Introduction

This reference manual targets application developers. It provides complete information on how to use the STM32H7R3, STM32H7S3, STM32H7R7, and STM32H7S7 memory and peripherals.

Microcontrollers of the STM32H7R3/7S3 and STM32H7R7/7S7 lines have different memory sizes, packages, and peripherals. They are referred to as STM32H7Rx/7Sx hereafter.

For ordering information, mechanical, and electrical device characteristics refer to the corresponding datasheets.

For information on the Arm® Cortex®-M7 with FPU core, refer to the corresponding Arm technical reference manual available from www.arm.com.

    10.3.2 I/O pin alternate function multiplexer and mapping .... 574
    10.3.3 I/O port control registers .................................... 574
    10.3.4 I/O port data registers ........................................ 575
    10.3.5 I/O data bitwise handling ..................................... 575
    10.3.6 GPIO locking mechanism ........................................ 575
    10.3.7 I/O alternate function input/output ......................... 575
    10.3.8 External interrupt/wakeup lines ............................... 576
    10.3.9 Input configuration ............................................. 576
    10.3.10 Output configuration .......................................... 577
10.3.11 Alternate function configuration .................................. 577
10.3.12 Analog configuration ............................................... 578
10.3.13 Using the HSE or LSE oscillator pins as GPIOs ............... 578
10.3.14 Using the GPIO pins in the RTC supply domain .............. 579
10.3.15 Privileged and unprivileged modes ............................. 579
10.3.16 High-speed low-voltage mode (HSLV) ......................... 579
10.3.17 I/O compensation cell ........................................... 580

10.4 GPIO registers ......................................................... 580
10.4.1 GPIO port mode register (GPIOx_MODER) 
(x = A to G, M to P) .................................................. 580
10.4.2 GPIO port output type register (GPIOx_OTYPER) 
(x = A to G, M to P) .................................................. 581
10.4.3 GPIO port output speed register (GPIOx_OSPEEDR) 
(x = A to G, M to P) .................................................. 581
10.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) 
(x = A to G, M to P) .................................................. 582
10.4.5 GPIO port input data register (GPIOx_IDR) (x = A to G, M to P) .................................................. 582
10.4.6 GPIO port output data register (GPIOx_ODR) (x = A to G, M to P) .................................................. 583
10.4.7 GPIO port bit set/reset register (GPIOx_BSRR)  
(x = A to G, M to P) .................................................. 583
10.4.8 GPIO port configuration lock register(GPIOx_LCKR) 
(x = A to G, M to P) .................................................. 584
10.4.9 GPIO alternate function low register (GPIOx_AFRL) 
(x = A to G, M to P) .................................................. 585
10.4.10 GPIO alternate function high register 
(GPIOx_AFRH) (x = A to G, M to P) .................................. 586
10.4.11 GPIO port bit reset register (GPIOx_BRR) 
(x = A to G, M to P) .................................................. 587
10.4.12 GPIO register map ................................................ 588

      37.4.4 CRYP symmetric cipher implementation .......... 1503
      37.4.5 CRYP encryption/decryption typical usage .......... 1504
37.4.6 CRYP authenticated encryption, decryption, and cipher-based message authentication ........................................... 1507
37.4.7 CRYP ciphertext stealing and data padding .......................... 1507
37.4.8 CRYP suspend and resume operations .............................. 1508
37.4.9 CRYP basic chaining modes (ECB, CBC) ............................ 1508
37.4.10 CRYP counter mode (CTR) ........................................ 1513
37.4.11 CRYP AES Galois/counter mode (GCM) ........................... 1515
37.4.12 CRYP AES Galois message authentication code (GMAC) ... 1521
37.4.13 CRYP AES Counter with CBC-MAC (CCM) ...................... 1522
37.4.14 AES key sharing with secure AES co-processor .................. 1527
37.4.15 CRYP data registers and data swapping .......................... 1528
37.4.16 CRYP key registers .................................................. 1531
37.4.17 CRYP initialization vector registers ............................... 1531
37.4.18 CRYP error management ............................................. 1532
37.5 CRYP interrupts ............................................................ 1532
37.6 CRYP DMA requests ...................................................... 1533
37.7 CRYP processing time .................................................... 1534
37.8 CRYP registers ............................................................. 1535
  37.8.1 CRYP control register (CRYP_CR) ................................. 1535
  37.8.2 CRYP status register (CRYP_SR) ................................. 1537
  37.8.3 CRYP data input register (CRYP_DINR) ......................... 1539
  37.8.4 CRYP data output register (CRYP_DOUTR) ...................... 1539
  37.8.5 CRYP DMA control register (CRYP_DMACR) .................... 1540
  37.8.6 CRYP interrupt mask set/clear register (CRYP_IMSCR) ...... 1540
  37.8.7 CRYP raw interrupt status register (CRYP_RISR) ............ 1541
  37.8.8 CRYP masked interrupt status register (CRYP_MISR) ....... 1541
  37.8.9 CRYP key register 0L (CRYP_K0LR) ............................. 1542
  37.8.10 CRYP key register 0R (CRYP_K0RR) ........................... 1543
  37.8.11 CRYP key register 1L (CRYP_K1LR) ........................... 1543
  37.8.12 CRYP key register 1R (CRYP_K1RR) ........................... 1543
  37.8.13 CRYP key register 2L (CRYP_K2LR) ........................... 1544
  37.8.14 CRYP key register 2R (CRYP_K2RR) ........................... 1544
  37.8.15 CRYP key register 3L (CRYP_K3LR) ........................... 1545
  37.8.16 CRYP key register 3R (CRYP_K3RR) ........................... 1545
  37.8.17 CRYP initialization vector register 0L (CRYP_IV0LR) ...... 1545
  37.8.18 CRYP initialization vector register 0R (CRYP_IV0RR) ...... 1546
  37.8.19 CRYP initialization vector register 1L (CRYP_IV1LR) ...... 1546
37.8.20 CRYP initialization vector register 1R (CRYP_IV1RR) .................................. 1547
37.8.21 CRYP context swap GCM-CCM registers (CRYP_CSGCMCCMxR) 1547
37.8.22 CRYP context swap GCM registers (CRYP_CSGCMxR) .............................. 1548
37.8.23 CRYP register map .................................................................................. 1548

38 Hash processor (HASH) ................................................................. 1550
38.1 Introduction .............................................................................. 1550
38.2 HASH main features .............................................................. 1550
38.3 HASH implementation ............................................................ 1551
38.4 HASH functional description .................................................... 1551
38.4.1 HASH block diagram .............................................................. 1551
38.4.2 HASH internal signals ............................................................. 1551
38.4.3 About secure hash algorithms .................................................. 1552
38.4.4 Message data feeding .............................................................. 1552
38.4.5 Message digest computing ....................................................... 1554
38.4.6 Message padding ..................................................................... 1555
38.4.7 HMAC operation .................................................................... 1557
38.4.8 HASH suspend/resume operations .............................................. 1559
38.4.9 HASH DMA interface ............................................................... 1561
38.4.10 HASH error management ......................................................... 1561
38.4.11 HASH processing time ............................................................ 1561
38.5 HASH interrupts ..................................................................... 1562
38.6 HASH registers ....................................................................... 1562
38.6.1 HASH control register (HASH_CR) .............................................. 1562
38.6.2 HASH data input register (HASH_DIN) ........................................... 1564
38.6.3 HASH start register (HASH_STR) ................................................. 1565
38.6.4 HASH digest registers .............................................................. 1566
38.6.5 HASH interrupt enable register (HASH_IMR) .............................. 1568
38.6.6 HASH status register (HASH_SR) .................................................. 1568
38.6.7 HASH context swap registers ..................................................... 1569
38.6.8 HASH register map ................................................................. 1570

39 Memory cipher engine (MCE) ....................................................... 1572
39.1 Introduction .............................................................................. 1572
39.2 MCE main features ................................................................. 1572
39.3 MCE implementation ............................................................... 1573
39.4  MCE functional description  ...................................................... 1574
  39.4.1  MCE block diagram ......................................................... 1574
  39.4.2  MCE internal signals ...................................................... 1574
  39.4.3  MCE programming .......................................................... 1575
  39.4.4  MCE reset and clocks ..................................................... 1576
  39.4.5  MCE block cipher encryption mode .................................... 1576
  39.4.6  MCE stream cipher encryption mode ................................... 1578
  39.4.7  MCE AXI traffic management ............................................ 1579
  39.4.8  MCE encryption disable options ...................................... 1579

#### 49.3.14 RTC reference clock detection ........................................... 2158
#### 49.3.15 RTC smooth digital calibration ........................................... 2159
#### 49.3.16 Timestamp function ............................................................ 2161
#### 49.3.17 Calibration clock output ..................................................... 2161
49.3.18 Tamper and alarm output ............................................ 2162
49.4 RTC low-power modes .................................................. 2162
49.5 RTC interrupts ........................................................... 2163
49.6 RTC registers ............................................................ 2163
  49.6.1 RTC time register (RTC_TR) ........................................ 2164
  49.6.2 RTC date register (RTC_DR) ....................................... 2165
  49.6.3 RTC subsecond register (RTC_SSR) ............................... 2166
  49.6.4 RTC initialization control and status register (RTC_ICSR) ..... 2166
  49.6.5 RTC prescaler register (RTC_PRER) .............................. 2168
  49.6.6 RTC wake-up timer register (RTC_WUTR) ....................... 2169
  49.6.7 RTC control register (RTC_CR) ................................... 2169
  49.6.8 RTC privilege mode control register (RTC_PRIVCFGR) ........ 2173
  49.6.9 RTC write protection register (RTC_WPR) ....................... 2175
  49.6.10 RTC calibration register (RTC_CALR) .......................... 2175
  49.6.11 RTC shift control register (RTC_SHIFTR) .................... 2177
  49.6.12 RTC timestamp time register (RTC_TSTR) .................... 2178
  49.6.13 RTC timestamp date register (RTC_TSDR) .................... 2179
  49.6.14 RTC timestamp subsecond register (RTC_TSSSR) ............. 2179
  49.6.15 RTC alarm A register (RTC_ALRMAR) ........................... 2180
  49.6.16 RTC alarm A subsecond register (RTC_ALRMASSR) ........... 2181
  49.6.17 RTC alarm B register (RTC_ALRMBR) ........................... 2182
  49.6.18 RTC alarm B subsecond register (RTC_ALRMBSSR) ........... 2183
  49.6.19 RTC status register (RTC_SR) .................................. 2184
  49.6.20 RTC masked interrupt status register (RTC_MISR) .......... 2186
  49.6.21 RTC status clear register (RTC_SCR) ......................... 2187
  49.6.22 RTC alarm A binary mode register (RTC_ALRABINR) .......... 2188
  49.6.23 RTC alarm B binary mode register (RTC_ALRBBINR) .......... 2188
  49.6.24 RTC register map ............................................... 2190

50 Tamper and backup registers (TAMP) ........................................... 2192
  50.1 Introduction ................................................................... 2192
  50.2 TAMP main features ..................................................... 2192
  50.3 TAMP functional description .......................................... 2193
    50.3.1 TAMP block diagram ............................................. 2193
    50.3.2 TAMP pins and internal signals ................................ 2194
    50.3.3 GPIOs controlled by the RTC and TAMP ...................... 2196
50.3.4 TAMP register write protection ................................................. 2196
50.3.5 Backup registers protection zones ............................................. 2197
50.3.6 TAMP privilege protection modes .............................................. 2197
50.3.7 Boot hardware key (BHK) ......................................................... 2197
50.3.8 Tamper detection ................................................................. 2198
50.3.9 TAMP backup registers and other device secrets erase .................... 2198
50.3.10 Tamper detection configuration and initialization ......................... 2200
50.4 TAMP low-power modes ............................................................ 2205
50.5 TAMP interrupts ................................................................. 2206
50.6 TAMP registers ................................................................. 2206
50.6.1 TAMP control register 1 (TAMP_CR1) .................................... 2206
50.6.2 TAMP control register 2 (TAMP_CR2) .................................... 2208
50.6.3 TAMP control register 3 (TAMP_CR3) .................................... 2210
50.6.4 TAMP filter control register (TAMP_FLTCR) ............................ 2212
50.6.5 TAMP active tamper control register 1 (TAMP_ATCR1) ................ 2213
50.6.6 TAMP active tamper seed register (TAMP_ATSEEDR) ................ 2216
50.6.7 TAMP active tamper output register (TAMP_ATOR) .................... 2216
50.6.8 TAMP active tamper control register 2 (TAMP_ATCR2) ................ 2217
50.6.9 TAMP configuration register (TAMP_CFGR) ............................ 2220
50.6.10 TAMP privilege configuration register (TAMP_PRIVCFGR) ........ 2221
50.6.11 TAMP interrupt enable register (TAMP_IER) .......................... 2222
50.6.12 TAMP status register (TAMP_SR) ....................................... 2224
50.6.13 TAMP masked interrupt status register (TAMP_MISR) .............. 2226
50.6.14 TAMP status clear register (TAMP_SCR) ............................... 2228
50.6.15 TAMP monotonic counter 1 register (TAMP_COUNT1R) ............. 2230
50.6.16 TAMP resources protection configuration register (TAMP_RPCFGR) 2230
50.6.17 TAMP backup x register (TAMP_BKPxR) ................................ 2231
50.6.18 TAMP register map .......................................................... 2232

51 Inter-integrated circuit interface (I2C) ........................................ 2234
51.1 Introduction ................................................................................. 2234
51.2 I2C main features ....................................................................... 2234
51.3 I2C implementation ..................................................................... 2235
51.4 I2C functional description .......................................................... 2235
51.4.1 I2C block diagram .................................................................. 2236
51.4.2 I2C pins and internal signals .................................................... 2236
51.4.3 I2C clock requirements ........................................... 2237
51.4.4 Mode selection .................................................... 2237
51.4.5 I2C initialization ................................................... 2238
51.4.6 I2C reset ............................................................ 2242
51.4.7 Data transfer ....................................................... 2243
51.4.8 I2C slave mode ..................................................... 2245
51.4.9 I2C master mode .................................................... 2254
51.4.10 I2C_TIMINGR register configuration examples ............... 2265
51.4.11 SMBus specific features .......................................... 2267
51.4.12 SMBus initialization .............................................. 2269
51.4.13 SMBus I2C_TIMEOUTR register configuration examples ...... 2271
51.4.14 SMBus slave mode ............................................... 2271
51.4.15 SMBus master mode .............................................. 2275
51.4.16 Wake-up from Stop mode on address match .................... 2278
51.4.17 Error conditions .................................................. 2279
51.5 I2C in low-power modes ............................................ 2281
51.6 I2C interrupts ......................................................... 2281
51.7 I2C DMA requests .................................................... 2282
51.8 I2C debug modes ..................................................... 2282
51.9 I2C registers .......................................................... 2283
  51.9.1 I2C control register 1 (I2C_CR1) ................................ 2283
  51.9.2 I2C control register 2 (I2C_CR2) ................................ 2286
  51.9.3 I2C own address 1 register (I2C_OAR1) ......................... 2288
  51.9.4 I2C own address 2 register (I2C_OAR2) ......................... 2288
  51.9.5 I2C timing register (I2C_TIMINGR) ............................ 2289
  51.9.6 I2C timeout register (I2C_TIMEOUTR) ......................... 2290
  51.9.7 I2C interrupt and status register (I2C_ISR) ................... 2291
  51.9.8 I2C interrupt clear register (I2C_ICR) ......................... 2294
  51.9.9 I2C PEC register (I2C_PECR) .................................. 2295
  51.9.10 I2C receive data register (I2C_RXDR) ......................... 2295
  51.9.11 I2C transmit data register (I2C_TXDR) ......................... 2296
  51.9.12 I2C register map ................................................ 2297

52 Improved inter-integrated circuit (I3C) .......................... 2298
  52.1 Introduction ....................................................... 2298
  52.2 I3C main features ................................................ 2298
52.3 I3C implementation ........................................... 2300
  52.3.1 I3C instantiation ........................................ 2300
  52.3.2 I3C wake-up from low-power mode(s) .................. 2300
  52.3.3 I3C FIFOs ................................................. 2300
  52.3.4 I3C triggers ............................................. 2300
  52.3.5 I3C interrupt(s) ......................................... 2300
  52.3.6 I3C MIPI® support ....................................... 2301
52.4 I3C block diagram ............................................ 2302
52.5 I3C pins and internal signals ................................. 2302
52.6 I3C reset and clocks .......................................... 2303
  52.6.1 I3C reset .................................................. 2303
  52.6.2 I3C clocks and requirements ............................... 2303
52.7 I3C peripheral state and programming ......................... 2305
  52.7.1 I3C peripheral state ...................................... 2305
  52.7.2 I3C controller state and programming sequence ......... 2305
  52.7.3 I3C target state and programming sequence ............. 2310
52.8 I3C registers and programming .................................. 2314
  52.8.1 I3C register set, as controller/target .................. 2314
  52.8.2 I3C registers and fields use vs. peripheral state, as controller ..... 2315
  52.8.3 I3C registers and fields usage vs. peripheral state, as target .... 2318
52.9 I3C bus transfers and programming ............................. 2320
  52.9.1 I3C command set (CCCs), as controller/target ........... 2320
  52.9.2 I3C broadcast/direct CCC transfer (except ENTDAA, RSTACT), as controller ...... 2324
  52.9.3 I3C broadcast ENTDAA CCC transfer, as controller ........ 2326
  52.9.4 I3C broadcast/direct RSTACT CCC transfer, as controller ...... 2326
  52.9.5 I3C broadcast/direct CCC transfer (except ENTDAA, DEFTGTS, DEFGRPA), as target ...... 2328
  52.9.6 I3C broadcast ENTDAA CCC transfer, as target .......... 2330
  52.9.7 I3C broadcast DEFTGTS CCC transfer, as target .......... 2331
  52.9.8 I3C broadcast DEFGRPA CCC transfer, as target .......... 2332

