one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The Synchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 011.
The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in Table 398).
2. Enable the CKGEN and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 011.
4. Set to 1 the SITFEN bit.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. When the trigger condition is met, the filter starts the acquisition and provides one data to the RXFIFO, then the filter is ready to accept a new trigger.

TRGSSENS allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing, or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSSENS = 0). Every-time a trigger rising edge is detected with DFLTEN = 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset. DFLTRUN is set to 0 and the filter is ready to start a new conversion.

**Figure 315. Synchronous single-shot mode (ACQMOD[2:0] = 011)**

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

**Figure 368** shows a case where the DFLTEN is set to 0 while an acquisition is ongoing (the sample S2 is lost). This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Clear DFLTEN to 0.

Note: The discard phase is optional.
Window continuous acquisition mode

This mode allows the application to start or stop a continuous acquisition controlled by consecutive edges of one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The window continuous acquisition mode is selected when ACQMOD[2:0] = 100.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in Table 398).
2. Enable the CKGEN and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter settings and set the ACQMOD[2:0] to 100.
4. Set to 1 the SITFEN bit.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. If TRGSENS = 0, the acquisition starts on trigger rising edge and stops on trigger falling edge. If TRGSENS = 1, the acquisition starts on trigger falling edge and stops on trigger rising edge.

Note: The acquisition may restart if the trigger condition becomes again active.

Figure 369 shows a simplified example of window continuous acquisition mode, with TRGSENS = 1. Once DFLTEN is set to 1, the ADF waits for a falling edge on the selected trigger input. When the trigger condition is met, DFLTRUN goes to 1 and the acquisition starts. The acquisition stops if the ADF detects a rising edge on the selected trigger input. If DFLTEN is still set to 1, the ADF waits again for a falling edge on the selected trigger input.

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.
Starting several filters synchronously

If the ADF is used with MDF instances (if present in the product), it is possible to start simultaneously the acquisition of all the filters. This synchronization capability depends on the way the triggers are connected in the product. Generally, an ADF is able to trigger MDF instances, if its adf_trgo signal is connected as trigger input to those blocks (see Section 40.4.2: ADF pins and internal signals to check trigger capabilities).

In the following programing example, one ADF has its adf_trgo signal connected to some MDFs. To start the acquisition of several filters synchronously, the following sequence must be performed (assuming that DFLTEN bits of the filters are set to 0):

On MDFs receiving the adf_trgo trigger:
1. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
2. Set to 1 the SITFEN bit of the requested data interfaces.
3. For each filter, set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. For each filter, set TRGSRC[3:0] in order to select the adf_trgo trigger input.
5. For each filter, set TRGSENS to 0 (rising edge).
6. For each filter, set DFLTEN to 1.

On the ADF generating the adf_trgo trigger:
1. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK[1:0] clocks.
2. Set to 1 the SITFEN bit of the requested data interfaces.
3. Set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. Set TRGSRC[3:0] to 0 (TRGO selected).
5. Set TRGSENS to 0 (rising edge).
6. Set DFLTEN to 1.
7. Read TRGO bit until it is read to 0.
8. Set TRGO to 1. Then the acquisition sequence for all selected filters starts immediately.

To trigger a new acquisition (in case of single-shot) the application must do the following:
- Check that the previous acquisition is completed, by waiting DFLTRUN = 0.
- Read TRGO until it is read to 0.
- Set again the bit TRGO to 1.

Discarded samples

The ADF offers the possibility to program the amount of samples to be discarded after each restart:
- to avoid capturing samples affected by the impulse response of the filter
- to delay the acquisition of filters by a specific amount of samples

The discard function is controlled via NBDIS[7:0] as follows:
- When NBDIS[7:0] = 0, the discard function is disabled.
- When NBDIS[7:0] ≠ 0, the discard function is activated in one of the following condition:
  - when the DFLTEN bit goes to 1
  - every time an acquisition is started in (A)synchronous single-shot modes

Refer to Figure 365 to Figure 369, and Figure 371.
In the example shown in the figure below, the discard function is used to drop the first five samples provided by the digital filter (S1 to S5). The first sample transferred to the RXFIFO is S6.

**Figure 317. Discard function example**

### 30.4.9 Start-up sequence examples

The figure below details a start of acquisition sequence of a digital filter triggered by DFLTEN (ACQMOD[2:0] = 0), with NBDIS[7:0] = 3 (three samples to discard before acquisition).

The DFLT0 is configured for audio application: MCIC, RSFLT and HPF activated. The data interface (SITF0 or ADCITF) is assumed to be already activated.

**Note:** NBDIS[7:0] is set on purpose to a small value to simplify the drawing.

**Figure 318. Start sequence with DFLTEN, in continuous mode, audio configuration**
The DFLTEN bit is re-sampled into the ADF processing clock domain. When DFLTEN is detected high, the filter chain is enabled, and the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

When the MCIC decimation counter reached its programmed value N, a sample is available for the RSFLT.

The RSFLT processes all the samples provided by the MCIC, and delivers a sample to the HPF every-time it processes four samples (decimation by 4). The RSFLT needs up to 24 cycles of adf_proc_ck clock before delivering a sample (P1).

The HPF processes all the samples provided by the RSFLT, but the NBDIS function prevents the data writing in the RXFIFO as long as NBDIS_CNTR does not reach 0.

When NBDIS_CNTR reaches 0, the samples provided by the HPF are stored into the RXFIFO.

### 30.4.10 Sound activity detection (SAD)

The SAD is based on the computation of the ambient noise level (ANLVL) and of the short-term sound level (SDLVL). The SAD offers the following ways to detect a sound:

- when the SDLVL reaches a threshold referenced to the ambient noise level
- when the SDLVL reaches a fixed threshold
- when the ANLVL reaches a fixed threshold

As shown in the figure below, the SAD takes the 16 MSB samples from the DFLT0 output.

**Figure 319. SAD block diagram**

The SAD is highly configurable, and the application can adjust several parameters:

- SAD detection behavior (SADMOD)
- number of samples used to compute the sound level (FRSIZE)
- number of frames used to compute the ambient noise level during the learning phase (LFRNB)
- slope of the ambient noise estimator (ANSLP)
- minimum expected ambient noise level (ANMIN)
- threshold level (SNTHR)
- threshold hysteresis (HYSTEN)
- hangover window in order to filter spurious transitions between DETECT and MONITOR states (HGOVR)
- data capture mode (DATCAP)

SAD detection behavior

The SAD can use the following ways to detect a sound, selected by SADMOD[1:0]:
- When SADMOD[1:0] = 0, the SAD works like a voice-activity detection. In this mode, the SAD estimates the ambient noise level according to the computed sound level values. The threshold of the trigger is elaborated from the estimated ambient noise. Finally the current sound level is compared to this threshold. In a first approximation, the SAD triggers if the peak-to-average value of the input signal reaches a level defined by SNTHR[3:0].
- When SADMOD[1:0] = 01, the SAD compares the current sound level (SDLVL) to a fixed trigger value defined by the application via SNTHR[3:0] and ANMIN[12:0]. This mode allows a fast SAD reaction as the amount of samples used to compute the sound level can be configured via FRSIZE[2:0].
- When SADMOD[1:0] = 1x, the SAD compares the estimated ambient noise level (ANLVL) to a fixed trigger value defined by the application via SNTHR[3:0] and ANMIN[12:0]. This mode avoids unwanted triggers, due to peak levels, but the SAD reacts more slowly to an input signal variation. It is nevertheless possible to adjust the reaction time via FRSIZE[2:0] and ANSLP[2:0].

SAD states

As shown in Figure 373, the SAD works as follows:

1. When enabled (SADEN = 1), the SAD is first in LEARN state to perform a first estimation of the ambient noise level.
2. The SAD continuously computes the short-term sound level (SDLVL) using the samples provided by the DFLT0. The amount of samples used to compute the sound level is given by FRSIZE[2:0]. The samples processed by the DFLT0 can be transferred into the memory or not depending on DATCAP[1:0] value.
3. The initial ambient noise level (ANLVL) is computed using the consecutive sound level values. The application can define how much sound level values are used to perform the computation of this initial ambient noise estimation (LFRNB).
4. When the initial ambient noise level (ANLVL) is computed, the SAD switches to the MONITOR state.
5. Every time a new short-term sound level value is available, the SAD updates the ambient noise level and the thresholds according to the selected detection mode.
6. If the SAD triggers, then the following happens:
   - The SAD switches to DETECT state.
   - The sddet_evt event is asserted.
   - The adf_sad_det signal is set to high.
7. The hangover function insures that the DETECT state is maintained even if the sound level goes below the threshold level for a time given by HGOVR.
Sound level computation (SDLVL)

Once enabled, the SAD computes continuously the sound level value. The sound level represents the average of the absolute value of an amount of PCM samples given by FRSIZE[2:0].

\[
SDLVL = \frac{1}{N_{FRSIZE}} \times \sum_{n=1}^{N_{FRSIZE}} |PCM(n)|
\]

where \(N_{FRSIZE}\) is the amount of PCM samples given by FRSIZE[2:0].
Ambient noise estimation (ANLVL)

The ambient noise level (ANLVL) is computed when SADMOD[1:0] is 00 or 10.

The ambient noise level is computed differently according to the state of the SAD as detailed below:

- **ANLVL computation during the LEARN state**
  
  Every time the SAD is enabled, a learning phase is initiated in order to estimate a first value of the ambient noise level. During this phase, the SAD cannot trigger.

  During the LEARN phase, the ambient noise level is computed as follows:

  \[
  \text{ANLVL} = \frac{1}{N_{\text{LFRNB}}} \sum_{n=1}^{N_{\text{LFRNB}}} |\text{SDLVL}(n)|
  \]

  where \( N_{\text{LFRNB}} \) is the amount of frames given by LFRNB[2:0] bitfield.

- **ANLVL computation during the MONITOR or DETECT state**

  When the learning phase is completed, the SAD updates the ambient noise level in the following way:

  a) The SAD computes the new possible values for the ambient noise level:

     \[
     \text{ANLVL\_UP} = \text{ANLVL} \times (1 + 2^{\text{ANSLP}-12})
     \]

     \[
     \text{ANLVL\_DN} = \text{ANLVL} \times (1 - 2^{\text{ANSLP}-10})
     \]

  b) The ANLVL takes the ANLVL\_DN value if the current sound level is lower than ANLVL\_DN, otherwise ANLVL takes the value of ANLVL\_UP.

     The ANLVL is not updated if the current sound level is higher than the threshold level, except if SADMOD[1:0] = 10.

  c) When SADMOD[1:0] = 0, if the new ANLVL value is lower than ANMIN[12:0], ANLVL is replaced by ANMIN.

The slope of the noise estimator can be adjusted to optimize the detection of the wanted signal. This slope is adjusted via ANSLP[2:0] in the ADF SAD configuration register (ADF_SADCFG).
The table below shows the allowed values according to the frame size and the sampling rate of the data observed by the SAD. The recommended values when the SADMOD[1:0] = 0 are the ones into the gray shaded cells.

**Table 265. ANSLP values versus FRSIZE and sampling rates**

</tbody>
</table>

1. The slow slope is equal to - 8.5 dB/s for the negative slope and + 2.1 dB/s for the positive slope.
2. The typical slope is equal to - 17.1 dB/s for the negative slope and + 4.2 dB/s for the positive slope.
3. The fast slope is equal to - 34.2 dB/s for the negative slope and + 8.5 dB/s for the positive slope.

The slopes can also be computed using the following formulas:

\[
SLC_{UP} = 20 \times \frac{F_s}{FSIZE} \times \log_{10}(1 + 2^{(ANSLP - 12)})
\]

\[
SLC_{DN} = 20 \times \frac{F_s}{FSIZE} \times \log_{10}(1 - 2^{(ANSLP - 10)})
\]

where \( F_s \) is the sampling rate of the stream observed by the SAD and \( F_{SIZE} \) is the frame size defined by \( FRSIZE[2:0] \).

**Threshold computation**

The way the threshold value is computed depends on SADMOD[1:0]:

- If SADMOD[1:0] = 0, THRH is obtained by multiplying the current ANLVL value with the gain defined in SNTHR[3:0].

\[
THR_H = ANLVL \times \frac{GdB_{SNTHR}}{20}
\]

This threshold value is then compared to the current sound level (SDLVL).

- If SADMOD[1:0] = 01, THRH is obtained by multiplying the current ANMIN[12:0] with the gain defined by SNTHR[3:0].

\[
THR_H = ANMIN \times \frac{GdB_{SNTHR}}{20}
\]

This threshold value is then compared to the current sound level (SDLVL).
If SADMOD[1:0] = 1x, THRH is obtained by multiplying the current ANMIN[12:0] by 4.

\[
\text{THR}_H = \text{ANMIN} \times 4
\]

This threshold value is then compared to:

\[
\frac{\text{ANLVL} \times 10^{\frac{\text{SNTHR}}{20}}}{G_{\text{dB}}}
\]

The hysteresis mode can be enabled to reduce the spurious transitions between MONITOR and DETECT states. In hysteresis mode (HYSTEN = 1), the following threshold values are used:

- THRH when the SAD is in MONITOR state.
- THRL when the SAD is in DETECT state.

The table below shows the thresholds values according to SNTHR.

<table>

</tbody>
</table>

1. LVL must be replaced by ANLVL when SADMOD[1:0] = 0 and by ANMIN for other SADMOD[1:0] values.

When the hysteresis function is disabled, the SAD always use THRH.

**Note:**  
*The hysteresis mode must not be used when SADMOD[1:0] = 1x.*

**Trigger logic**

The signal compared to this threshold depends also on SADMOD[1:0].

The trigger condition is reached when the selected signal (SELSIG) is bigger than the threshold level.

If the trigger condition is met, the following happens:

- The SAD switches to DETECT state.
- The SAD refreshes the hangover counter with HGOVR.
- The sddet_evt event is asserted if the SAD transits from MONITOR to DETECT.
• The adf_sad_det signal is set to high.

The SAD remains in DETECT state as long as the trigger condition is met or the hangover
down-counter is different from 0.

The sddet_evt event indicates when the SAD enters and/or exits the DETECT state. This
event is used to generate an interrupt when a sound is detected or when a sound is no
longer detected:
• When DETCFG = 0, the application receives an event only when the SAD enters the
DETECT state.
• When DETCFG = 1, the application receives an event when the SAD enters or exits the
DETECT state.

The adf_sad_det signal remains high as long as the SAD is in DETECT state.

The SAD also provides a flag indicating that a new sound level value is available (SDLVLF).
The last computed sound level (SDLVL[14:0]) is available in the ADF SAD sound level
register (ADF_SADSDLVR), and the last computed ambient noise level (ANLVL[14:0]), in
the ADF SAD ambient noise level register (ADF_SADANLVR).

Note: The SAD can work even when the AHB clock is not present. In that case, the SAD does not
update SDLVL[14:0] and ANLVL[14:0].

To get the latest valid SDLVL[14:0] and ANLVL[14:0] values, the application must read the
ADF_SADSDLVR, and ADF_SADANLVR registers, when the SDLVLF flag goes high. This
can be done in the following ways:
• by polling the SDLVLF flag:
  a) Clear the SDLVLF flag by writing SDLVLF to 1.
  b) Wait for SDLVLF = 1, by reading ADF_DFLTxISR.
  c) Read ADF_SADSDLVR and ADF_SADANLVR.
  d) Clear SDLVLF by writing it to 1.
  e) Go to step 2 if other values must to be read.
• by generating an interrupt:
  a) Read ADF_DFLTxISR.
  b) If SDLVLF = 1, read ADF_SADSDLVR and ADF_SADANLVR, and clear SDLVLF
     by writing it to 1.
  c) Handle other status flags and exit from ISR.

Sample transfer to memory

The SAD offers the following options to control the samples transfer from DFLT0 to the
system memory:
• If DATCAP[1:0] = 1x, the samples are transferred into the system memory as soon as
  DFLT0 and SAD are enabled. The transfer does not depend on the SAD state.
• If DATCAP[1:0] = 01, the samples are transferred into the system memory when the
  SAD detects a sound (when the SAD is in DETECT state), assuming that DFLT0 and
  SAD are enabled.
• If DATCAP[1:0] = 0, the samples are not transferred into the memory. This mode can
  be used if the application only wants to observe but does not need samples for other
  processing.
Note: DATCAP[1:0] is taken into account only when the SADEN = 1. For example, if the SAD configuration is DATCAP[1:0] = 0, SADEN = DFLTEN = 1, and if the application sets now SADEN to 0, the samples provided by the DFLT0 are transferred to the RXFIFO.

Programming recommendations

To make the SAD function working properly, the ADF must be programmed as follows:

1. Provide the proper kernel clock (adf_ker_ck) to the ADF.
2. Configure the CKGEN and enable it.
3. Configure the SITF and enable it (note that microphones have a settling time of several milliseconds).
4. Configure the DFLT0. A typical setting is the following:
   - CIC5 with a decimation ratio of 12, 16 or 24
   - RSFLT with a decimation ratio of 4
   - HPF with HPFC = 2 or 3
   For a very-low power implementation, the RSFLT can be bypassed.
5. Set SADEN to 0.
6. Wait for SADACTIVE = 0. If SADEN was previously enabled, this phase can take two periods of adf_hclk, and two periods of adf_proc_ck.
7. Configure the SAD as follows:
   - Set DATCAP[1:0] to 0, if the application does not want to store the samples into the system memory.
   - Set DATCAP[1:0] to 01, if the application wants to store the samples into the system memory only when the SAD detects a sound.
   - Set DATCAP[1:0] to 11, if the application wants to store the samples into the system memory continuously.
8. Configure the DMA (optional).
9. Enable the SAD.
10. Enable the DFLT0.

Figure 374 shows a simplified timing diagram when the SAD works with DATCAP[1:0] = 01.

Thanks to the kernel clock (adf_ker_ck), the SAD continuously monitors the audio signal provided by the DFLT0. The threshold is also continuously updated according to the ambient noise level estimation.

- When the SAD detects a sound higher than the programmed threshold (1), the ADF requests the bus clock (adf_bus_ckreq asserted).
- When the bus clock is available (see 2 in Figure 374) then:
  - The data transfer to the memory is triggered.
  - The event interrupt (adf_evt_it) can be generated.
- In this example, the event interrupt (adf_evt_it) is used to wake up the application. The interrupt line is released by clearing SDDETF by writing 1 to it.
- As long as the SAD remains in DETECT state, the application waits to get enough samples and calls, for example the keyword recognition algorithm (see 3 in Figure 374).
- In the case shown in the figure below, the SAD state (SADST) goes back to MONITOR before the keyword is recognized. If DETCFG is set to 1, an event signals when the SAD goes back to MONITOR state. The SAD stops the transfer of samples into the
memory and the application can clean up the receive buffer for the next detection (see 4 in Figure 374).

**Figure 321. SAD timing diagram example**

---

### 30.4.11 Data transfer to memory

#### Data format

The samples processed by DFLT0 are stored into a RXFIFO. The application can read the samples stored into these FIFOs via the ADF digital filter data register 0 (ADF_DFLT0DR). The samples inside this register are signed and left aligned. The bit 31 always represents the sign.

The ADF provides 24-bit left-aligned data. Performing a 16-bit access to ADF_DFLT0DR allows the application to get the 16 most significant bits. Performing a 32-bit access to ADF_DFLT0DR allows the application to get a 24-bit data size.

**Figure 322. ADF_DFLTxDR data format**
**Data re-synchronization**

The samples stored into the RXFIFO can be transferred into the memory by using either DMA requests or interrupt signaling.

*Note:* The RXFIFO is located into the adf_ker_ck clock domain, while ADF_DFLT0DR is located into the adf_hclk (AHB) clock domain.

When the AHB clock is available, if ADF_DFLT0DR is empty and if a sample is available into the RXFIFO, this sample is transferred into ADF_DFLT0DR.

The sample transfer from the RXFIFO to ADF_DFLT0DR takes two periods of the AHB clock (adf_hclk) and two periods of the adf_ker_ck clock. The ADF inserts automatically wait-states if the application performs a read operation of ADF_DFLT0DR while the transfer of the new sample from the RXFIFO to ADF_DFLT0DR is not yet completed.

**Data transfer**

The content of the RXFIFO can be transferred to the memory either by using a DMA channel or interrupt services.

Both single and burst, DMA transfers are supported by the ADF, but the application has to care about the following points:

- The RXFIFO must contain at least the same amount of samples than the burst size.
- The burst mode efficiency may be reduced due to the data re-synchronization explained in the previous section.

*Note:* The burst mode is not available in all products (see the DMA section to check if the product supports it).

In addition, the application can select the RXFIFO threshold (FTH bit) in order to trigger the data transfer: a data transfer can be triggered as soon as the RXFIFO is not empty, or when the RXFIFO is half-full (containing depth/2 samples).

For the DMA transfer, as soon as one of the RXFIFO reaches the threshold level, the DMA request is asserted in order to ask for data transfer. Successive DMA requests are performed as long as the RXFIFO is not empty.

The DMA mode of the RXFIFO is enabled via the DMAEN bit in ADF_DFLT0DR.

For the interrupt signaling, the following cases must be considered:

- If FTH = 0, as soon as a data is available in ADF_DFLT0DR, the FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as ADF_DFLT0DR is read.
- If FTH = 1, as soon as the RXFIFO reaches the threshold level and a data is available in ADF_DFLT0DR, the FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as one data is read. FTHF is set again if the threshold condition is
met again. In this mode, every time an interrupt occurs, the application is supposed to read FIFO_SIZE/2 data.

**RXFIFO overrun**

A RXFIFO overrun condition is detected when the RXFIFO is full, and a new sample from the DFLT0 must be written.

In this case, DOVRF is set and the new sample is dropped. When the RXFIFO has at least one location available, the new incoming sample is written into the RXFIFO.

*Figure 377* shows an example based on a RXFIFO depth of four words and FTH set to 1, so that FTHF goes to 1 when the RXFIFO is half-full.

The S7 sample is lost due to an overrun: the RXFIFO is full while S7 must be written into the RXFIFO. The S7 write operation is not performed. DOVRF is set to 1 at the moment where the write operation was expected. The overflow event remains to 1 as long as it is not cleared by the application.

In this example, DOVRIE is set to 1 to have an interrupt if an overrun condition is detected.

After the S7 sample, the application manages to read data from the RXFIFO, and the ADF can write the S8 sample and consecutive. Later, the application clears DOVR, allowing the detection of a new overrun situation.

In the adf_hclk line, the gray boxes indicate that the ADF requested the AHB clock. The figure below shows the AHB clock available only when the ADF requests it. In real applications, the AHB clock may also be present if the ADF does not request it.

*Figure 324. Example of overflow and transfer to memory*
30.4.12 Autonomous mode

The ADF can work even if the AHB bus clock is not available (Stop modes). The ADF uses the AHB clock only for the register interface. All the processing part is clocked with the kernel clock.

In Stop mode, the ADF receives a kernel clock if the following conditions are met:
- The ADF autonomous mode is enabled in the RCC.
- The selected kernel clock source is taken from an oscillator available in Stop mode.

In Stop mode, the ADF receives the AHB clock if the following conditions are met:
- The ADF autonomous mode is enabled in the RCC.
- The ADF requests the AHB clock in the following situations:
  - when the ADF must transfer data into memory via the DMA
    The data is directly transferred to the SRAM thanks to the DMA while the product remains in Stop mode. The AHB clock request is maintained until the DMA transfer is completed.
  - when the ADF needs to generate an interrupt
    An interrupt generally wakes up the device from Stop mode, as an action from the application is needed. Once the AHB clock is available, the interrupt is generated. The AHB clock request is maintained as long as an enabled interrupt flag is still active.

30.4.13 Register protection

The ADF embeds some hardware protection to prevent invalid situations. The table below shows the list of write-protected and unprotected fields.

<table>
<thead>
<tr>
<th>Registers</th>
<th>Unprotected fields</th>
<th>Write-protected fields</th>
<th>Write-protection condition</th>

<td>-</td>
<td>SKPDL[6:0]</td>
<td></td>
</tr>
</tbody>
</table>
All the ADF processing is performed in the adf_proc_ck clock domain. For that reason, enabling or disabling an ADF sub-block may take some time due to the re-synchronization between the AHB clock domain and the adf_proc_ck clock domain. XXXACTIVE flags are available to allow the application to check that the synchronization between the two clock domains is completed.

To change a write-protected bitfield, the application must follow this sequence:

1. Set the enable bit of the sub-block to 0.
2. Wait for corresponding flag XXXACTIVE = 0.
3. Modify the wanted fields.
4. Set the enable bit of the sub-block to 1.

Refer to the description of each sub-block for details.

### 30.5 ADF low-power modes

**Table 268. Effect of low-power modes on ADF**

<table>

</tr>
<tr>
<td>Standby</td>
<td>The ADF is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

1. Refer to Section 40.3: ADF implementation for details about Stop modes supported by the ADF.

### 30.6 ADF interrupts

To increase the CPU performance, the ADF offers an interrupt line (adf_flt0_it), sensitive to several events.

*Note:* The status flags are available even if the corresponding interrupt enable flag is not enabled.
The interrupt interface is controlled via the **ADF DFLT0 interrupt enable register (ADF_DFLT0IER)** and the **ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)**.

**Figure 325. ADF interrupt interface**

The table below shows which interrupt line is affected by which event, and how to clear and activate each interrupt/event.

30.7 ADF application information

30.7.1 ADF configuration examples for audio capture

Table 398 gives some examples of the ADF settings for the digital microphones, focusing on 16 and 48 kHz output data rate.

Configurations #1 and #2 are for very low-power use-cases and have a reduced signal-to-noise ratio. The user must also ensure that the selected digital microphone can work properly at 512 kHz. These configurations can be used for sound detection. The RSFLT is not used to reduce as much as possible the frequency of the kernel clock (adf_ker_ck).

Configurations #3, #4, #9, #10, #11 give signal-to-noise ratios around 115 dB, with an ideal microphone model, with a sinus signal of 997 Hz. Using the RSFLT allows a good control on the in-band ripple, and a good image rejection.

Configurations #7, #8, #10 give signal-to-noise ratio around 120 dB, with an ideal microphone model, using a sinus signal of 997 Hz.

30.7.3 Connection examples

*Figure 379* shows simple connection examples of the ADF to external sensors.

- **Picture on the left:** two digital microphones connected to the ADF
  
  In this connection, the amount of connections is optimized; DMIC1 and DMIC2 are sharing the same data line, and the same clock line. BSMX allows the application to connect the digital filter either to DMIC1 or to DMIC2. In this configuration when one of the microphone is used, the other is activated as well, as they share the same clock.

- **Picture in the center:** two digital microphones connected to the ADF
  
  In this connection, DMIC1 and DMIC2 are sharing the same data line, but have a dedicated clock line. BSMX allows the application to connect the filter either to DMIC1 or to DMIC2. When the application wants to use a microphone, it is possible to keep the other in low-power mode by forcing its clock line to 0 (CCKyEN = 0, CCKyDIR = 1).
Picture on the right: single sensor connected to the ADF

It is also possible to configure the CCK0 and CCK1 pins to input in order to connect sensors providing the clock.

**Figure 326. Sensor connection examples**

### 30.7.4 Global frequency response

*Figure 380* shows the global frequency response for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:
- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enabled with a cut-off frequency of 40 Hz

The figure below shows the theoretical frequency response using a CIC4 and a CIC5.

*Figure 327. Global frequency response*

*Figure 381* shows the in-band ripple for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:
- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enabled with a cut-off frequency of 20 Hz

The resulting in-band ripple is ± 0.41 dB for CIC5, and ± 0.45 dB for CIC4.

The -3 dB cut-off frequency is 7061 Hz.
30.7.5 Total ADF gain

This section details how to compute the signal level provided by the ADF according to the filter settings.

A signal level may be expressed in dBFS (decibel full scale). A 0 dBFS level is assigned to the maximum possible digital level. For example, a signal that reaches 50 % of the maximum level, has a −6 dBFS level (6 dB below full scale).

For example, for the ADF offering a final data width of 24 bits, a signal having an amplitude of $2 \times 10^6$ LSB has a level of:

$$20 \times \log_{10} \left( \frac{2 \times 10^6}{2^{24-1}} \right) = -12.45 \text{ dBFS}$$

In addition, the data size of a signal having an amplitude (Amp) expressed in LSB is given by:

$$DS = \left( \frac{\ln(Amp)}{\ln(2)} + 1 \right) \text{ bits}$$

One bit need to be added for negative values.

So a signal having an amplitude of $2 \times 10^6$ LSB, has a data size of 21.9 bits.

CIC gain

The CIC gain ($G_{\text{CIC}}$ and $G_{\text{dBCIC}}$) can be deduced from the following formula giving data size in bits ($DS_{\text{CIC}}$).

$$DS_{\text{CIC}} = (N \times \log_2(D1)) + DS_{\text{in}}$$

where $N$ represents the CIC order (selected by CICMOD[2:0]), and $D1$ is the decimation ratio (given by MCICD[8:0]).

$DS_{\text{in}}$ represents the data size (in bits) of the signal at CIC input.
Warning: DS\textsubscript{CIC} is very important for CIC filter. In order to work fine, DS\textsubscript{CIC} must not exceed 26 bits.

The CIC gain \( G\textsubscript{CIC} \) is given by:

\[ G\textsubscript{CIC} = (D1)^N \]

which gives in decibels:

\[ GdB\textsubscript{CIC} = 20 \times \log_{10}((D1)^N) \]

**Data size at SCALE output**

The data size at SCALE output (including the CIC gain), is a key information as the RSFLT starts to have some saturations, if the peak-to-peak signal amplitude at SCALE output is higher than 22 bits.

If the RSFLT is bypassed, then a peak-to-peak signal amplitude of 24 bits is accepted.

The signal amplitude at SCALE output is:

\[ Asout\textsubscript{SCALE} = D1^N \times \frac{GdB\textsubscript{SCALE}}{20} \times Asin\textsubscript{DFLT} \]

\( GdB\textsubscript{SCALE} \) represents the gain selected by SCALE[5:0], in dB.
\( Asout\textsubscript{SCALE} \) is the signal amplitude at SCALE output (in LSB), and \( Asin\textsubscript{DFLT} \) is the signal amplitude at CIC input (LSB).

\[ D\textsubscript{SCALE} = \frac{\ln(Asout\textsubscript{SCALE})}{\ln(2)} + 1 \]

The data size at SCALE output (\( D\textsubscript{SCALE} \)) is expressed in bits.

**RSFLT gain**

The RSFLT gain in the useful bandwidth is typically 9.5 dB, but due to ripple a margin of about \( \pm 0.41 \) dB must be considered.

\[ G\textsubscript{RSFLT} = \frac{9.5 dB}{20} = 0.298 \text{ typical} \]

*Note:* The HPF filter has a gain of 0 dB.

**SAD gain**

The SAD is using only the 16 MSB on the signal, as a consequence, from the SAD point of view, the truncation from 24 to 16 bits can be seen as an attenuation.
The figure below shows a simplified view of the filter path and gives, for each significant component, the expression of the bit growth and the gain.

**Figure 329. Simplified DFLT view with gain information**

The table below summarizes the final data size for different filter configurations.

**Table 273. Output signal levels**

**G_{\text{dB}}_{\text{SAD}} = -48.1 \text{dB}**

and

**G_{\text{SAD}} = 0.003906**

(1) The SAD is not always implemented (see the ADF implementation section for details.)
**Example using the main filter chain**

If the ADF filter is programmed as follows:
- The input signal is coming from a serial interface (DsinRSFLT = 1 bit).
- CIC order = 5 (N), with a decimation value of 24 (D1).
- SCALE[5:0] is set to -12 dB.
- RSFLT enabled, and the decimation by four is enabled.
- HPF is enabled.

Check first the data size at CIC output:

\[ DS_{CIC} = (5 \times \log_2(24)) + 1 \text{ bit} = 23.92 \text{ bits} \]

The size is lower than 26 bits, so the CIC works in good conditions.

The data size at CIC output is very close to 24 bits, so the SCALE must be adjusted in order to provide a 22-bit max signal to the RSFLT. An attenuation of 12 dB is needed.

Then the signal level provided to the RSFLT is:

\[ As_{in, SCALE} = 24^5 \times 10^{-12} \times 20^{-10} \times 1 = 2.10^6 \]

\[ DS_{SCALE} = \frac{\ln(2.10^6)}{\ln(2)} + 1 = 21.93 \text{ bits} \]

If a higher gain is used, the RSFLT may saturate the output signal for strong input signals.

At the end, the final signal amplitude is:

\[ As_{out, HPF} = 24^5 \times 10^{-12} \times 10^{-9.5} \times 10^{-10} \times 1 = 5.9711 \times 10^6 \]

\[ Ds_{out, HPF} = \frac{\ln(5.9711 \times 10^6)}{\ln(2)} + 1 \approx 23.51 \text{ bits} \]

or:

\[ SDB_{OUT} = 20 \times \log_{10} \left( \frac{2^{23.51}}{2^{24}} \right) = -2.84 \text{ dBFS} \]

**30.7.6 How to compute SAD thresholds**

The SAD does not compute the RMS value of the converted signal, but the average of the absolute values. As a consequence, the estimated level differs from the RMS value of the signal:
- For a sine signal having an RMS value of 1, the SAD computes a level of 0.9.
- For a white or pink noise signal having an RMS value of 1, the SAD computes a level of about 0.8.
Note: *FRSIZE*[2:0] has a big influence on the accuracy of the level estimation: big *FRSIZE*[2:0] values give better results.

**Threshold programming with SADMOD = 01**

Consider the case of a sound capture where the application wants to wake up the system when the captured sound is bigger than 63 dBSPL.

The sound capture can be performed with a digital microphone such as the MP45DT02.

The sensitivity of this microphone is typically -26 dBFS for an input signal of 94 dBSPL.

An acoustic signal at 63 dBSPL produces a digital signal of about:
- 26 dBFS - (94 - 63) = -57 dBFS.

- **SCALE value adjustment**
  For this example, the filter configuration is the following:
  - CIC5 with a decimation by 16
  - RSFLT enabled with a decimation by 4
  - HPF enabled
  A SCALE value of 3.5 dB is recommended for this configuration. As DFTL0 provides samples only used for a sound detection (samples not provided to the application), a bigger gain value can be applied: it increases the SAD accuracy and a saturation does not affect the SAD behavior (for example, a SCALE value of 15.6 dB).

- **Input signal amplitude**
  The input signal is -57 dBFS, corresponding to an amplitude
  \[A_{\text{in}} = 10^{-\frac{57}{20}} = 0.00141 \text{ LSB}\.\]

- **Signal level at SAD input**
  The total filter gain for the SAD is:

  \[G_{\text{SAD}} = 16^5 \times 10^{\frac{15.6}{20}} \times 10^{\frac{9.5}{20}} \times \frac{1}{256} = 73.68 \times 10^3 \text{ or 97.3 dB}\]

  The signal amplitude received by the SAD is:

  \[A_{\text{in,SAD}} = 0.00141 \times G_{\text{SAD}} \sim 104 \text{ LSB}\]

  The gain can be increased if the expected amplitude is too small. For the targeted application, 104 LSB is fine.

  If the input signal is expected to be a sine, the sound level for a signal amplitude of 104 LSB is:

  \[\text{SDLVL} = \frac{A_{\text{in,SAD}} \times \sqrt{2}}{2} \times 0.9 \sim 66 \text{ LSB}\]\n
  where 0.9 is the correction factor to apply with respect to the RMS value.
• Program the trigger value
ANMIN and SNTHR must be programmed to trigger the SAD when the input signal level reaches 66 LSB.

For SADMOD[1:0] = 01, the threshold value is given by:

\[
\text{THRH} = \text{ANMIN} \times \frac{\text{GdB}_{\text{SNTHR}}}{20}
\]

where GdB_{SNTHR} represents the decibel value selected by SNTHR[3:0].

When SNTHR[3:0] = 6 dB for example, this formula becomes:

\[
\text{THRH} = 2 \times \text{ANMIN}
\]

So \(\text{ANMIN} = \frac{\text{THRH}}{2} = \frac{66}{2} = 33 \text{ LSB}\).

In Figure 383, the trigger value (THRH in red) is fixed to 66 LSB. The input signal is at -65dBFS during 256 samples, then its value goes to -55 dB for 256 samples, and finally it is reduced to -60 dBFS.

The blue curve is showing the sound level estimation (SDLVL) versus time. Fluctuation on the estimated value can be observed due to windowing effect of FRSIZE samples.

The SAD DETECT state (when green signal is high) is maintained during four additional frames due to hangover function value.

In this example ANSLP = FRSIZE = 3 (64 samples), LFRNB = 0 (2 frames), HGOVR = 0 (4 frames), SNTHR = 1 (6 dB) and ANMIN = 33.

**Figure 330. SAD example working with SADMOD = 01**

**Threshold programming with SADMOD = 1x**

Consider the case of a sound capture where the application wants to wake up the system when the captured sound is bigger than 57 dBSPL.

The sound capture can be performed with a digital microphone such as the MP45DT02. The sensitivity of this microphone is typically -26 dBFS for an input signal of 94 dBSPL.
An acoustic signal at 57 dBSPL produces a digital signal of about:
- 26 dBFS - (94-63) = - 63 dBFS.

- Adjust SCALE value
  For this example, the filter configuration is the following:
  - CIC4 with a decimation by 48
  - RSFLT bypassed
  - HPF enabled

A SCALE value of 3.5 dB is recommended for this configuration. The samples provided by DFTL0 are only used for a sound detection, without providing the samples to the application, a bigger gain value can be provided: it increases the SAD accuracy and a saturation does not affect the SAD behavior (for example, a SCALE value of 24 dB).

- Input signal amplitude
  The input signal is - 63 dBFS, corresponding to an amplitude:
  \[ \text{Asin} = 10^{(-63/20)} = 0.000708 \text{ LSB}. \]
Signal level at SAD input
The total filter gain for the SAD is:

$$G_{\text{SAD}} = 48^4 \times 10^{24} \times 0.003906 \times 328.6 \times 10^3 = 328.6 \times 10^3 \text{ or } 110.3 \text{ dB}$$

The signal amplitude received by the SAD is:

$$A_{\text{in SAD}} = 0.000708 \times G_{\text{SAD}} \sim 232 \text{ LSB}$$

The gain can be increased if the expected amplitude is too small. 
If the input signal is expected to be a sine, the sound level for a signal amplitude of 232 LSB is:

$$\text{SDLVL} = \frac{A_{\text{in SAD}} \times \sqrt{2}}{2} \times 0.9 - 148 \text{ LSB}$$

where 0.9 is the correction factor to apply with respect to the RMS value.

**Note:** ANLVL converges to average of SDLVL values, with a long constant time. So SDLVL ~ ANLVL = 148 LSB for a constant input signal at 57 dBSPL.

Programming trigger value
For SADMOD = 1', the SAD compares the estimated ambient noise multiplied by the gain selected by SNTHR[3:0] to ANMIN[12:0] * 4. 
For simplification, SNTHR[3:0] is set to 1 (6 dB), meaning that ANLVL is multiplied by two. 
The SAD triggers if $2 \times \text{ANLVL} > \text{THRH}$. 
In this mode, 

$$\text{THRH} = 4 \times \text{ANMIN}$$

So the SAD triggers if:

$$\text{ANLVL} > 2 \times \text{ANMIN}$$

So ANMIN = 148 / 2 = 74 LSB

In **Figure 384**, the trigger value (THR in red) is fixed to 148 LSB. The input signal is at -75 dBFS during 512 samples, then its value goes to -62 dB for 11000 samples, and finally it is reduced to -70 dBFS. 
The blue curve shows the sound level estimation (SDLVL) versus time. The black curve shows the ambient noise estimation versus time, increasing or decreasing logarithmically. During the learning phase, it reaches the SDLVL value. 
In this example ANSLP = 6, FRSIZE = 3 (64 samples), LFRNB = 0 (2 frames),
HGOVR = 0 (4 frames), SNTHR = 1 (6 dB) and ANMIN = 74.

Figure 331. SAD example working with SADMOD = 1x

30.8  ADF registers

All the ADF registers must be accessed either in word (32-bit) or half-word (16-bit) formats.

30.8.1  ADF global control register (ADF_GCR)

Address offset: 0x000
Reset value: 0x0000 0000

Bits 31:1  Reserved, must be kept at reset value.

Bit 0  TRGO: Trigger output control

This bit is set by software and reset by hardware. It is used to start the acquisition of several filters synchronously. It is also used to synchronize several ADF together by controlling the adf_trgo signal.

0: Write 0 has no effect. Read 0 means that the trigger can be set again to 1.
1: Write 1 generates a positive pulse on the adf_trgo signal and triggers the acquisition on enabled filter having their ACQMOD[2:0] = 01x and selecting TRGO as trigger. Read 1 means that the trigger pulse is still active.
30.8.2 ADF clock generator control register (ADF_CKGCR)

Address offset: 0x004
Reset value: 0x0000 0000

This register is used to control the clock generator. The clock adf_proc_ck must be enabled before enabling other ADF parts.

Bits 19:16 **CCKDIV[3:0]**: Divider to control the ADF_CCK clock

This bitfield is set and reset by software. It is used to adjust the frequency of the ADF_CCK clock. The input clock of this divider is the clock provided to the SITF. More globally, the frequency of the ADF_CCK is given by the following formula:

\[ F_{ADF\_CCK} = \frac{F_{adf\_ker\_ck}}{(PROCDIV + 1) \times (CCKDIV + 1)} \]

This bitfield must not be changed if the filter is enabled (DFTEN = 1).

- 0000: The ADF_CCK clock is adf_proc_ck.
- 0001: The ADF_CCK clock is adf_proc_ck / 2.
- 0010: The ADF_CCK clock is adf_proc_ck / 3.
- ...
- 1111: The ADF_CCK clock is adf_proc_ck / 16.

*Note: This bitfield can be write-protected (see Section 40.4.13 for details).*

Bits 15:12 **TRGSRC[3:0]**: Digital filter trigger signal selection

This bitfield is set and cleared by software. It is used to select which external signals trigger the corresponding filter. This bitfield is not significant if the CKGMOD = 0.

- 0000: TRGO selected
- 0010: adf_trg1 selected
- Others: Reserved

*Note: This bitfield can be write-protected (see Section 40.4.13 for details).*

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: CKGEN trigger sensitivity selection

This bit is set and cleared by software. It is used to select the trigger sensitivity of the trigger signals. This bit is not significant if the CKGMOD = 0.

- 0: A rising edge event triggers the activation of CKGEN dividers.
- 1: A falling edge even triggers the activation of CKGEN dividers.

*Note: When the trigger source is TRGO, the sensitivity is forced to falling edge, thus TRGSENS value is not taken into account. This bit can be write-protected (see Section 40.4.13 for details).*

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CCK1DIR**: ADF_CCK1 direction

This bit is set and reset by software. It is used to control the direction of the ADF_CCK1 pin.

- 0: The ADF_CCK1 pin direction is in input.
- 1: The ADF_CCK1 pin direction is in output.

*Note: This bit can be write-protected (see Section 40.4.13 for details).*

Bit 5 **CCK0DIR**: ADF_CCK0 direction

This bit is set and reset by software. It is used to control the direction of the ADF_CCK0 pin.

- 0: The ADF_CCK0 pin direction is in input.
- 1: The ADF_CCK0 pin direction is in output.

*Note: This bit can be write-protected (see Section 40.4.13 for details).*

Bit 4 **CKGMOD**: Clock generator mode

This bit is set and reset by software. It is used to define the way the clock generator is enabled. This bit must not be changed if the filter is enabled (DFTEN = 1).

- 0: The kernel clock is provided to the dividers as soon as CKGDEN is set to 1.
- 1: The kernel clock is provided to the dividers when CKGDEN is set to 1 and the trigger condition met.

*Note: This bit can be write-protected (see Section 40.4.13 for details).*
Bit 3 Reserved, must be kept at reset value.

Bit 2 **CCK1EN**: ADF_CCK1 clock enable
This bit is set and reset by software. It is used to control the generation of the bitstream clock on the ADF_CCK1 pin.
- 0: Bitstream clock not generated
- 1: Bitstream clock generated on the ADF_CCK1 pin.

Bit 1 **CCK0EN**: ADF_CCK0 clock enable
This bit is set and reset by software. It is used to control the generation of the bitstream clock on the ADF_CCK0 pin.
- 0: Bitstream clock not generated
- 1: Bitstream clock generated on the ADF_CCK0 pin

Bit 0 **CKGDEN**: CKGEN dividers enable
This bit is set and reset by software. It is used to enable/disable the clock dividers of the CKGEN: PROCDIV and CCKDIV.
- 0: CKGEN dividers disabled
- 1: CKGEN dividers enabled

### 30.8.3 ADF serial interface control register 0 (ADF_SITF0CR)

Address offset: 0x080
Reset value: 0x0000 1F00

This register is used to control the serial interface SITF0.

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</th>

</table>

- **Bit 31 SITFACTIVE**: Serial interface active flag
  - This bit is set and cleared by hardware. It is used by the application to check if the serial interface is effectively enabled (active) or not. The protected fields of this function can only be updated when SITFACTIVE is set to 0 (see Section 40.4.13 for details).
  - The delay between a transition on SITFEN and a transition on SITFACTIVE is two periods of AHB clock and two periods of adf_proc_ck.
  - 0: The serial interface is not active, and can be configured if needed.
  - 1: The serial interface is active and protected fields cannot be configured.

- **Bits 30:13** Reserved, must be kept at reset value.

- **Bits 12:8 STH[4:0]**: Manchester symbol threshold/SPI threshold
  - This bitfield is set and cleared by software. It is used for Manchester mode to define the expected symbol threshold levels (see Manchester mode for details on computation).
  - In addition this bitfield is used to define the timeout value for the clock absence detection in Normal SPI mode. STH[4:0] values lower than four are invalid.
  - **Note:** This bitfield can be write-protected (see Section 40.4.13 for details).

- **Bits 7:6** Reserved, must be kept at reset value.
Bits 5:4 **SITFMOD[1:0]**: Serial interface type
   This bitfield is set and cleared by software. It is used to define the serial interface type.
   00: LF_MASTER SPI mode
   01: Normal SPI mode
   10: Manchester mode: rising edge = logic 0, falling edge = logic 1
   11: Manchester mode: rising edge = logic 1, falling edge = logic 0
   *Note:* This bitfield can be write-protected (see Section 40.4.13 for details).

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 **SCKSRC[1:0]**: Serial clock source
   This bitfield is set and cleared by software. It is used to select the clock source of the serial interface.
   00: Serial clock source is ADF_CCK0.
   01: Serial clock source is ADF_CCK1.
   others: reserved
   *Note:* This bitfield can be write-protected (see Section 40.4.13 for details).

Bit 0 **SITFEN**: Serial interface enable
   This bit is set and cleared by software. It is used to enable/disable the serial interface.
   0: Serial interface disabled
   1: Serial interface enabled

### 30.8.4 ADF bitstream matrix control register 0 (ADF_BSMX0CR)

Address offset: 0x084
Reset value: 0x0000 0000

This register is used to select the bitstream to be provided to DFLT0.

<table>
<thead>
<tr>
<th>BSMXACTIVE</th>
<th>BSSEL[4:0]</th>

Bit 31 **BSMXACTIVE**: BSMX active flag
   This bit is set and cleared by hardware. It is used by the application to check if the BSMX is effectively enabled (active) or not. BSSEL[4:0] can only be updated when BSMXACTIVE is set to 0. This BSMXACTIVE flag cannot go to 0 if DFLT0 is enabled.
   0: BSMX is not active and can be configured if needed.
   1: BSMX is active and protected fields cannot be configured.

Bits 30:5 Reserved, must be kept at reset value.

Bits 4:0 **BSSEL[4:0]**: Bitstream selection
   This bitfield is set and cleared by software. It is used to select the bitstream to be processed for DFLT0.
   00000: bs0_r provided to DFLT0
   00001: bs0_f provided to DFLT0
   others: reserved
   *Note:* This bitfield can be write-protected (see Section 40.4.13 for details).

Bit 31 DFLTACTIVE: DFLT0 active flag
This bit is set and cleared by hardware. It indicates if DFLT0 is active: can be running or waiting for events.
0: DFLT0 not active (can be re-enabled again, via DFLTEN bit, if needed)
1: DFLT0 active

Bit 30 DFLTRUN: DFLT0 run status flag
This bit is set and cleared by hardware. It indicates if DFLT0 is running or not.
0: DFLT0 not running and ready to accept a new trigger event
1: DFLT0 running

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:20 NBDIS[7:0]: Number of samples to be discarded
This bitfield is set and cleared by software. It is used to define the number of samples to be discarded every time DFLT0 is re-started.
0: No sample discarded
1: 1 sample discarded
2: 2 samples discarded
...
255: 255 samples discarded

Note: This bitfield can be write-protected (see Section 40.4.13 for details).

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:12 TRGSRC[3:0]: DFLT0 trigger signal selection
This bitfield is set and cleared by software. It is used to select which external signals trigger DFLT0.
0000: TRGO selected
0010: adf_trgi selected
Others: Reserved

Note: This bitfield can be write-protected (see Section 40.4.13 for details).

Bits 11:9 Reserved, must be kept at reset value.
Bit 8 **TRGSENS**: DFLT0 trigger sensitivity selection
This bitfield is set and cleared by software. It is used to select the trigger sensitivity of the external signals:
- 0: A rising edge event triggers the acquisition.
- 1: A falling edge event triggers the acquisition.

*Note: When the trigger source is TRGO, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge. This bit can be write-protected (see Section 40.4.13 for details).*

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ACQMOD[2:0]**: DFLT0 trigger mode
This bitfield is set and cleared by software. It is used to select the filter trigger mode:
- 000: Asynchronous continuous acquisition mode
- 001: Asynchronous single-shot acquisition mode
- 010: Synchronous continuous acquisition mode
- 011: Synchronous single-shot acquisition mode
- 100: Window continuous acquisition mode
- Others: Same as 000

*Note: This bitfield can be write-protected (see Section 40.4.13 for details).*

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FTH**: RXFIFO threshold selection
This bit is set and cleared by software. It is used to select the RXFIFO threshold:
- 0: RXFIFO threshold event generated when the RXFIFO is not empty
- 1: RXFIFO threshold event generated when the RXFIFO is half-full

*Note: This bit can be write-protected (see Section 40.4.13 for details).*

Bit 1 **DMAEN**: DMA requests enable
This bit is set and cleared by software. It is used to control the generation of DMA request to transfer the processed samples into the memory:
- 0: DMA interface for the corresponding digital filter disabled
- 1: DMA interface for the corresponding digital filter enabled

*Note: This bit can be write-protected (see Section 40.4.13 for details).*

Bit 0 **DFLTEN**: DFLT0 enable
This bit is set and cleared by software. It is used to control the start of acquisition of the DFLT0 path. This bit behavior depends on ACQMOD[2:0] and external events. The serial or parallel interface delivering the samples must be enabled as well:
- 0: Acquisition immediately stopped
- 1: Acquisition immediately started if ACQMOD[2:0] = 00x or 101, or acquisition started when the proper trigger event occurs if ACQMOD[2:0] = 01x.
30.8.6 ADF digital filter configuration register 0 (ADF_DFLT0CICR)

Address offset: 0x08C
Reset value: 0x0000 0000

This register is used to control the main CIC filter.

<table>

**SCALE[5:0]**: This bitfield is set and cleared by software. It is used to select the gain to be applied at CIC output (see Table 389 for details). If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back this bitfield informs the application on the current gain value.

- 000000: 0 dB
- 000001: + 3.5 dB
- 000010: + 6 dB or shift left by 1 bit
- ...
- 011000: + 72 dB or shift left by 12 bits
- 100000: - 48.2 dB or shift right by 8 bits (default value)
- 100001: - 44.6 dB
- 100010: - 42.1 dB or shift right by 7 bits
- 100011: - 38.6 dB
- ...
- 101110: -6 dB or shift right by 1 bit
- 101111: -2.5 dB
- Others: Reserved

**MCICD[8:0]**: This bitfield is set and cleared by software. It is used to select the CIC decimation ratio. A decimation ratio smaller than two is not allowed. The decimation ratio is given by (CICDEC+1).

- 0: Decimation ratio is 2.
- 1: Decimation ratio is 2.
- 2: Decimation ratio is 3.
- 3: Decimation ratio is 4.
- ...
- 511: Decimation ratio is 512.

Note: This bitfield can be write-protected (see Section 40.4.13 for details).

Bit 7 Reserved, must be kept at reset value.
Bits 6:4 **CICMOD[2:0]**: Select the CIC order

This bitfield is set and cleared by software. It is used to select the order of the MCIC.

- 100: MCIC configured in single Sinc^4 filter
- 101: MCIC configured in single Sinc^5 filter
- Others: Reserved

*Note: This bitfield can be write-protected (see Section 40.4.13 for details).*

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **DATSRC[1:0]**: Source data for the digital filter

This bitfield is set and cleared by software.

- 00: Stream coming from the BSMX selected
- 10: Stream coming from the ADCITF1 selected
- 11: Stream coming from the ADCITF2 selected

*Note: This bitfield can be write-protected (see Section 40.4.13 for details).*

### 30.8.7 ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)

**Address offset:** 0x090

**Reset value:** 0x0000 0000

This register is used to control the reshape and HPF filter.

**Bits 31:10** Reserved, must be kept at reset value.

**Bits 9:8** **HPFC[1:0]**: High-pass filter cut-off frequency

This bitfield is set and cleared by software. It is used to select the cut-off frequency of the high-pass filter. $F_{PCM}$ represents the sampling frequency at HPF input.

- 00: Cut-off frequency $= 0.000625 \times F_{PCM}$
- 01: Cut-off frequency $= 0.00125 \times F_{PCM}$
- 10: Cut-off frequency $= 0.00250 \times F_{PCM}$
- 11: Cut-off frequency $= 0.00950 \times F_{PCM}$

*Note: This bitfield can be write-protected (see Section 40.4.13 for details).*

**Bit 7** **HPFBYP**: High-pass filter bypass

This bit is set and cleared by software. It is used to bypass the high-pass filter.

- 0: HPF not bypassed (default value)
- 1: HPF bypassed

*Note: This bit can be write-protected (see Section 40.4.13 for details).*

**Bits 6:5** Reserved, must be kept at reset value.
Bit 4 RSFLTD: Reshaper filter decimation ratio
This bit is set and cleared by software. It is used to select the decimation ratio for the reshape
filter
0: Decimation ratio is 4 (default value).
1: Decimation ratio is 1.
*Note:* This bit can be write-protected (see Section 40.4.13 for details).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 RSFLTBYP: Reshaper filter bypass
This bit is set and cleared by software. It is used to bypass the reshape filter and its
decimation block.
0: Reshape filter not bypassed (default value)
1: Reshape filter bypassed
*Note:* This bit can be write-protected (see Section 40.4.13 for details).

30.8.8 ADF delay control register 0 (ADF_DLY0CR)

Address offset: 0x0A4
Reset value: 0x0000 0000

This register is used for the adjustment stream delays.

Bit 31 SKPBF: Skip busy flag
This bit is set and cleared by hardware. It is used to control if the delay sequence is
completed.
0: ADF ready to accept a new value into SKPDLY[6:0]
1: Last valid SKPDLY[6:0] still under precessing

Bits 30:7 Reserved, must be kept at reset value.

Bits 6:0 SKPDLY[6:0]: Delay to apply to a bitstream
This bitfield is set and cleared by software. It defines the number of input samples that are
skipped. Skipping is applied immediately after writing to this bitfield, if SKPBF = 0 and
DFLTEN = 1. If SKPBF = 1, the value written into the register is ignored by the delay state
machine.
0: No input sample skipped
1: 1 input sample skipped
...
127: 127 input samples skipped
30.8.9  **ADF DFLT0 interrupt enable register (ADF_DFLT0IER)**

Address offset: 0x0AC

Reset value: 0x0000 0000

This register is used for allowing or not the events to generate an interrupt.

Bits 31:14  Reserved, must be kept at reset value.

- **Bit 13 SDLVLIE**: SAD sound-level value ready enable
  This bit is set and cleared by software.
  0: Sound-level-ready interrupt disabled
  1: Sound-level-ready interrupt enabled

- **Bit 12 SDDETIE**: Sound activity detection interrupt enable
  This bit is set and cleared by software.
  0: Sound-trigger interrupt disabled
  1: Sound-trigger interrupt enabled

- **Bit 11 RFOVRIE**: Reshape filter overrun interrupt enable
  This bit is set and cleared by software.
  0: Reshape filter overrun interrupt disabled
  1: Reshape filter overrun interrupt enabled

- **Bit 10 CKABIE**: Clock absence detection interrupt enable
  This bit is set and cleared by software.
  0: Clock absence interrupt disabled
  1: Clock absence interrupt enabled

- **Bit 9 SATIE**: Saturation detection interrupt enable
  This bit is set and cleared by software.
  0: Saturation interrupt disabled
  1: Saturation interrupt enabled

Bits 8:2  Reserved, must be kept at reset value.

- **Bit 1 DOVRIE**: Data overflow interrupt enable
  This bit is set and cleared by software.
  0: Data overflow interrupt disabled
  1: Data overflow interrupt enabled

- **Bit 0 FTHIE**: RXFIFO threshold interrupt enable
  This bit is set and cleared by software.
  0: RXFIFO threshold interrupt disabled
  1: RXFIFO threshold interrupt enabled
30.8.10 ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)

Address offset: 0x0B0
Reset value: 0x0000 0000

This register contains the status flags for the digital filter path.

</tbody>
</table>

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **SDLVL**: Sound level value ready flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that new sound level value is not ready. Write 0 has no effect.
1: Read 1 means that new sound level value is ready. Write 1 clears this flag.

Bit 12 **SDDETF**: Sound activity detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no sound activity is detected. Write 0 has no effect.
1: Read 1 means that sound activity is detected. Write 1 clears this flag.

Bit 11 **RFOVRF**: Reshape filter overrun detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no reshape filter overrun is detected. Write 0 has no effect.
1: Read 1 means that reshape filter overrun is detected. Write 1 clears this flag.

Bit 10 **CKABF**: Clock absence detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no clock absence is detected. Write 0 has no effect.
1: Read 1 means that a clock absence is detected. Write 1 clears this flag.

Bit 9 **SATF**: Saturation detection flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no saturation is detected. Write 0 has no effect.
1: Read 1 means that a saturation is detected. Write 1 clears this flag.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **RXNEF**: RXFIFO not empty flag
This bit is set and cleared by hardware according to the RXFIFO level.
0: RXFIFO empty
1: RXFIFO not empty

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DOVRF**: Data overflow flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no overflow is detected. Write 0 has no effect.
1: Read 1 means that an overflow is detected; Write 1 clears this flag.
Bit 0 **FTHF**: RXFIFO threshold flag
This bit is set by hardware, and cleared by the hardware when the RXFIFO level is lower than
the threshold.
0: RXFIFO threshold not reached
1: RXFIFO threshold reached

### 30.8.11 ADF SAD control register (ADF_SADCR)

Address offset: 0x0B8
Reset value: 0x0000 0000

This register is used for the configuration and the control of the sound activity detection.

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>SADACTIVE: SAD Active flag</th>
</tr>
</thead>
<tbody>
<tr>
<td>30:14</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>13:12</td>
<td>SADMOD[1:0]: SAD working mode</td>
</tr>
<tr>
<td>11</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>

Note: This bitfield can be write-protected (see Section 40.4.13 for details).
Bits 10:8  FRSIZE[2:0]: Frame size
  This bitfield is set and cleared by software. It is used to define the size of one frame and also
to define how many samples are taken into account to compute the short-term signal level.
  000: 8 PCM samples used to compute the short-term signal level
  001: 16 PCM samples used to compute the short-term signal level
  010: 32 PCM samples used to compute the short-term signal level
  011: 64 PCM samples used to compute the short-term signal level
  100: 128 PCM samples used to compute the short-term signal level
  101: 256 PCM samples used to compute the short-term signal level
  11x: 512 PCM samples used to compute the short-term signal level
  Note: This bitfield can be write-protected (see Section 40.4.13 for details).

Bit 7  HYSTEN: Hysteresis enable
  This bit is set and cleared by software. It is used to enable/disable the hysteresis function
  (see Table 389 for details). This bit must be kept to 0 when SADMOD[1:0] = 1x.
  0: Hysteresis function disabled. THR_H is always used.
  1: Hysteresis function enabled. THR_H is used for MONITOR to DETECT transition and THR_L
      is used for DETECT to MONITOR transition.
  Note: This bit can be write-protected (see Section 40.4.13 for details).

Bit 6  Reserved, must be kept at reset value.

Bits 5:4  SADST[1:0]: SAD state
  This bitfield is set and cleared by hardware. It indicates the SAD state and is meaningful only
  when SADEN = 1. The SAD state can be:
    - LEARN when the SAD is in learning phase or in SDLVL computation mode
    - MONITOR when the SAD is in monitoring phase
    - DETECT when the SAD detects a sound
  00: SAD in LEARN state
  01: SAD in MONITOR state
  11: SAD in DETECT state

Bit 3  DETCFG: Sound trigger event configuration
  This bit is set and cleared by software. It is used to define if the sddet_evt event is generated
  only when the SAD enters to MONITOR state or when the SAD enters or exits the DETECT state.
  0: sddet_evt generated when SAD enters the MONITOR state
  1: sddet_evt generated when SAD enters or exits the DETECT state
  Note: This bit can be write-protected (see Section 40.4.13 for details).

Bits 2:1  DATCAP[1:0]: Data capture mode
  This bitfield is set and cleared by software. It is used to define in which conditions, the
  samples provided by DLFT0 are stored into the memory.
  00: Samples from DFLT0 not transfered into the memory
  01: Samples from DFLT0 transfered into the memory when SAD is in DETECT state
  1x: Samples from DFLT0 transfered into memory when SAD and DFLT0 are enabled
  Note: This bitfield can be write-protected (see Section 40.4.13 for details).

Bit 0  SADEN: Sound activity detector enable
  This bit is set and cleared by software. It is used to enable/disable the SAD.
  0: SAD disabled and SAD state reset
  1: SAD enabled
30.8.12 ADF SAD configuration register (ADF_SADCFGR)

Address offset: 0x0BC
Reset value: 0x0000 0000

This register is used for the configuration of the sound activity detection.

<table>

</table>

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **ANMIN[12:0]**: Minimum noise level

This bitfield is set and cleared by software. It is used to define the minimum noise level and then the sensitivity. It represents a positive number.

*Note:* This bitfield can be write-protected (see Section 40.4.13 for details).

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **HGOVR[2:0]**: Hangover time window

This bitfield is set and cleared by software. Once the SAD state is DETECT, this parameter is used to define the amount of time the sound is allowed to remain below the threshold, before switching the SAD to MONITOR state (see FRSIZE bitfield for the description of a frame).

000: SAD back to MONITOR state if sound is below threshold for 4 frames
001: SAD back to MONITOR state if sound is below threshold for 8 frames
010: SAD back to MONITOR state if sound is below threshold for 16 frames
011: SAD back to MONITOR state if sound is below threshold for 32 frames
100: SAD back to MONITOR state if sound is below threshold for 64 frames
101: SAD back to MONITOR state if sound is below threshold for 128 frames
110: SAD back to MONITOR state if sound is below threshold for 256 frames
111: SAD back to MONITOR state if sound is below threshold for 512 frames

*Note:* This bitfield can be write-protected (see Section 40.4.13 for details).

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **LFRNB[2:0]**: Number of learning frames

This bitfield is set and cleared by software. It is used to define the number of learning frames to perform the first estimate of the noise level.

000: 2 frames used to compute the initial noise level
001: 4 frames used to compute the initial noise level
010: 8 frames used to compute the initial noise level
011: 16 frames used to compute the initial noise level
1xx: 32 frames used to compute the initial noise level

*Note:* This bitfield can be write-protected (see Section 40.4.13 for details).

Bit 7 Reserved, must be kept at reset value.
30.8.13  ADF SAD sound level register (ADF_SADSDLVR)

Address offset: 0x0C0

Reset value: 0x0000 0000

This register contains the short-term sound-level computed by the SAD.

Bits 31:15  Reserved, must be kept at reset value.

Bits 14:0  SDLVL[14:0]: Short term sound level

This bitfield is set by hardware. It contains the latest sound level computed by the SAD. To refresh this value, SDLVLF must be cleared.
30.8.14  ADF SAD ambient noise level register (ADF_SADANLVR)

Address offset: 0x0C4
Reset value: 0x0000 0000

This register contains the ambient noise level computed by the SAD.

Bits 31:15  Reserved, must be kept at reset value.

Bits 14:0  ANLVL[14:0]: Ambient noise level estimation

This bitfield is set by hardware. It contains the latest ambient noise level computed by the SAD. To refresh this bitfield, the SDLVLF flag must be cleared.

30.8.15  ADF digital filter data register 0 (ADF_DFLT0DR)

Address offset: 0x0F0
Reset value: 0x0000 0000

This register is used to read the data processed by the digital filter.

Refer to Section 2.3 for the register boundary addresses.
31  Digital camera interface pixel pipeline (DCMIPP)

31.1  Introduction

The DCMIPP is the pixel pipeline section of a high-resolution camera subsystem: it gets pixels from a parallel interface, and after some processing (such as decimation, cropping) dumps them to the memory.

DCMIPP supports multiple types of external sensors, among others:
- dumb sensors (without internal ISP), which output raw Bayer pixels
- smart sensors (with an internal ISP), which usually output RGB or YUV pixels
- smart sensors with internal compression, which output a bit-stream (such as JPEG, or H264)

The DCMIPP input interface integrates a parallel interface (up to 16 bits at 120 MHz, with internal/external synchronization).

A first common part of the DCMIPP selects the input exclusively from the parallel interface. Data go to dedicated pipeline(s) before they are sent to memory for further processing or display purposes.

31.2 DCMIPP main features

- Parallel input interface:
  - Pixel rate: up to 16 bits in parallel, 100 Mpixel/s (typically 1080p30, maximum 2048x2048 on processing pipelines after decimation).
  - Pixel format: RGB565, RGB888, YUV422, raw Bayer/Mono 8/10/12/14, and ByteStream (JPEG)

- Pipeline maximum resolution:
  - Dimensioned for 5 Mpixel (typically 2560 x 2048 or 2688 x 1944) before decimation
  - Maximum pipe resolution: 4094 x 4094

- Maximum frame per second (fps): typical examples are defined with 30 fps, it is possible to reach higher rates (for example 120 fps) by decreasing image resolution to guarantee the maximum pixel rate constraints.

- Flow selection and frame control:
  - Capture mode in Continuous vs. Snapshot mode

- Decimation on Pipe0 (dump pipe)
  - Pure sub-sampling, ratio 1 vs. 1, 2, 4 in X and ratio 1 vs. 1, 2 in Y

- Parallel pipelines for parallel applications:
  - Pipe0 (for data dump) for a direct dump without processing

- Single Pipe0 (for data dump) for a direct dump from the camera to the memory (with only few operations like crop and basic decimation).

- Output pixel format:
  - Pipe0: any data as-is, Y/Rb: 8/10/12/14 statistics, bit streams

- AXI master:
  - Output FIFOs to drain pixel/data to the memory (linked to the memory latency) from the pipe(s)
  - The unique AXI-Master interface implements one client per pipe
  - Double buffer mode capability per pipe

- Overrun detection:
  - Notification in case of frame impacted by pixel congestion (no impact on the following frame if the congestion cause is solved)

### 31.3.3 DCMIPP reset and clocks
Clocks and pixel rate limitations

This paragraph lists the DCMIPP limitations and bottlenecks:

- **The target is to sustain an average pixel rate (PixRateAvg):**
  - A 5 Mpixel sensor at 15 fps requires 75 Mpixel/s

- **Vertical and horizontal blanking:**
  - The full system (sensor, interface, pipe, AXI) embeds limited capacity FIFOs. The idle times that the sensor inserts during its blanking periods impact all the downstream elements, including interface, pipe, and AXI. A pixel rate (PixRatePeak) higher than average must be used. The idle time due to the blanking can reach 33% of the frame duration, sometimes more (check sensor specification).
    - PixRatePeak = 1.33 * PixRateAvg

- **Parallel interface clock (dcmipp_pxclk):**
  - On the parallel interface, pixels are received sequentially, in one, two or three cycles. The maximum implemented clock (120 MHz) constrains the peak pixel rate, depending on the ratio of cycles per pixel.
    - PixRatePeak ≤ dcmipp_pxclk / (1, 2 or 3) = 120 / (1, 2 or 3)
    - Clock frequency:
      - > dcmipp_pxclk ≤ dcmipp_aclk
    - Consequences: see Table 281.

</tr>
</tbody>
</table>

- Clock setting: dcmipp_pxclk ≥ PixRatePeak * Ratio(1,2,3)
31.3.4  DCMIPP maximum resolution

The limitations related to the maximum resolution supported by the DCMIPP are:

- Maximum width and height across pipes: 4094 x 4094 pixels
  - Registers and counters are limited to 12 bits
- Maximum performance: 266 Mpixel/s
  - Larger pixel rate can be used, but with lower memory latency
  - Maximum pixel rate on each pipe must remain below the pixel clock
- Max line stride: 32767 bytes
  - Registers and counters, to handle 4094 pixels x 32 bits x 2 (provision for interleaving)

31.3.5  DCMIPP minimum requirements for frame structure

DCMIPP imposes the following minimum requirements for the frame architecture:

**Blanking phase**

- Dump pipe
  - The minimal duration of the blanking between two frames must be an equivalent of 666 datawords of 32 bits

**Data image area**

- Vertical image area: minimum one line
- Horizontal image area: minimum two pixels
- The minimum total frame size is fixed to 36 pixels

31.3.6  Description of DCMIPP pixel format support

*Table 282* lists the supported pixel formats in the input interfaces (parallel interface), and in the output Pipe0.

<table>

</tbody>
</table>

(1) Index in the table corresponds to the pixel format in the input interfaces.
(2) BPP indicates the number of bits per pixel.
(3) JPEG: Joint Photographic Experts Group
(4) Other data: can include 8 to 16 bits
(5) Y indicates a register that can be disabled.
31.4 DCMIPP input and flow control

This section describes the functional elements of the DCMIPP. For each, it details the features, the software configuration, and provides a software configuration example (when needed).

31.4.1 Parallel input interface

The parallel interface is a flexible pixel interface that clocks in a bus of 8- to 16-bit in parallel, with an externally provided clock, and adds vertical and horizontal synchronization, provided either with specific pins (external sync) or flagged via specific data (as in CCIR601).

Interface (all inputs)

- **Clk**: clock up to 120 MHz, internally named dcmipp_pxclk
- **Data**: 16 IO pins, up to 120 Mbps/pin, 8- to 16-bit, pixels potentially serialized
- **HSync, VSync**, but no enable (EN)
Features

- Horizontal and vertical synchronization:
  - External, via the HSync and VSync pins.
  - Internal, via the CCIR601 flagging.
  
Data provided during the horizontal or vertical blanking cannot be captured.

- Input pixel format (see Section 31.3.6)
  - Binary stream like JPG
  - Single cycle data:
    - Raw Bayer and monochrome: 8/10/12/14 bits in parallel
    - YUV422, RGB565:16 bpp on 16 bits in parallel
  - Double-cycle data:
    - YUV422, RGB565:16 bpp on 8 bits in parallel
    - RGB888/YUV444: 24 bpp on 12 bits in parallel
  - Triple-cycle data:
    - RGB888/YUV444: 24 bpp on 8 bits in parallel

- Flexible input:
  - MSB-vs-LSB bits can be swapped to ease PCB placement
  - Cycle0-vs-Cycle1 can be swapped (for 2-cycle long pixels).

Hardware synchronization mode

In this mode two synchronization signals (DCMIPP_HSYNC and DCMIPP_VSYNC) are used.

Depending on the camera module/mode, data can be transmitted during horizontal/vertical synchronization periods. DCMIPP_HSYNC/DCMIPP_VSYNC act as blanking signals, as all data received during DCMIPP_HSYNC/DCMIPP_VSYNC active periods are ignored.

To correctly transfer images in the RAM buffer, data transfer is synchronized with the DCMIPP_HSYNC/DCMIPP_VSYNC signals. When the hardware synchronization mode is selected, and capture is enabled (CPTREQ bit set in DCMIPP_PxFCTCR), data transfer is synchronized with the deassertion of the DCMIPP_VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by the IP-Plug to successive buffers or the same/circular buffer.

Embedded data synchronization mode

In this synchronization mode, the data flow is synchronized using embedded 32-bit codes, using the 0x00/0xFF values not used in data anymore. There are four types of codes, all with 0xFF00 00XY format. The embedded synchronization codes are supported only in 8-bit parallel data capture (in the DCMIPP_PRCR register, the EDM[2:0] bits must be programmed to “000”). For other data widths, this mode generates unpredictable results.

Note: Camera modules generate up to eight synchronization codes when in interleaved mode, while the DCMIPP reacts to one single code. As a consequence, an interleaved flow with an embedded synchronization has one every other frame discarded as not detected.
**Mode 2**

Four embedded codes signal the following events:
- Frame start (FS)
- Frame end (FE)
- Line start (LS)
- Line end (LE)

The XY values in the 0xFF00 00XY format of these codes are programmable (see Section 31.10.9). A 0xFF value programmed as a frame end means that all the unused codes are interpreted as valid frame end codes.

In this mode, once the camera interface has been enabled, the frame capture starts after the first occurrence of the frame end (FE) code followed by a frame start (FS) code.

**Mode 1**

An alternative coding is the camera mode 1. This mode is ITU656 compatible.

The codes signal another set of events:
- SAV (active line) - Line start
- EAV (active line) - Line end
- SAV (blanking) - Start of line during interframe blanking period
- EAV (blanking) - End of line during interframe blanking period

This mode can be supported by programming the following codes:
- FS ≤ 0xFF
- FE ≤ 0xFF
- LS ≤ SAV (active)
- LE ≤ EAV (active)

An embedded unmask code is also implemented for frame/line start and frame/line end codes. Using it, it is possible to compare only the selected unmasked bits with the programmed code. User can therefore select a bit to compare in the embedded code and detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

Example:
- FS = 0xA5
- Unmask code for FS = 0x10

In this case the frame start code is embedded in bit 4 of the frame start code.

*Note:* **FEC sequence must be sent before the transfer of the first frame, otherwise other codes are not decoded and the first frame can be lost after the DCMIPP has been enabled. After the first FE sequence, the following frame is captured based on FS sequence.**

**Error conditions**

Error conditions can be detected when using the embedding synchronization data modes. Flags PRERRF in DCMIPP_CMSR2 and ERRF in DCMIPP_PRSR are used for this function. An interruption can be triggered based on error detection if bit PRERRIE in
DCMIPP_CMIER is set for the global interrupt (or bit ERRIE in DCMIPP_PRIER for a local interrupt line).

For instance, such kind of wrong sequences or values generate an error:
- FF 00 00 XY sequence detected with XY value different from the one set for FS/LS/FE/LE
- LS = 0xFF or LE = 0xFF
- If an LS or FS sequence follows an LS sequence

**Software configuration**

<td>Masks for FSC and FEC codes</td>
</tr>
</tbody>
</table>
Sequence of swap operations

The sequence of the SWAP operators on bits, cycles and RB (red vs. blue) is induced by their functionality:

- the swap on bits (MSB vs. LSB on IOs) occurs first, as operating on the IOs
- the swap on cycles occurs afterwards, as it operates on words already sampled by still raw

31.4.2 Frame counter

A frame counter is available for a tag purpose and counts all the frame received on the selected pipe.

The counter is 32-bit, read-only. It is active at least when bit PIPEN of the pipe is enabled (PIPEN = 1).

It provides an (almost) unique frame number, with a loop time of 4.5 years (if 30 fps).

The counter can be incremented at the FrameStart event of the pipe when the camera sensor module is connected with parallel interface.

The frame counter is cleared by setting CFC in the DCMIPP_CMCR register.

Software configuration

The frame counter must be configured before it is used for the pipe. Software action(s) must be performed in the DCMIPP_CMCR register:

- Frame counter runs as soon as the selected pipe is active (PIPEN = 1)

Note: It is possible to have the Frame counter run on a pipe, while having the pipe not flowing any pixel: this is achieved with pipe enable active (PIPEN = 1) to have the frame counter run, but with CPTREQ = 0 to avoid any pixel flow.

31.4.3 Frame control

The module is replicated for the dump pipe. It handles the frame control and the capture of the pipe, grouping data into frames, and capturing them when requested.
Definitions

There are two notions of frame events

- Event used inside the hardware (provided by the input interfaces):
  - FrameStart: when a frame starts at the input of the pipe (at frame control)
    > Parallel interface with VSync fall
  - FrameEnd: when a frame finishes at the input of pipes (at frame control)
    > Parallel interface: VSync rise (End-of-Frame)

- Events exposed to software via DCMIPP events and interrupts:
  - VSYNC
    > When a frame starts, observed at the input of the pipe (at frame control)
    > It indicates that the current frame has started and has sampled its shadow registers, and that the software can start to configure the next frame
    > It is recommended to use that interrupt to trigger the software that reconfigures the DCMIPP.
  - FRAME END
    > When a frame finishes, observed at the output of pipe (when the last pixel has been written on the AXI)
    > It indicates that the current frame has finished writing all its data to memory, and that the application can immediately start using them
    > It is recommended to use that interrupt to trigger the software that forwards the memory buffer to other applications

Features

- Frame delineation: allows to dump data with the required frame granularity.
  - Extracts the FrameStart and FrameEnd event, based on the input Start-of-Frame and End-of-Frame.
    > The FrameStart immediately generates a VSYNC event.
    > The FrameEnd ripples till the end of the pipe, at the pixel packer level, where it generates the FRAME event.
  - Based on the algorithm detailed in Extraction algorithm for FrameStart and FrameEnd.

- Capture mode: can capture a frame snapshot, or capture continuously.
- Capture rate: can capture all frames, or one out of 2, 4, 8. It is only active when the Capture mode is in Continuous mode.

Extraction algorithm for FrameStart and FrameEnd

The extraction of the FrameStart and FrameEnd is straightforward.

Use cases

The Continuous mode is typically used to send to display or to software-analysis a continuous stream of frames.

The Snapshot mode is typically used to dump a high-resolution frame.

The Frame rate mode is typically used for a low-power continuous analysis, where only one frame every eight is dumped and analyzed.
The frame informations are typically used for interlaced video use cases, where the sensors transmit alternatively odd and even fields (top vs. bottom), and where software must be able to retrieve the type of field. Depending on the sensor, it can be retrieved from:

- the LSB of the counted number of lines in that frame (indicates if the number is odd or even)

**Software configuration**

The frame control supports two different capture modes:

- Snapshot mode: the software captures single frames
- Continuous mode: the software captures a continuous sequence.

The timing diagram of these two modes is shown in *Figure 334*.

---

**Figure 334. Snapshot (CPTMODE = 1) and Continuous (CPTMODE = 0) capture modes**

1. Bit read from the DCMIPP_PxSR register.
Configuration example

The software operations when using the Snapshot mode are the following:
1. Software sets CPTMODE = 1, to use the Snapshot mode.
2. Software sets PIPEN = 1, to let the flow selection send data to PipeN.
3. Software sets CPTREQ = 1, to request the capture of one frame.
4. At the first following VSVC, the HW samples CPTREQ at 1, with the following impact:
   a) The capture effectively starts: pixels flow into the pipe and are dumped in memory.
   b) CPTACT is set to 1, to mention that a capture is currently ongoing, and that it is best to not modify the configuration of the pipe operators, unless shadowed.
   c) CPTREQ is reset to 0, so that only a single frame is dumped.
5. At the following capture complete interrupt
   a) CPTACT is reset to 0, to signal that the capture is over.
   b) The capture is complete, no more pixels are flowing, hence software can restart to update the configuration of non-shadowed registers without any issue, and use the captured pixels in memory. Depending upon the sensor blanking, this period can be short.
6. At the next VSVC, CPTREQ usually is sampled at 0, so that no more frames are captured
   – As soon as CPTREQ is reset to 0 the software can set it again to 1, to request a capture at the following frame. It means that a continuous sequence of frame can be captured by setting again CPTREQ to 1, continuously frame after frame.

The software operations when using the Continuous mode are the following:
1. Software sets CPTMODE = 0, to use the Continuous mode.
2. Software sets PIPEN = 1, to let the flow selection send data to PipeN.
3. Software sets CPTREQ = 1, to request the continuous capture of frames.
4. At the first following VSVC, CPTREQ is sampled at 1, with the following impact:
   – As in Snapshot mode, the capture starts, and CPTACT is set at 1.
   – Unlike the Snapshot mode, CPTREQ is not modified and remains at 1.
5. At the following capture complete interrupt:
   – As in Snapshot mode, CPTACT is reset to 0, capture stops, software can shortly reconfigure the pipes, and software can use the captured pixels.
6. At the next VSVC, and as long as CPTREQ remains at 1, the capture restarts, similarly as described above.
7. To stop capturing later frames, software resets CPTREQ to 0.
   – An ongoing capture continues until completion.
8. At the next VSVC, CPTREQ is sampled at 0, and the next capture does not restart.

31.4.4 Pipe deactivation

It is possible to abort a pipe to stop any frame acquisition and to potentially offer a mean to reprogram it completely (including non-shadowed registers), or to let it fully disabled for some time. The following operating mode has to be considered to correctly stop the pipe:
1. Disable the CPTREQ bit of the DCMIPP_PxFCTCR register of the corresponding pipe
2. Poll CPTACT = 0 status bit in the DCMIPP_CMSR1 register to check if the pipe is no longer active (idle state)
3. Disable PIPE in the DCMIPP_PxFCTCR register.

When disabling the pipe, the last frame is processed completely by respecting the above operating mode.

Note: To disable the parallel interface (PREN = 0 in the DCMIPP_PxFSCR), it is recommended to first disable the pipe considering the above operation mode, before switching off the parallel interface.

31.5 Pipe0 (dump pipe)

31.5.1 Overview

Pipe0 works as a dump pipe: it extracts data from the camera sensor module and dumps them (as-is) to the targeted memory, with some basic decimation and cropping 2D operations in between.

Pipe0 retrieves data from the camera sensor module connected to the DCMIPP through the 16-bit parallel interface.

The frame controller handles mainly the camera acquisition mode (continuous or snapshot, frame rate), see Section 31.4.3.

When the input data from the camera is valid and supposed to be processed by Pipe0, 2D-cropping and decimation operations can be configured by the software. A dump counter combining with a limit amount of data to be set is offered to handle unknown length of data or to avoid the amount of data to be too wide within a frame.

31.5.2 Decimation

The decimation allows to cheaply downsize a frame.

Based on parallel interface camera module:

- Factor 1x, 2x, 4x at data/byte level depending on the configuration of bit field BSM[1:0] of the DCMIPP_P0PPPCR register. The decimation is not working directly at pixel level, but it is based on either byte or 16-bit word granularity (for padded...
raw 10, for instance) to make equivalent decimation to one pixel out of two. Bit OEBs is used to start from the odd or even byte (or data) to capture first.

- The decimation can also be based on entire line, by capturing all the lines, or one line out of two thanks to bit LSM. Here, again, choice is given to the software to reject odd or even lines within the frame by configuring bit OELS.

### 31.5.3 Crop/statistics selection/suppression

The dump pipe (Pipe0) has the capability to handle 2-D crop processing. The vertical cropping is based on line, thanks to HSYNC event (from the physical IOs or the embedded code detection if selected).

The horizontal area on which the crop is applied is based on data (32-bit wide), and not on pixels since this pipe is not directly considering the pixels. It handles the data flow with 32-bit granularity. The CROP functionality is not supported when the pipe is conveying JPEG format. The ENABLE bit must be kept cleared into DCMIPP_P0SCSZR to avoid any unpredictable behavior.

The area to be captured within the frame has to be specified configuring the registers DCMIPP_P0SCSTR and DCMIPP_P0SCSZR. The starting point on the two axis are set accordingly as well as the width in both directions. It is possible to take the data inside or outside this area by means of bit POSNEG in the DCMIPP_P0SCSZR register. Some sensors can send sensor configuration data and statistics (histogram) on the very first and last lines of a frame. By specifying active the area outside of this window selection (POSNEG = 1), only statistic data are extracted by the way, and the software can decide to apply some processing on the data to correct, such as contrast or exposure.

#### Features

- 2D-Crop operation with granularity:
  - Lines in the vertical axis
  - 32-bit data in the horizontal axis
- Possibility to capture data inside or outside the defined window (valid image data or statistic data)
- Cropping with 0 value for HSIZE[11:0] or VSIZE[11:0] has no crop effect to the dimension for which the 0 value has been applied (vertical or horizontal axis).

#### Software configuration

Registers DCMIPP_P0SCSTR and DCMIPP_P0SCSZR have to be configured to set the crop feature into the dump pipe:

<table>
<thead>
<tr>
<th>Bit ID</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSM[1:0]</td>
<td>To select how much byte/data have to be captured within a line. This feature is available only for a parallel interface camera module.</td>
</tr>
<tr>
<td>OEBs</td>
<td>Allows the user to chose if the filtering starts from the odd or the even byte.</td>
</tr>
<tr>
<td>LSM</td>
<td>Possibility to filter out one line out of two.</td>
</tr>
<tr>
<td>OELS</td>
<td>The software can select if the filtering rejects the odd or even lines.</td>
</tr>
</tbody>
</table>

Table 286. DCMIPP_P0PPCR bit function
1. Configure the cropped horizontal starting point with HSTART[11:0] and the width with HSIZE[11:0] (both with a 32-bit data granularity).
2. Configure the cropped lines, starting at line VSTART[11:0] and with a height of VSIZE[11:0] (both with a line granularity)
3. If any value HSIZE or VSIZE is set to 0, the hardware does not consider crop operation in the vertical or horizontal dimension for which the 0 value has been applied, so that all the pixels in that dimension are sampled.
4. Select the inner or the outer part of the window for the data capture by configuring POSNEG bit.
5. Enable the crop feature setting ENABLE bit. This bit must be cleared when JPEG is selected as the input format for Pipe0.

Note: Cropping out the picture size (with too large HSTART or VSTART) leads to a not guaranteed processed frame.

31.5.4 Dump counter

The dump counter is present on dump pipe. It is used to count the amount of data that are dumped in that frame, and to potentially limit the amount dumped if too large. It allows the software to know the size of dumped buffer, and to make sure that no dump is made out of a preallocated buffer.

It is specifically useful when dumping a content whose length is unknown prior to reception, like an encoded JPG stream. When dumping a pixel frame, the size is known thanks to the configured width and height of the frame.

The counter is counting 32-bit data for almost all the input formats, even if the value is expressed in number of bytes. The counter increment is 4-bytes granularity for all formats except the JPEG byte stream input mode, for which the counter granularity is 8-bit because the application does not know the amount of dumped data.

Features

- Dump counter, counting the amount of bytes dumped. It counts the amount of dumped 32-bit words (the increment is 4), except when connected to a parallel interface camera and dumping a 8-bit data in byte stream mode (see FORMAT bit field in the DCMIPP_PRCR register), where it counts per byte (the increment is 1).
  - The counter saturates at 0x03FF_FFFF.
  - At FrameEnd, the counter value is recopied in a readable shadow register and the counter itself is reset to start the count of the next frame.
- Dump limit, that clamps the dumped words below a maximum limit:
  - If the counter reaches the limit, all following bytes are deleted until the next VSync.
  - The counter continues to count over the limit, to indicate how many bytes have been received and must have been dumped if not deleted.
- Interrupt limit is triggered when some bytes are deleted due to dump limit crossed.
- Monochrome or raw Bayer padding (alignment of 10/12/14 bpp to 16 bpp) is also taken into account in data volumes.
Software configuration

Table 287. DCMIPP_P0DCCNTR and DCMIPP_P0DCLMTR bit function

<table>
<thead>
<tr>
<th>Bit ID</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENABLE</td>
<td>1: Enables the limit check.</td>
</tr>
<tr>
<td>CNT</td>
<td>Read-only, counts the amount of data with a 4-byte granularity for most of the input formats or with an 8-bit data granularity in JPEG byte stream mode selected into DCMIPP_PRCR FORMAT. The counter increment is based on dumped data at the pipe output standpoint. The value is expressed in bytes, whatever the input format.</td>
</tr>
<tr>
<td>LIMIT</td>
<td>Gives the maximum amount of 32-bit data that can be dumped. Limit value 0 is inconsistent and the processed frame is not guaranteed if ENABLE bit is set.</td>
</tr>
<tr>
<td>LIMITIE</td>
<td>DCMIPP_PxIER.LIMITIE bit enables the interrupt.</td>
</tr>
</tbody>
</table>

Note: Raw Bayer and monochrome pixels on 10/12/14 bpc are padded onto 16 bits, and are thus slightly larger than their 10/12/14 bit size.

31.5.5 Double buffer mode

The dump pipe uses an AXI master interface to dump the data from the internal FIFO to the external memory. In the application, it is possible to handle frame data swapping memory area frame by frame. The double buffer mode fills up this function. There are two memory address registers set to initialize the base addresses of these memories areas. Each start of captured frame event swaps the memory base address to handle double buffering mode.

The double buffer mode can be used to allow post-processing on a buffer (frame buffer) while the other buffer is read to be displayed (display buffer).

Software configuration

Double buffering mode requires an activation, as well as addresses configuration, to define the two memory areas in which data are consecutively stored frame by frame at the output of the pipeline:

- DCMIPP_PxPPM0AR1 and DCMIPP_PxPPM0AR2 must be filled with the memory addresses associated to the double buffer memory locations.
- Bit DBM in the DCMIPP_PxPPCR register(s) is set to enable the double buffer mode.

31.5.6 Pixel packing

This module works on the dump pipe (Pipe0), setting the arriving pixels in memory words.

Features

- DBM addresses: double buffer mode with their associated address locations if the application need to swap memory address for one frame to the next one.
- Pixel format: all usual formats, as indicated in Section 31.3.6.
- Padding: MSB vs. LSB padding of 10/12/14 bit onto 16 bit.
- Multi-line event: event generated (for DMA and INT) at each multiple of sent lines.
31.5.7 Overrun detection

This logic handles flow-control hazards: the DCMIPP is provided a continuous flow of data (via parallel interface) without any wait/hold capability, while downstream of DCMIPP, the access to memory can be temporarily stuck.

In some cases the internal FIFOs of the DCMIPP get full and pixels may be deleted. The overrun detection logic handles such hazard at best.

Features

- Software gets warned in case of an hazard:
  - Interrupt OVR is triggered at the first deletion of a pixel, repeated at every frame, as long as the overrun hazard is present.
  - It is recommended to skip / trash the impacted frame:
    > Overflowing pixels are deleted, so that when the access to memory resumes, the remaining of the line is discarded (not written out). The normal processing resumes at the start of the next line. Potentially, several full lines can get discarded.
- No Frame-to-Frame impact in case of an hazard:
  - VSync resets what is needed in the DCMIPP, so that any hazard on a previous frame has no impact at all on the pixels dumped in next frames.

Software configuration

- Interrupt DCMIPP_PxSR.OVRF is warned in case of hazard.

31.6 Pixel format description

This section describes the pixel formats used in the parallel interface and dump pipe.

The support for the pixel formats, per interface (parallel, dump output) are summarized in Table 289.

Note: In the following tables the components are represented with their symbolic color: red and Cr (= V) in red, blue and Cb (= U) in blue, green in green, and Y, monochrome, and all raw Bayer components in gray.

31.6.1 Parallel interface formats

This paragraph describes the input pixel format as supported by the parallel interface of the DCMIPP and the possible swap combinations.

Note: The parallel interface does not input specifically RGB444/RGB555 (and RGB666). However, a sensor with these output can connect them onto the DCMIPP, by selecting RGB565 (and RGB888), and by either connecting the missing bits with the MSB of the sensor output or by strapping them.

To adapt to non-standard sensors, the parallel interface is flexible and allows to swap bits, cycles, components, namely:

- Bits: LSB-vs.-MSB bits are swapped, across the whole 16-bit IO pins.
- Cycles: cycle 1/2 and cycle 2/2 are swapped. No impact for 1 or 3 cycles.

*Table 291* shows these permutations, based on the RGB565 format. It lists the sampled bits of cycles 1 and 2, on pins 0 to 7, and for each of them returns the assignation of the RGB output components.

### 31.6.2 Dump pipe formats

The dump pipe, thanks to its capability to dump, supports:

- Monochrome and raw Bayer pixels on 10/12/14 bits, padded on 16 bpp.

*Table 292* details the support for these additional pixel formats. Other formats are assumed to be pixels with the same width.

### 31.6.3 **AXI IP-Plug**

The AXI IP-Plug dumps the data of the pipe to the memory via the AXI.

**Features**

- Pipe ID: single ID, as a unique pipe dump (Pipe0) is deployed
- FIFOs: sized to handle external SDRAM
  - Pipe0: 200 MB/s, thus 256 bytes
- Burst length: 64 or 128 bytes for all pipes
- Outstanding capability: four, on 128-byte bursts
- Bandwidth limiter (via an outstanding limitation per pipe):
  - avoids a last-line dump to overload the memory bandwidth
- Unique AXI-QOS: unique QOS for the DCMIPP

**Common software configuration**

The AXI IP-Plug has a common configuration in the DCMIPP_IPGR1/2/3/8 registers.
The common registers R1 and R3 are writable only when the IP-Plug is in Idle mode.

- MEMORYPAGE: for efficient handling of DRAM (bursts do not cross this module).
- PSTART: request to freeze the plug, to reconfigure it safely.
- IDLE: status to mention the plug is frozen, to reconfigure it safely.
- IPPID[7:0], ARCHIID[4:0], REVID[4:0], DID[5:0]: version IDs of the IP-Plug.

**Per-client software configuration**

The AXI IP-Plug has a per-client configuration in registers DCMIPP_IPC0R1/2/3.

The client registers R1 and R3 are writable only when the IP-Plug is in Idle mode (see PSTART in common registers above to lock it, or below for an example).

- Client1 = Pipe0

The configurable per-client features are the following:

- OTR: Outstanding transactions per client (Oustd = OTR + 1)
- TRAFFIC[2:0]: Burst size: best select 128 bytes, thus TRAFFIC = 4
- WLRU[3:0]: Proportion of total bandwidth: WLRU = BWi / sum (all BW)
- SVC: System virtual channel. Keep SVC = 0
- DPREGSTART: Local base-address of start of FIFO for this client.
- DPREGEND: Local base-address of end of FIFO (included word) for this client.

**Configuration computations**

**IP-Plug common configuration:**

- PSTART: set to 1, to put IP-Plug idle and configure its registers G1/3, R1/3.
- IDLE: read and wait till = 1, to get it idle.
- MEMORYPAGE: 4 to optimize for memory pages of 256 bytes.

**IP-Plug per-client configuration:**

- OTR (client): Outstanding per client, among a total of four outstandings.
  - The provided value, OTR, is the outstanding amount minus 1.
- DPREG size (client): RAM shared size, 256 bytes
  - DPREGSTART = 0 (or after another client location)
  - DPREGEND = 2 for ((2 - 0) + 1) x 128 B = 256 bytes for this client. The value to be programmed is 1 because the word is included.
It results with the Client1 assigned to Pipe0:

- IP-Plug common registers:
  - DCMIPP_IPGR1.MEMORYPAGE = 2 (default, 256 bytes)
  - DCMIPP_IPGR2.PSTART = 1 (locks IP-Plug for reconfiguration)
  - DCMIPP_IPGR3.IDLE to wait until = 1 (wait before continuing)

- Video statically mapped onto IP-Plug Client1:
  - DCMIPP_IPC1R1.OTR = 4
  - DCMIPP_IPC1R1.TRAFFIC = 4 (default)
  - DCMIPP_IPC1R3.DPREGSTART = 0
  - DCMIPP_IPC1R3.DPREGEND = 4

- IP-Plug common registers:
  - DCMIPP_IPGR2.PSTART= 1 (unlocks IP-Plug after configuration)

31.7 **Shadow registers**

A dump pipe must have the capability to be reconfigured without stopping it. Some registers can be written in the middle of a frame without impacting the actual frame acquisition. The values are stored into some shadow registers before being written in their corresponding physical registers, based on a trigger event like described in Table 293.

Each physical register in the register map has its address increased by 0x200 respect to its own shadow register address.

<table>
<thead>
<tr>
<th>Shadow register</th>
<th>Physical register</th>
<th>Trigger event</th>

<td>Vsync boundaries</td>
</tr>
<tr>
<td>DCMIPP_P0PPM0AR2</td>
<td>DCMIPP_P0CPPM0AR2</td>
<td>Vsync boundaries</td>
</tr>
</tbody>
</table>

It is mandatory to refresh the shadow registers within a frame to prepare the context to be ready for the next start of frame, to avoid any unpredictable behavior during the acquisition. The software must then react to the following interrupt sources to launch the shadow registers accesses:

- At VSYNC interrupt (FrameStart at start of pipe) an interrupt is generated, and the software can update the shadow registers loaded into the physical registers at the end of the current frame (so active for the next frame). The software has an entire frame period to complete the update.

- At LINE interrupt line selection can be used also to trigger the software to update the physical registers with the new frame context to consider. The application code must ensure that the update takes place before the end of frame event (current frame). If not, the context can be partially considered from the next frame, dealing with inconsistent settings.
In any case, the software must ensure that the shadow registers are updated before the end of the current frame, to be active from the next frame. Updates started and not completed before the end of current frame result in inconsistent frame acquisition for the next frame (mixing old and new configurations).

It is recommended to change non-shadowed registers when the corresponding pipe is disabled and in an idle state (refer to Section 31.4.4: Pipe deactivation).

31.8 DCMIPP low power modes

This section describes the behavior of the DCMIPP versus the modes listed in Table 294.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stop</td>
<td>Peripheral content is kept. It is recommended to follow the pipe(s) disabling procedure before entering it.</td>
</tr>
<tr>
<td>Standby</td>
<td>Powered-down. The peripherals must be reinitialized after exiting this mode.</td>
</tr>
<tr>
<td>Sleep</td>
<td>No effect. DCMIPP is still working in this mode, peripheral interrupts cause the device to exit it.</td>
</tr>
</tbody>
</table>
31.9  **DCMIPP interrupts**

This section describes the DCMIPP interrupts, and more globally, the features that are related to real-time, namely:

- Free-running: DCMIPP can run without CPU involvement
- Shadow registers: relieve timing constrains from the software
- Interrupts: source of interrupt
- Event pins: to drive external IPs, like a DMA

31.9.1 **Free-running DCMIPP**

After a camera flow has been configured and established, it is able to run permanently, without any software involvement. The following features are available:

- Permanent pipe activation, for Pipe0: when set, the pipe dumps frame data, for an unlimited amount of frames.
  - DCMIPP_PxFCTCR.CPTMODE = 0
  - DCMIPP_PxSR.CPTACT = 1
  - DCMIPP_PxFCTCR.FRATExx (depending on desired frame subsampling rate)
- Double buffered frames: the DCMIPP can be defined with two BaseAddress pointers for the output buffers:
  - Software can set up the two BaseAddress pointers to let the hardware reacting to the VSYNC event to change from one buffer BaseAddress to the other one, and this alternatively.

31.9.2 **Interrupts**

The DCMIPP handles three interrupts pins, the third being the OR of the first two. A register set is associated to each interrupt to provide the following functionality:

- Unmasked events: reports an event that occurred and has not yet been cleared
- Masks: to mask unwanted events
- Masked events: not readable, any active unmasked bit triggers the interrupt pin
- Clear register: write to clear any active event

The interrupt pins are active when high: they go high when triggered by an unmasked event, and remain high until all the masked events of that interrupt are cleared.
The interrupts lines and registers are:

1. Parallel interface, with the next interrupt events handled:
   - ERR: bad embedded synchronization detected.
     > Unexpected behavior in the parallel interface, usually not triggered if no issues.
     > It is due to an unexpected sensor behavior, or to a transmission error.

2. Pipe0 (dump), with the next interrupt events handled:
   - OVR: data overflow: the memory was too slow vs. received pixels.
     > Unexpected behavior in Pipe0, usually not triggered if no issues.
     > Same recommendation as for above OVR: skip the impacted frame.
   - LIMIT: received volume is larger than the maximum allowed dump volume.
     > Unexpected behavior in Pipe0, usually not triggered if no issues.
     > The transmitted flow is too long. More space must be allocated in memory to store the transmission of a next frame.
   - VSYNC: main interrupt, where most software can sit.
     > Trigger: at VSync (mid blanking), permanent (even if no dump active).
     > Typically to reconfigure slowly the pipes (at least shadow registers) for next frame
     > Typically to trigger usage of the previously captured frame.
   - FRAME: secondary interrupt, as backup for fast-software
     > Trigger: after last data dump of this pipe, inactive if no capture has occurred.
     > Typically to quickly reconfigure non-shadow registers (during only vertical blanking)
     > Typically to trigger usage of the previously captured frame.
   - LINE: interruption for stripe-based operators trigger: after every 1/2/4/8/16/32/64/128 dumped lines and last line. It is measured and extracted at end of pipe, close to output to memory.
     > Typically to trigger fast/reactive software or hardware stripe-based operators.

Note: The LINE flag (LINEF bit) is set at the end of frame, to trigger out software event when the frame height is not a multiple of the selected number of lines for which the LINEF event is triggered. The last part of the frame can, in such case, have a lower number of lines than the selection. The event/interrupt is generated even if the number of lines is incomplete. The software must consider that this last event has a lower than expected number of lines when reaching the end of frame (FRAME event).

3. Common interrupt: groups the events of the above interrupts in a single register set and drives its own interrupt line.
   - The third interrupt is designed for systems where a single driver handles the whole DCMIPP: a single access to this interrupt status allows to retrieve the status of the whole DCMIPP.
   - The first two interrupts are designed for systems where a driver handles a pipe and (potentially) another one drives the parallel interface. In that case, each driver handles its own individual interrupt register set, without need for semaphores to arbitrate conflicting accesses.

There is also a common interrupt that can be generated if enabled, when a transfer error is detected during an AXI transfer from the IP-Plug to memories. Error flag
ATXERR in the DCMIPP_CMSR2 register is set and an interrupt can be generated to inform the software about this error status. There is no specific hardware action linked to this error, it is up to software to handle the transfer error situation.

The DCMIPP interrupts are summarized in Table 295. An event that generates an interrupt does it at two locations:
- once in the common interrupt register set (when driven by a single CPU)
- once in the local interrupt register set (when driven by multiple CPUs).

Table 295 provides the local (register and bit) and global (bit only, as all bits are in the same DCMIPP_CMSR2 register) locations.

### Table 295. DCMIPP interrupts

### 31.9.3 Event pins

Event pins are exposed to let an ancillary HW IP, like a central DMA, to synchronize with them. The event pins are the unmasked synchronization events (VSYNC, FRAME, LINE, HSYNC) of the pipes.

An internal events generates a pulse (15 APB cycles long) on its pin.

### Table 296. Event connection

Bits 31:21  Reserved, must be kept at reset value.

Bits 20:16  DPREGEND[4:0]: End word (AXI width = 64 bits) of the FIFO of Clientx.
The addressed word is included in the FIFO, so that next DPREGSTART is DPREGEND + 1.

Bits 15:5  Reserved, must be kept at reset value.

Bits 4:0  DPREGSTART[4:0]: Start word (AXI width = 64 bits) of the FIFO of Clientx.
31.10.8 DCMIPP parallel interface control register (DCMIPP_PRCR)

Address offset: 0x104
Reset value: 0x0000 0000

![Table](image)

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **SWAPBITS**: Swap LSB vs. MSB within each received component
- 0: As received
- 1: Swapped MSB vs. LSB

Bit 25 **SWAPCYCLES**: Swap data (cycle 0 vs. cycle 1) for pixels received on two cycles
- 0: Default
- 1: Swap active: the data of cycle 1 is used before the data of cycle 0.
  The swap must not be activated by software for pixels received in one or three cycles.

Bit 24 Reserved, must be kept at reset value.

Bits 23:16 **FORMAT[7:0]**:
- 0x1E: YUV422
- 0x22: RGB565
- 0x24: RGB888 (= YUV444)
- 0x2A: RAW8
- 0x2B: RAW10
- 0x2C: RAW12
- 0x2D: RAW14
- 0x4A: monochrome 8-bit
- 0x4B: monochrome 10-bit
- 0x4C: monochrome 12-bit
- 0x4D: monochrome 14-bit
- 0x5A: byte stream (JPEG, compressed video)
  Other values: data are captured and output as-is only through the data/dump pipeline
  (for example JPEG or byte input format).
  The monochrome Y input is inserted in the pipe as YUV pixels, with the U and V components
  set to neutral, to represent a gray color.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **ENABLE**: Parallel interface enable
- 0: Parallel interface disabled to lower power consumption
- 1: Parallel interface enabled
  The parallel interface configuration registers must be correctly programmed before enabling
  this bit.

Bit 13 Reserved, must be kept at reset value.
Bits 12:10 **EDM[2:0]**: Extended data mode
- 0x0: Interface captures 8-bit data on every pixel clock
- 0x1: Interface captures 10-bit data on every pixel clock
- 0x2: Interface captures 12-bit data on every pixel clock
- 0x3: Interface captures 14-bit data on every pixel clock
- 0x4: Interface captures 16-bit data on every pixel clock
Other values: Reserved

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **VSPOL**: Vertical synchronization polarity
- This bit indicates the level on the VSYNC pin when the data are not valid on the parallel interface.
  - 0: VSYNC active low
  - 1: VSYNC active high

Bit 6 **HSPOL**: Horizontal synchronization polarity
- This bit indicates the level on the HSYNC pin when the data are not valid on the parallel interface.
  - 0: HSYNC active low
  - 1: HSYNC active high

Bit 5 **PCKPOL**: Pixel clock polarity
- This bit configures the capture edge of the pixel clock
  - 0: Falling edge active
  - 1: Rising edge active

Bit 4 **ESS**: Embedded synchronization select
- 0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the HSYNC/VSYNC signals.
- 1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.
  Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when this bit is set.

Bits 3:0 Reserved, must be kept at reset value.

### 31.10.9 DCMIPP parallel interface embedded synchronization code register (DCMIPP_PRESER)

Address offset: 0x108

Reset value: 0x0000 0000
31.10.10 DCMIPP parallel interface embedded synchronization unmask register (DCMIPP_PRESUR)

Address offset: 0x10C
Reset value: 0x0000 0000

Bits 31:24 **FEC[7:0]**: Frame end delimiter code
This byte specifies the code of the frame end delimiter. The code consists of four bytes in the form of 0xFF, 0x00, 0x00, FEC.
If FEC is programmed to 0xFF, all the unused codes (0xFF00 00XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]**: Line end delimiter code
This byte specifies the code of the line end delimiter. The code consists of four bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]**: Line start delimiter code
This byte specifies the code of the line start delimiter. The code consists of four bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]**: Frame start delimiter code
This byte specifies the code of the frame start delimiter. The code consists of four bytes in the form of 0xFF, 0x00, 0x00, FSC.
If FSC is programmed to 0xFF, no frame start delimiter is detected, but the first occurrence of LSC after an FEC code is interpreted as the start of frame delimiter.

Bits 31:24 **FEU[7:0]**: Frame end delimiter unmask
This byte specifies the mask to be applied to the code of the frame end delimiter.
0: The corresponding bit in the FEC byte in DCMIPP_ESCR is masked while comparing the frame end delimiter with the received data.
1: The corresponding bit in the FEC byte in DCMIPP_ESCR is compared while comparing the frame end delimiter with the received data.

Bits 23:16 **LEU[7:0]**: Line end delimiter unmask
This byte specifies the mask to be applied to the code of the line end delimiter.
0: The corresponding bit in the LEC byte in DCMIPP_ESCR is masked while comparing the line end delimiter with the received data.
1: The corresponding bit in the LEC byte in DCMIPP_ESCR is compared while comparing the line end delimiter with the received data.

Bits 15:8 **LSU[7:0]**: Line start delimiter unmask
This byte specifies the mask to be applied to the code of the line start delimiter.
0: The corresponding bit in the LSC byte in DCMIPP_ESCR is masked while comparing the line start delimiter with the received data.
1: The corresponding bit in the LSC byte in DCMIPP_ESCR is compared while comparing the line start delimiter with the received data.

Bits 7:0 **FSU[7:0]**: Frame start delimiter unmask
This byte specifies the mask to be applied to the code of the frame start delimiter.
0: The corresponding bit in the FSC byte in DCMIPP_ESCR is masked while comparing the frame start delimiter with the received data.
1: The corresponding bit in the FSC byte in DCMIPP_ESCR is compared while comparing the frame start delimiter with the received data.

**Bits 7:0** **FSU[7:0]:** Frame start delimiter unmask  
This byte specifies the mask to be applied to the code of the frame start delimiter.  
0: The corresponding bit in the FSC byte in DCMIPP_ESCR is masked while comparing the frame start delimiter with the received data  
1: The corresponding bit in the FSC byte in DCMIPP_ESCR is compared while comparing the frame start delimiter with the received data
Bit 17 **VSYNC:**
This bit gives the state of the VSYNC pin with the correct programmed polarity if ENABLE bit is set into the DCMIPP_PRCR register and if the pixel clock is received. It is set during the blanking period whatever the polarity selected in VPOL bit, and cleared otherwise.
When embedded synchronization codes are used:
0: Active frame
1: Synchronization between frames
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMIPP_CR is set.

Bit 16 **HSYNC:**
This bit gives the state of the HSYNC pin with the correct programmed polarity if ENABLE bit is set into the DCMIPP_PRCR register and if the pixel clock is received. It is set during the blanking period whatever the polarity selected in HPOL bit, and cleared otherwise.
When embedded synchronization codes are used:
0: Active line
1: Synchronization between lines
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMIPP_CR is set.

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **ERRF:** Synchronization error raw interrupt status
0: No synchronization error detected
1: Embedded synchronization characters are not received in the correct order.
This bit is valid only in the embedded synchronization mode. It is cleared by writing 1 to the CERRF bit in DCMIPP_PRFCR.
This bit is available only in embedded synchronization mode.

Bits 5:0 Reserved, must be kept at reset value.

</tbody>
</table>

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CERRF:** Synchronization error interrupt status clear
Writing a 1 into this bit clears the ERRF bit in DCMIPP_PRSR.
This bit is available only in embedded synchronization mode.

Bits 5:0 Reserved, must be kept at reset value.

### 31.10.14 DCMIPP common configuration register (DCMIPP_CMCR)
Address offset: 0x204
Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CFC**: Clear frame counter
When this bit is set, the frame counter associated to a pipe is cleared. It resets DCMIPP_CMFRCR register. This bit is always read at 0.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 Reserved, must be kept at reset value.

### 31.10.15 DCMIPP common frame counter register (DCMIPP_CMFRCR)
Address offset: 0x208
Reset value: 0x0000 0000

Bits 31:0 **FRMCNT[31:0]**: Frame counter, read-only, loops around.
Incremented following VSYNC detection mapped to the pipe configured into bits PSFC[1:0] of the DCMIPP_CMCR register. The counter is cleared using the CRC bit of that register.

### 31.10.16 DCMIPP common interrupt enable register (DCMIPP_CMIER)
Address offset: 0x3F0
Reset value: 0x0000 0000

Bits 31:0 **P0 OVR IE**, **P0 LIMIT IE**, **P0 VSYNC IE**, **P0 FRAME IE**, **P0 LINE IE**, **PR ERR IE**, **ATX ERR IE**: Read-write

Bit 31  Reserved, must be kept at reset value.
Bits 30:28  Reserved, must be kept at reset value.
Bit 27  Reserved, must be kept at reset value.
Bits 26:24  Reserved, must be kept at reset value.
Bit 23  Reserved, must be kept at reset value.
Bits 22:20  Reserved, must be kept at reset value.
Bit 19  Reserved, must be kept at reset value.
Bits 18:16  Reserved, must be kept at reset value.
Bit 15 **P0OVRIE**: Overrun interrupt enable for Pipe0
  0: No interrupt generation
  1: An interrupt is generated

Bit 14 **P0LIMITIE**: Limit interrupt enable for Pipe0
  0: No interrupt generation
  1: An interrupt is generated

Bits 13:11  Reserved, must be kept at reset value.
Bit 10  **P0VSYNCIE**: Vertical sync interrupt enable for Pipe0
  0: No interrupt generation
  1: An interrupt is generated

Bit 9  **P0FRAMEIE**: Frame capture complete interrupt enable for Pipe0
  0: No interrupt generation
  1: An interrupt is generated

Bit 8  **P0LINEIE**: Multi-line capture complete interrupt enable for Pipe0
  0: No interrupt generation
  1: An interrupt is generated

Bit 7  Reserved, must be kept at reset value.
Bit 6  **PRERRIE**: Limit interrupt enable for the parallel Interface
  0: No interrupt generation
  1: An interrupt is generated

Bit 5  **ATXERRIE**: AXI transfer error interrupt enable for IP-Plug
  0: No interrupt generation
  1: An interrupt is generated

Bits 4:0  Reserved, must be kept at reset value.

### 31.10.17  DCMIPP common status register 1 (DCMIPP_CMSR1)

Address offset: 0x3F4
Reset value: 0x0000 0003
Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 Reserved, must be kept at reset value.

Bit 15 P0CPTACT: Active frame capture (active from start-of-frame to frame complete) for Pipe0

0: No capture currently active
1: Capture currently active

Bits 14:12 Reserved, must be kept at reset value.

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:2 Reserved, must be kept at reset value.

Bit 1 PRVSYNC:
This bit gives the state of the VSYNC pin with the correct programmed polarity on the parallel interface if ENABLE bit is set into the DCMIPP_PRCR register and if the pixel clock is received. It is set during the blanking period whatever the polarity selected in VPOL bit of the DCMIPP_PRCR register, and cleared otherwise.

When embedded synchronization codes are used, the meaning of this bit is the following:
0: Active frame
1: Synchronization between frames

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in the DCMIPP_PRCR register is set.

Bit 0 PRHSYNC:
This bit gives the state of the HSYNC pin with the correct programmed polarity on the parallel interface if ENABLE bit is set into the DCMIPP_PRCR register and if the pixel clock is received. It is set during the blanking period whatever the polarity selected in HPOL bit of the DCMIPP_PRCR register, and cleared otherwise.

When embedded synchronization codes are used the meaning of this bit is the following:
0: Active line
1: Synchronization between lines

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in the DCMIPP_PRCR register is set.

### 31.10.18 DCMIPP common status register 2 (DCMIPP_CMSR2)

Address offset: 0x3F8

Reset value: 0x0000 0000
### Digital camera interface pixel pipeline (DCMIPP)

#### Bits 31:28
Reserved, must be kept at reset value.

#### Bit 27
Reserved, must be kept at reset value.

#### Bits 26:24
Reserved, must be kept at reset value.

#### Bit 23
Reserved, must be kept at reset value.

#### Bits 22:20
Reserved, must be kept at reset value.

#### Bit 19
Reserved, must be kept at reset value.

#### Bits 18:16
Reserved, must be kept at reset value.

#### Bit 15 **P0OVRF**: Overrun raw interrupt status for Pipe0
- **0**: No data buffer overrun occurred
- **1**: A data buffer overrun occurred and this frame data are corrupted

This bit is cleared by writing 1 to the CP0OVRF bit in the DCMIPP_CMFCR register.

#### Bit 14 **P0LIMITF**: Limit raw interrupt status for Pipe0
This bit is set when the data counter DCMIPP_P0DCCNT reaches its maximum value DCMIPP_P0DCLIMIT. It is cleared by writing 1 to the CP0LIMITF bit in the DCMIPP_CMFCR register.

#### Bits 13:11
Reserved, must be kept at reset value.

#### Bit 10 **P0VSYNC**: VSYNC raw interrupt status for Pipe0
This bit is set when the VSYNC signal changes from the inactive state to the active state. In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMIPP_CR. It is cleared by writing 1 to the CP0VSYNCF bit in the DCMIPP_CMFCR register.

#### Bit 9 **P0FRAMEF**: Frame capture completed raw interrupt status for Pipe0
- **0**: No capture or ongoing capture
- **1**: All data of a frame have been captured

This bit is set when all data of a frame or window have been captured. In case of a cropped window, this bit is set at the end of line of the last line in the crop, even if the captured frame is empty (for example window cropped outside the frame). This bit is cleared by writing 1 to the CP0FRAMEF bit in the DCMIPP_CMFCR register.

#### Bit 8 **P0LINEF**: Multi-line capture completed raw interrupt status for Pipe0
This bit is set when one/more lines have been completed. The periodicity of LINEF event is configured by LINEMULT bits into DCMIPP_P0PPCR register. When reaching end of frame, this event is triggered out to allow software action even if the LINEMULT value set is not a multiple of the total lines frame. In the case of embedded synchronization, this bit is set only if the CAPTURE bit in the DCMIPP_CR register is set. It is cleared by writing 1 to the CP0LINEF bit in the DCMIPP_CMFCR register.

#### Bit 7 Reserved, must be kept at reset value.
Bit 6 **PRERRF**: Synchronization error raw interrupt status for the parallel interface.
- 0: No synchronization error detected
- 1: Embedded synchronization characters are not received in the correct order.
  This bit is valid only in the embedded synchronization mode. It is cleared by writing 1 to the CPRERRRF bit in the DCMIPP_CMFCR register.
  This bit is available only in embedded synchronization mode.

Bit 5 **ATXERRF**: AXI transfer error interrupt status flag for the IP-Plug.
- 0: No AXI transfer error detected
- 1: AXI transfer error occurred on an AXI client. This bit signals an error on a client without any specific hardware action, the software must handle the situation (normally used when debugging software application code).
  This bit is cleared by writing 1 to CATXERRRF bit in the DCMIPP_CMFCR register.

Bits 4:0 Reserved, must be kept at reset value.

## 31.10.19 DCMIPP common interrupt clear register (DCMIPP_CMFCR)

Address offset: 0x3FC

Reset value: 0x0000 0000

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 Reserved, must be kept at reset value.

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 Reserved, must be kept at reset value.

Bits 19:16 Reserved, must be kept at reset value.

Bit 15 **CP0OVRF**: Overrun interrupt status clear
- Writing 1 into this bit clears the P0OVRF bit in the DCMIPP_CMSR2 register

Bit 14 **CP0LIMITF**: limit interrupt status clear
- Writing 1 into this bit clears P0LIMITF in the DCMIPP_CMSR2 register

Bits 13:11 Reserved, must be kept at reset value.

Bit 10 **CP0VSYNCF**: Vertical synchronization interrupt status clear
- Writing 1 into this bit clears the P0VSYNCF bit in the DCMIPP_CMSR2 register.

Bit 9 **CP0FRAMEF**: Frame capture complete interrupt status clear
- Writing 1 into this bit clears the P0FRAMEF bit in the DCMIPP_CMSR2 register.
Bit 8 **CP0LINEF**: Multi-line capture complete interrupt status clear
Writing 1 into this bit clears P0LINEF in the DCMIPP_CMSR2 register.

Bit 7 **Reserved**, must be kept at reset value.

Bit 6 **CPRERRF**: Synchronization error interrupt status clear
Writing 1 into this bit clears the PRERRF bit in the DCMIPP_CMSR2 register.
This bit is available only in embedded synchronization mode.

Bit 5 **CATXERRF**: AXI transfer error interrupt status clear
Writing 1 into this bit clears the ATXERRF bit in the DCMIPP_CMSR2 register.

Bits 4:0 **Reserved**, must be kept at reset value.

### 31.10.20 DCMIPP Pipe0 flow selection configuration register
(DCMIPP_P0FSCR)

Address offset: 0x404

</tbody>
</table>

**Bits 31:4**: Reserved, must be kept at reset value.
Bit 3 CPTREQ: Capture requested
- 0: Capture not requested for next frame
- 1: Capture requested for next frame
When PIPEN = 1 and CPTREQ = 1, the pipe waits for the first VSync, automatically starts a capture, and sets CPTACT = 1 to mention it.
In Snapshot mode the CPTREQ bit is cleared at the start of the first received frame.
In Continuous grab mode, the capture remains active and CPTREQ = 1 until the software clears CPTREQ: the capture stops and CPTACT is reset at the end of the ongoing frame.
The DCMI and pipe configuration registers must be correctly programmed before enabling this bit.

Bit 2 CPTMODE: Capture mode
- 0: Continuous grab mode - The received data are transferred into the destination memory through the AXI master.
- 1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame, and then transfers a single frame through the AXI master. At the end of the frame, the CPTACT bit is automatically reset.

Bits 1:0 FRATE[1:0]: Frame capture rate control
These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode, ignored in Snapshot mode.
- 00: All frames are captured
- 01: one out of two frames captured (50% bandwidth reduction)
- 10: one out of four frames captured (75% bandwidth reduction)
- 11: one out of eight frames captured (87% bandwidth reduction)

31.10.22 DCMIPP Pipe0 statistic/crop start register (DCMIPP_P0SCSTR)
Address offset: 0x504
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:28 Reserved, must be kept at reset value.
Bits 27:16 VSTART[11:0]: Vertical start, from 0 to 4094 pixels high
Bits 15:12 Reserved, must be kept at reset value.
Bits 11:0 HSTART[11:0]: Horizontal start, from 0 to 4094 words wide

31.10.23 DCMIPP Pipe0 statistic/crop size register (DCMIPP_P0SCSZR)
Address offset: 0x508
Reset value: 0x0000 0000
Bit 31 **ENABLE**:  
This bit is set and cleared by software.  
0: Bypass. All the data are computed, if the statistic data are sent within the frame, they are sent to the processing pipe as pixels data.  
1: Enable. Depending on bit POSNEG value, the rectangle defined by VSIZE, HSIZE, VSTART and HSTART can be used to extract or to remove some data (statistical extraction or removal, or basic 2D crop features).  
if POSNEG = 0, the data inside the rectangle area are transmitted (it can correspond to a statistical data removal, or as a crop feature in a data valid image area).  
if POSNEG = 1, the data outside of the rectangle area are transmitted (it can correspond to a statistical data extraction, rejecting all data inside the window).  
This bit must be kept cleared if the input format is JPEG, to avoid unpredictable behavior of the pipe.

Bit 30 **POSNEG**:  
This bit is set and cleared by software. It has a meaning only if ENABLE bit is set.  
0: Positive area, the rectangle defined by VSIZE, HSIZE, and VSTART, HSTART  
1: Negative area, the area excluding the rectangle defined by VSIZE, HSIZE, and VSTART, HSTART

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:16 **VSIZE[11:0]**: Vertical size, from 0 to 4094 pixels high  
If the value is maintained at 0 when enabling the crop by means of ENABLE bit, the crop operation is not performed on vertical direction.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSIZE[11:0]**: Horizontal size, from 0 to 4094 word wide (data 32-bit)  
If the value is maintained at 0 when enabling the crop by means of ENABLE bit, the crop operation is not performed on horizontal direction.

</table>

Bits 31:26 Reserved, must be kept at reset value.
Bits 25:0 **CNT[25:0]**: Number of data dumped during the frame. The size of the data is expressed in bytes. It counts only the data selected by means of the CROP 2D function. The counter saturates at 0x3FFFFFF. Granularity is 32-bit for all the formats except for the byte stream formats (for example JPEG) having byte granularity.

### 31.10.25 DCMIPP Pipe0 dump limit register (DCMIPP_P0DCLMTR)

Address offset: 0x5B4
Reset value: 0x00FF FFFF

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>ENABLE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0: Disabled, no check on the amount of 32-bit words transmitted</td>
</tr>
<tr>
<td></td>
<td>1: Enabled, check done versus limit</td>
</tr>
</tbody>
</table>

Bits 30:24 Reserved, must be kept at reset value.

Bits 23:0 **LIMIT[23:0]**: Maximum number of 32-bit data that can be dumped during a frame, after the crop 2D operation.

### 31.10.26 DCMIPP Pipe0 pixel packer configuration register (DCMIPP_P0PPCR)

Address offset: 0x5C0
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:17</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 16</td>
<td><strong>DBM:</strong> Double buffer mode</td>
</tr>
<tr>
<td></td>
<td>This bit is set and cleared by software.</td>
</tr>
<tr>
<td></td>
<td>0: No double buffer mode activated. Pipe0 always dumps to memory address set by DCMIPP_P0PPM0AR1.</td>
</tr>
<tr>
<td></td>
<td>1: Double buffer mode activated. Dump address location switches from DCMIPP_P0PPM0AR1 to DCMIPP_P0PPM0AR2 alternatively on each frame.</td>
</tr>
</tbody>
</table>
Bits 15:13 **LINEMULT[2:0]**: Amount of capture completed lines for LINE event and interrupt
- 0x0: Event after one line
- 0x1: Event after two lines
- 0x2: Event after four lines
- 0x3: Event after eight lines
- 0x4: Event after sixteen lines
- 0x5: Event after 32 lines
- 0x6: Event after 64 lines
- 0x7: Event after 128 lines

Bit 12 Reserved, must be kept at reset value.

Bit 11 **OELS**: Odd/even line select (line select start)
This bit works in conjunction with LSM field (LSM = 1).
- 0: Interface captures first line after the frame start, second one is dropped
- 1: Interface captures second line from the frame start, first one is dropped

Bit 10 **LSM**: Line select mode
- 0: Interface captures all received lines
- 1: Interface captures one line out of two

Bit 9 **OEBLS**: Odd/even byte select (byte select start)
This bit works in conjunction with BSM field (BSM ≠ 00)
- 0: Interface captures the first data (byte or double byte) from the frame/line start, the second one is dropped
- 1: Interface captures the second data (byte or double byte) from the frame/line start, the first one is dropped

Bits 8:7 **BSM[1:0]**: Byte select mode
- 00: Interface captures all received data
- 01: Interface captures 1 data out of 2
- 10: Interface captures one byte out of four
- 11: Interface captures two bytes out of four

Modes 10 and 11 work only with EDM [2:0] = 000 into the DCMIPP_PRCR register.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **PAD**: Pad mode for monochrome and raw Bayer 10/12/14 bpp (MSB vs. LSB alignment)
- 0: Aligns on LSB (and pads null bits on MSB), for backward compatibility with former DCMI.
- 1: Aligns on MSB (and pads null bits on LSB), for better ease of software or GPU.

Bits 4:0 Reserved, must be kept at reset value.

**31.10.27 DCMIPP Pipe0 pixel packer Memory0 address register 1**

Bits 31:0  **M0A[31:0]: Memory0 address**  
Base address of memory area 0, to whom data are written. It is assumed to be a multiple of 16, hence its bits 3:0 are always at 0x0.

Bits 31:8  **Reserved, must be kept at reset value.**

Bit 7  **OVRIE**: Overrun interrupt enable  
0: No interrupt generation  
1: An interrupt is generated if the AXI master is unable to transfer the last data before new data (32-bit) are received.
Bit 6 **LIMITIE:** Limit interrupt enable
   0: No interrupt generation when the limit is reached
   1: An interrupt is generated when the limit is reached

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **VSYNCE:** VSYNC interrupt enable
   0: No interrupt generation
   1: An interrupt is generated on each VSYNC (captured or not)

Bit 1 **FRAMEIE:** Frame capture completed interrupt enable
   0: No interrupt generation
   1: An interrupt is generated after the full capture of a cropped frame

Bit 0 **LINEIE:** Multi-line capture completed interrupt enable
   0: No interrupt generation when the line is received
   1: An interrupt is generated after the full capture of a group of lines (or last line reached)

### 31.10.30 DCMIPP Pipe0 status register (DCMIPP_P0SR)

</tbody>
</table>

**Bit 23 CPTACT:** Capture immediate status
   0: Capture currently inactive
   1: Capture currently active
   This bit is automatically reset at the end of frame capture complete event (after all the data of that frame have been captured and the IP-Plug has started to emit the last burst on the AXI, usually before the next VSync).

**Bits 22:17 Reserved, must be kept at reset value.**

**Bits 16:8 Reserved, must be kept at reset value.**

**Bit 7 OVRF:** Overrun raw interrupt status
   0: No data buffer overrun occurred
   1: A data buffer overrun occurred and this frame data are corrupted
   This bit is cleared by writing 1 to the COVRF bit in the DCMIPP_P0FCR register.

**Bit 6 LIMITF:** Limit raw interrupt status
   This bit is set when the data counter DCMIPP_PxDCNTR reaches its maximum value DCMIPP_PxDCLIMITR.
   It is cleared by writing 1 to the CLIMITF bit in the DCMIPP_P0FCR register.

**Bits 5:3 Reserved, must be kept at reset value.**
31.10.31  DCMIPP Pipe0 interrupt clear register (DCMIPP_P0FCR)

Bits 31:8  Reserved, must be kept at reset value.

Bit 7  COVRF: Overrun interrupt status clear
Writing 1 into this bit clears the OVRF bit in the DCMIPP_P0SR register.

Bit 6  CLIMITF: Limit interrupt status clear
Writing 1 into this bit clears LIMITF in the DCMIPP_P0SR register.

Bits 5:3  Reserved, must be kept at reset value.

Bit 2  CVSYNCF: Vertical synchronization interrupt status clear
Writing 1 into this bit clears the VSYNC bit in the DCMIPP_P0SR register.

Bit 1  FRAMEF: Frame capture complete interrupt status clear
Writing 1 into this bit clears the FRAMEF bit in the DCMIPP_P0SR register.

Bit 0  CLINEF: Multi-line capture complete interrupt status clear
Writing 1 into this bit clears LINEF in the DCMIPP_P0SR register.
31.10.32  DCMIPP Pipe0 current flow control configuration register  
(DCMIPP_P0CFCTCR)

Bit 3 CPTREQ: Capture requested
0: Capture not requested for next frame.
1: Capture requested for next frame.
When PIPEN = 1, and when the CPTREQ is set to 1 the pipe waits for the first VSync, and automatically starts a capture and sets CPTACT = 1 to mention it.
In Snapshot mode the CPTREQ bit is automatically cleared at the start of the first frame received.
In continuous grab mode the capture remains active and CPTREQ = 1, until the software clears CPTREQ: the capture stops and CPTACT is reset at the end of the ongoing frame.
The DCMI and pipe configuration registers must be correctly programmed before enabling this bit.

Bit 2 CPTMODE: Capture mode
0: Continuous grab mode - The received data are transferred into the destination memory through the AXI master.
1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame, and then transfers a single frame through the AXI master. At the end of the frame the CPTACT bit is automatically reset.

Bits 1:0 FRATE[1:0]: Frame capture rate control
These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode, ignored in Snapshot mode.
00: all frames are captured
01: one out of two frames captured (50% bandwidth reduction)
10: one out of four frames captured (75% bandwidth reduction)
11: one out of eight frames captured (87% bandwidth reduction)

Reset value: 0x0000 0000

Bit 31 ENABLE: Current value of the ENABLE bit
0: Bypass. All data are computed, if the statistics data are sent within the frame, they are sent to the processing pipe as pixels data.
1: Enable: Depending on bit POSNEG value, the rectangle defined by the VSIZE, HSIZE, VSTART, HSTART can be used to extract or to remove certain amount of data (statistical extraction or removal, or basic 2D crop features)
if POSNEG = 0, the data inside the rectangle area are transmitted (can correspond to a statistical data removal, or as a crop feature in a data valid image area).
if POSNEG = 1, the data outside of the rectangle area are transmitted (can correspond to a statistical data extraction, rejecting all data inside the window).

Bit 30 POSNEG: Current value of the POSNEG bit
This bit has a meaning only if ENABLE bit is set.
0: Positive area. The rectangle defined by VSIZE, HSIZE, and VSTART, HSTART is the active area.
1: Negative area. The active area is the area excluding the rectangle defined by VSIZE, HSIZE, and VSTART, HSTART.

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:16 VSIZE[11:0]: Current vertical size, from 0 to 4094 pixels high.
If the value is maintained at 0 when enabling the crop by means of the ENABLE bit, the value is forced internally at 0xFFE which is the maximum value.

Bits 15:12 Reserved, must be kept at reset value.
31.10.35 DCMIPP Pipe0 current pixel packer configuration register (DCMIPP_P0CPPPCR)

Address offset: 0x7C0
Reset value: 0x0000 0000

</table>

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **DBM**: Double buffer mode
- 0: No double buffer mode activated. Pipe0 is always dump to memory address set by DCMIPP_P0PPM0AR1 register
- 1: Double buffer mode activated. Dump address location switches from DCMIPP_P0PPM0AR1 register to DCMIPP_P0PPM0AR2 register alternatively on each frame.

Bits 15:13 **LINEMULT[2:0]**: Current amount of capture completed lines for LINE event and interrupt
- 0x0: Event after every line
- 0x1: Event after two lines
- 0x2: Event after four lines
- 0x3: Event after eight lines
- 0x4: Event after sixteen lines
- 0x5: Event after 32 lines
- 0x6: Event after 64 lines
- 0x7: Event after 128 lines

Bit 12 Reserved, must be kept at reset value.

Bit 11 **OELS**: Current odd/even line select (line select start)
This bit works in conjunction with LSM field (LSM = 1)
- 0: Interface captures the first line after the frame start, the second one is dropped
- 1: Interface captures the second line from the frame start, the first one is dropped

Bit 10 **LSM**: Current Line select mode
- 0: Interface captures all received lines
- 1: Interface captures one line out of two

Bit 9 **OEBs**: Current odd/even byte select (byte select start)
This bit works in conjunction with BSM field (BSM ≠ 00)
- 0: Interface captures the first data (byte or double byte) from the frame/line start, the second one is dropped
- 1: Interface captures the second data (byte or double byte) from the frame/line start, the first one is dropped
Bits 8:7  **BSM[1:0]**: Current Byte select mode
00: Interface captures all received data
01: Interface captures one data out of two
10: Interface captures one byte out of four
11: Interface captures two bytes out of four
Modes 10 and 11 work only with EDM [2:0] = 000 into the DCMIPP_PRCR register.

Bit 6  Reserved, must be kept at reset value.

Bit 5  **PAD**: Current Pad mode for monochrome and raw Bayer 10/12/14 bpp (MSB vs. LSB alignment)
0: Aligns on LSB (and pads null bits on MSB), for backward compatibility with former DCMI
1: Aligns on MSB (and pads null bits on LSB), for better ease of software or GPU

Bits 4:0  Reserved, must be kept at reset value.

Table 298. DCMIPP register map and reset values (continued)
32 Parallel synchronous slave interface (PSSI)

32.1 Introduction

The PSSI is a generic synchronous 8/16-bit parallel data input/output slave interface. It enables the transmitter to send a data valid signal that indicates when the data is valid, and the receiver to output a flow control signal that indicates when it is ready to sample the data.

32.2 PSSI main features

The PSSI peripheral main features are the following:
- Slave mode operation
- 8-bit or 16-bit parallel data input or output
- 8-word (32-byte) FIFO
- Data enable (PSSI_DE) and Ready (PSSI_RDY) alternate function
  When selected, these signals can either enable the transmitter to indicate when the data is valid, allow the receiver to indicate when it is ready to sample the data, or both.
- Clock out mode

32.3 PSSI functional description

The PSSI is a synchronous parallel slave interface that can send or receive high-speed data flows. It consists of up to 16 data lines (PSSI_D[15:0]) plus a clock line (PSSI_PDCK). The clock polarity can be configured so that data can be captured or transmitted on either the clock rising or falling edge.

Usually, a general-purpose DMA channel is used to pass 32-bit packed data via the data register (PSSI_DR).

The data flow can either be continuous or synchronized by hardware using the optional PSSI_DE (Data enable), and PSSI_RDY (Ready) signals.

*Figure 336* shows the PSSI block diagram.
32.3.1 PSSI block diagram

The PSSI interface is composed of 19 pins, though nine signals are enough to transfer parallel data. *Table 299* shows the PSSI pins.

### Table 299. PSSI input/output pins

32.3.2 PSSI pins and internal signals

*Figure 336. PSSI block diagram*

*Figure 337. Top-level block diagram*
32.3.3 **PSSI clock**

The AHB clock frequency must be at least 2.5 times higher than the PSSI_PDCK frequency. At frequency ratios lower than 2.5, data might be corrupted or lost during transfers.

Data transfers are synchronous with PSSI_PDCK. The PSSI_PDCK polarity can be configured as follows, through CKPOL bit (bit 5 of PSSI_CR):

- When CKPOL = 0
  - Input pins are sampled on PSSI_PDCK falling edge
  - Output pins are driven on PSSI_PDCK rising edge
- When CKPOL = 1
  - Input pins are sampled on PSSI_PDCK rising edge
  - Output pins are driven on PSSI_PDCK falling edge

The PSSI_PDCK can be configured in input mode (default) or in output mode. When configured in output mode, the clock is generated by the device RCC.

32.3.4 **PSSI data management**

**Data direction**

The direction of data transfers is configured through the OUTEN control bit (bit 31 of PSSI_CR):

- When OUTEN is cleared to 0 (default setting), the PSSI operates in receive mode and the data is input on the data pins.
- When OUTEN is set to 1, the peripheral operates in transmit mode and the data is output on the data pins.

OUTEN can be modified only when the ENABLE bit is cleared to 0.
Data register and DMA

Data are transferred from/to the FIFO using the PSSI_DR data register:
- In receive mode, data must be read from the FIFO by reading PSSI_DR.
- In transmit mode, data must be written to the FIFO by writing into PSSI_DR.

Word (32-bit) accesses to PSSI_DR and half-word (16-bit) accesses to PSSI_DR[15:0] are permitted in all modes. Byte (8-bit) accesses to PSSI_DR[7:0] are permitted only when the PSSI is configured to transfer 8 bits at a time (EDM=00 in the PSSI_CR register).

To reduce the load on the CPU, it is recommended to use the DMA to transfer data from/to the PSSI FIFO. When it is used, the DMA must be configured to transfer data via the PSSI_DR register. Using 32-bit transfers optimizes bandwidth and reduces the bus load. However, 8-bit and 16-bit transfers are also permitted.

To use the DMA, set the PSSI DMA enable bit (DMAEN in PSSI_CR) to 1 (default setting). When DMAEN is set to 1, a DMA transfer is initiated when the FIFO is ready for a 32-bit transfer (four valid bytes in receive mode or four empty bytes in transmit mode). As a result, in receive mode, no DMA transfers are initiated if there are three bytes or fewer in the FIFO, even if the DMA is configured to perform 8-bit transfers.

The RTT4B and RTT1B status bits (PSSI_SR) are useful when the CPU directly perform transfers to and from the FIFO. RTT4B set to 1 indicates that the FIFO is ready to transfer four bytes: at least four valid bytes in the FIFO in receive mode or at least four free bytes in transmit mode. RTT1B set to 1 indicates that the FIFO is ready to transfer one byte: at least one valid byte in the FIFO in receive mode or at least one free byte in transmit mode.

8-bit data

The PSSI parallel interface can transfer either 8-bit (using D[7:0]) or 16-bit data (using D[15:0]) depending on the EDM[1:0] control bits (bits 11:10 of PSSI_CR). If the 8-bit configuration is selected (EDM[1:0] set to 00), the unused D[15:0] pins can be used for GPIO or other functions.

When EDM[1:0] in PSSI_CR are programmed to 00, the interface transfers 8 bits using the D[7:0] pins. In this case, D[15:8] are not used and four PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant byte (bits 7:0) correspond to the first byte transferred, and the most-significant byte (bits 31:28) corresponds to the forth byte transferred. Table 301 illustrates the positioning of the data bytes in two 32-bit words.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>D_{n+3}[7:0]</td>
<td>D_{n+2}[7:0]</td>
<td>D_{n+1}[7:0]</td>
<td>D_{n}[7:0]</td>
</tr>
<tr>
<td>4</td>
<td>D_{n+7}[7:0]</td>
<td>D_{n+6}[7:0]</td>
<td>D_{n+5}[7:0]</td>
<td>D_{n+4}[7:0]</td>
</tr>
</tbody>
</table>
16-bit data

When EDM[1:0] in PSSI_CR are programmed to 11, the interface transfers 16 bits using the D[15:0] pins. In this case, two PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant half word (bits 15:0) correspond to the first half word transferred, and the most-significant half-word (bits 31:16) corresponds to the second half word transferred. Table 302 illustrates the positioning of the data in two 32-bit words.

<table>
<thead>
<tr>

<td>D_{n}[15:0]</td>
</tr>
<tr>
<td>4</td>
<td>D_{n+3}[15:0]</td>
<td>D_{n+2}[15:0]</td>
</tr>
</tbody>
</table>

FIFO data buffer and error conditions

An eight-word FIFO helps improving performance and avoids overruns and underruns.

If the ready signal (PSSI_RDY) is disabled in receive mode, an overrun error is generated when a clock active edge occurs when the FIFO is full. In this case, the input data is lost.

If the data enable signal (PSSI_DE) is disabled in transmit mode, an underrun error is generated when a clock active edge occurs when the FIFO is empty. In this case, unpredictable data are output.

The OVR_RIS status bit indicates that either an overrun or an underrun occurred. An interrupt can be generated when these events occur.

32.3.5 PSSI optional control signals

Data Enable (PSSI_DE) alternate function input

The data enable signal, PSSI_DE, is an optional signal. It is driven by the data source/transmitter in order to indicate that the data is valid to be transferred during the current cycle. When PSSI_DE is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG (bits 20:18 of PSSI_CR) control bits. PSSI_DE polarity is configured through DEPOL control bit (bit 6 of PSSI_CR). PSSI_DE is active low when DEPOL is cleared to 0, and high when DEPOL is set to 1.

The direction of the PSSI_DE signal is defined by the OUTEN value. It is the same as the data direction.

If the PSSI_DE alternate function input is enabled (through DERDYCFG) in receive mode (OUTEN cleared to 0), the PSSI samples PSSI_DE on the same PSSI_PDCK edge as the one used for sampling the data (D[15:0]). If PSSI_DE is active, the sampled data is saved in the FIFO. Otherwise, the sampled data is considered invalid and discarded. The transmitting device can use PSSI_DE as a data valid signal, driving it inactive when the data in the current cycle is not valid. This flow control function allows avoiding underrun errors.
If the PSSI_DE alternate output function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI drives PSSI_DE on the same PSSI_PDCK edge that the one used to drive the data (D[15:0]). If a new 8 or 16-bit data (as programmed in the EDM[1:0] control bits in PSSI_CR) is available for transmission in the internal FIFO, this data is output on the data outputs (D[15:0]) and the PSSI_DE output becomes active on the current PSSI_PDCK edge. Otherwise (if the TX FIFO is empty), the D[15:0] outputs remains unchanged on the next clock edge and the PSSI_DE output becomes inactive.

**Ready (PSSI_RDY) alternate function output**

The ready signal, PSSI_RDY, is an optional signal. It is driven by the receiving device and indicates whether data is being accepted in the current cycle. When PSSI_RDY is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG control bits (bits 20:18 of PSSI_CR). PSSI_RDY polarity is configured through the RDYPOL control bit (bit 6 of PSSI_CR). PSSI_RDY is active low when RDYPOL is cleared to 0, and high when RDYPOL set to 1.

The direction of the PSSI_RDY signal is defined by the OUTEN (bit 31 of PSSI_CR). It is set in the opposite direction compared to the PSSI_DE and data signals.

If the PSSI_RDY alternate output function is enabled (through DERDYCFG) in receive mode (OUTEN=0), the PSSI drives PSSI_RDY one PSSI_PDCK half cycle after it samples
the data (D[15:0]). If the FIFO has enough free space to receive more data, the PSSI drives the PSSI_RDY signal active. Otherwise, if the FIFO is full and cannot accept more data, the PSSI drives the PSSI_RDY signal inactive. The transmitting device must repeat the current data in the next cycle when it detects that PSSI_RDY is inactive. This flow control function allows the PSSI to avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

![Figure 340. Ready in receive mode waveform diagram (CKPOL=0)](image)

If the PSSI_RDY alternate input function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI samples the PSSI_RDY signal on the opposite PSSI_PDCK edge to the one at which D[15:0] are driven. If the PSSI_RDY signal is inactive, the PSSI keeps the same data (D[15:0]) and PSSI_DE signals that valid data are available during the next PSSI_PDCK clock cycle. Otherwise, if PSSI_RDY signal is sampled as active, the next data from the TX FIFO (if available) is output on the data outputs (D[15:0]). If no new data are available in the TX FIFO, the PSSI keeps the data output values and outputs the PSSI_DE signal as inactive (if enabled).

The receiving device uses the PSSI_RDY to control the data flow and avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

**Bidirectional PSSI_DE/PSSI_RDY signal**

A single pin can be used for both data enable (PSSI_DE) and ready (PSSI_RDY) functions if DEPOL and RDYPOL are both set to 1 and DERDYCFG is set to 111 or 100 in the PSSI_CR register. In this case, the GPIO corresponding to selected alternate function (PSSI_DE when DERDYCFG=111 or PSSI_RDY when DERDYCFG=100) must be configured as open-drain. The other device must also be configured to drive the line as open-drain, and a weak pull-up must be applied to the line.

The signal thus becomes bidirectional. If either the sender drives the line low (to indicate that the data is not valid) or the receiver drives the line low (to indicate that it is not sampling the current data), then both devices know that the data is not being transferred in the current cycle.
32.4 PSSI interrupts

The PSSI generates only one interrupt (IT_OVR). It is consequently equivalent to the global interrupt (pssi_it). Refer to Table 303 for the list of interrupts.

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>

<tr>
<td>IT_OVR</td>
<td>indicates overrun in receive mode or underrun in transmit mode</td>
<td>OVR_RIS</td>
<td>OVR_IE</td>
<td>OVR_ISC</td>
<td>NA</td>
</tr>
</tbody>
</table>

32.5 PSSI registers

An 8-bit write or a 16-bit write operation to any PSSI register besides PSSI_DR, results in a bus error. 32-bit read and write operations are permitted.

32.5.1 PSSI control register (PSSI_CR)

Address offset: 0x00
Parallel synchronous slave interface (PSSI)

Reset value: 0x4000 0000

<table>
<thead>
<tr>

<td>Both PSSI_RDY and PSSI_DE features enabled - bidirectional on PSSI_DE pin (see Bidirectional PSSI_DE/PSSI_RDY signal on page 1367)</td>
</tr>
</tbody>
</table>

When the PSSI_RDY function is mapped to the PSSI_DE pin (settings 101 or 111), it is still the RDYPOL bit which determines its polarity. Similarly, when the PSSI_DE function is mapped to the PSSI_RDY pin (settings 110 or 111), it is still the DEPOL bit which determines its polarity.

| Bits 17:15 | Reserved, must be kept at reset value. |

<table>
<thead>

<th>ENABLE: PSSI enable</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>PSSI disabled</td>
</tr>
<tr>
<td>1</td>
<td>PSSI enabled</td>
</tr>
</tbody>
</table>

The contents of the FiFO are flushed when ENABLE is cleared to 0.

**Note:** When ENABLE=1, the content of PSSI_CR must not be changed, except for the ENABLE bit itself. All configuration bits can change as soon as ENABLE changes from 0 to 1.

The DMA controller and all PSSI configuration registers must be programmed correctly before setting the ENABLE bit to 1.

- This bit indicates the level on the PSSI_DE pin when the data are not valid on the parallel interface.
- 0: PSSI_DE active low (0 indicates that data is valid)
- 1: PSSI_DE active high (1 indicates that data is valid)

**Bit 5** **CKPOL:** Parallel data clock polarity
- This bit configures the capture edge of the parallel clock or the edge used for driving outputs, depending on OUTEN.
- 0: Falling edge active for inputs or rising edge active for outputs
- 1: Rising edge active for inputs or falling edge active for outputs

**Bits 4:0** Reserved, must be kept at reset value.
32.5.3 **PSSI raw interrupt status register (PSSI_RIS)**

Address offset: 0x08

Reset value: 0x0000 0000

PSSI_RIS gives the raw interrupt status. This register is read-only. When read, it returns the status of the corresponding interrupt before masking with the PSSI_IER register value.

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_RIS**: Data buffer overrun/underrun raw interrupt status

0: No overrun/underrun occurred
1: An overrun/underrun occurred: overrun in receive mode, underrun in transmit mode.

This bit is cleared by writing a 1 to the OVR_ISC bit in PSSI_ICR.

Bit 0 Reserved, must be kept at reset value.
### 32.5.4 PSSI interrupt enable register (PSSI_IER)

Address offset: 0x0C

Reset value: 0x0000 0000

The PSSI_IER register is used to enable interrupts. When one of the PSSI_IER bits is set, the corresponding interrupt is enabled. This register is accessible both in read and write modes.

<table>
<thead>
<tr>
<th>Bit 31:2</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 1</td>
<td><strong>OVR_IE</strong>: Data buffer overrun/underrun interrupt enable</td>
</tr>
<tr>
<td>0</td>
<td>No interrupt generation</td>
</tr>
<tr>
<td>1</td>
<td>An interrupt is generated if either an overrun or an underrun error occurred.</td>
</tr>
</tbody>
</table>

| Bit 0    | Reserved, must be kept at reset value. |

### 32.5.5 PSSI masked interrupt status register (PSSI_MIS)

This PSSI_MIS register is read-only. When read, it returns the current masked status value of the corresponding interrupt (depending on the value in PSSI_IER). A bit in this register is set if the corresponding enable bit in PSSI_IER is set and the corresponding bit in PSSI_RIS is set.

Address offset: 0x10

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:2</th>

<td>An interrupt is generated if there is either an overrun or an underrun error and the OVR_IE bit is set in PSSI_IER.</td>
</tr>
</tbody>
</table>

| Bit 0    | Reserved, must be kept at reset value. |
32.5.6 PSSI interrupt clear register (PSSI_ICR)

Address offset: 0x14
Reset value: 0x0000 0000

The PSSI_ICR register is write-only. Writing a 1 into a bit of this register clears the corresponding bit in the PSSI_RIS and PSSI_MIS registers. Writing a 0 has no effect. Reading this register always gives zeros.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_ISC**: Data buffer overrun/underrun interrupt status clear
   Writing this bit to 1 clears the OVR_RIS bit in PSSI_RIS.

Bit 0 Reserved, must be kept at reset value.

32.5.7 PSSI data register (PSSI_DR)

Address offset: 0x28
Reset value: 0x0000 0000

In receive mode (OUTEN = 0), the DMA controller must read the received data from this register. Write operations to PSSI_DR result in an error response. When more bytes than the number of valid bytes are read in the FIFO, the invalid bytes return zeros.

In transmit mode (OUTEN = 1), the DMA controller must write the data to be transmitted into this register. Read operations to PSSI_DR result in an error response.

32-bit, 16-bit, and 8-bit accesses are all supported for PSSI_DR. For instance, 16-bit read/write operations remove/add two bytes from/to the FIFO. However, 8-bit accesses are permitted only when the PSSI is configured to transfer 8 data bits at a time (EDM=00 in PSSI_CR). 8-bit accesses to PSSI_DR when EDM is not set to 0 result in an error response.

All accesses must include byte 0: 8-bit accesses must be performed to bits 7 to 0 and 16-bit accesses from bits 15 to 0. Accesses that do not include byte 0 results in an error response.

Accessing PSSI_DR when ENABLE bit in PSSI_CR is set to 0 results in an error response.
32.5.8 PSSI register map

Table 304. PSSI register map and reset values

| Offset | Register name reset value | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Refer to Section 2.3 for the register boundary addresses.
33 LCD-TFT display controller (LTDC)

33.1 Introduction

The LCD-TFT (liquid crystal display - thin film transistor) display controller provides a parallel digital RGB (red, green, blue) and signals for horizontal, vertical synchronization, pixel clock and data enable as output to interface directly to a variety of LCD and TFT panels.

33.2 LTDC main features

- 24-bit RGB parallel pixel output; 8 bits-per-pixel (RGB888)
- 2 display layers with dedicated FIFO (64x64-bit)
- Color look-up table (CLUT) up to 256 color (256x24-bit) per layer
- Programmable timings for different display panels
- Programmable background color
- Programmable polarity for HSYNC, VSYNC and data enable
- Up to 8 input color formats selectable per layer:
  - ARGB8888
  - RGB888
  - RGB565
  - ARGB1555
  - ARGB4444
  - L8 (8-bit luminance or CLUT)
  - AL44 (4-bit alpha + 4-bit luminance)
  - AL88 (8-bit alpha + 8-bit luminance)
- Pseudo-random dithering output for low bits per channel
  - Dither width 2 bits for red, green, blue
- Flexible blending between two layers using alpha value (per pixel or constant)
- Color keying (transparency color)
- Programmable window position and size
- Supports thin film transistor (TFT) color displays
- AXI master interface with burst of 16 double-words
- Up to 4 programmable interrupt events
33.3 LTDC functional description

33.3.1 LTDC block diagram

Figure 343. LTDC block diagram

33.3.2 LTDC pins and internal signals

The table below summarizes the LTDC signal interface.

<table>
<thead>
<tr>
<th>LCD-TFT signals</th>
<th>Signal type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LCD_CLK</td>
<td>Output</td>
<td>Clock output</td>

<td>8-bit Green data</td>
</tr>
<tr>
<td>LCD_B[7:0]</td>
<td>Output</td>
<td>8-bit Blue data</td>
</tr>
</tbody>
</table>

The LTDC pins must be configured by the user application. The unused pins can be used for other purposes.

For LTDC outputs up to 24 bits (RGB888), if less than 8 bpp are used to output for example RGB565 or RGB666 to interface on 16- or 18-bit displays, the RGB display data lines must be connected to the MSB of the LTDC RGB data lines.

As an example, in the case of an LTDC interfacing with a RGB565 16-bit display, the LTDC display R[4:0], G[5:0] and B[4:0] data lines pins must be connected to the LCD_R[7:3], LCD_G[7:2] and LCD_B[7:3] pins.
The internal signals of the LTDC are given in the table below.

#### 33.3.3 LTDC reset and clocks

The LTDC controller peripheral uses the following clock domains:
- **AXI clock domain (ltdc_aclk)**
  This domain contains the LTDC AXI master interface for data transfer from the memories to the layer FIFO and the frame-buffer configuration register.
- **APB clock domain (ltdc_pclk)**
  This domain contains the global configuration registers and the interrupt register.
- **Pixel clock domain (LCD_CLK)**
  This domain contains the pixel data generation, the layer configuration register as well as the LTDC interface signal generator. The LCD_CLK output must be configured following the panel requirements. The LCD_CLK is generated from a specific PLL output (refer to the reset and clock control section).

The table below summarizes the clock domain for each register.

### Table 308. Clock domain for each register

<table>
<thead>
<tr>
<th>LTDC register</th>
<th>Clock domain</th>

</table>

The LTDC controller can be reset by setting the corresponding bit in the RCC. It resets the three clock domains.
33.4 **LTDC programmable parameters**

The LTDC controller provides flexible configurable parameters. It can be enabled or disabled through the LTDC_GCR register.

33.4.1 **LTDC global configuration parameters**

**Synchronous timings**

The figure below presents the configurable timing parameters generated by the synchronous timings generator block presented in the block diagram *Figure 343*. It generates the horizontal and vertical synchronization timings panel signals, the pixel clock and the data enable signals.

*Figure 344. LTDC synchronous timings*

The LTDC programmable synchronous timings are the following:

- **HSYNC and VSYNC width**: horizontal and vertical synchronization width, configured by programming a value of HSYNC width - 1 and VSYNC width - 1 in the LTDC_SSCR register
- **HBP and VBP**: horizontal and vertical synchronization back porch width, configured by programming the accumulated value HSYNC width + HBP - 1 and the accumulated value VSYNC width + VBP - 1 in the LTDC_BPCR register.
- **Active width and active height**: the active width and active height are configured by programming the accumulated value HSYNC width + HBP + active width - 1 and the
accumulated value VSYNC width + VBP + active height - 1 in the LTDC_AWCR register.

- Total width: the total width is configured by programming the accumulated value HSYNC width + HBP + active width + HFP - 1 in the LTDC_TWCR register. The HFP is the horizontal front porch period.
- Total height: the total height is configured by programming the accumulated value VSYNC height + VBP + active height + VFP - 1 in the LTDC_TWCR register. The VFP is the vertical front porch period.

Note: When the LTDC is enabled, the timings generated start with X/Y = 0/0 position as the first horizontal synchronization pixel in the vertical synchronization area and following the back porch, active data display area and the front porch.
When the LTDC is disabled, the timing generator block is reset to X = total width - 1, Y = total height - 1 and held the last pixel before the vertical synchronization phase and the FIFO are flushed. Therefore only blanking data is output continuously.

Example of synchronous timings configuration

LTDC timings (must be extracted from panel datasheet):
- horizontal and vertical synchronization width: 0xA pixels and 0x2 lines
- horizontal and vertical back porch: 0x14 pixels and 0x2 lines
- active width and active height: 0x140 pixels, 0xF0 lines (320x240)
- horizontal front porch: 0xA pixels
- vertical front porch: 0x4 lines

The programmed values in the LTDC timings registers are:
- LTDC_SSCR register to be programmed to 0x00090001 (HSW[11:0] is 0x9 and VSH[10:0] is 0x1)
- LTDC_BPCR register to be programmed to 0x001D0003 (AHBP[11:0] is 0x1D (0xA+ 0x13) and AVBP[10:0]A is 0x3 (0x2 + 0x1))
- LTDC_AWCR register to be programmed to 0x015D00F3 (AAW[11:0] is 0x15D (0xA +0x14 +0x13F) and AAH[10:0] is 0xF3 (0x2 + 0x2 + 0xEF))
- LTDC_TWCR register to be programmed to 0x000000167 (TOTALW[11:0] is 0x167 (0xA +0x14 +0x140 + 0x9))
- LTDC_THCR register to be programmed to 0x000000F7 (TOTALH[10:0]is 0xF7 (0x2 +0x2 + 0xF0 + 3))

Programmable polarity

The horizontal and vertical synchronization, data enable and pixel clock output signals polarity can be programmed to active high or active low through the LTDC_GCR register.

Background color

A constant background color (RGB888) can programmed through the LTDC_BCCR register. It is used for blending with the bottom layer.

Dithering

The dithering pseudo-random technique using an LFSR is used to add a small random value (threshold) to each pixel color channel (R, G or B) value, thus rounding up the MSB in
some cases when displaying a 24-bit data on 18-bit display. Thus the dithering technique is used to round data which is different from one frame to the other.

The dithering pseudo-random technique is the same as comparing LSBs against a threshold value and adding a 1 to the MSB part only, if the LSB part is ≥ the threshold. The LSBs are typically dropped once dithering was applied.

The width of the added pseudo-random value is two bits for each color channel: two bits for red, two bits for green and two bits for blue.

Once the LTDC is enabled, the LFSR starts running with the first active pixel and it is kept running even during blanking periods and when dithering is switched off. If the LTDC is disabled, the LFSR is reset.

The dithering can be switched on and off on the fly through the LTDC_GCR register.

**Reload shadow registers**

Some configuration registers are shadowed. The shadow registers values can be reloaded immediately to the active registers when writing to these registers or at the beginning of the vertical blanking period following the configuration in the LTDC_SRCR register. If the immediate reload configuration is selected, the reload must be activated only when all new registers have been written.

The shadow registers must not be modified again before the reload is done. Reading from the shadow registers returns the actual active value. The new written value can only be read after the reload has taken place.

A register reload interrupt can be generated if enabled in the LTDC_IER register.

The shadowed registers are all Layer1 and Layer2 registers except LTDC_LxCLUTWR.

**Interrupt generation event**

Refer to [Section 33.5: LTDC interrupts](#) for the interrupt configuration.

### 33.4.2 Layer programmable parameters

Up to two layers can be enabled, disabled and configured separately. The layer display order is fixed and it is bottom up. If two layers are enabled, the layer2 is the top displayed window.

**Windowing**

Every layer can be positioned and resized and it must be inside the active display area.

The window position and size are configured through the top-left and bottom-right X/Y positions and the internal timing generator that includes the synchronous, back porch size and the active data area. Refer to LTDC_LxWHPCR and LTDC_WVPCR registers.

The programmable layer position and size defines the first/last visible pixel of a line and the first/last visible line in the window. It allows to display either the full image frame or only a part of the image frame (see [Figure 345](#)):

- The first and the last visible pixel in the layer are set by configuring the WHSTPOS[11:0] and WHSPPOS[11:0] in the LTDC_LxWHPCR register.
- The first and the last visible lines in the layer are set by configuring the WVSTPOS[10:0] and WVSPPOS[10:0] in the LTDC_LxWVPCR register.
Pixel input format

The programmable pixel format is used for the data stored in the frame buffer of a layer. Up to eight input pixel formats can be configured for every layer through the LTDC_LxPFCR register.

The pixel data is read from the frame buffer and then transformed to the internal 8888 (ARGB) format as follows: components having a width of less than 8 bits get expanded to 8 bits by bit replication. The selected bit range is concatenated multiple times until it is longer than 8 bits. Of the resulting vector, the 8 MSB bits are chosen. Example: 5 bits of an RGB565 red channel become (bit positions) 43210432 (the three LSBs are filled with the three MSBs of the five bits).

The table below describes the pixel data mapping depending on the selected format.

Table 310. Pixel data mapping versus color format

</table>
The CLUT can be enabled at run-time for every layer through the LTDC_LxCR register and it is only useful in case of indexed color when using the L8, AL44 and AL88 input pixel format.

First, the CLUT must be loaded with the R, G and B values that replace the original R, G, B values of that pixel (indexed color). Each color (RGB value) has its own address that is the position within the CLUT.

The R, G and B values and their own respective address are programmed through the LTDC_LxCLUTWR register:
- In case of L8 and AL88 input pixel format, the CLUT must be loaded by 256 colors. The address of each color is configured in the CLUTADD bits in the LTDC_LxCLUTWR register.

### Table 310. Pixel data mapping versus color format (continued)

</tbody>
</table>

**Color look-up table (CLUT)**

The CLUT can be enabled at run-time for every layer through the LTDC_LxCR register and it is only useful in case of indexed color when using the L8, AL44 and AL88 input pixel format.

First, the CLUT must be loaded with the R, G and B values that replace the original R, G, B values of that pixel (indexed color). Each color (RGB value) has its own address that is the position within the CLUT.

The R, G and B values and their own respective address are programmed through the LTDC_LxCLUTWR register:
- In case of L8 and AL88 input pixel format, the CLUT must be loaded by 256 colors. The address of each color is configured in the CLUTADD bits in the LTDC_LxCLUTWR register.
In case of AL44 input pixel format, the CLUT must be loaded by only 16 colors. The address of each color must be filled by replicating the 4-bit L channel to 8-bit as follows:

- L0 (indexed color 0), at address 0x00
- L1, at address 0x11
- L2, at address 0x22
- ......
- L15, at address 0xFF

**Color frame buffer address**

Every layer has a start address for the color frame buffer configured through the LTDC_LxCFBAR register.

When a layer is enabled, the data is fetched from the color frame buffer.

**Color frame buffer length**

Every layer has a total line length setting for the color frame buffer in bytes and a number of lines in the frame buffer configurable in the LTDC_LxCFBLR and LTDC_LxCFBLNR register respectively.

The line length and the number of lines settings are used to stop the prefetching of data to the layer FIFO at the end of the frame buffer:

- If it is set to less bytes than required, a FIFO underrun interrupt is generated if it has been previously enabled.
- If it is set to more bytes than actually required, the useless data read from the FIFO is discarded. The useless data is not displayed.

**Color frame buffer pitch**

Every layer has a configurable pitch for the color frame buffer, that is the distance between the start of one line and the beginning of the next line in bytes. It is configured through the LTDC_LxCFBLR register.

**Layer blending**

The blending is always active and the two layers can be blended following the blending factors configured through the LTDC_LxBFCR register.

The blending order is fixed and it is bottom up. If two layers are enabled, first the Layer 1 is blended with the Background color, then the layer 2 is blended with the result of blended color of layer 1 and the background. Refer to the figure below.

**Figure 346. Blending two layers with background**
**Default color**

Every layer can have a default color in the format ARGB which is used outside the defined layer window or when a layer is disabled.

The default color is configured through the LTDC_LxDCCR register.

The blending is always performed between the two layers even when a layer is disabled. To avoid displaying the default color when a layer is disabled, keep the blending factors of this layer in the LTDC_LxBFCR register to their reset value.

**Color keying**

A color key (RGB) can be configured to be representative for a transparent pixel.

If the color keying is enabled, the current pixels (after format conversion and before CLUT respectively blending) are compared to the color key. If they match for the programmed RGB value, all channels (ARGB) of that pixel are set to 0.

The color key value can be configured and used at run-time to replace the pixel RGB value.

The color keying is enabled through the LTDC_LxCKCR register.

The color keying is configured through the LTDC_LxCKCR register. The programmed value depends on the pixel format as it is compared to current pixel after pixel format conversion to ARGB888.

**Example**: if the a mid-yellow color (50 % red + 50 % green) is used as the transparent color key:

- In RGB565, the mid-yellow color is 0x8400. Set the LTDC_LxCKCR to 0x848200.
- In ARGB8888, the mid-yellow color is 0x808000. Set LTDC_LxCKCR to 0x808000.
- In all CLUT-based color modes (L8, AL88, AL44), set one of the palette entry to the mid-yellow color 0x808000 and set the LTDC_LxCKCR to 0x808000.

**33.5 LTDC interrupts**

The LTDC provides four maskable interrupts logically ORed to two interrupt vectors.

The interrupt sources can be enabled or disabled separately through the LTDC_IER register. Setting the appropriate mask bit to 1 enables the corresponding interrupt.

The two interrupts are generated on the following events:

- Line interrupt: generated when a programmed line is reached. The line interrupt position is programmed in the LTDC_LiPCR register
- Register reload interrupt: generated when the shadow registers reload is performed during the vertical blanking period
- FIFO underrun interrupt: generated when a pixel is requested from an empty layer FIFO
- Transfer error interrupt: generated when an AXI bus error occurs during data transfer
These interrupt events are connected to the NVIC controller as described in the figure below.