  52.12.2 Target error management ..................................................... 2354
52.13 I3C wake-up from low-power mode(s) ......................................... 2355
  52.13.1 Wake-up from Stop ............................................................. 2355
52.14 I3C in low-power modes ............................................................ 2358
52.15 I3C interrupts ............................................................................. 2359
52.16 I3C registers .............................................................................. 2360
  52.16.1 I3C message control register (I3C_CR) ................................... 2360
  52.16.2 I3C message control register [alternate] (I3C_CR) .................. 2362
  52.16.3 I3C configuration register (I3C_CFG) ...................................... 2364
  52.16.4 I3C receive data byte register (I3C_RDR) .............................. 2369
  52.16.5 I3C receive data word register (I3C_RDWR) .......................... 2369
  52.16.6 I3C transmit data byte register (I3C_TDR) ............................ 2370
  52.16.7 I3C transmit data word register (I3C_TDWR) .......................... 2371
  52.16.8 I3C IBI payload data register (I3C_IBIDR) ............................ 2373
  52.16.9 I3C target transmit configuration register (I3C_TGTDR) .......... 2374
  52.16.10 I3C status register (I3C_SR) ............................................... 2375
  52.16.11 I3C status error register (I3C_SER) ....................................... 2376
  52.16.12 I3C received message register (I3C_RMR) ............................ 2378
  52.16.13 I3C event register (I3C_EVR) ............................................... 2379
  52.16.14 I3C interrupt enable register (I3C_IER) ............................... 2383
  52.16.15 I3C clear event register (I3C_CEVR) .................................... 2385
  52.16.16 I3C own device characteristics register (I3C_DEVR0) ............ 2387
  52.16.17 I3C device x characteristics register (I3C_DEVRx) ............... 2389
  52.16.18 I3C maximum read length register (I3C_MAXRLR) ............... 2391
  52.16.19 I3C maximum write length register (I3C_MAXWLR) ............. 2392
52.16.20 I3C timing register 0 (I3C_TIMINGR0) ........................................... 2393
52.16.21 I3C timing register 1 (I3C_TIMINGR1) ........................................... 2394
52.16.22 I3C timing register 2 (I3C_TIMINGR2) ........................................... 2396
52.16.23 I3C bus characteristics register (I3C_BCR) ................................. 2397
52.16.24 I3C device characteristics register (I3C_DCR) ............................. 2398
52.16.25 I3C get capability register (I3C_GETCAPR) .................................. 2399
52.16.26 I3C controller-role capability register (I3C_CRCAPR) ..................... 2400
52.16.27 I3C get max data speed register (I3C_GETMXDSR) ....................... 2401
52.16.28 I3C extended provisioned ID register (I3C_EPIDR) ......................... 2403
52.16.29 I3C register map ........................................................................ 2403

53 Universal synchronous/asynchronous receiver transmitter (USART/UART) ........................................... 2407
53.1 Introduction ................................................................................. 2407
53.2 USART main features ................................................................. 2407
53.3 USART extended features ............................................................ 2408
53.4 USART implementation ............................................................... 2408
53.5 USART functional description ....................................................... 2410
  53.5.1 USART block diagram ............................................................. 2410
  53.5.2 USART pins and internal signals .............................................. 2410
  53.5.3 USART clocks ..................................................................... 2412
  53.5.4 USART character description ................................................. 2412
  53.5.5 USART FIFOs and thresholds ............................................... 2415
  53.5.6 USART transmitter ............................................................... 2415
  53.5.7 USART receiver .................................................................... 2418
  53.5.8 USART baud rate generation .................................................. 2425
  53.5.9 Tolerance of the USART receiver to clock deviation ................. 2427
  53.5.10 USART auto baud rate detection ......................................... 2428
  53.5.11 USART multiprocessor communication .................................. 2430
  53.5.12 USART Modbus communication .......................................... 2432
  53.5.13 USART parity control .......................................................... 2433
  53.5.14 USART LIN (local interconnection network) mode ................. 2434
  53.5.15 USART synchronous mode .................................................. 2436
  53.5.16 USART single-wire half-duplex communication ...................... 2440
  53.5.17 USART receiver timeout ....................................................... 2440
  53.5.18 USART smartcard mode ....................................................... 2441
  53.5.19 USART IrDA SIR ENDEC block ............................................ 2445
53.5.20 Continuous communication using USART and DMA .......................... 2448
53.5.21 RS232 hardware flow control and RS485 driver enable ................. 2450
53.5.22 USART low-power management ................................................. 2453
53.6 USART in low-power modes .......................................................... 2456
53.7 USART interrupts ................................................................. 2456
53.8 USART registers ................................................................. 2459
  53.8.1 USART control register 1 (USART_CR1) .................................... 2459
  53.8.2 USART control register 1 [alternate] (USART_CR1) ...................... 2463
  53.8.3 USART control register 2 (USART_CR2) .................................... 2466
  53.8.4 USART control register 3 (USART_CR3) .................................... 2470
  53.8.5 USART control register 3 [alternate] (USART_CR3) ...................... 2475
  53.8.6 USART baud rate register (USART_BRR) ................................ 2478
  53.8.7 USART guard time and prescaler register (USART_GTPR) ............... 2479
  53.8.8 USART receiver timeout register (USART_RTOR) ......................... 2480
  53.8.9 USART request register (USART_RQR) ..................................... 2481
  53.8.10 USART interrupt and status register (USART_ISR) ..................... 2482
  53.8.11 USART interrupt and status register [alternate] (USART_ISR) ....... 2488
  53.8.12 USART interrupt flag clear register (USART_ICR) ..................... 2493
  53.8.13 USART receive data register (USART_RDR) .............................. 2495
  53.8.14 USART transmit data register (USART_TDR) ............................. 2495
  53.8.15 USART prescaler register (USART_PRESC) ................................ 2496
  53.8.16 USART register map .......................................................... 2497

54 Low-power universal asynchronous receiver transmitter (LPUART) ........  2499
  54.1 Introduction ................................................................. 2499
  54.2 LPUART main features ........................................................ 2499
  54.3 LPUART implementation ...................................................... 2500
  54.4 LPUART functional description .............................................. 2502
    54.4.1 LPUART block diagram .................................................. 2502
    54.4.2 LPUART pins and internal signals .................................... 2503
    54.4.3 LPUART clocks .......................................................... 2504
    54.4.4 LPUART character description ........................................ 2504
    54.4.5 LPUART FIFOs and thresholds ....................................... 2506
    54.4.6 LPUART transmitter .................................................... 2506
    54.4.7 LPUART receiver ....................................................... 2510
54.4.8 LPUART baud rate generation ........................................ 2514
54.4.9 Tolerance of the LPUART receiver to clock deviation .......... 2516
54.4.10 LPUART multiprocessor communication .......................... 2517
54.4.11 LPUART parity control ............................................ 2519
54.4.12 LPUART single-wire half-duplex communication ............... 2520
54.4.13 Continuous communication using DMA and LPUART .......... 2520
54.4.14 RS232 hardware flow control and RS485 driver enable ....... 2523
54.4.15 LPUART low-power management .................................. 2525
54.5 LPUART in low-power modes ......................................... 2528
54.6 LPUART interrupts ..................................................... 2529
54.7 LPUART registers ....................................................... 2530
  54.7.1 LPUART control register 1 (LPUART_CR1) ..................... 2530
  54.7.2 LPUART control register 1 [alternate] (LPUART_CR1) ........ 2533
  54.7.3 LPUART control register 2 (LPUART_CR2) .................... 2536
  54.7.4 LPUART control register 3 (LPUART_CR3) .................... 2538
  54.7.5 LPUART control register 3 [alternate] (LPUART_CR3) ....... 2541
  54.7.6 LPUART baud rate register (LPUART_BRR) ................. 2544
  54.7.7 LPUART request register (LPUART_RQR) ...................... 2544
  54.7.8 LPUART interrupt and status register (LPUART_ISR) ........ 2545
  54.7.9 LPUART interrupt and status register [alternate] (LPUART_ISR) .... 2549
  54.7.10 LPUART interrupt flag clear register (LPUART_ICR) ....... 2552
  54.7.11 LPUART receive data register (LPUART_RDR) ............. 2553
  54.7.12 LPUART transmit data register (LPUART_TDR) ............ 2554
  54.7.13 LPUART prescaler register (LPUART_PRESC) .............. 2554
  54.7.14 LPUART register map ........................................... 2555

55 Serial peripheral interface (SPI) ..................................... 2557
  55.1 Introduction ......................................................... 2557
  55.2 SPI main features .................................................. 2557
  55.3 SPI implementation ................................................ 2558
  55.4 SPI functional description ....................................... 2559
    55.4.1 SPI block diagram .......................................... 2559
    55.4.2 SPI pins and internal signals ............................... 2560
    55.4.3 SPI communication general aspects ......................... 2561
    55.4.4 Communications between one master and one slave .......... 2561
    55.4.5 Standard multislave communication .......................... 2564
55.11.1 SPI/I2S control register 1 (SPI_CR1) ........................................... 2613
55.11.2 SPI/I2S control register 2 (SPI_CR2) ........................................ 2615
55.11.3 SPI/I2S configuration register 1 (SPI_CFG1) ................................ 2616
55.11.4 SPI/I2S configuration register 2 (SPI_CFG2) ................................ 2619
55.11.5 SPI/I2S interrupt enable register (SPI_IER) .................................. 2622
55.11.6 SPI/I2S status register (SPI_SR) .................................................. 2623
55.11.7 SPI/I2S interrupt/status flags clear register (SPI_IFCR) ...................... 2625
55.11.8 SPI/I2S transmit data register (SPI_TXDR) ...................................... 2626
55.11.9 SPI/I2S receive data register (SPI_RXDR) ....................................... 2627
55.11.10 SPI/I2S polynomial register (SPI_CRCPOLY) .................................. 2627
55.11.11 SPI/I2S transmitter CRC register (SPI_TXCRC) ............................... 2628
55.11.12 SPI/I2S receiver CRC register (SPI_RXCRC) ................................... 2629
55.11.13 SPI/I2S underrun data register (SPI_UDRDR) .................................. 2629
55.11.14 SPI/I2S configuration register (SPI_I2SCFGR) ................................ 2630
55.11.15 SPI/I2S register map ............................................................... 2632

56 Serial audio interface (SAI) .............................................................. 2634
56.1 Introduction ..................................................................................... 2634
56.2 SAI main features .......................................................................... 2634
56.3 SAI implementation ........................................................................ 2635
56.4 SAI functional description .............................................................. 2635
  56.4.1 SAI block diagram ..................................................................... 2635
  56.4.2 SAI pins and internal signals ..................................................... 2637
  56.4.3 Main SAI modes ....................................................................... 2637
  56.4.4 SAI synchronization mode ......................................................... 2638
  56.4.5 Audio data size ....................................................................... 2639
  56.4.6 Frame synchronization ............................................................. 2640
  56.4.7 Slot configuration ..................................................................... 2643
  56.4.8 SAI clock generator ................................................................. 2645
  56.4.9 Internal FIFOs ......................................................................... 2648
  56.4.10 PDM interface ....................................................................... 2650
  56.4.11 AC’97 link controller ............................................................... 2658
  56.4.12 SPDIF output ........................................................................... 2660
  56.4.13 Specific features ..................................................................... 2662
  56.4.14 Error flags ............................................................................. 2666
  56.4.15 Disabling the SAI .................................................................. 2669
  56.4.16 SAI DMA interface ................................................................. 2669
56.5 SAI interrupts ............................................................. 2670
56.6 SAI registers ............................................................ 2672
  56.6.1 SAI global configuration register (SAI_GCR) ............... 2672
  56.6.2 SAI configuration register 1 (SAI_ACR1) ..................... 2672
  56.6.3 SAI configuration register 2 (SAI_ACR2) ..................... 2675
  56.6.4 SAI frame configuration register (SAI_AFRCR) ............. 2677
  56.6.5 SAI slot register (SAI_A_SLOTR) ......................... 2678
  56.6.6 SAI interrupt mask register (SAI_AIM) ...................... 2679
  56.6.7 SAI status register (SAI_ASR) ............................... 2680
  56.6.8 SAI clear flag register (SAI_A_CLRFR) ..................... 2682
  56.6.9 SAI data register (SAI_ADR) .................................. 2683
  56.6.10 SAI configuration register 1 (SAI_BCR1) .................. 2684
  56.6.11 SAI configuration register 2 (SAI_BCR2) .................. 2686
  56.6.12 SAI frame configuration register (SAI_BFRCR) .......... 2688
  56.6.13 SAI slot register (SAI_B_SLOTR) ........................... 2689
  56.6.14 SAI interrupt mask register (SAI_BIM) .................... 2690
  56.6.15 SAI status register (SAI_BSR) .............................. 2692
  56.6.16 SAI clear flag register (SAI_B_CLRFR) ................... 2694
  56.6.17 SAI data register (SAI_BDR) ............................... 2695
  56.6.18 SAI PDM control register (SAI_PDMCR) ................. 2695
  56.6.19 SAI PDM delay register (SAI_PDM_DLY) .................. 2696
  56.6.20 SAI register map ............................................. 2698

57 SPDIF receiver interface (SPDIFRX) .............................. 2700
  57.1 SPDIFRX interface introduction ............................... 2700
  57.2 SPDIFRX main features ......................................... 2700
  57.3 SPDIFRX functional description ............................... 2700
    57.3.1 SPDIFRX pins and internal signals ...................... 2701
    57.3.2 S/PDIF protocol (IEC-60958) .......................... 2702
    57.3.3 SPDIFRX decoder (SPDIFRX_DC) ....................... 2704
    57.3.4 SPDIFRX tolerance to clock deviation .................. 2708
    57.3.5 SPDIFRX synchronization ............................... 2708
    57.3.6 SPDIFRX handling ....................................... 2710
    57.3.7 Data reception management .............................. 2712
    57.3.8 Dedicated control flow .................................. 2714
    57.3.9 Reception errors ........................................ 2715
    57.3.10 Clocking strategy ..................................... 2717
57.3.11 Symbol clock generation ........................................ 2717
57.3.12 DMA interface .................................................. 2719
57.3.13 Interrupt generation ........................................... 2720
57.3.14 Register protection ............................................. 2721
57.4 Programming procedures ......................................... 2721
  57.4.1 Initialization phase ........................................... 2722
  57.4.2 Handling of interrupts coming from SPDIFRX ............... 2723
  57.4.3 Handling of interrupts coming from DMA .................... 2723
57.5 SPDIFRX interface registers ..................................... 2724
  57.5.1 SPDIFRX control register (SPDIFRX_CR) .................... 2724
  57.5.2 SPDIFRX interrupt mask register (SPDIFRX_IMR) .......... 2726
  57.5.3 SPDIFRX status register (SPDIFRX_SR) ..................... 2727
  57.5.4 SPDIFRX interrupt flag clear register (SPDIFRX_IFCR) .. 2729
  57.5.5 SPDIFRX data input register (SPDIFRX_FMT0_DR) ......... 2730
  57.5.6 SPDIFRX data input register (SPDIFRX_FMT1_DR) ......... 2730
  57.5.7 SPDIFRX data input register (SPDIFRX_FMT2_DR) ......... 2731
  57.5.8 SPDIFRX channel status register (SPDIFRX_CSR) ......... 2732
  57.5.9 SPDIFRX debug information register (SPDIFRX_DIR) ...... 2732
  57.5.10 SPDIFRX interface register map ........................... 2733

58 Management data input/output (MDIOS) .......................... 2734
  58.1 MDIOS introduction ............................................. 2734
  58.2 MDIOS main features .......................................... 2734
  58.3 MDIOS functional description ................................... 2735
    58.3.1 MDIOS block diagram ...................................... 2735
    58.3.2 MDIOS pins and internal signals .......................... 2735
    58.3.3 MDIOS protocol ........................................... 2735
    58.3.4 MDIOS enabling and disabling ............................. 2736
    58.3.5 MDIOS data ................................................ 2737
    58.3.6 MDIOS APB frequency ...................................... 2738
    58.3.7 Write/read flags and interrupts ........................... 2738
    58.3.8 MDIOS error management ................................... 2739
    58.3.9 MDIOS in Stop mode ....................................... 2740
    58.3.10 MDIOS interrupts ......................................... 2740
  58.4 MDIOS registers ................................................ 2740
    58.4.1 MDIOS configuration register (MDIOS_CR) ............... 2740
58.4.2 MDIOS write flag register (MDIOS_WRFR) ........................................... 2741
58.4.3 MDIOS clear write flag register (MDIOS_CWRFR) .............................. 2742
58.4.4 MDIOS read flag register (MDIOS_RDFR) ........................................... 2742
58.4.5 MDIOS clear read flag register (MDIOS_CRDFR) ............................... 2743
58.4.6 MDIOS status register (MDIOS_SR) ...................................................... 2743
58.4.7 MDIOS clear flag register (MDIOS_CLRFR) .......................................... 2744
58.4.8 MDIOS input data register x (MDIOS_DINRx) ...................................... 2744
58.4.9 MDIOS output data register x (MDIOS_DOUTRx) .................................. 2745
58.4.10 MDIOS register map ........................................................................ 2745

59 Secure digital input/output MultiMediaCard interface (SDMMC) ............. 2747

59.1 SDMMC main features ........................................................................... 2747
59.2 SDMMC implementation ....................................................................... 2747
59.3 SDMMC bus topology .......................................................................... 2748
59.4 SDMMC operation modes ..................................................................... 2750
59.5 SDMMC functional description ............................................................. 2751
  59.5.1 SDMMC block diagram .................................................................. 2751
  59.5.2 SDMMC pins and internal signals .................................................... 2751