**Figure 347. Interrupt events**

### 33.6 LTDC programming procedure

The steps listed below are needed to program the LTDC:

1. Enable the LTDC clock in the RCC register.
2. Configure the required pixel clock following the panel datasheet.
3. Configure the synchronous timings: VSYNC, HSYNC, vertical and horizontal back porch, active data area and the front porch timings following the panel datasheet as described in the **Section 33.4.1**.
4. Configure the synchronous signals and clock polarity in the LTDC_GCR register.
5. If needed, configure the background color in the LTDC_BCCR register.
6. Configure the needed interrupts in the LTDC_IER and LTDC_LIPCR register.
7. Configure the layer1/2 parameters by:
   - programming the layer window horizontal and vertical position in the LTDC_LxWHPCR and LTDC_IWVPCR registers. The layer window must be in the active data area.
   - programming the pixel input format in the LTDC_LxPFPCR register
   - programming the color frame buffer start address in the LTDC_LxCFBAR register
   - programming the line length and pitch of the color frame buffer in the LTDC_LxCFBLR register
   - programming the number of lines of the color frame buffer in the LTDC_LxCFBLNR register
   - if needed, loading the CLUT with the RGB values and its address in the LTDC_LxCLUTWR register
   - If needed, configuring the default color and the blending factors respectively in the LTDC_LxDCCR and LTDC_LxBFCR registers
8. Enable layer1/2 and if needed the CLUT in the LTDC_LxCR register.
9. If needed, enable dithering and color keying respectively in the LTDC_GCR and LTDC_LxCKCR registers. They can be also enabled on the fly.
10. Reload the shadow registers to active register through the LTDC_SRCR register.
11. Enable the LTDC controller in the LTDC_GCR register.
12. All layer parameters can be modified on the fly except the CLUT. The new configuration must be either reloaded immediately or during vertical blanking period by configuring the LTDC_SRCR register.

Note: All layer’s registers are shadowed. Once a register is written, it must not be modified again before the reload has been done. Thus, a new write to the same register overrides the previous configuration if not yet reloaded.

### 33.7 LTDC registers

#### 33.7.1 LTDC synchronization size configuration register (LTDC_SSCR)

Address offset: 0x008
Reset value: 0x0000 0000

This register defines the number of horizontal synchronization pixels minus 1 and the number of vertical synchronization lines minus 1. Refer to Figure 344 and Section 33.4 for an example of configuration.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:28</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>27:16</td>
<td>HSW[11:0]: Horizontal synchronization width (in units of pixel clock period)</td>
</tr>
<tr>
<td>15:11</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>10:0</td>
<td>VSH[10:0]: Vertical synchronization height (in units of horizontal scan line)</td>
</tr>
</tbody>
</table>

#### 33.7.2 LTDC back porch configuration register (LTDC_BPCR)

Address offset: 0x00C
Reset value: 0x0000 0000

This register defines the accumulated number of horizontal synchronization and back porch pixels minus 1 (HSYNC width + HBP - 1) and the accumulated number of vertical
synchronization and back porch lines minus 1 (VSYNC height + VBP - 1).
Refer to Figure 344 and Section 33.4 for an example of configuration.

33.7.3 LTDC active width configuration register (LTDC_AWCR)

Address offset: 0x010
Reset value: 0x0000 0000

This register defines the accumulated number of horizontal synchronization, back porch and active pixels minus 1 (HSYNC width + HBP + active width - 1) and the accumulated number of vertical synchronization, back porch lines and active lines minus 1 (VSYNC height + VBP + active height - 1). Refer to Figure 344 and Section 33.4 for an example of configuration.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 AHW[11:0]: Accumulated horizontal back porch (in units of pixel clock period)
These bits defines the accumulated horizontal back porch width that includes the horizontal synchronization and horizontal back porch pixels minus 1.
The horizontal back porch is the period between horizontal synchronization going inactive and the start of the active display part of the next scan line.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 AVBP[10:0]: Accumulated Vertical back porch (in units of horizontal scan line)
The vertical back porch is the number of horizontal scan lines at a start of frame to the start of the first active scan line of the next frame.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 AAW[11:0]: Accumulated active width (in units of pixel clock period)
These bits define the accumulated active width which includes the horizontal synchronization, horizontal back porch and active pixels minus 1.
The active width is the number of pixels in active display area of the panel scan line.
Refer to device datasheet for maximum active width supported following maximum pixel clock.
33.7.4 LTDC total width configuration register (LTDC_TWCR)

Address offset: 0x014
Reset value: 0x0000 0000

This register defines the accumulated number of horizontal synchronization, back porch, active and front porch pixels minus 1 (HSYNC width + HBP + active width + HFP - 1) and the accumulated number of vertical synchronization, back porch lines, active and front lines minus 1 (VSYNC height + VBP + active height + VFP - 1). Refer to Figure 344 and Section 33.4 for an example of configuration.

| Bits 31:28 | Reserved, must be kept at reset value. |
| Bits 27:16 | TOTALW[11:0]: Total width (in units of pixel clock period) |
| Bits 15:11 | Reserved, must be kept at reset value. |
| Bits 10:0  | TOTALH[10:0]: Total height (in units of horizontal scan line) |

33.7.5 LTDC global control register (LTDC_GCR)

Address offset: 0x018
Reset value: 0x0000 2220

This register defines the global configuration of the LCD-TFT controller.

| Bits 31:28 | Reserved, must be kept at reset value. |
| Bits 27:16 | TOTALW[11:0]: Total width (in units of pixel clock period) |
| Bits 15:11 | Reserved, must be kept at reset value. |
| Bits 10:0  | TOTALH[10:0]: Total height (in units of horizontal scan line) |

ST
Bit 31 **HSPOL**: Horizontal synchronization polarity
   This bit is set and cleared by software.
   0: Horizontal synchronization polarity is active low.
   1: Horizontal synchronization polarity is active high.

Bit 30 **VSPOL**: Vertical synchronization polarity
   This bit is set and cleared by software.
   0: Vertical synchronization is active low.
   1: Vertical synchronization is active high.

Bit 29 **DEPOL**: Not data enable polarity
   This bit is set and cleared by software.
   0: Not data enable polarity is active low.
   1: Not data enable polarity is active high.

Bit 28 **PCPOL**: Pixel clock polarity
   This bit is set and cleared by software.
   0: Pixel clock polarity is active low.
   1: Pixel clock is active high.

Bits 27:17 Reserved, must be kept at reset value.

Bit 16 **DEN**: Dither enable
   This bit is set and cleared by software.
   0: Dither disabled
   1: Dither enabled

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **DRW[2:0]**: Dither red width
   These bits return the dither red bits.

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **DGW[2:0]**: Dither green width
   These bits return the dither green bits.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **DBW[2:0]**: Dither blue width
   These bits return the dither blue bits.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **LTDCEN**: LCD-TFT controller enable
   This bit is set and cleared by software.
   0: LTDC disabled
   1: LTDC enabled
33.7.6 LTDC shadow reload configuration register (LTDC_SRCR)

Address offset: 0x024
Reset value: 0x0000 0000

This register allows to reload either immediately or during the vertical blanking period, the shadow registers values to the active registers. The shadow registers are all Layer1 and Layer2 registers except the LTDC_L1CLUTWR and the LTDC_L2CLUTWR.

The shadow registers read back the active values. Until the reload has been done, the 'old' value is read.

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **VBR**: Vertical blanking reload
This bit is set by software and cleared only by hardware after reload (it cannot be cleared through register write once it is set).
0: No effect
1: The shadow registers are reloaded during the vertical blanking period (at the beginning of the first line after the active display area).

Bit 0 **IMR**: Immediate reload
This bit is set by software and cleared only by hardware after reload.
0: No effect
1: The shadow registers are reloaded immediately.

33.7.7 LTDC background color configuration register (LTDC_BCCR)

Address offset: 0x02C
Reset value: 0x0000 0000

This register defines the background color (RGB888).

Bits 31:4 Reserved, must be kept at reset value.

- **Bit 3** **CRRIF**: Clear register reload interrupt flag  
  0: No effect  
  1: Clear the RRIF flag in the LTDC_ISR register
Bit 2 **CTERRIF**: Clear the transfer error interrupt flag
0: No effect
1: Clear the TERRIF flag in the LTDC_ISR register.

Bit 1 **CFUIF**: Clear the FIFO underrun interrupt flag
0: No effect
1: Clear the FUDERRIF flag in the LTDC_ISR register.

Bit 0 **CLIF**: Clear the line interrupt flag
0: No effect
1: Clear the LIF flag in the LTDC_ISR register.

### 33.7.11 LTDC line interrupt position configuration register (LTDC_LIPCR)

Address offset: 0x040

Reset value: 0x0000 0000

This register defines the position of the line interrupt. The line value to be programmed depends on the timings parameters. Refer to *Figure 344*.

<table>

Bits 31:16 **CXPOS[15:0]**: Current X position
These bits return the current X position.

Bits 15:0 **CYPOS[15:0]**: Current Y position
These bits return the current Y position.
### 33.7.13 LTDC current display status register (LTDC_CDSR)

Address offset: 0x048  
Reset value: 0x0000 000F  

This register returns the status of the current display phase which is controlled by the HSYNC, VSYNC, and horizontal/vertical DE signals. 

Example: if the current display phase is the vertical synchronization, the VSYNCS bit is set (active high). If the current display phase is the horizontal synchronization, the HSYNCS bit is active high.

The returned status does not depend on the configured polarity in the LTDC_GCR register, instead it returns the current active display phase.

ST
33.7.15 LTDC layer x window horizontal position configuration register (LTDC_LxWHPCR)

Address offset: 0x088 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the horizontal position (first and last pixel) of the layer 1 or 2 window.

The first visible pixel of a line is the programmed value of AHBP[11:0] bits + 1 in the LTDC_BPCR register.

The last visible pixel of a line is the programmed value of AAW[11:0] bits in the LTDC_AWCR register.

Example: The LTDC_BPCR register is configured to 0x000E0005 (AHBP[11:0] is 0xE) and the LTDC_AWCR register is configured to 0x028E01E5 (AAW[11:0] is 0x28E). To configure the horizontal position of a window size of 630x460, with horizontal start offset of 5 pixels in the active data area:

- layer window first pixel, WHSTPOS[11:0], must be programmed to 0x14 (0xE+1+0x5).
- layer window last pixel, WHSPPOS[11:0], must be programmed to 0x28A.

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 CLUTEN: Color look-up table enable
This bit is set and cleared by software.
0: Color look-up table disable
1: Color look-up table enable
The CLUT is only meaningful for L8, AL44 and AL88 pixel format. Refer to Color look-up table (CLUT)

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 COLKEN: Color keying enable
This bit is set and cleared by software.
0: Color keying disable
1: Color keying enable

Bit 0 LEN: Layer enable
This bit is set and cleared by software.
0: Layer disabled
1: Layer enabled

Bits 27:16 WHSPPOS[11:0]: Window horizontal stop position
These bits configure the last visible pixel of a line of the layer window.
33.7.16  **LTDC layer x window vertical position configuration register (LTDC_LxWVPCR)**

Address offset: 0x08C + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the vertical position (first and last line) of the layer1 or 2 window.

The first visible line of a frame is the programmed value of AVBP[10:0] bits + 1 in the register LTDC_BPCR register.

The last visible line of a frame is the programmed value of AAH[10:0] bits in the LTDC_AWCR register.

**Example:**

The LTDC_BPCR register is configured to 0x000E0005 (AVBP[10:0] is 0x5) and the LTDC_AWCR register is configured to 0x028E01E5 (AAH[10:0] is 0x1E5).

To configure the vertical position of a window size of 630x460, with vertical start offset of eight lines in the active data area:

- layer window first line, WVSTPOS[10:0], must be programmed to 0xE (0x5 + 1 + 0x8).
- layer window last line, WVSPPOS[10:0] must be programmed to 0x1DA.

| Bits 31:27 | Reserved, must be kept at reset value. |
| Bits 26:16 | **WVSPPOS[10:0]**: Window vertical stop position |
| These bits configure the last visible line of the layer window. |
| Bits 15:11 | Reserved, must be kept at reset value. |
| Bits 10:0  | **WVSTPOS[10:0]**: Window vertical start position |
| These bits configure the first visible line of the layer window. |
| WVSTPOS[10:0] must be ≤ AAH[10:0] bits (programmed in LTDC_AWCR register). |
33.7.17  **LTDC layer x color keying configuration register (LTDC_LxCKCR)**

Address offset: \(0x090 + 0x80 \times (x - 1), (x = 1 \text{ to } 2)\)

Reset value: 0x0000 0000

This register defines the color key value (RGB), that is used by the color keying.

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **CKRED[7:0]**: Color key red value

Bits 15:8  **CKGREEN[7:0]**: Color key green value

Bits 7:0  **CKBLUE[7:0]**: Color key blue value

33.7.18  **LTDC layer x pixel format configuration register (LTDC_LxPFCR)**

Address offset: \(0x094 + 0x80 \times (x - 1), (x = 1 \text{ to } 2)\)

Reset value: 0x0000 0000

This register defines the pixel format that is used for the stored data in the frame buffer of a layer. The pixel data is read from the frame buffer and then transformed to the internal format 8888 (ARGB).

</tbody>
</table>

Bits 31:3  Reserved, must be kept at reset value.

Bits 2:0  **PF[2:0]**: Pixel format

These bits configure the pixel format

000: ARGB8888
001: RGB888
010: RGB565
011: ARGB1555
100: ARGB4444
101: L8 (8-bit luminance)
110: AL44 (4-bit alpha, 4-bit luminance)
111: AL88 (8-bit alpha, 8-bit luminance)
33.7.19 LTDC layer x constant alpha configuration register (LTDC_LxCACR)

Address offset: 0x098 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 00FF

This register defines the constant alpha value (divided by 255 by hardware), that is used in the alpha blending. Refer to LTDC_LxBFCR register.

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 CONSTA[7:0]: Constant alpha

These bits configure the constant alpha used for blending. The constant alpha is divided by 255 by hardware.

Example: if the programmed constant alpha is 0xFF, the constant alpha value is 255 / 255 = 1.

33.7.20 LTDC layer x default color configuration register (LTDC_LxDCCR)

Address offset: 0x09C + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the default color of a layer in the format ARGB. The default color is used outside the defined layer window or when a layer is disabled. The reset value of 0x00000000 defines a transparent black color.

Bits 31:24 DCALPHA[7:0]: Default color alpha

These bits configure the default alpha value.

Bits 23:16 DCRED[7:0]: Default color red

These bits configure the default red value.

Bits 15:8 DCGREEN[7:0]: Default color green

These bits configure the default green value.

Bits 7:0 DCBLUE[7:0]: Default color blue

These bits configure the default blue value.
33.7.21 LTDC layer x blending factors configuration register (LTDC_LxBFCR)

Address offset: 0x0A0 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0607

This register defines the blending factors F1 and F2.

The general blending formula is: BC = BF1 x C + BF2 x Cs
- \( BC \) = blended color
- \( BF1 \) = blend factor 1
- \( C \) = current layer color
- \( BF2 \) = blend factor 2
- \( Cs \) = subjacent layers blended color

The constant alpha value, is the programmed value in LTDC_LxCACR divided by 255 by hardware.

Example: Only layer1 is enabled, BF1 configured to constant alpha. BF2 configured to 1 - constant alpha. The constant alpha programmed in LTDC_LxCACR is 240 (0xF0). Thus, the constant alpha value is 240 / 255 = 0.94. C: current layer color is 128. Cs: background color is 48. Layer1 is blended with the background color.

\[ BC = \text{constant alpha} \times C + (1 - \text{constant alpha}) \times Cs = 0.94 \times 128 + (1 - 0.94) \times 48 = 123. \]

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 BF1[2:0]: Blending factor 1
These bits select the blending factor F1.
100: constant alpha
110: pixel alpha x constant alpha
Others: Reserved

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 BF2[2:0]: blending factor 2
These bits select the blending factor F2
101: 1 - constant alpha
111: 1 - (pixel alpha x constant alpha)
Others: Reserved
33.7.22  **LTDC layer x color frame buffer address register**  
(\texttt{LTDC\_LxCFBAR})

Address offset: 0x0AC + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the color frame buffer start address which has to point to the address where the pixel data of the top left pixel of a layer is stored in the frame buffer.

<table>

</table>

Bits 31:0  \texttt{CFBADD[31:0]}: Color frame buffer start address  
These bits define the color frame buffer start address.

33.7.23  **LTDC layer x color frame buffer length register**  
(\texttt{LTDC\_LxCFBLR})

Address offset: 0x0B0 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the color frame buffer line length and pitch.

**Example:**
- A frame buffer having the format RGB565 (2 bytes per pixel) and a width of 256 pixels (total number of bytes per line is 256 * 2 = 512), where pitch = line length requires a value of 0x02000207 to be written into this register.
- A frame buffer having the format RGB888 (3 bytes per pixel) and a width of 320 pixels (total number of bytes per line is 320 * 3 = 960), where pitch = line length requires a value of 0x03C003C7 to be written into this register.

Bits 31:29  Reserved, must be kept at reset value.

Bits 28:16  \texttt{CFBP[12:0]}: Color frame buffer pitch in bytes  
These bits define the pitch that is the increment from the start of one line of pixels to the start of the next line in bytes.

Bits 15:13  Reserved, must be kept at reset value.
33.7.24 **LTDC layer x color frame buffer line number register (LTDC_LxCFBLNR)**

Address offset: 0x0B4 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the number of lines in the color frame buffer.

The number of lines and line length settings define how much data is fetched per frame for every layer. If it is configured to less bytes than required, a FIFO underrun interrupt is generated if enabled.

The start address and pitch settings on the other hand define the correct start of every line in memory.

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0 **CFBLNBR[10:0]: Frame buffer line number**

These bits define the number of lines in the frame buffer that corresponds to the active high width.

33.7.25 **LTDC layer x CLUT write register (LTDC_LxCLUTWR)**

Address offset: 0x0C4 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the CLUT address and the RGB value.

The CLUT write register must be configured only during blanking period or if the layer is disabled. The CLUT can be enabled or disabled in the LTDC_LxCR register.

The CLUT is only meaningful for L8, AL44 and AL88 pixel format.

Table 312. LTDC register map and reset values (continued)
Refer to Section 2.3 for the register boundary addresses.
34 JPEG codec (JPEG)

34.1 Introduction
The hardware 8-bit JPEG codec encodes uncompressed image data stream or decodes JPEG-compressed image data stream. It also fully manages JPEG headers.

34.2 JPEG codec main features
- High-speed fully-synchronous operation
- Configurable as encoder or decoder
- Single-clock-per-pixel encode/decode
- RGB, YCbCr, YCMK and BW (grayscale) image color space support
- 8-bit depth per image component at encode/decode
- JPEG header generator/parser with enable/disable
- Four programmable quantization tables
- Single-clock Huffman coding and decoding
- Fully-programmable Huffman tables (two AC and two DC)
- Fully-programmable minimum coded unit (MCU)
- Concurrent input and output data stream interfaces
34.3 JPEG codec block functional description

34.3.1 General description

The block diagram of the JPEG codec is shown in Figure 348.

Figure 348. JPEG codec block diagram

34.3.2 JPEG internal signals

Table 313 lists the JPEG internal signals.

34.3.3 JPEG decoding procedure

The JPEG codec can decode a JPEG stream as defined in the ISO/IEC 10918-1 specification.

It can optionally parse the JPEG header and update accordingly the JPEG codec registers, the quantization tables and the Huffman tables.

The JPEG codec is configured in decode mode setting the DE bit (decode enable) of the JPEG_CONFR1 register.

The JPEG decode starts by setting the START bit of the JPEG_CONFR0 register.

The JPEG codec requests data for its input FIFO through generating one of:

- DMA request
- DMA trigger
- interrupts

**DMA generation for input FIFO**

DMA request is generated when the 32-byte input FIFO becomes at least half-empty, that is, when there is free room for writing 16 bytes of data.

The DMA request generation is independent of the START bit of the JPEG_CONFR0 register. If the input FIFO can accept 16 bytes and the DMA for the input FIFO is enabled (setting the IDMAEN bit of the JPEG_CR register), a DMA request is generated regardless of the state of the JPEG codec kernel.

A burst transfer is launched by the DMA to write 16 bytes of data.

Writes are ignored if the input FIFO is full.

At the end of the decoding process, extra bytes may remain in the input FIFO and/or a DMA request may be pending. The FIFO can be flushed by setting the IFF bit (input FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO, the DMA for the input FIFO must be disabled to prevent unwanted DMA request upon flushing the FIFO.
The consequence of not flushing the FIFO at the end of the decoding process is that any remaining data is taken into the next JPEG decoding.

DMA requests are no more generated once the EOCF flag of the JPEG_SR register is set.

**Interrupt or DMA trigger generation for input FIFO**

Input FIFO can be managed using interrupts or DMA triggers through two flags according to the FIFO state:
- Input FIFO not full flag: a 32-bit value can be written in.
- Input FIFO threshold flag: 8 words (32 bytes) can be written in.

The interrupt or DMA trigger generation is independent of the START bit of the JPEG_CONFR0 register. The input FIFO flags are generated regardless of the state of the JPEG codec kernel.

Writes are ignored if the input FIFO is full.

At the end of the decoding process, extra bytes may remain in the input FIFO and/or an interrupt request / DMA trigger may be pending. The FIFO can be flushed by setting the IFF (Input FIFO Flush) bit of the JPEG_CR register.

Prior to flushing the FIFO:
- The interrupts for the input FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The DMA channel must be stopped to prevent unwanted DMA trigger.

The consequence of not flushing the FIFO at the end of the decoding process is that any remaining data is taken into the next JPEG decoding.

**Header parsing**

The header parsing can be activated setting the HDR bit of the JPEG_CONFR1 register.

The JPEG header parser supports all markers relevant to the JPEG baseline algorithm indicated in Annex B of the ISO/IEC 10918-1.

When parsing a supported marker, the JPEG header parser extracts the required parameters and stores them in shadow registers. At the end of the parsing the JPEG codec registers are updated.

If a DQT marker segment is located, quantization data associated with it is written into the quantization table memory.

If a DHT marker segment is located, the Huffman table data associated with it is converted into three different table formats (HuffMin, HuffBase and HuffSymb) and stored in their respective memories.

Once the parsing operation is completed, the HPDF (header parsing done flag) bit of the JPEG_SR register is set. An interrupt is generated if the EHPIE (end of header parsing interrupt enable) bit of the JPEG_CR register is set.

**JPEG decoding**

Once the JPEG header is parsed or JPEG codec registers and memories are properly programmed, the incoming data stream is decoded and the resulting MCUs are sent to the output FIFO.
When decoding two images successively, the START bit of the JPEG_CONFR0 register must be set again (even if already 1) after the header processing of the second image is completed.

**DMA generation for output FIFO**

DMA request is generated when the 32-byte output FIFO becomes at least half-full, that is, when there are at least 16 bytes of data.

A burst transfer is launched by the DMA to read 16 bytes of data.

Reads return 0 if the output FIFO is empty.

Once the decoding process is done, no extra bytes must remain in the output FIFO and no DMA request must be pending as the JPEG decoding generates blocks of 64 bytes.

In case of abort of the JPEG codec operations by resetting the START bit of the JPEG_CONFR0 register, the output FIFO can be flushed by setting the OFF bit (input FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO, the DMA for the output FIFO must be disabled to prevent unwanted DMA request upon flushing the FIFO.

**Interrupt or DMA trigger generation for output FIFO**

The output FIFO can be managed using interrupts or DMA triggers through two flags according to the FIFO state:

- Output FIFO not empty flag: a 32-bit value can be read out.
- Output FIFO Threshold flag: 8 words (32 bytes) can be read out.

Reads return 0 if the output FIFO is empty.

In case of abort of the JPEG codec operations by resetting the START bit of the JPEG_CONFR0 register, the output FIFO can be flushed. If the FIFO needs to be flushed, it must be done by software setting the FF bit (FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO:

- The interrupts for the output FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The DMA channel must be stopped to prevent unwanted DMA trigger.

The output FIFO must be flushed at the end of processing before any JPEG configuration change.

### 34.3.4 JPEG encoding procedure

The JPEG codec can encode a JPEG stream as defined in the *ISO/IEC 10918-1* specification.

It can optionally generate the JPEG Header.

The JPEG codec is configured in encode mode resetting the DE bit (decode enable) of the JPEG_CONFR1 register.

The configuration used for encoding the JPEG must be loaded in the JPEG codec:

- JPEG codec configuration registers
- quantization tables
- Huffman tables
The JPEG codec is started setting the START bit of the JPEG_CONFR0 register.

Once the JPEG codec has been started, it request data for its input FIFO generating one of:
- DMA request
- DMA trigger
- interrupts

**DMA generation for input FIFO**

DMA request is generated when the 32-byte input FIFO becomes at least half-empty, that is, when there is free room for writing 16 bytes of data.

The DMA request generation is independent of the START bit of the JPEG_CONFR0 register. If the input FIFO can accept 16 bytes and the DMA for the input FIFO is enabled (setting the IDMAEN bit of the JPEG_CR register), a DMA request is generated regardless of the state of the JPEG codec kernel.

A burst transfer is launched by the DMA to write 16 bytes of data. Writes are ignored if the input FIFO is full.

At the end of the encoding process, extra bytes may remain in the input FIFO and/or a DMA request may be pending. The FIFO can be flushed by setting the IFF bit (input FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO, the DMA for the input FIFO must be disabled to prevent unwanted DMA request upon flushing the FIFO.

The consequence of not flushing the FIFO at the end of the encoding process is that any remaining data is taken into the next JPEG encoding.

The DMA requests are no more generated once the EOCF flag of the JPEG_SR register is set.

**Interrupt or DMA trigger generation for input FIFO**

Input FIFO can be managed using interrupts or DMA triggers through two flags according to the FIFO state:
- Input FIFO not full flag: a 32-bit value can be written in.
- Input FIFO threshold flag: 8 words (32 bytes) can be written in.

The interrupt or DMA trigger generation is independent of the START bit of the JPEG_CONFR0 register. The input FIFO flags are generated regardless of the state of the JPEG codec kernel.

Writes are ignored if the input FIFO is full.

At the end of the encoding process, extra bytes may remain in the input FIFO and/or an interrupt request / DMA trigger may be pending. The FIFO can be flushed by setting the IFF bit (input FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO:
- The interrupts for the input FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The DMA channel must be stopped to prevent unwanted DMA trigger.

The consequence of not flushing the FIFO at the end of the encoding process is that any remaining data is taken into the next JPEG encoding.
JPEG encoding

Once the JPEG header generated, the incoming MCUs are encoded and the resulting data stream sent to the output FIFO.

DMA generation for output FIFO

DMA request is generated when the 32-byte output FIFO becomes at least half-full, that is, when there are at least 16 bytes of data.

A burst transfer is launched by the DMA to read 16 bytes of data.

Read returns 0 if the output FIFO is empty.

At the end of the encoding process, the last bytes may remain in the output FIFO as the stream padding may not be on 16 bytes.

These additional bytes must be managed by the CPU using the output FIFO not empty flag.

In case of abort of the JPEG codec operations by resetting the START bit of the JPEG_CONFR0 register, the output FIFO can be flushed. The FIFO can be flushed by setting the OFF bit (output FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO, the DMA for the input FIFO must be disabled to prevent unwanted DMA request upon flushing the FIFO.

Interrupt or DMA trigger generation for output FIFO

Output FIFO can be managed using interrupts or DMA triggers through two flags according to the FIFO state:

- Output FIFO not empty flag: a 32-bit value can be read out.
- Output FIFO threshold flag: 8 words (32 bytes) can be read out.

Reads return 0 if the output FIFO is empty.

In case of abort of the JPEG codec operations by resetting the START bit of the JPEG_CONFR0 register, the output FIFO can be flushed. The FIFO can be flushed by setting the FF bit (FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO:

- The interrupts for the output FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The DMA channel must be stopped to prevent unwanted DMA trigger.

The output FIFO must be flushed at the end of processing before any JPEG configuration change.

The EOCF bit (end of conversion flag) of the JPEG_SR register can only be cleared when the output FIFO is empty.

Clearing either of the HDR bit (header processing) of the JPEG_CONFMR1 register and the JCEN bit (JPEG codec enable) of the JPEG_CR register is allowed only when the EOCF bit of the JPEG_SR register is cleared.
### 34.4 JPEG codec interrupts

An interrupt can be produced on the following events:
- input FIFO threshold reached
- input FIFO not full
- output FIFO threshold reached
- output FIFO not empty
- end of conversion
- header parsing done

Separate interrupt enable bits are available for flexibility.

#### Table 315. JPEG codec interrupt requests

**Bits 31:16 YSIZE[15:0]: Y Size**  
This field defines the number of lines in source image.

**Bits 15:9 Reserved, must be kept at reset value.**

**Bit 8 HDR: Header processing**  
This bit enables the header processing (generation/parsing).  
0: Disable  
1: Enable

**Bits 7:6 NS[1:0]: Number of components for scan**  
This field defines the number of components minus 1 for scan header marker segment.

**Bits 5:4 COLSPACE[1:0]: Color space**  
This field defines the number of quantization tables minus 1 to insert in the output stream.  
00: Grayscale (1 quantization table)  
01: YUV (2 quantization tables)  
10: RGB (3 quantization tables)  
11: CMYK (4 quantization tables)

**Bit 3 DE: Codec operation as coder or decoder**  
This bit selects the code or decode process  
0: Code  
1: Decode

**Bit 2 Reserved, must be kept at reset value.**

**Bits 1:0 NF[1:0]: Number of color components**  
This field defines the number of color components minus 1.  
00: Grayscale (1 color component)  
01: - (2 color components)  
10: YUV or RGB (3 color components)  
11: CMYK (4 color components)
34.5.3 JPEG codec configuration register 2 (JPEG_CONFR2)

Address offset: 0x008
Reset value: 0x0000 0000

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **NMCU[25:0]**: Number of MCUs
For encoding: this field defines the number of MCU units minus 1 to encode.
For decoding: this field indicates the number of complete MCU units minus 1 to be decoded
(this field is updated after the JPEG header parsing). If the decoded image size has not a X or
Y size multiple of 8 or 16 (depending on the sub-sampling process), the resulting incomplete
or empty MCU must be added to this value to get the total number of MCUs generated.

34.5.4 JPEG codec configuration register 3 (JPEG_CONFR3)

Address offset: 0x00C
Reset value: 0x0000 0000

Bits 31:16 **XSIZE[15:0]**: X size
This field defines the number of pixels per line.

Bits 15:0 Reserved, must be kept at reset value.
### 34.5.5 JPEG codec configuration register x (JPEG_CONFRx)

Address offset: $0x000 + 0x4 \times x$, ($x = 4$ to $7$)

Reset value: $0x0000\ 0000$

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 $\text{HSF}[3:0]$: Horizontal sampling factor
Horizontal sampling factor for component {x-4}.

Bits 11:8 $\text{VSF}[3:0]$: Vertical sampling factor
Vertical sampling factor for component {x-4}.

Bits 7:4 $\text{NB}[3:0]$: Number of blocks
Number of data units minus 1 that belong to a particular color in the MCU.

Bits 3:2 $\text{QT}[1:0]$: Quantization table
Selects quantization table used for component {x-4}.

00: Quantization table 0
01: Quantization table 1
10: Quantization table 2
11: Quantization table 3

Bit 1 $\text{HA}$: Huffman AC
Selects the Huffman table for encoding AC coefficients.

0: Huffman AC table 0
1: Huffman AC table 1

Bit 0 $\text{HD}$: Huffman DC
Selects the Huffman table for encoding DC coefficients.

0: Huffman DC table 0
1: Huffman DC table 1
34.5.6 JPEG control register (JPEG_CR)

Address offset: 0x030
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 OFF: Output FIFO flush
This bit flushes the output FIFO.
0: No effect
1: Output FIFO is flushed
Note: Reads always return 0.

Bit 13 IFF: Input FIFO flush
This bit flushes the input FIFO.
0: No effect
1: Input FIFO is flushed
Note: Reads always return 0.

Bit 12 ODMAEN: Output DMA enable
Enables DMA request generation for the output FIFO.
0: Disabled
1: Enabled

Bit 11 IDMAEN: Input DMA enable
Enables DMA request generation for the input FIFO.
0: Disabled
1: Enabled

Bits 10:7 Reserved, must be kept at reset value.

Bit 6 HPDIE: Header parsing done interrupt enable
This bit enables interrupt generation upon the completion of the header parsing operation.
0: Disabled
1: Enabled

Bit 5 EOCIE: End of conversion interrupt enable
This bit enables interrupt generation at the end of conversion.
0: Disabled
1: Enabled

Bit 4 OFNEIE: Output FIFO not empty interrupt enable
This bit enables interrupt generation when the output FIFO is not empty.
0: Disabled
1: Enabled
Bit 3 **OFTIE**: Output FIFO threshold interrupt enable
   This bit enables interrupt generation when the output FIFO reaches a threshold.
   0: Disabled
   1: Enabled

Bit 2 **IFNFIE**: Input FIFO not full interrupt enable
   This bit enables interrupt generation when the input FIFO is not empty.
   0: Disabled
   1: Enabled

Bit 1 **IFTIE**: Input FIFO threshold interrupt enable
   This bit enables interrupt generation when the input FIFO reaches a threshold.
   0: Disabled
   1: Enabled

Bit 0 **JCEN**: JPEG core enable
   This bit enables the JPEG codec core.
   0: Disabled (internal registers are reset).
   1: Enabled (internal registers are accessible).

### 34.5.7 JPEG status register (JPEG_SR)

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **COF**: Codec operation flag
   This bit flags code/decode operation in progress.
   0: Not in progress
   1: In progress

Bit 6 **HPDF**: Header parsing done flag
   In decode mode, this bit flags the completion of header parsing and updating internal registers.
   0: Not completed
   1: Completed

Bit 5 **EOCF**: End of conversion flag
   This bit flags the completion of encode/decode process and data transfer to the output FIFO.
   0: Not completed
   1: Completed
Bit 4 **OFNEF**: Output FIFO not empty flag
This bit flags that data is available in the output FIFO. This flag must not be considered when using DMA.
0: Empty (data not available)
1: Not empty (data available)

Bit 3 **OFTF**: Output FIFO threshold flag
This bit flags that the amount of data in the output FIFO reaches or exceeds a threshold. This flag must not be considered when using DMA.
0: Below threshold
1: At or above threshold

Bit 2 **IFNFF**: Input FIFO not full flag
This bit flags that the input FIFO is not full (data can be written). This flag must not be considered when using DMA.
0: Full
1: Not full

Bit 1 **IFTF**: Input FIFO threshold flag
This bit flags that the amount of data in the input FIFO is below a threshold. This flag must not be considered when using DMA.
0: At or above threshold
1: Below threshold.

Bit 0 Reserved, must be kept at reset value.

### 34.5.8 JPEG clear flag register (JPEG_CFR)

</table>
34.5.11 JPEG quantization memory x (JPEG_QMEMx_y)  
Address offset: 0x050 + 0x40 * x + 0x4 * y, (x = 0 to 3; y = 0 to 15)  
Reset value: 0xXXXX XXXX  
Four quantization tables as specified by ISO documentation.  
For decoding with header parsing, no quantization table programming is required, the coefficients are directly written in the quantization memories by header parser.  
For decoding without header parsing or for encoding, the quantization table must be written by software in zig zag order.

<table>
<thead>
<tr>
<th>Address offset</th>

</tbody>
</table>

34.5.12 JPEG Huffman min (JPEG_HUFFMINx_y)  
Address offset: 0x150 + 0x10 * x + 0x4 * y, (x = 0 to 3; y = 0 to 2)  
Reset value: 0xXXXX XXXX  
This memory stores the minimum Huffman values used internally by the JPEG decoder. The memory content is written by hardware during the header parsing.  
- DATA0: Min AC0 value  
- DATA1: Min DC0 value  
- DATA2: Min AC1 value  
- DATA3: Min DC1 value

<table>
<thead>
<tr>
<th>Address offset</th>
<th>0x150 + 0x10 * x + 0x4 * y</th>
<th>(x = 0 to 3; y = 0 to 2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reset value</td>
<td>0xXXXX XXXX</td>
<td></td>
</tr>
</tbody>
</table>
34.5.13 JPEG Huffman min x (JPEG_HUFFMINx_y)

Address offset: 0x150 + 0x10 * x + 0x4 * y, (x = 0 to 3; y = 3)
Reset value: 0xXXXX XXXX

This memory stores the minimum Huffman values used internally by the JPEG decoder. The memory content is written by hardware during the header parsing.

- DATA0: Min AC0 value
- DATA1: Min DC0 value
- DATA2: Min AC1 value
- DATA3: Min DC1 value

34.5.14 JPEG Huffman base (JPEG_HUFFBASEx)

Address offset: 0x190 + 0x4*x, (x = 0 to 31)
Reset value: 0xXXXX XXXX

This memory stores the base Huffman values used internally by the JPEG decoder. The memory content is written by hardware during the header parsing:

- DATA0 to DATA15: Base AC0 value
- DATA16 to DATA31: Base DC0 value
- DATA32 to DATA47: Base AC1 value
- DATA48 to DATA63: Base DC1 value
34.5.15 JPEG Huffman symbol (JPEG_HUFFSYMBx)

Address offset: 0x210 + 0x4 * x, (x = 0 to 83)
Reset value: 0xXXXX XXXX

This memory stores the Huffman symbols used internally by the JPEG decoder. The memory content is written by hardware during the header parsing:
- DATA0 to DATA161: AC0 symbols
- DATA162 to DATA173: DC0 and DC1 symbols
- DATA174 to DATA335: AC1 symbols

| Bits 31:25 | Reserved, must be kept at reset value. |
| Bits 24:16 | DATA(2x+1)[8:0]: Data (2x+1) |
| Bits 15:9  | Reserved, must be kept at reset value. |
| Bits 8:0  | DATA(2x)[8:0]: Data (2x) |

| Bits 31:24 | DATA(4x+3)[7:0]: Data (4x+3) |
| Bits 23:16 | DATA(4x+2)[7:0]: Data (4x+2) |
| Bits 15:8  | DATA(4x+1)[7:0]: Data (4x+1) |
| Bits 7:0   | DATA(4x)[7:0]: Data (4x) |
### 34.5.16 JPEG DHT memory (JPEG_DHTMEMx)

Address offset: \(0x360 + 0x4 \times x\), \((x = 0 \text{ to } 102)\)

Reset value: \(0xXXXX \text{ XXXX}\)

For encoding process with header generation, this memory stores the DHT marker segment AC and DC Huffman tables in the ISO/IEC specification format:

- DATA0 to DATA27: DC Huffman table0
- DATA28 to DATA205: AC Huffman table0
- DATA206 to DATA233: DC Huffman table1
- DATA234 to DATA411: AC Huffman table1

### 34.5.17 JPEG Huffman encoder ACx (JPEG_HUFFENC_ACx_y)

Address offset: \(0x500 + 0x160 \times x + 0x4 \times y\), \((x = 0 \text{ to } 1; \ y = 0 \text{ to } 87)\)

Reset value: \(0xXXXX \text{ XXXX}\)

This memory defines the Huffman codes used during the encoding process of AC components.

Bits 31:24 \(DATA\{4x+3\}[7:0]\): Huffman table data \(4x+3\)

Huffman table data for DHT marker segment generation.

Bits 23:16 \(DATA\{4x+2\}[7:0]\): Huffman table data \(4x+2\)

Huffman table data for DHT marker segment generation.

Bits 15:8 \(DATA\{4x+1\}[7:0]\): Huffman table data \(4x+1\)

Huffman table data for DHT marker segment generation.

Bits 7:0 \(DATA\{4x\}[7:0]\): Huffman table data \(4x\)

Huffman table data for DHT marker segment generation.

34.5.18 JPEG Huffman encoder DCx (JPEG_HUFFENC_DCx_y)

Address offset: 0x7C0 + 0x20\*x + 0x4\*y, (x = 0 to 1; y = 0 to 7)

Reset value: 0xFFFF XXXX

This memory defines the Huffman codes used during the encoding process of DC components.

| Bits 31:28 | Reserved, must be kept at reset value. |
| Bits 27:24 | HLEN(2\*y+1)[3:0]: Huffman length (2\*y+1) |
  | Number of bits in the Huffman code HCODE(2\*y+1) minus 1. |
| Bits 23:16 | HCODE(2\*y+1)[7:0]: Huffman code (2\*y+1) |
  | 8 least significant bits of the Huffman code. |
  | If the Huffman code is less than 8 bits long, the unused bits must be 0. |
| Bits 15:12 | Reserved, must be kept at reset value. |
| Bits 11:8  | HLEN(2\*y)[3:0]: Huffman length (2\*y) |
  | Number of bits in the Huffman code HCODE(2\*y) minus 1. |
| Bits 7:0   | HCODE(2\*y)[7:0]: Huffman code (2\*y) |
  | 8 least significant bits of the Huffman code. |
  | If the Huffman code is less than 8 bits long, the unused bits must be 0. |

| Bits 31:28 | Reserved, must be kept at reset value. |
| Bits 27:24 | HLEN(2\*y+1)[3:0]: Huffman length (2\*y+1) |
  | Number of bits in the Huffman code HCODE(2\*y+1) minus 1. |
| Bits 23:16 | HCODE(2\*y+1)[7:0]: Huffman code (2\*y+1) |
  | 8 least significant bits of the Huffman code. |
  | If the Huffman code is less than 8 bits long, the unused bits must be 0. |
| Bits 15:12 | Reserved, must be kept at reset value. |
| Bits 11:8  | HLEN(2\*y)[3:0]: Huffman length (2\*y) |
  | Number of bits in the Huffman code HCODE(2\*y) minus 1. |
| Bits 7:0   | HCODE(2\*y)[7:0]: Huffman code (2\*y) |
  | 8 least significant bits of the Huffman code. |
  | If the Huffman code is less than 8 bits long, the unused bits must be 0. |
## 34.5.19 JPEG codec register map

The following table summarizes the JPEG codec registers. Refer to the register boundary addresses table for the JPEG codec register base address.

Refer to Section 2.3 for the register boundary addresses.
35 True random number generator (RNG)

35.1 Introduction

The RNG is a true random number generator that provides full entropy outputs to the application as 32-bit samples. It is composed of a live entropy source (analog) and an internal conditioning component.

The RNG is a NIST SP 800-90B compliant entropy source that can be used to construct a nondeterministic random bit generator (NDRBG).

The RNG true random number generator can be certified NIST SP800-90B. It can also be tested using the German BSI statistical tests of AIS-31 (T0 to T8).

35.2 RNG main features

- The RNG delivers 32-bit true random numbers, produced by an analog entropy source conditioned by a NIST SP800-90B approved conditioning stage.
- It can be used as the entropy source to construct a nondeterministic random bit generator (NDRBG).
- In the NIST configuration, it produces four 32-bit random samples every 412 AHB clock cycles if \( f_{\text{AHB}} < f_{\text{threshold}} \) (256 RNG clock cycles otherwise).
- It embeds startup and NIST SP800-90B approved continuous health tests (repetition count and adaptive proportion tests), associated with specific error management.
- It can be disabled to reduce power consumption, or enabled with an automatic low power mode (default configuration).
- It has an AMBA® AHB slave peripheral, accessible through 32-bit word single accesses only (else an AHB bus error is generated, and the write accesses are ignored).
35.3 RNG functional description

35.3.1 RNG block diagram

*Figure 349* shows the RNG block diagram.

![Figure 349. RNG block diagram]

35.3.2 RNG internal signals

*Table 317* describes a list of useful-to-know internal signals available at the RNG level, not at the STM32 product level (on pads).

</tr>
</tbody>
</table>
35.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals.

Within its boundary RNG integrates all the required NIST components depicted on Figure 350. Those components are an analog noise source, a digitization stage, a conditioning algorithm, a health monitoring block and two interfaces that are used to interact with the entropy source: GetEntropy and HealthTest.

![Figure 350. NIST SP800-90B entropy source model](Figure 350)

The components pictured above are detailed hereafter.

**Noise source**

The noise source is the component that contains the non-deterministic, entropy-providing activity that is ultimately responsible for the uncertainty associated with the bitstring output by the entropy source. This noise source provides 1-bit samples. It is composed of:

- Multiple analog noise sources (x6), each based on three XORed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in Section 35.3.8: RNG low-power use. Multiple oscillators are also disabled for the configuration A (see Table 320: RNG configurations).
- The XORing of all the noise sources into a single analog output.
- A sampling stage of this output clocked by a dedicated clock input (rng_clk with integrated divider), delivering a 1-bit raw data output.

This noise source sampling is independent to the AHB interface clock frequency (rng_hclk), with a possibility for the software to decrease the sampling frequency by using the integrated divider.

*Note:* In Section 35.6: RNG entropy source validation the recommended RNG clock frequencies and associated divider value are given.
Post processing

In the NIST configuration no post-processing is applied to the sampled noise source. In non-NIST configuration B (as defined in Section 35.6.2) a normalization debiasing is applied, that is half of the bits are taken from the sampled noise source, half of the bits are taken from the inverted sampled noise source.

Conditioning

The conditioning component in the RNG is a deterministic function that increases the entropy rate of the resulting fixed-length bitstrings output (128-bit). The NIST SP800-90B target is full entropy on the output (128-bit).

The times required between two random number generations, and between the RNG initialization and availability of first sample are described in Section 35.5: RNG processing time.

Output buffer

A data output buffer can store up to four 32-bit words that have been output from the conditioning component. When four words have been read from the output FIFO through the RNG_DR register, the content of the 128-bit conditioning output register is pushed into the output FIFO, and a new conditioning round is automatically started. Four new words are added to the conditioning output register after a number of clock cycles specified in Section 35.5: RNG processing time.

Whenever a random number is available through the RNG_DR register, the DRDY flag changes from 0 to 1. This flag remains high until the output buffer becomes empty after reading four words from the RNG_DR register.

Note: When interrupts are enabled an interrupt is generated when this data ready flag transitions from 0 to 1. Interrupt is then cleared automatically by the RNG as explained above.
Health checks

This component ensures that the entire entropy source (with its noise source) starts then operates as expected, obtaining assurance that failures are caught quickly and with a high probability and reliability.

The RNG implements the following health check features in accordance with NIST SP800-90B. The described thresholds correspond to the value recommended for register RNG_HTCR (configuration A in Section 35.6.2).

1. Startup health tests, performed after reset and before the first use of the RNG as entropy source:
   – Repetition count test, flagging an error when the noise source has provided more than 42 consecutive bits at a constant value (0 or 1).
   – Adaptive proportion test running on a window of 1024 consecutive bits: the RNG verifies that the first bit on the outputs of the noise source is not repeated more than 711 times.
   – Known-answer tests, to verify the conditioning stage.

2. Continuous health tests, running indefinitely on the outputs of the noise source:
   – Repetition count test, similar to the one running in startup tests.
   – Adaptive proportion test, similar to the one running in startup tests.

3. Vendor specific continuous tests
   – Transition count test, flagging an error when the noise source has delivered more than 32 consecutive occurrences of 2-bit patterns (01 or 10).
   – Real-time “too slow” sampling clock detector, flagging an error when one RNG clock cycle (before divider) is smaller than AHB clock cycle divided by 32.

4. On-demand test of digitized noise source (raw data)
   – Supported by restarting the entropy source and rerunning the startup tests (see software reset sequence in Section 35.3.4: RNG initialization). Other kinds of on-demand testing (software based) are not supported.

The CECS and SECS status bits in the RNG_SR register indicate when an error condition is detected, as detailed in Section 35.3.7: Error management.

Note: An interrupt can be generated when an error is detected. Above the health test thresholds are modified by changing the value in the RNG_HTCR register. See Section 35.6: RNG entropy source validation for details.
35.3.4 RNG initialization

The RNG simplified state machine is pictured on Figure 351.

After enabling the RNG (RNGEN = 1 in RNG_CR), the following chain of events occurs:

1. The analog noise source is enabled, and by default the RNG waits 16 cycles of RNG clock cycles (before divider) before starting to sample the analog output and filling the 128-bit conditioning shift register.
2. The conditioning hardware initializes, automatically triggering startup behavior test on the raw data samples and known-answer tests.
3. When startup health tests are completed. During this time, three 128-bit noise source samples are used.
4. The conditioning stage internal input data buffer is filled again with 128-bit and a number of conditioning rounds defined by the RNG configuration (NIST or non-NIST) is performed. The output buffer is then filled with the post processing result.
5. The output buffer is refilled automatically according to the RNG usage.

The associated initialization time can be found in Section 35.5: RNG processing time.

Figure 351. RNG initialization overview
Figure 351 also highlights a possible software reset sequence, implemented by:

1. Writing bits RNGEN = 0 and CONDRST = 1 in the RNG_CR register with the same RNG configuration and a new CLKDIV if needed.
2. Then writing RNGEN = 1 and CONDRST = 0 in the RNG_CR register.
3. Wait for random number to be ready, after initialization completes.

Note: When the RNG peripheral is reset through RCC (hardware reset), the RNG configuration for optimal randomness is lost in the RNG registers. Software reset with CONFIGLOCK set preserves the RNG configuration.

35.3.5 RNG operation

Normal operations

To run the RNG using interrupts, the following steps are recommended:

1. Consult Section 35.6: RNG entropy source validation and verify if a specific RNG configuration is required for the application.
   - If it is the case, write in the RNG_CR register the bit CONDRST = 1 together with the correct RNG configuration. Then perform a second write to the RNG_CR register with the bit CONDRST = 0, the interrupt enable bit IE = 1 and the RNG enable bit RNGEN = 1.
   - If it is not the case perform a write to the RNG_CR register with the interrupt enable bit IE = 1 and the RNG enable bit RNGEN = 1.
2. An interrupt is now generated when a random number is ready or when an error occurs. Therefore, at each interrupt, check that:
   - No error occurred. The SEIS and CEIS bits must be set to 0 in the RNG_SR register.
   - A random number is ready. The DRDY bit must be set to 1 in the RNG_SR register.
   - If the above two conditions are true the content of the RNG_DR register can be read up to four consecutive times. If valid data is available in the conditioning output buffer, four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, the error recovery sequence described in Section 35.3.7 must be used.

To run the RNG in polling mode following steps are recommended:

1. Consult Section 35.6: RNG entropy source validation and verify if a specific RNG configuration is required for the application.
   - If it is the case write in the RNG_CR register the bit CONDRST = 1 together with the correct RNG configuration. Then perform a second write to the RNG_CR register with the bit CONDRST = 0 and the RNG enable bit RNGEN = 1.
   - If it is not the case only enable the RNG by setting the RNGEN bit to 1 in the RNG_CR register.
2. Read the RNG_SR register and check that:
   - No error occurred (the SEIS and CEIS bits must be set to 0)
   - A random number is ready (the DRDY bit must be set to 1)
3. If above conditions are true read the content of the RNG_DR register up to four consecutive times. If valid data is available in the conditioning output buffer four
additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, the error recovery sequence described in Section 35.3.7 must be used.

**Note:** When data is not ready (DRDY = 0) RNG_DR returns zero. It is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

If the random number generation period is a concern to the application and if NIST compliance is not required it is possible to select a faster RNG configuration by using the RNG configuration “B”, described in Section 35.6: RNG entropy source validation. The gain in random number generation speed is summarized in Section 35.5: RNG processing time.

**Low-power operations**

If the power consumption is a concern to the application, low-power strategies can be used, as described in Section 35.3.8: RNG low-power use.

**Software post-processing**

No specific software post-processing/conditioning is expected to meet the AIS-31 or NIST SP800-90B approvals. Built-in health check functions are described in Section 35.3.3: Random number generation.

### 35.3.6 RNG clocking

The RNG runs on two different clocks: the AHB bus clock and a dedicated RNG clock. The AHB clock is used to clock the AHB banked registers and conditioning component. The RNG clock, coupled with a programmable divider (see CLKDIV bitfield in the RNG_CR register) is used for noise source sampling. Recommended clock configurations are detailed in Section 35.6: RNG entropy source validation.

**Note:** When the CED bit in the RNG_CR register is set to 0, the RNG clock frequency before the internal divider must be higher than the AHB clock frequency divided by 32, otherwise the clock checker always flags a clock error (CECS = 1 in the RNG_SR register).

See Section 35.3.1: RNG block diagram for details (AHB and RNG clock domains).

### 35.3.7 Error management

In parallel to random number generation a health check block verifies the correct noise source behavior and the frequency of the RNG source clock as detailed in this section. Associated error state is also described.

**Clock error detection**

When the clock error detection is enabled (CED = 0) and if the RNG clock frequency is too low, the RNG sets to 1 both the CEIS and CECS bits to indicate that a clock error occurred. In this case, the application must check that the RNG clock is configured correctly (see Section 35.3.6: RNG clocking) and then it must clear the CEIS bit interrupt flag. The CECS bit is automatically cleared when the clocking condition is normal.
Note: The clock error has no impact on generated random numbers that is the application can still read the RNG_DR register.

**CEIS is set only when CECS is set to 1 by RNG.**

### Noise source error detection

When a noise source (or seed) error occurs, the RNG stops generating random numbers and sets to 1 both SEIS and SECS bits to indicate that a seed error occurred. If a value is available in the RNG_DR register, it must not be used as it may not have enough entropy.

The following sequence must be used to fully recover from a seed error:

1. **Software reset by writing CONDRST at 1 and at 0** (see bitfield description for details). This step is needed only if SECS is set. Indeed, when SEIS is set and SECS is cleared it means RNG performed the reset automatically (auto-reset). In this case application must clear the SEIS bit interrupt flag.
2. If SECS was set in step 1 (no auto-reset) wait for CONDRST to be cleared in the RNG_CR register, then confirm that SEIS is cleared in the RNG_SR register. Otherwise, just clear the SEIS bit in the RNG_SR register.
3. If SECS was set in step 1 (no auto-reset), wait for SECS to be cleared by RNG. The random number generation is now back to normal.

**Note:** After a seed error RNG restarts generating random numbers when SECS is cleared.

When the application sets the ARDIS bit in the RNG_CR register, the auto-reset is disabled. **CONDRST must be used in step 1.**

### RNG tamper errors

When an unexpected error is found by the RNG an internal tamper event is triggered in the TAMP peripheral, and the RNG stops delivering random data.

When this event occurs, the secure application needs to reset the RNG peripheral either using the central reset management or the global SoC reset. Then a proper initialization of the RNG is required, again.

### 35.3.8 RNG low-power use

If power consumption is a concern, the RNG can be disabled as soon as the DRDY bit is set to 1 by setting the RNGEN bit to 0 in the RNG_CR register. As the post-processing logic and the output buffer remain operational while RNGEN = 0 following features are available to the software:

- If there are valid words in the output buffer four random numbers can still be read from the RNG_DR register.
- If there are valid bits in the conditioning output internal register four additional random numbers can be still be read from the RNG_DR register. If it is not the case RNG must be reenabled by the application until the expected new noise source bits threshold is reached (128-bit in NIST mode) and a complete conditioning round is done. Four new random words are then available only if the expected number of conditioning round is reached (two if NISTC = 0). The overall time can be found in **Section 35.5: RNG processing time on page 1438.**

When disabling the RNG the user deactivates all the analog seed generators, whose power consumption is given in the datasheet electrical characteristics section. The user also gates
all the logic clocked by the RNG clock. Note that this strategy is adding latency before a random sample is available on the RNG_DR register, because of the RNG initialization time.

If the RNG block is disabled during initialization (that is well before the DRDY bit rises for the first time), the initialization sequence resumes from where it was stopped when RNGEN bit is set to 1, unless the application resets the conditioning logic using CONDRST bit in the RNG_CR register.

When the application wants to disable the RNG clock it is recommended to wait two RNG kernel clock cycles between clearing the RNGEN bit and disabling the RNG kernel clock using the RCC.

Also, when application needs to enter a power mode where RNG is de-activated, it is recommended to wait two RNG kernel clock cycles between clearing the RNGEN bit and entering the low power mode using the PWR.

In the two cases above, to avoid unexpected consumption when RNG analog oscillators stay active, application can set the bit 13 in RNG_CR register. Setting this bit adds some marginal power consumption while RNGEN bit is set (RNG activated).

Note: The power modes where RNG is deactivated (that is retained or not available) can be found in the PWR section.

35.4 RNG interrupts

In the RNG an interrupt can be produced on the following events:

- Data ready flag
- Seed error, see Section 35.3.7: Error management
- Clock error, see Section 35.3.7: Error management

Dedicated interrupt enable control bits are available as shown in Table 318.

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
</tr>
</thead>
<tbody>
<tr>
<td>RNG</td>
<td>Data ready flag</td>
<td>DRDY</td>
<td>IE</td>
<td>None (automatic)</td>
</tr>
<tr>
<td></td>
<td>Seed error flag</td>
<td>SEIS</td>
<td>IE</td>
<td>Write CONDRST to 1 then to 0 unless ARDIS is cleared (see Section 35.3.7: Error management)</td>
</tr>
<tr>
<td></td>
<td>Clock error flag</td>
<td>CEIS</td>
<td>IE</td>
<td>Write 0 to CEIS</td>
</tr>
</tbody>
</table>

The user can enable or disable the above interrupt sources individually by changing the mask bits or the general interrupt control bit IE in the RNG_CR register. The status of the individual interrupt sources can be read from the RNG_SR register.

Note: Interrupts are generated only when RNG is enabled.
35.5 RNG processing time

In recommended configuration A or C described in Table 320, the time between two sets of four 32-bit data is either:

- 203 x N AHB cycles if \( f_{\text{AHB}} < f_{\text{threshold}} \) (conditioning stage is limiting), or
- 128 x N RNG cycles \( f_{\text{AHB}} \geq f_{\text{threshold}} \) (noise source stage is limiting).

With \( f_{\text{threshold}} = 1.6 \times f_{\text{RNG}} \), for instance 77 MHz if \( f_{\text{RNG}} = 48 \text{ MHz} \). Value \( N \) is defined in Section 35.6: RNG entropy source validation.

Note: When CLKDIV is different from zero, \( f_{\text{RNG}} \) must take into account the internal divider ratio.

If configuration B is selected the performance figures become:

- 203 AHB cycles if \( f_{\text{AHB}} < f_{\text{threshold}} \) or
- 32 RNG cycles \( f_{\text{AHB}} \geq f_{\text{threshold}} \)

with \( f_{\text{threshold}} = 6.5 \times f_{\text{RNG}} \).

Initialization time

More time is needed for the first set of random numbers after the device exits reset (see Section 1.3.4: RNG initialization). Table below gives details on how to compute the time spent in each initialization step.

<table>
<thead>
<tr>
<th>Initialization step</th>
<th>Configuration A or C, reset value</th>
<th>Configuration B</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wait for noise source, then startup health tests</td>
<td>Max( (wait_noise(1) + 11 + 1024 x CLKDIV) RNG_cycles, 13 x 203 AHB_cycles)</td>
<td>Max(16 + 1035 RNG_cycles, 13 x 203 AHB_cycles)</td>
</tr>
<tr>
<td>Conditioning keys initialization</td>
<td>Max((1+2xN) x 128 x CLKDIV) RNG_cycles + 203 AHB_cycles, (128 x CLKDIV) RNG_cycles + (2xN+2) x 203 AHB_cycles)</td>
<td>Max (3 x 32 RNG_cycles + 203 AHB_cycles, 32 RNG_cycles + 4 x 203 AHB_cycles)</td>
</tr>
</tbody>
</table>

1. 192 RNG_cycles (configuration A or C), 16 RNG_cycles (reset value)

As an example, if AHB clock= 250 MHz and RNG clock= 48 MHz then the initialization time is around 40 \( \mu \text{s} \) in the configuration C (CLKDIV=1, N=2) and 26 \( \mu \text{s} \) in the configuration B.

35.6 RNG entropy source validation

35.6.1 Introduction

In order to assess the amount of entropy available from the RNG, STMicroelectronics has tested the peripheral using the German BSI AIS-31 statistical tests (T0 to T8), and NIST SP800-90B test suite.
35.6.2 Validation conditions

STMicroelectronics has tested the RNG true random number generator in the following conditions:

- RNG clock rng_clk= 48 MHz
- RNG configurations are described in Table 320: RNG configurations. Note that only configuration A can be certified NIST SP800-90B. Refer to Table 321: Configuration selection to select the best configuration for the application.
- Configuration C can be used when configuration A is not flagged as certified.

</tbody>
</table>

1. 0x1 value is recommended instead of 0x0 for RNG_CONFIG2[2:0], when RNG power consumption is critical. See the end of Section 35.3.8: RNG low-power use for details.
2. RNG_CONFIG3[1:0] defines the loop number N: 0x0 corresponds to N=1, 0x1 to N=2, 0x2 to N=3, 0x3 to N=4
3. The noise source sampling must be 48 MHz or less. Hence, if the RNG clock is different from 48 MHz, this value of CLKDIV must be adapted. See the CLKDIV bitfield description in Section 35.7.1 for details.
4. This value can be fixed in the RNG driver (it doesn’t depend on the STM32 family).

Table 321. Configuration selection

<table>
<thead>
<tr>
<th>Section criteria</th>
<th>Config A</th>
<th>Config B</th>
<th>Config C</th>
</tr>
</thead>
<tbody>
<tr>
<td>Suitable to generate NIST compliant cryptographic keys</td>
<td>Yes</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>Entropy(1)</td>
<td>Certified</td>
<td>Good</td>
<td>Very good</td>
</tr>
<tr>
<td>Speed(2)</td>
<td>Baseline</td>
<td>Faster</td>
<td>Baseline</td>
</tr>
</tbody>
</table>

1. For configurations B and C entropy is verified using AIS-31 test suite (T0 to T8).
2. When speed is not enough for application a NIST compliant DRBG can be used to increase throughput.

35.7 RNG registers

The RNG is associated with a control register, a data register and a status register.

35.7.1 RNG control register (RNG_CR)

Address offset: 0x000
Reset value: 0x0080 0D00

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>CONFIGLOCK: RNG Config lock</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Writes to the RNG_NSCR, RNG_HT CR and RNG_CR configuration bits [29:4] are allowed.</td>
</tr>
<tr>
<td>1</td>
<td>Writes to the RNG_NSCR, RNG_HT CR and RNG_CR configuration bits [29:4] are ignored until the next RNG reset.</td>
</tr>
<tr>
<td></td>
<td>Once set, this bit can only be cleared when RNG is reset (set once bit).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit 30</th>
<th>CONDRST: Conditioning soft reset</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Write 1 and then write 0 to reset the conditioning logic, clear all the FIFOs and start a new RNG initialization process, with RNG_SR cleared. Registers RNG_CR, RNG_NSCR and RNG_HT CR are not changed by CONDRST.</td>
</tr>
<tr>
<td></td>
<td>This bit must be set to 1 in the same access that set any configuration bits [29:4]. In other words, when CONDRST bit is set to 1 correct configuration in bits [29:4] must also be written.</td>
</tr>
<tr>
<td></td>
<td>When CONDRST is set to 0 by the software, its value goes to 0 when the reset process is done. It takes about 2 AHB clock cycles + 2 RNG clock cycles.</td>
</tr>
</tbody>
</table>

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:20 RNG_CONFIG1[5:0]: RNG configuration 1

Reserved to the RNG configuration (bitfield 1). Must be initialized using the recommended value documented in Section 35.6: RNG entropy source validation.

Writing any bit of RNG_CONFIG1 is taken into account only if the CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 19:16 CLKDIV[3:0]: Clock divider factor

This value used to configure an internal programmable divider (from 1 to 16) acting on the incoming RNG clock. These bits can be written only when the core is disabled (RNGEN = 0).

0x0: internal RNG clock after divider is similar to incoming RNG clock.
0x1: two RNG clock cycles per internal RNG clock.
0x2: \(2^2 = 4\) RNG clock cycles per internal RNG clock.
...
0xF: \(2^{15}\) RNG clock cycles per internal clock (for example, an incoming 48 MHz RNG clock becomes a 1.5 kHz internal RNG clock).

Writing these bits is taken into account only if the CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.
Bits 15:13 **RNG_CONFIG2[2:0]**: RNG configuration 2
Reserved to the RNG configuration (bitfield 2). Bit 13 can be set when RNG power consumption is critical. See [Section 35.3.8: RNG low-power use](#). Refer to the RNG_CONFIG1 bitfield for details.

**Bit 12 NISTC**: NIST custom
0: Hardware default values for NIST compliant RNG. In this configuration per 128-bit output two conditioning loops are performed and 256 bits of noise source are used.
1: Custom values for NIST compliant RNG. See [Section 35.6: RNG entropy source validation](#) for recommended configuration.
Writing this bit is taken into account only if CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 11:8 **RNG_CONFIG3[3:0]**: RNG configuration 3
Reserved to the RNG configuration (bitfield 3). Refer to RNG_CONFIG1 bitfield for details. If the NISTC bit is cleared in this register RNG_CONFIG3 bitfield values are ignored by RNG.

**Bit 7 ARDIS**: Auto reset disable
Set this bit to deactivate the auto-reset feature.
0: Auto-reset enabled
1: Auto-reset disabled
Keeping the auto-reset enabled (automatic clearance of the SECS bit) simplifies the management of noise source errors, as described in [Section 35.3.7: Error management](#).
Writing this bit is taken into account only if CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

**Bit 6 Reserved, must be kept at reset value.**

**Bit 5 CED**: Clock error detection
0: Clock error detection enabled
1: Clock error detection is disabled
The clock error detection cannot be enabled nor disabled on-the-fly when the RNG is enabled, that is to enable or disable CED, the RNG must be disabled.
Writing this bit is taken into account only if the CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

**Bit 4 Reserved, must be kept at reset value.**

**Bit 3 IE**: Interrupt enable
0: RNG interrupt is disabled
1: RNG interrupt is enabled. An interrupt is pending as soon as the DRDY, SEIS, or CEIS is set in the RNG_SR register.

**Bit 2 RNGEN**: True random number generator enable
0: True random number generator is disabled. Analog noise sources are powered off and logic clocked by the RNG clock is gated.
1: True random number generator is enabled.

**Bits 1:0** Reserved, must be kept at reset value.
35.7.2  RNG status register (RNG_SR)

Address offset: 0x004
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:7</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>

**Bit 6  SEIS:** Seed error interrupt status
This bit is set at the same time as SECS. It is cleared by writing 0 (unless CONDRST is used). Writing 1 has no effect.

- 0: No faulty sequence detected
- 1: At least one faulty sequence is detected. See SECS bit description for details.

An interrupt is pending if IE = 1 in the RNG_CR register.

**Bit 5  CEIS:** Clock error interrupt status
This bit is set at the same time as CECS. It is cleared by writing 0. Writing 1 has no effect.

- 0: The RNG clock is correct (fRNGCLK > fHCLK/32)
- 1: The RNG clock before the internal divider is detected too slow (fRNGCLK < fHCLK/32)

An interrupt is pending if IE = 1 in the RNG_CR register.

**Bits 4:3** Reserved, must be kept at reset value.

**Bit 2  SECS:** Seed error current status
0: No faulty sequence has currently been detected. If the SEIS bit is set, this means that a faulty sequence was detected and the situation has been recovered.
1: At least one of the following faulty sequences has been detected:
- Runtime repetition count test failed (noise source has provided more than 24 consecutive bits at a constant value 0 or 1, or more than 32 consecutive occurrence of two bits patterns 01 or 10)
- Startup or continuous adaptive proportion test on noise source failed.
- Startup post-processing/conditioning sanity check failed.

**Bit 1  CECS:** Clock error current status
0: The RNG clock is correct (fRNGCLK > fHCLK/32). If the CEIS bit is set, this means that a slow clock was detected and the situation has been recovered.
1: The RNG clock is too slow (fRNGCLK < fHCLK/32).

*Note:* CECS bit is valid only if the CED bit in the RNG_CR register is set to 0.

**Bit 0  DRDY:** Data ready
0: The RNG_DR register is not yet valid, no random data is available.
1: The RNG_DR register contains valid random data.

Once the output buffer becomes empty (after reading the RNG_DR register), this bit returns to 0 until a new random value is generated.

*Note:* The DRDY bit can rise when the peripheral is disabled (RNGEN = 0 in the RNG_CR register).

If IE=1 in the RNG_CR register, an interrupt is generated when DRDY = 1.
35.7.3 **RNG data register (RNG_DR)**

Address offset: 0x008
Reset value: 0x0000 0000

The RNG_DR register is a read-only register that delivers a 32-bit random value when read. The content of this register is valid when the DRDY = 1 and the value is not 0x0, even if RNGEN = 0.

<table>
<thead>

</tr>
</tbody>
</table>

Bits 31:0 **RNDATA[31:0]**: Random data
32-bit random data, which are valid when DRDY = 1. When DRDY = 0, the RNDATA value is zero.
When DRDY is set, it is recommended to always verify that RNG_DR is different from zero.
The zero value means that a seed error occurred between RNG_SR polling and RND_DR output reading (a rare event).

35.7.4 **RNG noise source control register (RNG_NSCR)**

Address offset: 0x00C
Reset value: 0x0003 FFFF

Writing in RNG_NSCR is taken into account only if the CONDRST bit is set, and the CONFIGLOCK bit is cleared in RNG_CR. Writing to this register is ignored if CONFIGLOCK= 1.

Refer to Section 2.3: Memory organization for the register boundary addresses.
36 Secure AES coprocessor (SAES)

36.1 Introduction

The secure AES coprocessor (SAES) encrypts or decrypts data in compliance with the advanced encryption standard (AES) defined by NIST. It incorporates a protection against side-channel attacks (SCA), including differential power analysis (DPA), certified SESIP and PSA security assurance level 3.

SAES supports ECB, CBC, CTR, GCM, GMAC, and CCM chaining modes for key sizes of 128 or 256 bits, as well as special modes such as hardware secret key encryption/decryption (wrapped-key mode) and key sharing with faster CRYP peripheral (shared-key mode).

SAES has the possibility to load by hardware STM32 hardware secret master keys (boot hardware key BHK, application hardware key AHK, and derived hardware unique key DHUK), usable but not readable by the application.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels are required). It is hardware-linked with the true random number generator (TRNG) and with the CRYP peripheral.

36.2 SAES main features

- Compliant with NIST FIPS publication 197 “Advanced encryption standard (AES)” (November 2001)
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- Protection against side-channel attacks (SCA), incl. differential power analysis (DPA), certified SESIP and PSA security assurance level 3
- 128-bit data block processing, supporting cipher key lengths of 128-bit and 256-bit
  - 480 or 680 clock cycle latency in ECB mode for processing one 128-bit block with, respectively, 128-bit or 256-bit key
- Hardware secret key encryption/decryption (Wrapped-key mode)
- Using dedicated key bus, optional key sharing with faster CRYP peripheral (shared-key mode), controlled by SAES
- Integrated key scheduler to compute the last round key for ECB/CBC decryption
- 256-bit of write-only registers for storing cryptographic keys (eight 32-bit registers)
  - Optional 128-bit or 256-bit hardware loading of two hardware secret keys (BHK, DHUK) that can be XOR-ed together
  - Optional 128-bit or 256-bit hardware loading of non-volatile application hardware keys (AHK), secret to software and stored in the embedded flash memory

SAES has the possibility to load by hardware STM32 hardware secret master keys (boot hardware key BHK, application hardware key AHK, and derived hardware unique key DHUK), usable but not readable by the application.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels are required). It is hardware-linked with the true random number generator (TRNG) and with the CRYP peripheral.
36.3 SAES implementation

The devices have one SAES peripheral, connected with TAMP backup registers (BHK - boot hardware key) and with the Flash memory interface (AHK - application hardware key), and implemented as per the following table. It shares the key with the CRYP peripheral. For comparison, the CRYP peripheral is also included in the table.

</tbody>
</table>
36.4.3 **SAES reset and clocks**

The SAES peripheral is clocked by the AHB bus clock. It has a dedicated reset bit and a dedicated kernel clock, controlled through the RCC.

36.4.4 **SAES symmetric cipher implementation**

The secure AES coprocessor (SAES) is a 32-bit AHB peripheral that encrypts or decrypts 16-byte blocks of data using the advanced encryption standard (AES). It also implements a set of approved AES symmetric key security functions summarized in Table 325. Those functions can be certified NIST PUB 140-3.

SAES can be used directly by the CPU, or indirectly, using two DMA channels (one for the plaintext, one for the ciphertext).

It is possible to suspend then resume any SAES processing, following the sequence described in Section 36.4.8.
36.4.5 SAES encryption or decryption typical usage

The following figure shows a typical operation for encryption or decryption.

**Figure 353. Encryption/decryption typical usage**

![Flowchart diagram](image)

**Initialization**

The SAES peripheral is initialized according to the chaining mode. Refer to Section 36.4.9: SAES basic chaining modes (ECB, CBC) and Section 36.4.10: SAES counter (CTR) mode for details.

**Data append**

This section describes different ways of appending data for processing. For ECB or CBC chaining modes, refer to Section 36.4.7: SAES ciphertext stealing and data padding if the size of data to process is not a multiple of 16 bytes. The last block management in these cases is more complex than what is described in this section.

**Appending data using the CPU in polling mode**

This method uses flag polling to control the data append through the following sequence:

1. Enable the SAES peripheral when KEYVALID is set, by setting the EN bit of the SAES_CR register (if not already done).
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the SAES_DINR register.
   b) Wait until the status flag CCF is set in the SAES_ISR register, then read the four data words from the SAES_DOUTR register.
   c) Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
   d) If the next processing block is the last block, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (using
NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong).

3. As the data block just processed is the last block of the message, optionally discard the data that is not part of the message/payload, then disable the SAES peripheral by clearing EN.

Note: Up to three wait cycles are automatically inserted between two consecutive writes to the SAES_DINR register, to allow sending the key to the AES co-processor. NPBLB[3:0] bitfield is not used in header phase of GCM, GMAC and CCM chaining modes.

Appending data using the CPU in interrupt mode

The method uses interrupt from the SAES peripheral to control the data append, through the following sequence:

1. Enable interrupts from SAES, by setting the CCFIE bit of the SAES_IER register.
2. Enable the SAES peripheral when KEYVALID is set, by setting EN (if not already done).
3. Write first four input data words into the SAES_DINR register.
4. Handle the data in the SAES interrupt service routine. Upon each interrupt:
   a) Read four output data words from the SAES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCF bit of the SAES_ICR register.
   c) If the next processing block is the last block of the message, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (through NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong). Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, optionally discard the data that are not part of the message/payload, then disable the SAES peripheral by clearing EN and quit the interrupt service routine.
   e) Write next four input data words into the SAES_DINR register and quit the interrupt service routine.

Note: SAES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two SAES computations.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

Appending data using DMA

With this method, all the transfers and processing are managed by DMA and SAES. Proceed as follows:

1. If the last block of the message to process is shorter than 16 bytes, prepare the last four-word data block by padding the remainder of the block with zeros.
2. Configure the DMA controller so as to transfer the data to process from the memory to the SAES peripheral input and the processed data from the SAES peripheral output to the memory, as described in Section 36.6: SAES DMA requests. Configure the DMA controller so as to generate an interrupt on transfer completion. For GCM payload encryption or CCM payload decryption, the DMA transfer must not include the last four-word block if padded with zeros. The sequence described in Appendix data using the CPU in polling mode must be used instead for this last block, because the
NPBLB[3:0] bitfield must be set up before processing the block, for SAES to compute a correct tag.

3. Enable the SAES peripheral when KEYVALID is set, by setting EN (if not already done).
4. Enable DMA requests, by setting DMAINEN and DMAOUTEN.
5. Upon DMA interrupt indicating the transfer completion, get the SAES-processed data from the memory.

Note: The CCF flag has no use with this method because the reading of the SAES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

36.4.6 SAES authenticated encryption, decryption, and cipher-based message authentication

The following figure shows a typical operation for authenticated encryption or decryption, and for cipher-based message authentication.

Figure 354. Typical operation with authentication

Section 36.4.11: SAES Galois/counter mode (GCM) and Section 36.4.13: SAES counter with CBC-MAC (CCM) describe detailed sequences supported by SAES.

Cipher-based message authentication flow omits the payload phase, as shown in the figure. Detailed sequence supported by SAES is described in Section 36.4.12: SAES Galois message authentication code (GMAC).

36.4.7 SAES ciphertext stealing and data padding

When using SAES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (16 bytes), the application must use ciphertext stealing techniques such as those described in NIST Special Publication 800-38A, Recommendation for Block
Ciphertext Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode. Since SAES does not implement such techniques, the application must complete the last block of input data using data from the second last block.

**Note:** Ciphertext stealing techniques are not documented in this reference manual.

Similarly, in modes other than ECB or CBC, an incomplete input data block (that is, a block with input data shorter than 16 bytes) must be padded with zeros prior to encryption. That is, extra bits must be appended to the trailing end of the data string. After decryption, the extra bits must be discarded. Since SAES does not implement automatic data padding operation to the last block, the application must follow the recommendation given in this document to manage messages the size of which is not a multiple of 16 bytes.

### 36.4.8 SAES suspend and resume operations

A message can be suspended to process another message with a higher priority. When the higher-priority message is sent, the suspended message can resume. This applies to both encryption and decryption mode. Suspend and resume operations do not break the chaining operation. The message processing can resume as soon as SAES is enabled again, to receive a next data block. *Figure 355* gives an example of suspend and resume operations: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

*Figure 355. Example of suspend mode management*

A detailed description of suspend and resume operations is in the sections dedicated to each chaining mode.

### 36.4.9 SAES basic chaining modes (ECB, CBC)

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately. When decrypting in ECB, a special key scheduling is required before processing the first block.
Figure 356 and Figure 357 describe the electronic codebook (ECB) chaining implementation in encryption and in decryption, respectively. To select ECB chaining mode, write CHMOD[2:0] with 0x0.

**Figure 356. ECB encryption**

![Diagram of ECB encryption](Image1)

**Figure 357. ECB decryption**

![Diagram of ECB decryption](Image2)

In CBC encryption mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing. When decrypting in CBC, a special key scheduling is required before processing the first block.
**Figure 358** and **Figure 359** describe the cipher block chaining (CBC) implementation in encryption and in decryption, respectively. To select this chaining mode, write CHMOD[2:0] with 0x1.

For more details, refer to NIST Special Publication 800-38A, *Recommendation for Block Cipher Modes of Operation.*
ECB and CBC encryption process

This process is described in Section 36.4.5, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follows:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in encryption mode (write MODE[1:0] with 0x0).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select normal key mode by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to Section 36.4.14 (wrapped keys) and Section 36.4.15 (shared keys).
4. Write the initialization vector into the SAES_IVRx registers if CBC mode is selected in the previous step.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to Section 36.4.17: SAES key registers for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Append cleartext data:
   a) If it is the second-last or the last block and the plaintext size of the message is not a multiple of 16 bytes, follow the guidance in Section 36.4.7.
   b) Append the cleartext block into SAES as described in Section 36.4.5, then read the SAES_DOUTR register four times to save the ciphertext block.
   c) Repeat the step b) until the third-last plaintext block is encrypted. For the last two blocks, follow the steps a) and b).
9. Finalize the sequence: disable the SAES peripheral, by clearing EN.

ECB/CBC decryption process

This process is described in Section 36.4.5, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follows:
   - Select the key derivation mode (write MODE[1:0] with 0x1). The CHMOD[2:0] bitfield is not significant during this operation.
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select normal key mode by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to Section 36.4.14 (wrapped keys) and Section 36.4.15 (shared keys).
4. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to Section 36.4.17: SAES key registers for details.
5. Wait until KEYVALID is set (the key loading completed).
6. Enable the SAES peripheral, by setting EN. The peripheral immediately starts an AES round for key preparation.

7. Wait until the CCF flag in the SAES_ISR register is set.

8. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register. The decryption key is available in the AES core and SAES is disabled automatically.

9. Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in decryption mode (write MODE[1:0] with 0x2). Do not change other parameters.

10. Write the initialization vector into the SAES_IVRx registers if CBC mode is selected in the previous step.

11. Enable the SAES peripheral, by setting EN.

12. Append encrypted data:
   a) If it is the second-last or the last block and the ciphertext size of the message is not a multiple of 16 bytes, follow the guidance in Section 36.4.7.
   b) Append the ciphertext block into SAES as described in Section 36.4.5, then read the SAES_DOUTR register four times to save the cleartext block (MSB first).
   c) Repeat the step b) until the third-last ciphertext block is decrypted. For the last two blocks, follow the steps a) and b).

13. Finalize the sequence: disable the SAES peripheral, by clearing EN.

**Suspend/resume operations in ECB/CBC modes**

The following sequences are valid for normal key mode (KMOD[1:0] at 0x0).

**To suspend the processing of a message**, proceed as follows:

1. If DMA is used, stop the SAES DMA transfers to the input FIFO, by clearing DMAINEN. If DMA is not used, wait until the CCF flag in the SAES_ISR register is set (computation completed).

2. If DMA is not used, read four times the SAES_DOUTR register to save the last processed block. If DMA is used, wait until the CCF flag is set in the SAES_ISR register then stop the DMA transfers from the output FIFO, by clearing DMAOUTEN.

3. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.

4. Save initialization vector registers (only required in CBC mode as the SAES_IVRx registers are altered during the data processing).

5. Disable the SAES peripheral, by clearing EN.

6. Save the SAES_CR register and clear the key registers if they are not needed, to process the higher-priority message.

7. If DMA is used, save the DMA controller status (pointers for SAES input and output data transfers, number of remaining bytes, and so on).

**To resume the processing of a message**, proceed as follows:

1. If DMA is used, configure the DMA controller so as to complete the remaining input FIFO and output FIFO transfers.

2. Disable the SAES peripheral, by clearing EN.

3. Restore the SAES_CR register (with correct KEYSIZE) then restore the SAES_KEYRx registers. For KEYSEL[2:0] selecting a key source different from key registers, refer to Section 36.4.17: SAES key registers for details.

4. Prepare the decryption key, as described in ECB/CBC decryption process (only required for ECB or CBC decryption).
5. Restore the SAES_IvRx registers, using the saved configuration (only required in CBC mode).
6. Enable the SAES peripheral, by setting EN.
7. If DMA is used, enable SAES DMA transfers, by setting DMAINEN and DMAOUTEN.

Note: It is not required to save the key registers as the application knows the original key.

36.4.10 SAES counter (CTR) mode

The CTR mode uses the AES core to generate a key stream. The keys are then XOR-ed with the plaintext to obtain the ciphertext. Unlike with ECB and CBC modes, no key scheduling is required for the CTR decryption since the AES core is always used in encryption mode.

A typical message construction in CTR mode is given in Figure 360.

Figure 360. Message construction in CTR mode

The structure of this message is:

- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - Initialization vector (IV): a 96-bit value that must be unique for each encryption cycle with a given key.
  - Counter: a 32-bit big-endian integer that is incremented each time a block processing is completed. The initial value of the counter must be set to 1.

- The plaintext P is encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.

For more details, refer to NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.

CTR encryption and decryption

Figure 361 describes the counter (CTR) chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x2.
Initialization vectors in SAES must be initialized as shown in Table 326.

Table 326. Counter mode initialization vector definition

CTR encryption and decryption process

This process is described in Section 36.4.5, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select CTR chaining mode (write CHMOD[2:0] with 0x2) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to Section 36.4.14 (wrapped keys) and Section 36.4.15 (shared keys).
4. Write the initialization vector into the SAES_IVRx registers according to Table 326.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to Section 36.4.17: SAES key registers for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Append data:
   a) If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in
      the block is less than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into SAES as described in Section 36.4.5, then read the
      SAES_DOUTR register four times to save the resulting block (MSB first).
   c) Repeat the step b) until the second-last block is processed. For the last block of
      plaintext (encryption only), follow the steps a) and b). For the last block, discard
      the bits that are not part of the message when the last block is smaller than 16
      bytes.

9. Finalize the sequence: disable the SAES peripheral, by clearing EN.

Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher-priority
message, then resume the interrupted message. Detailed CBC suspend and resume
sequence is described in Section 36.4.9: SAES basic chaining modes (ECB, CBC).

Note: Like for CBC mode, the IV registers must be reloaded during the resume operation.

36.4.11 SAES Galois/counter mode (GCM)

The AES Galois/counter mode (GCM) allows encrypting and authenticating a plaintext
message into the corresponding ciphertext and tag (also known as message authentication
code).

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a
fixed finite field for computing the message authentication code. The following figure shows
a typical message construction in GCM mode.

Figure 362. Message construction in GCM

![Figure 362. Message construction in GCM](MSv42157V1)
The message has the following structure:

- **16-byte initial counter block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV)**: a 96-bit value that must be unique for each encryption cycle with a given key. The GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.

- **Authenticated header AAD** (also known as additional authentication data) has a known length \( \text{Len}(A) \) that may be a non-multiple of 16 bytes, and must not exceed \( 2^{64} - 1 \) bits. This part of the message is only authenticated, not encrypted.

- **Plaintext message** \( P \) is both authenticated and encrypted as ciphertext \( C \), with a known length \( \text{Len}(P) \) that may be non-multiple of 16 bytes, and cannot exceed \( 2^{32} - 2 \) 16-byte blocks.

- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in Table 328.

The GCM standard specifies that ciphertext \( C \) has the same bit length as the plaintext \( P \).

When a part of the message (AAD or \( P \)) has a length that is a non-multiple of 16-bytes a special padding scheme is required.

For more details, refer to NIST Special Publication 800-38D, *Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC*. 
Figure 363 describes the GCM chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x3.

The first counter block (CB1) is derived from the initial counter block ICB by the application software, as defined in Table 327.

<table>

GCM encryption and decryption process

This process is described in Section 36.4.6, with the following sequence of events:

**GCM initialize**

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select GCM chaining mode (write CHMOD[2:0] with 0x3) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to Section 36.4.14 (wrapped keys) and Section 36.4.15 (shared keys).
   - Select the GCM initialization phase, by writing GCMPH[1:0] with 0x0.
4. Write the initialization vector in SAES_IVRx registers according to Table 327.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to Section 36.4.17: SAES key registers for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Set EN to start the calculation of the hash key. EN is automatically cleared when the calculation is completed.
8. Wait until the CCF flag is set in the SAES_ISR register, indicating that the GCM hash subkey (H) computation is completed.
9. Clear the CCF flag by setting the CCF bit of the SAES_ICR register.

**GCM header phase**

10. Initialize header phase:
    a) Select the GCM header phase, by writing 0x1 to GCMPH[1:0]. Do not change the other configurations written during GCM initialization.
    b) Enable the SAES peripheral, by setting EN.
11. Append header data:
    a) If it is the last block and the AAD in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in Section 36.4.5.
    c) Repeat the step b) until the second-last AAD data block is processed. For the last block, follow the steps a) and b).

*Note: This phase can be skipped if there is no AAD, that is, Len(A) = 0. No data are read during header phase.*

**GCM payload phase**

12. Initialize payload phase:
    a) Select the GCM payload phase, by writing GCMPH[1:0] with 0x2. Do not change the other configurations written during GCM initialization.
    b) If the header phase is skipped, enable the SAES peripheral by setting EN.
13. Append payload data:
   a) If it is the last block and the message in the block is smaller than 16 bytes, pad the
      remainder of the block with zeros.
   b) Append the data block into SAES as described in Section 36.4.5, then read the
      SAES_DOUTR register four times to save the resulting block
   c) Repeat the step b) until the second-last plaintext block is encrypted or until the last
      block of ciphertext is decrypted. For the last block of plaintext (encryption only),
      follow the steps a) and b). For the last block, discard the bits that are not part of
      the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(C)=0 (see GMAC mode).

GCM finalization

14. Encryption only: wait until the BUSY flag in the SAES_SR register is cleared.

15. Select the GCM final phase, by writing GCMFH[1:0] with 0x3. Do not change the other
    configurations written during GCM initialization.

16. Write the final GCM block into the SAES_DINR register. It is the concatenated AAD bit
    and payload bit lengths, as shown in Table 328.

17. Wait until the CCF flag in the SAES_ISR register is set.

18. Get the GCM authentication tag, by reading the SAES_DOUTR register four times.

19. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.

20. Disable the SAES peripheral, by clearing EN. If it is an authenticated decryption,
    compare the generated tag with the expected tag passed with the message.

Note: In the final phase, data are written to SAES_DINR normally (no swapping), while swapping
      is applied to tag data read from SAES_DOUTR.

When transitioning from the header or the payload phase to the final phase, the SAES
    peripheral must not be disabled, otherwise the result is wrong.

Suspend/resume operations in GCM mode

Suspend/resume operations are not supported in GCM mode.

36.4.12 SAES Galois message authentication code (GMAC)

The Galois message authentication code (GMAC) allows the authentication of a plaintext,
    generating the corresponding tag information (also known as message authentication code).

GMAC is similar to GCM, except that it is applied on a message composed only by plaintext
    authenticated data (that is, only header, no payload). The following figure shows typical
    message construction for GMAC.
Figure 364. Message construction in GMAC mode

For more details, refer to NIST Special Publication 800-38D, *Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC*. Figure 365 describes the GMAC chaining implementation in the SAES peripheral. To select this chaining mode, write CHMOD[2:0] with 0x3.

Figure 365. GMAC authentication mode

The GMAC algorithm corresponds to the GCM algorithm applied on a message that only contains a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.

**Suspend/resume operations in GMAC**

Suspend/resume operations are not supported in GMAC mode.
36.4.13 SAES counter with CBC-MAC (CCM)

The AES counter with cipher block chaining-message authentication code (CCM) algorithm allows encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES counter mode processing. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

*Note:* NIST does not approve CBC-MAC as an authentication mode outside the context of the CCM specification.

The following figure shows typical message construction for CCM.

**Figure 366. Message construction in CCM mode**

The structure of the message is:

- **16-byte first authentication block (B0),** composed of three distinct fields:
  - **Q:** a bit string representation of the octet length of P (Len(P))
  - **Nonce (N):** a single-use value (that is, a new nonce must be assigned to each new communication) of Len(N) size. The sum Len(N) + Len(P) must be equal to 15 bytes.
  - **Flags:** most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values t (MAC length expressed in bytes) and Q (plaintext length such that Len(P) < 2^8Q bytes). The counter blocks range associated to Q is equal to 2^8Q-4, that is, if the maximum value of Q is 8, the counter blocks used in cipher must be on 60 bits.

- **16-byte blocks (B) associated to the associated data (A).**
  This part of the message is only authenticated, not encrypted. This section has a known length Len(A) that can be a non-multiple of 16 bytes (see Figure 366). The standard also states that, on MSB bits of the first message block (B1), the associated data length expressed in bytes (a) must be encoded as follows:
  - If 0 < a < 2^16 - 2^8, then it is encoded as [a]16, that is, on two bytes.
  - If 2^16 - 2^8 < a < 2^32, then it is encoded as 0xff || 0xfe || [a]32, that is, on six bytes.
  - If 2^32 < a < 2^64, then it is encoded as 0xff || 0xff || [a]64, that is, on ten bytes.
• **16-byte blocks (B)** associated to the plaintext message P, which is both authenticated and encrypted as ciphertext C, with a known length Len(P). This length can be a non-multiple of 16 bytes (see Figure 366).

• **Encrypted MAC (T)** of length Len(T) appended to the ciphertext C of overall length Len(C).

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a special padding scheme is required.

**Note:** CCM chaining mode can also be used with associated data only (that is, no payload).

As an example, the C.1 section in NIST Special Publication 800-38C gives the following values (hexadecimal numbers):

- N: 10111213 141516 (Len(N) = 56 bits or 7 bytes)
- A: 00010203 04050607 (Len(A) = 64 bits or 8 bytes)
- P: 20212223 (Len(P) = 32 bits or 4 bytes)
- T: 6084341B (Len(T) = 32 bits or t = 4)
- B0: 4F101112 13141516 00000000 00000004
- B1: 00080001 02030405 06070000 00000000
- B2: 20212223 00000000 00000000 00000000
- CTR0: 0710111213 141516 00000000 00000000
- CTR1: 0710111213 141516 00000000 00000001

For more details, refer to NIST Special Publication 800-38C, *Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*. 
Figure 367 describes the CCM chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x4.

Figure 367. CCM mode authenticated encryption

The first block of a CCM message (B0) must be prepared by the application as defined in Table 329.

Table 329. Initialization of IV registers in CCM mode

<table>
<thead>
<tr>
<th>SAES_IVR3[31:0]</th>

</tr>
</thead>
<tbody>
<tr>
<td>B0[127:96]</td>
<td>B0[95:64]</td>
<td>B0[63:32]</td>
<td>B0[31:0]</td>
</tr>
</tbody>
</table>

1. The five most significant bits are cleared (flag bits).
2. Q length bits are cleared, except for the bit 0 that is set.

SAES supports counters up to 64 bits, as specified by NIST.
CCM encryption and decryption process

This process is described in Section 36.4.6, with the following sequence of events:

CCM initialize
1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select CCM chaining mode (write CHMOD[2:0] with 0x4) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to Section 36.4.14 (wrapped keys) and Section 36.4.15 (shared keys).
   - Select the CCM initialization phase, by writing GCMPH[1:0] with 0x0.
4. Write the B0 data in SAES_IVRx registers according to Table 329.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to Section 36.4.17: SAES key registers for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Set EN to start the first mask calculation. The EN bit is automatically cleared when the calculation is completed.
8. Wait until the CCF flag in the SAES_ISR register is set.
9. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.

CCM header phase
10. Initialize header phase:
   a) Prepare the first block of the (B1) data associated with the message, in accordance with CCM chaining rules.
   b) Select the CCM header phase, by writing GCMPH[1:0] with 0x1. Do not change the other configurations written during the CCM initialization.
   c) Enable the SAES peripheral, by setting EN.
11. Append header data:
   a) If it is the last block and the associated data in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into SAES as described in Section 36.4.5.
   c) Repeat the step b) until the second-last associated data block is processed. For the last block, follow the steps a) and b).

Note: This phase can be skipped if there is no associated data, that is, Len(A) = 0
No data are read during the header phase.
CCM payload phase

12. Initialize payload phase:
   a) Select the CCM payload phase, by writing GCMPH[1:0] with 0x2. Do not change the other configurations written during the CCM initialization.
   b) If the header phase is skipped, enable the SAES peripheral, by setting EN.

13. Append payload data:
   a) In encryption only, if it is the last block and the plaintext in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into SAES as described in Section 36.4.5, then read the SAES_DOUTR register four times to save the resulting block.
   c) Repeat the step b) until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps a) and b). For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(P) = 0 or Len(C) = Len(T).
Remove LSB_{Len(T)} encrypted tag information when decrypting ciphertext C.

CCM finalization

14. Select the CCM final phase, by writing GCMPH[1:0] with 0x3. Do not change the other configurations written during the CCM initialization.

15. Wait until CCF flag in the SAES_ISR register is set.

16. Get the CCM authentication tag, by reading the SAES_DOUTR register four times.

17. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.

18. Disable the SAES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message. Mask the authentication tag output with tag length to obtain a valid tag.

Note: In the final phase, swapping is applied to tag data read from SAES_DOUTR register.
When transiting from the header or the payload phase to the final phase, the SAES peripheral must not be disabled, otherwise the result is wrong.

Suspend and resume operations in CCM mode

To suspend the processing of a message in header or payload phase, proceed as follows:

1. If DMA is used, stop the SAES DMA transfers to the input FIFO, by clearing DMAINEN. If DMA is not used, wait until the CCF flag of the SAES_ISR register is set (computation completed).

2. In the payload phase, if DMA is not used, read four times the SAES_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag in the SAES_ISR register is set, then stop the DMA transfers from the output FIFO, by clearing DMAOUTEN.

3. Clear the CCF flag in the SAES_ISR register, by setting the CCF bit of the SAES_ICR register.

4. Save the SAES_SUSPRx registers in the memory.

5. Save the IV registers as they are altered during the data processing.

6. Disable the SAES peripheral, by clearing EN.
7. Save the current SAES_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.
8. If DMA is used, save the DMA controller status (pointer for SAES input data transfers, number of remaining bytes, and so on). In the payload phase, also save pointer for SAES output data transfers.

To resume the processing of a message, proceed as follows:
1. If DMA is used, configure the DMA controller in order to complete the remaining input FIFO transfers. In the payload phase, also configure the DMA controller for the remaining output FIFO transfers.
2. Disable the SAES peripheral, by clearing EN.
3. Write the suspend register values, previously saved in the memory, back into their corresponding SAES_SUSPRx registers.
4. Restore SAES_IVRx registers using the saved configuration.
5. Restore the initial setting values in the SAES_CR and SAES_KEYRx registers. For KEYSEL[2:0] selecting a key source different from the key registers, refer to Section 36.4.17: SAES key registers for details.
6. Enable the SAES peripheral, by setting EN.
7. If DMA is used, enable SAES DMA requests, by setting DMAINEN (and DMAOUTEN if in payload phase).

36.4.14 SAES operation with wrapped keys

SAES peripheral can wrap (encrypt) and unwrap (decrypt) application keys using hardware-secret key DHUK, XOR-ed or not with application key BHK or AHK. With this feature, AES keys can be made usable by application software without being exposed in clear-text (unencrypted).

Wrapped key sequences are too small to be suspended/resumed. SAES cannot unwrap a key using an unwrapped key.

Operation with wrapped keys for SAES in ECB and CBC modes

Figure 368 summarizes how to wrap or unwrap keys for SAES in ECB and CBC modes. To protect the wrapped key, select DHUK by writing KEYSEL[2:0] with 0x1, 0x5, or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral. AHK can also be selected, by writing KEYSEL[2:0] with 0x3.
Figure 368. Operation with wrapped keys for SAES in ECB and CBC modes

</tbody>
</table>

Note: DHUK value depends on privilege, KMOD[1:0], KEYSEL[2:0], CHMOD[2:0], and KEYSIZE.

Key wrapping for SAES

The recommended sequence to wrap (that is, encrypt) a key is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in encryption mode (MODE[1:0] at 0x0)
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size with KEYSIZE. This information is used both for the encryption key and for the key to be encrypt.
   - Select wrapped key mode by writing KMOD[1:0] with 0x1
4. Write the initialization vector in SAES_IVRx registers if CBC mode has been selected in previous step.
5. Select the DHUK key source by writing KEYSEL[2:0] with 0x1, 0x5 or 0x4. Optionally, select the BHK, by writing KEYSEL[2:0] with 0x2. Refer to Section 36.4.17 for details on the use of KEYSEL[2:0].
6. Wait until KEYVALID is set (DHUK loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Write the SAES_DINR register four times to input the key to encrypt (MSB first, see Table 331 on page 1479).
9. Wait until CCF flag is set in the SAES_ISR register.
10. Get the encrypted key (MSB first) by reading the SAES_DOUTR register four times. Then clear the CCF bit, by setting the CCF bit in SAES_ICR register.
11. Repeat steps 8. to 10. if KEYSIZE is set.
12. Disable the SAES peripheral, by clearing EN.

Note: Encryption in Wrapped-key mode is only supported when ECB or CBC is selected.
Key unwrapping for SAES

The recommended sequence to unwrap (or decrypt) a wrapped (encrypted) key using ECB/CBC is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select the chaining mode used during the wrapping process (CHMOD[2:0] at 0x0 or 0x1) in key derivation mode (MODE[1:0] at 0x1)
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size used during the wrapping process, with KEYSIZE. This information is used both for the decryption key and for the key to decrypt.
   - Select wrapped key mode, by writing KMOD[1:0] with 0x1.
4. With KEYSEL[2:0], select the same key source as when the key was wrapped/encrypted.
5. Wait until KEYVALID is set (the key loading completed).
6. Set EN bit in SAES_CR to enable the peripheral.
7. Wait until CCF flag is set in the SAES_ISR register.
8. Clear the CCF flag, by setting the CCF bit in SAES_ICR register. The decryption key is available in the AES core, and SAES is disabled automatically.
9. Select the decryption mode (MODE[1:0] at 0x2). Other parameters are unchanged.
10. Write the initialization vector in SAES_IVRx registers if CBC mode has been selected in previous step.
11. Enable the SAES peripheral, by setting EN.
12. Write the SAES_DINR register four times to input the key to decrypt (MSB first, see Table 331 on page 1479).
13. Wait until CCF flag is set in the SAES_ISR register. Then clear the CCF flag by setting the CCF bit in SAES_ICR register. Reading SAES_DOUTR returns zero and triggers a read error (RDERRF).
15. Disable the SAES peripheral, by clearing EN.

At the end of this sequence, the decrypted wrapped key is immediately usable by the application for any AES operation (normal key mode).

Note: When KMOD[1:0] = 0x1 (wrapped key) and MODE[1:0] = 0x2 (decryption) a read access to SAES_DOUTR register triggers a read error (RDERRF).

When KEYSEL[2:0] is at 0x1 (DHUK), 0x5 (DHUK XOR AHK), or 0x4 (DHUK XOR BHK), the application software must use the same privilege, KMOD[1:0], CHMOD[2:0] and KEYSIZE context for encryption and decryption. Otherwise, the result is incorrect.

Operation with wrapped keys for SAES in CTR mode

Figure 369 summarizes how to unwrap keys for SAES in CTR mode. To protect the derived key, select DHUK by writing KEYSEL[2:0] with 0x1, 0x5 or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMPER peripheral.
The recommended sequence for SAES wrapped key mode using CTR is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select the CTR chaining mode (CHMOD[2:0] at 0x2) in decryption mode (MODE[1:0] at 0x2). Other MODE[1:0] values are not supported.
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size with KEYSIZE. It is used for encryption key and for the key to share.
   - Select wrapped key mode, by writing KMOD[1:0] with 0x1.
4. Write the initialization vector in SAES_IVRx registers, keeping the two least significant bits of SAES_IVR0 at zero.
5. Select the DHUK key source by writing KEYSEL[2:0] with 0x1, 0x5 or 0x4. Optionally, select the BHK, by writing KEYSEL[2:0] with 0x2. Refer to Section 36.4.17 for details on the use of KEYSEL[2:0].
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Wait until CCF flag is set in the SAES_ISR register.
9. Clear the CCF flag, by setting the CCF bit in SAES_ICR register. The derived hardware secret key is available in SAES_KEYRx registers.
10. Repeat steps 8. and 9. if KEYSIZE is set.
11. Disable the SAES peripheral, by clearing EN.

At the end of this sequence, the hardware secret key derived from the public data in the SAES_IVRx registers is then immediately usable by the application for any AES operation (normal key mode).
Note: The configuration KMOD[1:0] at 0x1 (wrapped key), CHMOD[2:0] at 0x2 (CTR chaining), and MODE at 0x0 (encryption) disables the peripheral, by automatically clearing the EN bit of the SAES_CR register.

36.4.15 SAES operation with shared keys

SAES peripheral can share application keys wrapped with hardware-secret key DHUK, XOR-ed or not with application key BHK or AHK. With this feature, the application software can make the AES keys available to the CRYP peripheral, without exposing them in cleartext (unencrypted).

Shared key sequences are too small to be suspended/resumed. SAES cannot unwrap a shared key using an unwrapped key.

Figure 370 summarizes how to wrap or unwrap keys to share with CRYP peripheral. To protect the shared key, DHUK must be selected, by writing KEYSEL[2:0] with 0x1, 0x5, or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral. AHK can also be selected, by writing KEYSEL[2:0] with 0x3.

Note: Encryption in Shared-key mode is only supported when ECB or CBC is selected.
Key unwrapping for CRYP peripheral (shared key)

Each time SAES needs to share a key with the CRYP peripheral, shared encrypted key must be decrypted (unwrapped) in SAES, then loaded by CRYP. The overall sequence is described next.

Sequence in the SAES peripheral

The decryption sequence of a shared key is the same as for a wrapped key, with KMOD[1:0] at 0x2 (shared key) and KSHAREID[1:0] kept at 0x0 in the step 3 in Figure 370. See Key unwrapping for SAES for details.

In shared key mode when decryption mode is selected (MODE[1:0] at 0x2), a read access to the SAES_DOUTR register triggers a read error (RDERRF).

Note: Instead of being shared, a decrypted shared key can be used directly in SAES as the KEYSEL[2:0] bitfield is automatically cleared. In this case, KMOD[1:0] must be written with 0x0 (normal key mode).

Sequence in the CRYP peripheral

Once the shared key is decrypted in SAES key registers, it can be shared with the CRYP peripheral, while SAES peripheral remains in key sharing state, that is, with KMOD[1:0] at 0x2 and KEYVALID set. The sequence in the CRYP key share target peripheral is described in AES key sharing with secure AES co-processor of the corresponding section in this document. It can be run multiple times (for example, to manage a suspend/resume situation) as long as SAES is unused and duly remains in key sharing state.

Note: When KMOD[1:0] is at 0x2 and BUSY set in the CRYP peripheral, and KEYSIZE value of CRYP and SAES differs, the key sharing fails and the KEIF flag is raised in both peripherals.

36.4.16 SAES data registers and data swapping

Data input and output

A 16-byte data block enters the SAES peripheral with four successive 32-bit word writes into the SAES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 16-byte data block is retrieved from the SAES peripheral with four successive 32-bit word reads of the SAES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The four 32-bit words of a 16-byte data block must be stored in the memory consecutively and in big-endian order, that is, with the most significant word on the lowest address. See Table 330 “no swapping” option for details.

Data swapping

The SAES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the SAES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to
the SAES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through DATATYPE[1:0]. The selection applies to both SAES input and output.

Note: The data in SAES key registers (SAES_KEYRx) and initialization vector registers (SAES_IVRx) are not sensitive to the swap mode selection.

The SAES data swapping feature is summarized in Table 330 and Figure 371.

---

**Data padding**

*Figure 371* also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 84 message bits, with $\text{DATATYPE}[1:0] = 0x0$
- 48 message bits, with $\text{DATATYPE}[1:0] = 0x1$
- 56 message bits, with $\text{DATATYPE}[1:0] = 0x2$
- 34 message bits, with $\text{DATATYPE}[1:0] = 0x3$
### 36.4.17 SAES key registers

The eight SAES_KEYRx write-only registers store the encryption or decryption key information, as shown on Table 331. Reads are not allowed for security reason.

**Note:** In memory and in SAES key registers, keys are stored in little-endian format, with most significant byte on the highest address.

#### Table 331. Key endianness in SAES_KEYRx registers (128/256-bit keys)

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>

<td>-</td>
<td>KEY[127:96]</td>
<td>KEY[95:64]</td>
<td>KEY[63:32]</td>
<td>KEY[31:0]</td>
</tr>
</tbody>
</table>

The key registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield.

Write operations to the SAES_KEYRx registers are ignored when SAES peripheral is enabled (EN bit set) and KEYSEL[2:0] is different from zero. The application must check this before modifying key registers.

The entire key must be written before starting an AES computation.

In normal key mode (KMOD[1:0] at 0x0), with KEYSEL[2:0] at 0x0, the key registers must always be written in either ascending or descending order. The write sequence becomes:

- SAES_KEYRx (x = 0 to 3 or x=3 to 0) for KEYSIZE cleared
- SAES_KEYRx (x = 0 to 7 or x=7 to 0) for KEYSIZE set

**Note:** KEYSIZE must be written before the key.

As soon as the first key register is written, the KEYVALID flag is cleared. Once the key registers writing sequence is completed, KEYVALID is set and EN becomes writable. If an error occurs, KEYVALID is cleared and KEIF set (see Section 36.4.19).

#### Key selection

With KEYSEL[2:0] at 0x0, the application must write the key in the SAES_KEYRx registers.

With KEYSEL[2:0] at 0x1, a derived hardware unique key (DHUK), computed inside SAES from a non-volatile and secret root hardware unique key, is loaded directly into key registers, based on KEYSIZE information.

With KEYSEL[2:0] at 0x2, the boot hardware key (BHK), stored in tamper-resistant secure backup registers, is entirely transferred into key registers upon performing a single read of all TAMP_BKPxR registers (x = 0 to 3 for KEYSIZE cleared, x = 0 to 7 for KEYSIZE set) in ascending order. Refer to Table 331.

With KEYSEL[2:0] at 0x4, the XOR combination of DHUK and BHK is entirely transferred into key registers upon performing a single read of all TAMP_BKPxR registers (x = 0 to 3 for KEYSIZE cleared, x = 0 to 7 for KEYSIZE set) in ascending order. Refer to Table 331.
With KEYSEL[2:0] at 0x3, the application hardware key (AHK), stored in the embedded Flash memory, is entirely transferred into key registers upon performing a successful option byte key read.

With KEYSEL[2:0] at 0x5, the XOR combination of DHUK and AHK is entirely transferred into key registers upon performing a successful option byte read.

Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK, AHK, or BHK if KEYVALID is set. The recommended method to clear KEYVALID is to set IPRST. Such method is required for example when switching from ECB decryption to ECB encryption, selecting the same BHK (KEYSEL[2:0] at 0x2).

For all KEYSEL[2:0] values, initiating the key-loading sequence sets the BUSY flag and clears the KEYVALID flag. Once the amount of bits defined by KEYSIZE is transferred to the SAES_KEYRx registers, BUSY is cleared, KEYVALID set and the EN bit becomes writable.

If an error occurs, BUSY and KEYVALID are cleared and KEIF set (see Section 36.4.19).

Note: DHUK, AHK, BHK and their XOR combination are not readable by software.

### 36.4.18 SAES initialization vector registers

The four SAES_IVRx registers store the initialization vector (IV) information, as shown in Table 332. They can only be written if the SAES peripheral is disabled (EN cleared).

Note: In memory and in SAES IV registers, initialization vectors are stored in little-endian format, with most significant byte on the highest address.

<table>
<thead>
<tr>
<th>SAES_IVR3[31:0]</th>
<th>SAES_IVR2[31:0]</th>
<th>SAES_IVR1[31:0]</th>
<th>SAES_IVR0[31:0]</th>
</tr>
</thead>
</table>

Initialization vector information depends on the chaining mode selected. When used, SAES_IVRx registers are updated upon each AES computation cycle (useful for managing suspend mode).

The initialization vector registers are not affected by the data swapping feature controlled through DATATYPE[1:0].

### 36.4.19 SAES error management

The SAES peripheral manages the errors described in this section.

#### Read error flag (RDERRF)

Unexpected read attempt of the SAES_DOUTR register returns zero, setting the RDERRF flag and the RWEIF flag. RDERRF is triggered during the computation phase or during the input phase.

Note: Unless otherwise indicated, SAES is not disabled when RDERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to Section 36.5: SAES interrupts.
The RDERRF and RWEIF flags are cleared by setting the RWEIF bit of the SAES_ICR register.

**Write error flag (WRERRF)**

Unexpected write attempt of the SAES_DINR register is ignored, setting the WRERRF and the RWEIF flags. WRERRF is triggered during the computation phase or during the output phase.

*Note:* Unless otherwise indicated, SAES is not disabled when WRERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to Section 36.5: SAES interrupts.

The WRERRF and RWEIF flags are cleared by setting the RWEIF bit of the SAES_ICR register.

**Key error interrupt flag (KEIF)**

There are multiple sources of errors that set the KEIF flag of the SAES_ISR register and clear the KEYVALID bit of the SAES_SR register:

- **Key writing sequence error:** triggered upon detecting an incorrect sequence of writing key registers. See Section 36.4.17: SAES key registers for details.
- **Key sharing size mismatch error:** triggered when KMOD[1:0] is at 0x2 and KEYSIZE in CRYP peripheral does not match KEYSIZE in SAES peripheral.
- **Key sharing error:** triggered upon failing transfer of SAES shared key to CRYP peripheral. See Section 36.4.15: SAES operation with shared keys for details.
- **Hardware secret key loading error:** triggered upon failing load of DHUK, AHK, or BHK into SAES. KEYSEL[2:0] at 0x1 (DHUK), 0x2 (BHK), 0x3 (AHK), 0x5 (DHUK XOR AHK), or 0x4 (DHUK XOR BHK) is not functional.

The KEIF flag is cleared with corresponding bit of the SAES_ICR register. An interrupt is generated if the KEIE bit of the SAES_IER register is set. For more details, refer to Section 36.5: SAES interrupts.

Upon a key selection error, clearing the KEIF flag automatically restarts the key selection process. Persisting problems (for example, RHUK load failing) may require a power-on reset.

Upon a key sharing error, reset both CRYP and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

*Note:* For any key error, clear KEIF flag prior to disabling and re-configuring SAES.

**RNG error interrupt flag (RNGEIF)**

SAES fetches random numbers from the RNG peripheral automatically after an IP reset triggered in the RCC. SAES cannot be used when RNGEIF is set.

An error detected while fetching a random number from RNG peripheral (due to, for example, bad entropy) sets the RNGEIF flag of the SAES_ISR register. The flag is cleared by setting the corresponding bit of the SAES_ICR register. An interrupt is generated if the
RNGEIE bit of the SAES_IER register is set. For more details, refer to Section 36.5: SAES interrupts.

Upon an RNG error:

- Verify that the RNG peripheral AHB clock is enabled and no noise source (or seed) error is pending in this peripheral.
- Clear RNGEIF or reset the peripheral by setting IPRST. The clearance of the BUSY flag then indicates the completion of the random number fetch from RNG.

**Note:** To avoid RNGEIF errors, it is recommended to activate the RNG AHB clock each time SAES AHB clock is activated.

**About DPA errors**

An unexpected error triggers an SAES internal tamper event in the TAMP peripheral, and stops any SAES co-processor processing.

To resume normal operation, reset the SAES peripheral through RCC or global reset.

### 36.5 SAES interrupts

There are multiple individual maskable interrupt sources generated by the SAES peripheral to signal the following events:

- computation completed (CCF)
- read error (RDERRF)
- write error (WRERRF)
- key error (KEIF)
- RNG error (RNGEIF)

See Section 36.4.19: SAES error management for details on SAES errors.

These sources are combined into a common interrupt signal from the SAES peripheral that connects to the Cortex® CPU interrupt controller. Application can enable or disable SAES interrupt sources individually by setting/clearing the corresponding enable bit of the SAES_IER register.

The status of the individual maskable interrupt sources can be read from the SAES_ISR register. They are cleared by setting the corresponding bit of the SAES_ICR register.

**Table 333** gives a summary of the available features.

1. Bit of the SAES_ICR register.
2. Flag of the SAES_SR register, mirrored by the flag RWEIF of the SAES_ISR register.

36.6 SAES DMA requests

The SAES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the DMAINEN and DMAOUTEN bits of the SAES_CR register. When key derivation is selected (MODE[1:0] is at 0x1), setting those bits has no effect.

SAES only supports single DMA requests.

Detailed usage of DMA with SAES can be found in Appending data using DMA subsection of Section 36.4.5: SAES encryption or decryption typical usage.

Data input using DMA

Setting DMAINEN enables DMA writing into SAES. SAES then initiates, during the input phase, a set of single DMA requests for each 16-byte data block to write to the SAES_DINR register (quadruple 32-bit word, MSB first).

Note: According to the algorithm and the mode selected, special padding / ciphertext stealing might be required (see Section 36.4.7).

Data output using DMA

Setting DMAOUTEN enables DMA reading from SAES. SAES then initiates, during the output phase, a set of single DMA requests for each 16-byte data block to read from the SAES_DOUTR register (quadruple 32-bit word, MSB first).

After the output phase, at the end of processing of a 16-byte data block, SAES switches automatically to a new input phase for the next data block, if any.

In DMA mode, the CCF flag has no use because the reading of the SAES_DOUTR register is managed by DMA automatically at the end of the computation phase. The CCF flag must only be cleared when transiting back to managing the data transfers by software.

Note: According to the message size, extra bytes might need to be discarded by application in the last block.

Stopping DMA transfers

All DMA request signals are de-asserted when SAES is disabled (EN cleared) or the DMA enable bit (DMAINEN for input data, DMAOUTEN for output data) is cleared.

36.7 SAES processing latency

The following tables provide the 16-byte data block processing latency per operating mode.

<table>
<thead>
<tr>
<th>Key size</th>
<th>Mode of operation</th>
<th>Chaining algorithm</th>
<th>Clock cycles(1)</th>

</tr>
<tr>
<td></td>
<td></td>
<td>CCM</td>
<td>650</td>
<td>680</td>
<td>1350</td>
<td>650</td>
</tr>
</tbody>
</table>

1. Data insertion can include wait states forced by SAES on the AHB bus (maximum 3 cycles, typical 1 cycle).
2. SAES AHB clock cycles instead of kernel clock cycle (Galois multiplier only).
3. As a worst case in encryption mode, add extra 72 AHB clock cycles for the last block computation.
36.8 **SAES registers**

The registers are accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.

### 36.8.1 SAES control register (SAES_CR)

**Bit 31 IPRST**: SAES peripheral software reset

Setting the bit resets the SAES peripheral, putting all registers to their default values, except the IPRST bit itself. Hence, any key-relative data are lost. For this reason, it is recommended to set the bit before handing over the SAES to a less secure application.

The bit must be kept low while writing any configuration registers.

**Bits 30:28 KEYSEL[2:0]**: Key selection

The bitfield defines the source of the key information to use in the AES cryptographic core.

0x0: Software key, loaded in key registers SAES_KEYx

0x1: Derived hardware unique key (DHUK)

0x2: Boot hardware key (BHK)

0x3: Application hardware key (AHK)

0x4: XOR of DHUK and BHK

0x5: XOR of DHUK and AHK

Others: Reserved (if used, unfreeze SAES with IPRST)

When KEYSEL[2:0] is different from zero, selected key value is available in key registers when BUSY bit is cleared and KEYVALID is set in the SAES_SR register. Otherwise, the key error flag KEIF is set. Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK or BHK when KEYVALID is cleared.

When the application software changes the key selection by writing the KEYSEL[2:0] bitfield, the key registers are immediately erased and the KEYVALID flag cleared.

At the end of the decryption process, if KMOD[1:0] is other than zero, KEYSEL[2:0] is cleared. Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.
Bits 27:26 **KSHAREID[1:0]**: Key share identification
This bitfield defines, at the end of a decryption process with KMOD[1:0] at 0x2 (shared key), which target can read the SAES key registers using a dedicated hardware bus.
0x0: CRYP peripheral
Others: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 25:24 **KMOD[1:0]**: Key mode selection
The bitfield defines how the SAES key can be used by the application. KEYSIZE must be correctly initialized when setting KMOD[1:0] different from zero.
0x0: Normal key mode. Key registers are freely usable and no specific use or protection applies to SAES_DINR and SAES_DOUTR registers.
0x1: Wrapped key for SAES mode. Key loaded in key registers can only be used to encrypt or decrypt AES keys. Hence, when a decryption is selected, read-as-zero SAES_DOUTR register is automatically loaded into SAES key registers after a successful decryption process.
0x2: Shared key mode. After a successful decryption process (unwrapping), SAES key registers are shared with the peripheral described in KSHAREID[1:0] bitfield. This sharing is valid only while KMOD[1:0] at 0x2 and KEYVALID=1. When a decryption is selected, read-as-zero SAES_DOUTR register is automatically loaded into SAES key registers after a successful decryption process.
Others: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 23:20 **NPBLB[3:0]**: Number of padding bytes in last block
This padding information must be filled by software before processing the last block of GCM payload encryption or CCM payload decryption, otherwise authentication tag computation is incorrect.
0x0: All bytes are valid (no padding)
0x1: Padding for the last LSB byte
... 
0xF: Padding for the 15 LSB bytes of last block.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **KEYSIZE**: Key size selection
This bitfield defines the key length in bits of the key used by SAES.
0: 128-bit
1: 256-bit
When KMOD[1:0] is at 0x1 or 0x2, KEYSIZE also defines the length of the key to encrypt or decrypt. Attempts to write the bit are ignored when BUSY is set, as well as when the EN is set before the write access and it is not cleared by that write access.

Bit 17 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bits 14:13 **GCMPH[1:0]**: GCM or CCM phase selection
This bitfield selects the phase, applicable only with GCM, GMAC or CCM chaining modes.
0x0: Initialization phase
0x1: Header phase
0x2: Payload phase
0x3: Final phase
Bit 12 DMAOUTEN: DMA output enable
This bit enables automatic generation of DMA requests during the data phase, for outgoing data transfers from SAES via DMA.
0: Disable
1: Enable
Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bit 11 DMAINEN: DMA input enable
This bit enables automatic generation of DMA requests during the data phase, for incoming data transfers to SAES via DMA.
0: Disable
1: Enable
Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bits 10:7 Reserved, must be kept at reset value.

Bits 16, 6:5 CHMOD[2:0]: Chaining mode
This bitfield selects the AES chaining mode:
0x0: Electronic codebook (ECB)
0x1: Cipher-block chaining (CBC)
0x2: Counter mode (CTR)
0x3: Galois counter mode (GCM) and Galois message authentication code (GMAC)
0x4: Counter with CBC-MAC (CCM)
others: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 4:3 MODE[1:0]: Operating mode
This bitfield selects the SAES operating mode:
0x0: Encryption
0x1: Key derivation (or key preparation), for ECB/CBC decryption only
0x2: Decryption
0x3: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access.

Bits 2:1 DATATYPE[1:0]: Data type
This bitfield defines the format of data written in the SAES_DINR register or read from the SAES_DOUTR register, through selecting the mode of data swapping. This swapping is defined in Section 36.4.16: SAES data registers and data swapping.
0x0: No swapping (32-bit data).
0x1: Half-word swapping (16-bit data)
0x2: Byte swapping (8-bit data)
0x3: Bit-level swapping
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.
Bit 0  **EN**: Enable
This bit enables/disables the SAES peripheral.
0: Disable
1: Enable
At any moment, clearing then setting the bit re-initializes the SAES peripheral. When KMOD[1:0] is different from 0x0, using IPRST bit is recommended instead.
This bit is automatically cleared by hardware upon the completion of the key preparation (MODE[1:0] at 0x1) and upon the completion of GCM/GMAC/CCM initialization phase.
The bit cannot be set as long as KEYVALID is cleared, or when SAES is in one of the following configurations:
- KMOD[1:0] at 0x1 (wrap), CHMOD[2:0] at 0x3 (GCM)
- KMOD[1:0] at 0x1 (wrap), CHMOD[2:0] at 0x2 (CTR), MODE[1:0] at 0x0 (encryption).

### 36.8.2 SAES status register (SAES_SR)
Address offset: 0x004
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>

<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

Bits 31:8 Reserved, must be kept at reset value.

Bit 7  **KEYVALID**: Key valid flag
This bit is set by hardware when the key of size defined by KEYSIZE is loaded in SAES_KEYRx key registers.
0: Key not valid
1: Key valid
The EN bit can only be set when KEYVALID is set.
In normal mode when KEYSEL[2:0] is at zero, the key must be written in the key registers in the correct sequence, otherwise the KEIF flag is set and KEYVALID remains cleared.
When KEYSEL[2:0] is different from zero, the BUSY flag is automatically set by SAES. When the key is loaded successfully, BUSY is cleared and KEYVALID set. Upon an error, KEIF is set, BUSY cleared and KEYVALID remains cleared.
If set, KEIF must be cleared through the SAES_ICR register, otherwise KEYVALID cannot be set.
See the KEIF flag description for more details.
For further information on key loading, refer to Section 36.4.17: SAES key registers.

Bits 6:4 Reserved, must be kept at reset value.
Bit 3 **BUSY**: Busy
This flag indicates whether SAES is idle or busy.
0: Idle
1: Busy
SAES is flagged as idle when disabled (when EN is low) or when the last processing is completed. SAES is flagged as busy when processing a block data, preparing a key (ECB or CBC decryption only), fetching random number from the RNG, or transferring a shared key to the target peripheral. When GCM encryption payload phase is selected, this flag must be at zero before suspending current process to manage a higher-priority message. BUSY must also be cleared before selecting the GCM final phase.

Bit 2 **WRERRF**: Write error flag
This bit is set when an unexpected write to the SAES_DINR register occurred. When set WRERRF bit has no impact on the SAES operations.
0: No error
1: Unexpected write to SAES_DINR register occurred during computation or data output phase.
The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.
The flag is cleared by setting the RWEIF bit of the SAES_ICR register.

Bit 1 **RDERRF**: Read error flag
This bit is set when an unexpected read to the SAES_DOUTR register occurred. When set RDERRF bit has no impact on the SAES operations.
0: No error
1: Unexpected read to SAES_DOUTR register occurred during computation or data input phase.
The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.
The flag is cleared by setting the RWEIF bit of the SAES_ICR register.

Bit 0 Reserved, must be kept at reset value.

### 36.8.3 SAES data input register (SAES_DINR)

</table>

Bits 31:0 **DIN[31:0]**: Data input
A four-fold sequential write to this bitfield during the Input phase results in writing a complete 16-bytes block of input data to the SAES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 16-bytes input buffer.
Reads return zero.
36.8.4 SAES data output register (SAES_DOUTR)

Address offset: 0x00C
Reset value: 0x0000 0000

Read when KMOD[1:0] is at 0x1 or 0x2 while MODE[1:0] is at 0x2 and EN is set triggers a read error.

</table>

DOUT[31:16]: Data output

This read-only bitfield fetches a 32-bit output buffer. A four-fold sequential read of this bitfield, upon the computation completion (CCF flag set), virtually reads a complete 16-byte block of output data from the SAES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield.

Data weights from the first to the fourth read operation are: [127:96], [95:64], [63:32], and [31:0].

KEY[31:16]: Cryptographic key, bits [31:0]

These are bits [31:0] of the write-only bitfield KEY[255:0] AES encryption or decryption key, depending on the MODE[1:0] bitfield of the SAES_CR register.

Writes to SAES_KEYRx registers are ignored when SAES is enabled (EN bit set). When KEYSEL[2:0] is different from 0 and KEYVALID is 0, writes to key registers are also ignored and they result in setting the KEIF bit of the SAES_ISR register.

With KMOD[1:0] at 0x0, a special writing sequence is required. In this sequence, any valid write to AES_KEYRx register clears the KEYVALID flag except for the sequence-completing write that sets it. Also refer to the description of the KEYVALID flag in the AES_SR register.
36.8.6 SAES key register 1 (SAES_KEYR1)

Bits 31:4 Reserved, must be kept at reset value.

- **Bit 3 RNGEIE: RNG error interrupt enable**
  - This bit enables or disables (masks) the SAES interrupt generation when RNGEIF (RNG error flag) is set.
  - 0: Disabled (masked)
  - 1: Enabled (not masked)

- **Bit 2 KEIE: Key error interrupt enable**
  - This bit enables or disables (masks) the SAES interrupt generation when KEIF (key error flag) is set.
  - 0: Disabled (masked)
  - 1: Enabled (not masked)

- **Bit 1 RWEIE: Read or write error interrupt enable**
  - This bit enables or disables (masks) the SAES interrupt generation when RWEIF (read and/or write error flag) is set.
  - 0: Disabled (masked)
  - 1: Enabled (not masked)

- **Bit 0 CCFIE: Computation complete flag interrupt enable**
  - This bit enables or disables (masks) the SAES interrupt generation when CCF (computation complete flag) is set.
  - 0: Disabled (masked)
  - 1: Enabled (not masked)
36.8.19 SAES interrupt status register (SAES_ISR)

Address offset: 0x304
Reset value: 0x0000 0000

| Bits 31:4 | Reserved, must be kept at reset value. |
| Bit 3    | RNGEIF: RNG error interrupt flag |
|          | This read-only bit is set by hardware when an error is detected on RNG bus interface (for example bad entropy). |
|          | 0: RNG bus is functional |
|          | 1: Error detected on RNG bus interface (random seed fetching error) |
|          | The flag setting generates an interrupt if the RNGEIE bit of the SAES_IER register is set. |
|          | The flag is cleared by setting the corresponding bit of the SAES_ICR register. The clear action triggers the reload of a new random number from the RNG peripheral. |
| Bit 2    | KEIF: Key error interrupt flag |
|          | This read-only bit is set by hardware when the key information fails to load into key registers or when the key register use is forbidden. |
|          | 0: No key error detected |
|          | 1: Key information failed to load into key registers or the key register use is forbidden |
|          | The flag setting generates an interrupt if the KEIE bit of the SAES_IER register is set. It also clears the key registers and the KEYVALID flag in the SAES_SR register. |
|          | The flag is cleared by setting the corresponding bit of the SAES_ICR register. |
|          | KEIF is raised upon any of the following events: |
|          | –SAES fails to load the DHUK (KEYSEL[2:0] = 0x1 or 0x4). |
|          | –SAES fails to load the BHK (KEYSEL[2:0] = 0x2 or 0x4). |
|          | –SAES fails to load the AHK (KEYSEL[2:0] = 0x3 or 0x5). |
|          | –CRYP fails to load the key shared by SAES peripheral (KMOD[1:0] = 0x2). |
|          | –SAES_KEYRx register write does not respect the correct order. (For KEYSIZE cleared, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 register, or reverse. For KEYSIZE set, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 then SAES_KEYR4 then SAES_KEYR5 then SAES_KEYR6 then SAES_KEYR7, or reverse). |
|          | KEIF must be cleared by the application software, otherwise KEYVALID cannot be set. |
| Bit 1    | RWEIF: Read or write error interrupt flag |
|          | This read-only bit is set by hardware when a RDERRF or a WRERRF error flag is set in the SAES_SR register. |
|          | 0: No read or write error detected |
|          | 1: Read or write error detected |
|          | The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set. |
|          | The flag is cleared by setting the corresponding bit of the SAES_ICR register. |
|          | The flags has no meaning when key derivation mode is selected. |
|          | See the SAES_SR register for details. |

Refer to Section 2.3 on page 149 for the register boundary addresses.
37 Cryptographic processor (CRYP)

37.1 Introduction

The cryptographic processor (CRYP) encrypts or decrypts data in compliance with the advanced encryption standard (AES) defined by NIST. CRYP supports ECB, CBC, CTR, GCM, GMAC, and CCM chaining modes for key sizes of 128, 192 or 256 bits. CRYP has the possibility to load by hardware the key stored in SAES peripheral, under SAES control.

The peripheral supports both single and fixed DMA burst transfers for incoming and outgoing data (two DMA channels are required). CRYP also includes input and output FIFOs for better performance.

37.2 CRYP main features

- Compliant with NIST FIPS publication 197 “Advanced encryption standard (AES)” (November 2001)
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- 16-byte data block processing, supporting cipher key lengths of 128, 192 and 256 bits
  - 14 or 18 clock cycle latency in ECB mode for processing one 16-byte block with 128-bit or 256-bit key, respectively
- Using dedicated key bus, optional key sharing with side-channel resistant SAES peripheral (shared-key mode), controlled by SAES
- Integrated key scheduler to compute the last round key for ECB/CBC decryption
- 256-bit of write-only registers for storing the cryptographic keys (eight 32-bit registers)
- 128-bit of registers for storing initialization vectors (four 32-bit registers)
- 32-bit input buffer associated with an internal input FIFO of eight 32-bit words, corresponding to two AES blocks
- 32-bit output buffer associated with an internal output FIFO of eight 32-bit words, corresponding to two AES blocks
- Automatic data flow control supporting two direct memory access (DMA) channels, one for incoming data, one for processed data. The output FIFO supports both single and burst transfers, while the input FIFO supports only burst transfers.
- Data swapping logic to support 1-, 8-, 16- or 32-bit data
- AMBA AHB target peripheral, accessible through 32-bit word single accesses only. Other access types generates an AHB error, and write accesses are ignored.
- Possibility for software to suspend a message if CRYP needs to process another message with a higher priority, then resume the original message
37.3 CRYP implementation

The devices have one CRYP peripheral, implemented as per the following table. It can use the key generated by the SAES peripheral. For comparison, the SAES peripheral is also included in the table.

37.4.3 CRYP reset and clocks

The CRYP peripheral is clocked by the AHB clock.
The CRYP has a dedicated reset bit in the RCC.

37.4.4 CRYP symmetric cipher implementation

The cryptographic processor (CRYP) is a 32-bit AHB peripheral that encrypts or decrypts 16-byte blocks of data using the advanced encryption standard (AES). It also implements a set of approved AES symmetric key security functions summarized in Table 339. Those functions can be certified NIST PUB 140-3.

CRYP can be used directly by the CPU, or indirectly using two DMA channels (one for the plaintext, one for the ciphertext).
It is possible to suspend then resume any CRYP processing, following the sequence described in Section 37.4.8.
37.4.5 **CRYP encryption/ decryption typical usage**

The following figure shows a typical operation for encryption or decryption.

![Figure 373. Encryption/ decryption typical usage](MSv66120V1)

**Initialization**

The CRYP peripheral is initialized according to the chaining mode. Refer to **Section 37.4.9: CRYP basic chaining modes (ECB, CBC)** and **Section 37.4.10: CRYP counter mode (CTR)** for details.

**Data append**

This section describes different ways of appending data for processing. For ECB or CBC chaining modes, refer to **Section 37.4.7: CRYP ciphertext stealing and data padding** if the size of data to process is not a multiple of 16 bytes. The last block management in these cases is more complex than what is described in this section.

**General conditions for data processing**

The CRYP is busy and processing data (BUSY flag set) when all the conditions below are met:

- CRYPEN is set in CRYP_CR register.
- There are enough data in the input FIFO (at least four words).
- There is enough free-space in the output FIFO (at least four word locations).

It is possible to clear the CRYPEN bit while BUSY bit is set. In this case the ongoing AES processing first completes (that is, the word results are written to the output FIFO) before the BUSY bit is cleared by hardware.

*Note:* If the application needs to suspend a message to process another one with a higher priority, refer to **Section 37.4.8: CRYP suspend and resume operations**.
Appending data using the CPU in polling mode

This method uses flag polling to control the data append through the following sequence:

1. When KEYVALID is set, enable CRYP by setting the CRYPEN bit of the CRYP_CR register (if not already done).

2. Repeat the following subsequence until the payload is entirely processed:
   a) Write data in the input FIFO (one block or until the FIFO is full).
   b) Repeat until the second last block of data has been processed:
      – Wait until the not-empty flag OFNE is set, then read the output FIFO (one block or until the FIFO is empty).
      – Wait until the not-full flag IFNF is set, then write the input FIFO (one block or until the FIFO is full), except if it is the last block.
   c) The BUSY bit is set automatically by CRYP. At the end of the processing, the BUSY bit is cleared and both FIFOs are empty (input FIFO empty flag IFEM is set, output FIFO not-empty flag OFNE is cleared).
   d) If the next processing block is the last block, pad the data with zeros to obtain a complete block (when applicable), and specify the number of non-valid bytes (using NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong). This operation must be performed after checking that the BUSY bit is cleared.

3. As the data block just processed is the last block of the message, optionally discard the data that is not part of the message/payload, then disable the CRYP peripheral by clearing CRYPEN.

Note: NPBLB[3:0] bitfield is not used in header phase of GCM, GMAC and CCM chaining modes.

Appending data using the CPU in Interrupt mode

The method uses interrupt from the CRYP peripheral to control the data append, through the following sequence:

1. Enable interrupts from CRYP, by setting the INIM and OUTIM bits of the CRYP_IMSCR register.

2. When KEYVALID is set, enable the CRYP peripheral, by setting CRYPEN (if not already done).

3. Handle the data in the CRYP interrupt service routine that manages the input FIFO. Upon each interrupt:
   a) If the next processing block is the last block of the message, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (using NPBLB[3:0] bitfield) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong). This operation must be performed after checking that the BUSY bit is cleared. After that load the block into the input FIFO.
   b) If the next processing block is not the last block, load the data into the input FIFO. Application can load only one block (4 words), or load data until the input FIFO is full.
   c) After the last word of data has been written, disable the input FIFO interrupts by clearing the INIM bit (if applicable), then quit the interrupt service routine.
4. Handle the data in the CRYP interrupt service routine that manages the output FIFO. Upon each interrupt:
   a) Read data from the output FIFO. Application can read only one block (4 words), or read data until the FIFO is empty.
   b) When the last word of the message has been read, INIM and BUSY bits are cleared and both FIFOs are empty (IFEM is set, OFNE is cleared). Disable the output FIFO interrupt by clearing the OUTIM bit, and disable the peripheral by clearing the CRYPEN bit.
   c) If the data block just processed is the last block of the message, optionally discard the data that are not part of the message/payload, then quit the interrupt service routine.

Note: The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC and CCM chaining modes.

Appending data using the DMA

With this method, all the transfers and processing are managed by DMA and CRYP. Proceed as follows:

1. If the last block of the message to process is shorter than 16 bytes, prepare the last four-word data block by padding the remainder of the block with zeros.
2. Configure the DMA controller so as to transfer the data to process from the memory to the CRYP peripheral input and the processed data from the CRYP peripheral output to the memory, as described in Section 37.6: CRYP DMA requests. Configure the DMA controller so as to generate an interrupt on transfer completion. For GCM payload encryption or CCM payload decryption, the DMA transfer must not include the last block. The sequence described in Appending data using the CPU in polling mode must be used instead for this last block, because the NPBLB[3:0] bitfield must be set up before processing the block, for CRYP to compute a correct tag.
3. When KEYVALID is set, enable the CRYP peripheral, by setting CRYPEN (if not already done).
4. Enable DMA requests, by setting DIEN and DOEN of the CRYP_DMACR register.
5. Upon DMA interrupt indicating the transfer completion, get the CRYP-processed data from the memory. Both FIFOs are normally empty and BUSY flag is cleared.

Note: The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC and CCM chaining modes.

Caution: It is important that the DMA controller empties the CRYP output FIFO before filling up the CRYP input FIFO. To achieve this, the DMA controller must be configured so that the transfer from the CRYP to the memory has a higher priority than the transfer from the memory to the CRYP.
37.4.6 CRYP authenticated encryption, decryption, and cipher-based message authentication

The following figure shows a typical operation for authenticated encryption or decryption, and for cipher-based message authentication.

![Figure 374. Typical operation with authentication](image)

Section 37.4.11: CRYP AES Galois/counter mode (GCM) and Section 37.4.13: CRYP AES Counter with CBC-MAC (CCM) describe detailed sequences supported by CRYP.

Cipher-based message authentication flow omits the payload phase, as shown in the figure. Detailed sequence supported by CRYP is described in Section 37.4.12: CRYP AES Galois message authentication code (GMAC).

37.4.7 CRYP ciphertext stealing and data padding

When using ECB or CBC modes to manage messages the size of which is not a multiple of the block size (16 bytes), the application must use ciphertext stealing techniques such as those described in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode. Since CRYP does not implement such techniques, the application must complete the last block of input data using data from the second last block.

**Note:** Ciphertext stealing techniques are not documented in this reference manual.

Similarly, in other modes than ECB or CBC, an incomplete input data block (that is, a block with input data shorter than 16 bytes) must be padded with zeros prior to encryption. That is, extra bits must be appended to the trailing end of the data string. After decryption, the extra bits must be discarded. Since CRYP does not implement automatic data padding operation to the last block, the application must follow the recommendation given in this document to manage messages the size of which is not a multiple of 16 bytes.
37.4.8 CRYP suspend and resume operations

A message can be suspended to process another message with a higher priority. When the higher-priority message is sent, the suspended message can resume. This applies to both encryption and decryption mode.

Suspend and resume operations do not break the chaining operation. The message processing can resume as soon as CRYP is enabled again, to receive a next data block. Figure 375 gives an example of suspend and resume operation: message 1 is suspended in order to send a shorter and higher-priority message 2.

![Figure 375. Example of suspend mode management](image)

Detailed descriptions of suspend and resume operations are provided in the sections dedicated to each chaining mode.

37.4.9 CRYP basic chaining modes (ECB, CBC)

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately. When decrypting in ECB mode, a special key scheduling is required before processing the first block.

Figure 376 and Figure 377 describe the electronic codebook (ECB) chaining implementation in encryption and decryption, respectively. To select this chaining mode, write ALGOMODE[3:0] with 0x4.
In CBC encryption mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing. When decrypting in CBC mode, a special key scheduling is required before processing the first block.
Figure 378 and Figure 379 describe the cipher block chaining (CBC) implementation in encryption and decryption, respectively. To select this chaining mode, write ALGOMODE[3:0] with 0x5.

For more details, refer to NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.
ECB/CBC encryption process

This process is described in Section 37.4.5, with the following sequence of events:

1. Disable the CRYP peripheral by clearing CRYPEN.
2. Flush the FIFOs by setting FFLUSH.
3. Initialize the CRYP_CR register as follows:
   a) Select ECB or CBC chaining mode (write ALGOMODE[3:0] with 0x4 or 0x5) in encryption mode (ALGODIR = 0).
   b) Configure the data type through DATATYPE[1:0].
   c) Configure the key size through KEYSIZE.
   d) Select the key mode using KMOD[1:0]: if the key is coming from SAES peripheral, set KMOD[1:0] to 0x2, else keep it at 0x0.
4. Write the initialization vector into the CRYP_IVxL/R registers if CBC mode is selected in the previous step.
5. Write the key into the CRYP_KxL/R registers if KMOD[1:0] is 0x0. If KMOD[1:0] = 0x2, the key is being transferred from the SAES peripheral (see Section 37.4.14).
6. Wait until KEYVALID is set (the key loading completed).
7. Enable CRYP by setting CRYPEN.
8. Append cleartext data:
   a) If it is the second-last or the last block and the plaintext size of the message is not a multiple of 16 bytes, follow the guidance in Section 37.4.7.
   b) Append the cleartext block into CRYP as described in Section 37.4.5, then read the CRYP_DOUTR register to save the ciphertext block(s), MSB first.
   c) Repeat the step b) until the third-last plaintext block is encrypted. For the last two blocks, follow the steps a) and b).
9. Finalize the sequence: disable the CRYP peripheral, by clearing CRYPEN.

Note: KEYSIZE and ALGOMODE[3:0] must be written before the key, as explained above. KMOD[1:0] = 0x2 (shared key) must be written after ALGOMODE[3:0] or at the same time.
ECB/CBC decryption process

This process is described in Section 37.4.5, with the following sequence of events:

1. Disable the CRYP peripheral, by clearing CRYPEN.
2. Flush the FIFOs by setting FFLUSH.
3. Initialize the CRYP_CR register as follows:
   a) Select the key derivation mode (write ALGOMODE[3:0] with 0x7) in encryption mode (ALGODIR = 0).
   b) Configure the data type through DATATYPE[1:0].
   c) Configure the key size through KEYSIZE.
   d) Select the key mode, using KMOD[1:0]: if the key is coming from SAES peripheral set KMOD[1:0] to 0x2, else keep it at 0x0.
4. Write the key into the CRYP_KxL/R registers if KMOD[1:0] is 0x0. If KMOD[1:0] = 0x2, the key is being transferred from the SAES peripheral (see Section 37.4.14).
5. Wait until KEYVALID is set (the key loading completed).
6. Enable the CRYP peripheral by setting CRYPEN. The peripheral immediately starts an AES round for key preparation, setting the BUSY bit.
7. Wait until the BUSY bit is cleared, then select ECB or CBC chaining mode (write ALGOMODE[3:0] with 0x4 or 0x5) in decryption mode (ALGODIR = 1). Do not change other parameters.
8. Write the initialization vector into the CRYP_IVxL/R registers if CBC mode is selected in the previous step.
9. Enable CRYP by setting CRYPEN.
10. Append encrypted data:
    a) If it is the second-last or the last block and the ciphertext size of the message is not a multiple of 16 bytes, follow the guidance in Section 37.4.7.
    b) Append the ciphertext block into CRYP as described in Section 37.4.5, then read the CRYP_DOUTR register to save the cleartext block(s), MSB first.
    c) Repeat the step b) until the third-last ciphertext block is decrypted. For the last two blocks, follow the steps a) and b).
11. Finalize the sequence: disable the CRYP peripheral, by clearing CRYPEN.

Note: KEYSIZE and ALGOMODE[3:0] must be written before the key, as explained above.
KM0D[1:0] = 0x2 (shared key) must be written after ALGOMODE[3:0] or at the same time.

Suspend and resume operations in ECB/CBC modes

To suspend the processing of a message, proceed as follows:

1. If DMA is used, stop the CRYP DMA transfers to the input FIFO by clearing the DIEN bit of the CRYP_DMACR register.
2. Wait until both FIFOs are empty (IFEM = 1 and OFNE = 0 in CRYP_SR) and the BUSY bit is cleared.
3. If DMA is used, stop the CRYP DMA transfers from the output FIFO, by clearing the DOEN bit of the CRYP_DMACR register.
4. Disable the CRYP peripheral, by clearing CRYPEN.
5. Save the CRYP_CR register and clear the key registers if they are not needed, to process the higher-priority message.
6. Save initialization vector registers (only required in CBC mode as the CRYP_IVxL/R registers are altered during the data processing).
7. If DMA is used, save the DMA controller status (pointers for CRYP input and output data transfers, number of remaining bytes, and so on).

**To resume the processing of a message,** proceed as follows:
1. If DMA is used, configure the DMA controller so as to complete the remaining input FIFO and output FIFO transfers.
2. Disable the CRYP peripheral, by clearing CRYPEN.
3. Restore the CRYP_CR register (with correct KEYSIZE), then restore the CRYP_KxL/R registers. If KMOD[1:0] = 0x2 the key needs to be transferred again from the SAES peripheral (see Section 37.4.14).
4. Prepare the decryption key as described in **ECB/CBC decryption process** (only required for ECB or CBC decryption).
5. Restore the CRYP_IVxL/R registers, using the saved configuration (only required in CBC mode).
6. Enable the CRYP peripheral by setting CRYPEN.
7. If DMA is used, enable CRYP DMA transfers, by setting DIEN and DOEN.

**Note:** Key registers do not need to be saved as the original key value is known by the application.

### 37.4.10 CRYP counter mode (CTR)

The CTR mode uses the AES core to generate a key stream. The keys are then XOR-ed with the plaintext to obtain the ciphertext. Unlike with ECB and CBC modes, no key scheduling is required for the CTR decryption since the AES core is always used in encryption mode.

A typical message construction in CTR mode is given in **Figure 380**.

**Figure 380. Message construction in CTR mode**
The structure of this message is:

- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - **Initialization vector** (IVI): a 96-bit value that must be unique for each encryption cycle with a given key.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is complete. The initial value of the counter must be set.
- The plaintext P is encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.

For more details, refer to NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.

**CTR encryption and decryption**

*Figure 381* describes the counter (CTR) chaining implementation in the CRYP peripheral (encryption). To select this chaining mode, write ALGOMODE[3:0] with 0x6.

**Figure 381. CTR encryption**

Initialization vectors in CRYP must be initialized as shown in *Table 340*.

**Table 340. Counter mode initialization vector definition**

<table>
<thead>
<tr>
<th>CRYP_IV0LR[31:0]</th>
<th>CRYP_IV0RR[31:0]</th>
<th>CRYP_IV1LR[31:0]</th>
<th>CRYP_IV1RR[31:0]</th>

<td>32-bit counter = 0x1</td>
</tr>
</tbody>
</table>
CTR encryption and decryption process

This process is described in Section 37.4.5, with the following sequence of events:

1. Disable the CRYP peripheral, by clearing CRYPEN.
2. Flush the FIFOs by setting FFLUSH.
3. Initialize the CRYP_CR register as follows:
   a) Select CTR chaining mode (write ALGOMODE[3:0] with 0x6) in encryption or decryption mode (write ALGODIR with 0 or 1).
   b) Configure the data type through DATATYPE[1:0].
   c) Configure the key size through KEYSIZE.
   d) Select the key mode, using KMOD[1:0]: if the key is coming from SAES peripheral set KMOD[1:0] to 0x2 else keep it at 0x0.
4. Write the initialization vector into the CRYP_IVxL/R registers according to Table 340.
5. Write the key into the CRYP_KxL/R registers if KMOD[1:0] is 0x0. If KMOD[1:0]= 0x2 the key is being transferred from the SAES peripheral (see Section 37.4.14).
6. Wait until KEYVALID is set (the key loading completed).
7. Enable CRYP by setting CRYPEN.
8. Append data:
   a) If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in the block is less than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into CRYP as described in Section 37.4.5, then read the CRYP_DOUTR register to save the resulting block(s), MSB first.
   c) Repeat the step b) until the second-last block is processed. For the last block of plaintext (encryption only), follow the steps a) and b). For the last block, discard the bits that are not part of the message when the last block is smaller than 16 bytes.
9. Finalize the sequence: disable the CRYP peripheral, by clearing CRYPEN.

Note: KEYSIZE and ALGOMODE[3:0] must be written before the key, as explained above.

KMOD[1:0] = 0x2 (shared key) must be written after ALGOMODE[3:0] or at the same time.

Suspend and resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher priority message, then resume the interrupted message. Detailed CBC suspend and resume sequence is described in Section 37.4.9: CRYP basic chaining modes (ECB, CBC).

Note: Like for CBC mode, IVI registers must be reloaded during the resume operation.

37.4.11 CRYP AES Galois/counter mode (GCM)

The AES Galois/counter mode (GCM) enables encrypting and authenticating a plaintext message into the corresponding ciphertext and tag (also known as message authentication code).

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. The following figure shows a typical message construction in GCM mode.
The structure of this message is defined as below:

- **16-byte Initial Counter Block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV)**: a 96-bit value that must be unique for each encryption cycle with a given key. The GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is complete. According to NIST specification, the counter value is 0x2 when processing the first block of payload.

- **Authenticated header AAD** (also known as additional authentication data) has a known length Len(A) that may be a non-multiple of 16 bytes, and must not exceed $2^{64} - 1$ bits. This part of the message is only authenticated, not encrypted.

- **Plaintext message P** is both authenticated and encrypted as ciphertext C, with a known length Len(P) that may be non-multiple of 16 bytes, and cannot exceed $2^{32} - 2$ 16-bytes blocks.

- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in Table 342.

The GCM standard specifies that ciphertext C has the same bit length as the plaintext P. A special padding scheme is required when a part of the message (AAD or P) has a length that is a non-multiple of 16-bytes.

For more details, refer to NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

Figure 383 describes the GCM chaining implementation in the CRYP peripheral (encryption). To select this chaining mode, write ALGOMODE[3:0] with 0x6.
Figure 383. GCM authenticated encryption

The first counter block (CB1) is derived from the initial counter block ICB by the application software, as defined in Table 341.

Table 341. GCM mode IVI registers initialization

<table>
<thead>

GCM encryption and decryption process

This process is described in Section 37.4.6, with the following sequence of events:

**GCM initialize**
1. Disable the CRYP peripheral, by clearing CRYPEN.
2. Flush the FIFOs by setting FFLUSH.
3. Initialize the CRYP_CR register:
   a) Select GCM chaining mode (write ALGOMODE[3:0] with 0x8) in encryption or decryption mode (write ALGODIR with 0 or 1).
   b) Configure the data type through DATATYPE[1:0]
   c) Configure the key size through KEYSIZE.
   d) Select the key mode, using KMOD[1:0]: if the key is coming from SAES peripheral set KMOD[1:0] to 0x2 else keep it at 0x0.
   e) Select the GCM initialization phase, by writing 0x0 to GCM_CCMPH[1:0]
4. Write the initialization vector in CRYP_IVxL/R registers according to Table 341.
5. Write the key in CRYP_KxL/R registers if KMOD[1:0] is 0x0. If KMOD[1:0]= 0x2, the key is being transferred from the SAES peripheral (see Section 37.4.14).
6. Wait until KEYVALID is set (the key loading completed).
7. Set CRYPEN to start the calculation of the hash key. CRYPEN is automatically cleared when the calculation is complete.
8. Wait for the CRYPEN bit to be cleared, indicating that the GCM hash subkey (H) computation is complete.

**GCM header phase**
9. Initialize header phase:
   a) Select the GCM header phase, by writing 0x1 to GCM_CCMPH[1:0]. Do not change the other configurations written during GCM initialization.
   b) Set CRYPEN to start accepting data.
10. Append header data:
    a) If it is the last block and the AAD in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data into CRYP as described in Section 37.4.5.
    c) Repeat the step b) until the second-last AAD data block is processed. For the last block follow the steps a) and b).
11. Wait until the BUSY flag is cleared.

*Note:* This phase can be skipped if there is no AAD, that is, Len(A) = 0.

No data are read during header phase.
GCM payload phase

12. Initialize payload phase:
   a) Disable the CRYP peripheral, by clearing CRYPEN.
   b) Select the GCM payload phase, by writing GCM_CCMPH[1:0] with 0x2. Do not change the other configurations written during GCM initialization.
   c) Enable the CRYP peripheral by setting CRYPEN, to start accepting data.

13. Append payload data:
   a) If it is the last block and the message in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data into CRYP as described in Section 37.4.5, then read the CRYP_DOUTR register to save the resulting block(s).
   c) Repeat the step b) until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps a) and b). For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

14. Wait until the BUSY flag is cleared.

Note: This phase can be skipped if there is no payload, that is, Len(C) = 0 (see GMAC mode).

GCM finalization

15. Select the GCM final phase, by writing GCM_CCMPH[1:0] with 0x3, and clear the ALGODIR bit (encryption). Do not change the other configurations written during GCM initialization.

16. Write the final GCM block into the CRYP_DINR register. It is the concatenated AAD bit and payload bit lengths, as shown in Table 342.

17. Wait until the OFNE flag in the CRYP_SR register is set.

18. Get the GCM authentication tag, by reading the CRYP_DOUTR register four times.

19. Disable the CRYP peripheral, by clearing CRYPEN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message.

Note: In the final phase, data are written to CRYP_DINR normally (no swapping).
Suspend and resume operations in GCM mode

To suspend the processing of a message, proceed as follows:

1. If DMA is used, stop the CRYP DMA transfers to the input FIFO, by clearing DIEN bit of the CRYP_DMACR register.
2. Wait until both FIFOs are empty (IFEM = 1 and OFNE = 0 in CRYP_SR) and the BUSY bit is cleared.
3. In the payload phase, if DMA is used, stop the CRYP DMA transfers from the output FIFO, by clearing the DOEN bit of the CRYP_DMACR register.
4. Disable the CRYP by clearing CRYPEN.
5. Save the current CRYP_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.
6. In the payload phase, save the CRYP_IVxL/R registers as, during the data processing, they changed from their initial values. In the header phase, this step is not required.
7. Save the CRYP_CSGCMCCMRx and CRYP_CSGCMRx registers in memory.
8. If DMA is used, save the DMA controller status (pointer for CRYP input data transfers, number of remaining bytes, and so on). In the payload phase, also save pointer for CRYP output data transfers.

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller in order to complete the remaining input FIFO transfers. In the payload phase, also configure the DMA controller for the remaining output FIFO transfers.
2. Disable the CRYP peripheral, by clearing CRYPEN.
3. Restore the initial setting values in the CRYP_CR and CRYP_KxL/R registers. If KMOD[1:0]= 0x2 the key needs to be transferred again from the SAES peripheral (see Section 37.4.14).
4. Write the suspend register values, previously saved in the memory, back into their corresponding CRYP_CSGCMCCMRx and CRYP_CSGCMRx registers.
5. In the payload phase, write the initialization vector register values, previously saved in the memory, back into their corresponding CRYP_IVxL/R registers. In the header phase, write initial setting values back into the CRYP_IVxL/R registers.
6. Enable the CRYP peripheral by setting CRYPEN.
7. If DMA is used, enable CRYP DMA requests, by setting DIEN (and DOEN if in payload phase).
37.4.12 CRYP AES Galois message authentication code (GMAC)

The Galois message authentication code (GMAC) enables the authentication of a plaintext, generating the corresponding tag information (also known as message authentication code).

GMAC is similar to GCM, except that it is applied on a message composed only by plaintext authenticated data (that is, only header, no payload). The following figure shows typical message construction for GMAC.

**Figure 384. Message construction in GMAC mode**

For more details, refer to NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*

**Figure 385** describes the GMAC chaining implementation in the CRYP peripheral. To select this chaining mode, write ALGOMODE[3:0] with 0x6.

**Figure 385. GMAC authentication mode**
The GMAC algorithm corresponds to the GCM algorithm applied on a message only containing a header. As a consequence, all steps and settings are the same as for the GCM, except that the payload phase is omitted.

**Suspend and resume operations in GMAC**

In GMAC mode, the sequence described for the GCM applies except that only the header phase can be interrupted.

### 37.4.13 CRYP AES Counter with CBC-MAC (CCM)

The AES counter with cipher block chaining-message authentication code (CCM) algorithm enables encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES in counter mode. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

**Note:** *NIST does not approve CBC-MAC as an authentication mode outside the context of the CCM specification.*

The following figure shows typical message construction for CCM.

**Figure 386. Message construction in CCM mode**

The structure of the message is:

- **16-byte first authentication block (B0),** composed of three distinct fields:
  - **Q:** a bit string representation of the octet length of P (**Len(P)**)
  - **Nonce (N):** a single-use value (that is, a new nonce must be assigned to each new communication) of **Len(N)** size. The sum **Len(N) + Len(P)** must be equal to 15 bytes.
  - **Flags:** most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values **t** (MAC length expressed in bytes) and **Q** (plaintext length such that **Len(P)** < 2^{8Q} bytes). The counter blocks range associated to **Q** is equal to 2^{8Q-4}, that is, if the maximum value of **Q** is 8, the counter blocks used in cipher must be on 60 bits.
- **16-bytes blocks (B)** associated to the Associated Data (A).
  This part of the message is only authenticated, not encrypted. This section has a known length Len(A) that can be a non-multiple of 16 bytes (see Figure 386). The standard also states that, on the MSB bits of the first message block (B1), the associated data length expressed in bytes (a) must be encoded as follows:
  - If $0 < a < 2^{16} - 2^8$, then it is encoded as $[a]_{16}$, that is, on two bytes.
  - If $2^{16} - 2^8 < a < 2^{32}$, then it is encoded as $0xFF \ || \ 0xFE \ || \ [a]_{32}$, that is, on six bytes.
  - If $2^{32} < a < 2^{64}$, then it is encoded as $0xFF \ || \ 0xFF \ || \ [a]_{64}$, that is, on ten bytes.

- **16-byte blocks (B)** associated to the plaintext message P, which is both authenticated and encrypted as ciphertext C, with a known length Len(P). This length can be a non-multiple of 16 bytes (see Figure 386).

- **Encrypted MAC (T)** of length Len(T) appended to the ciphertext C of overall length Len(C).

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a special padding scheme is required.

**Note:** *CCM chaining mode can also be used with associated data only (that is, no payload).*

As an example, the C.1 section in NIST Special Publication 800-38C gives the following values (hexadecimal numbers):

- **N:** 10111213 141516 (Len(N) = 56 bits or 0x7 bytes)
- **A:** 00010203 04050607 (Len(A) = 64 bits or 0x8 bytes)
- **P:** 20212223 (Len(P) = 32 bits i.e. Q = 0x4 bytes)
- **T:** 6084341b (Len(T) = 32 bits or t = 4)
- **B0:** 4f101112 13141516 00000000 00000004
- **B1:** 00080001 02030405 06070000 00000000
- **B2:** 20212223 00000000 00000000 00000000
- **CTR0:** 0710111213 141516 00000000 00000000
- **CTR1:** 0710111213 141516 00000000 00000001

For more details, refer to NIST Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality.
Figure 387 describes the CCM chaining implementation in the CRYP peripheral (encryption). To select this chaining mode, write ALGOMODE[3:0] with 0x9.

The first block of a CCM message (B0) must be prepared by the application as defined in Table 343.

Table 343. CCM mode IVI registers initialization

<table>
<thead>
<tr>
<th>Register</th>
<th>CRYP_IV0LR[31:0]</th>

</tr>
</tbody>
</table>

1. The 5 most significant bits are cleared (flag bits).
2. Q length bits are cleared, except for bit 0 that is set.

CRYP supports counters up to 64 bits, as specified by NIST.
CCM encryption and decryption process

This process is described in Section 37.4.6, with the following sequence of events:

CCM initialize
1. Disable the CRYP peripheral, by clearing CRYPEN.
2. Flush the FIFOs by setting FFLUSH.
3. Initialize the CRYP_CR register:
   a) Select CCM chaining mode (write ALGOMODE[3:0] with 0x9) in encryption or decryption mode (write ALGODIR with 0 or 1).
   b) Configure the data type through DATATYPE[1:0]
   c) Configure the key size through KEYSIZE.
   d) Select the key mode, using KMOD[1:0]: if the key is coming from SAES peripheral set KMOD[1:0] to 0x2 else keep it at 0x0.
   e) Select the CCM initialization phase, by writing 0x0 to GCM_CCMPH[1:0]
4. Write the initialization vector into the CRYP_IVxL/R registers with CTR1 information, as defined in Table 343
5. Write the key in CRYP_KxL/R registers if KMOD[1:0] is 0x0. If KMOD[1:0]= 0x2 the key is being transferred from the SAES peripheral (see Section 37.4.14).
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the CRYP peripheral by setting CRYPEN.
8. Write the B0 data in CRYP_DINR registers according to Table 343, then wait for the CRYPEN bit to be cleared.

Note: In this initialization phase, data have to be inserted normally (no swapping).

CCM header phase
9. Initialize header phase:
   a) Prepare the first block of the (B1) data associated with the message, in accordance with CCM chaining rules.
   b) Select the GCM header phase, by writing GCM_CCMPH[1:0] with 0x1. Do not change the other configurations written during the GCM initialization.
   c) Set CRYPEN to start accepting data.
10. Append header data:
    a) If it is the last block and the associated data in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data into CRYP as described in Section 37.4.5.
    c) Repeat the step b) until the second-last associated data block is processed. For the last block follow the steps a) and b).
11. Wait until the BUSY flag is cleared.

Note: This phase can be skipped if there is no associated data, that is, Len(A) = 0

No data are read during the header phase.
CCM payload phase

12. Initialize payload phase:
   a) Disable the CRYP peripheral, by clearing CRYPEN.
   b) Select the GCM payload phase, by writing GCM_CCMPH[1:0] with 0x2. Do not change the other configurations written during GCM initialization.
   c) Enable the CRYP peripheral by setting CRYPEN, to start accepting data.

13. Append payload data:
   a) In encryption only, if it is the last block and the plaintext in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data into CRYP as described in Section 37.4.5, then read the CRYP_DOUTR register to save the resulting block(s).
   c) Repeat the step b) until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps a) and b). For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

14. Wait until the BUSY flag is cleared.

Note: This phase can be skipped if there is no payload, that is, Len(P) = 0 or Len(C) = Len(T).
Remove LSB_{Len(T)} encrypted tag information when decrypting ciphertext C.

CCM finalization

15. Select the GCM final phase, by writing GCM_CCMPH[1:0] with 0x3, and clear the ALGODIR bit (encryption). Do not change the other configurations written during GCM initialization.

16. Write the CTR0 information into the CRYP_DINR register. CTR0 information is described in Table 343, with the bit[0] cleared.

17. Wait until the OFNE flag in the CRYP_SR register is set.

18. Get the CCM authentication tag, by reading the CRYP_DOUTR register four times.

19. Disable the CRYP peripheral by clearing CRYPEN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message. Mask the authentication tag output with tag length to obtain a valid tag.

Note: In this final phase, data have to be inserted normally (no swapping).
Suspend and resume operations in CCM mode

To suspend the processing of a message in header or payload phase, proceed as follows:

1. If DMA is used, stop the CRYP DMA transfers to the input FIFO, by clearing DIEN bit of the CRYP_DMACR register.
2. Wait until both FIFOs are empty (IFEM = 1 and OFNE = 0 in CRYP_SR) and the BUSY bit is cleared.
3. In the payload phase, if DMA is used, stop the CRYP DMA transfers from the output FIFO, by clearing the DOEN bit of the CRYP_DMACR register.
4. Disable the CRYP by clearing CRYPEN.
5. Save the current CRYP_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.
6. In the payload phase, save the CRYP_IVxL/R registers as, during the data processing, they changed from their initial values. In the header phase, this step is not required.
7. Save the CRYP_CSGCMCCMRx registers in the memory.
8. If DMA is used, save the DMA controller status (pointer for CRYP input data transfers, number of remaining bytes, and so on). In the payload phase, also save pointer for CRYP output data transfers.

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller in order to complete the remaining input FIFO transfers. In the payload phase, also configure the DMA controller for the remaining output FIFO transfers.
2. Disable the CRYP peripheral, by clearing CRYPEN.
3. Restore the initial setting values in the CRYP_CR and CRYP_KxL/R registers. If KMOD[1:0]= 0x2 the key needs to be transferred again from the SAES peripheral (see Section 37.4.14).
4. Write the suspend register values, previously saved in the memory, back into their corresponding CRYP_CSGCMCCMRx registers.
5. In the payload phase, write the initialization vector register values, previously saved in the memory, back into their corresponding CRYP_IVxL/R registers. In the header phase, write initial setting values back into the CRYP_IVxL/R registers.
6. Enable the CRYP peripheral by setting CRYPEN.
7. If DMA is used, enable CRYP DMA requests, by setting DIEN (and DOEN if in payload phase).

37.4.14 AES key sharing with secure AES co-processor

The CRYP peripheral can use the SAES peripheral as security co-processor. The secure application prepares the key in the robust SAES peripheral. When it is ready, the CRYP application can load this prepared key through a dedicated hardware key bus.

The recommended sequence is described hereafter and in section SAES operations with shared keys in section Secure AES coprocessor (SAES) of this document.
1. In SAES peripheral, the application encrypts the key to share in shared-key mode (KMOD[1:0] at 0x2). When applicable, the proper CRYP instance must be selected through KSHAREID[1:0].

2. Each time the shared key is required in the CRYP peripheral, the application decrypts it in the SAES peripheral in shared-key mode (KMOD[1:0] at 0x2). When applicable, the proper CRYP instance must be selected through KSHAREID[1:0].

3. Once the shared key is decrypted and loaded in SAES_KEYRx registers it can be shared with CRYP. To load the shared key in CRYP, the application sets KEYSIZE as appropriate and writes KMOD[1:0] with 0x2. When KEYVALID is cleared, the key is automatically transferred by hardware into the CRYP_KxL/R registers and the BUSY flag in the CRYP_SR register set.