59.6 Card functional description .................................................................. 2780
  59.6.1 SD I/O mode .................................................................................. 2780
  59.6.2 CMD12 send timing ....................................................................... 2788
  59.6.3 Sleep (CMD5) ................................................................................ 2792
  59.6.4 Interrupt mode (Wait-IRQ) .............................................................. 2793
  59.6.5 Boot operation ................................................................................ 2794
  59.6.6 Response R1b handling ................................................................. 2797
  59.6.7 Reset and card cycle power ............................................................. 2798
59.7 Hardware flow control .......................................................................... 2799
59.8 Ultra-high-speed phase I (UHS-I) voltage switch .................................. 2799
59.9 SDMMC interrupts .............................................................................. 2802
59.10 SDMMC registers ................................................................................ 2804
  59.10.1 SDMMC power control register (SDMMC_POWER) ....................... 2804
## 59.10.2 SDMMC clock control register (SDMMC_CLKCR)

59.10.3 SDMMC argument register (SDMMC_ARGR)

59.10.4 SDMMC command register (SDMMC_CMDR)

59.10.5 SDMMC command response register (SDMMC_RESPCMDR)

59.10.6 SDMMC response x register (SDMMC_RESPxR)

59.10.7 SDMMC data timer register (SDMMC_DTIMER)

59.10.8 SDMMC data length register (SDMMC_DLENR)

59.10.9 SDMMC data control register (SDMMC_DCTRL)

59.10.10 SDMMC data counter register (SDMMC_DCCTR)

59.10.11 SDMMC status register (SDMMC_STAR)

59.10.12 SDMMC interrupt clear register (SDMMC_ICR)

59.10.13 SDMMC mask register (SDMMC_MASKR)

59.10.14 SDMMC acknowledgment timer register (SDMMC_ACKTIMER)

59.10.15 SDMMC DMA control register (SDMMC_IDMACTRLR)

59.10.16 SDMMC DMA buffer size register (SDMMC_IDMABSIZER)

59.10.17 SDMMC DMA buffer base address register (SDMMC_IDMABASER)

59.10.18 SDMMC DMA linked list address register (SDMMC_IDMALAR)

59.10.19 SDMMC DMA linked list memory base register (SDMMC_IDMABAR)

59.10.20 SDMMC data FIFO registers x (SDMMC_FIFORx)

59.10.21 SDMMC register map

## 60 FD controller area network (FDCAN)

### 60.1 Introduction

### 60.2 FDCAN main features

### 60.3 FDCAN functional description

60.3.1 Bit timing

60.3.2 Operating modes

60.3.3 Message RAM

60.3.4 FIFO acknowledge handling

60.3.5 FDCAN Rx FIFO element

60.3.6 FDCAN Tx buffer element

60.3.7 FDCAN Tx event FIFO element

60.3.8 FDCAN standard message ID filter element

60.3.9 FDCAN extended message ID filter element

### 60.4 FDCAN registers
60.4.1  FDCAN core release register (FDCAN_CREL) ........................................ 2861
60.4.2  FDCAN endian register (FDCAN_ENDN) .................................................... 2861
60.4.3  FDCAN data bit timing and prescaler register (FDCAN_DBTP) ................... 2861
60.4.4  FDCAN test register (FDCAN_TEST) ....................................................... 2862
60.4.5  FDCAN RAM watchdog register (FDCAN_RWD) ......................................... 2863
60.4.6  FDCAN CC control register (FDCAN_CCCR) ............................................. 2864
60.4.7  FDCAN nominal bit timing and prescaler register (FDCAN_NBTP) ............. 2865
60.4.8  FDCAN timestamp counter configuration register (FDCAN_TSCC) ............. 2867
60.4.9  FDCAN timestamp counter value register (FDCAN_TSCV) ......................... 2867
60.4.10 FDCAN timeout counter configuration register (FDCAN_TOCC) ............. 2868
60.4.11 FDCAN timeout counter value register (FDCAN_TOCV) ............................ 2869
60.4.12 FDCAN error counter register (FDCAN_ECR) ........................................... 2869
60.4.13 FDCAN protocol status register (FDCAN_PSR) ....................................... 2870
60.4.14 FDCAN transmitter delay compensation register (FDCAN_TDCR) .......... 2872
60.4.15 FDCAN interrupt register (FDCAN_IR) .................................................... 2872
60.4.16 FDCAN interrupt enable register (FDCAN_IE) ......................................... 2875
60.4.17 FDCAN interrupt line select register (FDCAN_ILS) ................................ 2877
60.4.18 FDCAN interrupt line enable register (FDCAN_ILE) ................................. 2878
60.4.19 FDCAN global filter configuration register (FDCAN_RXGFC) ................. 2878
60.4.20 FDCAN extended ID and mask register (FDCAN_XIDAM) .......................... 2880
60.4.21 FDCAN high-priority message status register (FDCAN_HPMS) ................ 2880
60.4.22 FDCAN Rx FIFO 0 status register (FDCAN_RXF0S) .................................. 2881
60.4.23 CAN Rx FIFO 0 acknowledge register (FDCAN_RXF0A) .......................... 2882
60.4.24 FDCAN Rx FIFO 1 status register (FDCAN_RXF1S) .................................. 2882
60.4.25 FDCAN Rx FIFO 1 acknowledge register (FDCAN_RXF1A) ........................ 2883
60.4.26 FDCAN Tx buffer configuration register (FDCAN_TXBC) .......................... 2883
60.4.27 FDCAN Tx FIFO/queue status register (FDCAN_TXFQS) ........................... 2884
60.4.28 FDCAN Tx buffer request pending register (FDCAN_TXBRP) ...................... 2884
60.4.29 FDCAN Tx buffer add request register (FDCAN_TXBAR) ........................... 2885
60.4.30 FDCAN Tx buffer cancellation request register (FDCAN_TXBCR) ............ 2886
60.4.31 FDCAN Tx buffer transmission occurred register (FDCAN_TXBTO) ........... 2886
60.4.32 FDCAN Tx buffer cancellation finished register (FDCAN_TXBCF) ............ 2887
60.4.33 FDCAN Tx buffer transmission interrupt enable register (FDCAN_TXBTIE) .................. 2887
60.4.34 FDCAN Tx buffer cancellation finished interrupt enable register (FDCAN_TXBCIE) .................. 2888
60.4.35 FDCAN Tx event FIFO status register (FDCAN_TXEFS) ............................ 2888
60.4.36 FDCAN Tx event FIFO acknowledge register (FDCAN_TXEFA) ................. 2889
61 USB on-the-go full-speed (OTG_FS) .............................. 2894
61.1 Introduction .................................................. 2894
61.2 OTG_FS main features ........................................ 2895
   61.2.1 General features ....................................... 2895
   61.2.2 Host-mode features .................................... 2896
   61.2.3 Peripheral-mode features ............................... 2896
61.3 OTG_FS implementation ....................................... 2897
61.4 OTG_FS functional description ............................... 2898
   61.4.1 OTG_FS block diagram .................................. 2898
   61.4.2 OTG_FS pin and internal signals ....................... 2898
   61.4.3 OTG_FS core ............................................. 2899
   61.4.4 Embedded full-speed OTG PHY connected to OTG_FS .... 2899
   61.4.5 OTG detections ........................................... 2900
61.5 OTG_FS dual role device (DRD) .............................. 2900
   61.5.1 ID line detection ....................................... 2900
61.6 OTG_FS as a USB peripheral ................................ 2901
   61.6.1 Peripheral states ....................................... 2901
   61.6.2 Peripheral endpoints ................................... 2902
61.7 OTG_FS as a USB host ........................................ 2905
   61.7.1 USB host states ......................................... 2905
   61.7.2 Host channels .......................................... 2906
   61.7.3 Host scheduler ......................................... 2908
61.8 OTG_FS SOF trigger .......................................... 2909

1 Documentation conventions

1.1 General information

STM32H7Rx/7Sx devices have an Arm® Cortex®-M7 with FPU core.

1.2 List of abbreviations for registers

The following abbreviations(b) are used in register descriptions:

- **read/write (rw)**: Software can read and write to this bit.
- **read-only (r)**: Software can only read this bit.
- **write-only (w)**: Software can only write to this bit. Reading this bit returns the reset value.
- **read/clear write0 (rc_w0)**: Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
- **read/clear write1 (rc_w1)**: Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
- **read/clear write (rc_w)**: Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
- **read/clear by read (rc_r)**: Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
- **read/set by read (rs_r)**: Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
- **read/set (rs)**: Software can read as well as set this bit. Writing 0 has no effect on the bit value.
- **read/write once (rwo)**: Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
- **toggle (t)**: The software can toggle this bit by writing 1. Writing 0 has no effect.
- **read-only write trigger (rt_w1)**: Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
- **Reserved (Res.)**: Reserved bit, must be kept at reset value.
- **OBKey**: Option byte keys

---

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.

b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.
1.3 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **AHB**: advanced high-performance bus.

1.4 Availability of peripherals

For availability of peripherals and their number across all devices, refer to the particular device datasheet.

1.5 Availability of security features

For security feature availability refer to the table below:

<table>

## 2 Memory and bus architecture

### 2.1 System architecture

The STM32H7Rx/7Sx architecture relies on a Arm Cortex-M7 core optimized for execution by means of Cache, TCM, AXI, and an AHB bus matrix. This architecture also features a 64-bit AXI, an 32-bit multilayer AHB bus matrix, and bus bridges allow interconnection of bus masters with bus slaves, as shown in Table 2.

</table>

1. **Bold** font type denotes 64-bit bus, plain type denotes 32-bit bus.
2. “X” = access possible, “-” = access not possible.
3. Every transfer can be done in 64 bits
4. Refer to Table 102: Programmed HPDMA1 request for the AHB/APB peripheral request.
The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously. This architecture is shown in the figure below.

**Figure 1. System architecture**
2.1.1 Bus matrices

AXI bus matrix

The multi AXI bus matrix ensures and arbitrates concurrent accesses from multiple masters to multiple slaves. This allows efficient simultaneous operation of high-speed peripherals.

The arbitration uses a round-robin algorithm with QoS capability.

Refer to Section 2.2: AXI interconnect matrix (AXIM) for more information on AXI interconnect.

AHB bus matrices

The AHB bus matrices ensure and arbitrate concurrent accesses from multiple masters to multiple slaves. This allows efficient simultaneous operation of high-speed peripherals.

The arbitration uses a round-robin algorithm.

2.1.2 Bus-to-bus bridges

To allow peripherals with different types of buses to communicate together, there is a number of bus-to-bus bridges in the system.

The AHB/APB bridges allow connecting peripherals on APB1, APB2, APB4, APB5 to AHB1, AHB2, AHB4 and AHB5, respectively. These AHB/APB bridges provide full synchronous interfacing, which allows the APB peripherals to operate with clocks independent of AHB that they connect to.

The AHB/APB bridges also allow APB1, APB2 and APB4 peripherals to connect to GPDMA1 peripheral buses, without transiting through the AHB BUS.

The AHB/APB bridges convert 8-bit / 16-bit APB data to 32-bit AHB data, by replicating it to the three upper bytes / the upper half-word of the 32-bit word.

The AXI bus matrix incorporates AHB/AXI bus bridge functionality on its slave bus interfaces. The AXI/AHB bus bridges on its master interfaces marked as 32-bit in Figure 1: System architecture are outside the matrix.

The Cortex-M7 CPU provides AHB/TCM-bus (ITCM and DTCM buses) translation from its AHBS slave AHB, allowing the HPDMA controller to access the ITCM and DTCM.

Note: When a 8- or 16-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 8- or 16-bit data to feed the 32-bit vector.

2.1.3 TCM-buses

The DTCM and ITCM (data and instruction tightly coupled RAMs) are connected through dedicated TCM buses directly to the Cortex-M7 core. The HPDMA controller can access the DTCM and ITCM through AHBS, a specific CPU slave AHB. The DTCM and ITCM are accessed by Cortex-M7 at CPU clock speed, with zero wait states.

2.1.4 CPU buses

Cortex-M7 AXIM bus

The Cortex-M7 CPU uses the 64-bit AXIM bus to access all memories (excluding ITCM, and DTCM)
The AXIM bus connects the CPU to the AXI bus matrix in the core domain.

**Cortex-M7 ITCM bus**

The Cortex-M7 CPU uses the 64-bit ITCM bus for fetching instructions from and accessing data in the ITCM.

**Cortex-M7 DTCM bus**

The Cortex-M7 CPU uses the 2x32-bit DTCM bus for accessing data in the DTCM. The 2x32-bit DTCM bus allows load/load and load/store instruction pairs to be dual-issued on the DTCM memory. It can also fetch instructions.

**Cortex-M7 AHBS bus**

The Cortex-M7 CPU uses the 32-bit AHBS slave bus to allow the HPDMA controller to access the ITCM and the DTCM.

**Cortex-M7 AHBP bus**

The Cortex-M7 CPU uses the 32-bit AHBP bus for accessing AHB1, AHB2, AHB3, AHB4, APB1, APB2 and APB4 peripherals via the AHB bus matrix.

### 2.1.5 Bus master peripherals

**SDMMC1-bus**

The SDMMC1 uses a 32-bit bus, connected to the AXI bus matrix, through which it can access internal AXI SRAM and Flash memories, and external memories through the XSPIs controller and the FMC.

**SDMMC2-bus**

The SDMMC2 uses a 32-bit bus, connected to the AHB bus matrix. Through the system bus matrices, it can access the internal AXI SRAM, SRAM1, SRAM2, SRAM3 SRAM4, backup RAM, Flash memory, and external memories through the XSPIs controller and the FMC.

**HPDMA-bus**

The HPDMA controller has two bus masters: an AXI 64-bit bus, connected to the AXI bus matrix and an AHB 32-bit bus connected to the Cortex-M7 AHBS slave bus.

The HPDMA is optimized for DMA data transfers between memories since it supports linked list transfers that allow performing a chained list of transfers without the need for CPU intervention. Through the system bus matrices and the Cortex-M7 AHBS slave bus, the HPDMA can access all internal and external memories through the CTOSPIs controller and the FMC.

**GPDMA-bus**

The GPDMA controller has two 32-bit AHB bus masters connected to the AHB bus matrix. The memory bus allows the GPDMA data transfers between memories. Through the system bus matrices, the memory bus can access all internal memories except ITCM and DTCM, and external memories through the XSPIs controller and the FMC. It also supports linked list transfers.
The peripheral bus allows the GPDMA data transfers between two peripherals, between two memories or between a peripheral and a memory. Through the system bus matrices, the peripheral bus can access all internal memories except ITCM and DTCM, external memories through the XSPIs controller and the FMC, and all AHB and APB peripherals. A direct access to APB1 and APB2 is available, without passing through AHB1.

**DMA2D-bus (Chrom-Art Accelerator)**

The DMA2D graphics accelerator uses a 64-bit bus, connected to the AXI bus matrix. Through the system bus matrices, internal AXI SRAM, SRAM1, SRAM2, SRAM3, SRAM4 Flash memories and external memories through the XSPIs controller and the FMC.

**LTDC-bus (LCD-TFT controller)**

The LCD-TFT display controller, LTDC, uses a 64-bit bus, connected to the AXI bus matrix, through which it can access internal AXI SRAM and external memories through the XSPIs controller and the FMC.

**Ethernet MAC-bus**

The Ethernet MAC uses a 32-bit bus, connected to the AHB bus matrix. Through the system bus matrices, it can access all internal memories except backup RAM, ITCM, DTCM it can also access external memories, through the XSPIs controller and the FMC.

**USB OTG-bus**

The USBHS1 peripheral uses 32-bit buses, connected to the AHB bus matrix. Through the system bus matrices, it can access all internal memories except backup RAM, ITCM, DTCM and it access the external memories, through the XSPIs controller and the FMC.

### 2.1.6 GPU2D-bus

These buses connect the GPU2D master interfaces to the bus matrix. These buses are used to load/store data from/to the memory. These buses target the GFXMMU in addition to the data memories: internal Flash memory, internal SRAMs (SRAM1, SRAM2, SRAM3 and SRAM4) and external memories through FMC, XSPIs. A 16-Kbyte data cache (ICACHE) is present on the GPU2D M0 bus in order to improve performances.

### 2.1.7 GFXMMU-bus

This bus connects the GFXMMU master interface to the bus matrix. This bus is used only by the GFXMMU to load/store data from/to the memory. This bus targets the data memories: internal Flash memory, internal SRAMs (SRAM1, SRAM2, SRAM3 and SRAM4) and external memories through FMC, XSPIs. The GFXMMU has also a slave bus connection to be accessed by graphical peripheral master buses.

### 2.1.8 Clocks to functional blocks

Upon reset, clocks to blocks such as peripherals and some memories are disabled (except for the SRAM, DTCM, ITCM and Flash memory). To operate a block with no clock upon reset, the software must first enable its clock through RCC_AHBxENR or RCC_APBxENR register, respectively.
2.2 AXI interconnect matrix (AXIM)

2.2.1 AXI introduction

The AXI (advanced extensible interface) interconnect is based on the Arm® CoreLink™ NIC-400 Network Interconnect. The interconnect has eleven initiator ports, or ASIBs (AMBA slave interface blocks), and ten target ports, or AMIBs (AMBA master interface blocks). The ASIBs are connected to the AMIBs via an AXI switch matrix.

Each ASIB is a slave on an AXI bus or AHB (advanced high-performance bus). Similarly, each AMIB is a master on an AXI or AHB bus. Where an ASIB or AMIB is connected to an AHB, it converts between the AHB and the AXI protocol.

The AXI interconnect includes a GPV (global programmer view) which contains registers for configuring certain parameters, such as the QoS (quality of service) level at each ASIB.

Any accesses to unallocated address space are handled by the default slave, which generates the return signals. This ensures that such transactions complete and do not block the issuing master and ASIB.

2.2.2 AXI interconnect main features

- 64-bit AXI bus switch matrix with eleven ASIBs and ten AMIBs
- AHB/AXI bridge function built into the ASIBs
- concurrent connectivity of multiple ASIBs to multiple AMIBs
- programmable traffic priority management (QoS - quality of service)
- software-configurable via GPV
2.2.3 AXI interconnect functional description

Block diagram

The AXI interconnect is shown in Figure 2.