4. Once the key transfer is complete, the BUSY flag is cleared and the KEYVALID flag set in the CRYP_SR register. If KEYVALID is not set when BUSY bit is cleared, or if the KERF flag is set in the CRYP_SR register, it means that the KEYSIZE value is incorrect or an unexpected event occurred during the transfer (such as DPA error, tamper event or KEYVALID in SAES_SR cleared before the end of the transfer). When such errors occur, reset both peripherals through their IPRST bits and restart the whole key sharing process.

When the key sharing sequence is complete, the CRYP is initialized with a valid, shared key. The application can then process data in normal key mode, by writing KMOD[1:0] with 0x0.

Note: This sequence in CRYP peripheral can be run multiple times (for example, to manage a suspend/resume situation), as long as SAES peripheral is unused and duly remains in key sharing state.

When sharing keys KEYSIZE in CRYP must be identical to SAES value (128 or 256 bits).

37.4.15 CRYP data registers and data swapping

Data input and output

A 16-byte data block enters the CRYP peripheral with four successive 32-bit word writes into the CRYP_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 16-byte data block is retrieved from the CRYP peripheral with four successive 32-bit word reads of the CRYP_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The four 32-bit words of a 16-byte data block must be stored in the memory consecutively and in big-endian order, that is, with the most significant word on the lowest address. See Table 344 “no swapping” option for details.

Data swapping

The CRYP peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the CRYP input FIFO, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the CRYP output FIFO. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through the DATATYPE[1:0]. The selection applies both to the input and the output of the CRYP, except in GCM/CCM final phase (data must be inserted normally).
Note: The data in CRYP key registers (CRYP_KxL/R) and initialization vector registers (CRYP_IVxL/R) are not sensitive to the swap mode selection.

The CRYP data swapping feature is summarized in Table 344 and Figure 388.

<table>

</tr>
</tbody>
</table>
Data padding

Figure 388 also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 84 message bits, with DATATYPE[1:0] = 0x0
- 48 message bits, with DATATYPE[1:0] = 0x1
- 56 message bits, with DATATYPE[1:0] = 0x2
- 34 message bits, with DATATYPE[1:0] = 0x3
37.4.16 CRYP key registers

The eight CRYP_KxR/LR write-only registers store the encryption or decryption key information, as shown in Table 345. Reads are not allowed for security reason.

Note: In memory and in CRYP key registers, keys are stored in big-endian format, with most significant byte on the lowest address.

| Table 345. Key endianness in CRYP_KxR/LR registers (128/192/256-bit keys) |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| -               | -               | -               | -               | k[127:96]      | k[95:64]       | k[63:32]       | k[31:0]        |

The key registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield.

Write operations to the CRYP_KxL/R registers are ignored when BUSY bit is set. The application must check this before modifying key registers.

The entire key must be written before starting an AES computation. In normal key mode (KMOD[1:0] at 0x0), the key registers must always be written in either ascending or descending order. The write sequence becomes (in ascending order):

- K2LR, K2RR, K3LR, then K3RR registers for KEYSIZE = 0x0
- K1LR, K1RR, K2LR, K2RR, K3LR, then K3RR register for KEYSIZE = 0x1
- K0LR, K0RR, K1LR, K1RR, K2LR, K2RR, K3LR, then K3RR register for KEYSIZE = 0x2

Note: KEYSIZE must be written before the key.

As soon as the first key register is written, the KEYVALID bit is cleared. Once the key registers writing sequence is complete, KEYVALID is set and CRYPEN bit becomes writable. If an error occurs, KEYVALID is cleared and KERF set (see Section 37.4.18).

37.4.17 CRYP initialization vector registers

The four CRYP_IVxR/LR registers store the initialization vector (IVI) information, as shown in Table 346. They can only be written if BUSY bit is cleared.

Note: In memory and in CRYP IVI registers, initialization vectors are stored in big-endian format, with most significant byte on the lowest address.

| Table 346. Initialization vector endianness in CRYP_IVxR registers (AES) |
|-----------------|-----------------|-----------------|-----------------|
| CRYP_IV0L[31:0] | CRYP_IV0R[31:0] | CRYP_IV1L[31:0] | CRYP_IV1R[31:0] |

Initialization vector information depend on the chaining mode selected. When used, CRYP_IVxR/LR registers are updated upon each AES computation cycle (useful for
managing suspend mode).

The initialization vector registers are not affected by the data swapping feature controlled by DATATYPE[1:0].

### 37.4.18 CRYP error management

The CRYP peripheral manages the errors described in this section.

**Key error flag (KERF)**

There are multiple sources of errors that set the KERF flag and clear the KEYVALID bit of the CRYP_SR register:

- **Key writing sequence error**: triggered upon detecting an incorrect sequence of writing key registers. See Section 37.4.16: CRYP key registers for details.
- **Key sharing size mismatch error**: triggered when KMOD[1:0] is at 0x2 and KEYSIZE in CRYP does not match KEYSIZE in SAES peripheral, or KEYSIZE is at 0x1 in CRYP_CR (192-bit key).
- **Key sharing error**: triggered upon failing transfer of SAES shared key to CRYP. See Section 37.4.14: AES key sharing with secure AES co-processor for details.

Upon a key writing sequence error, KERF flag is cleared when a correct key writing sequence starts.

Upon a key sharing error, reset both CRYP and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

>Note: For any key error, clear KERF flag prior to setting CRYPEN.

### 37.5 CRYP interrupts

There are two individual maskable interrupt sources generated by the CRYP peripheral to signal the following events:

- Input FIFO empty (IFEM) or not full (IFNF)
- Output FIFO full (OFFU) or not empty (OFNE)

These sources are combined into a common interrupt signal from the CRYP peripheral that connects to the Arm® Cortex® interrupt controller. The application can enable or disable CRYP interrupt sources individually by setting/clearing the corresponding mask bit of the CRYP_IMSCR register. The status of the individual source of event flags can be read from the CRYP_SR register.

The global status of the two source of interrupts can be read either from the CRYP_RISR register (raw, that is unmasked), or from the CRYP_MISR register (masked).

*Table 347* gives a summary of the available features.
Output FIFO service interrupt (OUTMIS)

The output FIFO service interrupt is asserted when there is one or more (32-bit word) data items in the output FIFO. This interrupt is cleared by reading data from the output FIFO until there is no valid (32-bit) word left (that is, when the interrupt follows the state of the output FIFO not empty flag OFNE).

The output FIFO service interrupt OUTMIS is active also when CRYP is disabled. Consequently, when CRYPEN bit is cleared, the OUTMIS bit is not cleared when the output FIFO is not empty.

Input FIFO service interrupt (INMIS)

The input FIFO service interrupt is asserted when there are less than four words in the input FIFO. It is cleared by performing write operations to the input FIFO until it holds four or more words.

The input FIFO service interrupt INMIS is active only when CRYP is enabled. Consequently, when CRYPEN bit is cleared, the INMIS bit stay low even if the input FIFO is empty.

37.6 CRYP DMA requests

The CRYP peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the DIEN and DOEN bits of the CRYP_DMACR register.

Detailed usage of DMA with CRYP can be found in Appending data using the DMA subsection of Section 37.4.5: CRYP encryption/decryption typical usage.
Data input using DMA

Setting DIEN enables DMA writing into CRYP. The CRYP then initiates, during the input phase, a DMA request for each 16-byte data block to write to the CRYP_DINR register (quadruple 32-bit word, MSB first).

The CRYP supports both single and burst DMA transfers. Recommended configuration is fixed burst size of four words.

CRYP issues a DMA transfer request to its input FIFO every time a 16-bytes block has been read from the FIFO.

Note: According to the algorithm and the mode selected, special padding / ciphertext stealing might be required (see Section 37.4.7).

Data output using DMA

Setting DOEN enables DMA reading from CRYP. The CRYP then initiates, during the output phase, a DMA request for each 16-byte data block to read from the CRYP_DOUTR register (quadruple 32-bit word, MSB first).

The CRYP supports both single and burst DMA transfers. Recommended configuration is fixed burst size of four words.

CRYP issues a DMA transfer request from output FIFO every time one 16-byte block has been written into the FIFO.

Note: According to the message size, extra bytes might need to be discarded by application in the last block.

Stopping DMA transfers

All DMA request signals are de-asserted when CRYP is disabled (CRYPEN cleared) or the DMA enable bit (DIEN for input data, DOEN for output data) is cleared.

37.7 CRYP processing time

The following tables provide the 16-byte data block processing latency per operating mode.

<table>
<thead>
<tr>
<th>Key size</th>
<th>Mode of operation</th>
<th>Chaining algorithm</th>
<th>Clock cycles</th>
</tr>
</thead>
<tbody>
<tr>
<td>128 bits</td>
<td>encryption or decryption(^{(1)})</td>
<td>ECD, CBC, CTR</td>
<td>14</td>

</table>

Attempts to write the bitfield are ignored when BUSY is set.
Bits 23:20 **NPBLB[3:0]**: Number of padding bytes in last block

This padding information must be filled by software before processing the last block of GCM payload encryption or CCM payload decryption, otherwise authentication tag computation is incorrect.

0x0: All bytes are valid (no padding)
0x1: Padding for the last LSB byte
...
0xF: Padding for the 15 LSB bytes of last block.

Attempts to write the bitfield are ignored when BUSY is set.

Bit 18 **Reserved, must be kept at reset value.**

Bits 17:16 **GCM_CCMPH[1:0]**: GCM or CCM phase selection

This bitfield selects the phase, applicable only with GCM, GMAC or CCM chaining modes.

0x0: Initialization phase
0x1: Header phase
0x2: Payload phase
0x3: Final phase

Attempts to write the bitfield are ignored when BUSY is set.

Bit 15 **CRYPEN**: CRYP enable

This bit enables/disables the CRYP peripheral.

0: CRYP disabled
1: CRYP enabled

This bit is automatically cleared by hardware upon the completion of the key preparation (ALGOMODE[3:0] at 0x7) and upon the completion of GCM/GMAC/CCM initialization phase. The bit cannot be set as long as KEYVALID is cleared.

Bit 14 **FFLUSH**: FIFO flush

This bit enables/disables the flushing of CRYP input and output FIFOs. Reading this bit always returns 0.

0: No effect
1: FIFO flush enabled

When CRYPEN is cleared, writing this bit to 1 flushes both input and output FIFOs (that is read and write pointers of the FIFOs are reset).

FFLUSH bit must be set when BUSY is cleared, otherwise the FIFO is flushed, but the block being processed may be pushed into the output FIFO just after the flush operation, resulting in a non-empty FIFO condition.

Attempts to write FFLUSH are ignored when CRYPEN is set.

Bits 13:10 **Reserved, must be kept at reset value.**

Bits 9:8 **KEYSIZE[1:0]**: Key size selection

This bitfield defines the key length in bits of the key used by CRYP.

0x0: 128-bits
0x1: 192 bits
0x2: 256 bits
0x3: Reserved

When KEYSIZE is changed, KEYVALID bit is cleared.

Attempts to write the bitfield are ignored when BUSY is set.
Bits 7:6  **DATATYPE[1:0]: Data type**  
This bitfield defines the format of data written in the CRYP_DINR register or read from the CRYP_DOUTR register, through selecting the mode of data swapping. This swapping is defined in *Section 37.4.15: CRYP data registers and data swapping.*  
0x0: No swapping (32-bit data).  
0x1: Half-word swapping (16-bit data).  
0x2: Byte swapping (8-bit data).  
0x3: Bit-level swapping.  
Attempts to write the bitfield are ignored when BUSY is set.  

Bits 19, 5:3  **ALGOMODE[3:0]: Algorithm mode**  
This bitfield selects the AES algorithm/chaining mode.  
0x4: Electronic codebook (ECB)  
0x5: Cipher Block Chaining (CBC)  
0x6: Counter mode (CTR)  
0x7: AES key preparation for ECB or CBC decryption  
0x8: Galois counter mode (GCM) and Galois message authentication code (GMAC)  
0x9: Counter with CBC-MAC (CCM)  
Others: Reserved  
Attempts to write the bitfield are ignored when BUSY is set.  

Bit 2  **ALGODIR:** Algorithm direction  
This bit selects the algorithm direction.  
0: Encryption  
1: Decryption  
Attempts to write the bitfield are ignored when BUSY is set.  

Bits 1:0  Reserved, must be kept at reset value.  

### 37.8.2  **CRYP status register (CRYP_SR)**  
Address offset: 0x04  
Reset value: 0x0000 0003

</tbody>
</table>
Bits 31:8  Reserved, must be kept at reset value.

Bit 7  KEYVALID: Key valid flag
   This read-only bit is set by hardware when the key of size defined by KEYSIZE is loaded in
   CRYP_KxR/LR key registers.
   0: Key not valid
   1: Key valid
   The CRYPEN bit can only be set when KEYVALID is set.
   In normal mode when KMOD[1:0] is at zero, the key must be written in the key registers in the
   correct sequence, otherwise the KERF flag is set and KEYVALID remains cleared.
   When KMOD[1:0] is different from zero, the BUSY flag is automatically set by CRYP. When
   the key is loaded successfully, BUSY is cleared and KEYVALID set. Upon an error, KERF is
   set, BUSY cleared and KEYVALID remains cleared.
   If set, KERF must be cleared, otherwise KEYVALID cannot be set. For further information on
   key loading, refer to Section 37.4.16: CRYP key registers.

Bit 6  KERF: Key error flag
   This read-only bit is set by hardware when key information failed to load into key registers.
   0: No key error detected
   1: Key information failed to load into key registers
   KERF is triggered upon any of the following errors:
   – CRYP_KxR/LR register write does not respect the correct order (refer to
     Section 37.4.16: CRYP key registers for details).
   – CRYP fails to load the key shared by SAES peripheral (KMOD = 0x2).
   KERF must be cleared by the application software, otherwise KEYVALID cannot be set. It
   can be done through IPRST bit of CRYP_CR, or when a correct key writing sequence starts.

Bit 5  Reserved, must be kept at reset value.

Bit 4  BUSY: Busy bit
   This flag indicates whether CRYP is idle or busy.
   0: Idle
   1: Busy
   CRYP is flagged as idle when disabled (CRYPEN = 0) or when the AES core is not
   processing any data. It happens when the last processing has completed, or CRYP is waiting
   for enough data in the input FIFO or enough free space in the output FIFO (that is in each
   case at least 4 words).
   CRYP is flagged as busy when processing a block data, preparing a key (ECB or CBC
   decryption only), or transferring a shared key from SAES peripheral.

Bit 3  OFFU: Output FIFO full flag
   0: Output FIFO is not full
   1: Output FIFO is full

Bit 2  OFNE: Output FIFO not empty flag
   0: Output FIFO is empty
   1: Output FIFO is not empty

Bit 1  IFNF: Input FIFO not full flag
   0: Input FIFO is full
   1: Input FIFO is not full

Bit 0  IFEM: Input FIFO empty flag
   0: Input FIFO is not empty
   1: Input FIFO is empty
37.8.3 CRYP data input register (CRYP_DINR)

Address offset: 0x08

<td>3</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

Bits 31:0 DIN[31:0]: Data input
A four-fold sequential write to this bitfield during the Input phase results in pushing a complete 16-byte block into the CRYP input FIFO. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0].
Input FIFO can receive up to two 16-byte blocks of plaintext (when encrypting) or ciphertext (when decrypting).
If EN bit is set in CRYP_CR register, when at least four 32-bit words have been pushed into the input FIFO, and when at least four 32-bit words are free in the output FIFO, the CRYP automatically starts an encryption or decryption process, setting the BUSY bit.
Reading this register pops data off the input FIFO (oldest value is returned). The data present in the input FIFO are returned only if CRYPEN is cleared (undefined value is returned otherwise). Following one or more reads the FIFO must be flushed (setting the FFLUSH bit) prior to processing new data.

Bits 31:0 DOUT[31:0]: Data output
A four-fold sequential read to this bitfield during the output phase results in retrieving a complete 16-byte block from the CRYP output FIFO. From the first to the fourth read, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0].
Output FIFO can store up to two 16-byte blocks of plaintext (when decrypting) or ciphertext (when encrypting).
When the output FIFO is empty a read returns an undefined value. Writes are ignored.
37.8.5  CRYP DMA control register (CRYP_DMACR)

Bits 31:2  Reserved, must be kept at reset value.

Bit 1  **DOEN**: DMA output enable
- When this bit is set, DMA requests are automatically generated by the peripheral during the output data phase.
- 0: Outgoing data transfer from CRYP via DMA is disabled
- 1: Outgoing data transfer from CRYP via DMA is enabled

Bit 0  **DIEN**: DMA input enable
- When this bit is set, DMA requests are automatically generated by the peripheral during the input data phase.
- 0: Incoming data transfer to CRYP via DMA is disabled
- 1: Incoming data transfer to CRYP via DMA is enabled

Bits 31:2  Reserved, must be kept at reset value.

Bit 1  **OUTIM**: Output FIFO service interrupt mask
- This bit enables or disables (masks) the CRYP output FIFO service interrupt generation when OUTRIS is set.
- 0: Output FIFO interrupt is disabled (masked), masked interrupt status (OUTMIS) stays cleared
- 1: Output FIFO interrupt is enabled (not masked)
Bit 0  **INIM**: Input FIFO service interrupt mask  
This bit enables or disables (masks) the CRYP input FIFO service interrupt generation when INRIS is set.  
0: Input FIFO interrupt is disabled (masked), masked interrupt status (INMIS) stays cleared  
1: Input FIFO interrupt is enabled (not masked)

### 37.8.7 CRYP raw interrupt status register (CRYP_RISR)

Address offset: 0x18  
Reset value: 0x0000 0001

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |  1 |  0 |  1 |  2 |  3 |  4 |  5 |  6 |  7 |  8 |  9 | 10 |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:2  Reserved, must be kept at reset value.

Bit 1  **OUTRIS**: Output FIFO service raw interrupt status  
This read-only bit is set by hardware when an output FIFO flag (OFFU or OFNE) is set in CRYP_SR register, regardless of the OUTIM mask bit value in CRYP_IMSCR register.  
0: No output FIFO event detected  
1: Output FIFO full or not empty detected; an interrupt is generated if OUTIM bit is set in CRYP_IMSCR register

Bit 0  **INRIS**: Input FIFO service raw interrupt status  
This read-only bit is set by hardware when an input FIFO flag (IFNF or IFEM) is set in CRYP_SR register, regardless of the INIM mask bit value in CRYP_IMSCR register.  
0: No input FIFO event detected  
1: Input FIFO empty or not full detected; an interrupt is generated if CRYPEN is set and if INIM bit is set in CRYP_IMSCR register

### 37.8.8 CRYP masked interrupt status register (CRYP_MISR)

Address offset: 0x1C  
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:2  Reserved, must be kept at reset value.
Bit 1 **OUTMIS**: Output FIFO service masked interrupt status

This read-only bit is set by hardware when an output FIFO flag (OFFU or OFNE) is set in CRYP_SR register. If the OUTIM mask bit is cleared in CRYP_IMSCR register, the OUTMIS bit stays cleared (masked).

0: No output FIFO event detected or OUTIM mask cleared in CRYP_IMSCR
1: Output FIFO full or not empty detected, with an interrupt pending

The OUTMIS bit is cleared by reading data from the output FIFO until OFNE flag is cleared (output FIFO empty). It is not cleared by disabling CRYP with CRYPEN bit.

Bit 0 **INMIS**: Input FIFO service masked interrupt status

This read-only bit is set by hardware when an input FIFO flag (IFNF or IFEM) is set in CRYP_SR register. If the INIM mask bit is cleared in CRYP_IMSCR register, the INMIS bit stays cleared (masked).

0: No input FIFO event detected or INIM mask cleared in CRYP_IMSCR or CRYPEN bit cleared.
1: Input FIFO empty or not full detected, with an interrupt pending

The INMIS bit is cleared by writing data to the input FIFO until IFEM flag is cleared (there is at least one word in input FIFO), or by clearing CRYPEN.

When CRYP is disabled, INMIS bit stays low even if the input FIFO is empty.

**37.8.9 CYP key register 0L (CRYP_K0LR)**

</tbody>
</table>

 Bits 31:0 **K[255:224]**: Key bit x (x = 255 to 224)

This write-only bitfield contains the bits [255:224] of the AES encryption or decryption key, depending on the operating mode.

Write to CRYP_KxR/LR registers is ignored when CRYP is busy (BUSY bit set). When key is coming from the SAES peripheral (KMOD[1:0] = 0x2), write is also ignored. With KMOD[1:0] at 0x0, a special writing sequence is required. In this sequence, any valid write to CRYP_KxR/LR register clears the KEYVALID flag except for the sequence-completing write that sets it. Also refer to the description of the KEYVALID flag in the CRYP_SR register.
### 37.8.10 CRYP key register 0R (CRYP_K0RR)

Bits 31:0 **IV[127:112]**: Initialization vector bits
This read/write bitfield contains the 16 initialization vector bits for the AES encryption or decryption operation, depending on the operating mode. Refer to the CRYP_K0LR register for information relative to writing CRYP_KxR/LR registers.
Bits 31:0 **IVI[127:96]**: Initialization vector bit x (x = 127 to 96)  
This bitfield stores the initialization vector bits [127:96] for AES chaining modes other than ECB.  
The value stored in CRYP_IVxR/LR registers is updated by hardware after each computation round (when applicable).  
Write to this register is ignored when CRYP is busy (BUSY bit set).

### 37.8.18 CRYP initialization vector register 0R (CRYP_IV0RR)

38 Hash processor (HASH)

38.1 Introduction

The hash processor is a fully compliant implementation of the secure hash algorithm (SHA-1, SHA-2 family) and the HMAC (keyed-hash message authentication code) algorithm. HMAC is suitable for applications requiring message authentication.

The hash processor computes FIPS (Federal Information Processing Standards) approved digests of length of 160, 224, 256 bits, for messages of any length less than $2^{64}$ bits (for SHA-1, SHA-224 and SHA-256) or less than $2^{128}$ bits (for SHA-384, SHA-512).

38.2 HASH main features

- Suitable for data authentication applications, compliant with:
  - Federal Information Processing Standards Publication FIPS PUB 180-4, Secure Hash Standard (SHA-1 and SHA-2 family)
  - Federal Information Processing Standards Publication FIPS PUB 186-4, Digital Signature Standard (DSS)
- Fast computation of SHA-1, SHA2-224, SHA2-256, SHA2-384, and SHA2-512
  - 82 (respectively 66) clock cycles for processing one 512-bit block of data using SHA-1 (respectively SHA-256) algorithm
  - 98 clock cycles for processing one 1024-bit block of data using either SHA2-384 or SHA2-512 algorithm
  - Support for SHA-2 truncated outputs (SHA2-512/224, SHA2-512/256)
- Support for HMAC mode with all supported algorithm
- Corresponding 32-bit words of the digest from consecutive message blocks are added to each other to form the digest of the whole message
  - Automatic 32-bit words swapping to comply with the internal little-endian representation of the input bit-string
  - Supported word swapping format: bits, bytes, half-words, and 32-bit words
- Single 32-bit, write-only, input register associated to an internal input FIFO, corresponding to a 64-byte block size (16 x 32 bits)
- Automatic padding to complete the input bit string to fit digest minimum block size
- AHB slave peripheral, accessible by 32-bit words only (else an AHB error is generated)
- $8 \times 32$-bit words (H0 to H15) for output message digest
- Automatic data flow control supporting direct memory access (DMA) using one channel.
- Support for both single and fixed DMA burst transfers of four words.
- Interruptible message digest computation, on a per-block basis
  - Reloadable digest registers
  - Hashing computation suspend/resume mechanism, including DMA
38.3 HASH implementation
The devices have a single instance of HASH peripheral.

38.4 HASH functional description

38.4.3 About secure hash algorithms

The hash processor is a fully compliant implementation of the secure hash algorithm defined by FIPS PUB 180-4 standard.

With each algorithm, the HASH computes a condensed representation of a message or data file. More specifically, when a message is presented on the input, the HASH processing core produces a fixed-length output string called a message digest (see Table 352).

Table 352. Information on supported hash algorithms

</tr>
</tbody>
</table>

1. Block size = (NBWE-1) * 4 bytes. NBWE[4:0] bitfield can be read from the HASH_SR register after ALGO and INIT bits are written in the HASH_CR register.
2. Digest size is 224 bits for SHA2-512/224 and 256 bits for SHA2-512/256 (truncated modes).

The message digest can then be processed with a digital signature algorithm in order to generate or verify the signature for the message.

Signing the message digest rather than the message often improves the efficiency of the process since the message digest is usually much smaller in size than the message. The verifier of a digital signature has to use the same hash algorithm as the one used by the creator of the digital signature.

The SHA-2 functions supported by the hash processor are qualified as “secure” by NIST because it is computationally infeasible to find a message that corresponds to a given message digest, or to find two different messages that produce the same message digest (SHA-1 does not qualify as secure since February 2017). Any change to a message in transit results, with very high probability, in a different message digest, and the signature fails to verify.

38.4.4 Message data feeding

The message (or data file) to be processed by the HASH must be considered as a bit string. Per FIPS PUB 180-4 standard this message bit string grows from left to right, with hexadecimal words expressed in “big-endian” convention, so that within each word, the most significant bit is stored in the left-most bit position. For example message string "abc" with a bit string representation of "01100001 01100010 01100011" is represented by a 32-bit word \texttt{0x00636261}, and 8-bit words \texttt{0x61626300}.

Data are entered into the HASH one 32-bit word at a time, by writing them into the HASH_DIN register. The current contents of the HASH_DIN register are transferred to the 16 words input FIFO each time the register is written with new data. Hence, HASH_DIN and the FIFO form a seventeen 32-bit words length FIFO (named the IN buffer).

In accordance to the kind of data to be processed (for example byte swapping when data are ASCII text stream) there must be a bit, byte, half-word, or no swapping operation to be
performed on data from the input FIFO before entering the little-endian hash processing core. Figure 390 shows how the hash processing core 32-bit data block \( M_0 \ldots 31 \) is constructed from one 32-bit words popped into input FIFO by the driver, according to the DATATYPE bitfield in the HASH control register (HASH_CR).

HASH_DIN data endianness when bit swapping is disabled (DATATYPE = 00) can be described as following: the least significant bit of the message has to be at MSB position in the first word entered into the hash processor, the 32nd bit of the bit string has to be at MSB position in the second word entered into the hash processor and so on.

**Figure 390. Message data swapping feature**
38.4.5 Message digest computing

The hash processor sequentially processes several blocks when computing the message digest. Block sizes can be found in Table 352: Information on supported hash algorithms.

Each time the DMA or the CPU writes a block to the hash processor, the HASH automatically starts computing the message digest. This operation is known as partial digest computation.

As described in Section 38.4.4: Message data feeding, the message to be processed is entered into the HASH 32-bit word at a time, writing to the HASH_DIN register to fill the input FIFO. In order to perform the hash computation on this data the application must follow below sequence.

1. Initialize the hash processor using the HASH_CR register:
   - Write to the HASH_CR register to select the right algorithm using the ALGO bitfield, and set the INIT bit (other bits are kept at zero). Then read the NBWE bitfield from the HASH_SR register to deduce the algorithm block size, which equals \((\text{NBWE}-1) \times 4\). This step is not required if the block size is already known (see Table 352 for details).
   - Select the right algorithm using the ALGO[3:0] field. If needed, program the correct swapping operation on the message input words using the DATATYPE[1:0] bitfield.
   - When HMAC mode is required, set the MODE bit as well as the LKEY bit if the HMAC key size is greater than the known block size of the algorithm (otherwise keep LKEY cleared). Refer to Section 38.4.7: HMAC operation for details.
   - Update NBLW[4:0] in the HASH_STR register to define the number of valid bits in the last word of the message if it is different from 32 bits. NBLW information is used to correctly perform the automatic message padding before the final message digest computation.

2. Complete the initialization by setting the INIT bit in HASH_CR register. Also set the DMAE bit if data are transferred via DMA.

Caution: When programming step 2, it is important that the correct configuration values (ALGO, DATATYPE, HMAC mode, key length, NBLW) are set up before or at the same time.

3. Start filling data by writing to the HASH_DIN register, unless data are automatically transferred via DMA. Note that the processing of a block can start only once the last value of the block has entered the input FIFO. The way the partial or final digest computation is managed depends on the way data are fed into the processor:
   - Data are filled by software:
     Partial digest computations are triggered each time the application writes the first word of the next block, the block size being defined by NBWE bits in HASH_SR. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write new data to HASH_DIN. This mechanism avoids the introduction of wait states by the HASH.
     The final digest computation is triggered when the last block is entered and the software sets the DCAL bit. If the message length is not an exact multiple of the
block size, the NBLW field in HASH_STR register must be written prior to writing DCAL bit (see Section 38.4.6 for details).

– Data are filled as a single DMA transfer (MDMAT = 0):
Partial digest computations are triggered automatically each time the FIFO is full. The final digest computation is triggered automatically when the last block has been transferred to the HASH_DIN register by DMA (DCAL bit is set by hardware). If the message length is not an exact multiple of the block size, the NBLW field in HASH_STR register must be written prior to enabling the DMA (see Section 38.4.6 for details).

– Data are filled using multiple DMA transfers (MDMAT = 1):
Partial digest computations are triggered as for single DMA transfers (refer to the above description). However, the final digest computation is not triggered automatically when the last block has been transferred by DMA to the HASH_DIN register (DCAL bit is not set by hardware). It enables the hash processor to receive a new DMA transfer as part of this digest computation. To launch the final digest computation, the software must clear MDMAT bit before the last DMA transfer in order to trigger the final digest computation as it is done for single DMA transfers.

4. Once the digest calculation is completed (DCIS = 1), the resulting digest can be read from the output registers, as described in Table 353.

1. Digest size is 224 bits for SHA2-512/224 and 256 bits for SHA2-512/256 (truncated modes)

For more information about HMAC detailed instructions, refer to Section 38.4.7: HMAC operation.

38.4.6 Message padding

Overview

When computing a condensed representation of a message, the process of feeding data into the hash processor (with automatic partial digest computation every block size transfer) loops until the last bits of the original message are written to the HASH_DIN register.

As the length (number of bits) of a message can be any integer value, the last word written to the hash processor may have a valid number of bits between 1 and 32. This number of valid bits in the last word, NBLW, has to be written to the HASH_STR register, so that message padding is correctly performed before the final message digest computation.
Padding processing
Detailed padding sequences, with DMA enabled or disabled, are described in Section 38.4.5: Message digest computing.

Padding example
As specified by Federal Information Processing Standards PUB 180-4, message padding consists in appending a “1” followed by \( k \) “0”s, itself followed by a 64-bit integer that is equal to the length \( L \) in bits of the message. These three padding operations generate a padded message of length \( L + 1 + k + 64 \), which by construction is a multiple of 512 bits.

For the hash processor, the “1” is added to the last word written to the HASH_DIN register at the bit position defined by the NBLW bitfield, and the remaining upper bits are cleared (“0”s).

Example from FIPS PUB180-4
Let us assume that the original message is the ASCII binary-coded form of "abc", of length \( L = 24 \):

\[
\begin{array}{cccc}
\text{byte 0} & \text{byte 1} & \text{byte 2} & \text{byte 3} \\
01100001 & 01100010 & 01100011 & \text{UUUUUUU} \\
& \text{--- 1st word written to HASH_DIN ---} & \\
\end{array}
\]

NBLW has to be loaded with the value 24: a “1” is appended at bit location 24 in the bit string (starting counting from left to right in the above bit string), which corresponds to bit 31 in the HASH_DIN register (little-endian convention):

\[
01100001 \ 01100010 \ 01100011 \ \text{UUUUUUU}
\]

Since \( L = 24 \), the number of bits in the above bit string is 25, and 423 “0” bits are appended, making now 448 bits.

This gives in hexadecimal (byte words in big-endian format):

\[
\begin{array}{cccc}
616263 & 80 & 0000000 & 0000000 \\
& 0000000 & 0000000 & 0000000 \\
& 0000000 & 0000000 & 0000000 \\
& 0000000 & 0000000 \\
\end{array}
\]

The message length value, \( L \), in two-word format (that is 00000000 00000018) is appended. Hence, the final padded message in hexadecimal (byte words in big-endian format):

\[
\begin{array}{cccc}
61626380 & 00000000 & 00000000 & 00000000 \\
& 00000000 & 00000000 & 00000000 \\
& 00000000 & 00000000 & 00000000 \\
& 00000000 & 00000000 & 00000018 \\
\end{array}
\]
If the hash processor is programmed to swap byte within HASH_DIN input register (DATATYPE = 10 in HASH_CR), the above message has to be entered using following sequence:

1. **0xUU636261** is written to the HASH_DIN register (where 'U' means don’t care)
2. **0x18** is written to the HASH_STR register (the number of valid bits in the last word written to the HASH_DIN register is 24, as the original message length is 24 bits)
3. **0x10** is written to the HASH_STR register to start the message padding (described above) and then perform the digest computation.
4. The hash computing is complete with the message digest available in the HASH_HRx registers (x = 0 to 4) for the SHA-1 algorithm. For this FIPS example, the expected value is as follows:

   - HASH_HR0 = 0xA9993E36
   - HASH_HR1 = 0x4706816A
   - HASH_HR2 = 0xBA3E2571
   - HASH_HR3 = 0x7850C26C
   - HASH_HR4 = 0x9CD0D89D

### 38.4.7 HMAC operation

#### Overview

As specified by Internet Engineering Task Force RFC2104 and NIST FIPS PUB 198-1, the HMAC algorithm is used for message authentication by irreversibly binding the message being processed to a key chosen by the user. The algorithm consists of two nested hash operations:

\[
\text{HMAC(message)} = \text{Hash((Key | pad) XOR opad | Hash((Key | pad) XOR ipad | message))}
\]

Where:

- **opad** = [0x5C]_n (outer pad) and **ipad** = [0x36]_n (inner pad)
- \([X]_n\) represents a repetition of \(X\) \(n\) times, where \(n\) equal to the byte size of the underlying hash function data block (\(n = 64\) when block size is 512 bits).
- **pad** is a sequence of zeroes needed to extend the key to the length \(n\) defined above. If the key length is greater than \(n\), the application must first hash the key using Hash() function and then use the resultant byte string as the actual key to HMAC.
- | represents the concatenation operator.

**Note:** *HMAC mode of the hash processor can be used with all supported algorithms.*

#### HMAC processing

Four different steps are required to compute the HMAC:

1. The software sets the INIT bit, with the MODE bit set and the ALGO bits selecting the desired algorithm. The LKEY bit must also be set if the key being used is longer than the block size. In this case, as required by HMAC specifications, the hash processor uses the hash of the key instead of the real key.
2. The software provides the key to be used for the inner hash function, using the same mechanism as the message string loading that is by writing the key data into
HASH_DIN register and then completing the transfer by setting DCAL bit and the correct NBLW to HASH_STR register.

3. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write the message string to HASH_DIN. When the last word of the last block is entered and the software sets DCAL bit in HASH_STR register, the NBLW bitfield must be programmed at the same time to a value different from zero if the message length is not an exact multiple of the block size. Note that the DMA can also be used to feed the message string, as described in Section 38.4.5: Message digest computing.

4. Once the processor is ready again (DINIS = 1 in HASH_SR), the software provides the key to be used for the outer hash function, writing the key data into HASH_DIN register, and then completing the transfer by setting DCAL bit and programming the correct NBLW to HASH_STR register. The HMAC result can be found in the valid output registers (HASH_HRx) as soon as DCIS bit is set.

Note: The computation latency of the HMAC primitive depends on the lengths of the keys and message, as described in Section 38.4.11: HASH processing time.

Endianness management details can be found in Section 38.4.4: Message data feeding.

HMAC example

Below is an example of HMAC SHA-1 algorithm (ALGO = 00 and MODE = 1 in HASH_CR) as specified by NIST. SHA-1 block size is 64 bytes.

Let us assume that the original message is the ASCII binary-coded form of “Sample message for keylen = blocklen”, of length L = 34 bytes. If the HASH is programmed in no swapping mode (DATATYPE = 00 in HASH_CR), the following data must be loaded sequentially into HASH_DIN register:

1. Inner hash key input (length = 64, that is, no padding), specified by NIST. As key length = 64, LKEY bit is cleared in HASH_CR register

   00010203 04050607 08090A0B 0C0D0E0F 10111213 14151617 18191A1B 1C1D1E1F 20212223 24252627 28292A2B 2C2D2E2F 30313233 34353637 38393A3B 3C3D3E3F

2. Message input (length = 34, that is, padding required). HASH_STR must be set to 0x20 to start message padding and inner hash computation (see ‘U’ as don’t care)

   53616D70 6C65206D 65737361 67652066 6F722065 6E3D626C 656EUUUU

3. Outer hash key input (length = 64, that is, no padding). A key identical to the inner hash key is entered here.

4. Final outer hash computing is then performed by the HASH. The HMAC-SHA1 digest result is available in the HASH_HRx registers, as shown below:

   HASH_HR0 = 0xF5FD596EE
   HASH_HR1 = 0x78D5555C
   HASH_HR2 = 0x8FF4E72D
   HASH_HR3 = 0x266DFD19
   HASH_HR4 = 0x2366DA29
38.4.8 HASH suspend/resume operations

Overview

It is possible to interrupt a hash/HMAC operation to perform another processing with a higher priority. The interrupted process completes later when the higher-priority task has been processed, as shown in Figure 391.

![Figure 391. HASH suspend/resume mechanism](image)

To do so, the context of the interrupted task must be saved from the HASH registers to memory, and then be restored from memory to the HASH registers.

The procedures where the data flow is controlled by software or by DMA are described hereafter.
Data loaded by software

When the DMA is not used to load the message into the hash processor, the context can be saved only when no block processing is ongoing.

To suspend the processing of a message, proceed as follows after writing the number of words defined in NBWE:

1. In Polling mode, wait for BUSY = 0 then poll if the DINIS status bit is set.
   In Interrupt mode, implement the next step in DINIS interrupt handler (recommended).
2. Store the contents of the following registers into memory:
   - HASH_IMR
   - HASH_STR
   - HASH_CR
   - HASH_CSR0 to HASH_CSR37, when SHA-1 or SHA2-256 is selected, plus HASH_CSR38 to HASH_CSR53 if an HMAC operation was ongoing
   - HASH_CSR0 to HASH_CSR90, when SHA2-384 or SHA2-512 (truncated or not) is selected, plus HASH_CSR91 to HASH_CSR102 if an HMAC operation was ongoing.

To resume the processing of a message, proceed as follows:

1. Write the following registers with the values saved in memory: HASH_IMR, HASH_STR, HASH_CR.
2. Initialize the hash processor by setting the INIT bit in the HASH_CR register
3. Write the HASH_CSRx registers with the values saved in memory.
4. Restart the processing from the point where it has been interrupted.

Data loaded by DMA

When the DMA is used to load the message into the hash processor, it is recommended to suspend and then restore a secure digest computing as described below.

In this sequence the DMA channel allocated to the hash peripheral remains allocated to the processing of message 1 (see Figure 391).

To suspend the processing of a message using DMA, proceed as follows:

1. Clear the DMAE bit to disable the DMA interface. The hash peripheral automatically fetches enough data via the DMA to complete the current burst transfer.
2. Wait until the last DMA transfer is complete (DMAS = 0 in HASH_SR).
3. Disable the DMA channel.
4. In Polling or Interrupt mode (recommended), wait until the hash processor is ready (no block is being processed), that is wait for DINIS = 1 in HASH_SR. If DCIS is also set in HASH_SR, the hash result is available and the context swapping is useless. Else go to step 5.
5. Save HASH_IMR, HASH_STR and HASH_CR registers. Also save a number of HASH_CSRx registers depending on the SHA algorithm that is used:
   - When SHA-1 or SHA2-256 is selected, save HASH_CSR0 to HASH_CSR37, plus HASH_CSR38 to HASH_CSR53 if an HMAC operation was ongoing.
   - When SHA2-384 or SHA2-512 is selected, save HASH_CSR0 to HASH_CSR90, plus HASH_CSR91 to HASH_CSR102 if an HMAC operation was ongoing.
To resume the processing of a message using DMA, proceed as follows:

1. Reconfigure the DMA controller so that it proceeds with the transfer of the message up to the end if it is not interrupted again.
2. Program the values saved in memory to HASH_IMR, HASH_STR and HASH_CR registers.
3. Initialize the hash processor by setting the INIT bit in the HASH_CR register.
4. Program the values saved in memory to the HASH_CSRx registers.
5. Restart the processing from the point where it was interrupted by setting the DMAE bit.

### 38.4.9 HASH DMA interface

The HASH supports both single and fixed DMA burst transfers of four words.

The hash processor provides an interface to connect to the DMA controller. This DMA can be used to write data to the HASH by setting the DMAE bit in the HASH_CR register. When this bit is set, the HASH initiates a DMA request each time a block has to be written to the HASH_DIN register.

Once four 32-bit words have been received, the HASH automatically triggers a new request to the DMA. For more information, refer to Section 38.4.5: Message digest computing.

Before starting the DMA transfer, the software must program the number of valid bits in the last word that is copied into HASH_DIN register. This is done by writing in HASH_STR register the following value:

\[ NBLW = \text{Len}(\text{Message}) \mod 32 \]

where \( x \mod 32 \) gives the remainder of \( x \) divided by 32.

The DMAS bit of the HASH_SR register provides information on the DMA interface activity. This bit is set with DMAE and cleared when DMAE is cleared and no DMA transfer is ongoing.

*Note:* No interrupt is associated to DMAS bit. When MDMAT is set, the size of the transfer must be a multiple of four words.

### 38.4.10 HASH error management

No error flags are generated by the hash processor.

### 38.4.11 HASH processing time

*Table 354* summarizes the time required to process an intermediate block for each mode of operation.

<table>
<thead>
<tr>
<th>Mode of operation</th>
<th>Block size (in bytes)</th>
<th>FIFO load&lt;sup&gt;(1)&lt;/sup&gt;</th>
<th>Computation phase</th>
<th>Total</th>
</tr>
</thead>

<td>128</td>
<td>32</td>
<td>66</td>
<td>98</td>
</tr>
</tbody>
</table>

---

<sup>(1)</sup> Add the time required to load the block into the processor.
2. SHA2-512 includes SHA2-512/224 and SHA2-512/256 modes.

The time required to process the last block of a message (or of a key in HMAC) can be longer. This time depends on the length of the last block and the size of the key (in HMAC mode).

Compared to the processing of an intermediate block, it can be increased by the factor below:

- 1 to 2.5 for a hash message
- ~2.5 for an HMAC input-key
- 1 to 2.5 for an HMAC message
- ~2.5 for an HMAC output key in case of a short key
- 3.5 to 5 for an HMAC output key in case of a long key

38.5 HASH interrupts

Two individual maskable interrupt sources are generated by the hash processor to signal the following events:

- Digest calculation completion (DCIS)
- Data input buffer ready (DINIS)

Both interrupt sources are connected to the same global interrupt request signal (hash_it), which is in turn connected to the device interrupt controller. Each interrupt source can individually be enabled or disabled by changing the mask bits in the HASH_IMR register. Setting the appropriate mask bit enables the interrupt.

The status of each maskable interrupt source can be read from the HASH_SR register. Table 355 gives a summary of the available features.

<table>

</tbody>
</table>

38.6 HASH registers

The hash core is associated with several control and status registers and several message digest registers. All these registers are accessible through 32-bit word accesses only, else an AHB error is generated.

 Bits 31:21: Reserved, must be kept at reset value.

 Bits 20:17 **ALGO[3:0]:** Algorithm selection

These bits select the hash algorithm. This selection is only taken into account when the INIT bit is set. Changing this bitfield during a computation has no effect.

When the ALGO bitfield is updated and INIT bit is set, NBWE in HASH_SR is automatically updated to 0x11.

0000: SHA-1
0001: reserved
0010: SHA2-224
0011: SHA2-256
1100: SHA2-384
1101: SHA2-512/224
1110: SHA2-512/256
1111: SHA2-512

 Bit 16 **LKEY:** Long key selection

The application must set this bit if the HMAC key is greater than the block size corresponding to the hash algorithm (see Table 352: Information on supported hash algorithms for details). For example the block size is 64 bytes for SHA2-256.

This selection is only taken into account when the INIT and MODE bits are set (HMAC mode selected). Changing this bit during a computation has no effect.

0: HMAC key is shorter or equal to the block size (short key). The actual key value written in HASH_DIN is used during the HMAC computation.
1: HMAC key is longer than the block size (long key). The hash of the key is used instead of the real key during the HMAC computation.

 Bit 15: Reserved, must be kept at reset value.

 Bit 14: Reserved, must be kept at reset value.

 Bit 13 **MDMAT:** Multiple DMA transfers

This bit is set when hashing large files when multiple DMA transfers are needed.

0: DCAL is automatically set at the end of a DMA transfer.
1: DCAL is not automatically set at the end of a DMA transfer.

 Bit 12 **DINNE:** DIN not empty

Refer to DINNE bit of HASH_SR for a description of DINNE bit. This bit is read-only.

 Bits 11:8 **NBW[3:0]:** Number of words already pushed

Refer to NBWP[3:0] bitfield of HASH_SR for a description of NBW[3:0] bitfield. This bit is read-only.

 Bit 7: Reserved, must be kept at reset value.
38.6.2 HASH data input register (HASH_DIN)

Address offset: 0x004
Reset value: 0x0000 0000

HASH_DIN is the data input register. It is 32-bit wide. This register is used to enter the message by blocks defined by the hash algorithm (see Table 352: Information on supported hash algorithms for details). For example the block size is 64 bytes for SHA2-256.

When the HASH_DIN register is programmed, the value presented on the AHB bus is ‘pushed’ into the hash core and the register takes the new value presented on the AHB bus. To get a correct message format, the DATATYPE bits must have been previously configured in the HASH_CR register.
When a complete block has been written to the HASH_DIN register, an intermediate digest calculation is launched:

- by writing first data of the next block into the HASH_DIN register, if the DMA is not used
- automatically, if the DMA is used

When the last block has been written to the HASH_DIN register, the final digest calculation (including padding) is launched by setting the DCAL bit in the HASH_STR register (final digest calculation). This operation is automatic if the DMA is used and MDMAT bit is cleared.

Reading the HASH_DIN register returns zeros.

**Note:** When the HASH is busy, a write access to the HASH_DIN register might stall the AHB bus if the digest calculation (intermediate or final) is not complete.

### Bits 31:0 DATAIN[31:0]: Data input

- Writing this register pushes the current register content into the FIFO, and the register takes the new value presented on the AHB bus.
- Reading this register returns zeros.

### 38.6.3 HASH start register (HASH_STR)

- **Address offset:** 0x008
- **Reset value:** 0x0000 0000

The HASH_STR register has two functions:

- It is used to define the number of valid bits in the last word of the message entered in the hash processor (that is the number of valid least significant bits in the last data written to the HASH_DIN register)
- It is used to start the processing of the last block in the message by setting the DCAL bit.
38.6.4 HASH digest registers

These registers contain the message digest result defined as follows:

- HASH_HR0, HASH_HR1, HASH_HR2, HASH_HR3 and HASH_HR4 registers return the SHA-1 digest result.
- HASH_HR0 to HASH_HR6 registers return the SHA2-224, SHA2-512/224 digest result.
- HASH_HR0 to HASH_HR7 registers return the SHA2-256, SHA2-512/256 digest result.
- HASH_HR0 to HASH_HR11 registers return the SHA2-384 digest result.
- HASH_HR0 to HASH_HR15 registers return the SHA2-512 digest result.

In all cases, the digest most significant bit is stored in HASH_HR0[31], and unused HASH_HRx registers reads as zero.

If a read access to one of these registers is performed while the hash core is calculating an intermediate digest or a final message digest (DCIS bit equals 0), then the read operation returns zeros.

**Note:** When starting a digest computation for a new message (by setting the INIT bit), HASH_HRx registers are forced to their reset values.

HASH_HR0 to HASH_HR4 registers can be accessed through two different addresses (register aliasing).
**HASH aliased digest register x (HASH_HRAx)**

Address offset: 0x00C + 0x4 * x, (x = 0 to 4)

Reset value: 0x0000 0000

The content of the HASH_HRAx registers is identical to the one of the HASH_HRx registers located at address offset 0x310.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 NBWE[4:0]: Number of words expected
This bitfield reflects the number of words in the message that must be pushed into the FIFO to trigger a partial computation. NBWE is decremented by 1 when a write access is performed to the HASH_DIN register.
NBWE is set to the expected block size +1 in words (0x11) when INIT bit is set in HASH_CR. It is set to the expected block size (0x10) when the partial digest calculation ends.

Bit 15 DINNE: DIN not empty
This bit is set when the HASH_DIN register holds valid data (that is after being written at least once). It is cleared when either the INIT bit (initialization) or the DCAL bit (completion of the previous message processing) is set.
0: No data are present in the data input buffer
1: The input buffer contains at least one word of data
Bits 13:9 **NBWP[4:0]:** Number of words already pushed

This bitfield is the exact number of words in the message that have already been pushed into the FIFO. NBWP is incremented by 1 when a write access is performed to the HASH_DIN register.

When a digest calculation starts, NBWP is updated to NBWP - block size (in words), and NBWP goes to zero when the INIT bit is set.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **BUSY:** Busy bit

0: No block is currently being processed
1: The hash core is processing a block of data

Bit 2 **DMAS:** DMA Status

This bit provides information on the DMA interface activity. It is set with DMAE and cleared when DMAE = 0 and no DMA transfer is ongoing. No interrupt is associated with this bit.

0: DMA interface is disabled (DMAE = 0) and no transfer is ongoing
1: DMA interface is enabled (DMAE = 1) or a transfer is ongoing

Bit 1 **DCIS:** Digest calculation completion interrupt status

This bit is set by hardware when a digest becomes ready (the whole message has been processed). It is cleared by writing it to 0 or by setting the INIT bit in the HASH_CR register.

0: No digest available in the HASH_HRx registers (zeros are returned)
1: Digest calculation complete, a digest is available in the HASH_HRx registers. An interrupt is generated if the DCIE bit is set in the HASH_IMR register.

Bit 0 **DINIS:** Data input interrupt status

This bit is set by hardware when the FIFO is ready to get a new block (16 locations are free).

It is cleared by writing it to 0 or by writing the HASH_DIN register.

When DINIS = 0, HASH_CSRx registers reads as zero.

0: Less than 16 locations are free in the input buffer
1: A new block can be entered into the input buffer. An interrupt is generated if the DINIE bit is set in the HASH_IMR register.

38.6.7 **HASH context swap registers**

These registers contain the complete internal register states of the hash processor. They are useful when a suspend/resume operation has to be performed because a high-priority task needs to use the hash processor while it is already used by another task.

When such an event occurs, the HASH_CSRx registers have to be read and the read values have to be saved in the system memory space. Then the hash processor can be used by the preemptive task. When the hash computation is complete, the saved context can be read from memory and written back into the HASH_CSRx registers.

HASH_CSRx registers can be read only when DINIS equals to 1, otherwise zeros are returned.
HASH context swap register x (HASH_CSRx)

Address offset: 0x0F8 + 0x4 * x, (x = 0 to 102)
Reset value: 0x0022 0002 (HASH_CSR0)
Reset value: 0x0020 0000 (HASH_CSR2)
Reset value: 0x0000 0000 (others)

39 Memory cipher engine (MCE)

39.1 Introduction

Memory cipher engine (MCE) defines, in a given address space, multiple regions with specific security setup (encryption, privilege, write). All system bus traffic going through an encrypted region is managed on-the-fly by the MCE, automatically decrypting reads and encrypting writes if authorized.

Multiple ciphering option (stream, block, fast block) are available to offer the best security versus performance trade-off.

Note: When MCE is used in conjunction with XSPI it is mandatory to access the flash memory using the memory map mode of the flash memory controller.

39.2 MCE main features

- System bus in-line encryption (for writes) and decryption (for reads), based on embedded firewall programming
  - Four encryption modes per region (maximum 4 regions available): no encryption (bypass mode), stream cipher, block cipher and fast block cipher modes
  - Start and end of regions defined with 4-Kbytes granularity
  - Default filtering (region 0): any access granted
  - Region 1 to 4 access filtering criteria: privilege, write
- Supported block ciphers: AES or Noekeon (12 round version)
- Supported chaining modes: block and stream
  - Block mode with AES cipher is compatible with ECB mode specified in NIST FIPS publication 197 Advanced encryption standard (AES) (normal or fast).
  - Stream mode with AES cipher is compliant with CTR mode specified in NIST SP800-38A Recommendation for Block Cipher Modes of Operation.
  - Includes a leakage resilient mode of operation as defense against side channel attacks (SCA).
- One set of write-only and lockable master key registers per block cipher (normal, fast)
- Two sets of lockable cipher contexts (128-bit key, IV), usable for stream and block ciphers
- Optimization for XSPI data pre-fetching mechanism (stream cipher only)
- Read-write arbitration scheme, for better read performances
- AHB configuration port, privileged aware
- AXI system bus master/slave interfaces (64-bit)
  - Support for any AXI-64bit read transactions
  - When encryption is enabled, support for AXI-64bit INCRx (x=1 to 8) and WRAPx (x=4) write transactions
39.3 MCE implementation

This manual describes the full set of features implemented in MCE peripheral. In this device MCE1, MCE2 and MCE3 instances implement the set of features defined on Table 357.

1. All digital.
39.4.3 MCE programming

Overview

Through MCE registers application software defines security regions, as shown on Figure 393.

Figure 393. MCE region programming

1. Covers all addressable space.

There are three types of accesses filtered by MCE:

1. Access to an area located in one enabled region (accesses 1). In this case region filtering rules apply. If encryption is enabled cipher engine is used accordingly.
2. Access to an area overlapping two enabled regions (access 2):
   - If one region is encrypted, this region defines the write and privilege accesses, as well as the encryption.
   - If both regions are encrypted, access is automatically rejected with an error.
   - If both regions are not encrypted, lowest index region defines the write and privilege accesses.

Access to an area not belonging to any enabled region (accesses 3). In this case primary region 0 filtering applies (any access granted, no encryption).

Configuring regions

When application needs to use any region x following sequence can be used, for example at boot time.

1. Application sets a start and end address for each of the required region x, using MCE_SADDRx and MCE_EADDRx registers.
2. For each of the above region x application programs MCE_ATTRx, granting write access to the memory or not.
3. Application finalizes the programming by configuring MCE_REGCRx setting up security parameters (encryption, privilege). Initializing encryption is detailed in Section 39.4.5 and Section 39.4.5.
4. After final check on above configuration application enables each required region z, setting BREN bit in MCE_REGCRz.
MCE configuration can be fixed until next SoC reset when GLOCK is set in MCE_CR register.

Above application must be privileged if PRIV bit is set in register MCE_PRIVCFGR.

**Note:** When ENCDIS bit is set in MCE_SR, if ENC bit and BREN bits are set in MCE_REGCRx all writes to this region x are ignored and all read requests return zero. See Section 39.4.8 for details.

**Note:** When an MCE instance uses at least one crypto context, to avoid issues at runtime it is recommended to verify in MCE_CCxCFGR registers that, each time CCEN=1, KEYCRC is different from zero. After this check it is recommended to set GLOCK in MCE_CR to freeze the MCE configuration.

### Runtime modification of region configuration

While it is possible to update on-the-fly the enabled region access filtering (write, privilege), changes to the following configurations are ignored when BREN bit is set in MCE_REGCRx register:

- MCE_SADDRx and MCE_EADDRx address registers
- ENC and CTXID bitfields in MCE_REGCx register

**Note:** When BREN is cleared primary region 0 access rules applies instead of base region rules (see Overview).

GLOCK bit should be used to write lock the following registers: MCE_MKEYRx, MCE_FMKEYRx, MCE_CCxCFGR, MCE_CCxNR0/1 and MCE_CCxKEYR, in order to avoid unexpected changes to the cipher keys/context while used by the MCE.

### Encrypting with MCE

MCE automatically encrypts on-the-fly any granted write transaction to a region with encryption properly initialized. When stream cipher is selected it is important to activate write protection as soon as the whole region has been encrypted (read-only region).

When MCE is used in conjunction with XSPI it is mandatory to set the Flash memory controller in memory map mode. It is also required to use the DMA to perform writes to the flash memory using 16 bytes bursts.

### 39.4.4 MCE reset and clocks

MCE configuration port is clocked by the AHB bus clock.

MCE system bus interface is clocked by the AXI clock. AHB interface does not need to be clocked for the system bus to be usable.

When MCE is kept under reset, no traffic can go through the system bus. Out of reset default firewall configuration applies, as described in Section 39.4.3.

The clocks of MCE peripheral and its associated memory controller are enabled together in the RCC, and the MCE peripheral is reset by a system reset or when associated memory controller is reset (see Section 7: Reset and clock control (RCC)).

### 39.4.5 MCE block cipher encryption mode

**Caution:** When MCE is used in conjunction with XSPI it is mandatory to read or write the flash memory using the memory map mode of the flash memory controller.
Figure 394 details the block cipher implementations in the MCE peripheral. Top figure is a standard encryption (for writes), bottom figure is a fast decryption (for reads).

**Figure 394. MCE implementation of block ciphers**

1. Operation starts from the capture of the address.
2. Operation starts from availability of data input.
3. Only required for AES cipher.

Address \( i \) is most significant bits of physical address of block \( i \) + block \( i+1 \). Result of key derivation primitive can be used for two consecutive 16-byte data words. Since the normal key derivation function is leakage resilient the master key information is protected against side channel attacks (SCA).

**MASTER_KEY** must be stored in write-only MCE_MKEYRx registers.
**FAST_MASTER_KEY** must be stored in write-only MCE_FMKEYRx registers. Alternatively, MCE_CCzKEYRx registers can be used if cipher context \( z \) is selected in MCE_REGCR (CTXID=z).

Each time a key material has been successfully written in MCE, the following flags are set:
- MK VALID bit in MCE_SR is set when a complete key has been written in MCE_MKEYR registers.
- FMK VALID bit in MCE_SR is set when a complete key has been written in MCE_FMKEYR registers.
- KEYCRC[7:0] in MCE_CCzCFGR is loaded with 8-bit checksum when a complete key has been written in MCE_CCzKEYR registers. See KEYCRC bitfield for details.
Bypass mode is selected instead of cipher mode if the selected key is not marked as valid with above flags. See ENC bitfield description for details.

**Note:** With AES block cipher, writing (encryption) requires extra cycles in order to perform the required key scheduling to obtain the encryption key. See next table for details.

Fast key derivation function may be sensitive against side channel attacks. Hence master key used in normal mode is never used in fast mode.

Relative performances are described on Table 359. Refer to Section 39.3: MCE implementation to identify which cipher is used for which MCE instance.

### Table 359. MCE block cipher latencies

<td>4+7x2= 18</td>
</tr>
</tbody>
</table>

1. Additional 10 cycles are required when performing encryption/ writes
2. Leakage resilient mode of operation as defense against side channel attacks.

### 39.4.6 MCE stream cipher encryption mode

*Figure 395* details the stream cipher implementations in the MCE peripheral. It pictures encryptions for AXI writes.

### Figure 395. MCE implementation of stream cipher

1. Operation starts from the capture of the address.

Every 128-bit data block (i), a counter (i) information is computed, as defined below:

- Counter[127:0] = MCE_CCzNR1[31:0] || MCE_CCzNR0[31:0] || 0b0000000000000000 || MCE_CCzCFGR[31:16] || 0b0000 || Address_i [31:4].
Address \(_i\) is the physical address of block \((i)\), modulo 16 bytes.

Version and nonce are stored by application respectively in MCE CCzCFGR and MCE CCzNReq registers, with cipher context \(z\) selected in MCE_REGCR (CTXID=\(z\)).

The least significant byte of Data_IN and Data_OUT are stored in the first 8 bits of the data blocks.

CC_KEY is stored in write-only MCE CCzKEYRx registers, with cipher context \(z\) selected in MCE_REGCR (CTXID=\(z\)). Bypass mode is selected instead of stream cipher mode if the selected key is not marked as valid, i.e. KEYCRC[7:0] in MCE_CCyCFGR is different from 0x0.

Note: Stream cipher mode offers no protection against bit-flip attacks, and is sensitive against side channel attacks.

Caution: In order to secure the confidentiality of the information encrypted with the stream cipher in region \(x\), it is important to clear the WREN bit in MCE_ATTRx register as soon as the whole region has been encrypted by the application (read-only region).

Caution: When MCE is used in conjunction with XSPI it is mandatory to read or write the flash memory using the memory map mode of the flash memory controller.

Relative performances are described on Table 360. Refer to Section 39.3: MCE implementation to identify which cipher is used for which MCE instance.

<table>
<thead>
<tr>
<th>Cipher type</th>
<th>Stream mode</th>

<th>Latency for 16 bytes data (in AXI cycles)</th>
<th>Optimization for sequential accesses</th>
</tr>
</thead>
<tbody>
<tr>
<td>AES</td>
<td>Normal</td>
<td>01</td>
<td>11</td>
<td>Yes</td>
</tr>
</tbody>
</table>

39.4.7 MCE AXI traffic management

MCE includes a special AXI-64 read-write arbitration scheme, designed to speed-up multiple reads. More specifically, when no write is on-going in MCE the two cipher cores can be allocated to decrypt two reads in parallel. In this case an incoming write request is stalled until the cipher core allocated to writes is free.

Note: Best performances are obtained when transactions are aligned on two 64-bit words for regions where block cipher is selected. See Section 39.4.5 for details.

39.4.8 MCE encryption disable options

When MCE feature is not available in the product encryption/decryption feature of MCE is not usable, for any region. It means that reads (resp. writes) through MCE are not decrypted (resp. encrypted).

When an unexpected event occurs, the ENCDIS bit is set in MCE_SR register and the following effects apply:

- All previously written key materials are erased.
- If ENC bit and BREN bits are set in MCE_REGCRx, all writes to this region \(x\) are ignored and all read requests return zero.

In such an event, the application must reset the MCE peripheral to be able to use encrypted regions again.

Table 360. MCE stream cipher latencies
39.4.9 MCE error management

When an illegal access to a configuration register occurs (bad privilege) corresponding CAEF bit is set in MCE_IASR. Application cleans this flag using CAEF bit in MCE_IACR.

When an illegal access through the system bus occurs (bad privilege, forbidden write, overlapping encrypted regions) corresponding IAEF bit is set in MCE_IASR. Application cleans this flag using IAEF bit in MCE_IACR.

Additional debug information on system bus illegal accesses can be read in illegal access error status register (MCE_IAESR) and optionally the illegal address register (MCE_IADDR).

Illegal read (resp. write) through the system bus returns zero (resp. is ignored).

Read to write-only or write to read-only registers do not trigger an interrupt. Reading any MCE key register returns zeros.

39.5 MCE interrupts

There are two individual maskable interrupt sources generated by the MCE, signaling the following error events:

- Illegal access through the configuration bus (CAEF), see Section 39.4.9
- Illegal access through the system bus (IAEF), see Section 39.4.9

Those interrupt sources are connected to the same global interrupt request signal mce_it.

Setting the appropriate mask bit in MCE_IAIER register enables the interrupt. The status of the individual interrupt events can be read from MCE_IASR, and cleared in MCE_IACR register.

Table 361 gives a summary of the available features.

Bits 31:2 Reserved, must be kept at reset value.  

**Bit 1 IAEF**: Illegal access error flag clear  
Set this bit to clear IAEF bit in MCE_IASR register. Clearing IAEF bit permits to capture new error information in MCE_IAESR and MCE_IADDR registers.  
Note that clearing this bit does not clear RISAB_IADDR register.

**Bit 0 CAEF**: Configuration access error flag clear  
Set this bit to clear CAEF bit in MCE_IASR register.

### 39.6.5 MCE illegal access interrupt enable register (MCE_IAIER)

Address offset: 0x010  
Reset value: 0x0000 0000  
Privileged read and write access only if PRIV is set in MCE_PRIVCFGR.

<p>| | | | | | | | | | | | | | | | |</p>

Bits 31:2 Reserved, must be kept at reset value.  

**Bit 1 IAEIE**: Illegal access error interrupt enable  
0: Interrupt generation on illegal access errors is disabled  
1: Interrupt generation when an illegal access error occurs (IAEF=1)  

**Bit 0 CAEIE**: Configuration access error interrupt enable  
0: Interrupt generation on configuration access errors is disabled  
1: Interrupt generation when a configuration access error occurs (CAEF=1)
39.6.6 MCE privileged configuration register (MCE_PRIVCFGR)

Address offset: 0x1C
Reset value: 0x0000 0000
Privileged write access only.
Any read is allowed. Writes are ignored if GLOCK is set in MCE_CR register.

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 IANRW: Illegal access read/write
When IAEF bit is set in MCE_IASR register IANRW bit captures the access type of the illegal access detected.
0: Illegal access was a data read or an instruction fetch.
1: Illegal access was a data write.

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 IAPRIV: Illegal access privilege
When IAEF bit is set in MCE_IASR register IAPRIV bit captures the privileged state of the master that issued the illegal access detected on the AXI system bus.
0: Illegal access was unprivileged.
1: Illegal access was privileged.

Bits 3:0 Reserved, must be kept at reset value.
39.6.8 MCE illegal address register (MCE_IADDR)

Address offset: 0x024
Reset value: 0x0000 0000

Privileged read access only if PRIV is set in MCE_PRIVCFGR.

Bits 31:0 IADD[31:0]: Illegal address
When IAEF bit is set in MCE_IASR register IADD bitfield captures the 32-bit bus address of the erroneous access. Additional information can be found in MCE_IAESR register.

39.6.9 MCE region x configuration register (MCE_REGCRx)

Address offset: 0x040 + 0x10 * (x - 1), (x = 1 to 4)
Reset value: 0x0000 0000

Privileged read and write access only if PRIV is set in MCE_PRIVCFGR. Writes are ignored if GLOCK is set in MCE_CR register.

rw rw rw rw rw rw rw
Bits 31:17  Reserved, must be kept at reset value.

Bit 16  PRIV: Privileged region
This bit is taken into account only if BREN is set.
0: Application can access to region x in privileged and unprivileged mode.
1: Application can access to region x in privileged mode only.

Bits 15:14  ENC[1:0]: Encrypted region
Those bits are taken into account only if BREN is set and if the corresponding encryption feature is available in the MCE instance (see Section 39.3: MCE implementation). Write to those bits is ignored if BREN is set.
00: No effects
01: Stream cipher - All allowed read (resp. write) requests are decrypted (resp. encrypted) using the stream cipher, when CCEN bit is set in MCE_CCzCFGR (where CTXID=z).
10: Block cipher - All allowed read (resp. write) requests are decrypted (resp. encrypted) using the SCA resistant block cipher. If CTXID=0 and MKVALID=0 bypass mode is selected instead. If CTXID=z and CCEN bit is cleared in MCE_CCzCFGR bypass mode is also selected.
11: Fast block cipher - All allowed read (resp. write) requests are decrypted (resp. encrypted) using the fast block cipher. If CTXID=0 and FMKVALID=0 bypass mode is selected instead. If CTXID=z and CCEN bit is cleared in MCE_CCzCFGR bypass mode is also selected.

Bits 13:11  Reserved, must be kept at reset value.

Bits 10:9  CTXID[1:0]: Context ID
This bitfield defines the cryptographic context used by the cipher engine assigned to this region. If ENC=00 bitfield CTXID is ignored. If BREN is set write to this bitfield is ignored.
00: If ENC=10 (resp. 11) the key stored in MCE_MKEYR (resp. MCE_FMKEYR) registers is used by the block cipher. If ENC=01 bypass mode is selected instead of stream cipher.
01: If ENC=10 or 11 the key stored in MCE_CC1KEYR is used by the block cipher.
If ENC=01 the key stored in MCE_CC1KEYR is used by the stream cipher. The nonce in MCE_CC1NRx registers and the version in MCE_CC1CR register are also used.
10: If ENC=10 or 11 the key stored in MCE_CC2KEYR is used by the block cipher.
If ENC=01 the key stored in MCE_CC2KEYR is used by the stream cipher. The nonce in MCE_CC2NRx registers and the version in MCE_CC2CR register are also used.
11: reserved

Bits 8:1  Reserved, must be kept at reset value.

Bit 0  BREN: Base region enable
0: Region x is disabled. Access control of primary region (privileged or unprivileged, no encryption) applies to any access between this region start and end addresses.
1: Region x is enable. Access controls and encryption option defined in this region apply to any access between this region start and end addresses.
BREN cannot be set if BADDRSTART > BADDREN.
39.6.10 MCE start address for region x register (MCE_SADDRx)

Address offset: 0x044 + 0x10 * (x - 1), (x = 1 to 4)
Reset value: 0x0000 0000

Privileged read and write access only if PRIV is set in MCE_PRIVCFGR. Writes are ignored if GLOCK is set in MCE_CR register, or if BREN is set in MCE_REGCRx.

Bits 31:12 BADDSTART[31:12]: Region address start
This bitfield defines the absolute start address of the region x on 4 kBytes boundary (inclusive).
BREN cannot be set if BADDRSTART > BADDREND.
When MCE determines the region, the first 12 bits (LSB) and the last 4 bits (MSB) in this register are ignored, and when this register is accessed in read the 4 MSB bits and the 12 LSB bits return zeros (reference value in MCE).

Bits 11:0 Reserved, must be kept at reset value.

39.6.11 MCE end address for region x register (MCE_EADDRx)

Address offset: 0x048 + 0x10 * (x - 1), (x = 1 to 4)
Reset value: 0x0000 0FFF

Privileged read and write access only if PRIV is set in MCE_PRIVCFGR. Writes are ignored if GLOCK is set in MCE_CR register, or if BREN is set in MCE_REGCRx.

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **WREN**: Write enable
This bit is taken into account only if BREN is set.
0: Writes to region x are ignored. Reads are allowed.
1: Region x can be read and written. Restrictions linked to PRIV bit in MCE_REGCRx apply.

39.6.13 MCE master key x (MCE_MKEYRx)

Address offset: 0x200 + 0x4 * x, (x = 0 to 3)
Reset value: 0x0000 0000
Privileged write access only if PRIV is set in MCE_PRIVCFGR.
Writes are ignored if MKLOCK or GLOCK bit is set in MCE_CR register.

<table>

<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:0 **MKEY{32 * x + i}**: Master key bit (i = 0 to 31)
This key is used by the MCE block cipher in normal, SCA resistant mode, if CTXID=0x0 in MCE_REGCR register.

39.6.14 MCE fast master key x (MCE_FMKEYRx)

Address offset: 0x220 + 0x4 * x, (x = 0 to 3)
Reset value: 0x0000 0000
Privileged write access only if PRIV is set in MCE_PRIVCFGR.
39.6.15 MCE cipher context z configuration register (MCE_CCzCFGR)

Address offset: 0x240 + 0x30 * (z - 1) (z = 1 to 2)
Reset value: 0x0000 0000

Privileged read and write access only if PRIV is set in MCE_PRIVCFGR.

Writes are ignored if CCLOCK bit is set in this register. Writes are also ignored if GLOCK is set in MCE_CR register.

Refer to Section 39.3 to verify if this instance of MCE implements those registers.
Bits 31:16 **VERSION[15:0]:** Version

This 16-bit bitfield must be correctly initialized before CCEN bit is set. Bitfield usage is defined in Section 39.4.6: MCE stream cipher encryption mode.

Bits 15:8 **KEYCRC[7:0]:** Key CRC

When KEYLOCK=0, KEYCRC information is automatically computed by hardware while loading the key of this region in this exact sequence: KEYR0 then KEYR1 then KEYR2 then finally KEYR3 (all written once). A new KEYCRC computation starts as soon as a new valid sequence is initiated. KEYCRC bitfield reads as zero until a valid sequence is completed (after it return the computed CRC value).

When GLOCK=1, KEYCRC bitfield always return the computed CRC value until the next reset.

CRC computation is an 8-bit checksum using the standard CRC-8-CCITT algorithm \( X^8 + X^2 + X + 1 \) (according the convention).

*Note: CRC information is updated, and the key is usable by MCE, only after the last bit of the key has been written.*

When GLOCK=0 any write to MCE_CCxKEYR registers clears KEYCRC in MCE_CCxCFGR, and makes the cipher context key un-usable (bypass mode is selected instead). To be able to use the key again application must perform this sequence: write to KEYR0 then KEYR1 then KEYR2 then finally KEYR3 (all written once). As KEYLOCK=1 all those writes are ignored, so the correct key is used instead.

*Bits 7:3* Reserved, must be kept at reset value.

*Bit 2** KEYLOCK: Key lock

0: Writes to MCE_CCzKEYR registers are allowed
1: Writes to MCE_CCzKEYR registers are ignored until next MCE reset.

*Note: This bit is set once. If this bit is set, it can only be cleared to 0 if MCE is reset.*

*Bit 1** CCLOCK: Cipher context lock

0: Writes to MCE_CCzCFGR and MCE_CCzNR registers are allowed
1: Writes to MCE_CCzCFGR and MCE_CCzNR registers are ignored until next MCE reset.

*Note: This bit is set once. If this bit is set, it can only be cleared to 0 if MCE is reset. Setting this bit forces KEYLOCK bit to 1.*

*Bit 0** CCEN: Cipher context enable

0: If an enabled region selects CTXID=z bypass mode is selected by MCE
1: If an enabled region selects CTXID=z with ENC=01 MCE selects with the stream cipher the information stored in MCE_CCzCFGR, MCE_CCzNR and MCE_CCzKEYR. If the enabled region selects ENC=10 or 11 instead MCE selects with the block cipher the key information stored in MCE_CCzKEYR.
39.6.16 MCE cipher context z nonce register 0 (MCE_CCzNR0)

Address offset: 0x244 + 0x30 *(z - 1) (z = 1 to 2)
Reset value: 0x0000 0000

Privileged read and write access only if PRIV is set in MCE_PRIVCFGR.
Writes are ignored if CCLOCK is set in MCE_CCzCFGR register, or GLOCK bit is set in MCE_CR register.

Refer to Section 39.3 to verify if this instance of MCE implements those registers.

SCNONCE[31:16]

Bits 31:0 SCNONCE[31:0]: Stream cipher nonce, bits [31:0]
This register is used by stream cipher to compute keystream. It must be correctly initialize before CCEN bit is set in MCE_CCzCFGR register. Bitfield usage is defined in Section 39.4.6: MCE stream cipher encryption mode.

39.6.17 MCE cipher context z nonce register 1 (MCE_CCzNR1)

Address offset: 0x248 + 0x30 *(z - 1) (z = 1 to 2)
Reset value: 0x0000 0000

Privileged read and write access only if PRIV is set in MCE_PRIVCFGR.
Writes are ignored if CCLOCK is set in MCE_CCzCFGR register, or GLOCK bit is set in MCE_CR register.

Refer to Section 39.3 to verify if this instance of MCE implements those registers.

Bits 31:0 KEY[31:0]: cipher key, bits [31:0]
This register is used by the block or stream cipher of MCE when CTXID = z in encrypted region configuration register. KEY[127:0] must be correctly initialize before CCEN bit is set in MCE_CCzCFGR register.

39.6.19 MCE cipher context z key register 1 (MCE_CCzKEYR1)

Address offset: 0x250 + 0x30 *(z - 1) (z = 1 to 2)
Reset value: 0x0000 0000
Privileged write access only if PRIV is set in MCE_PRIVCFGR.
Writes are ignored if CCLOCK or KEYLOCK are set in MCE_CCzCFGR register, or GLOCK bit is set in MCE_CR register.
Refer to Section 39.3 to verify if this instance of MCE implements those registers.

Refer to the MCE_CCzKEYR0 register for description of the KEY[127:0] bitfield.
### 39.6.20 MCE cipher context z key register 2 (MCE_CCzKEYR2)

Address offset: \(0x254 + 0x30 \times (z - 1)\) (\(z = 1\) to \(2\))  
Reset value: \(0x0000\ 0000\)  
Privileged write access only if PRIV is set in MCE_PRIVCFGR.  
Writes are ignored if CCLOCK or KEYLOCK are set in MCE_CCzCFGR register, or GLOCK bit is set in MCE_CR register.  
Refer to Section 39.3 to verify if this instance of MCE implements those registers.

### Table 362. MCE register map and reset values

- **Offset**: Memory address offset from the start of the register map.
- **Register name**: Name of the register.
- **Register name (reset value)**: Initial value of the register.
- **31**: Value at bit 31.
- **30**: Value at bit 30.
- **29**: Value at bit 29.
- **28**: Value at bit 28.
- **27**: Value at bit 27.
- **26**: Value at bit 26.
- **25**: Value at bit 25.
- **24**: Value at bit 24.
- **23**: Value at bit 23.
- **22**: Value at bit 22.
- **21**: Value at bit 21.
- **20**: Value at bit 20.
- **19**: Value at bit 19.
- **18**: Value at bit 18.
- **17**: Value at bit 17.
- **16**: Value at bit 16.
- **15**: Value at bit 15.
- **14**: Value at bit 14.
- **13**: Value at bit 13.
- **12**: Value at bit 12.
- **11**: Value at bit 11.
- **10**: Value at bit 10.
- **9**: Value at bit 9.
- **8**: Value at bit 8.
- **7**: Value at bit 7.
- **6**: Value at bit 6.
- **5**: Value at bit 5.
- **4**: Value at bit 4.
- **3**: Value at bit 3.
- **2**: Value at bit 2.
- **1**: Value at bit 1.
- **0**: Value at bit 0.

### Memory Address Calculations
- **Offset**: `0x000` to `0x240`.
- **Reset value**: `0x000` to `0x04C`.

### Register Descriptions
- **MCE_CR**: Memory cipher engine control register.
- **MCE_SR**: Memory cipher engine status register.
- **MCE_IASR**: Memory cipher engine input status register.
- **MCE_IACR**: Memory cipher engine input access control register.
- **MCE_IAIER**: Memory cipher engine input access control enable register.
- **MCE_PRIVCFGR**: Memory cipher engine private configuration register.
- **MCE_IAESR**: Memory cipher engine input access enable status register.
- **MCE_IADDR**: Memory cipher engine input address register.
- **MCE_REGCRx**: Memory cipher engine register control register `x`.
- **MCE_SADDRx**: Memory cipher engine source address register `x`.
- **MCE_EADDRx**: Memory cipher engine end address register `x`.
- **MCE_ATTRx**: Memory cipher engine attribute register `x`.
- **MCE_MKEYRx**: Memory cipher engine key register `x`.
- **MCE_FMKEYRx**: Memory cipher engine frequency key register `x`.
- **MCE_CC1CFGR**: Memory cipher engine configuration register.

### Reset Values
- **Reset value**: `0x000` to `0x04C`.

### Memory Address Calculations
- **0x000**: Start of the register map.
- **0x200**: Start of the key registers.
- **0x220**: Start of the frequency key registers.
- **0x240**: Start of the configuration register.

### Additional Information
- **Offset 0x040**: MCE_REGCRx register.
- **Offset 0x044**: MCE_SADDRx register.
- **Offset 0x048**: MCE_EADDRx register.
- **Offset 0x04C**: MCE_ATTRx register.
- **Offset 0x200**: MCE_MKEYRx register.
- **Offset 0x220**: MCE_FMKEYRx register.
- **Offset 0x240**: MCE_CC1CFGR register.

### STMicroelectronics
- **STMicroelectronics**: Manufacturer of the memory cipher engine (MCE).

### Revision Details
- **RM0477**: Revision of the document.
- **1594/3791**: Document identification number.

Refer to Section 2.3 on page 149 for the register boundary addresses.
40  Public key accelerator (PKA)

40.1  Introduction

PKA (public key accelerator) is intended for the computation of cryptographic public key primitives, specifically those related to RSA, Diffie-Hellmann or ECC (elliptic curve cryptography) over GF(p) (Galois fields). To achieve high performance at a reasonable cost, these operations are executed in the Montgomery domain.

For a given operation, all needed computations are performed within the accelerator, so no further hardware/software elaboration is needed to process the inputs or the outputs.

When manipulating secrets, the PKA incorporates a protection against side-channel attacks (SCA), including differential power analysis (DPA), certified SESIP and PSA security assurance level 3.

40.2  PKA main features

- Acceleration of RSA, DH and ECC over GF(p) operations, based on the Montgomery method for fast modular multiplications. More specifically:
  - RSA modular exponentiation, RSA chinese remainder theorem (CRT) exponentiation
  - ECC scalar multiplication, point on curve check, complete addition, double base ladder, projective to affine
  - ECDSA signature generation and verification
- Capability to handle operands up to 4160 bits for RSA/DH and 640 bits for ECC
- When manipulating secrets: protection against side-channel attacks (SCA), including differential power analysis (DPA), certified SESIP and PSA security assurance level 3
  - Applicable to modular exponentiation, ECC scalar multiplication and ECDSA signature generation
- Arithmetic and modular operations such as addition, subtraction, multiplication, modular reduction, modular inversion, comparison, and Montgomery multiplication
- Built-in Montgomery domain inward and outward transformations
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
40.3 PKA functional description

40.3.1 PKA block diagram

Figure 396. PKA block diagram

40.3.2 PKA internal signals

Table 363 lists the internal signals available at the PKA level, not necessarily available on product bonding pads.

<table>
<thead>
<tr>
<th>Signal name</th>

<td>AHB bus clock</td>
</tr>
<tr>
<td>pka_it</td>
<td>Digital output</td>
<td>Public key accelerator IP global interrupt request</td>
</tr>
<tr>
<td>pka_itamp_out</td>
<td>Digital output</td>
<td>PKA internal tamper event signal to TAMP (XOR-ed), triggered when an unexpected fault occurs while PKA manipulates secrets, or when the programmed input point is not found on the input curve (ECDSA signature and ECC scalar multiplication only). This signal is asserted as soon as a fault is detected. When asserted, read access to PKA registers are reset to 0 and writes are ignored. The signal is de-asserted when PKA memory is cleared.</td>
</tr>
</tbody>
</table>

40.3.3 PKA reset and clocks

PKA is clocked on the AHB bus clock. When the PKA peripheral reset signal is released PKA_RAM is cleared automatically, taking 667 clock cycles. During this time the setting of bit EN in PKA_CR register is ignored. Once EN bit is set, refer to Section 40.3.6 for details about PKA initialization sequence.

According to the security policy applied to the device, PKA RAM can also be reset following a tamper event. Refer to Tamper detection and response in the System security section (if applicable to this product).
40.3.4  PKA public key acceleration

Overview

Public key accelerator (PKA) is used to accelerate Rivest, Shamir and Adleman (RSA), Diffie-Hellman (DH) as well as ECC over prime field operations. Supported operand sizes is up to 4160 bits for RSA and DH, and up to 640 bits for ECC.

The PKA supports all non-singular elliptic curves defined over prime fields, that can be described with a short Weierstrass equation $y^2 = x^3 + ax + b \pmod{p}$. More information can be found in Section 40.5.1.

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

A memory of 5336 bytes (667 words of 64 bits) called PKA RAM is used to provide initial data to the PKA, and to hold the results after computation is completed. Access is done though the PKA AHB interface.

PKA operating modes

The list of operations the PKA can perform is detailed in Table 364 and Table 365, respectively, for integer arithmetic functions and prime field (Fp) elliptic curve functions.

</table>
Each of these operating modes has an associated code that has to be written to the MODE field in the PKA_CR register. If the application selects any value that is not documented below the write to MODE bitfield is ignored, and an operation error (OPERRF) is triggered. When this happens, a new operation must be selected after the error is cleared.

Some operations in Table 364 and Table 365 are indicated as protected. Those operations are used when manipulating secret keys (modular exponentiation for RSA decryption, scalar multiplication and signature for ECC). Those secrets (protected against side channel attacks) and any intermediate values are automatically erased when PKA RAM is cleared at the end of the protected operations (BUSY goes low). They are also protected against side channel attacks.

Caution: For security reason it is very important to select protected modular exponentiation (MODE = 0x3) when performing RSA decryption.

Montgomery space and fast mode operations

For efficiency reason the PKA internally performs modular multiply operations in the Montgomery domain, automatically performing inward and outward transformations.

As Montgomery parameter computation is time consuming the application can decide to use a faster mode of operation, during which the precomputed Montgomery parameter is supplied before starting the operation. Performance improvement is detailed in Section 40.5.2: Computation times.

The only operation using fast mode is modular exponentiation (MODE = 0x02).
40.3.5 Typical applications for PKA

Introduction
The PKA can be used to accelerate a number of public key cryptographic functions. In particular:

• RSA encryption and decryption
• RSA key finalization
• CRT-RSA decryption
• DSA and ECDSA signature generation and verification
• DH and ECDH key agreement

Specifications of the above functions are given in following publications:

• FIPS PUB 186-4, Digital Signature Standard (DSS), July 2013 by NIST
• PKCS #1, RSA Cryptography Standard, v1.5, v2.1 and v2.2. by RSA Laboratories

The principles of the main functions are described in this section, for a more detailed description refer to the above cited documents.

RSA key pair
For the following RSA operations a public key and a private key information are defined as below:

• Alice transmits her public key \((n, e)\) to Bob. Numbers \(n\) and \(e\) are very large positive integers.
• Alice keeps secret her private key \(d\), also a very large positive integer. Alternatively this private key can also be represented by a quintuple \((p, q, dp, dq, q\text{inv})\).

For more information on the above representations refer to the RSA specification.

RSA encryption/decryption principle
As recommended by the PKCS#1 specification, Bob, to encrypt message \(M\) using Alice’s public key \((n, e)\) must go through the following steps:

1. Compute the encoded message \(EM = \text{ENCODE}(M)\), where ENCODE is an encoding method.
2. Turn \(EM\) into an integer \(m\), with \(0 \leq m < n\) and \((m, n)\) being coprimes.
3. Compute ciphertext \(c = m^e \mod n\).
4. Convert the integer \(c\) into a string ciphertext \(C\).
Alice, to decrypt ciphertext c using her private key d, follows the steps indicated below:

1. Convert the ciphertext C to an integer ciphertext representative c.
2. If necessary, retrieve the prime factors (p, q) using (n, e, d) information, then compute \( \phi = (p - 1) \cdot (q - 1) \). Refer to NIST SP800-56B Appendix C for details.
3. Recover plaintext \( m = c^d \mod n = (m^n)^d \mod n \). If the private key is the quintuple (p, q, dp, dq, qInv), then plaintext m is obtained by performing the operations:
   a) \( m_1 = c^{dp} \mod p \)
   b) \( m_2 = c^{dq} \mod q \)
   c) \( h = qInv \cdot (m_1 - m_2) \mod p \)
   d) \( m = m_2 + h \cdot q \)
4. Convert the integer message representative m to an encoded message EM.
5. Recover message M = DECODE(EM), where DECODE is a decoding method.

Above operations can be accelerated by PKA using Modular exponentiation \( A^e \mod n \) if the private key is d, or RSA CRT exponentiation if the private key is the quintuple (p, q, dp, dq, qInv).

Note: The decoding operation and the conversion operations between message and integers are specified in PKCS#1 standard.

For the decryption process protected version of modular exponentiation (MODE = 0x3) is strongly recommended for security reason. For encryption process MODE = 0x3 cannot be used, as it requires the knowledge of the private key.

Elliptic curve selection

For following ECC operations curve parameters are defined as below:
- Curve corresponds to the elliptic curve field agreed among actors (Alice and Bob). Supported curves parameters are summarized in Section 40.5.1: Supported elliptic curves.
- G is the chosen elliptic curve base point (also known as generator), with a large prime order n (that is, \( n \times G = \text{identity element} \ O \)).

ECDSA message signature generation

ECDSA (elliptic curve digital signature algorithm) signature generation function principle is the following: Alice, to sign a message m using her private key integer dA, goes through the following steps.

1. Calculate \( e = HASH(m) \), where HASH is a cryptographic hash function.
2. Let \( z \) be the \( L_n \) leftmost bits of e, where \( L_n \) is the bit length of the group order n.
3. Select a cryptographically secure random integer k where \( 0 < k < n \).
4. Calculate the curve point \((x_1, y_1) = k \times G\).
5. Calculate \( r = x_1 \mod n \). If \( r = 0 \) go back to step 3.
6. Calculate \( s = k^{-1} \cdot (z + rd_A) \mod n \). If \( s = 0 \) go back to step 3.
7. The signature is the pair \((r, s)\).
Steps 4 to 7 are accelerated by PKA using:

- **ECDSA sign** or
- All of the operations below:
  - **ECC Fp scalar multiplication** \( k \times P \)
  - **Modular reduction** \( A \mod n \)
  - **Modular inversion** \( A^{-1} \mod n \)
  - **Modular addition** and **Modular and Montgomery multiplication**

**ECDSA signature verification**

ECDSA (elliptic curve digital signature algorithm) signature verification function principle is the following: Bob, to authenticate Alice's signature, must have a copy of her public key curve point \( Q_A \).

Bob can verify that \( Q_A \) is a valid curve point going through the following steps:

1. check that \( Q_A \) is not equal to the identity element \( O \)
2. check that \( Q_A \) is on the agreed curve
3. check that \( n \times Q_A = O \).

Then Bob follows the procedure detailed below:

1. verify that \( r \) and \( s \) are integer in \([1, n-1]\)
2. calculate \( e = \text{HASH}(m) \), where \( \text{HASH} \) is the agreed cryptographic hash function
3. let \( z \) be the \( L_n \) leftmost bits of \( e \)
4. calculate \( w = s^{-1} \mod n \)
5. calculate \( u_1 = zw \mod n \) and \( u_2 = rw \mod n \)
6. calculate the curve point \((x_1, y_1) = u_1 \times G + u_2 \times Q_A\)
7. the signature is valid if \( r = x_1 \mod n \), it is invalid otherwise.

Steps 4 to 7 are accelerated by PKA using **ECDSA verification**.

### 40.3.6 PKA procedure to perform an operation

**Enabling/disabling PKA**

Setting the EN bit to 1 in PKA_CR register enables the PKA peripheral. The PKA becomes available when INITOK bit is set in PKA_SR. When EN = 0, the PKA peripheral is kept under reset, with PKA memory still accessible by the application through the AHB interface.

*Note: When PKA is in the process of clearing its memory EN bit cannot be set.*

When setting EN bit in PKA_CR make sure that the value of MODE bitfield corresponds to an authorized PKA operation (see OPERRF in Section 40.3.7).

Clearing EN bit to 0 while a calculation is in progress causes the operation to be aborted. In this case, the content of the PKA memory is not guaranteed, with the exception of the PKA modes 0x03, 0x20 and 0x24. For these operations, the PKA memory is cleared after abort, making the memory unavailable for 667 cycles. During this clearing time only PKA registers can be accessed, with writes to EN bits ignored.

If INITOK bit stays at 0, make sure that the RNG peripheral is clocked and properly initialized, then try to enable PKA again.
Data formats

The format of the input data and the results in the PKA RAM are specified, for each operation, in Section 40.4.

Executing a PKA operation

Each of the supported PKA operation is executed using the following procedure:

1. Load initial data into the PKA internal RAM, which is located at address offset 0x400.
2. Write in the MODE field of PKA_CR register, specifying the operation which is to be executed and then assert the START bit, also in PKA_CR register.
3. Wait until the PROCENDF bit in the PKA_SR register is set to 1, indicating that the computation is complete.
4. Read the result data from the PKA internal RAM, then clear PROCENDF bit by setting PROCENDFC bit in PKA_CLRFR.

Note: When PKA is busy (BUSY = 1) any access by the application to PKA RAM is ignored, and the flag RAMERRF is set in PKA_SR.

Selecting an illegal or unknown operation in step 2 triggers an OPERRF error, and step 3 (PROCENDF = 1) never happens. See Section 40.3.7 for details.

Using precomputed Montgomery parameters (PKA Fast mode)

As explained in Section 40.3.4, when computing many operations with the same modulus it can be beneficial for the application to compute only once the corresponding Montgomery parameter (see, for example, Section 40.4.5). This is know as “Fast mode”.

To manage the usage of Fast mode it is recommended to follow the procedure described below:

1. Load in PKA RAM the modulus size and value information. Such information is compiled in Section 40.5.1.
2. Program in PKA_CR register the PKA in Montgomery parameter computation mode (MODE="0x1") then assert the START bit.
3. Wait until the PROCENDF bit in the PKA_SR register is set to 1, then read back from PKA memory the corresponding Montgomery parameter, and then clear PROCENDF bit by setting PROCENDFC bit in PKA_CLRFR.
4. Proceed with the required PKA operation, loading on top of regular input data the Montgomery information R2 mod m. All addresses are indicated in Section 40.4.

40.3.7 PKA error management

When PKA is used some errors can occur:

- The access to PKA RAM falls outside the expected range. In this case the address error flag (ADDRERRF) is set in the PKA_SR register.
- An AHB access to the PKA RAM occurred while the PKA core was using it. In this case the RAM error flag (RAMERRF) is set in the PKA_SR register, reads to PKA RAM return 0, while writes are ignored.
- The selected operating mode using MODE bitfield is not listed in PKA operating modes (see bitfield description), or PKA is running in limited mode (see LMF bit in PKA_SR). In this case the operation error flag (OPERRF) is set in the PKA_SR register, and write to MODE bitfield is ignored.
For each error flag above PKA generates an interrupt if the application sets the corresponding bit in PKA_CR register (see Section 40.6 for details).

ADDRERRF, OPERRF and RAMERRF errors are cleared by setting the corresponding bit in PKA_CLRFR.

OPERRF error must be cleared using OPERRFC bit in PKA_CLRFR before a new operation is written in PKA_CR register.

**Note:** The PKA can be re-initialized at any moment by resetting the EN bit in the PKA_CR register.

### 40.4 PKA operating modes

#### 40.4.1 Introduction

The various operations supported by PKA are described in the following subsections, defining the format of the input data and of the results, both stored in the PKA RAM.

---

**Warning:** The validity of all input parameters to the PKA must be checked before starting any operation, as PKA assumes that all of them are valid and consistent with each other. Input parameters must not exceed the operand size specified in the operation tables.

---

The following information applies to all PKA operations.

- PKA core processes 64-bit words in its RAM. Hence hereafter all word size is 64-bit.
- When an element is written as input in the PKA RAM, an additional word with all bits equal to zero has to be added after the most significant input word. This rule does not apply if the operand has a fixed size of 1.
- All reported RAM storage addresses refer to the least significant word of the data, and to obtain the actual address to use application must add to the indicated offset the base address of the PKA.
- Supported operand “Size” are:
  - ROS (RSA operand size): data size is \( \lceil \text{rsa\_size} / 64 \rceil + 1 \) words, with \( \text{rsa\_size} \) equal to the chosen modulus length in bits. For example, when computing RSA with an operand size of 1024 bits, ROS is equal to 17 words, or 1088 bits.
  - EOS (ECC operand size): data size is \( \lceil \text{ecc\_size} / 64 \rceil + 1 \) words, with \( \text{ecc\_size} \) equal to the chosen prime modulus length in bits. For example, when computing ECC with an operand size of 192 bits, EOS is equal to 4 words, or 256 bits.
  - ROS and EOS values include the required additional all 0 word.
- Unless indicated otherwise, all operands in the tables are integers.

**Note:** Fractional results for above formulas must be rounded up to the nearest integer since PKA core processes 64-bit words.

**Note:** The maximum ROS is 66 words (4160-bit max exponent size), while the maximum EOS is 11 words (640-bit max operand size).

As a first example (and to better understand the endianess in PKA memory), to prepare the operation ECC Fp scalar multiplication, when the application writes the x coordinate of point
P for an ECC P256 curve (EOS = 5 words), the least significant bit must be placed in bit 0 at address offset 0x578, and the most significant bit in bit 63 at address offset 0x590. Then, as mentioned above, the application must write the empty word 0x0000000000000000 at address offset 0x598.

As a second example, still to prepare the operation ECC Fp scalar multiplication, when the application need to write the information a = -3, on a curve with a modulus length of 224 bits (that is, four 64-bit words, rounded up, plus one) following data must be written in PKA memory:

@RAM+410 0x0000000000000001 /* curve coefficient 'a' sign without extra word */
@RAM+418 0x0000000000000011 /* value of |a| LSB */
@RAM+420 0x0000000000000000 ...
@RAM+428 0x0000000000000000 ...
@RAM+430 0x0000000000000000 value of |a| MSB */
@RAM+438 0x0000000000000000 /* additional all 0 word */

40.4.2 Montgomery parameter computation

This function is used to compute the Montgomery parameter \((R^2 \mod n)\) used by PKA to convert operands into the Montgomery residue system representation. This operation can be very useful when fast mode operation is used, because in this case the Montgomery parameter is passed as input, saving the time for its computation.

Note: This operation can also be used with ECC curves. In this case prime modulus length and EOS size must be used.

Operation instructions for Montgomery parameter computation are summarized in
Table 366.

40.4.3 Modular addition

Modular addition operation consists in the computation of \(A + B \mod n\). Operation instructions are summarized in Table 367.
40.4.4 Modular subtraction

Modular subtraction operation consists in the following computations:
- If \( A \geq B \) result equals \( A - B \mod n \)
- If \( A < B \) result equals \( A + n - B \mod n \)

Operation instructions are summarized in Table 368.

40.4.5 Modular and Montgomery multiplication

To be more efficient when performing a sequence of multiplications the PKA accelerates multiplication which has at least one input in the Montgomery domain. The two main uses of this operation are:
- Map a value from natural domain to Montgomery domain and vice-versa
- Perform a modular multiplication \( A \times B \mod n \)

The method to perform above operations are described below. Note that “\( x \)” function is this operation, and \( A, B, C \) operands are in the natural domain.
1. Inward (or outward) conversion into (or from) Montgomery domain
   a) Assuming that A is an integer in the natural domain:
      – Compute \( r_2 \text{mod} n \) using Montgomery parameter computation.
      – Result \( AR = A \times r_2 \text{mod} n \) is A in the Montgomery domain.
   b) Assuming that \( BR \) is an integer in the Montgomery domain:
      – Result \( B = BR \times 1 \text{mod } n \) is B in the natural domain.
      – Similarly, above value \( AR \) computed in a) can be converted into the natural domain by computing \( A = AR \times 1 \text{mod } n \).

2. Simple modular multiplication \( A \times B \text{mod } n \)
   a) Compute \( r_2 \text{mod} n \) using Montgomery parameter computation.
   b) Compute \( AR = A \times r_2 \text{mod} n \). Output is in the Montgomery domain.
   c) Compute \( AB = AR \times B \text{mod } n \). Output is in natural domain.

3. Multiple modular multiplication \( A \times B \times C \text{mod } n \)
   a) Compute \( r_2 \text{mod} n \) using Montgomery parameter computation.
   b) Compute \( AR = A \times r_2 \text{mod} n \). Output is in the Montgomery domain.
   c) Compute \( BR = B \times r_2 \text{mod} n \). Output is in the Montgomery domain.
   d) Compute \( ABR = AR \times BR \text{mod } n \). Output is in the Montgomery domain.
   e) Compute \( CR = C \times r_2 \text{mod} n \). Output is in the Montgomery domain.
   f) Compute \( ABCR = ABR \times CR \text{mod } n \). Output is in the Montgomery domain.
   g) (optional) Repeat the two steps above if more operands need to be multiplied.
   h) Compute \( ABC = ABCR \times 1 \text{mod } n \) to retrieve the result in natural domain.

Operation instructions for Montgomery multiplication are summarized in Table 369.

### Table 369. Montgomery multiplication

1. Result in Montgomery domain or in natural domain, depending upon the inputs nature (see examples 2 and 3).

### 40.4.6 Modular exponentiation

Modular exponentiation operation is commonly used to perform a single-step RSA operation. It consists in the computation of \( A^e \text{mod } n \).

RSA operation involving public information (RSA encryption) can use the normal or fast mode detailed on Table 370 and Table 371. RSA operation involving secret information (RSA decryption) must use the protected mode detailed on Table 372, for security reason.

**Note:** Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

---

RM0477 Rev 6 1607/3791
When this operation completes with errors due to unexpected hardware events a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware.

Note: When MODE = 0x03, the error code is not affected when PKA automatically clears the PKA RAM at the end of this protected operation. When the error output equals 0xD60D, the result output is not affected either.

Operation instructions for modular exponentiation are summarized in Table 370 (normal mode), Table 371 (fast mode) and in Table 372 (protected mode). Fast mode usage is explained in Section 40.3.6.

<td>RAM@0x838</td>
<td></td>
</tr>
</tbody>
</table>
40.4.7 Modular inversion

Modular inversion operation consists in the computation of multiplicative inverse \( A^{-1} \mod n \).

If the modulus \( n \) is prime, for all values of \( A (1 \leq A < n) \) modular inversion output is valid. If the modulus \( n \) is not prime, \( A \) has an inverse only if the greatest common divisor between \( A \) and \( n \) is 1.

If the operand \( A \) is a divisor of the modulus \( n \) the result is a multiple of a factor of \( n \).

Operation instructions for modular inversion are summarized in Table 373.

<table>

40.4.8 Modular reduction

Modular reduction operation consists in the computation of the remainder of \( A \) divided by \( n \).

Operation instructions are summarized in Table 374.

---

1. Euler totient function of \( n \) with \( \phi = (p - 1) \times (q - 1) \), where \( p \) and \( q \) are prime factors of modulus \( n \) (see NIST SP800-56B Appendix C or RSA encryption/decryption principle for details). As optimization it is recommended to keep \( \phi \) information as part of the key pair generation. Alternative is to store the key as \((p, q, e, d)\) instead of \((N, e, d, \phi)\), in this case, to derive \( N \) and \( \phi \) using PKA arithmetic multiplier: \( N = p \times q \), and \( \phi = (p - 1) \times (q - 1) \).
40.4.9 Arithmetic addition

Arithmetic addition operation consists in the computation of $A + B$. Operation instructions are summarized in Table 375.

**Table 375. Arithmetic addition**

</tbody>
</table>

40.4.10 Arithmetic subtraction

Arithmetic subtraction operation consists in the following computations:
- If $A \geq B$ result equals $A - B$
- If $A < B$ and $M/32$ residue is > 0 result equals $A + 2^{\text{int}(M/32)^*32+1} - B$
- If $A < B$ and $M/32$ residue is 0 result equals $A + 2^{\text{int}(M/32)^*32} - B$

For the last two bullets the 32-bit word following the most significant word of the output equals 0xFFFF FFFF, as result is negative.

Operation instructions are summarized in Table 376.

40.4.13 RSA CRT exponentiation

For efficiency many popular crypto libraries such as OpenSSL RSA use the following optimization for decryption and signing based on the chinese remainder theorem (CRT):
- p and q are precomputed primes, stored as part of the private key
- dp = d mod (p -1)
- dq = d mod (q -1) and
- dq = d mod (q -1) and
- d_{inv} = q^{-1} mod p
These values allow the recipient to compute the exponentiation $m = A^d \mod pq$ more efficiently as follows:

- $m_1 = A^{dP} \mod p$
- $m_2 = A^{dQ} \mod q$
- $h = q_{inv} (m_1 - m_2) \mod p$, with $m_1 > m_2$
- $m = m_2 + hq \mod pq$

Operation instructions for computing CRT exponentiation $A^d \mod pq$ are summarized in **Table 379**.

1. Must be different from 2.

#### 40.4.14 Point on elliptic curve Fp check

This operation consists in checking whether a given point $P (x, y)$ satisfies or not the curves over prime fields equation $y^2 = (x^3 + ax + b) \mod p$, where $a$ and $b$ are elements of the curve.

Operation instructions for point on elliptic curve Fp check are summarized in **Table 380**.
40.4.15 ECC Fp scalar multiplication

This operation consists in the computation of \( k \times P (x_P, y_P) \), where \( P \) is a point on a curve over prime fields and \( "x" \) is the elliptic curve scalar point multiplication. Result of the computation is a point that belongs to the same curve or a point at infinity.

Operation instructions for ECC Fp scalar multiplication are summarized in Table 381.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events, a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware. PKA tamper is also triggered when the programmed input point is not found on the input ECC curve. PKA operation "Point on elliptic curve" can be used to avoid this.

<td>64 bits</td>
</tr>
</tbody>
</table>
When performing this operation the following special cases must be noted:

- For $k = 0$ this function returns a point at infinity $(0, 0)$ if curve parameter $b$ is nonzero, $(0, 1)$ otherwise. For $k$ different from 0 it might happen that a point at infinity is returned. When the application detects this behavior a new computation must be carried out.

- For $k < 0$ (that is, a negative scalar multiplication is required) the multiplier absolute value $k = |-k|$ must be provided to the PKA. After the computation completion, the formula $-P = (x, -y)$ can be used to compute the $y$ coordinate of the effective final result (the $x$ coordinate remains the same).

**Note:** The error code is not affected when PKA automatically clears the PKA RAM at the end of this protected operation. When the error output equals 0xD60D, the result output is not affected either.

### 40.4.16 ECDSA sign

ECDSA signing operation (outlined in Section 40.3.5) is summarized in Table 382 (input parameters) and in Table 383 (output parameters).

The application has to check if the output error is equal to 0xD60D, if it is different a new $k$ must be generated and the ECDSA sign operation must be repeated.

**Note:** Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware. PKA tamper is also triggered when the programmed input point is not found on the input ECC curve. PKA operation "Point on elliptic curve" can be used to avoid this.
Note: The error code is not affected when PKA automatically clears the PKA RAM at the end of this protected operation. When the error output equals 0xD60D, the result output is not affected either.

Extended ECDSA support

PKA also supports extended ECDSA signature, for which the inputs and the outputs are the same as ECDSA signature (Table 382 and Table 383, respectively), with the addition of the coordinates of the point kG. This extra output is defined in Table 384.
40.4.17 ECDSA verification

ECDSA verification operation (outlined in Section 40.3.5) is summarized in Table 385 (input parameters) and Table 386 (output parameters).

The application has to check if the output error is equal to 0xD60D, if different the signature is not verified.

1. Padding with zeroes or hash truncation must be used to have the hash parameter size equal to the curve prime order n length.
40.4.18 ECC complete addition

ECC complete addition computes the addition of two given points on an elliptic curve.

Operation instructions are summarized in Table 387.

Note: The two input points and the resulting point are represented in Jacobian coordinates (X,Y,Z). To input a point in affine coordinates (x,y) conversion (X,Y,Z) = (x,y,1) can be used. To convert resulting point to Jacobian coordinates conversion (x,y) = (X/Z², Y/Z³) can be used.

40.4.19 ECC double base ladder

ECC double base ladder operation consists in the computation of k*P+m*Q, where (P,Q) are two points on an elliptic curve and (k,m) are two scalars. Operation instructions are summarized in Table 388.

If the resulting point is the point at infinity (error code 0xA3B7), resulting coordinate equals (0, 0).
Note: The two input points are represented in Jacobian coordinates \((X, Y, Z)\). To input a point in affine coordinates \((x, y)\) conversion \((X, Y, Z) = (x, y, 1)\) can be used. The result is represented in affine coordinates \((x, y)\).

This operation requires the input point \(Z\) coordinate to be equal to 1 (input point represented in affine coordinates).

### 40.4.20 ECC projective to affine

ECC projective to affine operation computes the conversion between the representation of a point \(P\) in homogeneous projective coordinates and the representation of the point \(P\) in affine coordinates. Namely, if the point is represented by the triple \((X, Y, Z)\), it computes the affine coordinates \((x, y) = (X/Z, Y/Z)\).

All the operations are performed modulo the modulus \(p\) of the curve, which the point belongs to. If the resulting point is the point at infinity (error code 0xA3B7), resulting coordinate equals \((0,0)\).

Operation instructions are summarized in Table 389.
### 40.5 Example of configurations and processing times

#### 40.5.1 Supported elliptic curves

The PKA supports all non-singular elliptic curves defined over prime fields. Those curves can be described with a short Weierstrass equation, $y^2 = x^3 + ax + b \pmod p$.

**Note:** Binary curves, Edwards curves and Curve25519 are not supported by the PKA. The maximum supported operand size for ECC operations is 640 bits.

When publishing the ECC domain parameters of those elliptic curves, standard bodies define the following parameters:

- the prime integer $p$, used as the modulus for all point arithmetic in the finite field $GF(p)$
- the (usually prime) integer $n$, the order of the group generated by $G$, defined below
- the base point of the curve $G$, defined by its coordinates $(Gx, Gy)$
- the integers $a$ and $b$, coefficients of the short Weierstrass equation.

For the last bullet, when standard bodies define $a$ as negative, PKA supports two representations:

1. **a defined as $p$-[a]** in the finite field $GF(p)$, for example $p$-3:
   - Curve coefficient $p = 0xFFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF$  
   - Curve coefficient a sign= 0x0 (positive)
   - Curve coefficient a = 0xFFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF

2. **a defined as negative**, for example -3:
   - Curve coefficient $p = 0xFFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF$  
   - Curve coefficient a sign= 0x1 (negative)
   - Curve coefficient a = 0x00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000003

---

40.5.2 Computation times

The following tables summarize the PKA computation times, expressed in AHB clock cycles.

### Table 391. Modular exponentiation

<table>
<thead>
<tr>
<th>Exponent length (in bits)</th>
<th>Mode</th>
<th>Modulus length (in bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Normal</td>
<td>1024</td>
</tr>
<tr>
<td></td>
<td>Fast</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Normal</td>
<td>124600</td>
</tr>
<tr>
<td></td>
<td>Fast</td>
<td>22700</td>
</tr>
<tr>
<td>17</td>
<td>Normal</td>
<td>135700</td>
</tr>
<tr>
<td></td>
<td>Fast</td>
<td>33800</td>
</tr>
<tr>
<td>$2^{16} + 1$</td>
<td>Normal</td>
<td>180000</td>
</tr>
<tr>
<td></td>
<td>Fast</td>
<td>78200</td>
</tr>
</tbody>
</table>

#### Table 392. ECC scalar multiplication

<table>
<thead>
<tr>
<th>Modulus length (in bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>160</td>
</tr>
<tr>
<td>1590000</td>
</tr>
</tbody>
</table>

1. CRT stands for Chinese remainder theorem optimization (MODE bitfield= 0x07).

1. These times depend on the number of 1s included in the scalar parameter, and include the computation of Montgomery parameter R2.
Table 393. ECDSA signature average computation time

<table>
<thead>
<tr>
<th>Modulus length (in bits)</th>
<th>160</th>
<th>192</th>
<th>256</th>
<th>320</th>
<th>384</th>
<th>512</th>
<th>521</th>
<th>640</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1500</td>
<td>2744</td>
<td>4579</td>
<td>7184</td>
<td>1445</td>
<td>1668</td>
<td>2496</td>
<td>2958</td>
</tr>
</tbody>
</table>

1. These values are average execution times of random moduli of given length, as they depend upon the length and the value of the modulus.

2. The execution time for the moduli that define the finite field of NIST elliptic curves is shorter than that needed for the moduli used for Brainpool elliptic curves or for random moduli of the same size.

Table 394. ECDSA verification average computation times

<table>
<thead>
<tr>
<th>Modulus length (in bits)</th>

<th>521</th>
<th>640</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>3400</td>
<td>4200</td>
<td>6100</td>
<td>8300</td>
<td>10900</td>
<td>17200</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>
There are four individual maskable interrupt sources generated by the public key accelerator, signaling the following events:

1. PKA unsupported operation error (OPERRF), see Section 40.3.7
2. Access to unmapped address (ADDRERRF), see Section 40.3.7
3. PKA RAM access while PKA operation is in progress (RAMERRF), see Section 40.3.7
4. PKA end of operation (PROCENDF)

The interrupt sources are connected to the same global interrupt request signal pka_it. The user can enable or disable above interrupt sources individually by changing the mask bits in the PKA control register (PKA_CR). Setting the appropriate mask bit to 1 enables the interrupt. The status of the individual interrupt events can be read from the PKA status register (PKA_SR), and it is cleared in PKA_CLRFR register.

Table 400 gives a summary of the available features.

### Table 399. Montgomery parameters average computation times(1)

<table>
<thead>
<tr>
<th>Modulus length (in bits)</th>
<th>192</th>
<th>256</th>
<th>320</th>
<th>512</th>
<th>1024</th>
<th>2048</th>
<th>3072</th>
<th>4096</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>8600</td>
<td>8710</td>
<td>11870</td>
<td>17000</td>
<td>102000</td>
<td>410000</td>
<td>506000</td>
<td>822000</td>
</tr>
</tbody>
</table>

1. The computation times depend upon the length and the value of the modulus, hence these values are average execution times of random moduli of given length.

#### 40.6 PKA interrupts

There are four individual maskable interrupt sources generated by the public key accelerator, signaling the following events:

1. PKA unsupported operation error (OPERRF), see Section 40.3.7
2. Access to unmapped address (ADDRERRF), see Section 40.3.7
3. PKA RAM access while PKA operation is in progress (RAMERRF), see Section 40.3.7
4. PKA end of operation (PROCENDF)

The interrupt sources are connected to the same global interrupt request signal pka_it. The user can enable or disable above interrupt sources individually by changing the mask bits in the PKA control register (PKA_CR). Setting the appropriate mask bit to 1 enables the interrupt. The status of the individual interrupt events can be read from the PKA status register (PKA_SR), and it is cleared in PKA_CLRFR register.

Table 400 gives a summary of the available features.

40.7   PKA registers

40.7.1   PKA control register (PKA_CR)

Address offset: 0x00
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:22</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved</td>
<td>Reserved, must be kept at reset value.</td>
<td></td>
</tr>
</tbody>
</table>

Bit 21   **OPERRIE**: Operation error interrupt enable
0: No interrupt is generated when OPERRF flag is set in PKA_SR.
1: An interrupt is generated when OPERRF flag is set in PKA_SR.

Bit 20   **ADDRERRIE**: Address error interrupt enable
0: No interrupt is generated when ADDRERRF flag is set in PKA_SR.
1: An interrupt is generated when ADDRERRF flag is set in PKA_SR.

Bit 19   **RAMERRIE**: RAM error interrupt enable
0: No interrupt is generated when RAMERRF flag is set in PKA_SR.
1: An interrupt is generated when RAMERRF flag is set in PKA_SR.

Bit 18   Reserved, must be kept at reset value.

Bit 17   **PROCENDIE**: End of operation interrupt enable
0: No interrupt is generated when PROCENDF flag is set in PKA_SR.
1: An interrupt is generated when PROCENDF flag is set in PKA_SR.

Bits 16:14   Reserved, must be kept at reset value.
Bits 13:8 **MODE[5:0]**: PKA operation code

- 000000: Montgomery parameter computation then modular exponentiation
- 000001: Montgomery parameter computation only
- 000010: Modular exponentiation (protected, used when manipulating secrets)
- 100000: Montgomery parameter computation then ECC scalar multiplication (protected)
- 000100: ECDSA sign (protected)
- 100100: ECDSA verification
- 100110: ECC projective to affine
- 000011: Modular parameter computation only
- 000100: Modular exponentiation only (Montgomery parameter must be loaded first)
- 000110: Modular exponentiation
- 101000: Point on elliptic curve Fp check
- 000111: RSA CRT exponentiation
- 001000: Modular inversion
- 001001: Arithmetic addition
- 001010: Arithmetic subtraction
- 001011: Arithmetic multiplication
- 001100: Arithmetic comparison
- 001101: Modular reduction
- 001110: Modular addition
- 001111: Modular subtraction
- 001111: Modular subtraction
- 100000: Montgomery multiplication
- 100011: ECC complete addition
- 100111: ECC double base ladder
- 101111: ECC projective to affine

When an operation not listed here is written by the application with EN bit set, OPERRF bit is set in PKA_SR register, and the write to MODE bitfield is ignored. When PKA is configured in limited mode (LMF = 1 in PKA_SR), writing a MODE different from 0x26 with EN bit to 1 triggers OPERRF bit to be set and write to MODE bit is ignored.

Bits 7:2: Reserved, must be kept at reset value.

Bit 1 **START**: start the operation

Set this bit to start the operation selected by the MODE[5:0] bitfield, using the operands and data already written to the PKA RAM. This bit is always read as 0.

When an illegal operation is selected while START bit is set no operation is started, and OPERRF bit is set in PKA_SR.

**Note**: **START** is ignored if PKA is busy.

Bit 0 **EN**: PKA enable

- 0: Disable PKA
- 1: Enable PKA. PKA becomes functional when INITOK is set by hardware in PKA_SR.

When an illegal operation is selected while EN = 1, OPERRF bit is set in PKA_SR. See PKA_CR.MODE bitfield for details.

**Note**: When EN = 0, PKA RAM can still be accessed by the application.
### 40.7.2 PKA status register (PKA_SR)

Address offset: 0x04  
Reset value: 0x0000 0000

| Bit 31 | Bit 30 | Bit 29 | Bit 28 | Bit 27 | Bit 26 | Bit 25 | Bit 24 | Bit 23 | Bit 22 | Bit 21 | Bit 20 | Bit 19 | Bit 18 | Bit 17 | Bit 16 | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9 | Bit 8 | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserved| Reserve| OPERRF | ADDRERRF| RAMERRF| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| Reserve| LMF | INITOK |
| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      | 7      | 6      | 5      | 4      | 3      | 2      | 1      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      |

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **OPERRF**: Operation error flag
- 0: No event error
- 1: An illegal or unknown operation has been selected in PKA_CR register
This bit is cleared using OPERRFC bit in PKA_CLRFR.

Bit 20 **ADDRERRF**: Address error flag
- 0: No address error
- 1: Address access is out of range (unmapped address)
This bit is cleared using ADDRERRFC bit in PKA_CLRFR.

Bit 19 **RAMERRF**: PKA RAM error flag
- 0: No PKA RAM access error
- 1: An AHB access to the PKA RAM occurred while the PKA core was computing and using its internal RAM (AHB PKA_RAM access are not allowed while PKA operation is in progress).
This bit is cleared using RAMERRFC bit in PKA_CLRFR.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDF**: PKA end of operation flag
- 0: Operation in progress
- 1: PKA operation is completed. This flag is set when the BUSY bit is deasserted.

Bit 16 **BUSY**: Busy flag
This bit is set whenever a PKA operation is in progress (START = 1 in PKA_CR). It is automatically cleared when the computation is complete, making PKA RAM accessible again.
- 0: No operation is in progress (default)
- 1: An operation is in progress
If PKA is started with a wrong opcode, it stays busy for a couple of cycles, then it aborts automatically the operation and goes back to ready (BUSY = 0).

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **LMF**: Limited mode flag
This bit is updated when EN bit in PKA_CR is set
- 0: All values documented in MODE bitfield can be used.
- 1: Only ECDSA verification (MODE = 0x26) is supported by the PKA.
Bit 0  **INITOK**: PKA initialization OK
- This bit is asserted when PKA initialization is complete. When RNG is not able to output proper random numbers INITOK stays at 0.
- 0: PKA is not initialized correctly. START bit cannot be set.
- 1: PKA is initialized correctly and can be used normally.

### 40.7.3 PKA clear flag register (PKA_CLRFR)

Address offset: 0x08
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>

<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:22 Reserved, must be kept at reset value.

- Bit 21  **OPERRFC**: Clear operation error flag
  - 0: No action
  - 1: Clear the OPERRF flag in PKA_SR

- Bit 20  **ADDRERRFC**: Clear address error flag
  - 0: No action
  - 1: Clear the ADDRERRF flag in PKA_SR

- Bit 19  **RAMERRFC**: Clear PKA RAM error flag
  - 0: No action
  - 1: Clear the RAMERRF flag in PKA_SR

- Bit 18 Reserved, must be kept at reset value.

- Bit 17  **PROCENDFC**: Clear PKA end of operation flag
  - 0: No action
  - 1: Clear the PROCENDF flag in PKA_SR

- Bits 16:0 Reserved, must be kept at reset value.

**Note:** Reading PKA_CLRFR returns all 0s.

### 40.7.4 PKA RAM

The PKA RAM is mapped at the offset address of 0x0400 compared to the PKA base address. Only 32-bit word single accesses are supported, through PKA_AHB interface.

- RAM size is 5336 bytes (max word offset: 0x14D0)

**Note:** PKA RAM cannot be used just after a PKA reset or a product reset, as described in Section 40.3.3: PKA reset and clocks.
## 40.7.5 PKA register map

### Table 401. PKA register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Refer to Section 2.3 on page 149 for the register boundary addresses.
41 Advanced-control timers (TIM1)

In this section, “TIMx” should be understood as “TIM1” since there is only one instance of this type of timer for the products to which this reference manual applies.

41.1 TIM1 introduction

The advanced-control timer (TIM1) consists of a 16-bit autoreload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1) and general-purpose (TIMy) timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 41.3.30: Timer synchronization.
41.2 TIM1 main features

TIM1 timer features include:

- 16-bit up, down, up/down autoreload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency by any factor from 1 to 65536.
- Up to six independent channels for:
  - Input capture (but channels 5 and 6)
  - Output compare
  - PWM generation (edge and center-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- 2 break inputs to put the timer’s output signals in a safe user selectable configuration.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization, or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management
41.3 TIM1 functional description

41.3.1 Block diagram

Figure 397. Advanced-control timer block diagram

Notes:

- **Preload registers transferred to active registers on UEV event according to control bit**
- Event
- Interrupt & DMA output

1. This feature is not available on all timers, refer to Section 41.3.2: TIM1 pins and internal signals.
2. See Figure 444: Break and Break2 circuitry overview for details.
### 41.3.2 TIM1 pins and internal signals

The tables in this section summarize the TIM inputs and outputs.

41.3.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related autoreload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the autoreload register and the prescaler register can be written or read by software, even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Autoreload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The autoreload register is preloaded. Writing to or reading from the autoreload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the autoreload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note: The counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler divides the counter clock frequency by any factor from 1 to 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 398* and *Figure 399* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

41.3.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the autoreload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The autoreload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

Write a new value in TIMx_ARR
**Downcounting mode**

In downcounting mode, the counter counts from the autoreload value (content of the TIMx_ARR register) down to 0, then restarts from the autoreload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter underflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current autoreload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The autoreload active register is updated with the preload value (content of the TIMx_ARR register). Note that the autoreload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

**Figure 406. Counter timing diagram, internal clock divided by 1**
Figure 407. Counter timing diagram, internal clock divided by 2

Figure 408. Counter timing diagram, internal clock divided by 4
Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the autoreload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the...
autoreload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to 00. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = 01), the counter counts up (Center aligned mode 2, CMS = 10) the counter counts up and down (Center aligned mode 3, CMS = 11).

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current autoreload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The autoreload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the autoreload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.
Figure 411. Counter timing diagram, internal clock divided by 1, TIMx_ARR = 0x6

1. Here, center-aligned mode 1 is used (for more details refer to Section 41.6: TIM1 registers).

41.3.5 Repetition counter

Section 41.3.3: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR autoreload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented:
- At each counter overflow in upcounting mode,
- At each counter underflow in downcounting mode,
- At each counter overflow and at each counter underflow in center-aligned mode.

Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is 2xTck due to the symmetry of the pattern.

The repetition counter is an autoreload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 417). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
In Center aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was launched: if the RCR was written before launching the counter, the UEV occurs on the underflow. If the RCR was written after launching the counter, the UEV occurs on the overflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event depending on when the RCR was written.

**Figure 417. Update rate examples depending on mode and TIMx_RCR register settings**

### 41.3.6 External trigger input

The timer features an external trigger input tim_etr_in. It can be used as:

- external clock (external clock mode 2, see Section 41.3.7)
- trigger for the slave mode (see Section 41.3.30)
- PWM reset input for cycle-by-cycle current regulation (see Section 41.3.9)

**Figure 418** below describes the tim_etr_in input conditioning. The input polarity is defined with the ETP bit in TIMxSMCR register. The trigger can be prescaled with the divider programmed by the ETPS[1:0] bitfield and digitally filtered with the ETF[3:0] bitfield. The resulting signal (tim_etrf) is available for three purposes: as an external clock, to condition...
the output (typically to reset a PWM output for a current limitation), and as a trigger for the Slave mode controller.

**Figure 418. External trigger input block**

The tim_etr_in input comes from multiple sources: input pins (default configuration), or internal sources. The selection is done with the ETRSEL[3:0] bitfield in the TIMx_AF1 register.

Refer to *Section 41.3.2: TIM1 pins and internal signals* for the list of sources connected to the etr_in input in the product.

### 41.3.7 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2)
- External clock mode2: external trigger input (tim_etr_in)
- Encoder mode

**Internal clock source (tim_ker_ck)**

If the slave mode controller is disabled (SMS = 000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

*Figure 419* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
**Figure 419. Control circuit in normal mode, internal clock divided by 1**

- `tim_ker_ck`
- `CEN`
- `UG`
- `counter initialization (internal)`
- `tim_cnt_ck, tim_psc_ck`
- `Counter register`

**External clock source mode 1**

This mode is selected when `SMS = 111` in the `TIMx_SMCR` register. The counter can count at each rising or falling edge on a selected input.

**Figure 420. tim_ti2 external clock connection example**

1. Codes ranging from `01000` to `11111` are reserved.
For example, to configure the upcounter to count in response to a rising edge on the `tim_ti2` input, use the following procedure:

1. Configure channel 2 to detect rising edges on the `tim_ti2` input by writing `CC2S = 01` in the TIMx_CCMR1 register.
2. Configure the input filter duration by writing the `IC2F[3:0]` bits in the TIMx_CCMR1 register (if no filter is needed, keep `IC2F = 0000`).
3. Select rising edge polarity by writing `CC2P = 0` and `CC2NP = 0` in the TIMx_CCER register.
4. Configure the timer in external clock mode 1 by writing `SMS = 111` in the TIMx_SMCR register.
5. Select `tim_ti2` as the trigger input source by writing `TS = 00110` in the TIMx_SMCR register.
6. Enable the counter by writing `CEN = 1` in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on `tim_ti2`, the counter counts once and the TIF flag is set. The delay between the rising edge on `tim_ti2` and the actual clock of the counter is due to the resynchronization circuit on `tim_ti2` input.

**Figure 421. Control circuit in external clock mode 1**

**External clock source mode 2**

This mode is selected by writing `ECE = 1` in the TIMx_SMCR register. The counter counts at each rising or falling edge on the external trigger input `tim_etr_in`. The **Figure 422** gives an overview of the external trigger input block.
For example, to configure the upcounter to count each 2 rising edges on \texttt{tim\_etr\_in}, use the following procedure:

1. As no filter is needed in this example, write \texttt{ETF[3:0] = 0000} in the \texttt{TIMx\_SMCR} register.
2. Set the prescaler by writing \texttt{ETPS[1:0] = 01} in the \texttt{TIMx\_SMCR} register.
3. Select rising edge detection on the \texttt{tim\_etr\_in} input by writing \texttt{ETP = 0} in the \texttt{TIMx\_SMCR} register.
4. Enable external clock mode 2 by writing \texttt{ECE = 1} in the \texttt{TIMx\_SMCR} register.
5. Enable the counter by writing \texttt{CEN = 1} in the \texttt{TIMx\_CR1} register.

The counter counts once each 2 \texttt{tim\_etr\_in} rising edges.

The delay between the rising edge on \texttt{tim\_etr\_in} and the actual clock of the counter is due to the resynchronization circuit on the \texttt{tim\_etr} signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most \(1/4\) of \texttt{tim\_ker\_ck} frequency. When the \texttt{ETRP} signal is faster, the user must apply a division of the external signal by a proper \texttt{ETPS} prescaler setting.

---

1. Refer to Section 41.3.2: TIM1 pins and internal signals.
41.3.8 Capture/compare channels

Each capture/compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

*Figure 424* to *Figure 427* give an overview of one capture/compare channel.

The input stage samples the corresponding `tim_tix` input to generate a filtered signal `tim_tixf`. Then, an edge detector with polarity selection generates a signal (`tim_tixfpy`) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

*Figure 424. Capture/compare channel (example: channel 1 input stage)*
The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

**Figure 425. Capture/compare channel 1 main circuit**

**Figure 426. Output stage of capture/compare channel (channel 1, idem ch. 2, 3 and 4)**

1. tim_ocxref, where x is the rank of the complementary channel
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 41.3.9 Input capture mode

In Input capture mode, the capture/compare registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the overcapture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

- Select the active input: TIMx_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input, and the TIMx_CCR1 register becomes read-only.

- Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most five internal clock cycles. We must program a filter duration longer than these five clock cycles. We can validate a transition on tim_ti1 when eight consecutive samples with the new level
have been detected (sampled at $f_{DTS}$ frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.

- Select the edge of the active transition on the tim_t11 channel by writing CC1P and CC1NP bits to 0 in the TIMx_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

**Note:** IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

### 41.3.10 PWM input mode

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges).
- The TIM_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges).

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same tim_tixfp1 input.
- These two ICx signals are active on edges with opposite polarity.
- One of the two tim_tixfp signals is selected as trigger input and the slave mode controller is configured in reset mode.
The period and the pulsewidth of a PWM signal applied on tim_ti1 can be measured using the following procedure:

- Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_ti1 selected).
- Select the active polarity for tim_ti1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to 0 (active on rising edge).
- Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_ti1 selected).
- Select the active polarity for tim_ti1fp2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to CC2P/CC2NP = 10 (active on falling edge).
- Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_ti1fp1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the TIMx_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to 1 in the TIMx_CCER register.

![Figure 428. PWM input mode timing](image)

**41.3.11 Forced output mode**

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx/tim_ocxn) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, user just needs to write 0101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP = 0 (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 0100 in the TIMx_CCMRx register.
Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

### 41.3.12 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 4 can be output, while channel 5 and 6 are only available inside the microcontroller (for instance, for compound waveform generation or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCMRx register). The output pin can keep its level (OCxM = 0000), be set active (OCxM = 0001), be set inactive (OCxM = 0010) or can toggle (OCxM = 0011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

#### Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 0011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE = 0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 429.
41.3.13 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per TIMx output) by writing 0110 (PWM mode 1) or 0111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the autoreload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSl, and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.
PWM edge-aligned mode

- Upcounting configuration
  Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to Upcounting mode.
  In the following example, the mode is PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the autoreload value (in TIMx_ARR) then tim_ocxref is held at 1. If the compare value is zero then tim_ocxref is held at 0. Figure 430 shows some edge-aligned PWM waveforms in an example where TIMx_ARR = 8.

</tbody>
</table>

- Downcounting configuration
  Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to the Downcounting mode.
  In PWM mode 1, the reference signal tim_ocxref is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the autoreload value in TIMx_ARR, then tim_ocxref is held at 1. 0% PWM is not possible in this mode.

PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from 00 (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit
(DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to Center-aligned mode (up/down counting).

Figure 431 shows some center-aligned PWM waveforms in an example where:
- TIMx_ARR = 8
- PWM mode is the PWM mode 1
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS = 01 in TIMx_CR1 register.

Figure 431. Center-aligned PWM waveforms (ARR = 8)

Hints on using center-aligned mode:
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit.
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  -- The direction is not updated if a value greater than the autoreload value is written in the counter (TIMx_CNT > TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  -- The direction is updated if 0 or the TIMx_ARR value is written in the counter but no update event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

Dithering mode

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. **Figure 432** presents the dithering principle applied to four consecutive PWM cycles.

**Figure 432. Dithering principle**

When the dithering mode is enabled, the register coding is changed as follows (see **Figure 433** for example):

- The four LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value.

**Note:** The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset.
2. The DITHEN bit must be reset.
3. The CCIF flags must be cleared.
4. The CEN bit can be set (eventually with ARPE = 1).
The minimum frequency is given by the following formula:

\[ \text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{pwm Min}} = \frac{F_{\text{Tim Max}}}{\text{Resolution}} \]

Dithering mode disabled: \( F_{\text{pwm Min}} = \frac{F_{\text{Tim}}}{65536} \)

Dithering mode enabled: \( F_{\text{pwm Min}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}} \)

**Note:** The maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on Figure 434, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.
The duty cycle and/or period changes are spread over 16 consecutive periods, as described in Figure 435.
The autoreload and compare values increments are spread following specific patterns described in Table 413. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

The dithering mode is also available in center-aligned PWM mode (CMS bits in TIMx_CR1 register are not equal to 00). In this case, the dithering pattern is applied over eight consecutive PWM periods, considering the up and down counting phases as shown in Figure 436.

Table 414 shows how the dithering pattern is added in center-aligned PWM mode.

Table 414. CCR register change dithering pattern in center-aligned PWM mode
41.3.14 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx register. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channel (one tim_ocx output per pair of CCR registers) by writing 1110 (Asymmetric PWM mode 1) or 1111 (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

Note: The OCxM[3:0] bitfield is split into two parts for compatibility reasons, the most significant bit is not contiguous with the three least significant ones.

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an tim_oc1refc signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the tim_oc2refc signal on channel 2, or an tim_oc2refc signal resulting from asymmetric PWM mode 1.

Figure 437 represents an example of signals that can be generated using asymmetric PWM mode (channels 1 to 4 are configured in asymmetric PWM mode 2). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.
41.3.15 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, \( \text{tim\_ocxrefc} \), are made of an OR or AND logical combination of two reference PWMs:

- \( \text{tim\_oc1refc} \) (or \( \text{tim\_oc2refc} \)) is controlled by TIMx_CCR1 and TIMx_CCR2
- \( \text{tim\_oc3refc} \) (or \( \text{tim\_oc4refc} \)) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one \( \text{tim\_ocx} \) output per pair of CCR registers) by writing 1100 (Combined PWM mode 1) or 1101 (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

*Note:* The OCxM[3:0] bitfield is split into two parts for compatibility reasons, the most significant bit is not contiguous with the three least significant ones.

*Figure 438* represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2.
- Channel 2 is configured in PWM mode 1.
- Channel 3 is configured in Combined PWM mode 2.
- Channel 4 is configured in PWM mode 1.
41.3.16 Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The tim_oc5ref signal is used to define the resulting combined signal. The 3-bits GC5C[3:1] in the TIMx_CCR5 allow selection on which reference signal the tim_oc5ref is combined. The resulting signals, tim_ocxrefc, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, tim_oc1refc is controlled by TIMx_CCR1 and TIMx_CCR5.
- If GC5C2 is set, tim_oc2refc is controlled by TIMx_CCR2 and TIMx_CCR5.
- If GC5C3 is set, tim_oc3refc is controlled by TIMx_CCR3 and TIMx_CCR5.

Combined 3-phase PWM mode can be selected independently on channels 1 to 3 by setting at least one of the 3-bits GC5C[3:1].
The *tim_trgo2* waveform shows how the ADC can be synchronized on given 3-phase PWM signals. Refer to Section 41.3.31: ADC triggers for more details.

### 41.3.17 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (such as intrinsic delays of level-shifters, or delays due to power switches).

The polarity of the outputs (main output *tim_ocx* or complementary *tim_ocxn*) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals *tim_ocx* and *tim_ocxn* are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI, and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 422: Output control bits for complementary *tim_ocx* and *tim_ocxn* channels with break feature for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a
reference waveform tim_ocxref, it generates two outputs tim_ocx and tim_ocxn. If tim_ocx and tim_ocxn are active high:

- The tim_ocx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The tim_ocxn output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (tim_ocx or tim_ocxn) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal tim_ocxref considering CCxP = 0, CCxNP = 0, MOE = 1, CCxE = 1 and CCxNE = 1 in these examples.

**Figure 440. Complementary output with symmetrical dead-time insertion**

The DTAE bit in the TIMx_DTR2 is used to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on Figure 441.

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIMx_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIMx_DTR2 register. The DTAE bit must be written before enabling the counter and must not be modified while CEN = 1.

It is possible to have the deadtime value updated on-the-fly during pwm operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set, in the TIMX_DTR2 register. The preload value is loaded in the active register on the next update event.

**Note:** If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 41.6.20: TIM1 break and dead-time register (TIM1_BDTR) for delay calculation.
Redirecting `tim_ocxref` to `tim_ocx` or `tim_ocxn`

In output mode (forced, output compare or PWM), `tim_ocxref` can be redirected to the `tim_ocx` output or to `tim_ocxn` output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This is used to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

**Note:** When only `tim_ocxn` is enabled (CCxE = 0, CCxNE = 1), it is not complemented and becomes active as soon as `tim_ocxref` is high. For example, if CCxNP = 0 then `tim_ocxn = tim_ocxref`. On the other hand, when both `tim_ocx` and `tim_ocxn` are enabled (CCxE = CCxNE = 1) `tim_ocx` becomes active when `tim_ocxref` is high whereas `tim_ocxn` is complemented and becomes active when `tim_ocxref` is low.

### 41.3.18 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The two break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state. A number of internal MCU events can also be selected to trigger an output shut-down.

The break features two channels. A break channel which gathers both system-level fault (clock failure, ECC/parity errors,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration. A break2 channel which only includes application faults and is able to force the outputs to an inactive state.

The output enable signal and output levels during break are depending on several control bits:

- The MOE bit in TIMx_BDTR register is used to enable/disable the outputs by software and is reset in case of break or break2 event.
- The OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- The OISx and OISxN bits in the TIMx_CR2 register which are setting the output shut-down level, either active or inactive. The `tim_ocx` and `tim_ocxn` outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 422: Output control bits for complementary `tim_ocx` and `tim_ocxn` channels with break feature for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break functions can be enabled by setting the BKE and BK2E bits in the TIMx_BDTR register. The break input polarities can be selected by configuring the BKP and BK2P bits in the same register. BKEx and BKPx can be modified at the same time. When the BKEx and BKPx bits are written, a delay of one APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait one APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous
and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

The sources for break (tim_brk) channel are:

- External sources connected to one of the TIMx_BKIN pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources:
  - coming from a tim_brk_cmpx input (refer to Section 41.3.2: TIM1 pins and internal signals for product specific implementation)
  - coming from a system break request (refer to Section 41.3.2: TIM1 pins and internal signals for product specific implementation)

The sources for break2 (tim_brk2) are:

- External sources connected to one of the TIMx_BKIN2 pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources coming from a tim_brk2_cmpx input (refer to Section 41.3.2: TIM1 pins and internal signals for product specific implementation)

Break events can also be generated by software using BG and B2G bits in the TIMx_EGR register.

All sources are ORed before entering the timer tim_brk or tim_brk2 inputs, as per Figure 444 below.
Note: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When one of the breaks occurs (selected level on one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state, or even releasing the control to the GPIO controller (selected by the OSSI bit). This feature is enabled even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE = 0. If OSSI = 0, the timer releases the output control (taken over by the GPIO controller), otherwise the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_ocx and tim_ocxn cannot be driven to

Note: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.
their active level together. Note that because of the resynchronization on MOE, the dead-time duration is slightly longer than usual (around 2 tim_ker_ck clock cycles).

- If OSSI = 0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state), otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.

- The break status flag (SBIF, BIF, and B2IF bits in the TIMx_SR register) is set. An interrupt is generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.

- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event (UEV). As an example, this can be used to perform a regulation. Otherwise, MOE remains low until the application sets it to 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors, or any security components.

Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSI value. If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIMx_CR2 register.

The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It is used to freeze the configuration of several parameters (dead-time duration, tim_ocx/tim_ocxn polarities and state when disabled, OCxM configurations, break enable, and polarity). The application can choose from three levels of protection selected by the LOCK bits in the TIMx_BDTR register. Refer to Section 41.6.20: TIM1 break and dead-time register (TIM1_BDTR). The LOCK bits can be written only once after an MCU reset.

Figure 445 shows an example of behavior of the outputs in response to a break.
The two break inputs have different behaviors on timer outputs:

- The `tim_brk` input can either disable (inactive state) or force the PWM outputs to a predefined safe state.
- `tim_brk2` can only disable (inactive state) the PWM outputs.
The `tim_brk` has a higher priority than `tim_brk2` input, as described in Table 415.

**Note:** `tim_brk2` must only be used with OSSR = OSSI = 1.

**Table 415. Behavior of timer outputs versus `tim_brk`/`tim_brk2` inputs**

**Figure 446** gives an example of `tim_ocx` and `tim_ocxn` output behavior in case of active signals on `tim_brk` and `tim_brk2` inputs. In this case, both outputs have active high polarities (CCxP = CCxNP = 0 in TIMx_CCER register).

**Figure 446. PWM output state following `tim_brk` and `tim_brk2` assertion (OSSI = 1)**
41.3.19 Bidirectional break inputs

The TIM1 features bidirectional break I/Os, as represented on Figure 448.

This provides support for:
- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin.
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged.

The tim_brk and tim_brk2 inputs are configured in bidirectional mode using the BKBID and BK2BID bits in the TIMxBDTR register. The BKBID programming bits can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode is available for both the tim_brk and tim_brk2 inputs, and require the I/O to be configured in open-drain mode with active low polarity (using BKINP, BK2INP and BK2P bits). Any break request coming either from system (for example CSS), from on-chip peripherals, or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software events (BG and B2G) also cause the break I/O to be forced to 0 to indicate to the external components that the timer is entered in break state. However, this is valid only if the break is enabled (BKE or B2KE = 1). When a software break event is generated with BKE or B2KE = 0), the outputs are put in safe state and the break flag is set, but there is no effect on the TIMx_BKIN and TIMx_BKIN2 I/Os.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the BKDSRM (BK2DSRM) bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:
- The break input path is always active: a break event is active even if the BKDSRM (BK2DSRM) bit is set and the open drain control is released. This prevents the PWM output to be restarted as long as the break condition is present.
- The BKDSRM (BK2DSRM) bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see Table 416).
Arming and rearming break circuitry

The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).

The following procedure must be followed to re-arm the protection after a break (break2) event:

- The BKDSRM (BK2DSRM) bit must be set to release the output control.
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before rearming).
- The software must poll the BKDSRM (BK2DSRM) bit until it is cleared by hardware (when the application break condition disappears).

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

### Table 416. Break protection disarming conditions

**Figure 448. Output redirection (tim_brk2 request not represented)**

---

**41.3.20 Clearing the tim_ocxref signal on an external event**

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocxref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM
cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

tim_etr_in must be configured as follows:
1. The external trigger prescaler must be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to 00.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to application needs (as per polarity of the source connected to the trigger and eventual need to remove noise using the filter).

*Figure 449* shows the behavior of the tim_ocxref signal when the tim_etrf input becomes high, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

**Figure 449. Clearing TIMx tim_ocxref**

![Figure 449](MSv62342V1)

**Note:** In case of a PWM with a 100% duty cycle (if CCRx>ARR), then tim_ocxref is enabled again at the next counter overflow.

### 41.3.21 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE, and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on tim_trgi rising edge).
A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

Figure 450 describes the behavior of the tim_ocx and tim_ocxn outputs when a COM event occurs, in three different examples of programmed configurations.

**41.3.22 One-pulse mode**

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.
A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: CNT < CCRx ≤ ARR (in particular, 0 < CCRx)
- In downcounting: CNT > CCRx

**Figure 451. Example of one pulse mode.**

In the following example, the user wants to generate a positive pulse on tim_oc1 with a length of tPULSE and after a delay of tDELAY as soon as a positive edge is detected on the tim_ti2 input pin.

Use tim_ti2fp2 as trigger 1:

- Map tim_ti2fp2 to tim_ti2 by writing CC2S = 01 in the TIMx_CCMR1 register.
- tim_ti2fp2 must detect a rising edge, write CC2P = 0 and CC2NP = 0 in the TIMx_CCER register.
- Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS = 00110 in the TIMx_SMCR register.
- tim_ti2fp2 is used to start the counter by writing SMS to 110 in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The tDELAY is defined by the value written in the TIMx_CCR1 register.
- The tPULSE is defined by the difference between the autoreload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Suppose the user wants to build a waveform with a transition from 0 to 1 when a compare match occurs and a transition from 1 to 0 when the counter reaches the auto-reload value. This is achieved by enabling PWM mode 2 (OC1M = 111 in TIMx_CCMR1). Optionally the preload registers can be enabled by writing OC1PE = 1 in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the autoreload value in the
TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to 0 in this example.

In this example, the DIR and CMS bits in the TIMx_CR1 register must be low. Since only one pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the autoreload value back to 0). When OPM bit in the TIMx_CR1 register is set to 0, so the Repetitive mode is selected.

Particular case: tim_ocx fast enable:

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay \( t_{\text{DELAY min}} \) that can be achieved.

To output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 41.3.23 Retriggerable One-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with nonretriggerable one-pulse mode described in Section 41.3.22:

- The pulse starts as soon as the trigger occurs (no programmable delay).
- The pulse is extended if a new trigger occurs before the previous one is completed.

The timer must be in Slave mode, with the bits SMS[3:0] = 1000 (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to 1000 or 1001 for retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

**Note:** The OCxM[3:0] and SMS[3:0] bitfields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the three least significant ones. This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.
41.3.24 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulsewidth generated when the counter value equals a given compare value, for debugging or synchronization purposes.

This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on Figure 453.

**Figure 453. Pulse generator circuitry**

*Figure 454* shows how the pulse is generated for edge-aligned and encoder operating modes.
This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bitfields in TIMx_CCMR2 register.

The pulsewidth is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

\[ t_{PW} = PW[7:0] \times t_{PWG} \]

where \( t_{PWG} = \left(2^{(PWPRSC[2:0])}\right) \times t_{tim\_ker\_ck} \)

gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

Note: If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the first arriving trigger is extended (because of the retrigger), while the pulse width of the last arriving trigger is correct (as shown on Figure 455).
41.3.25 Encoder interface mode

**Quadrature encoder**

To select Encoder Interface mode write SMS = 0001 in the TIMx_SMCR register if the counter is counting on tim_ti1 edges only, SMS = 0010 if it is counting on tim_ti2 edges only and SMS = 0011 if it is counting on both tim_ti1 and tim_ti2 edges.

Select the tim_ti1 and tim_ti2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs tim_ti1 and tim_ti2 are used to interface to a quadrature encoder. Refer to Table 417. The counter is clocked by each valid transition on tim_ti1fp1 or tim_ti2fp2 (tim_ti1 and tim_ti2 after input filter and polarity selection, tim_ti1fp1 = tim_ti1 if not filtered and not inverted, tim_ti2fp2 = tim_ti2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to 1). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_ti1 or tim_ti2), whatever the counter is counting on tim_ti1 only, tim_ti2 only or both tim_ti1 and tim_ti2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the autoreload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_ti1 and tim_ti2 do not switch at the same time.
A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to the external trigger input and trigger a counter reset.

*Figure 456* gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example the configuration is the following:

- CC1S = 01 (TIMx_CCMR1 register, tim_ti1fp1 mapped on tim_ti1).
- CC2S = 01 (TIMx_CCMR1 register, tim_ti2fp2 mapped on tim_ti2).
- CC1P = 0 and CC1NP = 0 (TIMx_CCER register, tim_ti1fp1 noninverted, tim_ti1fp1 = tim_ti1).
- CC2P = 0 and CC2NP = 0 (TIMx_CCER register, tim_ti1fp2 noninverted, tim_ti1fp2 = tim_ti2).
- SMS = 0011 (TIMx_SMCR register, both inputs are active on both rising and falling edges).
- CEN = 1 (TIMx_CR1 register, Counter enabled).

In this table, each row represents a different configuration of the counter. The columns represent the level on the opposite signal and the signal on tim_ti1fp1 and tim_ti2fp2. The final columns indicate the counting direction for each edge.
Figure 456. Example of counter operation in encoder interface mode.

Figure 457 gives an example of counter behavior when tim_token1 polarity is inverted (same configuration as above except CC1P = 1).

Figure 458 shows the timer counter value during a speed reversal, for various counting modes.
The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register’s bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

### Clock plus direction encoder mode

In addition to the quadrature encoder mode, the timer offers support for other types of encoders.

In the clock plus direction mode shown on Figure 459, the clock is provided on a single line, on tim_ti2, while the direction is forced using the tim_ti1 input.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- **1010**: x2 mode, the counter is updated on both rising and falling edges of the clock
- **1011**: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity

**Figure 458. Quadrature encoder counting modes**

![Diagram of quadrature encoder counting modes](image-url)
The polarity of the direction signal on tim_t1 is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when tim_t1 is high and down-counting when tim_t1 is low) and CC1P = 1 corresponds to negative polarity (up-counting when tim_t1 is low).

**Figure 459. Direction plus clock encoder mode**

![Directional clock encoder mode diagram](MSv62352V1)

**Directional clock encoder mode**

In the directional clock mode on Figure 460, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- 1100: x2 mode, the counter is updated on both rising and falling edges of any of the two clock line. The CC1P and CC2P bits are coding for the clock idle state. CCxP = 0 corresponds to high-level idle state (refer to Figure 460) and CCxP = 1 corresponds to low-level idle state (refer to Figure 461).

- 1101: x1 mode, the counter is updated on a single clock edge, as per CC1P and CC2P bit value. CCxP = 0 corresponds to falling edge sensitivity and high-level idle state (refer to Figure 460), CCxP = 1 corresponds to rising edge sensitivity and low-level idle state (refer to Figure 461).

Index input

The counter can be reset by an index signal coming from the encoder, indicating an absolute reference position. The index signal must be connected to the tim_etr_in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMX_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0001, 0010, 011, 1010, 1011, 1100, 1101, 1110, 1111.
Available encoders are proposed with several options for index pulse conditioning, as per Figure 462:

- gated with A and B: the pulsewidth is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulsewidth is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulsewidth is up to one channel period, without any alignment to the edges

**Figure 462. Index gating options**

The circuitry tolerates jitter on index signal, whatever the gating mode, as shown on Figure 463.

In ungated mode, the signal must be strictly below two encoder periods. If the pulsewidth is greater or equal to two encoder period, the counter is reset multiple times.

**Figure 463. Jittered Index signals**

The timer supports the three gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (for example channel A and
channel B state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIMx_ECR register.

The index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:

- The counter is reset during up-counting (DIR bit = 0).
- The counter is set to TIMx_ARR when down counting.

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. Figure 464 shows at which position is the index generated, for a simplistic example (an encoder providing four edges per mechanical rotation).

**Figure 464. Index generation for IPOS[1:0] = 11**

---

**Figure 465** presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is 11 (ChA = 1, ChB = 1), when up-counting (DIR bit = 0).
- Counter set to TIMx_ARR when exiting the 11 state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.

**Figure 465. Counter reading with index gated on channel A (IPOS[1:0] = 11)**
Figure 466. presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.

**Figure 466. Counter reading with index ungated (IPOS[1:0] = 00)**

Figure 467. shows how the ‘gated on A & B’ mode is handled, for various pulse alignment scenario. The arrows are indicating on which transition is the index event generated.

**Figure 470. Index behavior in x1 and x2 mode (IPOS[1:0] = 01)**

![Diagram showing index behavior in x1 and x2 mode](MSv45773V1)

**Directional index sensitivity**

The IDIR[1:0] bitfield in the TIMx_ECR register allows the index to be active only in a selected counting direction.

Figure 471 shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

**Figure 471. Directional index sensitivity**

![Diagram showing directional index sensitivity](MSv45774V1)
Special first index event management

The FIDX bit in the TIMx_ECR register allows the index to be taken only once, as shown on Figure 472. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be rearmed by writing the FIDX bit to 0 and setting it again to 1.

**Figure 472. Counter reset as function of FIDX bit setting**

Index blanking

The index event can be blanked using the tim_ti3 or tim_ti4 inputs. During the blanking window, the index events are no longer resetting the counter, as shown on the Figure 473 below.

This mode is enabled using the IBLK[1:0] bitfield in the TIMx_ECR register, as following:

- IBLK[1:0] = 00: Index signal always active
- IBLK[1:0] = 01: Index signal blanking on tim_ti3 input
- IBLK[1:0] = 10: Index signal blanking on tim_ti4 input

**Figure 473. Index blanking**
Index management in nonquadrature mode

*Figure 474* and *Figure 475* detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[3:0] bitfield is equal to 1010, 1011, 1100, 1101.

For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:

- IPOS[0] = 0: Index is detected on clock low level
- IPOS[0] = 1: Index is detected on clock high level

The IPOS[1] bit is not-significant.

### Figure 474. Index behavior in clock + direction mode, IPOS[0] = 1

![Figure 474](image1)

### Figure 475. Index behavior in directional clock mode, IPOS[0] = 1

![Figure 475](image2)

Encoder error management

For encoder configurations where two quadrature signals are available, it is possible to detect transition errors. The reading on the two inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on *Figure 476*. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIMx_SR...
status register. A transition error interrupt is generated if the TERRIE bit is set in the TIMx_DIER register.

Figure 476. State diagram for quadrature encoded signals

For encoder having an index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIMx_ARR to 0 or decremented from 0 to TIMxARR value without any index event, this is reported as an index position error.

The overflow threshold is programmed using the TIMx_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIMx_ARR = 3999 + 1 = 4000.
The error assertion is delayed to the transition 0 to 1 when in up-counting. This is cope with narrow index pulses in gated A and B mode, as shown on Figure 477.

**Figure 477. Up-counting encoder error detection**
In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on Figure 478, to avoid any false error detection in case the encoder dithers between TIMx_ARR and 0 immediately after the index detection.

**Figure 478. Down-counting encode error detection**

An index error sets the IERRF interrupt flag in the TIMx_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIMx_DIER register.

**Functional encoder interrupts**

The following interrupts are also available in encoder mode

- Direction change: any change of the counting direction in encoder mode causes the DIR bit in the TIMx_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIMx_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIMx_DIER register.

- Index event: the index event sets the IDXF interrupt flag in the TIMx_SR status register. An index interrupt is generated if the IDXIE bit is set in the TIMx_DIER register.
Slave mode selection preload for run-time encoder mode update

It may be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the update interrupt rate, by switching from x4 to x2 to x1 mode, as shown on Figure 479.

For this purpose, the SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value can be selected with the SMSPS bit in the TIMx_SMCR register.

- SMSPS = 0: the transfer is triggered by the update event (UEV) occurring when the counter overflows when upcounting, and underflows when downcounting.
- SMSPS = 1: the transfer is triggered by the index event.

Figure 479. Encoder mode change with preload transferred on update (SMSPS = 0)

Encoder clock output

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIMx_CR2 register. It is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

41.3.26 Direction bit output

It is possible to output a direction signal out of the timer, on the tim_oc3n and tim_oc4 output signals (copy of the DIR bit in the TIMx_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bitfield to 1011 in the TIMx_CCMR2 register.
This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

### 41.3.27 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag UIF into the timer counter register’s bit 31 (TIMx_CNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flags assertion.

### 41.3.28 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins TIMt1, TIMt2 and TIMt3.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per Figure 480.

*Figure 480. Measuring time interval between edges on three signals*

### 41.3.29 Interfacing with Hall sensors

This is done using the advanced-control timers to generate PWM signals to drive the motor and another timer TIMx referred to as “interfacing timer” in Figure 481. The “interfacing timer” captures the three timer input pins (TIMt1, TIMt2 and TIMt3) connected through a XOR to the TIMt1 input channel (selected by setting the TI1S bit in the TIMx_CR2 register).

The slave mode controller is configured in reset mode; the slave input is TIMt1f_ed. Thus, each time one of the three inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is TIM_trc (See Figure 424). The captured value, which corresponds to the time elapsed between two changes on the inputs, gives information about motor speed.
The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (by triggering a COM event). The advanced-control timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer through the tim_trgo output.

In this example the user wants to change the PWM configuration of the advanced-control timer after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure three timer inputs ORed to the tim_ti1 input channel by writing the TI1S bit in the TIMx_CR2 register to 1.
- Program the time base: write the TIMx_ARR to the max value (the counter must be cleared by the tim_ti1 change. Set the prescaler to get a maximum counter period longer than the time between two changes on the sensors.
- Program the channel 1 in capture mode (tim_trc selected): write the CC1S bits in the TIMx_CCMR1 register to 01. The digital filter can also be programmed if needed.
- Program the channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to 111 and the CC2S bits to 00 in the TIMx_CCMR1 register.
- Select tim_oc2ref as trigger output on tim_trgo: write the MMS bits in the TIMx_CR2 register to 101.

In the advanced-control timer, the right tim_itr0 input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC = 1 in the TIMx_CR2 register) and the COM event is controlled by the trigger input (CCUS = 1 in the TIMx_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of tim_oc2ref).

Figure 481 describes this example.
### 41.3.30 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 42.4.23: Timer synchronization for details. They can be synchronized in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger, and gated + reset modes.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.
In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

- Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P = 0 and CC1NP = 0 in TIMx_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS = 100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS = 0010 in TIMx_SMCR register.
- Start the counter by writing CEN = 1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the autoreload register TIMx_ARR = 0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_ti1 input is low:

- Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in TIMx_CCMR1 register. Write CC1P = 1 and CC1NP = 0 in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS = 101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS = 0010 in TIMx_SMCR register.
- Enable the counter by writing CEN = 1 in the TIMx_CR1 register (in gated mode, the counter does not start if CEN = 0, whatever is the trigger input level).
The counter starts counting on the internal clock as long as tim_t1 is low and stops as soon as tim_t1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_t1 and the actual stop of the counter is due to the resynchronization circuit on tim_t1 input.

**Slave mode: Trigger mode**

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on tim_t2 input:

- Configure the channel 2 to detect rising edges on tim_t2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S = 01 in TIMx_CCMR1 register. Write CC2P = 1 and CC2NP = 0 in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS = 110 in TIMx_SMCR register. Select tim_t2 as the input source by writing TS = 00110 in TIMx_SMCR register.

When a rising edge occurs on tim_t2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_t2 and the actual start of the counter is due to the resynchronization circuit on tim_t2 input.
Slave mode: Combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter. This mode is used for One-pulse mode.

Slave mode: Combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled. This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode: external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIMx_SMCR register.
In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_ti1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS = 00: prescaler disabled
   - ETP = 0: detection of rising edges on tim_etr_in and ECE = 1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F = 0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S = 01 in TIMx_CCMR1 register to select only the input capture source
   - CC1NP = 0 and CC1NP = 0 in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS = 110 in TIMx_SMCR register.
   Select tim_ti1 as the input source by writing TS = 00101 in TIMx_SMCR register.

   A rising edge on tim_ti1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.

**Figure 485. Control circuit in external clock mode 2 + trigger mode**

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
41.3.31 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events. It is also possible to generate a pulse issued by internal edge detectors, such as:

- Rising and falling edges of OC4ref
- Rising edge on OC5ref or falling edge on OC6ref

The triggers are issued on the tim_trgo2 internal line which is redirected to the ADC. There is a total of 16 possible events, which can be selected using the MMS2[3:0] bits in the TIMx_CR2 register.

An example of an application for 3-phase motor drives is given in Figure 439.

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

The clock of the ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the timer.

41.3.32 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to reprogram part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR register define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:

00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

The DBSS[3:0] bits in the TIMx_DCR register defines the interrupt source that triggers the DMA burst transfers (see Section 41.6.29: TIM1 DMA control register (TIM1_DCR) for details).

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.
This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address.
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (see note below).
   - Circular mode disabled.

2. Configure the DCR register by configuring the DBA and DBL bitfields as follows:
   - DBL = 3 transfers, DBA = 0xE and DBSS = 1.

3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).

4. Enable TIMx.

5. Enable the DMA channel.

This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let’s take the example of a buffer in the RAM containing data1, data2, data3, data4, data5, and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3, and data6 is transferred to CCR4.

**Note:** A null value can be written to the reserved registers.

### 41.3.33 TIM1 DMA requests

The TIM1 can generate a DMA request, as shown in the table below.

<table>
<thead>
<tr>
<th>DMA request signal</th>
<th>DMA request</th>
<th>Enable control bit</th>

<td>TDE</td>
</tr>
</tbody>
</table>

### 41.3.34 Debug mode

When the microcontroller enters debug mode (Cortex®-M7 core halted), the TIMx counter can either continue to work normally or stop, depending on DBG_TIMx_STOP configuration bit in DBG module.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.
For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0), typically to force a Hi-Z.
For more details, refer to section Debug support (DBG).

41.4 TIM1 low-power modes

Table 420. Effect of low-power modes on TIM1

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.</td>

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable
- 0: Dithering disabled
- 1: Dithering enabled

*Note: The DITHEN bit can only be modified when CEN bit is reset.*

Bit 11 **UIFREMAP**: UIF status bit remapping
- 0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
- 1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bitfield indicates the division ratio between the timer clock (tim_ker_ck) frequency and the dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters (tim_etru_in, tim_fix),
- 00: tDTS = ttim_ker_ck
- 01: tDTS = 2*ttim_ker_ck
- 10: tDTS = 4*ttim_ker_ck
- 11: Reserved, do not program this value

Bit 7 **ARPE**: Autoreload preload enable
- 0: TIMx_ARR register is not buffered
- 1: TIMx_ARR register is buffered

Bits 6:5 **CMS[1:0]**: Center-aligned mode selection
- 00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).
- 01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIMx_CCMRx register) are set only when the counter is counting down.
- 10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIMx_CCMRx register) are set only when the counter is counting up.
- 11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIMx_CCMRx register) are set both when the counter is counting up or down.

*Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN = 1)*
Bit 4 **DIR**: Direction
0: Counter used as upcounter
1: Counter used as downcounter

*Note:* This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled.
These events can be:
– Counter overflow/underflow
– Setting the UG bit
– Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
– Counter overflow/underflow
– Setting the UG bit
– Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value
(ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is
set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled

*Note:* External clock, gated mode and encoder mode can work only if the CEN bit has been
previously set by software. However trigger mode can set the CEN bit automatically by hardware.

Bits 31:26 Reserved, must be kept at reset value.

Bit 24 Reserved, must be kept at reset value.

Bits 23:20 **MMS2[3:0]**: Master mode selection 2

These bits allow the information to be sent to ADC for synchronization (tim_trgo2) to be selected. The combination is as follows:

- **0000**: *Reset* - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo2). If the reset is generated by the trigger input (slave mode controller configured in reset mode), the signal on tim_trgo2 is delayed compared to the actual reset.
- **0001**: *Enable* - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo2). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between the CEN control bit and the trigger input when configured in Gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo2, except if the Master/Slave mode is selected (see the MSM bit description in TIMx_SMCR register).
- **0010**: *Update* - the update event is selected as trigger output (tim_trgo2). For instance, a master timer can then be used as a prescaler for a slave timer.
- **0011**: *Compare pulse* - the trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or compare match occurs (tim_trgo2).
- **0100**: *Compare* - tim_oc1refc signal is used as trigger output (tim_trgo2)
- **0101**: *Compare* - tim_oc2refc signal is used as trigger output (tim_trgo2)
- **0110**: *Compare* - tim_oc3refc signal is used as trigger output (tim_trgo2)
- **0111**: *Compare* - tim_oc4refc signal is used as trigger output (tim_trgo2)
- **1000**: *Compare* - tim_oc5refc signal is used as trigger output (tim_trgo2)
- **1001**: *Compare* - tim_oc6refc signal is used as trigger output (tim_trgo2)
- **1010**: *Compare Pulse* - tim_oc4refc rising or falling edges generate pulses on tim_trgo2
- **1011**: *Compare pulse* - tim_oc6refc rising or falling edges generate pulses on tim_trgo2
- **1100**: *Compare pulse* - tim_oc4refc or tim_oc6refc rising edges generate pulses on tim_trgo2
- **1101**: *Compare pulse* - tim_oc4refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2
- **1110**: *Compare pulse* - tim_oc5refc or tim_oc6refc rising edges generate pulses on tim_trgo2
- **1111**: *Compare pulse* - tim_oc5refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

**Note**: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **OIS6**: Output idle state 6 (tim_oc6 output)
Refer to OIS1 bit

Bit 17 Reserved, must be kept at reset value.

Bit 16 **OIS5**: Output idle state 5 (tim_oc5 output)
Refer to OIS1 bit

Bit 15 **OIS4N**: Output idle state 4 (tim_oc4n output)
Refer to OIS1N bit

Bit 14 **OIS4**: Output idle state 4 (tim_oc4 output)
Refer to OIS1 bit
Bit 13 **OIS3N**: Output idle state 3 (tim_oc3n output)  
Refer to OIS1N bit

Bit 12 **OIS3**: Output idle state 3 (tim_oc3n output)  
Refer to OIS1 bit

Bit 11 **OIS2N**: Output idle state 2 (tim_oc2n output)  
Refer to OIS1N bit

Bit 10 **OIS2**: Output idle state 2 (tim_oc2 output)  
Refer to OIS1 bit

Bit 9 **OIS1N**: Output idle state 1 (tim_oc1n output)  
0: tim_oc1n = 0 after a dead-time when MOE = 0  
1: tim_oc1n = 1 after a dead-time when MOE = 0  
**Note**: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **OIS1**: Output idle state 1 (tim_oc1 output)  
0: tim_oc1 = 0 (after a dead-time) when MOE = 0  
1: tim_oc1 = 1 (after a dead-time) when MOE = 0  
**Note**: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7 **TI1S**: tim_ti1 selection  
0: The tim_ti1_in[15:0] multiplexer output is connected to tim_ti1 input  
1: tim_ti1_in[15:0], tim_ti2_in[15:0] and tim_ti3_in[15:0] multiplexers outputs are XORed and connected to the tim_ti1 input
Bits 25, 6:4 **MMS[3:0]**: Master mode selection

These bits select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

- **0000**: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.

- **0001**: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).

- **0010**: **Update** - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

- **0011**: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (tim_trgo).