1. Conversion to AHB protocol is done via an AXI/AHB bridge sitting between AXI interconnect and the connected slave.
2. SRAM shared with the ECC (*Table 11: SRAM4 / ECC configurations*).
3. SRAM shared with the DTCM (*SRAM3 / DTCM configurations*).
4. SRAM shared with the ITCM (*SRAM1 / ITCM configurations*).
Quality of service (QoS)

The AXI switch matrix uses a priority-based arbitration when two ASIB simultaneously attempt to access the same AMIB. Each ASIB has programmable read channel and write channel priorities, known as QoS, from 0 to 15, such that the higher the value, the higher the priority. The read channel QoS value is programmed in the AXI interconnect - INI x read QoS register (AXI_INIx_READ_QOS), and the write channel in the AXI interconnect - INI x write QoS register (AXI_INIx_WRITE_QOS). The default QoS value for all channels is 0 (lowest priority).

If two coincident transactions arrive at the same AMIB, the higher priority transaction passes before the lower priority. If the two transactions have the same QoS value, then a least-recently-used (LRU) priority scheme is adopted.

The QoS values should be programmed according to the latency requirements for the application. Setting a higher priority for an ASIB ensures a lower latency for transactions initiated by the associated bus master. This can be useful for real-time-constrained tasks, such as graphics processing (LTDC, DMA2D). Assigning a high priority to masters that can make many and frequent accesses to the same slave (such as the Cortex-M7 CPU) can block access to that slave by other lower-priority masters.

Global programmer view (GPV)

The GPV contains configuration registers for the AXI interconnect. These registers are only accessible by the Cortex-M7 CPU.

Column headers: Offset, Register name, 31-0, WRITE_ISS_OVERRIDE, READ_ISS_OVERRIDE.
2.3 Memory organization

2.3.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word’s least significant byte and the highest numbered byte the most significant.
2.3.2 Memory map and register boundary addresses

Figure 3. Memory map
All the memory map areas that are not allocated to on-chip memories and peripherals are considered “Reserved”. For the detailed mapping of available memory and register areas, refer to the following table.

The following tables gives, the default memory attribute and the boundary addresses of the peripherals available in the devices.

### Table 6. Memory map and default device memory area attribute

\(^{(1)}\) Memory map and register boundary addresses
2.4 Embedded SRAM

The STM32H7Rx/7Sx devices include up to 456 Kbytes of AXI-SRAM mapped onto the AXI bus divided and shared as described in the following section.

- Up to 192 Kbytes of instruction TCM RAM Table 9: SRAM1 / ITCM configurations. This feature can be configured through the ITCM_AXI_SHARE[1:0] option byte in FLASH_OBW2SRP register as described in the FLASH option byte word 2 status register (FLASH_OBW2SR).

- Up to 192 Kbytes of data TCM RAM Table 10: SRAM3 / DTCM configurations. This feature can be configured through the DTCM_AXI_SHARE[1:0] option byte in described in the FLASH option byte word 2 status register (FLASH_OBW2SR).

- Up to 72 Kbytes when ECC is disabled Table 11: SRAM4 / ECC configurations. This feature can be configured through the ECC_ON_SRAM option byte in FLASH_OBW2SRP register as described in the FLASH option byte word 2 status register (FLASH_OBW2SR).

- 16 Kbyte AHB_SRAM1
- 16 Kbyte AHB_SRAM2

The system AHB SRAM can be accessed as bytes, half-words (16-bit units) or words (32-bit units), while the system AXI SRAM can be accessed as bytes, half-words, words or double-words (64-bit units). These memories can be addressed at maximum system clock frequency without wait state.

The AHB masters can read/write-access an SRAM section concurrently with the Ethernet MAC or the USB OTG HS peripheral accessing another SRAM section. For example, the Ethernet MAC accesses the SRAM2 while the CPU accesses the SRAM1, concurrently.

The TCM SRAMs are dedicated to the Cortex®-M7:

- DTCM-RAM on TCM interface is mapped at the address 0x2000 0000 and accessible by Cortex®-M7, and by HPDMA through AHBS slave bus of the Cortex®-M7 CPU. The DTCM-RAM can be used as read-write segment to host critical real-time data (such as stack and heap) for application running on Cortex®-M7 CPU.

- ITCM-RAM on TCM interface mapped at the address 0x0000 0000 and accessible by Cortex®-M7 and by HPDMA through AHBS slave bus of the Cortex®-M7 CPU. The ITCM-RAM can be used to host code for time-critical routines (such as interrupt handlers) that requires deterministic execution.

The backup RAM is mapped at the address 0x3880 0000 and is accessible by most of the system masters. With a battery connected to the VBAT pin, the backup SRAM can be used to retain data during low-power mode (Standby and VBAT mode).
These SRAMs are made of several blocks that are maintained but not usable in Stop mode (AXI SRAM):

- **AXI SRAM**
  - SRAM1 is split in fix allocation and shared part depending on the user option byte define in `FLASH option byte word 2 status register (FLASH_OBW2SR)`: 1x64-Kbyte fix allocation + 2x64 Kbytes shared with the ITCM.
  - SRAM2: 128-Kbyte not shared (no ECC).
  - SRAM3: 128-Kbytes shared by block of 64-Kbytes with DTCM0 and DTCM1. When shared the same amount is affected to each DTCM per 32-Kbytes each. The amount of memory allocated to each DTCM is defined in `FLASH option byte word 2 status register (FLASH_OBW2SR)`.
  - SRAM4: 72-Kbyte (no ECC) coming from SRAM1 (24-Kbytes) and SRAM3 (48-Kbytes) when ECC is disabled `FLASH option byte word 2 status register (FLASH_OBW2SR)`.

- **backup SRAM**
  - The backup SRAM (BKPSRAM) can be retained in all low-power modes and when VDD is off in VBAT mode. Refer to Section 6.4.4: Backup domain for more details.
  - The backup SRAM is protected by the tamper detection circuit, and are erased by hardware in case of tamper detection. They are also erased by hardware in case of a Backup domain reset. Refer to (link to Section 50: Tamper and backup registers (TAMP)) for more details.

The tables below summarize the different configuration supported by each internal SRAM:

### Table 8. SRAMs structure

<table>
<thead>
<tr>
<th>SRAM</th>
<th>STM32H7Rx/7Sx</th>
</tr>
</thead>
<tbody>
<tr>
<td>SRAM1</td>
<td>From 0 to 128 Kbytes, shared with ITCM</td>
</tr>
<tr>

</tr>
<tr>
<td>DTCM1 allocation</td>
<td>96</td>
</tr>
</tbody>
</table>
128 Kbyte of RAM (SRAM1 for ITCM, SRAM3 for DTCM) can be used either as TCM or as AXI SRAM. This feature can be configured through the ITCM_AXI_SHARED[1:0] and DTCM_AXI_SHARED[1:0] option byte in FLASH_OBW2SRP register, in Section 5: Embedded flash memory (FLASH), as described in Table 12 and Table 14.

<table>
<thead>
<tr>
<th>ITCM_AXI_SHARED[1,0]</th>
<th>ITCM size (Kbyte)</th>
<th>ITCM memory mapping(1)</th>
<th>AXI size (Kbyte)</th>
<th>AXI SRAM1 memory mapping(2)</th>
</tr>
</thead>
<tbody>
<tr>

<td>0</td>
<td>-</td>
</tr>
</tbody>
</table>

1. Access to an unmapped area gives a TCM error.
2. Access to an unmapped area gives a bus error.

72 Kbyte of RAM (SRAM4) can be used either by ECC or as AXI SRAM. This feature can be configured through the ECC_ON_SRAM option byte in FLASH_OBW2SRP register as described in Table 14.

<table>
<thead>
<tr>
<th>ECC_ON_SRAM</th>
<th>AXI size (Kbytes)</th>
<th>AXI SRAM4 memory mapping(1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>72</td>
<td>0x2406 0000 - 0x2407 FFFF</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>-</td>
</tr>
</tbody>
</table>

1. Access to an unmapped area gives a bus error.
2.5 Flash memory overview

The Flash memory interface manages accesses to the Flash memory. It implements the erase and program Flash memory operations and the read and write protection mechanisms.

The Flash memory is organized as follows:
- A main memory block divided into sectors.
- An information block:
  - System memory from which the device boots in System memory boot mode
  - Option bytes to configure read and write protection, BOR level, watchdog software/hardware and reset when the device is in Standby or Stop mode.

Refer to Section 5: Embedded flash memory (FLASH) for further details.

2.6 Boot configuration

In the STM32H7Rx/7Sx, two different boot areas can be selected through the BOOT0 pin as shown in the Table 15.

<table>
<thead>
<tr>
<th>PRODUCT_STATE</th>
<th>NVSTATE</th>
<th>BOOT0</th>
<th>IROT_SELECT(1)</th>
<th>Boot area</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>OPEN</td>
<td>0</td>
<td>-</td>
<td>Boot from the user flash memory at 0x0800 0000</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
<td>-</td>
<td>Boot from the bootloader</td>
</tr>
<tr>
<td>Provisioning</td>
<td>CLOSE</td>
<td>-</td>
<td>Not 0xB4 or H7R</td>
<td>Boot from the RSS in system flash memory Then jump into the bootloader</td>
</tr>
<tr>
<td>Closed/Locked</td>
<td>CLOSE</td>
<td>0xB4</td>
<td>-</td>
<td>Boot from the RSS in system flash memory Then jump into the user flash memory at 0x0800 0000(2)</td>
</tr>
</tbody>
</table>

1. IROT_SELECT is relevant only on H7S.
2. MPU is enabled when executing OEM FW in user flash memory; depending on needed resources, OEM FW should update MPU configuration or disable MPU.

The values on the BOOT0 pin are latched on the 4th rising edge of SYSCLK after reset release. It is up to the user to set the BOOT0 pin after reset.

The BOOT0 pin is re-sampled when the device exits Standby mode. Consequently, the values must be kept in the required Boot mode configuration when the device is in Standby mode.
After startup delay, the selection of the boot area is done before releasing the processor reset.

**Embedded bootloader**

The embedded bootloader code is located in system memory. It is programmed by ST during production. It is used to reprogram the flash memory using one of the following serial interfaces:

- DFU: USB OTG FS (PM12/PM11) in device mode
- USART1: PA10/PA9
- USART2: PA3/PA2
- USART3: PD9/PD8
- UART4: PD0/PD1
- FDCAN2: PB5/PB1
- I2C1: PB8/PB7
- I2C2: PB10/PB11
- I2C3: PA8/PC9
- I3C1: PB8/PB7
- SPI1: PA4/PA5/PA6/PA7
- SPI2: PB15/PB14/PB13/PB12
- SPI3: PC12/PB4/PB3/PA15

For additional information, refer to *Section 8: System configuration, boot and security (SBS) on page 539*. 
3  RAMECC monitoring (RAMECC)

3.1  Introduction

STM32H7Rx/7Sx devices feature a RAM ECC monitoring unit (RAMECC). This provides a means for application software to enable, verify the ECC status, and execute service routines when an error occurs.

3.2  RAMECC main features

The internal SRAM can be protected by ECC when enabled. The ECC mechanism is based on the SECDED algorithm. It supports single- and double-error detection, as well as single-error correction:

- 7 ECC bits are added per 32-bit word.
- 8 ECC bits are added per 64-bit word for ITCM-RAM.

RAM data word integrity is checked at each memory read access, or partial RAM word write operation. Two cycles are required to perform a partial RAM word write (read-modify-write).

The RAMECC monitoring unit includes the following features:

- RAM ECC monitoring per domain
- RAM failing address/data identification
- Error code correction (ECC)

When a half word is written to an internal SRAM (except DTCM and ITCM) and a reset occurs, this half word is not really written to the SRAM after reset. This due to the ECC behavior.

To ensure the data are effectively written to DTCM and ITCM internal memories, read back the programmed data.

3.3  RAMECC functional description

The ECC is supported by SRAM1, SRAM3, BKPSRAM and TCM. The ECC is enabled / disabled by the user option byte ECC_ON_SRAM in Section 5.9.34: FLASH option byte word 2 status register (FLASH_OBW2SR).

Seven ECC bits are added per 32-bit access, and nine for 64-bit access, allowing two bits for error detection, and one bit for error correction on memory read access.

As the ECC is calculated and checked for a 32/64-bit word, the byte and half-word write accesses are managed by the SRAM interface by first reading the whole word, then write the word again with the new byte/half-word value. ECC double errors are also detected during these byte or half-word AHB write accesses (read/modify/write done by interface). The byte or half-word write access latency is increased by 2 bus clock cycles.

Caution: In case of a byte or half-word write on SRAM with ECC, the read/modify/write operation is done in a buffer. The buffer content is written into the SRAM. The SRAM is then released.
**RAMECC block diagram**

An ECC controller is associated to each RAM area. It performs the following functions:

- **ECC encoding**: ECC code computation and storage.
- **ECC decoding**: RAM data word loading and ECC code decoding to detect errors.
- **Error detection**: single- and double-error detection.
- **Error correction**: single-error correction.

The following figure describes the implementation of RAM ECC controllers.

![RAM ECC controller implementation schematic](image)

A dedicated RAM ECC monitoring area is defined for each domain (see Section 3.3.2: RAMECC monitor mapping). The RAMECC allows the collection of ECC diagnostic events from each RAM ECC controller and provides a mean for the CPU to verify the ECC status.

*Figure 5* shows the connection schematic between the RAM ECC controller and the RAMECC monitoring unit.
3.3.1 RAMECC internal signals

*Table 16* lists the internal signals that control the RAMECC unit.

**Table 16. RAMECC internal input/output signals**

<table>
<thead>
<tr>
<th>Internal signal name</th>
<th>Signal type</th>
<th>Description</th>

</tr>
</tbody>
</table>
3.3.2 RAMECC monitor mapping

STM32H7Rx/7Sx devices feature two RAMECC monitoring units. The inputs from the ECC controllers are mapped as described in Table 17. The RAM ECC event monitoring status and configuration registers are described in Section 3.6: RAMECC registers.

Table 17. ECC controller mapping

<td>0x40</td>
</tr>
</tbody>
</table>

1. See Table 7: Register boundary addresses.

Single and double ECC errors

When a single error is detected, it is automatically corrected and the SEDCF bits are set in the RAMECC monitor x status register (ramecc_mxsr). When a double error is detected, the DEDF bit is set in the RAMECC monitor x status register (ramecc_mxsr). An interrupt is generated if enabled by the GECCSEIE and GIE bits in the RAMECC interrupt enable register (ramecc_ier).

For single and double errors:

- An interrupt is generated if enabled by the GECCSEIE and GIE bit in the RAMECC interrupt enable register (ramecc_ier). Single errors cannot be detected when the SEDC bit is set.
- The context: failing address, data, ECC code are stored in the RAMECC monitor x failing address register (ramecc_mxfar), RAMECC monitor x failing data low register (ramecc_mxfdrl), RAMECC monitor x failing data high register (ramecc_mxfdrh) and RAMECC monitor x failing ECC error code register (ramecc_mxfecr) if enabled by the ECCELEN bit in the RAMECC monitor x configuration register (ramecc_mxcf).

Caution: Double errors cannot be detected when the DEDF bit is set.
3.3.3 ECC fault injection test on SRAM1, SRAM3, and TCM

In order to test the ECC a mechanism, allow to test, 1 or 2 bits by word (for single or double error test respectively) and ECC alteration.

- ECCTEA[1:0] = 00 or 11: Normal mode, ECC and DATA memory access granted
- ECCTEA[1:0] = 01: ECC memory access mode granted, data memory access gated
- ECCTEA[1:0] = 10: ECC memory access mode gated, data memory access granted

Example:

initialization
1. Set the normal mode: ECCTEA[1:0] = 00
2. Write 0xCAFEDECA, ECC = 0x19 (computed by ECC module)

data modification
3. Block ECC memory access: ECCTEA[1:0] = 10
4. Grant data modification: Write 0xCAFEDECB (last bit flipped)
5. Return to normal mode: ECCTEA[1:0] = 00
6. READ 0xCAFEDECB with ECC = 19 single error = ’1’ (if enabled a flag is set and an interrupt to the NVIC is generated)

An ECC fault injection test triggers a system break events in TIM1/TIM15/TIM16/TIM17 if one of the following bits is set in the SBS_BKLOCKR register:

- ARAM1ECC_BL
- ARAM3ECC_BL
- ITCMECC_BL
- DTCMECC_BL

This implies that the test must be performed while the PWM outputs of the timers are in idle state.

3.3.4 Read access latency

To correctly read data from SRAMs, the number of wait states automatically set to one when ECC is enabled.

3.4 RAMECC low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. RAMECC interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The content of RAMECC registers is kept. The ECC is functional and ECC error interrupt causes the device to exit from Stop.</td>
</tr>
<tr>
<td>Standby</td>
<td>The RAMECC peripheral is powered down and must be reinitialized after exiting Standby.</td>
</tr>
</tbody>
</table>
3.5 RAMECC interrupts

*Table 19* lists the RAMECC interrupt requests.

<table>

</tbody>
</table>
### 3.6 RAMECC registers

RAM ECC registers can be accessed only in 32-bit (word) mode. Byte and half-word formats are not allowed.

In the registers described below, x refers to:
- SRAM1/2/3/4 when x = 1/2/3/4 respectively
- BKPSRAM when x = 5

#### 3.6.1 RAMECC interrupt enable register (RAMECC_IER)

Bits 31:4 Reserved, must be kept at reset value.

**Bit 3 GECCDEBWIE**: Global ECC double error on byte write (BW) interrupt enable

- When GECCDEBWIE bit is set to 1, an interrupt is generated when an ECC double detection error occurs during a byte write operation to RAM (incomplete word write).
  - 0: no interrupt generated when an ECC double detection error occurs on byte write
  - 1: interrupt generated if an ECC double detection error occurs on byte write

**Bit 2 GECCDEIE**: Global ECC double error interrupt enable

- When GECCDEIE bit is set to 1, an interrupt is generated when an ECC double detection error occurs during a read operation from RAM.
  - 0: no interrupt generated when an ECC double detection error occurs
  - 1: interrupt generated if an ECC double detection error occurs

**Bit 1 GECCSEIE**: Global ECC single error interrupt enable

- When GECCSEIE bit is set to 1, an interrupt is generated when an ECC single error occurs during a read operation from RAM.
  - 0: no interrupt generated when an ECC single error occurs
  - 1: interrupt generated when an ECC single error occurs

**Bit 0 GIE**: Global interrupt enable

- When GIE bit is set to 1, an interrupt is generated when an enabled global ECC error (GECCDEBWIE, GECCDEIE or GECCSEIE) occurs.
  - 0: no interrupt generated when an ECC error occurs
  - 1: interrupt generated when an ECC error occurs
3.6.2 RAMECC monitor x configuration register (RAMECC_MxCR)

Address offset: 0x00 + 0x20 * (x+1), (x = 0 to 4)

Reset value: 0x0000 0000

x is the ECC monitoring unit number

<table>

Bits 17:16 **ECCTEA[1:0]**: ECC Test ECC access

00: inactive
01: write and read access blocked on data memory
10: write and read access blocked on ECC memory
11: inactive

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **ECCDEBWCEN**: ECC double error on byte write (BW) counter enable
When ECCDEBWCEN bit is set to 1, the occurrence counter is incremented when an ECC double detection error occurs during a byte write operation to RAM.
0: no counter increment when an ECC double detection error occurs on byte write
1: counter increment when an ECC double detection error occurs on byte write

Bit 7 **ECCDECEN**: ECC double error counter enable
When ECCDECEN bit is set to 1, the occurrence counter is incremented when an ECC double error occurs during a read operation from RAM.
0: no counter increment when an ECC double error occurs
1: counter increment when an ECC double error occurs

Bit 6 **ECCSECEN**: ECC single error counter enable
When ECCSECEN bit is set to 1, the occurrence counter is incremented when an ECC single error occurs during a read operation from RAM.
0: no counter increment when an ECC single error occurs
1: counter increment when an ECC single error occurs

Bit 5 **ECCELEN**: ECC error latching enable
When ECCELEN bit is set to 1, if an ECC error occurs (both for single error correction or double detection) during a read operation, the context (address, data and ECC code) that generated the error are latched to their respective registers.
0: no error context preserved when an ECC error occurs
1: error context preserved when an ECC error occurs

Bit 4 **ECCDEBWIE**: ECC double error on byte write (BW) interrupt enable
When ECCDEBWIE bit is set to 1, monitor x generates an interrupt when an ECC double detection error occurs during a byte write operation to RAM.
0: no interrupt generated when an ECC double detection error occurs on byte write
1: interrupt generated if an ECC double detection error occurs on byte write
Bit 3 **ECCDEIE**: ECC double error interrupt enable
When ECCDEIE bit is set to 1, monitor x generates an interrupt when an ECC double
detection error occurs during a read operation from RAM.
0: no interrupt generated when an ECC double detection error occurs
1: interrupt generated if an ECC double detection error occurs

Bit 2 **ECCSEIE**: ECC single error interrupt enable
When ECCSEIE bit is set to 1, monitor x generates an interrupt when an ECC single error
occurs during a read operation from RAM.
0: no interrupt generated when an ECC single error occurs
1: interrupt generated when an ECC single error occurs

Bits 1:0 Reserved, must be kept at reset value.
3.6.3 RAMECC monitor x status register
(RAMECC_MxSR)

Address offset: 0x24 + 0x20 * x, (x = 0 to 4)
Reset value: 0x0000 0000

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **DEBWDF**: ECC double error on byte write (BW) detected flag
This bit is set by hardware. It is cleared by software by writing a 0
0: no error detected
1: error detected

Bit 1 **DEDF**: ECC double error detected flag
This bit is set by hardware. It is cleared by software by writing a 0
0: no error detected
1: error detected

Bit 0 **SEDCF**: ECC single error detected and corrected flag
This bit is set by hardware. It is cleared by software by writing a 0
0: no error detected and corrected
1: error detected and corrected

3.6.4 RAMECC monitor x failing address register

Bits 31:0 **FADD[31:0]**: ECC error failing address
When an ECC error occurs the FADD bitfield contains the address that generated the ECC error.
3.6.5 RAMECC monitor x failing data low register  
(RAMECC_MxFDRL)  
Address offset: 0x2C + 0x20 * x, (x = 0 to 4)  
Reset value: 0x0000 0000

Bits 31:0  FDATAL[31:0]: Failing data low  
When an ECC error occurs the FDATAL bitfield contains the LSB part of the data that  
generated the error. For 32-bit word SRAM, this bitfield contains the full memory word that  
generated the error.

3.6.6 RAMECC monitor x failing data high register  
(RAMECC_MxFDRH)  
Address offset: 0x30 + 0x20 * x, (x = 0 to 4)  
Reset value: 0x0000 0000

Bits 31:0  FDATH[31:0]: Failing data high (64-bit memory)  
When an ECC error occurs the FDATH bitfield contains the MSB part of the data that  
generated the error.
### 3.6.7 RAMECC monitor x failing ECC error code register (RAMECC\_MxFECR)

Address offset: 0x34 + 0x20 * x, (x = 0 to 4)

Reset value: 0x0000 0000

4 System security

The STM32H7Rx/7Sx products are designed with a comprehensive set of security features. This section explains the different security features available on STM32H7Rx/7Sx devices.

4.1 Key security features

- **Secure firmware installation (SFI):** with device unique cryptographic key pair
  - leveraging the on-chip immutable bootloader that supports the download of image through USART, USB, I²C, I³C, SPI, FDCAN and JTAG
- **Boot entry:** the platform allows selection between native immutable root of trust, or proprietary boot entry (in user flash memory).
- **Security services:** The platform comes with native security services. The services are embedded in the system memory to manage root of trust services. Native root of trust takes care of: platform security including secure boot, secure updates of next boot level (uROT: updatable root of trust), secure debug control (debug reopening, regression control). Security services can be personalized for each OEMs. OEM personalization is done thanks to provisioning tools.
- **Temporal isolation:** boot levels are isolated thanks to HDPL (hide protect level) monotonic counter.
- **Secure storage,** featuring:
  - three nonvolatile areas dedicated to secure storage. Areas are protected with HDPL.
  - Battery-powered volatile secure storage, automatically erased in case of tamper
  - Write-only key registers in the AES engines
  - Device 96-bit unique ID
  - Secure storage can rely to SAES engine to encrypt the stored data to benefit of DHUK properties. All data encrypted with the DHUK benefit of temporal isolations (HDPL), RHUK (Root Hardware Unique Key), EPOCH (regression counter) properties.
    a) Data are isolated: each data encrypted/decrypted relying to SAES+DHUK benefit of the variation of the DHUK for each different isolated area (HDPL0, HDPL1, HDPL2)
    b) RHUK: hardware secret nonvolatile unique per device keys (copy protection).
    c) EPOCH: counter incremented each time a regression is done (anti rollback).
- **General purpose cryptographic acceleration:**
  - AES 256-bit engine, supporting ECB, CBC, CTR, GCM and CCM chaining modes
  - Secure AES 256-bit security co-processor, supporting ECB, CBC, CTR, GCM and CCM chaining modes with side-channel counter-measures and mitigations
  - HASH processor, supporting SHA-1 checksums and SHA-2 secure hash (SHA2, SHA2-384, SHA2-512)
  - Public key accelerator (PKA) for RSA/DH (up to 4096 bits) and ECC (up to 640 bits), implementing side-channel counter measures and mitigations when manipulating secrets
  - True random number generator (RNG), NIST SP800-90B pre-certified
• **3 MCEs**: for memory cipher engine of external memories
  – System bus in-line encryption and decryption
  – Crypto: Support block ciphering AES and Noekeon, and chaining modes and stream mode with AES.
  – Automatic key-erase in case of tamper
  – Optimization for octo-SPI/hexa-SPI/FMC data pre-fetching mechanism.

• **New flexible lifecycle scheme**: Allows product maintenance in-the-field (debug re-opening or regressions)

• **Active tamper and protection**: against temperature, voltage and frequency attacks
  – Up to eight active inputs, eight active output tamper pins, available in different power modes (refer to Section 50.4: TAMP low-power modes).

### 4.2 Secure install

The secure firmware install (SFI) is an immutable secure service embedded by STMicroelectronics in the devices. The SFI allows secure and counted installation of OEM firmware in untrusted production environment (such as OEM contract manufacturer).

The confidentiality of the installed images written in the internal flash memory is also protected using the AES.

The SFI native service leverages the following hardware security features:

- secure boot (see Section 4.3)
- temporal isolation using hide protection (see Section 4.5.1)
- secure execution (see Section 4.6)
- secure storage, with associated cryptographic engines (see Section 4.7 and Section 4.8) and flash dedicated areas

Further information can be found in the application note *Overview secure firmware install (SFI)* (AN4992).
4.3 **Secure boot**

Secure boot is an immutable code that is always executed after a system reset. As a root of trust, this code checks the device static protections and activates available device runtime protections, reducing the risk that invalid or malicious code runs on the platform. As root of trust, the secure boot also checks the integrity and authenticity of the next level firmware before executing it.

The STM32H7Sx offers two options using IROT_SELECT option byte for the immutable code to be executed after a reset. The STiRoT takes advantage of the security services already embedded in the STM32. The other option allows OEMs to manage the secure boot path:

- Security services when STiRoT (ST immutable root of trust, code natively present in the system memory) is selected managing the secure boot of the next boot level. STiRoT takes care of the next level integrity, authenticity and updates using configuration done by OEMs. To do so, the H7Sxx STiRoT manages a boot sequence using several system resets to load the first application boot level from external memory to the SRAM, then launch a reset. The loaded image in SRAM is then verified by STiRoT, before the concerned level is launched. STiRoT can also manage the update of such firmware.

- Proprietary boot entry when the full chain is managed by the OEM (called OEM-iROT). The iROT is to be installed in user flash memory with proper security activation (WRP, HDP).

In the devices, the secure boot takes advantage of hardware security features such as:

- temporal isolation using hide protection levels (HDPL) (see [Section 4.5.1: Temporal isolation using secure hide protection (HDP)])
- secure install and update (see [Section 4.2: Secure install] and [Section 4.4: Secure update])
- per-domain secure storage, with associated cryptographic engines if available (see [Section 4.7: Secure storage] and [Section 4.8: Crypto engines])

This section describes the features specifically designed for secure boot.

### 4.3.1 Unique boot entry

The IROT_SELECT option byte allows boot through the STiRoT or OEM-iROT (user flash memory). This selection is possible only for products embedding cryptographic acceleration (STM32H7Sx).

For more information on the boot mechanisms, see [Section 2.6: Boot configuration].
4.3.2 **Security services in system flash memory**

The security services located in the system flash memory, cover the root secure services (RSS), the STiRoT (immutable root of trust), and ST-DA (debug authentication).

The RSS (root secure service) allows the control of ST extensions loaded in SRAM (called RSS-e). One of the RSS-e manages the SFI (secure firmware Install). SFI allows secure and counted installation of OEM firmware in untrusted production environments (such as OEM contract manufacturer).

The STMicroelectronics immutable code also includes secure runtime services that can be called at runtime when a secure application sets the SBS_RSSCMDR register to a non-null value before triggering a system reset. This runtime feature is deactivated when the product state is different to “Provisioning”.

STM32H7Rx/7Sx products offer the following security services:

- **ST-DA (debug authentication control)**: This allows control of the product life cycle for field return. It controls debug reopening or regression following OEM choices. It manages the debug authentication control feature, giving control of the debug reopening and regressions of the product for after sales (field return) of the product.
- **RSS and RSSe SFI**: to handle secure provisioning and secure firmware installation in the user flash memory.

STM32H7Sxx products offer the following security services:

- **STiRoT (immutable root of trust)**. This allows management of the boot of the system, ensuring the secure boot and secure update of the following stage. It handles the secure provisioning, secure boot, secure updates of the first updatable level of the platform. As the product is an “hybrid” between flashless and flash memory, the different boots from STiRoT are based on a multi-reset flow.

For this multi-reset flow, STiRoT secure boot or secure update sequence rely on:

- An OEM-iLoader that have to be installed in the user flash memory. OEM-iLoader is in charge of loading the first boot level from external memory to the SRAM. If OEM-iLoader detect an update (of the first boot level), it loads it to the SRAM. When an image is ready to be processed by STiRoT, a system reset is launched to let the STiRoT manage the proper action.
- OEM-iLoader relies on a library to access the external flash memory (external memory management).
A typical secure boot flow is as follows:

Hypothesis: The IROT_SELECT has been set to STiRoT and the STiRoT has been provisioned. OEM-iLoader code has been installed and write protected in user flash memory. The first updatable boot level has been provisioned in the external memory.

Flow execution:
1. On the STiRoT initial execution, it verifies then launch the OEM-iLoader.
2. Then OEM-iLoader is able to read external memories:
   a) OEM-iLoader checks if an update image is present for the OEM-uROT. If so, it loads it to the SRAM then launch a reset, to let the STiRoT managing the secure controls before install.
   b) If no update image is present then OEM-iLoader loads OEM-uROT from external memory then launch a reset, to let the STiRoT managing the verification of the image before launching it.
4.4 Secure update

The secure update is the capacity of the product to update its firmware, allowing improvement of the product features, or fixing of vulnerabilities.

The product update is considered to be done in almost 2 parts:
- The iROT takes care of the next updatable level (uROT) hosted in external memory.
- The uROT must manage the overall application updates.

When STiRoT is selected, the secure update is executed in several steps. See the previous paragraph for more details.

When OEM-iROT is selected, it is hosted in the internal flash memory. It can be partially or fully immutable. It must manage the external memories, including the hardware setup, the secure boot, the secure update of the next updatable level (uROT).

The update process is performed in a secure way to prevent unauthorized updates and access to confidential on-device data.

4.5 Resource isolation using hide protect levels

In the STM32H7Rx/7Sx devices, the hardware and software resources used for boot can be isolated using the temporal isolation proposed with the HDPL (HiDe protect level) mechanism.

It is based on a monotonic counter, which by definition allows only incrementing of the levels. When the counter is incremented, the resources of the previous levels become hidden (code and data).

A typical usage of the HDPL, is to allocate the HDPL=1 to the iROT. Then the HDPL=2 to the uROT (including OEM-iLoader), then the application is executed in HDPL=3.

4.5.1 Temporal isolation using secure hide protection (HDP)

The embedded flash memory allows definition of an HDP area associated to an HDPL with an 8-Kbyte page granularity (defined through the option bytes). The code executed in this HDP area, with its related data and keys, can be hidden after boot until the next system reset.

The hide protection is related to HDPL=1 (hidden when HDPL becomes equal or greater than 2) when OEM-iROT is selected.

The hide protection is related to HDPL=2 (hidden when HDPL become equal or greater than 3) when STiRoT is selected.

Typically, the activation of an HDP area in user flash memory is related to HDPL1. This means that as soon as the HDPL becomes greater than or equal to 2. Then data read, write and instruction fetch (on the area defined by HDP_AREA_START and HDP_AREA_END in FLASH_HDP option bytes), are denied until the next device reset.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area).
4.6 Secure execution

Through a mix of special software and hardware features, the devices ensure their correct functional operation under abnormal situations. These can be caused by: programmer errors, software attacks through network access, or local attempt for tampering code execution.

This section describes the hardware features specifically designed for secure execution.

4.6.1 Memory protection unit (MPU)

The Cortex-M7 includes a memory protection unit (MPU) that can restrict read and write accesses to memory regions (including regions mapped to peripherals), based on one or more of the following parameters:

- Cortex-M7 operating mode (privileged, unprivileged)
- data/instruction fetch.

4.6.2 Embedded flash memory write protection

The embedded flash memory write protection (WRP) prevents illegal or unwanted write/erase to special sections of the embedded flash memory user area (the system area is permanently write protected).

Any 8 Kbyte sector can be independently write-protected or unprotected by clearing/setting the corresponding WRPS bit in the FLASH_WRP register.

The embedded flash memory write-protection user option bits can be modified when HDPL=0 or 1 in the SBS_HDPLSR register, using FLASH_WRP.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area).

4.6.3 Tamper detection and response

Principle

The devices include active protection of critical security assets against temperature, voltage and frequency attacks, with the following features:

- erasure of device secrets upon tamper detection
- improved guarantee of safe execution for the CPU and its associated security peripherals, including:
  - out-of-range voltage (example: \(V_{BAT}\), \(V_{DDA}\)), temperature and clocking (LSE) detection
  - security watchdog IWDG clocked by the internal oscillator LSI
  - possible selection of internal oscillator HSI as system clock
- power supply protection
  - RTC/TAMP domain powered automatically with \(V_{DD}\) or \(V_{BAT}\)

See Section 50: Tamper and backup registers (TAMP) for more details.
**Tamper detection sources**

The devices support eight active input/output pins, allowing four independent active-tamper meshes, or up to seven meshes if the same output pin is shared by several input pins (for a total of eight active-tamper I/Os).

The active pins are clocked by the LSE, and are functional in different system operating modes (Run, Sleep, Stop, or Standby), and in VBAT mode. Refer to Section 50.4: TAMP low-power modes for a list of tamper pins and their availability across power modes.

The detection time is programmable, and a digital filtering is available (tamper is triggered after two false comparison in four consecutive comparison samples).

*Note:* Timestamps are automatically generated when a tamper event occurs.

The internal tamper sources are listed in the table below.