- **0100**: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo)

- **0101**: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo)

- **0110**: **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo)

- **0111**: **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo)

- **1000**: **Encoder Clock output** - The encoder clock signal is used as trigger output (tim_trgo). This code is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

Other codes reserved

*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 3 **CCDS**: Capture/compare DMA selection

- 0: CCx DMA request sent when CCx event occurs
- 1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

- 0: When capture/compare control bits are preloaded (CCPC = 1), they are updated by setting the COMG bit only
- 1: When capture/compare control bits are preloaded (CCPC = 1), they are updated by setting the COMG bit or when an rising edge occurs on tim_trgi

*Note: This bit acts only on channels that have a complementary output.*

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

- 0: CCxE, CCxNE and OCxM bits are not preloaded
- 1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on tim_trgi, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*
41.6.3 TIM1 slave mode control register (TIM1_SMCR)

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **SMSPS**: SMS preload source
This bit selects whether the events that triggers the SMS[3:0] bitfield transfer from preload to active
0: The transfer is triggered by the Timer’s Update event
1: The transfer is triggered by the Index event

Bit 24 **SMSPE**: SMS preload enable
This bit selects whether the SMS[3:0] bitfield is preloaded
0: SMS[3:0] bitfield is not preloaded
1: SMS[3:0] preload is enabled

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **TS[4:3]**: Trigger selection - bit 4:3
Refer to TS[2:0] description - bits 6:4

Bits 19:17 Reserved, must be kept at reset value.

Bit 15 **ETP**: External trigger polarity
This bit selects whether tim_etr_in or tim_etr_in is used for trigger operations
0: tim_etr_in is non-inverted, active at high level or rising edge.
1: tim_etr_in is inverted, active at low level or falling edge.

Bit 14 **ECE**: External clock enable
This bit enables External clock mode 2.
0: External clock mode 2 disabled
1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_etrf signal.

**Note**: Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_etrf (SMS = 111 and TS = 00111).
It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etrf in this case (TS bits must not be 00111).
If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etrf.
Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal tim_etrp frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce tim_etrp frequency. It is useful when inputting fast external clocks on tim_etr_in.

00: Prescaler OFF
01: tim_etr_in frequency divided by 2
10: tim_etr_in frequency divided by 4
11: tim_etr_in frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bitfield then defines the frequency used to sample tim_etrp signal and the length of the digital filter applied to tim_etrp. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at fDTS
0001: fSAMPLING = ftim_ker_ck, N = 2
0010: fSAMPLING = ftim_ker_ck, N = 4
0011: fSAMPLING = ftim_ker_ck, N = 8
0100: fSAMPLING = fDTS/2, N = 6
0101: fSAMPLING = fDTS/2, N = 8
0110: fSAMPLING = fDTS/4, N = 6
0111: fSAMPLING = fDTS/4, N = 8
1000: fSAMPLING = fDTS/8, N = 6
1001: fSAMPLING = fDTS/8, N = 8
1010: fSAMPLING = fDTS/16, N = 5
1011: fSAMPLING = fDTS/16, N = 6
1100: fSAMPLING = fDTS/16, N = 8
1101: fSAMPLING = fDTS/32, N = 5
1110: fSAMPLING = fDTS/32, N = 6
1111: fSAMPLING = fDTS/32, N = 8

Bit 7 **MSM**: Master/slave mode

0: No action
1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.
Bits 6:4  **TS[2:0]: Trigger selection**

This bitfield is combined with TS[4:3] bits. This bitfield selects the trigger input to be used to synchronize the counter.

00000: Internal Trigger 0 (tim_itr0)
00001: Internal Trigger 1 (tim_itr1)
00010: Internal Trigger 2 (tim_itr2)
00011: Internal Trigger 3 (tim_itr3)
00100: tim_ti1 Edge Detector (tim_ti1f_ed)
00101: Filtered Timer Input 1 (tim_ti1fp1)
00110: Filtered Timer Input 2 (tim_ti2fp2)
00111: External Trigger input (tim_etrf)
01000: Internal Trigger 4 (tim_itr4)
01001: Internal Trigger 5 (tim_itr5)
01010: Internal Trigger 6 (tim_itr6)
01011: Internal Trigger 7 (tim_itr7)
01100: Internal Trigger 8 (tim_itr8)
01101: Internal Trigger 9 (tim_itr9)
01110: Internal Trigger 10 (tim_itr10)
01111: Internal trigger 11 (tim_itr11)
10000: Internal trigger 12 (tim_itr12)
10001: Internal trigger 13 (tim_itr13)
10010: Internal trigger 14 (tim_itr14)
10011: Internal trigger 15 (tim_itr15)
Others: Reserved

See Table 408: Internal trigger connection for more details on tim_itrx meaning for each Timer.

**Note:** These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3  Reserved, must be kept at reset value.
Bits 16, 2:0 **SMS[3:0]**: Slave mode selection

When external signals are selected, the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (refer to ETP bit in TIMx_SMCR for tim_etr_in and CCxP/CCxNP bits in TIMx_CCER register for tim_ti1fp1 and tim_ti2fp2).

0000: Slave mode disabled - if CEN = 1 then the prescaler is clocked directly by the internal clock.

0001: Quadrature encoder mode 1, x2 mode - Counter counts up/down on tim_ti1fp1 edge depending on tim_ti2fp2 level.

0010: Quadrature encoder mode 2, x2 mode - Counter counts up/down on tim_ti2fp2 edge depending on tim_ti1fp1 level.

0011: Quadrature encoder mode 3, x4 mode - Counter counts up/down on both tim_ti1fp1 and tim_ti2fp2 edges depending on the level of the other input.

0100: Reset mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

0101: Gated mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

0111: External Clock mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset as soon as the trigger becomes low. Both start and stop of the counter are controlled.

1010: Encoder mode: Clock plus direction, x2 mode.

1011: Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by CC2P

1100: Encoder mode: Directional Clock, x2 mode.

1101: Encoder mode: Directional Clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity is set by CC1P and CC2P.

1110: Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge sensitivity is set by CC1P.

1111: Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge sensitivity is set by CC2P.

**Note:** The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS = 00100). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on Ti1F, whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
## TIM1 DMA/interrupt enable register (TIM1_DIER)

**Note**: The table shows the bits and their respective functions for the TIM1 status register (TIM1_SR).
Bits 31:24  Reserved, must be kept at reset value.

Bit 23  **TERRF**: Transition error interrupt flag
   This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to 0.
   0: No encoder transition error has been detected.
   1: An encoder transition error has been detected

Bit 22  **IERRF**: Index error interrupt flag
   This flag is set by hardware when an index error is detected. It is cleared by software by writing it to 0.
   0: No index error has been detected.
   1: An index error has been detected

Bit 21  **DIRF**: Direction change interrupt flag
   This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIMx_CR is changing). It is cleared by software by writing it to 0.
   0: No direction change
   1: Direction change

Bit 20  **IDXF**: Index interrupt flag
   This flag is set by hardware when an index event is detected. It is cleared by software by writing it to 0.
   0: No index event occurred.
   1: An index event has occurred

Bits 19:18  Reserved, must be kept at reset value.

Bit 17  **CC6IF**: Compare 6 interrupt flag
   Refer to CC1IF description
   *Note: Channel 6 can only be configured as output.*

Bit 16  **CC5IF**: Compare 5 interrupt flag
   Refer to CC1IF description
   *Note: Channel 5 can only be configured as output.*

Bits 15:14  Reserved, must be kept at reset value.

Bit 13  **SBIF**: System break interrupt flag
   This flag is set by hardware as soon as the system break input goes active. It can be cleared by software if the system break input is not active.
   This flag must be reset to re-start PWM operation.
   0: No break event occurred.
   1: An active level has been detected on the system break input. An interrupt is generated if BIE = 1 in the TIMx_DIER register.

Bit 12  **CC4OF**: Capture/compare 4 overcapture flag
   Refer to CC1OF description

Bit 11  **CC3OF**: Capture/compare 3 overcapture flag
   Refer to CC1OF description

Bit 10  **CC2OF**: Capture/compare 2 overcapture flag
   Refer to CC1OF description
Bit 9 **CC1OF**: Capture/compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to 0.
0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set.

Bit 8 **B2IF**: Break 2 interrupt flag
This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active.
0: No break event occurred.
1: An active level has been detected on the break 2 input. An interrupt is generated if BIE = 1 in the TIMx_DIER register.

Bit 7 **BIF**: Break interrupt flag
This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
0: No break event occurred.
1: An active level has been detected on the break input. An interrupt is generated if BIE = 1 in the TIMx_DIER register.

Bit 6 **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred.
1: Trigger interrupt pending.

Bit 5 **COMIF**: COM interrupt flag
This flag is set by hardware on COM event (when capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.
0: No COM event occurred.
1: COM interrupt pending.

Bit 4 **CC4IF**: Capture/compare 4 interrupt flag
Refer to CC1IF description.

Bit 3 **CC3IF**: Capture/compare 3 interrupt flag
Refer to CC1IF description.
Bit 2  **CC2IF**: Capture/compare 2 interrupt flag
Refer to CC1IF description

Bit 1  **CC1IF**: Capture/compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0  **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
  -- At overflow or underflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS = 0 in the TIMx_CR1 register.
  -- When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS = 0 and UDIS = 0 in the TIMx_CR1 register.
  -- When CNT is reinitialized by a trigger event (refer to Section 41.6.3: TIM1 slave mode control register (TIM1_SMCR)), if URS = 0 and UDIS = 0 in the TIMx_CR1 register.

Bits 15:9  Reserved, must be kept at reset value.

Bit 8  **B2G**: Break 2 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled.

Bit 7  **BG**: Break generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.
Bit 6 **TG**: Trigger generation  
This bit is set by software in order to generate an event, it is automatically cleared by hardware.  
0: No action  
1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 **COMG**: Capture/compare control update generation  
This bit can be set by software, it is automatically cleared by hardware  
0: No action  
1: CCxE, CCxNE and OCxM bits update (providing CCPC bit is set)  
*Note*: This bit acts only on channels having a complementary output.

Bit 4 **CC4G**: Capture/compare 4 generation  
Refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation  
Refer to CC1G description

Bit 2 **CC2G**: Capture/compare 2 generation  
Refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation  
This bit is set by software in order to generate an event, it is automatically cleared by hardware.  
0: No action  
1: A capture/compare event is generated on channel 1:  
*If channel CC1 is configured as output:*  
CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.  
*If channel CC1 is configured as input:*  
The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation  
This bit can be set by software, it is automatically cleared by hardware.  
0: No action  
1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR = 0 (upcounting), else it takes the autoreload value (TIMx_ARR) if DIR = 1 (downcounting).

### 41.6.7 TIM1 capture/compare mode register 1 (TIM1_CCMR1)

Address offset: 0x018  
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).
### Input capture mode:

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:12  **IC2F[3:0]**: Input capture 2 filter

Bits 11:10  **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8  **CC2S[1:0]**: Capture/compare 2 selection

- This bitfield defines the direction of the channel (input/output) as well as the used input.
- 00: CC2 channel is configured as output
- 01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
- 10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
- 11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).*
Bits 7:4  **IC1F[3:0]**: Input capture 1 filter

This bitfield defines the frequency used to sample tim_t1 input and the length of the digital filter applied to tim_t1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at fDTS
- 0001: fSAMPLING = fTIm_ker_ck, N = 2
- 0010: fSAMPLING = fTIm_ker_ck, N = 4
- 0011: fSAMPLING = fTIm_ker_ck, N = 8
- 0100: fSAMPLING = fDTS/2, N = 6
- 0101: fSAMPLING = fDTS/2, N = 8
- 0110: fSAMPLING = fDTS/4, N = 6
- 0111: fSAMPLING = fDTS/4, N = 8
- 1000: fSAMPLING = fDTS/8, N = 6
- 1001: fSAMPLING = fDTS/8, N = 8
- 1010: fSAMPLING = fDTS/16, N = 6
- 1011: fSAMPLING = fDTS/16, N = 8
- 1100: fSAMPLING = fDTS/32, N = 6
- 1101: fSAMPLING = fDTS/32, N = 8
- 1110: fSAMPLING = fDTS/32, N = 8
- 1111: fSAMPLING = fDTS/32, N = 8

Bits 3:2  **IC1PSC[1:0]**: Input capture 1 prescaler

This bitfield defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E = 0 (TIMx_CCER register).

- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 1:0  **CC1S[1:0]**: Capture/compare 1 Selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, tim_ic1 is mapped on tim_t1
- 10: CC1 channel is configured as input, tim_ic1 is mapped on tim_t2
- 11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*

### 41.6.8 TIM1 capture/compare mode register 1 [alternate]

**TIM1_CCMR1**

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).
Output compare mode:

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15  **OC2CE**: Output compare 2 clear enable

Bits 24, 14:12  **OC2M[3:0]**: Output compare 2 mode

Bit 11  **OC2PE**: Output compare 2 preload enable

Bit 10  **OC2FE**: Output compare 2 fast enable

Bits 9:8  **CC2S[1:0]**: Capture/compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

**Note**: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).

Bit 7  **OC1CE**: Output compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr_int signal
1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal
(tim_ocref_clr input or tim_etrf input)
Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal \( \text{tim}_\text{oc1ref} \) from which \( \text{tim}_\text{oc1} \) and \( \text{tim}_\text{oc1n} \) are derived. \( \text{tim}_\text{oc1ref} \) is active high whereas \( \text{tim}_\text{oc1} \) and \( \text{tim}_\text{oc1n} \) active level depends on CC1P and CC1NP bits.

- 0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.
- 0001: Set channel 1 to active level on match. \( \text{tim}_\text{oc1ref} \) signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- 0010: Set channel 1 to inactive level on match. \( \text{tim}_\text{oc1ref} \) signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- 0011: Toggle - \( \text{tim}_\text{oc1ref} \) toggles when TIMx_CNT = TIMx_CCR1.
- 0100: Force inactive level - \( \text{tim}_\text{oc1ref} \) is forced low.
- 0101: Force active level - \( \text{tim}_\text{oc1ref} \) is forced high.
- 0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (\( \text{tim}_\text{oc1ref} = 0 \)) as long as TIMx_CNT>TIMx_CCR1 else active (\( \text{tim}_\text{oc1ref} = 1 \)).
- 0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.
- 1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on \( \text{tim}_\text{trgi} \) signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on \( \text{tim}_\text{trgi} \) signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.
- 1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on \( \text{tim}_\text{trgi} \) signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on \( \text{tim}_\text{trgi} \) signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.
- 1010: Reserved,
- 1011: Reserved,
- 1100: Combined PWM mode 1 - \( \text{tim}_\text{oc1refc} \) has the same behavior as in PWM mode 1. \( \text{tim}_\text{oc1refc} \) is the logical OR between \( \text{tim}_\text{oc1ref} \) and \( \text{tim}_\text{oc2ref} \).
- 1101: Combined PWM mode 2 - \( \text{tim}_\text{oc1refc} \) has the same behavior as in PWM mode 2. \( \text{tim}_\text{oc1refc} \) is the logical AND between \( \text{tim}_\text{oc1ref} \) and \( \text{tim}_\text{oc2ref} \).
- 1110: Asymmetric PWM mode 1 - \( \text{tim}_\text{oc1refc} \) has the same behavior as in PWM mode 1. \( \text{tim}_\text{oc1refc} \) outputs \( \text{tim}_\text{oc1ref} \) when the counter is counting up, \( \text{tim}_\text{oc2ref} \) when it is counting down.
- 1111: Asymmetric PWM mode 2 - \( \text{tim}_\text{oc1refc} \) has the same behavior as in PWM mode 2. \( \text{tim}_\text{oc1ref} \) outputs \( \text{tim}_\text{oc1ref} \) when the counter is counting up, \( \text{tim}_\text{oc2ref} \) when it is counting down.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S = 00 (the channel is configured in output).

**Note:** In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

**Note:** On channels having a complementary output, this bitfield is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.
### TIM1 capture/compare mode register 2 (TIM1_CCMR2)

**Address offset:** 0x001C  
**Reset value:** 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 3 in input capture mode and channel 4 in output compare mode).

**Input capture mode**

- Bits 31:16: Reserved, must be kept at reset value.
- Bits 15:12: **IC4F[3:0]:** Input capture 4 filter
- Bits 11:10: **IC4PSC[1:0]:** Input capture 4 prescaler
Advanced-control timers (TIM1) RM0477

41.6.10 TIM1 capture/compare mode register 2 [alternate] (TIM1_CCMR2)

Address offset: 0x01C
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 3 in input capture mode and channel 4 in output compare mode).

Bits 9:8 CC4S[1:0]: Capture/compare 4 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC4 channel is configured as output
01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx_CCER).

Bits 7:4 IC3F[3:0]: Input capture 3 filter

Bits 3:2 IC3PSC[1:0]: Input capture 3 prescaler

Bits 1:0 CC3S[1:0]: Capture/compare 3 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC3 channel is configured as output
01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4
11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx_CCER).

Output compare mode

Bits 31:25 Reserved, must be kept at reset value.
Bits 23:17 Reserved, must be kept at reset value.
Bit 15 OC4CE: Output compare 4 clear enable

Bits 24, 14:12 OC4M[3:0]: Output compare 4 mode
Refer to OC3M[3:0] bit description

Bit 11 OC4PE: Output compare 4 preload enable

Bit 10 OC4FE: Output compare 4 fast enable
Bits 9:8  **CC4S[1:0]**: Capture/compare 4 selection

- 00: CC4 channel is configured as output
- 01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
- 10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
- 11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note*: **CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx_CCER).**

Bit 7  **OC3CE**: Output compare 3 clear enable
Bits 16, 6:4  **OC3M[3:0]: Output compare 3 mode**

These bits define the behavior of the output reference signal tim_oc3ref from which tim_oc3 and tim_oc3n are derived. tim_oc3ref is active high whereas tim_oc3 and tim_oc3n active level depends on CC3P and CC3NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR3 and the counter TIMx_CNT has no effect on the outputs. (this mode is used to generate a timing base).

0001: Set channel 3 to active level on match. tim_oc3ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 3 (TIMx_CCR3).

0010: Set channel 3 to inactive level on match. tim_oc3ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 3 (TIMx_CCR3).

0011: Toggle - tim_oc3ref toggles when TIMx_CNT = TIMx_CCR3.

0100: Force inactive level - tim_oc3ref is forced low.

0101: Force active level - tim_oc3ref is forced high.

0110: PWM mode 1 - In upcounting, channel 3 is active as long as TIMx_CNT<TIMx_CCR3 else inactive. In downcounting, channel 3 is inactive (tim_oc3ref = 0) as long as TIMx_CNT>TIMx_CCR3 else active (tim_oc3ref = 1).

0111: PWM mode 2 - In upcounting, channel 3 is inactive as long as TIMx_CNT<TIMx_CCR3 else active. In downcounting, channel 3 is active as long as TIMx_CNT>TIMx_CCR3 else inactive.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Pulse on compare: a pulse is generated on tim_oc3ref upon CCR3 match event, as per PWPRSC[2:0] and PW[7:0] bitfields programming in TIMxECR.

1011: Direction output. The tim_oc3ref signal is overridden by a copy of the DIR bit.

1100: Combined PWM mode 1 - tim_oc3ref has the same behavior as in PWM mode 1. tim_oc3refc is the logical OR between tim_oc3ref and tim_oc4ref.

1101: Combined PWM mode 2 - tim_oc3ref has the same behavior as in PWM mode 2. tim_oc3refc is the logical AND between tim_oc3ref and tim_oc4ref.

1110: Asymmetric PWM mode 1 - tim_oc3ref has the same behavior as in PWM mode 1. tim_oc3refc outputs tim_oc3ref when the counter is counting up, tim_oc4ref when it is counting down.

1111: Asymmetric PWM mode 2 - tim_oc3ref has the same behavior as in PWM mode 2. tim_oc3refc outputs tim_oc3ref when the counter is counting up, tim_oc4ref when it is counting down.

*Note:* These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S = 00 (the channel is configured in output).

*Note:* In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

On channels having a complementary output, this bitfield is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC3M active bits take the new value from the preloaded bits only when a COM event is generated.
Bit 3 **OC3PE**: Output compare 3 preload enable

Bit 2 **OC3FE**: Output compare 3 fast enable

Bits 1:0 **CC3S[1:0]**: Capture/compare 3 selection

- This bitfield defines the direction of the channel (input/output) as well as the used input.
  - 00: CC3 channel is configured as output
  - 01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
  - 10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4
  - 11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx_CCER).*

  Refer to CC1NP description
Bit 10  **CC3NE**: Capture/compare 3 complementary output enable  
Refer to CC1NE description

Bit 9  **CC3P**: Capture/compare 3 output polarity  
Refer to CC1P description

Bit 8  **CC3E**: Capture/compare 3 output enable  
Refer to CC1E description

Bit 7  **CC2NP**: Capture/compare 2 complementary output polarity  
Refer to CC1NP description

Bit 6  **CC2NE**: Capture/compare 2 complementary output enable  
Refer to CC1NE description

Bit 5  **CC2P**: Capture/compare 2 output polarity  
Refer to CC1P description

Bit 4  **CC2E**: Capture/compare 2 output enable  
Refer to CC1E description

Bit 3  **CC1NP**: Capture/compare 1 complementary output polarity  

**CC1 channel configured as output:**  
0: tim_oc1n active high.  
1: tim_oc1n active low.

**CC1 channel configured as input:**  
This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1 and tim_ti2fp1.  
Refer to CC1P description.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S = 00 (channel configured as output).

Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 2  **CC1NE**: Capture/compare 1 complementary output enable  
0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.  
1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NE active bit takes the new value from the preloaded bit only when a Commutation event is generated.
Bit 1  **CC1P**: Capture/compare 1 output polarity
0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)
When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of T11FP1 and T12FP1 for trigger or capture operations.
CC1NP = 0, CC1P = 0: non-inverted/rising edge. The circuit is sensitive to T1xFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), T1xFP1 is not inverted (trigger operation in gated mode or encoder mode).
CC1NP = 0, CC1P = 1: inverted/falling edge. The circuit is sensitive to T1xFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), T1xFP1 is inverted (trigger operation in gated mode or encoder mode).
CC1NP = 1, CC1P = 1: non-inverted/both edges. The circuit is sensitive to both T1xFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), T1xFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.
CC1NP = 1, CC1P = 0: the configuration is reserved, it must not be used.

**Note**: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

**Note**: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0  **CC1E**: Capture/compare 1 output enable
0: Capture mode disabled / OC1 is not active (see below)
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

When CC1 channel is configured as output, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to Table 422 for details.

**Note**: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR1[19:0]**: Capture/compare 1 value

If channel CC1 is configured as output: CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input: CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

Non-dithering mode (DITHEN = 0)

The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR2[19:0]**: Capture/compare 2 value

*If channel CC2 is configured as output*: CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

**Non-dithering mode (DITHEN = 0)**
The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

**Dithering mode (DITHEN = 1)**
The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

*If channel CC2 is configured as input*: CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

**Non-dithering mode (DITHEN = 0)**
The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.

**Dithering mode (DITHEN = 1)**
The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR4[19:0]: Capture/compare value**

**If channel CC4 is configured as output:** CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on tim_oc4 output.

*Non-dithering mode (DITHEN = 0)*

The register holds the compare value in CCR4[15:0]. The CCR4[19:16] bits are reset.

*Dithering mode (DITHEN = 1)*

The register holds the integer part in CCR4[19:4]. The CCR4[3:0] bitfield contains the dithered part.

**If channel CC4 is configured as input:** CCR4 is the counter value transferred by the last input capture 4 event (tim_ic4). The TIMx_CCR4 register is read-only and cannot be programmed.

*Non-dithering mode (DITHEN = 0)*

The register holds the capture value in CCR4[15:0]. The CCR4[19:16] bits are reset.

*Dithering mode (DITHEN = 1)*

The register holds the capture in CCR4[19:4]. The CCR4[3:0] bits are reset.

### 41.6.20  TIM1 break and dead-time register (TIM1_BDTR)

Address offset: 0x044

</tr>
</tbody>
</table>

**Note:** As the bits BK2BID/BK2BID/BK2P, BK2E, BK2F[3:0], BKF[3:0], AOE, BKP, BKE, OSSR, OSSR, and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx_BDTR register.
Bits 31:30  Reserved, must be kept at reset value.

Bit 29 **BK2BID**: Break2 bidirectional
Refer to BKBDID description

Bit 28 **BKBDID**: Break bidirectional
0: Break input tim_brk in input mode
1: Break input tim_brk in bidirectional mode
In the bidirectional mode (BKBDID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27 **BK2DSRM**: Break2 disarm
Refer to BKDSRM description

Bit 26 **BKDSRM**: Break disarm
0: Break input tim_brk is armed
1: Break input tim_brk is disarmed
This bit is cleared by hardware when no break source is active.
The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled it until it is reset by hardware, indicating that the fault condition has disappeared.

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 25 **BK2P**: Break 2 polarity
0: Break input tim_brk2 is active low
1: Break input tim_brk2 is active high

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 24 **BK2E**: Break 2 enable
This bit enables the complete break 2 protection (including all sources connected to bk_acth and BKIN sources, as per Figure 444: Break and Break2 circuitry overview).
0: Break2 function disabled
1: Break2 function enabled

*Note:* The BKIN2 must only be used with OSSR = OSSI = 1.

*Note:* This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bits 23:20 **BK2F[3:0]**: Break 2 filter

This bitfield defines the frequency used to sample tim_brk2 input and the length of the digital filter applied to tim_brk2. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, tim_brk2 acts asynchronously
0001: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), \( N = 2 \)
0010: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), \( N = 4 \)
0011: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), \( N = 8 \)
0100: \( f_{\text{SAMPLING}} = f_{DTS}/2 \), \( N = 6 \)
0101: \( f_{\text{SAMPLING}} = f_{DTS}/2 \), \( N = 8 \)
0110: \( f_{\text{SAMPLING}} = f_{DTS}/4 \), \( N = 6 \)
0111: \( f_{\text{SAMPLING}} = f_{DTS}/4 \), \( N = 8 \)
1000: \( f_{\text{SAMPLING}} = f_{DTS}/6 \), \( N = 6 \)
1001: \( f_{\text{SAMPLING}} = f_{DTS}/6 \), \( N = 8 \)
1010: \( f_{\text{SAMPLING}} = f_{DTS}/16 \), \( N = 5 \)
1011: \( f_{\text{SAMPLING}} = f_{DTS}/16 \), \( N = 6 \)
1100: \( f_{\text{SAMPLING}} = f_{DTS}/32 \), \( N = 5 \)
1101: \( f_{\text{SAMPLING}} = f_{DTS}/32 \), \( N = 6 \)
1110: \( f_{\text{SAMPLING}} = f_{DTS}/32 \), \( N = 8 \)
1111: \( f_{\text{SAMPLING}} = f_{DTS}/32 \), \( N = 8 \)

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 19:16 **BKF[3:0]**: Break filter

This bitfield defines the frequency used to sample tim_brk input and the length of the digital filter applied to tim_brk. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, tim_brk acts asynchronously
0001: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), \( N = 2 \)
0010: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), \( N = 4 \)
0011: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), \( N = 8 \)
0100: \( f_{\text{SAMPLING}} = f_{DTS}/2 \), \( N = 6 \)
0101: \( f_{\text{SAMPLING}} = f_{DTS}/2 \), \( N = 8 \)
0110: \( f_{\text{SAMPLING}} = f_{DTS}/4 \), \( N = 6 \)
0111: \( f_{\text{SAMPLING}} = f_{DTS}/4 \), \( N = 8 \)
1000: \( f_{\text{SAMPLING}} = f_{DTS}/6 \), \( N = 6 \)
1001: \( f_{\text{SAMPLING}} = f_{DTS}/6 \), \( N = 8 \)
1010: \( f_{\text{SAMPLING}} = f_{DTS}/16 \), \( N = 5 \)
1011: \( f_{\text{SAMPLING}} = f_{DTS}/16 \), \( N = 6 \)
1100: \( f_{\text{SAMPLING}} = f_{DTS}/32 \), \( N = 5 \)
1101: \( f_{\text{SAMPLING}} = f_{DTS}/32 \), \( N = 6 \)
1110: \( f_{\text{SAMPLING}} = f_{DTS}/32 \), \( N = 8 \)
1111: \( f_{\text{SAMPLING}} = f_{DTS}/32 \), \( N = 8 \)

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as one of the break inputs is active (tim_brk or tim_brk2). It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: In response to a break 2 event. OC and OCN outputs are disabled

In response to a break event or if MOE is written to 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.

1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register).

See OC/OCN enable description for more details ([Section 41.6.11: TIM1 capture/compare enable register (TIM1_CCER)]).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software

1: MOE can be set by software or automatically at the next update event (if none of the break inputs tim_brk and tim_brk2 is active)

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 **BKP**: Break polarity

0: Break input tim_brk is active low

1: Break input tim_brk is active high

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 **BKE**: Break enable

This bit enables the complete break protection (including all sources connected to bk_acth and BKIN sources, as per [Figure 444: Break and Break2 circuitry overview]).

0: Break function disabled

1: Break function enabled

*Note:* This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE = 1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details ([Section 41.6.11: TIM1 capture/compare enable register (TIM1_CCER)]).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic, which forces a Hi-Z state).

1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE = 1 or CCxNE = 1 (the output is still controlled by the timer).

*Note:* This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 10 **OSSI**: Off-state selection for idle mode

This bit is used when MOE = 0 due to a break event or by a software write, on channels configured as outputs.

See OC/OCN enable description for more details (Section 41.6.11: TIM1 capture/compare enable register (TIM1_CCER)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic and which imposes a Hi-Z state).

1: When inactive, OC/OCN outputs are first forced with their inactive level then forced to their idle level after the deadtime. The timer maintains its control over the output.

*Note*: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected.

01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKBI/BK2BID/BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note*: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bitfield defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5] = 0xx => DT = DTG[7:0]x t_dtg with t_dtg = tDTS.

DTG[7:5] = 10x => DT = (64+DTG[5:0])xtdtg with Tdtg = 2xTdts.

DTG[7:5] = 110 => DT = (32+DTG[5:0])xtdtg with Tdtg = 8xTdts.

DTG[7:5] = 111 => DT = (32+DTG[5:0])xtdtg with Tdtg = 16xTdts.

Example if T_DTS = 125 ns (8 MHz), dead-time possible values are:

0 to 15875 ns by 125 ns steps,
16 µs to 31750 ns by 250 ns steps,
32 µs to 63 µs by 1 µs steps,
64 µs to 126 µs by 2 µs steps

*Note*: This bitfield can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

</tbody>
</table>

Bits 28:20 Reserved, must be kept at reset value.

Bits 19:0 CCR5[19:0]: Capture/compare 5 value

CCR5 is the value to be loaded in the actual capture/compare 5 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC5PE). Else the preload value is copied in the active capture/compare 5 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc5 output.

Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR5[15:0]. The CCR5[19:16] bits are reset.

Dithering mode (DITHEN = 1)
The register holds the integer part in CCR5[19:4]. The CCR5[3:0] bitfield contains the dithered part.
41.6.23 TIM1 capture/compare mode register 3 (TIM1_CCMR3)

Address offset: 0x050
Reset value: 0x0000 0000

Refer to the above CCMR1 register description. Channels 5 and 6 can only be configured in output.

| Bits 31:25 | Reserved, must be kept at reset value. |
| Bit 23:17 | Reserved, must be kept at reset value. |
| Bit 15 | OC6CE: Output compare 6 clear enable |
| Bits 24, 14:12 | OC6M[3:0]: Output compare 6 mode |
| Bit 11 | OC6PE: Output compare 6 preload enable |
| Bit 10 | OC6FE: Output compare 6 fast enable |
| Bits 9:8 | Reserved, must be kept at reset value. |
| Bit 7 | OC5CE: Output compare 5 clear enable |
| Bits 16, 6:4 | OC5M[3:0]: Output compare 5 mode |
| Bit 3 | OC5PE: Output compare 5 preload enable |
| Bit 2 | OC5FE: Output compare 5 fast enable |
| Bits 1:0 | Reserved, must be kept at reset value. |
### 41.6.24 TIM1 timer deadtime register 2 (TIM1_DTR2)

</table>

**Bits 31:18** Reserved, must be kept at reset value.

**Bit 17** **DTPE**: Deadtime preload enable  
0: Deadtime value is not preloaded  
1: Deadtime value preload is enabled  
*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

**Bit 16** **DTAE**: Deadtime asymmetric enable  
0: Deadtime on rising and falling edges are identical, and defined with DTG[7:0] register  
1: Deadtime on rising edge is defined with DTG[7:0] register and deadtime on falling edge is defined with DTGF[7:0] bits.  
*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

**Bits 15:8** Reserved, must be kept at reset value.

**Bits 7:0** **DTGF[7:0]**: Dead-time falling edge generator setup  
This bitfield defines the duration of the dead-time inserted between the complementary outputs, on the falling edge.  
DTGF[7:5] = 0xx => DTF = DTGF[7:0] \* tdtg with tdtg = tDTS.  
DTGF[7:5] = 10x => DTF = (64+DTGF[5:0])\*xtdtg with Tdtg = 2\*tDTS.  
DTGF[7:5] = 110 => DTF = (32+DTGF[4:0])\*xtdtg with Tdtg = 4\*tDTS.  
DTGF[7:5] = 111 => DTF = (32+DTGF[4:0])\*xtdtg with Tdtg = 8\*tDTS.  
Example if T_{DTS} = 125 ns (8 MHz), dead-time possible values are:  
0 to 15875 ns by 125 ns steps,  
16 μs to 31750 ns by 250 ns steps,  
32 μs to 63 μs by 1 μs steps,  
64 μs to 126 μs by 2 μs steps  
*Note: This bitfield can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

**Bits 31:27**  
Reserved, must be kept at reset value.

**Bits 26:24**  
**PWPRSC[2:0]:** Pulse width prescaler  
This bitfield sets the clock prescaler for the pulse generator, as following:  
\[ t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim.ker.ck} \]

**Bits 23:16**  
**PW[7:0]:** Pulse width  
This bitfield defines the pulse duration, as following:  
\[ t_{PW} = PW[7:0] \times t_{PWG} \]

**Bits 15:8**  
Reserved, must be kept at reset value.

**Bits 7:6**  
**IPOS[1:0]:** Index positioning  
In quadrature encoder mode (SMS[3:0] = 0001, 0010, 0011, 1110, 1111), this bit indicates in which AB input configuration the Index event resets the counter.  
00: Index resets the counter when AB = 00  
01: Index resets the counter when AB = 01  
10: Index resets the counter when AB = 10  
11: Index resets the counter when AB = 11  
In directional clock mode or clock plus direction mode (SMS[3:0] = 1010, 1011, 1100, 1101), these bits indicates on which level the Index event resets the counter. In bidirectional clock mode, this applies for both clock inputs.  
x0: Index resets the counter when clock is 0  
x1: Index resets the counter when clock is 1  
*Note:* **IPOS[1]** bit is not significant

**Bit 5**  
**FIDX:** First index  
This bit indicates if the first index only is taken into account  
0: Index is always active  
1: the first Index only resets the counter
41.6.26  TIM1 timer input selection register (TIM1_TISEL)

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:14 **ETRSEL[3:0]: etr_in source selection**

These bits select the etr_in input source.

0000: tim_etr0: TIMx_ETR input

0001: tim_etr1

... 1111: tim_etr15

Refer to Section 41.3.2: TIM1 pins and internal signals for product specific implementation.

Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 **BKCMP4P: tim_brk_cmp4 input polarity**

This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp4 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)

1: tim_brk_cmp4 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 12 **BKCMP3P**: tim\_brk\_cmp3 input polarity

This bit selects the tim\_brk\_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim\_brk\_cmp3 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim\_brk\_cmp3 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 11 **BKCMP2P**: tim\_brk\_cmp2 input polarity

This bit selects the tim\_brk\_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim\_brk\_cmp2 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim\_brk\_cmp2 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 10 **BKCMP1P**: tim\_brk\_cmp1 input polarity

This bit selects the tim\_brk\_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim\_brk\_cmp1 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim\_brk\_cmp1 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 9 **BKINP**: TIMx\_BKin input polarity

This bit selects the TIMx\_BKin alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

0: TIMx\_BKin input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: TIMx\_BKin input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 8 **BKCMP8E**: tim\_brk\_cmp8 enable

This bit enables the tim\_brk\_cmp8 for the timer’s tim\_brk input. tim\_brk\_cmp8 output is 'ORed' with the other tim\_brk sources.

0: tim\_brk\_cmp8 input disabled
1: tim\_brk\_cmp8 input enabled

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 7 **BKCMP7E**: tim\_brk\_cmp7 enable

This bit enables the tim\_brk\_cmp7 for the timer’s tim\_brk input. tim\_brk\_cmp7 output is 'ORed' with the other tim\_brk sources.

0: tim\_brk\_cmp7 input disabled
1: tim\_brk\_cmp7 input enabled

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 6 **BKCMP6E**: tim\_brk\_cmp6 enable

This bit enables the tim\_brk\_cmp6 for the timer’s tim\_brk input. tim\_brk\_cmp6 output is 'ORed' with the other tim\_brk sources.

0: tim\_brk\_cmp6 input disabled
1: tim\_brk\_cmp6 input enabled

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).
Bit 5 **BKCMP5E**: tim_brk_cmp5 enable
This bit enables the tim_brk_cmp5 for the timer's tim_brk input. tim_brk_cmp5 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp5 input disabled
1: tim_brk_cmp5 input enabled
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 4 **BKCMP4E**: tim_brk_cmp4 enable
This bit enables the tim_brk_cmp4 for the timer's tim_brk input. tim_brk_cmp4 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp4 input disabled
1: tim_brk_cmp4 input enabled
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 3 **BKCMP3E**: tim_brk_cmp3 enable
This bit enables the tim_brk_cmp3 for the timer's tim_brk input. tim_brk_cmp3 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp3 input disabled
1: tim_brk_cmp3 input enabled
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 2 **BKCMP2E**: tim_brk_cmp2 enable
This bit enables the tim_brk_cmp2 for the timer's tim_brk input. tim_brk_cmp2 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp2 input disabled
1: tim_brk_cmp2 input enabled
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 1 **BKCMP1E**: tim_brk_cmp1 enable
This bit enables the tim_brk_cmp1 for the timer's tim_brk input. tim_brk_cmp1 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp1 input disabled
1: tim_brk_cmp1 input enabled
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 0 **BKINE**: TIMx_BKIN input enable
This bit enables the TIMx_BKIN alternate function input for the timer's tim_brk input. TIMx_BKIN input is 'ORed' with the other tim_brk sources.
0: TIMx_BKIN input disabled
1: TIMx_BKIN input enabled
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Refer to **Section 41.3.2: TIM1 pins and internal signals** for product specific implementation.

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 BK2CMP4P: tim_brk2_cmp4 input polarity

This bit selects the tim_brk2_cmp4 input sensitivity. It must be programmed together with the BK2P polarity bit.
0: tim_brk2_cmp4 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
1: tim_brk2_cmp4 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 12 BK2CMP3P: tim_brk2_cmp3 input polarity

This bit selects the tim_brk2_cmp3 input sensitivity. It must be programmed together with the BK2P polarity bit.
0: tim_brk2_cmp3 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
1: tim_brk2_cmp3 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 11 BK2CMP2P: tim_brk2_cmp2 input polarity

This bit selects the tim_brk2_cmp2 input sensitivity. It must be programmed together with the BK2P polarity bit.
0: tim_brk2_cmp2 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
1: tim_brk2_cmp2 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 10 **BK2CMP1P**: tim_brk2_cmp1 input polarity
This bit selects the tim_brk2_cmp1 input sensitivity. It must be programmed together with the BK2P polarity bit.
0: tim_brk2_cmp1 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
1: tim_brk2_cmp1 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 9 **BK2INP**: TIMx_BKIN2 input polarity
This bit selects the TIMx_BKIN2 alternate function input sensitivity. It must be programmed together with the BK2P polarity bit.
0: TIMx_BKIN2 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
1: TIMx_BKIN2 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **BK2CMP8E**: tim_brk2_cmp8 enable
This bit enables the tim_brk2_cmp8 for the timer’s tim_brk2 input. tim_brk2_cmp8 output is 'ORed' with the other tim_brk2 sources.
0: tim_brk2_cmp8 input disabled
1: tim_brk2_cmp8 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7 **BK2CMP7E**: tim_brk2_cmp7 enable
This bit enables the tim_brk2_cmp7 for the timer’s tim_brk2 input. tim_brk2_cmp7 output is 'ORed' with the other tim_brk2 sources.
0: tim_brk2_cmp7 input disabled
1: tim_brk2_cmp7 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 6 **BK2CMP6E**: tim_brk2_cmp6 enable
This bit enables the tim_brk2_cmp6 for the timer’s tim_brk2 input. tim_brk2_cmp6 output is 'ORed' with the other tim_brk2 sources.
0: tim_brk2_cmp6 input disabled
1: tim_brk2_cmp6 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 5 **BK2CMP5E**: tim_brk2_cmp5 enable
This bit enables the tim_brk2_cmp5 for the timer’s tim_brk2 input. tim_brk2_cmp5 output is 'ORed' with the other tim_brk2 sources.
0: tim_brk2_cmp5 input disabled
1: tim_brk2_cmp5 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 4 **BK2CMP4E**: tim_brk2_cmp4 enable
This bit enables the tim_brk2_cmp4 for the timer’s tim_brk2 input. tim_brk2_cmp4 output is 'ORed' with the other tim_brk2 sources.
0: tim_brk2_cmp4 input disabled
1: tim_brk2_cmp4 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
### 41.6.29 TIM1 DMA control register (TIM1_DCR)

**Bit 3 BK2CMP3E:** tim_brk2_cmp3 enable  
This bit enables the tim_brk2_cmp3 for the timer’s tim_brk2 input. tim_brk2_cmp3 output is 'ORed' with the other tim_brk2 sources.  
0: tim_brk2_cmp3 input disabled  
1: tim_brk2_cmp3 input enabled  
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Bit 2 BK2CMP2E:** tim_brk2_cmp2 enable  
This bit enables the tim_brk2_cmp2 for the timer’s tim_brk2 input. tim_brk2_cmp2 output is 'ORed' with the other tim_brk2 sources.  
0: tim_brk2_cmp2 input disabled  
1: tim_brk2_cmp2 input enabled  
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Bit 1 BK2CMP1E:** tim_brk2_cmp1 enable  
This bit enables the tim_brk2_cmp1 for the timer’s tim_brk2 input. tim_brk2_cmp1 output is 'ORed' with the other tim_brk2 sources.  
0: tim_brk2_cmp1 input disabled  
1: tim_brk2_cmp1 input enabled  
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Bit 0 BK2INE:** TIMx_BKIN2 input enable  
This bit enables the TIMx_BKIN2 alternate function input for the timer’s tim_brk2 input. TIMx_BKIN2 input is ‘ORed’ with the other tim_brk2 sources.  
0: TIMx_BKIN2 input disabled  
1: TIMx_BKIN2 input enabled  
*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Refer to Section 41.3.2: TIM1 pins and internal signals for product specific implementation.
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:16  **DBSS[3:0]: DMA burst source selection**

This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).

- 0000: Reserved
- 0001: Update
- 0010: CC1
- 0011: CC2
- 0100: CC3
- 0101: CC4
- 0110: COM
- 0111: Trigger
- Others: reserved

Bits 15:13  Reserved, must be kept at reset value.

Bits 12:8  **DBL[4:0]: DMA burst length**

This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e., the number of transfers. Transfers can be in half-words or in bytes (see example below).

- 00000: 1 transfer
- 00001: 2 transfers
- 00010: 3 transfers
- ...
- 11010: 26 transfers

**Example:** Let us consider the following transfer: DBL = 7 bytes & DBA = TIM2_CR1.

- If DBL = 7 bytes and DBA = TIM2_CR1 represents the address of the byte to be transferred, the address of the transfer is given by the following equation:
  
  \[(\text{TIMx_CR1 address}) + \text{DBA} + \text{(DMA index)}\]

  In this example, 7 bytes are added to (TIMx_CR1 address) + DBA, which gives us the address from/to which the data are copied. In this case, the transfer is done to 7 registers starting from the following address: (TIMx_CR1 address) + DBA

  According to the configuration of the DMA Data Size, several cases may occur:

  - If the DMA Data Size is configured in half-words, 16-bit data are transferred to each of the 7 registers.
  - If the DMA Data Size is configured in bytes, the data are also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on.

So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0  **DBA[4:0]: DMA base address**

This 5-bit vector defines the base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

**Example:**

- 00000: TIMx_CR1
- 00001: TIMx_CR2
- 00010: TIMx_SMCR
- ...
41.6.30 TIM1 DMA address for full transfer (TIM1_DMAR)

</table>

Bits 31:0 DMAB[31:0]: DMA register for burst accesses
A read or write operation to the DMAR register accesses the register located at the address
(TIMx_CR1 address) + (DBA + DMA index) x 4
where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base
address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA
transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).

41.6.31 TIM1 register map

Refer to Section 2.3 on page 149 for the register boundary addresses.
42 General-purpose timers (TIM2/TIM3/TIM4/TIM5)

42.1 TIM2/TIM3/TIM4/TIM5 introduction

The general-purpose timers consist of a 16-bit or 32-bit autoreload counter driven by a programmable prescaler.

They can be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare and PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 42.4.23: Timer synchronization.

42.2 TIM2/TIM3/TIM4/TIM5 main features

General-purpose TIMx timer features include:

• 16-bit or 32-bit up, down, up/down autoreload counter.
• 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
• Up to four independent channels for:
  – Input capture.
  – Output compare.
  – PWM generation (edge- and center-aligned modes).
  – One-pulse mode output.
• Synchronization circuit to control the timer with external signals and to interconnect several timers.
• Interrupt/DMA generation on the following events:
  – Update: counter overflow/underflow, counter initialization (by software or internal/external trigger).
  – Trigger event (counter start, stop, initialization, or count by internal/external trigger).
  – Input capture.
  – Output compare.
• Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes.
• Trigger input for external clock or cycle-by-cycle current management.
42.3 TIM2/TIM3/TIM4/TIM5 implementation

42.4.3 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related autoreload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the autoreload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Autoreload register (TIMx_ARR).

The autoreload register is preloaded. Writing to or reading from the autoreload register accesses the preload register. The content of the preload register is transferred into the shadow register permanently or at each update event (UEV), depending on the autoreload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when down-counting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the actual counter enable signal CNT_EN is set one clock cycle after CEN.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIMx_PSC...
register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 487* and *Figure 488* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

**Figure 487. Counter timing diagram with prescaler division change from 1 to 2**

![Counter timing diagram with prescaler division change from 1 to 2](image)
42.4.4 Counter modes

Up-counting mode

In up-counting mode, the counter counts from 0 to the autoreload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The autoreload shadow register is updated with the preload value (TIMx_ARR).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

Write a new value in TIMx_ARR
Figure 494. Counter timing diagram, Update event when ARPE = 1 (TIMx_ARR preloaded)

Down-counting mode

In down-counting mode, the counter counts from the autoreload value (content of the TIMx_ARR register) down to 0, then restarts from the autoreload value and generates a counter underflow event.

An update event can be generated at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current autoreload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate does not change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The autoreload active register is updated with the preload value (content of the TIMx_ARR register). Note that the autoreload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

### Center-aligned mode (up/down-counting)

In center-aligned mode, the counter counts from 0 to the autoreload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the
autoreload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to 00. The output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = 01), the counter counts up (Center aligned mode 2, CMS = 10) the counter counts up and down (Center aligned mode 3, CMS = 11).

In this mode, the direction bit (DIR from TIMx_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current autoreload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The autoreload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the autoreload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.
Figure 500. Counter timing diagram, internal clock divided by 1, TIMx_ARR = 0x6

1. Here, center-aligned mode 1 is used (for more details refer to Section 42.5.1: TIMx control register 1 (TIMx_CR1)(x = 2 to 5)).

42.4.5 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck).
- External clock mode1: external input pin (tim_t1 or tim_t2).
- External clock mode2: external trigger input (tim_etr_in).
- Internal trigger inputs (tim_itr): using one timer as prescaler for another timer, for example, timer 1 can be configured to act as a prescaler for timer 2. Refer to Using one timer as prescaler for another timer for more details.

**Internal clock source (tim_ker_ck)**

If the slave mode controller is disabled (SMS = 000 in the TIMx_SMCR register), then the CEN, DIR (in the TIMx_CR1 register), and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

*Figure 506* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
External clock source mode 1

This mode is selected when SMS = 111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

For example, to configure the upcounter to count in response to a rising edge on the TIM2 input, use the following procedure:

1. Select the proper TIM2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the TIM2 input by writing CC2S = 01 in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F = 0000).
Note: The capture prescaler is not used for triggering, so it does not need to be configured.

4. Select rising edge polarity by writing CC2P = 0 and CC2NP = 0 in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS = 111 in the TIMx_SMCR register.
6. Select tim_ti2 as the input source by writing TS = 00110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN = 1 in the TIMx_CR1 register.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 508. Control circuit in external clock mode 1

External clock source mode 2

This mode is selected by writing ECE = 1 in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input tim_etr_in.

Figure 509 gives an overview of the external trigger input block.
For example, to configure the upcounter to count each two rising edges on TIM_ETR_in, use the following procedure:

1. Select the proper TIM_ETR_in source (internal or external) with the ETRSEL[3:0] bits in the TIMx_AF1 register.
2. As no filter is needed in this example, write ETF[3:0] = 0000 in the TIMx_SMCR register.
3. Set the prescaler by writing ETPS[1:0] = 01 in the TIMx_SMCR register.
4. Select rising edge detection on the TIM_ETR_in by writing ETP = 0 in the TIMx_SMCR register.
5. Enable external clock mode 2 by writing ECE = 1 in the TIMx_SMCR register.
6. Enable the counter by writing CEN = 1 in the TIMx_CR1 register.

The counter counts once each two TIM_ETR_in rising edges.

The delay between the rising edge on TIM_ETR_in and the actual clock of the counter is due to the resynchronization circuit on the TIM_ETRP signal. As a consequence, the maximum frequency that can be correctly captured by the counter is at most ¼ of TIMxCLK frequency. When the ETRP signal is faster, the user must apply a division of the external signal by a proper ETPS prescaler setting.
42.4.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of one Capture/Compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfpy) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 511. Capture/compare channel (example: channel 1 input stage)
The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

**Figure 512. Capture/compare channel 1 main circuit**

![Capture/compare channel 1 main circuit diagram]

**Figure 513. Output stage of capture/compare channel (channel 1, idem ch.2, 3 and 4)**

![Output stage of capture/compare channel diagram]

1. Available on some instances only. If not available, tim_etrf is directly connected to tim_ocref_clr_int.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.
In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

**42.4.7 Input capture mode**

In input capture mode, the capture/compare registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCXIF flag was already high, then the overcapture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

1. Select the proper tim_tix_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the needed input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most five internal clock cycles. We must program a filter duration longer than these five clock cycles. We can validate a transition on tim_ti1 when eight consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the tim_ti1 channel by writing the CC1P and CC1NP bits to 000 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In this example, the capture is to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

**Note:** IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.
42.4.8 PWM input mode

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges).
- The TIM_CCR2 register holds the pulse width (interval between two consecutive rising and falling edges).

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same tim_tix input.
- These two ICx signals are active on edges with opposite polarity.
- One of the two T1xFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

The period and the pulse width of a PWM signal applied on tim_t1 can be measured using the following procedure:

1. Select the proper tim_tix_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_t1 selected).
3. Select the active polarity for tim_t1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P to 0 and the CC1NP bit to 0 (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_t1 selected).
5. Select the active polarity for tim_t1fp2 (used for capture in TIMx_CCR2): write the CC2P bit to 1 and the CC2NP bit to 0 (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_t1fp1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to 1 in the TIMx_CCER register.
42.4.9 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (TIMx_OCxref and then TIMx_OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (TIMx_OCxref/TIMx_OCx) to its active level, the user just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus TIMx_OCxref is forced high (TIMx_OCxref is always active high) and TIMx_OCx get opposite value to CCxP polarity bit.

For example: CCxP = 0 (TIMx_OCx active high) => TIMx_OCx is forced to high level.

TIMx_OCxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the Output Compare mode section.

42.4.10 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCXM = 000), be set

1. The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only TIMx_CH1fp1 and TIMx_CH2fp2 are connected to the slave mode controller.
active (OCxM = 001), be set inactive (OCxM = 010) or can toggle (OCxM = 011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

**Procedure**

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example:
   a) Write OCxM = 0011 to toggle tim_ocx output pin when CNT matches CCRx.
   b) Write OCxPE = 0 to disable preload register.
   c) Write CCxP = 0 to select active high polarity.
   d) Write CCxE = 1 to enable the output.
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE = 0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in *Figure 515*. 
42.4.11 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing 110 (PWM mode 1) or 111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the autoreload preload register (in up-counting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxE bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter). The tim_ocref_clr can be cleared by an external event through the tim_etr_in or the tim_ocref_clr signals. In this case the tim_ocref_clr signal is asserted only:

- After a compare match event.
- When the output compare mode (OCxM bits in TIMx_CCMRx register) switches from the “frozen” configuration (no comparison, OCxM = 000) to one of the PWM modes (OCxM = 110 or 111). This forces the PWM by software while the timer is running.

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.
PWM edge-aligned mode

- Up-counting configuration
- Up-counting is active when the DIR bit in the TIMx_CR1 register is low. Refer to Up-counting mode.

In the following example, we consider PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the autoreload value (in TIMx_ARR) then tim_ocxref is held at 1. If the compare value is 0 then tim_ocxref is held at 0. Figure 516 shows some edge-aligned PWM waveforms in an example where TIMx_ARR = 8.

![Figure 516. Edge-aligned PWM waveforms (ARR = 8)](image)

Down-counting configuration

- Down-counting is active when DIR bit in TIMx_CR1 register is high. Refer to Down-counting mode.

In PWM mode 1, the reference signal tim_ocxref is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the autoreload value in TIMx_ARR, then tim_ocxref is held at 100%. PWM is not possible in this mode.

PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from 00 (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit
(DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to Center-aligned mode (up/down-counting).

Figure 517 shows some center-aligned PWM waveforms in an example where:

- TIMx_ARR = 8.
- PWM mode is the PWM mode 1.
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS = 01 in TIMx_CR1 register.

Hints on using center-aligned mode:
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit.
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the autoreload value is written in the counter (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no update event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

**Dithering mode**

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. *Figure 518* presents the dithering principle applied to four consecutive PWM cycles.

*Figure 518. Dithering principle*

When the dithering mode is enabled, the register coding is changed as following (see *Figure 519* for example):

- The four LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted by four places and are coding for the base value. In 16-bit mode, the 16-bit format is maintained.
Note: The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset.
2. The DITHEN bit must be reset.
3. The CCIF flags must be cleared.
4. The CEN bit can be set (eventually with ARPE = 1).

Figure 519. Data format and register coding in dithering mode

The minimum frequency is given by the following formula:

\[
\text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \\Rightarrow F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{\text{Max Resolution}}
\]

Dithering mode disabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65536} \)

Dithering mode (16-bit timer): \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}} \)

Dithering mode (32-bit timer): \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{268435454 + \frac{15}{16}} \)

Note: For 16-bit timers, the maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFFE in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).
For 32-bit timers, the maximum TIMx_ARR and TIMxCCRy values are limited to
0xFFFFFEEF in dithering mode (corresponds to 264435454 for the integer part and 15 for the dithered part).

As shown on Figure 520 and Figure 521, the dithering mode is used to increase the PWM resolution.

Figure 520. PWM resolution vs frequency (16-bit mode)

Figure 521. PWM resolution vs frequency (32-bit mode)

The duty cycle and/or period changes are spread over 16 consecutive periods, as described in Figure 522.
The autoreload and compare values increments are spread following specific patterns described in Table 433. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.
The dithering mode is also available in center-aligned PWM mode (CMS bits in TIMx_CR1 register are not equal to 00). In this case, the dithering pattern is applied over eight consecutive PWM periods, considering the up and down-counting phases as shown in Figure 523.

42.4.12 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx registers. One register controls the PWM during up-counting, the second during down-counting, so that PWM is adjusted every half PWM cycle:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2.
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4.

Asymmetric PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing 1110 (Asymmetric PWM mode 1) or 1111 (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

Note: The OCxM[3:0] bitfield is split into two parts for compatibility reasons, the most significant bit is not contiguous with the three least significant ones.

When a given channel is used as asymmetric PWM channel, its secondary channel can also be used. For instance, if an tim_oc1refc signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the tim_oc2ref signal on channel 2, or an tim_oc2refc signal resulting from asymmetric PWM mode 2.
Figure 524 shows an example of signals that can be generated using asymmetric PWM mode (channels 1 to 4 are configured in asymmetric PWM mode 2).

**42.4.13 Combined PWM mode**

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing 1100 (Combined PWM mode 1) or 1101 (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its secondary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bitfield is split into two parts for compatibility reasons, the most significant bit is not contiguous with the three least significant ones.

Figure 525 shows an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2.
- Channel 2 is configured in PWM mode 1.
- Channel 3 is configured in Combined PWM mode 2.
- Channel 4 is configured in PWM mode 1.
42.4.14 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The tim_ocref_clr_int source depends on the OCREF clear selection feature implementation, refer to Section 42.3: TIM2/TIM3/TIM4/TIM5 implementation.

If the OCREF clear selection feature is implemented, the tim_ocref_clr_int can be selected between the tim_ocref_clr input and the tim_etrf input (tim_etrf_in after the filter) by configuring the OCCE bit in the TIMx_SMCR register. The tim_ocref_clr input can be selected among several tim_ocref_clr[7:0] inputs, using the OCRSEL[2:0] bitfield in the TIMx_AF2 register, as shown in Figure 526.
If the OCREF clear selection feature is not implemented, the tim_ocref_clr_int input is directly connected to the tim_etrf input.

For example, the tim_ocref_clr_int signal can be connected to the output of a comparator to be used for current handling. In this case, tim_etrf must be configured as follows:

1. The external trigger prescaler must be kept off: bits ETPS[1:0] in the TIMx_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application’s needs.

Figure 527 shows the behavior of the tim_ocxref signal when the tim_etrf input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.
Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), tim_ocxref is enabled again at the next counter overflow.

42.4.15 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

CNT<CCRx ≤ ARR (in particular, 0<CCRx).

Figure 528. Example of One-pulse mode

For example if the user wants to generate a positive pulse on tim_oc1 with a length of tPULSE and after a delay of tDELAY as soon as a positive edge is detected on the tim_ti2 input pin.

Use tim_ti2fp2 as trigger 1:
1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map tim_ti2fp2 on tim_ti2 by writing CC2S = 01 in the TIMx_CCMR1 register.
3. tim_ti2fp2 must detect a rising edge, write CC2P = 0 and CC2NP = 0 in the TIMx_CCER register.
4. Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS = 00110 in the TIMx_SMCR register.
5. tim_ti2fp2 is used to start the counter by writing SMS to 110 in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).
- The tDELAY is defined by the value written in the TIMx_CCR1 register.
- The tPULSE is defined by the difference between the autoreload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Suppose the user wants to build a waveform with a transition from 0 to 1 when a compare match occurs and a transition from 1 to 0 when the counter reaches the autoreload value. To do this PWM mode 2 must be enabled by writing OC1M = 111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE = 1 in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the autoreload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2, CC1P is written to 0 in this example.

In this example, the DIR and CMS bits in the TIMx_CR1 register must be low.

Since only one pulse (Single mode) is needed, a one must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the autoreload value back to 0). When OPM bit in the TIMx_CR1 register is set to 0, so the Repetitive mode is selected.

**Particular case: tim_ocx fast enable:**

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay tDELAY min we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 42.4.16 Retriggerable one-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with non-retriggerable one-pulse mode described in Section 42.4.15:
- The pulse starts as soon as the trigger occurs (no programmable delay).
- The pulse is extended if a new trigger occurs before the previous one is completed.
The timer must be in Slave mode, with the bits SMS[3:0] = 1000 (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to 1000 or 1001 for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in down-counting mode CCRx must be above or equal to ARR.

**Note:** In Retriggerable one-pulse mode, the CCxIF flag is not significant.

The OCxM[3:0] and SMS[3:0] bitfields are split into two parts for compatibility reasons, the most significant bit is not contiguous with the three least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

### 42.4.17 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulse width generated when the counter value equals a given compare value, for debugging or synchronization purposes.

This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on Figure 530.
**General-purpose timers (TIM2/TIM3/TIM4/TIM5)**

**Figure 530. Pulse generator circuitry**

![Pulse generator circuitry diagram](image)

**Figure 531. Pulse generation on compare event, for edge-aligned and encoder modes**

![Pulse generation diagram](image)

This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bitfields in TIMx_CCMR2 register.
The pulse width is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

\[ t_{PW} = PW[7:0] \times t_{PWG} \]

where \( t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim\_ker\_ck} \)

gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

**Note:** If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the first arriving trigger is extended (because of the retrigger), while the pulse width of the last arriving trigger is correct (as shown on Figure 532).

![Figure 532. Extended pulse width in case of concurrent triggers](MSv62348V1)

### 42.4.18 Encoder interface mode

**Quadrature encoder**

To select Encoder interface mode write SMS = 0001 in the TIMx_SMCR register if the counter is counting on tim_t1 edges only, SMS = 0010 if it is counting on tim_t2 edges only and SMS = 0011 if it is counting on both tim_t1 and tim_t2 edges.

Select the tim_t1 and tim_t2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. CC1NP and CC2NP must be kept cleared. When needed, the input filter can be programmed as well.

The two inputs tim_t1 and tim_t2 are used to interface to an incremental encoder. Refer to Table 435. The counter is clocked by each valid transition on tim_t1fp1 or tim_t2fp2 (tim_t1 and tim_t2 after input filter and polarity selection, tim_t1fp1 = tim_t1 if not filtered and not inverted, tim_t2fp2 = tim_t2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to 1). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_t1 or
tim_t12), whatever the counter is counting on tim_t1 only, tim_t12 only or both tim_t1 and tim_t12.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the autoreload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction corresponds to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_t1 and tim_t12 do not switch at the same time.

A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicates the mechanical zero position, can be connected to the external trigger input and trigger a counter reset.

**Figure 533** gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are
selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S = 01 (TIMx_CCMR1 register, tim_ti1fp1 mapped on tim_ti1).
- CC2S = 01 (TIMx_CCMR1 register, tim_ti2fp2 mapped on tim_ti2).
- CC1P and CC1NP = 0 (TIMx_CCER register, tim_ti1fp1 noninverted, tim_ti1fp1 = tim_ti1).
- CC2P and CC2NP = 0 (TIMx_CCER register, tim_ti2fp2 noninverted, tim_ti2fp2 = tim_ti2).
- SMS = 0011 (TIMx_SMCR register, both inputs are active on both rising and falling edges).
- CEN = 1 (TIMx_CR1 register, counter is enabled).

**Figure 533. Example of counter operation in encoder interface mode**

![Counter Operation Diagram](MSv62349V1)

*Figure 534* gives an example of counter behavior when tim_ti1fp1 polarity is inverted (same configuration as above except CC1P = 1).

**Figure 534. Example of encoder interface mode with tim_ti1fp1 polarity inverted**

![Polarity Inverted Diagram](MSv62350V1)
Figure 535 shows the timer counter value during a speed reversal, for various counting modes.

**Figure 535. Quadrature encoder counting modes**

The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register’s bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

**Clock plus direction encoder mode**

In addition to the quadrature encoder mode, the timer offers support for other types of encoders.

In the “clock plus direction” mode shown on Figure 536, the clock is provided on a single line, on tim_ti2, while the direction is forced using the tim_ti1 input.
This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- **1010**: x2 mode, the counter is updated on both rising and falling edges of the clock.
- **1011**: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity.

The polarity of the direction signal on tim_ti1 is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when tim_ti1 is high and down-counting when tim_ti1 is low) and CC1P = 1 corresponds to negative polarity (up-counting when tim_ti1 is low).

**Figure 536. Direction plus clock encoder mode**

**Directional clock encoder mode**

In the “directional clock” mode on Figure 537, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- **1100**: x2 mode, the counter is updated on both rising and falling edges of any of the two clock lines. The CC1P and CC2P bits are coding for the clock idle state. CCxP = 0 corresponds to high-level idle state (refer to Figure 537) and CCxP = 1 corresponds to low-level idle state (refer to Figure 538).
- **1101**: x1 mode, the counter is updated on a single clock edge, as per CC1P and CC2P bit value. CCxP = 0 corresponds to falling edge sensitivity and high-level idle state (refer to Figure 537), CCxP = 1 corresponds to rising edge sensitivity and low-level idle state (refer to Figure 538).

**Index input**

The counter can be reset by an index signal coming from the encoder, indicating an absolute reference position. The index signal must be connected to the tim_etr_in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMx_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0001, 0010, 011, 1010, 1011, 1100, 1101, 1110, 1111.

Available encoders are proposed with several options for index pulse conditioning, as per Figure 539:

- Gated with A and B: the pulse width is 1/4 of one channel period, aligned with both A and B edges.
- Gated with A (or gated with B): the pulse width is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B).
- Ungated: the pulse width is up to one channel period, without any alignment to the edges.
The circuitry tolerates jitter on index signal, whatever the gating mode, as shown on Figure 540.

In ungated mode, the signal must be strictly below two encoder periods. If the pulse width is greater or equal to two encoder period, the counter is reset multiple times.

The timer supports the three gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (for example channel A and channel B state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIMx_ECR register.

The index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:

- The counter is reset during up-counting (DIR bit = 0).
- The counter is set to TIMx_ARR when down-counting.

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. Figure 541 shows at which position is the index generated, for a simplistic example (an encoder providing four edges per mechanical rotation).
Figure 541. Index generation for IPOS[1:0] = 11

Figure 542 presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is 11 (ChA = 1, ChB = 1), when up-counting (DIR bit = 0).
- Counter set to TIMx_ARR when exiting the 11 state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.
The arrows are indicating on which transition is the index event interrupt generated.

**Figure 547** shows how the index is managed in x1 and x2 modes.

![Index behavior in x1 and x2 mode (IPOS[1:0] = 01)](image)

**Directional index sensitivity**

The IDIR[1:0] bitfield in the TIMx_ECR register allows the index to be active only in a selected counting direction.

**Figure 548** shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

![Directional index sensitivity](image)
Special first index event management

The FIDX bit in the TIMx_ECR register allows the index to be taken only once, as shown on Figure 549. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be rearmed by writing the FIDX bit to 0 and setting it again to 1.

**Figure 549. Counter reset as function of FIDX bit setting**

Index blanking

The index event can be blanked using the tim_ti3 or tim_ti4 inputs. During the blanking window, the index events are no longer resetting the counter, as shown on Figure 550.

This mode is enabled using the IBLK[1:0] bitfield in the TIMx_ECR register, as following:
- IBLK[1:0] = 00: Index signal always active.
- IBLK[1:0] = 01: Index signal blanking on tim_ti3 input.
- IBLK[1:0] = 10: Index signal blanking on tim_ti4 input.

**Figure 550. Index blanking**
Index management in nonquadrature mode

*Figure 551* and *Figure 552* detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[3:0] bitfield is equal to 1010, 1011, 1100, 1101.

For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:
- IPOS[0] = 0: Index is detected on clock low level.
- IPOS[0] = 1: Index is detected on clock high level.

The IPOS[1] bit is not-significant.

**Figure 551. Index behavior in clock + direction mode, IPOS[0] = 1**

**Figure 552. Index behavior in directional clock mode, IPOS[0] = 1**

Encoder error management

For encoder configurations where two quadrature signals are available, it is possible to detect transition errors. The reading on the two inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on *Figure 553*. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIMx_SR
status register. A transition error interrupt is generated if the TERRIE bit is set in the TIMx_DIER register.

**Figure 553. State diagram for quadrature encoded signals**

For encoder having an index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIMx_ARR to 0 or decremented from 0 to TIMxARR value without any index event, this is reported as an index position error.

The overflow threshold is programmed using the TIMx_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIMx_ARR = 3999 + 1 = 4000.
The error assertion is delayed to the transition 0 to 1 when in up-counting. This is to cope with narrow index pulses in gated A and B mode, as shown on Figure 554.

Error detected | Error asserted
In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on Figure 555, to avoid any false error detection in case the encoder dithers between TIMx_ARR and 0 immediately after the index detection.

**Figure 555. Down-counting encode error detection**

An index error sets the IERRF interrupt flag in the TIMx_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIMx_DIER register.

**Functional encoder interrupts**

The following interrupts are also available in encoder mode:

- **Direction change**: any change of the counting direction in encoder mode causes the DIR bit in the TIMx_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIMx_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIMx_DIER register.

- **Index event**: the index event sets the IDXF interrupt flag in the TIMx_SR status register. An index interrupt is generated if the IDXIE bit is set in the TIMx_DIER register.
Slave mode selection preload for run-time encoder mode update

It can be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the update interrupt rate, by switching from x4 to x2 to x1 mode, as shown on Figure 556.

For this purpose, the SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value can be selected with the SMPS bit in the TIMx_SMCR register.

- SMPS = 0: the transfer is triggered by the update event (UEV) occurring when the counter overflows when up-counting, and underflows when down-counting.
- SMPS = 1: the transfer is triggered by the index event.

Figure 556. Encoder mode change with preload transferred on update (SMPS = 0)

Encoder clock output

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIMx_CR2 register. It is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

42.4.19 Direction bit output

It is possible to output a direction signal out of the timer, on the tim_oc3 and tim_oc4 output signals (copy of the DIR bit in the TIMx_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bitfield to 1011 in the TIMx_CCMR2 register.
This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

42.4.20 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into bit 31 of the timer counter register’s bit 31 (TIMxCNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

42.4.21 Timer input XOR function

The TI1S bit in the TIM1xx_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3.

The XOR output can be used with all the timer input functions such as trigger or input capture.

An example of this feature used to interface Hall sensors is given in Section 41.3.29: Interfacing with Hall sensors.

42.4.22 Timers and external trigger synchronization

The TIMx timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

1. Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P = 0 and CC1NP = 0 in TIMx_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS = 100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIMx_SMCR register.
3. Start the counter by writing CEN = 1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the
trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the autoreload register TIMx_ARR = 0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

![Control circuit in reset mode](MSv62361V1)

**Figure 557. Control circuit in reset mode**

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_ti1 input is low:

1. Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in TIMx_CCMR1 register. Write CC1P = 1 and CC1NP = 0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS = 101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN = 1 in the TIMx_CR1 register (in gated mode, the counter does not start if CEN = 0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.
Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TIM\_ti2 input:

1. Configure the channel 2 to detect rising edges on TIM\_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. CC2S bits are selecting the input capture source only, CC2S = 01 in TIMx\_CCMR1 register. Write CC2P = 1 and CC2NP = 0 in TIMx\_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS = 110 in TIMx\_SMCR register. Select TIM\_ti2 as the input source by writing TS = 00110 in TIMx\_SMCR register.

When a rising edge occurs on TIM\_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TIM\_ti2 and the actual start of the counter is due to the resynchronization circuit on TIM\_ti2 input.
Slave mode selection preload for run-time encoder mode update

The SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value is the update event (UEV) occurring when the counter overflows.

Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

Slave mode – combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode – external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode, or trigger mode. It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_ti1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter.
   - ETPS = 00: prescaler disabled.
   - ETP = 0: detection of rising edges on tim_etr_in and ECE = 1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F = 0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S = 01 in TIMx_CCMR1 register to select only the input capture source.
   - CC1P = 0 and CC1NP = 0 in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS = 110 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIMx_SMCR register.

A rising edge on tim_ti1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.
42.4.23 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one timer is configured in Master mode, it can reset, start, stop, or clock the counter of another timer configured in Slave mode.

*Figure 561* and *Figure 562* show examples of master/slave timer connections.
Figure 562. Master/slave connection example with 1 channel only timers

Note: The timers with one channel only (see Figure 562) do not feature a master mode. However, the tim_oc1 output signal can serve as trigger for slave timer (see TIMx internal trigger connection table in Section 42.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals). The tim_oc1 signal pulse width must be programmed to be at least two clock cycles of the destination timer, to make sure the slave timer detects the trigger. For instance, if the destination timer tim_ker_ck clock is four times slower than the source timer, the OC1 pulse width must be eight clock cycles.

Using one timer as prescaler for another timer

For example, TIM_mstr can be configured to act as a prescaler for TIM_slv. Refer to Figure 561. To do this:

1. Configure TIM_mstr in master mode so that it outputs a periodic trigger signal on each update event UEV. If MMS = 010 is written in the TIM_mstr_CR2 register, a rising edge is output on tim_trgo each time an update event is generated.
2. To connect the tim_trgo output of TIM_mstr to TIM_slv, TIM_slv must be configured in slave mode using ITR2 as internal trigger. This is selected through the TS bits in the TIM_slv_SMCR register (writing TS = 00010).
3. Then the slave mode controller must be put in external clock mode 1 (write SMS = 111 in the TIM_slv_SMCR register). This causes TIM_slv to be clocked by the rising edge of the periodic TIM_mstr trigger signal (which correspond to the TIM_mstr counter overflow).
4. Finally both timers must be enabled by setting their respective CEN bits (TIMx_CR1 register).

Note: If tim_ocx is selected on TIM_mstr as the trigger output (MMS = 1xx), its rising edge is used to clock the counter of TIM_slv.

Using one timer to enable another timer

In this example, we control the enable of TIM_slv with the output compare 1 of TIM_mstr. Refer to Figure 561 for connections. TIM_slv counts on the divided internal clock only when tim_oc1ref of TIM_mstr is high. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck (f_{tim_cnt_ck} = f_{tim_ker_ck}/3).
1. Configure TIM_mstr master mode to send its output compare 1 reference (tim_oc1ref) signal as trigger output (MMS = 100 in the TIM_mstr_CR2 register).

2. Configure the TIM_mstr tim_oc1ref waveform (TIM_mstr_CCMR1 register).

3. Configure TIM_slv to get the input trigger from TIM_mstr (TS = 00010 in the TIM_slv_SMCR register).

4. Configure TIM_slv in gated mode (SMS = 101 in TIM_slv_SMCR register).

5. Enable TIM_slv by writing 1 in the CEN bit (TIM_slv_CR1 register).

6. Start TIM_mstr by writing 1 in the CEN bit (TIM_mstr_CR1 register).

**Note:** The slave timer counter clock is not synchronized with the master timer counter clock, this mode only affects the TIM_slv counter enable signal.

**Figure 563. Gating TIM_slv with tim_oc1ref of TIM_mstr**

In the example in *Figure 563*, the TIM_slv counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting TIM_mstr. Then any value can be written in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx_EGR registers.
In the next example (refer to Figure 564), we synchronize TIM_mstr and TIM_slv. TIM_mstr is the master and starts from 0. TIM_slv is the slave and starts from 0x7E. The prescaler ratio is the same for both timers. TIM_slv stops when TIM_mstr is disabled by writing 0 to the CEN bit in the TIM_mstr_CR1 register:

1. Configure TIM_mstr master mode to send its output compare 1 reference (tim_oc1ref) signal as trigger output (MMS = 100 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr tim_oc1ref waveform (TIM_mstr_CCMR1 register).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS = 00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in gated mode (SMS = 101 in TIM_slv_SMCR register).
5. Reset TIM_mstr by writing 1 in UG bit (TIM_mstr_EGR register).
6. Reset TIM_slv by writing 1 in UG bit (TIM_slv_EGR register).
7. Initialize TIM_slv to 0x7E by writing 0x7E in the TIM_slv counter (TIM_slv_CNT).
8. Enable TIM_slv by writing 1 in the CEN bit (TIM_slv_CR1 register).
9. Start TIM_mstr by writing 1 in the CEN bit (TIM_mstr_CR1 register).
10. Stop TIM_mstr by writing 0 in the CEN bit (TIM_mstr_CR1 register).

Figure 564. Gating TIM_slv with Enable of TIM_mstr

Using one timer to start another timer

In this example, we set the enable of TIM_slv with the update event of TIM_mstr. Refer to Figure 561 for connections. TIM_slv starts counting from its current value (which can be nonzero) on the divided internal clock as soon as the update event is generated by TIM_mstr. When TIM_slv receives the trigger signal its CEN bit is automatically set and the counter counts until we write 0 to the CEN bit in the TIM_slv_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck (f_{tim_ker_ck} = f_{tim_ker_ck}/3).
1. Configure TIM_mstr master mode to send its update event (UEV) as trigger output (MMS = 010 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr period (TIM_mstr_ARR registers).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS = 00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in trigger mode (SMS = 110 in TIM_slv_SMCR register).
5. Start TIM_mstr by writing 1 in the CEN bit (TIM_mstr_CR1 register).

**Figure 565. Triggering TIM_slv with update of TIM_mstr**

As in the previous example, both counters can be initialized before starting counting. **Figure 566** shows the behavior with the same configuration as in **Figure 565** but in trigger mode (SMS = 110 in the TIM_slv_SMCR register) instead of gated mode.

**Figure 566. Triggering TIM_slv with Enable of TIM_mstr**
Starting two timers synchronously in response to an external trigger

In this example, we set the enable of TIM_mstr when its tim_ti1 input rises, and the enable of TIM_slv with the enable of TIM_mstr. Refer to Figure 561 for connections. To ensure the counters are aligned, TIM_mstr must be configured in Master/Slave mode (slave with respect to tim_ti1, master with respect to TIM_slv):

1. Configure TIM_mstr master mode to send its enable as trigger output (MMS = 001 in the TIM_mstr_CR2 register).
2. Configure TIM_mstr slave mode to get the input trigger from tim_ti1 (TS = 00100 in the TIM_mstr_SMCR register).
3. Configure TIM_mstr in trigger mode (SMS = 110 in the TIM_mstr_SMCR register).
4. Configure the TIM_mstr in Master/Slave mode by writing MSM = 1 (TIM_mstr_SMCR register).
5. Configure TIM_slv to get the input trigger from TIM_mstr (TS = 00000 in the TIM_slv_SMCR register).
6. Configure TIM_slv in trigger mode (SMS = 110 in the TIM_slv_SMCR register).

When a rising edge occurs on tim_ti1 (TIM_mstr), both counters start counting synchronously on the internal clock and both TIF flags are set.

Note: In this example both timers are initialized before starting (by setting their respective UG bits). Both counters starts from 0, but an offset can easily be inserted between them by writing any of the counter registers (TIMx_CNT). One can see that the master/slave mode inserts a delay between CNT_EN and CK_PSC on TIM_mstr.

Figure 567. Triggering TIM_mstr and TIM_slv with TIM_mstr tim_ti1 input

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

42.4.24 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.
Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

42.4.25 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to reprogram part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write accesses are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:

00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

The DBSS[3:0] bits in the TIMx_DCR register defines the interrupt source that triggers the DMA burst transfers (see Section 42.5.23: TIMx DMA control register (TIMx_DCR)(x = 2 to 5) for details).

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address.
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.

2. Configure the DCR register by configuring the DBA and DBL bitfields as follows: DBL = 3 transfers, DBA = 0xE and DBSS = 1.

3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).

4. Enable TIMx.

5. Enable the DMA channel.

This example is for the case where every CCRx register has to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let’s take the example of a buffer in the RAM containing data1, data2, data3, data4, data5,
and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3, and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

42.4.26 TIM2/TIM3/TIM4/TIM5 DMA requests

The TIM2/TIM3/TIM4/TIM5 can generate a DMA requests, as shown in Table 437.

<table>
<thead>

Note: Some timer's DMA requests may not be connected to the DMA controller. Refer to the DMA section(s) for more details.

42.4.27 Debug mode

When the microcontroller enters debug mode (Cortex®-M7 core halted), the TIMx counter can either continue to work normally or stops.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to section Debug support (DBG).

42.4.28 TIM2/TIM3/TIM4/TIM5 low-power modes

<table>

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering Enable

0: Dithering disabled
1: Dithering enabled

*Note: The DITHEN bit can only be modified when CEN bit is reset.*

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bitfield indicates the division ratio between the timer clock (tim_ker_ck) frequency and sampling clock used by the digital filters (tim_etr_in, tim_tix),

00: tDTS = tim_ker_ck
01: tDTS = 2 × tim_ker_ck
10: tDTS = 4 × tim_ker_ck
11: Reserved

Bit 7 **ARPE**: Autoreload preload enable

0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:5 **CMS[1:0]**: Center-aligned mode selection

00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).
01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIMx_CCMRx register) are set only when the counter is counting down.
10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIMx_CCMRx register) are set only when the counter is counting up.
11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIMx_CCMRx register) are set both when the counter is counting up or down.

*Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN = 1)*
Bit 4 **DIR**: Direction
0: Counter used as upcounter
1: Counter used as downcounter
*Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.*

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled.
These events can be:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled
*Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*
CEN is cleared automatically in one-pulse mode, when an update event occurs.

Bits 24:8  Reserved, must be kept at reset value.

Bit 7  **TI1S**: tim_t1 selection

0: The \( \text{tim_t1}_\text{in}[15:0] \) multiplexer output is to \( \text{tim_t1}_\text{input} \) input
1: The \( \text{tim_t1}_\text{in}[15:0], \text{tim_t2}_\text{in}[15:0] \) and \( \text{tim_t3}_\text{in}[15:0] \) multiplexers outputs are XORed
and connected to the \( \text{tim_t1}_\text{input} \). See also **Section 41.3.29: Interfacing with Hall sensors**.

Bits 25, 6, 5, 4  **MMS[3:0]**: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for
synchronization (tim_trgo). The combination is as follows:

0000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo). If

the reset is generated by the trigger input (slave mode controller configured in reset
mode) then the signal on tim_trgo is delayed compared to the actual reset.

0001: **Enable** - the Counter enable signal, CNT_EN, is used as trigger output (tim_trgo). It is

useful to start several timers at the same time or to control a window in which a slave
timer is enabled. The Counter Enable signal is generated by a logic AND between
CEN control bit and the trigger input when configured in gated mode.

When the Counter Enable signal is controlled by the trigger input, there is a delay on
tim_trgo, except if the master/slave mode is selected (see the MSM bit description in
TIMx_SMCR register).

0010: **Update** - The update event is selected as trigger output (tim_trgo). For instance a

master timer can then be used as a prescaler for a slave timer.

0011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to

be set (even if it was already high), as soon as a capture or a compare match
occurred (tim_trgo).

0100: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo)
0101: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo)
0110: **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo)
0111: **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo)

1000: **Encoder clock output** - The encoder clock signal is used as trigger output (tim_trgo).

This code is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011,

1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to
unexpected behavior.

Others: Reserved

**Note**: The clock of the slave timer or ADC must be enabled prior to receive events from the
master timer, and must not be changed on-the-fly while triggers are received from the
master timer.