<table>

</tr>
</tbody>
</table>

\(^1\) LSE missing or over frequency detection (> 2 MHz), Glitch filter (> 2 MHz).
Response to tampers

Each source of tamper in the device can be configured to trigger the following events:

- Generate an interrupt, capable of waking up the device from Stop and Standby modes (see the TAMPxMSK bits in the TAMP_CR2 register).
- Generate a hardware trigger for the low-power timers.
- Erase device secrets if the corresponding TAMPxPOM bit is cleared in TAMP_CR2 (for tamper pins) or TAMP_CR3 (for internal tamper). These erasable secrets are:
  - symmetric keys stored in backup registers (x32), in AES, HASH and MCE (encrypted flash memory regions are read as zero)
  - asymmetric keys stored in PKA SRAM, erased when \(V_{DD}\) is present
  - CPU instruction cache memory
  - nonvolatile information used to derive the DHUK in SAES is zeroed
  - 4-Kbyte backup SRAM (depending on configuration bit), erased when \(V_{DD}\) is present
  - MCEs keys.

Read/write accesses by software to all these secrets can be blocked, by setting the BKBLOCK bit in the TAMP_CR2 register. Access to device secrets is possible only when BKBLOCK is cleared, and no tamper flag is set for any enabled tamper source.

If \(V_{DD}\) is not present, the secrets that are erased when \(V_{DD}\) is present are only erased at the next \(V_{DD}\) power on.

Note: Device secret erase is also triggered by setting the BKERASE bit in the TAMP_CR2 register, or by performing a PRODUCT_STATE regression, as defined in Section 4.9.2. Device secrets are not reset by system reset or when the device wakes up from Standby mode.

Software filtering mechanism

Each tamper source can be configured not to launch an immediate erase, by setting the corresponding TAMPxPOM bit in the TAMP_CR2 register (for external tamper pin), or TAMP_CR3 (for internal tamper).

In such situations, when the tamper flag is raised, access to the secrets below is blocked until all tamper flags are cleared:

- DHUK in SAES: fixed to a dummy value
- Backup registers, backup SRAM: read-as-zero, write-ignored
- AES, SAES and HASH peripherals: automatically reset by RCC
- PKA peripheral: reset, with memory use blocked (meaning PKA not usable)
- MCEs: Keys

Once the application is notified by the tamper event, it analyzes the situation. There are two possible cases:

- The application launches secrets erase with a software command (confirmed tamper).
- The application just clears the flags to release secrets blocking (false tamper).

Note: If the tamper software fails to react to such a tamper flag, an IWDG reset automatically triggers the erase of secrets.
Tamper detection and low-power modes

The effect of low-power modes on tamper detection are summarized on the table below.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect on tamper detection features &lt;br&gt;TAMP interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>No effect on tamper detection features, except for level detection with filtering and active tamper modes that remain active only when the clock source is LSE or LSI &lt;br&gt;Tamper events cause the device to exit the Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>No effect on tamper detection features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE or LSI &lt;br&gt;Tamper events cause the device to exit the Standby mode.</td>
</tr>
</tbody>
</table>

### 4.7 Secure storage

A critical feature of any security system is how long-term keys are stored, protected, and provisioned. Such keys are typically used for loading a boot image, or handling of critical user data.

*Figure 7* shows how a key management-service application can use the AES engine, for example to compute external image decryption keys. Nonvolatile keys are stored in a dedicated flash memory area, including access control (see *Section 4.5.1*), while volatile key storage consists of the battery-powered, tamper-protected SRAM or registers-TAMP.

*Figure 7* also shows keys that are manipulated by software (such as MCE keys), or keys that are managed only by hardware (such as DHUK). More information on those hardware keys can be found in *Section 4.7.1*. 
Details of tamper protection are given in Section 4.6.3.

### 4.7.1 Hardware secret key management

As shown in the previous figure, the devices propose a better protection for application keys by using hardware secret keys. These AES keys can be made usable to the application, without exposing them in clear-text (unencrypted). Such keys also become immediately unusable in the case of tamper.

There are three different sources of hardware secret keys:

- **DHUK**: derived keys based on 256-bit nonvolatile device unique secret in flash memory. The flash memory provides a value provisioned during product manufacturing (called RHUK). The generation of a DHUK key takes into account the OBK-HDPLx (temporal isolation counter), the EPOCH (regression counter allowing anti-replay protection), and key use state (KMOD).
- **BHK**: 256-bit application key stored in tamper-resistant volatile storage in TAMP. This key is written at boot time, then read/write locked to application until next reset.
- **XORK**: result of a XOR of BHK and DHUK

These keys can be used in the following modes:

- as a normal key, loading in write-only key registers (software key mode)
- as an encryption/decryption key for another key, to be used in the DPA-resistant SAES (wrapped key mode)
- as an encryption/decryption key for another key, to be used in a faster AES engine (shared key mode).
4.7.2 Unique ID

The devices store a 96-bit ID that is unique to each device (see Section 67.1: Unique device ID register (96 bits)).

Application services can use this unique identity key to identify the product in the cloud network, or to make it difficult for counterfeit devices or clones to inject untrusted data into the network.

Alternatively, the 256-bit device unique key (DHUK) can be used (see Section 4.7.1).

4.8 Crypto engines

The devices implement state-of-the-art cryptographic algorithms featuring key sizes and computing protection as recommended by national security agencies. These agencies include: NIST for the U.S.A, BSI for Germany or ANSSI for France. The algorithms are used to support privacy, authentication, integrity, entropy and identity attestation.

The crypto engines embedded in STM32 reduce weaknesses in the implementation of critical cryptographic functions. They prevent, for example, the use of weak cryptographic algorithms and key sizes. They also enable shorter processing times and lower power consumption when performing cryptographic operations, by offloading those computations from Cortex-M7. This is especially true for asymmetric cryptography.

For product certification purposes, ST can provide certified device information on how these security functions are implemented and validated.

For more information on crypto engine processing times, refer to their respective sections in the reference manual.

4.8.1 Crypto engines features

The table below lists the accelerated cryptographic operations available in the devices. Two AES accelerators are available. One is side-channel attack protected (SAES), while the second is more performance oriented (CRYP).

Note: Additional operations can be added using firmware.

The PKA can accelerate asymmetric crypto operations (like key pair generation, ECC scalar multiplication, point on curve check). See Section 40: Public key accelerator (PKA) for more details.

<table>

</tr>
</tbody>
</table>
Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

4.8.2 Secure AES co-processor (SAES)

The devices provide an on-chip hardware AES encryption and decryption engine, which implements countermeasures and mitigations against power and electromagnetic side-channel attacks.

Clocked by the AHB bus clock, the SAES offers very good performance for a DPA resistant hardware accelerator. The SAES engine supports 128-bit or 256-bit keys in electronic code book (ECB), cipher block chaining (CBC), (CTR), (GCM), (CCM), (GMAC) modes.

As shown in Section 4.7, the SAES can be used for extra-secure on-chip storage for sensitive information.

For more information, refer to Section 36: Secure AES coprocessor (SAES).

4.8.3 Memory cipher engine (MCE)

Three MCEs propose on-the-fly encryption and decryption on external non volatile or volatile memories. Up to 4 regions can be defined on each MCE, with a granularity of 4 kbytes. Access filtering can be applied on different regions (privilege, write).

When a tamper event is confirmed in TAMP, all MCE keys are erased.
4.9 **Product life cycle**

The product life cycle of the STM32H7Rx/7Sx is the result of combining the following settings:

- the flash interface state: `FLASH_NVSRP -> NVSTATE = OPEN /CLOSE`
- the option byte: `FLASH_ROTSR->OEM_PRVD = iROT- provisioned or not`
- the option byte: `FLASH_ROTSR->DBG_AUTH = select the debug authentication control method, between locked, ECDSA (certificates), and password.`

![Figure 8. Product life-cycle security](MSv55538V2)
The features described below contribute to secure the device life-cycle.

### 4.9.1 Product configurations and security services

The product is provisioned with ST native security services. However, the product can be configured to leave full control of the boot chain to OEMs.

This is done by means of the unique boot entry (FLASH_ROTSRP: IROT_SELECT) option byte. This allows selection between the security services (STiRoT: ST immutable root of trust), or OEM boot implementation (OEM-iROT: OEM immutable root of trust) to be installed in the user part of the flash memory. The product boots on the STiRoT only when the IROT_SELECT is set to STiRoT and when the product state is Closed or Locked.

Security services are provisioned by ST in system flash memory (immutable). They provide the root of trust of the platform managing the verification, and update of the first updatable code (uROT).

STiRoT and OEM-iROT are only available on products embedding cryptographic acceleration (STM32H7Sx).

#### Table 24. Product life-cycle states

<table>
<thead>
<tr>

<td></td>
<td>OEM_PROVD=0xB4</td>
<td></td>
</tr>
<tr>
<td></td>
<td>DBG_AUTH=0x51 or 0x8A</td>
<td></td>
</tr>
<tr>
<td>Locked</td>
<td>NVSTATE = CLOSE</td>
<td>This state considers that the product configuration is finalized. The debug authentication is not permitted. The product is definitively in this state.</td>
</tr>
<tr>
<td></td>
<td>OEM_PROVD=0xB4</td>
<td></td>
</tr>
<tr>
<td></td>
<td>DBG_AUTH=0xB4</td>
<td></td>
</tr>
</tbody>
</table>
4.9.2 Recommended product settings

To ease the product maintenance (in-the-field), we recommend taking advantage of the called debug authentication control feature. This enables product maintenance by activating debug, and makes regression management possible, while considering the security of sensitive information.

This implies setting the product state to provisioning state then provision the DA-config and selecting the final product state (closed)

A dedicated application note is available to help when configuring the debug authentication control of the platform.

4.10 System memory

4.10.1 Introduction

System memory stores RSS (root secure services) firmware programmed by ST during production. The RSS provides runtime services to user firmware.

4.10.2 RSS user functions

The RSS provides runtime services thanks to RSS library, whose functions are exposed to user within the CMSIS device header file provided by the STM32CubeH7RS firmware package (see AN5935 “Getting started with MCU hardware development for STM32H7R3/7S3 and STM32H7R7/7S7 product lines” for more details).

RSS provides services through the RSSLIB library, dedicated to secure user firmware. Before calling RSSLIB functions, if MPU is enabled, the secure user firmware must:

- Define a MPU region to have read access on this location, starting from RSSLIB_SYS_FLASH_PFUNC_START (0x1FF1FD4C), up to RSSLIB_SYS_FLASH_PFUNC_END (0x1FF1FD78). These addresses are provided within the CMSIS device header file.
- Define a MPU region to allow execution of RSSLIB FW, starting from 0x1FF16800 up to 0x1FF17FFF.

<table>
<thead>
<tr>
<th>C defined macro</th>
<th>Location in system memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>RSSLIB_PFUNC</td>
<td>0x1FF1FD4C</td>
</tr>
<tr>
<td>&quot;&quot;</td>
<td>&quot;&quot;</td>
</tr>
</tbody>
</table>
**RSSLIB**

The user firmware calls RSSLIB functions using `RSSLIB_PFUNC` C defined macro, which points to a location within non-secure system memory.

**Table 26. RSS lib interface functions**

</table>

1. Functions used for OEM personalization done using provisioning tools.

**SetSecOB**

Prototype:

```c
uint32_t SetSecOB(uint32_t ObAddr, uint32_t ObMask, uint32_t ObValue, uint32_t ObPos)
```

User code function call example:

```c
RSSLIB_PFUNC->SetSecOB((uint32_t) ObAddr, (uint32_t) ObMask, (uint32_t) ObValue, (uint32_t) ObPos);
```

Arguments:

- **ObAddr**:  
  - Input parameter, address of the secure OB to configure, must be one of:  
    `(FLASH->WRPSRP)`  
    `(FLASH->HDPSRP)`  
    `(FLASH->ROTSRP)`
- **ObMask**:  
  - Input parameter, mask of the OB part to be updated (example `0x000000FF` for updating WRP OB).
- **ObValue**:  
  - Input parameter, OB value to be applied.
- **ObPos**:  
  - Input parameter, OB bit shift to be applied on ObValue (`ObValue<<ObPos` must be aligned on ObMask).

The user calls `SetSecOB` to configure secure OB, the configuration is done by RSS after reset. This function is only available in provisioning product state.

On successful call, the function does not return and does not push LR onto the stack.

In case of failure (bad product state), `SetSecOB` returns `0xF5F5F5F5`. 

---

RM0477 Rev 6 193/3791
To retrieve OB change status (after RSS execution), need to call GetRssStatus function or read back the OB (for example read FLASH_WRPSR register).

**GetRssStatus**

Prototype:
```
uint32_t GetRssStatus(void)
```

User code function call example:
```
RSSLIB_PFUNC->GetRssStatus();
```

Arguments: None

The user calls GetRssStatus to get RSS execution status of previous RSSLIB function call that trigger a reset for execution by RSS (SetSecOB or DataProvisioning).

Returned values:
- 0xEAEEAEAEA Success
- 0xF5F5F5F5 Error
- 0xF5F5E0E0 Bad input address range
- 0xF5F50E0E Bad size
- 0xF5F5E0EE Bad encryption value in DoEncryption
- 0xF5F50880 Hardware cryptography not available (H7R)
- 0xF5F50EE0 Encryption error
- 0xF5F50808 Programming error
- 0xF5F50008 Bad value in Destination

**SetProductState**

Prototype:
```
uint32_t SetProductState(uint32_t ProductState)
```

User code function call example:
```
RSSLIB_PFUNC->SetProductState((uint32_t) ProductState);
```

Arguments:
- **ProductState:**
  - Input parameter, STM32 product state to reach, must be one of:
    - 0x17: Provisioning product state, allowed when current product state is Open.
    - 0x72: Closed product state, allowed when current product state is Provisioning and Data provisioning has been made.
    - 0x5C: Locked product state, allowed when current product state is Provisioning.

User calls SetProductState to change STM32 product state, the configuration is done by RSS after reset.

On successful call, the function does not return and does not push LR onto the stack.

To retrieve new product state (after RSS execution), need to call **GetProductState** function.

In the case of failure (bad product state), SetProductState returns 0xF5F5F5F5.
DataProvisioning

Prototype:

```c
uint32_t DataProvisioning(RSSLIB_DataProvisioningConf_t *pConfig)
```

User code function call example:

```c
RSSLIB_PFUNC->DataProvisioning((RSSLIB_DataProvisioningConf_t*)pConfig));
```

Arguments:

- `pConfig`: input parameter. `RSSLIB_DataProvisioningConf_t`

C structure definition is described below:

```c
typedef struct
{
    uint32_t *pSource;
    uint32_t Destination;
    uint32_t Size;
    uint32_t DoEncryption;
    uint32_t Crc;
} RSSLIB_DataProvisioningConf_t;
```

Structure elements:

- **pSource**: Provides the address of data to be provisioned. Must be within SRAM3 address range.
- **Destination**: Provides the destination information (where to provision the data).
  - 0xDADAHHII:
    - II provides OBKey starting index.
    - HH provides OBKey HDPL.
    - DADA provides Debug Authentication configuration, only relevant when OBKey HDPL0.
- **Size**: Provides the size of data to be provisioned (the number of bytes, must be a multiple of 32).
- **DoEncryption**: Notifies the DataProvisioning function if it must encrypt or not data within OBKeys.
  - DoEncrypt can be either 0xF5F5A0AAU (mandatory on STM32H7Sx) or 0xCACA0AA0U (mandatory on STM32H7Rx)
  - 0xF5F5A0AAU: notifies the DataProvisioning to encrypt data with relevant AHK before programming it within OBKeys. AHK is selected according to the `Destination` value.
  - 0xCACA0AA0U: notifies DataProvisioning to program in clear data within OBKeys.
- **Crc**: CRC over full source data buffer, `pConfig->Destination` value, `pConfig->Size` value and finally `pConfig->DoEncryption` value.

CRC computation uses CRC-32 (Ethernet):
- CRC polynomial: 0x04C11DB7U
- Initial value: 0xFFFFFFFFU
Returned values
0xEAEAEAEAU  Success
0xF5F5F5F5U  Error: bad product state
DataProvisioning only available in Open product state (encryption not supported) and Provisioning product state (encryption supported only on STM32H7Sx).
0xF5F5E0EU  Error: bad input address range.
  pConfig or pSource are not in SRAM3
0xF5F5E0EU  Error: bad provisioning size
  – Size is not a multiple of 32
  – OBKey starting index + Size does not fit within an OBKey section
0xF5F808U   Error: computed CRC is not the expected one provided within pConfig->CRC
0xF5F5E0EU  Error: wrong DoEncryption parameter value
0xF5F0808U  Error: OBKeys programming error
0xF5F5008U  Error: bad Destination information
  – OBKey index not in the range 0 to 31
  – OBKey HDPL not in the range 0 to 2 (representing HDPL0, HDPL1 and HDPL2)
  – On OBKey HDPL0, debug authentication not one of ECDSA, PASSWORD or LOCKED

DataProvisioning receives in input a data buffer and programs it within OBKeys. A CRC prevents any data and parameters tampering issue.

When requested through the pConfig->DoEncryption parameter, DataProvisioning encrypts data before programming them within OBKeys.

DataProvisioning uses AES CBC 128 bits with:
• IV: defined as (using C definition format)
  
  uint32_t IV = {0x8001D1CEU, 0xD1CED1CEU, 0xD1CE8001U, 0xCED1CED1U};
• Key: AHK corresponding to the targeted OBKeys HDPL that is randomly generated during the DA (HDPL0) provisioning that must be done first.

Note: Data encryption within OBkeys is supported only by STM32H7S devices.

JumpHDPLv2

Prototype:
uint32_t JumpHDPLv2(uint32_t VectorTableAddr, uint32_t MPUIndex)

User code function call example:
RSSLIB_PFUNC->JumpHDPLv2((uint32_t)NextVectorTableAddr, 1U);

Arguments:
• VectorTableAddr:
  – Input parameter, address of the next vector table to apply
  – The vector table format is the one used by the Cortex-M7 core
• MPUIndex:
  – Input parameter, MPU region index, (index 0 to 31 allowed). Caller function must define (but keep disabled) the corresponding MPU region before calling
JumpHDPLvl2. The function enables the MPU region before jumping to the reset handler of the vector table. The vector table reset handler function belongs to the MPU region.