Bit 3  **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bits 2:0  Reserved, must be kept at reset value.
42.5.3 TIMx slave mode control register (TIMx_SMCR)(x = 2 to 5)

Address offset: 0x008
Reset value: 0x0000 0000

| Bit 31:26 | Reserved, must be kept at reset value. |
| Bit 25   | **SMSPS**: SMS preload source |
|          | This bit selects whether the events that triggers the SMS[3:0] bitfield transfer from preload to active |
|          | 0: The transfer is triggered by the Timer’s Update event |
|          | 1: The transfer is triggered by the Index event |
| Bit 24   | **SMSPE**: SMS preload enable |
|          | This bit selects whether the SMS[3:0] bitfield is preloaded |
|          | 0: SMS[3:0] bitfield is not preloaded |
|          | 1: SMS[3:0] preload is enabled |
| Bit 15   | **ETP**: External trigger polarity |
|          | This bit selects whether tim_etr_in or tim_etr_in is used for trigger operations |
|          | 0: tim_etr_in is non-inverted, active at high level or rising edge |
|          | 1: tim_etr_in is inverted, active at low level or falling edge |
| Bit 14   | **ECE**: External clock enable |
|          | This bit enables External clock mode 2. |
|          | 0: External clock mode 2 disabled |
|          | 1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_etrf signal. |
|          | **Note**: Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_etrf (SMS = 111 and TS = 00111). |
|          | It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etrf in this case (TS bits must not be 00111). |
|          | If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etrf. |
| Bit 13:12| **ETPS[1:0]**: External trigger prescaler |
|          | External trigger signal tim_etrp frequency must be at most 1/4 of tim_ker_ck frequency. A prescaler can be enabled to reduce tim_etrp frequency. It is useful when inputting fast external clocks on tim_etr_in. |
|          | 00: Prescaler OFF |
|          | 01: tim_etrp frequency divided by 2 |
|          | 10: tim_etrp frequency divided by 4 |
|          | 11: tim_etrp frequency divided by 8 |
Bits 11:8 **ETF[3:0]: External trigger filter**

This bitfield then defines the frequency used to sample tim_etrp signal and the length of the digital filter applied to tim_etrp. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- **0000**: No filter, sampling is done at fDTS
- **0001**: fSAMPLING = ftim_ker_ck, N = 2
- **0010**: fSAMPLING = ftim_ker_ck, N = 4
- **0011**: fSAMPLING = ftim_ker_ck, N = 8
- **0100**: fSAMPLING = fDTS/2, N = 6
- **0101**: fSAMPLING = fDTS/2, N = 8
- **0110**: fSAMPLING = fDTS/4, N = 6
- **0111**: fSAMPLING = fDTS/4, N = 8
- **1000**: fSAMPLING = fDTS/8, N = 6
- **1001**: fSAMPLING = fDTS/8, N = 8
- **1010**: fSAMPLING = fDTS/16, N = 5
- **1011**: fSAMPLING = fDTS/16, N = 6
- **1100**: fSAMPLING = fDTS/16, N = 8
- **1101**: fSAMPLING = fDTS/32, N = 5
- **1110**: fSAMPLING = fDTS/32, N = 6
- **1111**: fSAMPLING = fDTS/32, N = 8

Bit 7 **MSM: Master/Slave mode**

- **0**: No action
- **1**: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4  **TS[4:0]:** Trigger selection
   This bitfield selects the trigger input to be used to synchronize the counter.
   00000: Internal trigger 0 (tim_itr0)
   00001: Internal trigger 1 (tim_itr1)
   00010: Internal trigger 2 (tim_itr2)
   00011: Internal trigger 3 (tim_itr3)
   00100: tim_ti1 edge detector (tim_ti1f_ed)
   00101: Filtered timer input 1 (tim_ti1fp1)
   00110: Filtered timer input 2 (tim_ti2fp2)
   00111: External trigger input (tim_etrf)
   01000: Internal trigger 4 (tim_itr4)
   01001: Internal trigger 5 (tim_itr5)
   01010: Internal trigger 6 (tim_itr6)
   01011: Internal trigger 7 (tim_itr7)
   01100: Internal trigger 8 (tim_itr8)
   01101: Internal trigger 9 (tim_itr9)
   01110: Internal trigger 10 (tim_itr10)
   01111: Internal trigger 11 (tim_itr11)
   10000: Internal trigger 12 (tim_itr12)
   10001: Internal trigger 13 (tim_itr13)
   10010: Internal trigger 14 (tim_itr14)
   10011: Internal trigger 15 (tim_itr15)
   Others: Reserved
   See Section 42.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals for product specific implementation details.

   **Note:** These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3  **OCCS:** OCREF clear selection
   This bit is used to select the OCREF clear source
   0: tim_ocref_clr_int is connected to the tim_ocref_clr input
   1: tim_ocref_clr_int is connected to tim_etrf

   **Note:** If the OCREF clear selection feature is not supported, this bit is reserved and forced by hardware to 0. Section 42.3: TIM2/TIM3/TIM4/TIM5 implementation.
Bits 16, 2, 1, 0  **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (refer to ETP bit in TIMx_SMCR for tim_etra_in and CCxP/CCxNP bits in TIMx_CCER register for tim_ti1fp1 and tim_ti2fp2).
0000: Slave mode disabled - if CEN = 1 then the prescaler is clocked directly by the internal clock.
0001: Encoder mode 1 - Counter counts up/down on tim_t1f1fp1 edge depending on tim_t1f2fp2 level.
0010: Encoder mode 2 - Counter counts up/down on tim_t1f2fp2 edge depending on tim_t1f1fp1 level.
0011: Encoder mode 3 - Counter counts up/down on both tim_t1f1fp1 and tim_t1f2fp2 edges depending on the level of the other input.
0100: Reset mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.
0101: Gated mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
0110: Trigger mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.
0111: External clock mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.
1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.
1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
1010: Encoder mode: Clock plus direction, x2 mode.
1011: Encoder mode: Clock plus direction, x1 mode, tim_t1f2fp2 edge sensitivity is set by CC2P.
1100: Encoder mode: Directional clock, x2 mode.
1101: Encoder mode: Directional clock, x1 mode, tim_t1f1fp1 and tim_t1f2fp2 edge sensitivity is set by CC1P and CC2P.
1110: Quadrature encoder mode: x1 mode, counting on tim_t1f1fp1 edges only, edge sensitivity is set by CC1P.
1111: Quadrature encoder mode: x1 mode, counting on tim_t1f2fp2 edges only, edge sensitivity is set by CC2P.

**Note:** The gated mode must not be used if tim_t1f_ed is selected as the trigger input (TS = 00100). Indeed, tim_t1f_ed outputs 1 pulse for each transition on tim_t1f, whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
### 42.5.4 TIMx DMA/Interrupt enable register (TIMx_DIER)(x = 2 to 5)

Address offset: 0x00C  
Reset value: 0x0000 0000

<table>

           0: CC2 DMA request disabled  
           1: CC2 DMA request enabled |
| Bit 23    | CC1DE: Capture/Compare 1 DMA request enable  
           0: CC1 DMA request disabled  
           1: CC1 DMA request enabled |
| Bit 22    | UDE: Update DMA request enable  
         0: Update DMA request disabled  
         1: Update DMA request enabled |

| Bit 1:0  | Reserved, must be kept at reset value. |

---

**Notes:**
- The TIMx DMA/Interrupt enable register (TIMx_DIER) is used to enable or disable various DMA and interrupt requests for the TIMx timer. The register is accessed through a specific address offset and has a reset value to ensure proper functionality.
- Each bit in the register controls a specific DMA or interrupt request, such as transition error, index error, direction change, and others.
- The register is configured in read-write mode, allowing users to read the current state and write new configurations as needed.
- Proper configuration of these bits is crucial for ensuring the correct operation of the timer and its associated peripherals in applications requiring precise timing and event handling.
General-purpose timers (TIM2/TIM3/TIM4/TIM5)

42.5.5 TIMx status register (TIMx_SR)(x = 2 to 5)

Address offset: 0x010
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:24</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bit 23 | **TERRF**: Transition error interrupt flag  
This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to 0.  
0: No encoder transition error has been detected.  
1: An encoder transition error has been detected |
| Bit 22 | **IERRF**: Index error interrupt flag  
This flag is set by hardware when an index error is detected. It is cleared by software by writing it to 0.  
0: No index error has been detected.  
1: An index error has been detected |
Bit 21  **DIRF**: Direction change interrupt flag
   This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIMx_CR is changing). It is cleared by software by writing it to 0.
   0: No direction change
   1: Direction change

Bit 20  **IDXF**: Index interrupt flag
   This flag is set by hardware when an index event is detected. It is cleared by software by writing it to 0.
   0: No index event occurred.
   1: An index event has occurred

Bits 19:13  Reserved, must be kept at reset value.

Bit 12  **CC4OF**: Capture/Compare 4 overcapture flag
   refer to CC1OF description

Bit 11  **CC3OF**: Capture/Compare 3 overcapture flag
   refer to CC1OF description

Bit 10  **CC2OF**: Capture/compare 2 overcapture flag
   refer to CC1OF description

Bit 9  **CC1OF**: Capture/Compare 1 overcapture flag
   This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to 0.
   0: No overcapture has been detected.
   1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:7  Reserved, must be kept at reset value.

Bit 6  **TIF**: Trigger interrupt flag
   This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input) when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
   0: No trigger event occurred.
   1: Trigger interrupt pending.

Bit 5  Reserved, must be kept at reset value.

Bit 4  **CC4IF**: Capture/Compare 4 interrupt flag
   Refer to CC1IF description

Bit 3  **CC3IF**: Capture/Compare 3 interrupt flag
   Refer to CC1IF description
Bit 2  **CC2IF**: Capture/Compare 2 interrupt flag  
Refer to CC1IF description

Bit 1  **CC1IF**: Capture/compare 1 interrupt flag  
This flag is set by hardware. It is cleared by software (input capture or output compare mode)  
or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred

**If channel CC1 is configured as output:** this flag is set when the content of the counter  
TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of  
TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the  
counter overflow (in up-counting and up/down-counting modes) or underflow (in down- 
counting mode). There are three possible options for flag setting in center-aligned mode,  
refer to the CMS bits in the TIMx_CR1 register for the full description.

**If channel CC1 is configured as input:** this bit is set when counter value has been captured  
in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity  
defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0  **UIF**: Update interrupt flag  
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred
1: Update interrupt pending. This bit is set by hardware when the registers are updated:  
At overflow or underflow and if UDIS = 0 in the TIMx_CR1 register.
When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS = 0 and  
UDIS = 0 in the TIMx_CR1 register.
When CNT is reinitialized by a trigger event (refer to the synchro control register description),  
if URS = 0 and UDIS = 0 in the TIMx_CR1 register.

### 42.5.6 TIMx event generation register (TIMx_EGR)(x = 2 to 5)

Address offset: 0x014
Reset value: 0x0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 15| 14| 13| 12| 11| 10| 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|   |   |   |   |   |   | TG| CC4G| CC3G| CC2G| CC1G| UG |
| w | w | w | w | w | w |

Bits 15:7  Reserved, must be kept at reset value.

Bit 6  **TG**: Trigger generation  
This bit is set by software in order to generate an event, it is automatically cleared by  
hardware.
0: No action
1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if  
enabled.

Bit 5  Reserved, must be kept at reset value.

Bit 4  **CC4G**: Capture/compare 4 generation  
Refer to CC1G description

Bit 3  **CC3G**: Capture/compare 3 generation  
Refer to CC1G description
42.5.7 TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 2 to 5)

Address offset: 0x018
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

Input capture mode

- Bits 31:16: Reserved, must be kept at reset value.
- Bits 15:12: **IC2F[3:0]**: Input capture 2 filter
- Bits 11:10: **IC2PSC[1:0]**: Input capture 2 prescaler
Bits 9:8 **CC2S[1:0]:** Capture/compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.
- 00: CC2 channel is configured as output.
- 01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2.
- 10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1.
- 11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).*

Bits 7:4 **IC1F[3:0]:** Input capture 1 filter

This bitfield defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:
- 0000: No filter, sampling is done at f_DTS
- 0001: f_SAMPLING = f_tim_ker_ck, N = 2
- 0010: f_SAMPLING = f_tim_ker_ck, N = 4
- 0011: f_SAMPLING = f_tim_ker_ck, N = 8
- 0100: f_SAMPLING = f_DTS/2, N = 6
- 0101: f_SAMPLING = f_DTS/2, N = 8
- 0110: f_SAMPLING = f_DTS/4, N = 6
- 0111: f_SAMPLING = f_DTS/4, N = 8
- 1000: f_SAMPLING = f_DTS/8, N = 6
- 1001: f_SAMPLING = f_DTS/8, N = 8
- 1010: f_SAMPLING = f_DTS/16, N = 5
- 1011: f_SAMPLING = f_DTS/16, N = 6
- 1100: f_SAMPLING = f_DTS/16, N = 8
- 1101: f_SAMPLING = f_DTS/32, N = 5
- 1110: f_SAMPLING = f_DTS/32, N = 6
- 1111: f_SAMPLING = f_DTS/32, N = 8

Bits 3:2 **IC1PSC[1:0]:** Input capture 1 prescaler

This bitfield defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E = 0 (TIMx_CCER register).
- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]:** Capture/Compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
- 10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
- 11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*
42.5.8 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 2 to 5)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

### Output compare mode

| Bit 31-25 | Reserved, must be kept at reset value. |
| Bit 23-17 | Reserved, must be kept at reset value. |
| Bit 15 | OC2CE: Output compare 2 clear enable |
| Bit 24, 14-12 | OC2M[3:0]: Output compare 2 mode refer to OC1M description on bits 6:4 |
| Bit 11 | OC2PE: Output compare 2 preload enable |
| Bit 10 | OC2FE: Output compare 2 fast enable |
| Bit 9-8 | CC2S[1:0]: Capture/Compare 2 selection This bitfield defines the direction of the channel (input/output) as well as the used input. 00: CC2 channel is configured as output 01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2 10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1 11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register) |
| Bit 7 | OC1CE: Output compare 1 clear enable 0: tim_oc1ref is not affected by the tim_ocref_clr_int input 1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int input |

Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCMR).
Bits 16, 6:4 **OC1M[3:0]:** Output compare 1 mode

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 is derived. tim_oc1ref is active high whereas tim_oc1 active level depends on CC1P bit.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - tim_oc1ref toggles when TIMx_CNT = TIMx_CCR1.

0100: Force inactive level - tim_oc1ref is forced low.

0101: Force active level - tim_oc1ref is forced high.

0110: PWM mode 1 - In up-counting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In down-counting, channel 1 is inactive (tim_oc1ref = 0) as long as TIMx_CNT> TIMx_CCR1 else active (tim_oc1ref = 1).

0111: PWM mode 2 - In up-counting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In down-counting, channel 1 is active as long as TIMx_CNT> TIMx_CCR1 else inactive.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved.

1011: Reserved.

1100: Combined PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc is the logical OR between tim_oc1ref and tim_oc2ref.

1101: Combined PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc is the logical AND between tim_oc1ref and tim_oc2ref.

1110: Asymmetric PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

1111: Asymmetric PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

**Note:** In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.
42.5.9 **TIMx capture/compare mode register 2 (TIMx_CCMR2)(x = 2 to 5)**

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

**Input capture mode**

- Bits 31:16: Reserved, must be kept at reset value.
- Bits 15:12: *IC4F[3:0]*: Input capture 4 filter
- Bits 11:10: *IC4PSC[1:0]*: Input capture 4 prescaler
Bits 9:8 **CC4S[1:0]**: Capture/Compare 4 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC4 channel is configured as output
01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
10: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)
11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note:** **CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx_CCER).**

Bits 7:4 **IC3F[3:0]**: Input capture 3 filter

Bits 3:2 **IC3PSC[1:0]**: Input capture 3 prescaler

Bits 1:0 **CC3S[1:0]**: Capture/Compare 3 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC3 channel is configured as output
01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4
11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note:** **CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx_CCER).**

**Output compare mode**

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC4CE:** Output compare 4 clear enable

Bits 24, 14:12 **OC4M[3:0]:** Output compare 4 mode
Refer to OC3M[3:0]

Bit 11 **OC4PE:** Output compare 4 preload enable

Bit 10 **OC4FE:** Output compare 4 fast enable
Bits 9:8 **CC4S[1:0]**: Capture/Compare 4 selection
   
   This bitfield defines the direction of the channel (input/output) as well as the used input.
   
   00: CC4 channel is configured as output
   01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
   10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
   11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

   **Note:** CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx_CCER).

Bit 7 **OC3CE**: Output compare 3 clear enable
Bits 16, 6:4 **OC3M[3:0]**: Output compare 3 mode

These bits define the behavior of the output reference signal tim_oc3ref from which tim_oc3 and tim_oc3n are derived. tim_oc3ref is active high whereas tim_oc3 and tim_oc3n active level depends on CC3P and CC3NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR3 and the counter TIMx_CNT has no effect on the outputs. (this mode is used to generate a timing base).

0001: Set channel 3 to active level on match. tim_oc3ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 3 (TIMx_CCR3).

0010: Set channel 3 to inactive level on match. tim_oc3ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 3 (TIMx_CCR3).

0011: Toggle - tim_oc3ref toggles when TIMx_CNT = TIMx_CCR3.

0100: Force inactive level - tim_oc3ref is forced low.

0101: Force active level - tim_oc3ref is forced high.

0110: PWM mode 1 - In up-counting, channel 3 is active as long as TIMx_CNT<TIMx_CCR3 else inactive. In down-counting, channel 3 is active as long as TIMx_CNT>TIMx_CCR3 else active (tim_oc3ref = 1).

0111: PWM mode 2 - In up-counting, channel 3 is inactive as long as TIMx_CNT<TIMx_CCR3 else active. In down-counting, channel 3 is active as long as TIMx_CNT>TIMx_CCR3 else inactive.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1010: Pulse on compare: a pulse is generated on tim_oc3ref upon CCR3 match event, as per PWPRSC[2:0] and PW[7:0] bitfields programming in TIMxECR.

1011: Direction output. The tim_oc3ref signal is overridden by a copy of the DIR bit.

1100: Combined PWM mode 1 - tim_oc3ref has the same behavior as in PWM mode 1. tim_oc3refc is the logical OR between tim_oc3ref and tim_oc4ref.

1101: Combined PWM mode 2 - tim_oc3ref has the same behavior as in PWM mode 2. tim_oc3refc is the logical AND between tim_oc3ref and tim_oc4ref.

1110: Asymmetric PWM mode 1 - tim_oc3ref has the same behavior as in PWM mode 1. tim_oc3refc outputs tim_oc3ref when the counter is counting up, tim_oc4ref when it is counting down.

1111: Asymmetric PWM mode 2 - tim_oc3ref has the same behavior as in PWM mode 2. tim_oc3refc outputs tim_oc3ref when the counter is counting up, tim_oc4ref when it is counting down.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S = 00 (the channel is configured in output).

**Note:** In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.

On channels having a complementary output, this bitfield is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC3M active bits take the new value from the preloaded bits only when a COM event is generated.
Bit 3 **OC3PE**: Output compare 3 preload enable

Bit 2 **OC3FE**: Output compare 3 fast enable

Bits 1:0 **CC3S[1:0]**: Capture/Compare 3 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output
01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4
11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note*: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx_CCER).

### 42.5.11 TIMx capture/compare enable register (TIMx_CCER)(x = 2 to 5)

Address offset: 0x020

Bit 15 **CC4NP**: Capture/Compare 4 output Polarity.
Refer to CC1NP description

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC4P**: Capture/Compare 4 output Polarity.
Refer to CC1P description

Bit 12 **CC4E**: Capture/Compare 4 output enable.
Refer to CC1E description

Bit 11 **CC3NP**: Capture/Compare 3 output Polarity.
Refer to CC1NP description

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC3P**: Capture/Compare 3 output Polarity.
Refer to CC1P description

Bit 8 **CC3E**: Capture/Compare 3 output enable.
Refer to CC1E description

Bit 7 **CC2NP**: Capture/Compare 2 output Polarity.
Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output Polarity.
Refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable.
Refer to CC1E description
Bit 3 **CC1NP**: Capture/Compare 1 output Polarity.

**CC1 channel configured as output**: CC1NP must be kept cleared in this case.

**CC1 channel configured as input**: This bit is used in conjunction with CC1P to define Tim_T1fp1/Tim_T2fp1 polarity. Refer to CC1P description.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/Compare 1 output Polarity.

- 0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
- 1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of T11FP1 and T12FP1 for trigger or capture operations.

- **CC1NP = 0, CC1P = 0**: non-inverted/rising edge. The circuit is sensitive to TixFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TixFP1 is not inverted (trigger operation in gated mode or encoder mode).
- **CC1NP = 0, CC1P = 1**: inverted/falling edge. The circuit is sensitive to TixFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TixFP1 is inverted (trigger operation in gated mode or encoder mode).
- **CC1NP = 1, CC1P = 1**: non-inverted/both edges. The circuit is sensitive to both TixFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TixFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.
- **CC1NP = 1, CC1P = 0**: this configuration is reserved, it must not be used.

Bit 0 **CC1E**: Capture/Compare 1 output enable.

- 0: Capture mode disabled / OC1 is not active
- 1: Capture mode enabled / OC1 signal is output on the corresponding output pin

<table>

Bits 31:0  ARR[31:0]: Autoreload value
ARR is the value to be loaded in the actual autoreload register.
Refer to the Section 42.4.3: Time-base unit for more details about ARR update and behavior.
The counter is blocked while the autoreload value is null.
Non-dithering mode (DITHEN = 0)
The register holds the autoreload value.
Dithering mode (DITHEN = 1)
The register holds the integer part in ARR[31:4]. The ARR[3:0] bitfield contains the dithered part.

Bits 31:0 **CCR1[31:0]**: Capture/compare 1 value  
*If channel CC1 is configured as output:*  
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit O1C1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.  
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.  
**Non-dithering mode (DITHEN = 0)**  
The register holds the compare value.  
**Dithering mode (DITHEN = 1)**  
The register holds the integer part in CCR1[31:4]. The CCR1[3:0] bitfield contains the dithered part.  
*If channel CC1 is configured as input:*  
CCR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.  
**Non-dithering mode (DITHEN = 0)**  
The register holds the capture value.  
**Dithering mode (DITHEN = 1)**  
The register holds the capture in CCR1[31:0]. The CCR1[3:0] bits are reset.

### 42.5.16 TIMx capture/compare register 2 (TIMx_CCR2)(x = 2 to 5)

Address offset: 0x038  
Reset value: 0x0000 0000

| CCR2[31:16] | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| `rw`        | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` |
| CCR2[15:0]  | 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |
| `rw`        | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` | `rw` |
Bits 31:0  **CCR2[31:0]**: Capture/compare 2 value

**If channel CC2 is configured as output:**
CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

**Non-dithering mode (DITHEN = 0)**
The register holds the compare value.

**Dithering mode (DITHEN = 1)**
The register holds the integer part in CCR2[31:4]. The CCR2[3:0] bitfield contains the dithered part.

**If channel CC2 is configured as input:**
CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

**Non-dithering mode (DITHEN = 0)**
The register holds the capture value.

**Dithering mode (DITHEN = 1)**
The register holds the capture in CCR2[31:0]. The CCR2[3:0] bits are reset.

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **DBSS[3:0]**: DMA burst source selection
This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).
- 0000: Reserved
- 0001: Update
- 0010: CC1
- 0011: CC2
- 0100: CC3
- 0101: CC4
- 0110: COM
- 0111: Trigger
- Others: reserved

Bits 15:13 Reserved, must be kept at reset value.
42.5.24 TIMx DMA address for full transfer (TIMx_DMAR)(x = 2 to 5)

Address offset: 0x3E0
Reset value: 0x0000 0000
Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address

\[(\text{TIMx} \_\text{CR1 address}) + (\text{DBA} + \text{DMA index}) \times 4\]

where **TIMx\_CR1 address** is the address of the control register 1, **DBA** is the DMA base address configured in **TIMx\_DCR** register, **DMA index** is automatically controlled by the DMA transfer, and ranges from 0 to **DBL** (DBL configured in **TIMx\_DCR**).
### 42.5.25 TIMx register map

43 Basic timers (TIM6/TIM7)

43.1 TIM6/TIM7 introduction

The basic timers TIM6/TIM7 consist in a 16-bit autoreload counter driven by a programmable prescaler.
They can be used as generic timers for time-base generation.
The timers are completely independent, and do not share any resources.

43.2 TIM6/TIM7 main features

Basic timer (TIM6/TIM7) features include:
- 16-bit autoreload upcounter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Interrupt/DMA generation on the update event: counter overflow.

43.3 TIM6/TIM7 functional description

43.3.1 TIM6/TIM7 block diagram

Figure 568. Basic timer block diagram

Notes:
- Reg Preload registers transferred to active registers on U event according to control bit
- Event
- Interrupt & DMA
43.3.2 TIM6/TIM7 internal signals

The table in this section summarizes the TIM inputs and outputs.

<table>
<thead>
<tr>

<td>Output</td>
<td>Timer update dma request</td>
</tr>
</tbody>
</table>

43.3.3 TIM6/TIM7 clocks

The timer bus interface is clocked by the tim_pclk APB clock.

The counter clock tim_ker_ck is connected to the tim_pclk input.

The CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

*Figure 569* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

*Figure 569. Control circuit in normal mode, internal clock divided by 1*
43.3.4 Time-base unit

The main block of the programmable timer is a 16-bit upcounter with its related autoreload register. The counter clock can be divided by a prescaler.

The counter, the autoreload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-Reload register (TIMx_ARR).

The autoreload register is preloaded. The preload register is accessed each time an attempt is made to write or read the autoreload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the autoreload preload enable bit (ARPE) in the TIMx_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in the TIMx_CR1 register is set.

Note that the actual counter enable signal tim_cnt_en is set one clock cycle after CEN bit set.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as the TIMx_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 570 and Figure 571 give some examples of the counter behavior when the prescaler ratio is changed on the fly.
**Figure 570. Counter timing diagram with prescaler division change from 1 to 2**

Prescaler buffer: 0  3

Prescaler counter: 0  0  1  2  3  0  1  2  3
43.3.5 Counting mode

The counter counts from 0 to the autoreload value (contents of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generate at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been written to 0, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIMx_CR1 register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx_PSC register).
- The autoreload shadow register is updated with the preload value (TIMx_ARR).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

**Figure 572. Counter timing diagram, internal clock divided by 1**
Figure 573. Counter timing diagram, internal clock divided by 2

Figure 574. Counter timing diagram, internal clock divided by 4
Figure 575. Counter timing diagram, internal clock divided by N

Figure 576. Counter timing diagram, update event when ARPE = 0 (TIMx_ARR not preloaded)
Dithering mode

The time base effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This affects the way the TIMx_ARR is behaving, and is useful for adjusting the average counter period when the timer is used as a trigger.

The operating principle is to have the actual ARR value slightly changed (adding or not one timer clock period) over 16 consecutive counting periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average counting period.
Figure 578 presents the dithering principle applied to four consecutive counting periods.

**Figure 578. Dithering principle**

When the dithering mode is enabled, the register coding is changed as follows (see Figure 579 for example):

- The four LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value.

**Note:** The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The DITHEN bit must be reset
3. The CEN bit can be set (eventually with ARPE = 1).

**Figure 579. Data format and register coding in dithering mode**

The minimum frequency is given by the following formula:
Resolution = \( \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{PWMmin}} = \frac{F_{\text{Tim}}}{\text{MaxResolution}} \)

Dithering mode disabled: \( F_{\text{PWMmin}} = \frac{F_{\text{Tim}}}{65536} \)

Dithering mode enabled: \( F_{\text{PWMmin}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}} \)

Note: The maximum TIMx_ARR value is limited to 0xFFFFE in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on Figure 580, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

Figure 580. FCnt resolution vs frequency

The period changes are spread over 16 consecutive periods, as described in Figure 581.

Figure 581. PWM dithering pattern

The autoreload and compare values increments are spread following the specific patterns described in Table 443. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.
43.3.6 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag UIF into the timer counter register’s bit 31 (TIMxCNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

43.3.7 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

*Note:* The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receiving events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

43.3.8 TIM6/TIM7 DMA requests

The TIM6/TIM7 can generate a single DMA request, as shown in Table 444.

<table>
<thead>
<tr>
<th>DMA acronym</th>
<th>DMA request</th>
<th>Enable control bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>tim_upd_dma</td>
<td>Update</td>
<td>UDE</td>
</tr>
</tbody>
</table>

43.3.9 Debug mode

When the microcontroller enters debug mode (Cortex®-M7 core halted), the TIMx counter can either continue to work normally or be stopped.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to section Debug support (DBG).

43.3.10 TIM6/TIM7 low-power modes

<table>
<thead>
<tr>
<th>Mode</th>

</tbody>
</table>

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable
  0: Dithering disabled
  1: Dithering enabled
  
  *Note:* The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 **UIFREMAP**: UIF status bit remapping
  0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
  1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **ARPE**: Auto-reload preload enable
  0: TIMx_ARR register is not buffered.
  1: TIMx_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
  0: Counter is not stopped at update event
  1: Counter stops counting at the next update event (clearing the CEN bit).
Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generates an update interrupt or DMA request if enabled.
These events can be:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value
(ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled
CEN is cleared automatically in one-pulse mode, when an update event occurs.
43.4.2 TIMx control register 2 (TIMx_CR2)\((x = 6 \text{ to } 7)\)

Address offset: 0x04
Reset value: 0x0000

</tbody>
</table>

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 MMS[2:0]: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

- **000:** Reset - the UG bit from the TIMx_EGR register is used as a trigger output (tim_trgo).
- **001:** Enable - the Counter enable signal, tim_cnt_en, is used as a trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated when the CEN control bit is written.
- **010:** Update - the update event is selected as a trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

**Note:** The clock of the slave timer or the peripheral receiving the tim_trgo must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bits 3:0 Reserved, must be kept at reset value.

43.4.3 TIMx DMA/Interrupt enable register (TIMx_DIER)\((x = 6 \text{ to } 7)\)

Address offset: 0x0C
Reset value: 0x0000

<table>
<thead>

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 UDE: Update DMA request enable
- 0: Update DMA request disabled.
- 1: Update DMA request enabled.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 UIE: Update interrupt enable
- 0: Update interrupt disabled.
- 1: Update interrupt enabled.
### 43.4.4 TIMx status register (TIMx_SR)(x = 6 to 7)

Address offset: 0x10  
Reset value: 0x0000

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|---|

Bits 15:1 Reserved, must be kept at reset value.

- **Bit 0** **UIF**: Update interrupt flag  
  - This bit is set by hardware on an update event. It is cleared by software.
  - 0: No update occurred.
  - 1: Update interrupt pending. This bit is set by hardware when the registers are updated:  
    - On counter overflow if UDIS = 0 in the TIMx_CR1 register.
    - When CNT is reinitialized by software using the UG bit in the TIMx_EGR register, if URS = 0 and UDIS = 0 in the TIMx_CR1 register.

### 43.4.5 TIMx event generation register (TIMx_EGR)(x = 6 to 7)

Address offset: 0x14  
Reset value: 0x0000

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|---|

Bits 15:1 Reserved, must be kept at reset value.

- **Bit 0** **UG**: Update generation  
  - This bit can be set by software, it is automatically cleared by hardware.
  - 0: No action.
  - 1: Re-initializes the timer counter and generates an update of the registers. Note that the prescaler counter is cleared too (but the prescaler ratio is not affected).

### 43.4.6 TIMx counter (TIMx_CNT)(x = 6 to 7)

Address offset: 0x24  
Reset value: 0x00000000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>

|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|---|
| CNT[15:0] |
| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
Bit 31 **UIFCPY**: UIF copy

This bit is a read-only copy of the UIF bit of the TIMx_ISR register. If the UIFREMAP bit in TIMx_CR1 is reset, bit 31 is reserved and read as 0.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

* Non-dithering mode (DITHEN = 0)
  The register holds the counter value.

* Dithering mode (DITHEN = 1)
  The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

### 43.4.7 TIMx prescaler (TIMx_PSC)(x = 6 to 7)

**Address offset**: 0x28

**Reset value**: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency \( f_{\text{tim_cnt_ck}} \) is equal to \( f_{\text{tim_psc_ck}} / (\text{PSC[15:0] + 1}) \).

PSC contains the value to be loaded into the active prescaler register at each update event. (including when the counter is cleared through UG bit of TIMx_EGR register.

### 43.4.8 TIMx autoreload register (TIMx_ARR)(x = 6 to 7)

**Address offset**: 0x2C

**Reset value**: 0x0000 FFFF

<table>
<thead>
<tr>
<th>31</th>

<td>rw</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]**: Auto-reload value

ARR is the value to be loaded into the actual auto-reload register.

Refer to **Section 43.3.4: Time-base unit** for more details about ARR update and behavior.

* Non-dithering mode (DITHEN = 0)
  The counter is blocked while the auto-reload value is null.

* Dithering mode (DITHEN = 1)
  The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reserved.
### 43.4.9 TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

| Offset | Register name | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|--------|---------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 0x00   | TIMx_CR1      |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | Reset value   | 0   | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| 0x04   | TIMx_CR2      |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | Reset value   | 0   | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| 0x08   | Reserved      |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| 0x0C   | TIMx_DIER     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

Refer to Section 2.3 for the register boundary addresses.
44 General-purpose timers (TIM9/TIM12/TIM13/TIM14)

44.1 TIM9/TIM12/TIM13/TIM14 introduction

The TIM9/TIM12/TIM13/TIM14 general-purpose timers consist in a 16-bit autoreload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM9/TIM12/TIM13/TIM14 timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 44.4.20: Timer synchronization (TIM9/TIM12 only).

44.2 TIM9/TIM12 main features

The features of the TIM9/TIM12 general-purpose timers include:

- 16-bit autoreload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- Up to two independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal trigger)
  - Trigger event (counter start, stop, initialization, or count by internal trigger)
  - Input capture
  - Output compare
44.3 TIM13/TIM14 main features

The features of general-purpose timers TIM13/TIM14 include:

- 16-bit autoreload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- Independent channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software)
  - Input capture
  - Output compare
44.4 TIM9/TIM12/TIM13/TIM14 functional description

44.4.1 Block diagram

Figure 582. General-purpose timer block diagram (TIM9/TIM12)

Notes:
- Preload registers transferred to active registers on U event according to control bit
- Event
- Interrupt
**Figure 583. General-purpose timer block diagram (TIM13/TIM14)**

1. This signal can be used as trigger for some slave timer (see internal trigger connection table in next section). See Section 44.4.21: Using timer output as trigger for other timers (TIM13/TIM14 only) for details.

### 44.4.2 TIM9/TIM12/TIM13/TIM14 pins and internal signals

Table 448 and Table 449 in this section summarize the TIM inputs and outputs.

#### Table 448. TIM input/output pins

<table>
<thead>
<tr>
<th>Pin name</th>
<th>Signal type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIM_CH1</td>
<td>Input/Output</td>
<td>Timer multi-purpose channels. Each channel can be used for capture, compare, or PWM. TIM_CH1 and TIM_CH2 can also be used as external clock (below 1/4 of the tim_ker_ck clock) and external trigger inputs.</td>
</tr>
<tr>
<td>TIM_CH2</td>
<td>Input/Output</td>
<td></td>
</tr>
</tbody>
</table>

1. Available for TIM9/TIM12 only.

#### Table 449. TIM internal input/output signals

<table>
<thead>
<tr>
<th>Internal signal name</th>
<th>Signal type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tim_ti1_in[15:0]</td>

### 44.4.3 Time-base unit

The main block of the timer is a 16-bit up-counter with its related autoreload register. The counter clock can be divided by a prescaler.

The counter, the autoreload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Autoreload register (TIMx_ARR).

The autoreload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register is transferred into the shadow register permanently or at each update event (UEV), depending on the autoreload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in details for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting one clock cycle after setting the CEN bit in the TIMx_CR1 register.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 584* and *Figure 585* give some examples of the counter behavior when the prescaler ratio is changed on the fly.
Figure 584. Counter timing diagram with prescaler division change from 1 to 2

Figure 585. Counter timing diagram with prescaler division change from 1 to 4
44.4.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the autoreload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller on TIM9/TIM12) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The autoreload shadow register is updated with the preload value (TIMx_ARR).
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

44.4.5 Clock selection

The counter clock can be provided by the following clock sources:

- **Internal clock (tim_ker_ck)**
- **External clock mode1** (for TIM9/TIM12): external input pin (tim_ti1 or tim_ti2, if available)
- **Internal trigger inputs (tim_itrx)** (for TIM9/TIM12): connecting the trigger output from another timer. For instance, another timer can be configured as a prescaler for TIM12. Refer to Section: Using one timer as prescaler for another timer for more details.

**Internal clock source (tim_ker_ck)**

The internal clock source is the default clock source for TIM13/TIM14.

For TIM9/TIM12, the internal clock source is selected when the slave mode controller is disabled (SMS = 000). The CEN bit in the TIMx_CR1 register and the UG bit in the TIMx_EGR register are then used as control bits and can be changed only by software (except for UG which remains cleared). As soon as the CEN bit is programmed to 1, the prescaler is clocked by the internal clock tim_ker_ck.

*Figure 592* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
Figure 592. Control circuit in normal mode, internal clock divided by 1

External clock source mode 1 (TIM9/TIM12 only)

This mode is selected when SMS = 111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 593. tim_ti2 external clock connection example

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:
1. Select the proper \textit{tim\_ti2\_in}[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx\_TISEL register.

2. Configure channel 2 to detect rising edges on the \textit{tim\_ti2} input by writing CC2S = 01 in the TIMx\_CCMR1 register.

3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx\_CCMR1 register (if no filter is needed, keep IC2F = 0000).

4. Select the rising edge polarity by writing CC2P = 0 and CC2NP = 0 in the TIMx\_CCER register.

5. Configure the timer in external clock mode 1 by writing SMS = 111 in the TIMx\_SMCR register.

6. Select \textit{tim\_ti2} as the trigger input source by writing TS = 110 in the TIMx\_SMCR register.

7. Enable the counter by writing CEN = 1 in the TIMx\_CR1 register.

\textit{Note: The capture prescaler is not used for triggering, it is not necessary to configure it.}

When a rising edge occurs on \textit{tim\_ti2}, the counter counts once and the TIF flag is set.

The delay between the rising edge on \textit{tim\_ti2} and the actual clock of the counter is due to the resynchronization circuit on \textit{tim\_ti2} input.

**Figure 594. Control circuit in external clock mode 1**

### 44.4.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler), and an output stage (with comparator and output control).

\textit{Figure 595, Figure 596, Figure 597} and \textit{Figure 598} give an overview of a capture/compare channel.

The input stage samples the corresponding \textit{tim\_tix} input to generate a filtered signal \textit{tim\_tixf}. Then, an edge detector with polarity selection generates a signal (\textit{tim\_tixfp}) which
can be used as trigger input by the slave mode controller or as the capture command. It is
prescaled before the capture register (ICxPS).

Figure 595. Capture/compare channel 1 input stage (TIM13/TIM14)

Figure 596. Capture/compare channel 1 input stage (TIM9/TIM12)

The output stage generates an intermediate waveform which is then used for reference:
tim_ocxref (active high). The polarity acts at the end of the chain.
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 44.4.7 Input capture mode

In input capture mode, the capture/compare registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding tim_icx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the overcapture flag CCxOF (TIMx_SR register) is set. CCxIF can be
cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

1. Select the proper tim_ti1_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input mode, and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (by programming the ICxF bits in the TIMx_CCMRx register if the input is one of the tim_tix inputs). Let’s imagine that, when toggling, the input signal is not stable during at most five internal clock cycles. The user must program a filter duration longer than these five clock cycles. The user can validate a transition on tim_ti1 when eight consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the tim_ti1 channel by programming CC1P and CC1NP bits to 00 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In this example, the user wishes the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register.

When an input capture occurs:
• The TIMx_CCR1 register gets the value of the counter on the active transition.
• CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
• An interrupt is generated depending on the CC1E bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

Note: IC interrupt requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

44.4.8 PWM input mode (TIM9/TIM12 only)

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:
• The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges).
• The TIM_CCR2 register holds the pulse width (interval between two consecutive rising and falling edges).
This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two `tim_icx` signals are mapped on the same `tim_tix` input.
- These two `tim_icx` signals are active on edges with opposite polarity.
- One of the two `tim_tixfpy` signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on tim_ti1 using the following procedure (depending on tim_ker_ck frequency and prescaler value):

1. Select the proper `tim_ti1_in[15:0]` source (internal or external) with the `TI1SEL[3:0]` bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the `CC1S` bits to 01 in the TIMx_CCMR1 register (`tim_ti1` selected).
3. Select the active polarity for `tim_ti1fp1` (used both for capture in TIMx_CCR1 and counter clear): program the `CC1P` and `CC1NP` bits to 00 (active on rising edge).
4. Select the active input for TIMx_CCR2: write the `CC2S` bits to 10 in the TIMx_CCMR1 register (`tim_ti1` selected).
5. Select the active polarity for `tim_ti1fp2` (used for capture in TIMx_CCR2): program the `CC2P` and `CC2NP` bits to 10 (active on falling edge).
6. Select the valid trigger input: write the `TS` bits to 00101 in the TIMx_SMCR register (`tim_ti1fp1` selected).
7. Configure the slave mode controller in reset mode: write the `SMS` bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the `CC1E` and `CC2E` bits to 1 in the TIMx_CCER register.

![PWM input mode timing](image)

**Figure 599. PWM input mode timing**

### 44.4.9 Forced output mode

In output mode (`CCxS` bits = 00 in the TIMx_CCMRx register), each output compare signal (`tim_ocxref` and then `tim_ocx`) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.
To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write 0101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP = 0 (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 0100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt requests can be sent accordingly. This is described in the output compare mode section below.

### 44.4.10 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

1. Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM = 0000), be set active (OCxM = 0001), be set inactive (OCxM = 0010) or can toggle (OCxM = 0011) on match.
2. Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
3. Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 0011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE = 0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 600.
44.4.11 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per TIM_OCx output) by writing 0110 (PWM mode 1) or 0111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the autoreload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

The TIM_OCx polarity is software programmable using the CCxE bit in the TIMx_CCER register. It can be programmed as active high or active low. The TIM_OCx output is enabled by the CCxP bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CNT ≤ TIMx_CCRx.

The timer is able to generate PWM in edge-aligned mode only since the counter is upcounting.

In the following example, the user considers PWM mode 1. The reference PWM signal TIM_OCxRef is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the autoreload value (in TIMx_ARR) then TIM_OCxRef is held at 1. If the compare value is 0 then TIM_OCxRef is held at 0. Figure 601 shows some edge-aligned PWM waveforms in an example where TIMx_ARR = 8.
Dithering mode

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. Figure 602 presents the dithering principle applied to four consecutive PWM cycles.
When the dithering mode is enabled, the register coding is changed as follows (see Figure 603 for example):

- The four LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value.

**Note:** The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The DITHEN bit must be reset
3. The CCIF flags must be cleared
4. The CEN bit can be set (eventually with ARPE = 1).

**Figure 603. Data format and register coding in dithering mode**

The minimum frequency is given by the following formula:

\[
\text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{\max_{\text{Resolution}}}
\]
The maximum TIMx_ARR and TIMxCC Ry values are limited to 0xFFFFF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on Figure 604, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

**Figure 604. PWM resolution vs frequency**

The duty cycle and/or period changes are spread over 16 consecutive periods, as described in Figure 605.
Figure 605. PWM dithering pattern

The autoreload and compare values increments are spread following specific patterns described in Table 453. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

44.4.12 Combined PWM mode (TIM9/TIM12 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers.

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing 1100 (Combined PWM mode 1) or 1101 (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in combined PWM mode 2).

**Note:** The OCxM[3:0] bitfield is split into two parts for compatibility reasons, the most significant bit is not contiguous with the three least significant ones.

*Figure 606* represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in combined PWM mode 2.
- Channel 2 is configured in PWM mode 1.
44.4.13 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be as follows:

\[ CNT < CCRx \leq ARR \] (in particular, \( 0 < CCRx \))
Figure 607. Example of one pulse mode

For example one may want to generate a positive pulse on tim_oc1 with a length of tPULSE and after a delay of tDELAY as soon as a positive edge is detected on the tim_ti2 input pin.

Use tim_ti2fp2 as trigger 1:
1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map tim_ti2fp2 to tim_ti2 by writing CC2S = 01 in the TIMx_CCMR1 register.
3. tim_ti2fp2 must detect a rising edge, write CC2P = 0 and CC2NP = 0 in the TIMx_CCER register.
4. Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS = 00110 in the TIMx_SMCR register.
5. tim_ti2fp2 is used to start the counter by writing SMS to 110 in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).
- The tDELAY is defined by the value written in the TIMx_CCR1 register.
- The tPULSE is defined by the difference between the autoreload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Assuming the user wants to build a waveform with a transition from 0 to 1 when a compare match occurs and a transition from 1 to 0 when the counter reaches the autoreload value. To do this PWM mode 2 must be enabled by writing OC1M = 0111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE = 1 in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the autoreload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to 0 in this example.

Since only one pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over
from the autoreload value back to 0). When OPM bit in the TIMx_CR1 register is set to 0, so the Repetitive mode is selected.

**Particular case: tim_ocx fast enable**

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY min}}$ that can be obtained.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 44.4.14 Retriggerable one pulse mode (TIM9/TIM12 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with nonretriggerable one pulse mode described in Section 44.4.13: One-pulse mode:

- The pulse starts as soon as the trigger occurs (no programmable delay).
- The pulse is extended if a new trigger occurs before the previous one is completed.

The timer must be in Slave mode, with the bits SMS[3:0] = 1000 (Combined reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to 1000 or 1001 for retriggerable OPM mode 1 or 2.

If the timer is configured in up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in down-counting mode, CCRx must be above or equal to ARR.

*Note:* The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the three least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

---

MSv62349v2
44.4.15 **UIF bit remapping**

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

44.4.16 **Timer input XOR function**

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the two input pins tim_t1 and tim_t2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in Figure 609.

![Figure 609. Measuring time interval between edges on 2 signals](M5v63068V1)

44.4.17 **TIM9/TIM12 external trigger synchronization**

The TIM9/TIM12 timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger, and Gated + reset mode.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on tim_t1 input:

1. Configure the channel 1 to detect rising edges on tim_t1. Configure the input filter duration (in this example, the user does not need any filter, so the user keeps IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the
1. Configure the channel 1 to detect low levels on TIM_t1. Configure the input filter duration (in this example, the user does not need any filter, so the user keeps IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in TIMx_CCMR1 register. Program CC1P = 1 and CC1NP = 0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS = 101 in TIMx_SMCR register. Select TIM_t1 as the input source by writing TS = 00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN = 1 in the TIMx_CR1 register (in gated mode, the counter does not start if CEN = 0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TIM_t1 is low and stops as soon as TIM_t1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TIM_t1 and the actual stop of the counter is due to the resynchronization circuit on TIM_t1 input.

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TIM_t1 input is low:

1. Configure the channel 1 to detect low levels on TIM_t1. Configure the input filter duration (in this example, the user does not need any filter, so the user keeps IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in TIMx_CCMR1 register. Program CC1P = 1 and CC1NP = 0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS = 101 in TIMx_SMCR register. Select TIM_t1 as the input source by writing TS = 00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN = 1 in the TIMx_CR1 register (in gated mode, the counter does not start if CEN = 0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TIM_t1 is low and stops as soon as TIM_t1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TIM_t1 and the actual stop of the counter is due to the resynchronization circuit on TIM_t1 input.
Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on `tim_ti2` input:

1. Configure the channel 2 to detect rising edges on `tim_ti2`. Configure the input filter duration (in this example, the user does not need any filter, so the user keeps `IC2F = 0000`). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, `CC2S = 01` in TIMx_CCMR1 register. Program `CC2P = 1` and `CC2NP = 0` in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing `SMS = 110` in TIMx_SMCR register. Select `tim_ti2` as the input source by writing `TS = 00110` in TIMx_SMCR register.

When a rising edge occurs on `tim_ti2`, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on `tim_ti2` and the actual start of the counter is due to the resynchronization circuit on `tim_ti2` input.
44.4.18 Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

44.4.19 Slave mode – combined reset + gated mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
44.4.20 Timer synchronization (TIM9/TIM12 only)

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 42.4.23: Timer synchronization for details.

Note: The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

44.4.21 Using timer output as trigger for other timers (TIM13/TIM14 only)

The timers with one channel only do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any timer on the device to identify which timers can be targeted as slave.

The OC1 signal pulse width must be programmed to be at least two clock cycles of the destination timer, to make sure the slave timer detects the trigger.

For instance, if the destination's timer CK_INT clock is four times slower than the source timer, the OC1 pulse width must be eight clock cycles.
44.4.22 ADC triggers (TIM9/TIM12 only)

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

44.4.23 Debug mode

When the microcontroller enters debug mode (Cortex®-M7 core halted), the TIMx counter can either continue to work normally or stop.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to the debug section.

44.5 TIM9/TIM12/TIM13/TIM14 low-power modes

Table 454. Effect of low-power modes on TIM9/TIM12/TIM13/TIM14

<table>
<thead>

1. Available for TIM9/TIM12 only.
44.7 TIM9/TIM12 registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits), or words (32 bits).

44.7.1 TIMx control register 1 (TIMx_CR1)(x = 9, 12)

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable

0: Dithering disabled
1: Dithering enabled

Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bitfield indicates the division ratio between the timer clock (tim_ker_ck) frequency and sampling clock used by the digital filters (tim_tix),

00: tDTS = tim_ker_ck
01: tDTS = 2 × tim_ker_ck
10: tDTS = 4 × tim_ker_ck
11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx_ARR register is not buffered.
1: TIMx_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped on the update event
1: Counter stops counting on the next update event (clearing the CEN bit).
Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generates an update interrupt if enabled. These events can be:
– Counter overflow
– Setting the UG bit
– Update generation through the slave mode controller
1: Only counter overflow generates an update interrupt if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable update event (UEV) generation.
0: UEV enabled. An UEV is generated by one of the following events:
– Counter overflow
– Setting the UG bit

Buffered registers are then loaded with their preload values.
1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCRx). The counter and the prescaler are reinitialized if the UG bit is set.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled
CEN is cleared automatically in one-pulse mode, when an update event occurs.
*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

### 44.7.2 TIM12 control register 2 (TIMx_CR2)(x = 9, 12)

Address offset: 0x004
Reset value: 0x0000
RM0477 General-purpose timers (TIM9/TIM12/TIM13/TIM14)

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **T11S**: tim_ti1 selection
- **0**: The tim_ti1_in[15:0] multiplexer output is connected to tim_ti1 input
- **1**: The tim_ti1_in[15:0] and tim_ti2_in[15:0] multiplexers output are connected to the tim_ti1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection
These bits allow to select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:
- **000**: Reset - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.
- **001**: Enable - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).
- **010**: Update - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.
- **011**: Compare Pulse - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (tim_trgo).
- **100**: Compare - tim_oc1refc signal is used as trigger output (tim_trgo).
- **101**: Compare - tim_oc2refc signal is used as trigger output (tim_trgo).

Bits 3:0 Reserved, must be kept at reset value.

### 44.7.3 TIMx slave mode control register (TIMx_SMCR)(x = 9, 12)

Address offset: 0x008
Reset value: 0x0000 0000

Bits 31:22 Reserved, must be kept at reset value.

Bits 19:17 Reserved, must be kept at reset value.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **MSM**: Master/Slave mode
- **0**: No action
- **1**: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful in order to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4  **TS[4:0]: Trigger selection**

This TS[4:0] bitfield selects the trigger input to be used to synchronize the counter.

- 00000: Internal Trigger 0 (tim_itr0)
- 00001: Internal Trigger 1 (tim_itr1)
- 00010: Internal Trigger 2 (tim_itr2)
- 00011: Internal Trigger 3 (tim_itr3)
- 00100: tim_ti1 Edge Detector (tim_ti1f_ed)
- 00101: Filtered Timer Input 1 (tim_ti1fp1)
- 00110: Filtered Timer Input 2 (tim_ti2fp2)
- 01000: Internal Trigger 4 (tim_itr4)
- 01001: Internal Trigger 5 (tim_itr5)
- 01010: Internal Trigger 6 (tim_itr6)
- 01011: Internal Trigger 7 (tim_itr7)
- 01100: Internal Trigger 8 (tim_itr8)
- 01101: Internal Trigger 9 (tim_itr9)
- 01110: Internal Trigger 10 (tim_itr10)
- 01111: Internal Trigger 10 (tim_itr11)
- 10000: Internal Trigger 10 (tim_itr12)
- 10001: Internal Trigger 10 (tim_itr13)
- 10010: Internal Trigger 10 (tim_itr14)
- 10011: Internal Trigger 10 (tim_itr15)
- Others: Reserved

See **Table 452: TIMx internal trigger connection** for more details on the meaning of tim_itrx for each timer.

**Note:** These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3  **Reserved**, must be kept at reset value.
Bits 16, 2, 1, 0  **SMS[3:0]:** Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (see input control register and control register description.

0000: Slave mode disabled - if CEN = 1 then the prescaler is clocked directly by the internal clock.
0001: Reserved
0010: Reserved
0011: Reserved
0100: Reset mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.
0101: Gated mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
0110: Trigger mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.
0111: External clock mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.
1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.
1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

Other codes: reserved.

**Note:** The gated mode (including gated + reset mode) must not be used if tim_tif_ed is selected as the trigger input (TS = 00100). Indeed, tim_tif_ed outputs 1 pulse for each transition on tim_tif, whereas the gated mode checks the level of the trigger signal.

The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signals must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

### 44.7.5 TIMx status register (TIMx_SR)(x = 9, 12)

Address offset: 0x010  
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15-11</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>10</td>
<td><strong>CC2OF</strong>: Capture/compare 2 overcapture flag refer to CC1OF description</td>
</tr>
</tbody>
</table>
| 9     | **CC1OF**: Capture/Compare 1 overcapture flag  
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to 0.  
0: No overcapture has been detected.  
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set  
| 8-7   | Reserved, must be kept at reset value.                                      |
| 6     | **TIF**: Trigger interrupt flag  
This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.  
0: No trigger event occurred.  
1: Trigger interrupt pending.  
| 5-3   | Reserved, must be kept at reset value.                                      |
Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag  
 refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag  
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).  
0: No compare match / No input capture occurred  
1: A compare match or an input capture occurred. 

**If channel CC1 is configured as output**: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description. 

**If channel CC1 is configured as input**: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on TIM_IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCR1).

Bit 0 **UIF**: Update interrupt flag  
This bit is set by hardware on an update event. It is cleared by software.  
0: No update occurred.  
1: Update interrupt pending. This bit is set by hardware when the registers are updated:  
  – At overflow and if UDIS = 0 in the TIMx_CR1 register.  
  – When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS = 0 and UDIS = 0 in the TIMx_CR1 register.  
  – When CNT is reinitialized by a trigger event (refer to Section 44.7.3: TIMx slave mode control register (TIMx_SMCR)(x = 9, 12)), if URS = 0 and UDIS = 0 in the TIMx_CR1 register.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on tim_ti2
10: CC2 channel is configured as input, IC2 is mapped on tim_ti1
11: CC2 channel is configured as input, IC2 is mapped on tim_trc. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note: The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).*
44.7.8 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 9, 12)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits in this register have different functions in input and output modes.
Output compare mode:

- Bits 31:25: Reserved, must be kept at reset value.
- Bits 23:17: Reserved, must be kept at reset value.
- Bit 15: Reserved, must be kept at reset value.
- Bits 24, 14:12: **OC2M[3:0]**: Output compare 2 mode
  - Refer to **OC1M[3:0]** for bit description.
- Bit 11: **OC2PE**: Output compare 2 preload enable
- Bit 10: **OC2FE**: Output compare 2 fast enable
- Bits 9:8: **CC2S[1:0]**: Capture/Compare 2 selection
  - This bitfield defines the direction of the channel (input/output) as well as the used input.
    - 00: CC2 channel is configured as output
    - 01: CC2 channel is configured as input, IC2 is mapped on tim_ti2
    - 10: CC2 channel is configured as input, IC2 is mapped on tim_ti1
    - 11: CC2 channel is configured as input, IC2 is mapped on tim_trc. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)
  - **Note**: The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).
- Bit 7: Reserved, must be kept at reset value.
Bits 16, 6:4 \textbf{OC1M}[3:0]: Output compare 1 mode (refer to bit 16 for \textbf{OC1M}[3])

These bits define the behavior of the output reference signal \textit{tim\_oc1ref} from which \textit{tim\_oc1} is derived. \textit{tim\_oc1ref} is active high whereas the active level of \textit{tim\_oc1} depends on the \textit{CC1P}.

0000: Frozen - The comparison between the output compare register TIM\textsubscript{x} CCR1 and the counter TIM\textsubscript{x} CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. The \textit{tim\_oc1ref} signal is forced high when the TIM\textsubscript{x} CNT counter matches the capture/compare register 1 (TIM\textsubscript{x} CCR1).

0010: Set channel 1 to inactive level on match. The \textit{tim\_oc1ref} signal is forced low when the TIM\textsubscript{x} CNT counter matches the capture/compare register 1 (TIM\textsubscript{x} CCR1).

0011: Toggle - \textit{tim\_oc1ref} toggles when TIM\textsubscript{x} CNT = TIM\textsubscript{x} CCR1

0100: Force inactive level - \textit{tim\_oc1ref} is forced low

0101: Force active level - \textit{tim\_oc1ref} is forced high

0110: PWM mode 1 - channel 1 is active as long as TIM\textsubscript{x} CNT<TIM\textsubscript{x} CCR1 else it is inactive

0111: PWM mode 2 - channel 1 is inactive as long as TIM\textsubscript{x} CNT<TIM\textsubscript{x} CCR1 else it is active

1000: Retriggable OPM mode 1 - The channel is active until a trigger event is detected (on \textit{tim\_trgi} signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1001: Retriggable OPM mode 2 - The channel is inactive until a trigger event is detected (on \textit{tim\_trgi} signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - \textit{tim\_oc1ref} has the same behavior as in PWM mode 1. \textit{tim\_oc1refc} is the logical OR between \textit{tim\_oc1ref} and \textit{tim\_oc2ref}.

1101: Combined PWM mode 2 - \textit{tim\_oc1ref} has the same behavior as in PWM mode 2. \textit{tim\_oc1refc} is the logical AND between \textit{tim\_oc1ref} and \textit{tim\_oc2ref}.

1110: Reserved,

1111: Reserved

\textbf{Note:} In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.
Bit 3 **OC1PE**: Output compare 1 preload enable
- 0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken into account immediately
- 1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded into the active register at each update event

Bit 2 **OC1FE**: Output compare 1 fast enable
This bit is used to accelerate the effect of an event on the trigger in input on the CC output.
- 0: CC1 behaves normally depending on the counter and CCR1 values even when the trigger is ON. The minimum delay to activate the CC1 output when an edge occurs on the trigger input is 5 clock cycles
- 1: An active edge on the trigger input acts like a compare match on the CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
- 10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
- 11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

Note: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).

### 44.7.9 TIMx capture/compare enable register (TIMx_CCER)(x = 9, 12)

Address offset: 0x020
Reset value: 0x0000

<table>

</tbody>
</table>

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **CC2NP**: Capture/Compare 2 output Polarity
Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output Polarity
Refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable
Refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 complementary output Polarity
CC1 channel configured as output: CC1NP must be kept cleared
CC1 channel configured as input: CC1NP is used in conjunction with CC1P to define tim_ti1fp1/tim_ti2fp1 polarity (refer to CC1P description).
Bit 2  Reserved, must be kept at reset value.

Bit 1  **CC1P**: Capture/Compare 1 output Polarity.
0: tim_oc1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: tim_oc1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When **CC1 channel is configured as input**, both CC1NP/CC1P bits select the active polarity of tim_t1fp1 and tim_t2fp1 for trigger or capture operations.

- **CC1NP = 0, CC1P = 0**: non-inverted/rising edge. The circuit is sensitive to tim_t1fp1 rising edge (capture or trigger operations in reset, external clock or trigger mode), tim_t1fp1 is not inverted (trigger operation in gated mode).
- **CC1NP = 0, CC1P = 1**: inverted/falling edge. The circuit is sensitive to tim_t1fp1 falling edge (capture or trigger operations in reset, external clock or trigger mode), tim_t1fp1 is inverted (trigger operation in gated mode).
- **CC1NP = 1, CC1P = 1**: non-inverted/both edges/ The circuit is sensitive to both tim_t1fp1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), tim_t1fp1 is not inverted (trigger operation in gated mode).
- **CC1NP = 1, CC1P = 0**: This configuration is reserved, it must not be used.

Bit 0  **CC1E**: Capture/Compare 1 output enable.
0: Capture mode disabled / tim_oc1 is not active
1: Capture mode enabled / tim_oc1 signal is output on the corresponding output pin

Table 456. Output control bit for standard tim_ocx channels

44.7.11 TIMx prescaler (TIMx_PSC)(x = 9, 12)

Address offset: 0x028
Reset value: 0x0000

Bit 31 **UIFCPY**: UIF Copy
This bit is a read-only copy of the UIF bit in the TIMx_ISR register.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

- **Non-dithering mode (DITHEN = 0)**
  The register holds the counter value.

- **Dithering mode (DITHEN = 1)**
  The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

44.7.12 TIMx autoreload register (TIMx_ARR)(x = 9, 12)

Address offset: 0x02C
Reset value: 0x0000 FFFF

Bits 31:0 **ARR[19:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the Section 44.4.3: Time-base unit for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.

- **Non-dithering mode (DITHEN = 0)**
  The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reset.

- **Dithering mode (DITHEN = 1)**
  The register holds the integer part in ARR[15:4]. The ARR[3:0] bitfield contains the dithered part.
### 44.7.13 TIMx capture/compare register 1 (TIMx_CCR1)(x = 9, 12)

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR2[19:0]**: Capture/compare 2 value

- **If channel CC2 is configured as output:**
  - CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).
  - It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.
  - The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on TIM_OC2 output.

  - **Non-dithering mode (DITHEN = 0)**
    - The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.
  - **Dithering mode (DITHEN = 1)**
    - The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

- **If channel CC2 is configured as input:**
  - CCR2 is the counter value transferred by the last input capture 1 event (TIM_IC2). The TIMx_CCR2 register is read-only and cannot be programmed.

  - **Non-dithering mode (DITHEN = 0)**
    - The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.
  - **Dithering mode (DITHEN = 1)**
    - The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

Table 457. TIMx register map and reset values (x = 9, 12) (continued)
44.8 TIM13/TIM14 registers

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits), or words (32 bits).

44.8.1 TIMx control register 1 (TIMx_CR1)(x = 13, 14)

Address offset: 0x000
Reset value: 0x0000

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable
0: Dithering disabled
1: Dithering enabled

*Note: The DITHEN bit can only be modified when CEN bit is reset.*

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bitfield indicates the division ratio between the timer clock (tim_ker_ck) frequency and sampling clock used by the digital filters (tim_tix),
00: tDTS = tim_ker_ck
01: tDTS = 2 × tim_ker_ck
10: tDTS = 4 × tim_ker_ck
11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable
0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped on the update event
1: Counter stops counting on the next update event (clearing the CEN bit).
Bit 2  **URS**: Update request source
This bit is set and cleared by software to select the update interrupt (UEV) sources.
0: Any of the following events generate an UEV if enabled:
   - Counter overflow
   - Setting the UG bit
1: Only counter overflow generates an UEV if enabled.

Bit 1  **UDIS**: Update disable
This bit is set and cleared by software to enable/disable update interrupt (UEV) event generation.
0: UEV enabled. An UEV is generated by one of the following events:
   - Counter overflow
   - Setting the UG bit.
   Buffered registers are then loaded with their preload values.
1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCRx). The counter and the prescaler are reinitialized if the UG bit is set.

Bit 0  **CEN**: Counter enable
0: Counter disabled
1: Counter enabled

*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

### 44.8.2  TIMx interrupt enable register (TIMx_DIER)(x = 13, 14)
Address offset: 0x00C
Reset value: 0x0000

### Bits 15:10
Reserved, must be kept at reset value.

#### Bit 9 CC1OF
Capture/Compare 1 overcapture flag
- This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to 0.
- 0: No overcapture has been detected.
- 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

#### Bits 8:2
Reserved, must be kept at reset value.

#### Bit 1 CC1IF
Capture/compare 1 interrupt flag
- This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
- 0: No compare match / No input capture occurred
- 1: A compare match or an input capture occurred.

**If channel CC1 is configured as output:** this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

**If channel CC1 is configured as input:** this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on TIM_IN1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

#### Bit 0 UIF
Update interrupt flag
- This bit is set by hardware on an update event. It is cleared by software.
- 0: No update occurred.
- 1: Update interrupt pending. This bit is set by hardware when the registers are updated:
  - At overflow and if UDIS = 0 in the TIMx_CR1 register.
  - When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS = 0 and UDIS = 0 in the TIMx_CR1 register.

## 44.8.4 TIMx event generation register (TIMx_EGR)(x = 13, 14)

RM0477 Rev 6 1955/3791
Bits 15:2  Reserved, must be kept at reset value.

Bit 1  **CC1G**: Capture/compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
   - **If channel CC1 is configured as output**: CC1IF flag is set, Corresponding interrupt or is sent if enabled.
   - **If channel CC1 is configured as input**: The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0  **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared.

### 44.8.5 TIMx capture/compare mode register 1
**(TIMx_CCMR1)(x = 13, 14)**

Address offset: 0x018
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode:**

<table>

</tbody>
</table>

Bits 31:17: Reserved, must be kept at reset value.

Bits 15:7: Reserved, must be kept at reset value.

Bits 16, 6, 4 **OC1M[3:0]:** Output compare 1 mode (refer to bit 16 for OC1M[3])

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 is derived. tim_oc1ref is active high whereas tim_oc1 active level depends on CC1P bit.

0000: Frozen. The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - tim_oc1ref toggles when TIMx_CNT = TIMx_CCR1.

0100: Force inactive level - tim_oc1ref is forced low.

0101: Force active level - tim_oc1ref is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIMx_CNT < TIMx_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT < TIMx_CCR1 else active

Others: Reserved

**Note:** In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.
44.8.7 TIMx capture/compare enable register
(TIMx_CCER)(x = 13, 14)

Address offset: 0x020
Reset value: 0x0000

<table>
<thead>
<tr>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **CC1NP**: Capture/Compare 1 complementary output Polarity.

CC1 channel configured as output: CC1NP must be kept cleared.
CC1 channel configured as input: CC1NP bit is used in conjunction with CC1P to define tim_ti1fp1 polarity (refer to CC1P description).
General-purpose timers (TIM9/TIM12/TIM13/TIM14)

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/Compare 1 output Polarity.
0: tim_oc1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: tim_oc1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When **CC1 channel is configured as input**, both CC1NP/CC1P bits select the active polarity of tim_t1f1p1 for capture operations.

- CC1NP = 0, CC1P = 0: non-inverted/rising edge. The circuit is sensitive to tim_t1f1p1 rising edge (capture or trigger operations in reset, external clock or trigger mode), tim_t1f1p1 is not inverted (trigger operation in gated mode).
- CC1NP = 0, CC1P = 1: inverted/falling edge. The circuit is sensitive to tim_t1f1p1 falling edge (capture or trigger operations in reset, external clock or trigger mode), tim_t1f1p1 is inverted (trigger operation in gated mode).
- CC1NP = 1, CC1P = 1: non-inverted/both edges/ The circuit is sensitive to both tim_t1f1p1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), tim_t1f1p1 not inverted (trigger operation in gated mode).
- CC1NP = 1, CC1P = 0: This configuration is reserved, it must not be used.

Bit 0 **CC1E**: Capture/Compare 1 output enable.
0: Capture mode disabled / tim_oc1 is not active
1: Capture mode enabled / tim_oc1 signal is output on the corresponding output pin

**Table 458. Output control bit for standard tim_ocx channels**

<table>
<thead>
<tr>
<th>CCxE bit</th>

1960/3791 RM0477 Rev 6
Bit 31 **UIFCPY**: UIF Copy
This bit is a read-only copy of the UIF bit in the TIMx_ISR register.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

- **Non-dithering mode (DITHEN = 0)**
  - The register holds the counter value.
- **Dithering mode (DITHEN = 1)**
  - The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

### 44.8.9 TIMx prescaler (TIMx_PSC)(x = 13, 14)

**Address offset**: 0x028  
**Reset value**: 0x0000

![PSC Register](image)

Bits 15:0 **PSC[15:0]**: Prescaler value

- The counter clock frequency \( f_{\text{tim_cnt_ck}} \) is equal to \( f_{\text{tim_psc_ck}} / (\text{PSC}[15:0] + 1) \).
- PSC contains the value to be loaded in the active prescaler register at each update event. (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

### 44.8.10 TIMx autoreload register (TIMx_ARR)(x = 13, 14)

**Address offset**: 0x02C  
**Reset value**: 0x0000 FFFF

![ARR Register](image)

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]**: Auto-reload value

- **ARR[19:0]** is the value to be loaded in the actual auto-reload register.
- Refer to the **Section 44.4.3: Time-base unit** for more details about ARR update and behavior.
- The counter is blocked while the auto-reload value is null.

- **Non-dithering mode (DITHEN = 0)**
  - The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reset.
- **Dithering mode (DITHEN = 1)**
44.8.11 TIMx capture/compare register 1 (TIMx_CCR1)(x = 13, 14)

Address offset: 0x034
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>

<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 CCR1[19:0]: Capture/compare 1 value

If channel CC1 is configured as output:
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input:
CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.
Non-dithering mode (DITHEN = 0)
The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

44.8.12 TIMx timer input selection register (TIMx_TISEL)(x = 13, 14)

Address offset: 0x05C
Reset value: 0x0000

<table>
<thead>

Refer to Section 2.3 for the register boundary addresses.
45 General purpose timers (TIM15/TIM16/TIM17)

45.1 TIM15/TIM16/TIM17 introduction

The TIM15/TIM16/TIM17 timers consist of a 16-bit autoreload counter driven by a
programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input
signals (input capture) or generating output waveforms (output compare, PWM,
complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several
milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM15/TIM16/TIM17 timers are completely independent, and do not share any
resources. TIM15 can be synchronized as described in Section 45.4.26: Timer
synchronization (TIM15 only).

45.2 TIM15 main features

TIM15 includes the following features:

- 16-bit autoreload upcounter
- 16-bit programmable prescaler used to divide (also "on the fly") the counter clock
  frequency by any factor between 1 and 65535
- Up to two independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time (for channel 1 only)
- Synchronization circuit to control the timer with external signals and to interconnect
  several timers together
- Repetition counter to update the timer registers only after a given number of cycles of
  the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow counter initialization (by software or internal/external
    trigger)
  - Trigger event (counter start, stop, initialization, or count by internal/external
    trigger)
  - Input capture
  - Output compare
  - Break input (interrupt request)
45.3 TIM16/TIM17 main features

The TIM16/TIM17 timers include the following features:

- 16-bit autoreload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- One channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow
  - Input capture
  - Output compare
  - Break input
45.4 TIM15/TIM16/TIM17 functional description

45.4.1 Block diagram

Figure 613. TIM15 block diagram

Notes:
- Reg: Preload registers transferred to active registers on U event according to control bit
- Event
- Interrupt & DMA output

1. Refer to Section 45.4.15: Using the break function for details.
1. Refer to Section 45.4.15: Using the break function for details.

2. This signal can be used as trigger for some slave timer (see internal trigger connection table in next section). See Section 45.4.27: Using timer output as trigger for other timers (TIM16/TIM17 only) for details.

### 45.4.2 TIM15/TIM16/TIM17 pins and internal signals

Table 460 and Table 461 in this section summarize the TIM inputs and outputs.

<table>
<thead>
<tr>
<th>Pin name</th>

### 45.4.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit upcounter with its related autoreload register. The counter clock can be divided by a prescaler.

The counter, the autoreload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Autoreload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The autoreload register is preloaded. Writing to or reading from the autoreload register accesses the preload register. The content of the preload register is transferred into the shadow register permanently or at each update event (UEV), depending on the autoreload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).
Note that the counter starts counting one clock cycle after setting the CEN bit in the TIMx_CR1 register.

**Prescaler description**

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 615* and *Figure 616* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

**Figure 615. Counter timing diagram with prescaler division change from 1 to 2**

![Counter timing diagram with prescaler division change from 1 to 2](image)
### 45.4.4 Counter modes

#### Upcounting mode

In upcounting mode, the counter counts from 0 to the autoreload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The autoreload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

**Figure 617. Counter timing diagram, internal clock divided by 1**

![Diagram of counter timing](image-url)
Figure 618. Counter timing diagram, internal clock divided by 2

Figure 619. Counter timing diagram, internal clock divided by 4
Figure 620. Counter timing diagram, internal clock divided by N

Figure 621. Counter timing diagram, update event when ARPE = 0 (TIMx_ARR not preloaded)
45.4.5 Repetition counter

Section 45.4.3: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR autoreload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented at each counter overflow.

The repetition counter is an autoreload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 623). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
**45.4.6 Clock selection**

The counter clock can be provided by the following clock sources:

- **Internal clock (tim_ker_ck)**
- **External clock mode1: external input pin (tim_ti1 or tim_ti2, if available)**
- **Internal trigger inputs (tim_itrx) (only for TIM15): using one timer as the prescaler for another timer, for example, TIM1 can be configured to act as a prescaler for TIM15. Refer to *Using one timer to enable another timer* for more details.**

**Internal clock source (tim_ker_ck)**

If the slave mode controller is disabled (SMS = 000), then the CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed.
only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 624 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

**Figure 624. Control circuit in normal mode, internal clock divided by 1**

![Control circuit in normal mode, internal clock divided by 1](image)

**External clock source mode 1**

This mode is selected when SMS = 111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

**Figure 625. tim_ti2 external clock connection example**

![tim_ti2 external clock connection example](image)

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:
1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the tim_ti2 input by writing CC2S = 01 in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F = 0000).
4. Select rising edge polarity by writing CC2P = 0 in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS = 111 in the TIMx_SMCR register.
6. Select tim_ti2 as the trigger input source by writing TS = 00110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN = 1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set.
The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to
the resynchronization circuit on tim_ti2 input.

Figure 626. Control circuit in external clock mode 1

45.4.7 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a
shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and
an output stage (with comparator and output control).

Figure 627 to Figure 630 give an overview of one Capture/Compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal
tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfpy) which
can be used as trigger input by the slave mode controller or as the capture command. It is
prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

Figure 627. Capture/compare channel (example: channel 1 input stage)

Figure 628. Capture/compare channel 1 main circuit
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

45.4.8 Input capture mode

In Input capture mode, the capture/compare registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding tim_icx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was
already high, then the overcapture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_t1 input rises. To do this, use the following procedure:

1. Select the proper tim_t1_in[15:1] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.

2. Select the active input: TIMx_CCR1 must be linked to the tim_t1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input, and the TIMx_CCR1 register becomes read-only.

3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at least 5 internal clock cycles. The user must program a filter duration longer than these five clock cycles. The user can validate a transition on tim_t1 when eight consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.

4. Select the edge of the active transition on the tim_t1 channel by writing CC1P bit to 0 in the TIMx_CCER register (rising edge in this case).

5. Program the input prescaler. In this example, the user wants the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).

6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.

7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.
45.4.9 **PWM input mode (only for TIM15)**

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single `tim_tix` input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIMx_CCR2 register holds the pulse width (interval between two consecutive rising and falling edges)

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two `tim_icx` signals are mapped on the same `tim_tix` input.
- These two `tim_icx` signals are active on edges with opposite polarity.
- One of the two `tim_tixfp` signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on `tim_t1` using the following procedure (depending on TIM_ker_ck frequency and prescaler value):

1. Select the proper `tim_t1`[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (`tim_t1` selected).
3. Select the active polarity for `tim_t1fp1` (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to 0 (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (`tim_t1` selected).
5. Select the active polarity for `tim_t1fp2` (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to 10 (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (`tim_t1fp1` selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to 1 in the TIMx_CCER register.
45.4.10 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx/tim_ocxn) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP = 0 (tim_ocx active high) → tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

45.4.11 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCXM = 000), be set
active (OCxM = 001), be set inactive (OCxM = 010) or can toggle (OCxM = 011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE = 0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 632.
45.4.12 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing 110 (PWM mode 1) or 111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the autoreload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI, and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The TIM15/TIM16/TIM17 are capable of upcounting only. Refer to Upcounting mode on page 1973.
In the following example applies to PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the autoreload value (in TIMx_ARR) then tim_ocxref is held at 1. If the compare value is 0 then tim_ocxref is held at 0. Figure 633 shows some edge-aligned PWM waveforms in an example where TIMx_ARR = 8.

**Figure 633. Edge-aligned PWM waveforms (ARR = 8)**

| Counter register | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 1 |
| tim_ocxref       |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

**Dithering mode**

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The Figure 634 below presents the dithering principle applied to four consecutive PWM cycles.
When the dithering mode is enabled, the register coding is changed as follows (see Figure 635 for example):

- The four LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value.

Note: The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The ARR[3:0] bits must be reset
3. The CCIF flags must be cleared
4. The CEN bit can be set (eventually with ARPE = 1).

The minimum frequency is given by the following formula:

$$\text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{\text{MaxResolution}}$$
Dithering mode disabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65536} \)

Dithering mode enabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}} \)

Note: The maximum TIMx.ARR and TIMx.CCRy values are limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on the Figure 636 below, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

**Figure 636. PWM resolution vs frequency**

The duty cycle and/or period changes are spread over 16 consecutive periods, as described in the Figure 637 below.
The autoreload and compare values increments are spread following specific patterns described in the Table 467 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

**Table 467. CCR and ARR register change dithering pattern**

45.4.13 Combined PWM mode (TIM15 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers.

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing 1100 (Combined PWM mode 1) or 1101 (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bitfield is split into two parts for compatibility reasons, the most significant bit is not contiguous with the three least significant ones.

*Figure 638* represents an example of signals that can be generated using Combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2.
- Channel 2 is configured in PWM mode 1.
45.4.14 Complementary outputs and dead-time insertion

The TIM15/TIM16/TIM17 general-purpose timers can output one complementary signal and manage the switching-off and switching-on of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (such as intrinsic delays of level-shifters and delays due to power switches).

The polarity of the outputs (main output tim_ocx or complementary tim_ocxn) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals tim_ocx and tim_ocxn are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 474: Output control bits for complementary tim_oc1 and tim_oc1n channels with break feature (TIM16/TIM17) on page 2054 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).
Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a reference waveform tim_ocxref, it generates two outputs tim_ocx and tim_ocxn. If tim_ocx and tim_ocxn are active high:

- The tim_ocx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The tim_ocxn output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (tim_ocx or tim_ocxn) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal tim_ocxref. (in these examples CCxP = 0, CCxNP = 0, MOE = 1, CCxE = 1 and CCxNE = 1)

Figure 639. Complementary output with symmetrical dead-time insertion.

![Diagram](MSv62332V1)

The DTAE bit in the TIMx_DTR2 is used to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on Figure 640.

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIMx_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIMx_DTR2 register. The DTAE bit must be written before enabling the counter and must not be modified while CEN = 1.

It is possible to have the deadtime value updated on-the-fly during pwm operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set in the TIMX_DTR2 register. The preload value is loaded in the active register on the next update event.

**Note:** If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 45.8.14: TIMx break and dead-time register (TIMx_BDTR) (x = 16 to 17) on page 2058 for delay calculation.
Redirecting tim_ocxref to tim_ocx or tim_ocxn

In output mode (forced, output compare or PWM), tim_ocxref can be redirected to the tim_ocx output or to tim_ocxn output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This is used to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

*Note:* When only tim_ocxn is enabled (CCxE = 0, CCxNE = 1), it is not complemented and becomes active as soon as tim_ocxref is high. For example, if CCxNP = 0 then tim_ocxn = tim_ocxref. On the other hand, when both tim_ocx and tim_ocxn are enabled (CCxE = CCxNE = 1) tim_ocx becomes active when tim_ocxref is high whereas tim_ocxn is complemented and becomes active when tim_ocxref is low.

45.4.15 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The break input is usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state.

The break channel gathers both system-level fault (such as clock failure, ECC/parity, and errors) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration.

The output enable signal and output levels during break are depending on several control bits:

- The MOE bit in TIMx_BDTR register is used to enable/disable the outputs by software and is reset in case of break or break2 event.
- The OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode).
- The OISx and OISxN bits in the TIMx_CR2 register which are setting the output shutdown level, either active or inactive. The tim_ocx and tim_ocxn outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 474: Output control bits for complementary tim_oc1 and tim_oc1n channels with break feature (TIM16/TIM17) on page 2054 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break function is enabled by setting the BKE bit in the TIMx_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. When the BKE and BKP bits are written, a delay of one APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait one APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.
The break is generated by the tim_brk inputs which have:
- Programmable polarity (BKP bit in the TIMx_BDTR register).
- Programmable enable bit (BKE bit in the TIMx_BDTR register).
- Programmable filter (BKF[3:0] bits in the TIMx_BDTR register) to avoid spurious events.

The break can be generated from multiple sources which can be individually enabled and with programmable edge sensitivity, using the TIMx_AF1 register.

The sources for break (tim_brk) channel are:
- External sources connected to one of the TIM_BKIN pins (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering.
- Internal sources:
  - Coming from a tim_brk_cmpx input (refer to Section 45.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation).
  - Coming from a system break request on the tim_sys_brk inputs (refer to Section 45.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation).

Break events can also be generated by software using BG bit in the TIMx_EGR register. All sources are ORed before entering the timer tim_brk inputs, as per Figure 643 below.

**Figure 643. Break circuitry overview**

Caution: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail-safe clock mode (for example, using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.
When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state, or even releasing the control to the GPIO (selected by the OSSI bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE = 0. If OSSI = 0, the timer releases the output control (taken over by the GPIO) else the enable outputs remains high.
- When complementary outputs are used:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_ocx and tim_ocxn cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2 tim_ker_ck clock cycles).
  - If OSSI = 0 then the timer releases the enable outputs (taken over by the GPIO which forces a Hi-Z state) else the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.
- The break status flag (BIF bit in the TIMx_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.
- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance. Else, MOE remains low until it is written with 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSI value. If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIMx_CR2 register.

The break inputs are acting on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF cannot be cleared.

The break can be generated by the tim_brk input which has a programmable polarity and an enable bit BKE in the TIMx_BDTR register.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It is used to freeze the configuration of several parameters (dead-time duration, tim_ocx/tim_ocxn polarities and state when disabled, OCxM configurations, break enable, and polarity). The protection can be selected among 3 levels with the LOCK bits in the TIMx_BDTR register. Refer to Section 45.8.14: TIMx break and dead-time register (TIMx_BDTR) (x = 16 to 17). The LOCK bits can be written only once after an MCU reset.

The Figure 644 shows an example of behavior for the outputs in response to a break.
Figure 644. Output behavior in response to a break event on tim_brk

- tim_ocxn (CCxE=1, CCxP=0, CCxNE=0, CCxNP=0, OISx=0 or OISx=OISxN=1)
45.4.16 Bidirectional break input

The TIM15/TIM16/TIM17 are featuring bidirectional break I/Os, as represented on Figure 645.

They are used to have:
- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin.
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged.

The tim_brk input is configured in bidirectional mode using the BKBID bit in the TIMxBDTR register. The BKBID programming bit can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode requires the I/O to be configured in open-drain mode with active low polarity (using BKINP and BKP bits). Any break request coming either from system (for example CSS), from on-chip peripherals, or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.