User calls JumpHDPLvl2 to close user Flash HDPL1 area by incrementing HDPL to 2, then jump to the reset handler embedded within the vector table, whose address is passed as input parameter.

After closing HDPL1, JumpHDPLvl2 enables the MPU region provided as input parameter. Once the MPU is enabled, the function sets the SP to the address provided by the passed vector table, and jumps to the reset handler function supported by it. JumpHDPLvl2 does not set the new vector table.

On successful execution, the function does not return and does not push LR onto the stack.

In case of failure (bad input parameter value), JumpHDPLvl2 returns 0xF5F5F5F5F5.

JumpHDPLvl3

Secure attribute: Secure callable function.

Prototype:

```
uint32_t JumpHDPLvl3(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
RSSLIB_PFUNC->JumpHDPLvl3((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- **VectorTableAddr:**
  - Input parameter, address of the next vector table to apply.
  - The vector table format is the one used by the Cortex-M7 core.
- **MPUIndex:**
  - Input parameter, MPU region index, (index 0 to 31 allowed). Caller function must define but keep disabled the corresponding MPU region before calling JumpHDPLvl3. The function enables the MPU region before jumping to the reset handler of the vector table, whose function belongs to the MPU region.

User calls JumpHDPLvl3 to close user Flash HDPL1 and HDPL2 areas by incrementing HDPL up to 3, then jump to the reset handler embedded within the vector table, whose address is passed as input parameter.

After closing HDPL1/2, JumpHDPLvl3 enables the MPU region provided as input parameter. Once the MPU region is enabled, the function sets the SP to the address provided by the passed vector table, and jumps to the reset handler function supported by the vector table. JumpHDPLvl3 does not set the new vector table.

On successful execution, the function does not return and does not push LR onto the stack.

In the case of failure (bad input parameter value), JumpHDPLvl3 returns 0xF5F5F5F5.
GetProductState

Prototype:
uint32_t GetProductState(void)

User code function call example:
RSSLIB_PFUNC->GetProductState();

Arguments: None

User calls GetProductState to get STM32 product state.

In case of failure (bad product configuration), GetProductState returns 0xF5F5F5F5 (Bad state).

On successful call, the function return one of the following product state:
  • 0x39: Open product state.
  • 0x17: Provisioning product state.
  • 0x72: Closed product state.
  • 0x5C: Locked product state.
5 Embedded flash memory (FLASH)

5.1 Introduction

The embedded flash memory (FLASH) manages the accesses to 196 Kbytes of embedded non-volatile memory (NVM) split into different functional areas such as the immutable root of trust, the STM32 secure firmware install (SFI) or the application’s one-time-programmable information.

FLASH implements the read, program and erase operations, error corrections as well as various integrity and confidentiality protection mechanisms associated to those various functional areas.

The embedded flash memory manages the automatic loading of non-volatile user option bytes at power-on reset, and implements the dynamic update of those options. Those options includes non-volatile application keys that are protected by the device HDPL counter.

5.2 FLASH main features

- 64 Kbytes of non-volatile user flash memory
- Flash memory read operations supporting multiple length (64 bits, 32 bits, 16 bits or one byte)
- Flash memory programming by 128 bits (user area) and 16 bits (OTP area)
- 8 Kbytes sector erase, and bank erase (conditioned)
- Error Code Correction (ECC): one error detection/correction or two error detections per 128-bit flash word using 9 ECC bits
- Cyclic redundancy check (CRC) hardware module
- User configurable non-volatile option byte words
- Up to 1 Kbyte of protected non-volatile option byte keys, readable either by software or usable as a secret AES key through SAES peripheral (as AHK keys)
- Non-volatile security life cycle management of the device
  - Includes controlled security regression with RAM and flash automatic erase
- Temporal isolation enforcement based on application HDPL stored in SBS register
  - Securing one user flash area, and a set of option byte keys
  - Unique boot entry enforcement on a closed device
- 8 Kbytes sector write-protection (WRPS)
- 512 words of 16-bit of one-time programmable (OTP) reserved for user information
- 512-byte read-only area reserved to STMicroelectronics information
- Read command queue to streamline flash operations
- Support for ST immutable Root of Trust in system flash (STM32H7S only)
- Non-volatile 256-bit seed to compute derived root hardware keys (DHUK) in SAES peripheral
- Non-volatile key storage revocation counter (EPOCH)
5.3 **FLASH functional description**

5.3.1 **FLASH block diagram**

*Figure 9* shows the embedded flash memory block diagram, with its interaction with the rest of the device.

*Figure 9. FLASH block diagram*

For more information on **RCC**, **SBS** (with its debug management) and **SAES**, refer to their dedicated chapters.
5.3.2  FLASH internal signals

*Table 27* describes a list of the useful to know internal signals available at embedded flash memory level. These signals are not available on the microcontroller pads.

1. Only digital signals

5.3.3  FLASH architecture and integration in the system

The embedded flash memory is a central resource for the whole microcontroller. It serves as an interface to a single non-volatile memory bank, and organizes the memory in a very specific way. The embedded flash memory also proposes a set of security features to protect the assets stored in the non-volatile memory at boot time, at run-time and during firmware and configuration upgrades.

The embedded flash memory offers three different interconnect interfaces:
- An AXI 64-bit slave port to access code/data
- An AHB 32-bit system slave port to access read-only and OTP area
- An AHB 32-bit configuration slave port to access register bank

*Note:* The application can simultaneously request a read and a write operation through the AXI slave port.

The embedded flash memory micro-architecture is shown in *Figure 10.*
Behind the system interfaces, the embedded flash memory implements various command queues and buffers to perform flash read, write and erase operations with maximum efficiency.

By the addition of a read and write data buffer, the AXI slave port handles the following access types:

- Multiple length: 64 bits, 32 bits, 16 bits and 8 bits
- Single or burst accesses
- Write wrap burst must not cross 16-byte aligned address boundaries to target exactly one flash word

The AHB system slave port supports only 16-bit or 32-bit word accesses. For 8-bit accesses, an AHB bus error is generated and write accesses are ignored.

The AHB configuration slave port supports 8-bit, 16-bit and 32-bit word accesses.

The embedded flash memory is built in such a way that only one read or write operation can be executed at a time.
5.3.4 Flash memory architecture and usage

Flash memory architecture

Figure 11 shows the non-volatile memory organization in the embedded flash memory.

Figure 11. Embedded flash memory organization

The embedded flash non-volatile memory is composed of:

- A 64 Kbyte user memory block, organized as one bank divided in 8 sectors of 8 Kbytes each. This bank features flash-word rows of 128 bits + 9 bits of ECC per word. A user-defined address range benefits from a hide protection mechanism.

- A 128 Kbytes system memory block, organized as one bank divided in 16 sectors of 8 Kbytes each. The system flash memory features the same flash-word rows of 128 bits + 9 bits of ECC per word. A specific range, starting from the system boot sector, also benefit from a hide protection mechanism.

- A set of non-volatile user option byte words, loaded at reset by the embedded flash memory and accessible by the application software only through the AHB configuration register interface.

- Three sets of non-volatile option byte keys, loaded at any time by the application software through the AHB configuration register interface. All the option byte keys benefit from a hide protection mechanism.

- A 1 Kbyte one-time-programmable (OTP) area that can be written only once by the application software.

- A 512-byte read-only area written by STMicroelectronics during SoC manufacturing.
Note: The system flash memory cannot be programmed nor erased by any application. Since the OTP area has no specific protection, it must not be used to store confidential information.

The overall flash memory architecture and its corresponding access interface is summarized in Table 28.

1. SSN contains the target sector number for an erase operation. See Section 2.
2. Cannot be erased by application software

### Partition usage

In the life of the product embedded flash memory stores different kinds of data. Data availability also vary according to the hide protection level (HDPL) selected by the application at any given time. See Section 8: System configuration, boot and security (SBS) for more details.

For STM32H7R devices the typical flash usages are described on Figure 12 and below.

1. Device on a Nucleo board for s/w development, or in production warehouses.
2. Device is being provisioned with immutable root of trust firmware and root of trust keys on an untrusted OEM production line, using secure firmware install (SFI).
3. Device on the final personalization line of the customer, and as used in the final product.
1. In this state OEM_PROVD option byte is not 0xB4
2. This boot code could be protected via the HDPL area refer to Section 5.5.5: Hide protected user flash area.

For STM32H7S devices the typical flash memory usage and options are described on Figure 13 and below:

1. Device on a Nucleo board for software development, or in production warehouses.
2. Device is being provisioned with updatable root of trust firmware and root of trust keys on an untrusted OEM production line, using Secure Keys Provisioning (SKP) service. Alternatively, the device is being provisioned with immutable root of trust firmware and root of trust keys on an untrusted OEM production line, using secure firmware install (SFI).
3. Device on the final personalization line of the customer, and as used in the final product
Figure 13. Embedded flash memory usage (STM32H7S)

1. In this state OEM_PROVD option byte is not 0xB4
2. ST iRoT is selected through IROT_SELECT option byte
3. OEM iRoT is selected through IROT_SELECT option byte. When OEM iRoT executes ST iRoT is hidden.

Figure 14 shows how the embedded flash memory is used when an OEM returns a provisioned production device to an open state (for field return to ST) or to a closed state to build a product. Two decommissioning scenarios are proposed:
1. Device opening for devices with OEM iRoT
2. Device opening for devices with ST iRoT (STM32H7S only).

Note: In any device, if application knows the decommissioning key it can open the device using STM32 tools.
5.3.5 Flash hide protection schemes

*Figure 11* gives an overview of the protection mechanism supported by the embedded flash memory:

- A user flash area can be defined as user HDP area, with an hardware defined access policy based on STM32 hide protection level (HDPL).
- A system flash starting from sector zero is defined as system HDP area, also with a hardware defined access policy based on STM32 hide protection level (HDPL).
- Three sets of option byte keys are each reserved to a specific hide protection level. Some of those keys can be reserved to be used exclusively by the side channel attacks protected SAES engine, as application hardware keys (AHK).

For more information on both HDP areas, refer to *Section 5.5.4: Hide protected system flash area* and *Section 5.5.5: Hide protected user flash area*. More details on option byte keys can be found in *Section 5.4.4: Option byte key management*. 
5.3.6 Overview of FLASH operations

Read operations

The embedded flash memory can perform read operations on the whole non-volatile memory using various granularities: 64 bits, 32 bits, 16 bits or one byte. User and system flash memories are read through the AXI interface, while the option bytes are read through the register interface. Read-only and OTP special region are read through the system AHB interface.

To increase efficiency, the embedded flash memory implements the buffering of consecutive read requests.

For more details on read operations, refer to Section 5.3.7: FLASH read operations.

Program/erase operations

The embedded flash memory supports the following program and erase operations:

- Single flash word write (128-bit granularity for user flash memory, 16-bit granularity for OTP area), with the possibility for the application to force-write a user flash word with less than 128 bits in user flash memory
- Single sector erase
- Bank erase
- Option byte words update, option byte key write (if allowed)

**Note:** Program and erase operations are subject to the various protection that could be set on the embedded flash memory (see next).

For more details, refer to Section 5.3.8: FLASH program operations and Section 5.3.9: FLASH erase operations.

Protection mechanisms

The embedded flash memory supports different protection mechanisms:

- Configuration protection
- Write protection
- Temporal isolation enforcement of non-volatile secrets (code/data, keys), based on the hide protection level information stored in SBS_HDPLSR register.
- Life cycle management, based on flash root of trust option bytes
- OTP locking

For more details refer to Section 5.5: FLASH protection mechanisms.

Option byte loading

As part of the life cycle management, the embedded flash memory reliably loads the non-volatile option bytes stored in non-volatile memory after every power on reset, enforcing boot and security options to the whole device when the embedded flash memory becomes functional again. For more details refer to Section 5.4: FLASH option bytes.
5.3.7 FLASH read operations

Read operation overview

The embedded flash memory supports the execution of one read command while two are waiting in the read command queue. Multiple read access types are also supported as defined in Section 5.3.3: FLASH architecture and integration in the system.

The read commands are associated with a 128-bit read data buffer. These commands can be issued either by the AHB (OTP or read-only areas) or by the AXI interface (user flash or system flash memory).

Note: The embedded flash memory can perform single error correction and double error detection while read operations are being executed (see Section 5.3.10: Flash memory error protections).

The AXI interface read channel operates as follows:
- When the read command queue is full, any new AXI read request stalls the bus read channel interface and consequently the master that issued that request.
- If several consecutive read accesses request data that belong to the same flash data word (128 bits), the data are read directly from the current data read buffer, without triggering additional flash read operations. This mechanism occurs each time a read access is granted. When a read access is rejected for security reasons (e.g., HDP protected word), the corresponding read error response is issued by the embedded flash memory and no read operation to flash memory is triggered.

The AHB system interface operates as follows:
- Until the AHB read request has been served, the embedded flash memory stalls the AHB bus and consequently the master that issued that request.

The Read pipeline architecture is summarized in Figure 15.

For more information on bus interfaces, refer to Section 5.3.3: FLASH architecture and integration in the system.

Figure 15. FLASH read pipeline architecture
Single read sequence

The recommended simple read sequence is the following:

1. For AXI interface: Freely perform read accesses to any AXI-mapped area. For AHB interface: perform either 16-bit or 32-bit read accesses to the AHB-mapped area (byte accesses generate a bus error).

2. The embedded flash memory effectively executes the read operation from the read command queue buffer as soon as the non-volatile memory is ready and the previously requested operations have been served.

Note: When reading an OTP data that has not been previously written, a double ECC error is reported and only 1’s are returned (see Section 5.3.11 for details).

Adjusting read timing constraints

The embedded flash memory clock must be enabled and running before reading data from non-volatile memory.

To correctly read data from flash memory, the number of wait states (LATENCY) must be correctly programmed in the flash access control register (FLASH_ACR) according to the embedded flash memory AXI interface clock frequency (sys_ck) and the internal voltage range of the device ($V_{core}$).

Table 29 shows the correspondence between the number of wait states (LATENCY), the programming delay parameter (WRHIGHFREQ), the embedded flash memory clock frequency and its supply voltage ranges.

Table 29. FLASH recommended read wait states and programming delays

</tbody>
</table>

Adjusting the system frequency

After power-on, the embedded flash memory is clocked by the 64 MHz high-speed internal oscillator (HSI), with a voltage range set at $V_{OS}$ low.

When changing the AXI bus frequency, the application software must follow the below sequence in order to tune the number of wait states required to access the non-volatile memory.
To increase the embedded flash memory clock source frequency:

1. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in the FLASH_ACR register, as described in Table 29.
2. Check that the new number of wait states is taken into account by reading back the FLASH_ACR register.
3. Modify the embedded flash memory clock source and/or the AXI bus clock prescaler in the RCC_CFGR register of the reset and clock controller (RCC).
4. Check that the new embedded flash memory clock source and/or the new AXI bus clock prescaler value are taken into account by reading back the embedded flash memory clock source status and/or the AXI bus prescaler value in the RCC_CFGR register of the reset and clock controller (RCC).

To decrease the embedded flash memory clock source frequency:

1. Modify the embedded flash memory clock source and/or the AXI bus clock prescaler in the RCC_CFGR register of reset and clock controller (RCC).
2. Check that the embedded flash memory new clock source and/or the new AXI bus clock prescaler value are taken into account by reading back the embedded flash memory clock source status and/or the AXI interface prescaler value in the RCC_CFGR register of reset and clock controller (RCC).
3. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in FLASH_ACR register, as described in Table 29.
4. Check that the new number of wait states has been taken into account by reading back the FLASH_ACR register.

Read errors

The embedded flash memory embeds an error correction mechanism, as described in Section 5.3.10.

Single error correction and double error detection are performed for each read operation. In both cases the embedded flash memory reports read errors as described in Section 5.7.6: Error correction code error (SNECCERRF/DBECCERRF).

Read interrupts

See Section 5.8: FLASH interrupts for details.

5.3.8 FLASH program operations

Program operation overview

The virgin state of each non-volatile memory bitcell is 1. The embedded flash memory supports programming operations that can change any memory bitcell to 0. However these operations do not support the return of a bit to its virgin state. In this case an erase operation of the entire sector is required.
Program operation consists in issuing write commands. For write accesses issued by the AXI interface, since a 9-bit ECC code is associated to each 128-bit data flash word, the embedded flash memory must always perform write operations to non-volatile memory with a 128-bit word granularity.

**Note:** The application can decide to write as few as 8 bits to a 128-bit flash word. In this case, a force-write mechanism to the 128 bits + ECC is used (see FW bit of FLASH_CR register).

System flash memory cannot be written by the application software.

It is not recommended to overwrite a flash word that is not virgin. The result may lead to an inconsistent ECC code that is systematically reported by the embedded flash memory, as described in Section 5.7.6: Error correction code error (SNECCERRF/DBECCERRF).

Write access requests issued by the AHB system interface are serialized with AXI commands and can only be used to program the memory OTP area. In this area, since a 6-bit ECC code is associated to each 16-bit data flash word, the embedded flash memory supports 16-bit or 32-bit write operations (8-bit write operations are not supported).

**Note:** The OTP area is typically write-protected on the final product, as described in Section 5.3.11: FLASH one-time programmable area.

Erase operations to the OTP area are not supported.

The AXI interface write channel operates as follows:

- A 128-bit write data buffer is associated with the AXI interface. It supports multiple write access types (64 bits, 32 bits, 16 bits and 8 bits).
- When the write queue is full, any new AXI write request stalls the bus write channel interface and consequently the master that issued that request.

The AHB system interface operates as follows:

- Write commands issued by the AHB system interface are associated with a 137-bit flash word buffer. Byte accesses are not supported.
- When the write queue is full, any new AHB request stalls the bus interface and consequently the master that issued that request.

The write pipeline architecture is described in Figure 16.

For more information on bus interfaces, refer to Section 5.3.3: FLASH architecture and integration in the system.
Managing write protections

Before programming a user sector, the application software must check the protection of the targeted flash memory area.

The embedded flash memory checks the protection properties of the write transaction target at the output of the write queue buffer, just before the effective write operation to the non-volatile memory:

- If a write protection violation is detected, the write operation is canceled and write protection error (WRPERRF) is raised in FLASH_ISR register.
- If the write operation is valid, the 9-bit ECC code is concatenated to the 128 bits of data and the write to non-volatile memory is effectively executed.

Note: No write protection check is performed when the embedded flash memory accepts AXI write requests.

A similar mechanism exists for OTP areas with the following differences:

- If the write operation is valid, the 6-bit ECC code is concatenated to the 16 bits of data and the write to non-volatile memory is effectively executed.

The write protection flag does not need to be cleared before performing a new programming operation.

Monitoring ongoing write operations

The application software can use three status flags located in FLASH_SR in order to monitor ongoing write operations.

- **BUSY**: this bit indicates in real-time that an effective write, erase or option byte change operation is ongoing to the non-volatile memory. It is possible to know what type of
operation is being executed polling the bits IS_PROGRAM, IS_ERASE and IS_OPTCHANGE in the same register.

- **QW**: this bit indicates that a write, erase or option byte change operation is pending in the write queue or command queue buffer. It remains high until the write operation is complete. It supersedes the BUSY status bit.

- **WBNE**: this bit indicates that the embedded flash memory is waiting for new data to complete the 128-bit write buffer. In this state the write buffer is not empty. It is reset as soon as the application software fills the write buffer, force-writes the operation using FW bit in FLASH_CR, or disables all write operations.

**Enabling write operations**

Before programming the user flash memory, the application software must make sure that PG bit is set in FLASH_CR. If it is not set an unlock sequence must be used once (see Section 5.5.1: FLASH configuration protection) and the PG bit must be set.

Before programming an option byte word or an option byte key, the application software must make sure that PG_OPT bit is set in FLASH_OPTCR. If it is not set an unlock sequence must be used once (see Section 5.5.1: FLASH configuration protection). For more information on option byte word (resp. option byte key) modification, refer to Section 5.4.3 (or Section 5.4.4 respectively).

**Note:**
The application software must not unlock a register that is already unlocked, otherwise this register remains locked until next system reset.

If needed, the application software can update the programming delay as described at the end of this section.

**Single write sequence**

The recommended single write sequence is the following:

1. Unlock the FLASH_CR register, as described in Section 5.5.1: FLASH configuration protection (only if register is not already unlocked).
2. Enable write operations by setting the PG bit in the FLASH_CR register.
3. Check the protection of the targeted memory area.
4. Write one flash-word corresponding to 16-byte data starting at 16-byte aligned address.
5. Check that QW has been raised and wait until it is cleared to 0.

If step 4 is executed incrementally (for example byte per byte), the write buffer can become partially filled. In this case the application software can decide to force-write what is stored in the write buffer by using FW bit in FLASH_CR register. In this particular case, the unwritten bits are automatically set to 1. If no bit in the write buffer is cleared to 0, the FW bit has no effect.

**Note:**
Using a force-write operation prevents the application from updating later the missing bits with a value different from 1, which is likely to lead to a permanent ECC error.

Any write access requested while the PG bit is cleared to 0 is rejected. In this case, no error is generated on the bus, but the PGSERRF flag is raised.

Clearing the programming sequence error (PGSERRF) and inconsistency error (INCERRF) is mandatory before attempting a write operation (see Section 5.7: FLASH error management for details).
Adjusting programming timing constraints

Program operation timing constraints depend on the embedded flash memory clock frequency, which directly impacts the performance. If timing constraints are too tight, the non-volatile memory does not operate correctly, if they are too lax, the programming speed is not optimal.

The user must therefore trim the optimal programming delay through the WRHIGHFREQ parameter in the FLASH_ACR register. Refer to Table 29 in Section 5.3.7: FLASH read operations for the recommended programming delay depending on the embedded flash memory clock frequency.

The application software must check that no program/erase operation is ongoing before modifying WRHIGHFREQ parameter.

Caution: Modifying WRHIGHFREQ while programming/erasing the flash memory might corrupt the flash memory content.

Programming errors

When a program operation fails, an error can be reported as described in Section 5.7: FLASH error management.

Programming interrupts

See Section 5.8: FLASH interrupts for details.

5.3.9 FLASH erase operations

Erase operation overview

The embedded flash memory can perform erase operations (if allowed) on 8-Kbyte user sectors or on the whole user flash memory.

Note: System flash memory and read-only/OTP area cannot be erased by the application software.

The erase operation forces all non-volatile bit cells to high state, which corresponds to the virgin state. It clears existing data and corresponding ECC, allowing a new write operation to be performed. If the application software reads back a word that has been erased or not programmed, all the bits are read at 1. No ECC error is generated if the word is located in user flash memory, while a double ECC error is raised if the word is located in read-only or OTP area.

Erase operations are similar to read or program operations except that the commands are queued in a special buffer (a one-command deep erase queue).

Erase commands are issued through the AHB configuration interface. If the embedded flash memory receives simultaneously a write and an erase request, both operations are accepted but the write operation is executed first.

Erase and security

A user sector can be erased only if it does not contain hide protected or write-protected data (see Section 5.5: FLASH protection mechanisms for details). In other words, if the application software attempts to erase a user sector with at least one flash word that is protected, the sector erase operation is aborted and the WRPERRF flag is raised in the FLASH_ISR register, as described in Section 5.7.2.
The only method to erase HDP protected sectors is to perform a regression, triggering a
NVSTATE change from CLOSE to OPEN. See Section 5.5.3 for details.

**Enabling erase operations**

Before erasing a sector, the application software must make sure that FLASH_CR is
unlocked. If it is not the case, an unlock sequence must be used (see Section 5.5.1: FLASH
configuration protection).

*Note:* The application software must not unlock a register that is already unlocked, otherwise this
register remains locked until next system reset.

Similar constraints apply to bank erase requests.

**Flash sector erase sequence**

To erase a 8-Kbyte user sector, proceed as follows:

1. Check and clear (optional) all the error flags due to previous programming/erase
   operation. Refer to Section 5.7: FLASH error management for details.
2. Unlock the FLASH_CR register, as described in Section 5.5.1: FLASH configuration
   protection (only if register is not already unlocked).
3. Set the SER bit and SSN bitfield in the corresponding FLASH_CR register. SER
   indicates a sector erase operation, while SSN contains the target sector number.
4. Set the START bit in the FLASH_CR register.
5. Wait for the QW bit to be cleared in the FLASH_SR register.

*Note:* If a bank erase is requested simultaneously to the sector erase (BER and SER bits set), the
bank erase operation supersedes the sector erase operation.

**Flash bank erase sequence**

To erase all bank sectors except for those containing hide protected data, proceed as
follows:

1. Check and clear (optional) all the error flags due to previous programming/erase
   operation. Refer to Section 5.7: FLASH error management for details.
2. Unlock the FLASH_CR register, as described in Section 5.5.1: FLASH configuration
   protection (only if register is not already unlocked).
3. Set the BER bit in the FLASH_CR register.
4. Set the START bit in the FLASH_CR register to start the bank erase operation. Then
   wait until the QW bit is cleared in FLASH_SR register.

*Note:* BER and START bits can be set together, so above steps 3 and 4 can be merged.

If a sector erase is requested simultaneously to the bank erase (SER bit set), the bank
erase operation supersedes the sector erase operation.
5.3.10 Flash memory error protections

Error correction codes (ECC)

The embedded flash memory supports an error correction code (ECC) mechanism. It is based on the SECDED algorithm in order to correct single errors and detects double errors.

Per 128-bit system and user flash word the embedded flash memory uses 9 ECC bits. During each read operation from a 128-bit flash word, FLASH retrieves the 9-bit ECC information, computes the ECC of the flash word, and compares the result with the reference value. If they do not match, the corresponding ECC error is raised as described in Section 5.7.6: Error correction code error (SNECCERRF/DBECCERRF). During each program operation, a 9-bit ECC code is associated to each 128-bit data flash word, and the resulting 137-bit flash word information is written in non-volatile memory.

For read-only and OTP areas, the embedded flash memory uses a stronger 6 ECC bits per 16-bit word. For option byte words and keys a double ECC scheme is used. For more information on read-only and OTP refer to Section 5.3.11 and Section 5.3.12. For more information on option byte words and keys refer to Section 5.4.

Note: A double ECC error is generated for an OTP virgin word (i.e. a word with 22 bits at 1). When this OTP word is no more virgin, the ECC error disappears.

Cyclic redundancy codes (CRC)

The embedded flash memory implements a cyclic redundancy check (CRC) hardware module. This module checks the integrity of a given user flash memory area content.

The area processed by the CRC module can be defined either by sectors or by start/end addresses.

When enabled, the CRC hardware module performs multiple reads by chunks of 4, 16, 64 or 256 consecutive flash-word (i.e. chunks of 64, 256, 1024 or 4096 bytes). These consecutive read operations are pushed by the CRC module into the required read command queue together with other AXI read requests, thus avoiding to deny AXI read commands.

CRC computation uses CRC-32 (Ethernet) polynomial 0x4C11DB7:

\[ x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1 \]

The CRC operation is concurrent with the reading or writing of option byte user words, keys or OTP, because the same hardware is used for all those operations. To avoid corruption to the CRC computation the flash stalls above incoming requests when a CRC operation is ongoing.

The sequence recommended to configure a CRC operation is the following:

1. Unlock FLASH_CR register, if not already unlocked.
2. Enable the CRC feature by setting the CRC_EN bit in FLASH_CR.
3. Program the desired data size in the CRC_BURST field of FLASH_CRCRR.
4. Define the user flash memory area on which the CRC has to be computed. Three solutions are possible:
   - Select all user flash sectors by setting the ALL_SECT bit in FLASH_CRCRR
   - Define the area start and end addresses by programing FLASH_CRCADDR and FLASH_CRCADDR, respectively,
   - Select the targeted sectors by setting the CRC_BY_SECT bit in FLASH_CRCRR.

Also program consecutively the target sector numbers using the CRC_SECT field
of the FLASH_CRCCR register. Set ADD_SECT bit after each CRC_SECT programming.

5. When step 4 is completed start the CRC operation by setting the START_CRC bit in FLASH_CRCCR.

6. Wait until the CRC_BUSY flag is reset in FLASH_SR.

7. Retrieve the CRC result in FLASH_CRCDATAR.

**Note:** The application should avoid running a CRC on HDP user flash memory area when the hide protection level prevents access to it. Indeed, doing so may alter the expected CRC value. A special error flag defined in Section 5.7.8: CRC read error (CRCRDERRF) can be used to detect such a case.

CRC computation does not raise standard read error flags such as RDSERRF and DBECCERRF. Only CRCRDERRF is raised.

### 5.3.11 FLASH one-time programmable area

The embedded flash memory offers a 1024-byte memory area dedicated to application non-confidential one-time programmable data (OTP). It is composed of 512 words of 16 bits that cannot be erased, and can be written only once.

**Note:** The OTP area is virgin when the device is delivered by STMicroelectronics.

OTP data can be accessed through the AHB system port. They are organized as 16 blocks of 32 OTP words, as shown in Table 30. An entire OTP block can be protected (locked) from write accesses by setting the corresponding OTPL bit in the FLASH_OTPLSRP register, as shown. There is no special read protection mechanism on the OTP area.

**Note:** The OTP block locking operation is irreversible and independent from the life cycle management described in Section 5.5.3.

A block can be write-protected whether or not it has been programmed (even partially).

OTP error protection

OTP data are organized as 16 blocks of 32 OTP words, as shown on Table 30. Each 16-bit half-word is protected by 6 bits of ECC. Hence application must avoid overwriting a 16-bit half-word that has already been programmed, as it is leading to systematic ECC error. Similarly, do not write twice an 16-bit OTP word, as it could lead to systematic ECC error.

When reading OTP data with a single error corrected or a double error detected, the embedded flash memory reports the corresponding error, as described in Section 5.7.6: Error correction code error (SNECCERRF/DBECCERRF).

When reading OTP data that has not been written by the application software (that is, virgin OTP), the ECC correction reports a double error detection (DBECCERRF), and all 1’s are returned. It is therefore recommended that the application always writes the OTP data before trying to read it.

OTP write sequence

Follow the sequence below to write an OTP word:

1. Check the protection status of the target OTP word (see Table 30). The corresponding OTPLi bit must be cleared in FLASH_OTPLSR register.
2. Unlock FLASH_CR if the register is not already unlocked, and then set PG_OTP bit in the FLASH_CR register.
3. Write two OTP words (32 bits) corresponding to the 4-byte aligned address shown in Table 30. Alternatively, the application software can program separately the 16-bit MSB or 16-bit LSB. In this case the first 16-bit write operation starts immediately without waiting for the second one.
4. Check that the QW bit in FLASH_SR has been set and wait until it is cleared.
5. Optionally, lock the OTP block using OTPLi bit in FLASH_OTPLSRP in order to prevent further data changes. PG_OTP bit in the FLASH_CR register can also be cleared if needed.

Note: To avoid data corruption, it is important to complete the OTP write process (for example by reading back the OTP value), before starting a new option byte change.

No error sequence and no inconsistency error are generated during OTP write operations. Writing OTP data at byte level is not supported and generates a bus error.

...
5.3.12 FLASH read-only area

The embedded flash memory offers a 512-byte memory area dedicated to non-confidential and read-only information usable by application software.

Read-only area can be accessed through the AHB system port. It is organized as shown in Table 31. This information is provisioned by STMicroelectronics during the device manufacturing.

<table>
<thead>
<tr>
<th>AHB address (read-only)</th>
<th>Read-only data name and usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x08FF F800</td>
<td>U_ID[31:0]</td>
</tr>
<tr>
<td>0x08FF F804</td>
<td>U_ID[63:32]</td>
</tr>
<tr>
<td>0x08FF F808</td>

<td>Flash memory size[15:0]</td>
</tr>
<tr>
<td>0x08FF F810 to 0x08FF F9FF</td>
<td>Reserved information</td>
</tr>
</tbody>
</table>

Read-only area error protection

Read-only area is protected by a robust ECC scheme. When reading a 32-bit word in this area with a single error corrected or a double error detected, the embedded flash memory reports the corresponding error, as described in Section 5.7.6: Error correction code error (SNECCERRF/DBECCERRF).

5.3.13 FLASH reset and clocks

Reset management

Following a power-on reset embedded flash selects two security states, as shown on Figure 17. For more details on those states, refer to Section 5.5.3.

Figure 17. FLASH stateful initialization

Embedded flash memory stateful initialization is based on the overloading of option bytes default values by non-volatile values automatically loaded when the reset signal rises.
During this loading sequence, other parts of the device remains under reset and the embedded flash memory is not accessible from its interfaces.

The embedded flash memory can be reset at any time by the application through the RCC peripheral, with the following effects:

- All registers, except for option byte registers, are cleared, including read and write latencies. Option byte register list is found in Section 5.4.5.
- Most control registers are automatically protected against write operations, as described in Section 5.5.1: FLASH configuration protection.

It is important to note that the contents of the flash memory (except option bytes) are not guaranteed if a power-on-reset occurs during a flash memory write or erase operation. For option bytes a valid content is always guaranteed, as embedded flash uses the old option byte values when an option byte modification is interrupted by a reset. In this case a new option byte change request must be issued to modify those option bytes.

**Clock management**

The embedded flash memory uses the AXI interface clock. Depending on the device clock and internal supply voltage, specific read and write latency settings usually need to be set in the flash access control register (FLASH_ACR), as explained in Section 5.3.7: FLASH read operations and Section 5.3.8: FLASH program operations.

### 5.4 FLASH option bytes

#### 5.4.1 About option bytes

The embedded flash memory includes a set of non-volatile option bytes that are either freely modified through configuration registers (option byte words), or are managed as non-volatile keys with a special temporal isolation protection mechanism.

This section explains:

- how option byte words and keys are loaded
- how application software can change option byte words, under which conditions
- how application software can program option byte keys
- what is the detailed list of option byte words, together with their default factory values (that is, before the first option byte change).

#### 5.4.2 Option byte loading

When the device is first powered, the embedded flash memory automatically loads all the option byte words, and few selected option byte keys. During the option byte loading sequence, the device remains under reset and the embedded flash memory cannot be accessed.

When an ECC issue is detected during this option byte loading sequence OBLERRF flag is raised, as described in Section 5.7.12.
5.4.3 Option byte words modification

Changing option byte words

A option byte word change operation can modify the configuration and the protection settings saved in the non-volatile option byte area, if allowed.

The embedded flash memory features two sets of option byte words registers:
- The first register set contains the current values of the option bytes. Their names have the SR extension. All “SR” registers are read-only. Unless documented otherwise, their values are automatically loaded from the non-volatile memory after power-on reset, or after a successful option byte change operation.
- The second register set allows the modification of the option bytes. Their names end with the SRP extension. All “SRP” registers can be accessed in read/write mode.

Note: When the OPTLOCK bit in FLASH_OPTCR register is set, writes to SRP registers are ignored.

When option byte word register “SRP” is written the embedded flash memory checks if at least one option byte needs to be programmed by comparing the current values in corresponding “SR” register. If a change is detected, if associated change conditions are met (see Changing security option bytes) and if PG_OPT bit is set in FLASH_OPTCR, the embedded flash memory launches the option byte modification in its non-volatile memory and update the “SR” register.

If one of the condition described in Changing security option bytes is not respected, the embedded flash memory sets the OPTERRF flag in the FLASH_OPTISR register and aborts the option byte change operation.

Unlocking the option byte modification

After reset, the OPTLOCK bit is set and the FLASH_OPTCR is locked. As a result, the application software must unlock the option configuration register before attempting to change the option byte words, setting PG_OPT bit. The FLASH_OPTCR unlock sequence is described in Section 5.5.1

Option byte modification sequence

To modify an option byte word, follow the sequence below:
1. Unlock FLASH_OPTCR register as described in Section 5.5.1: FLASH configuration protection (only if the register is not already unlocked).
2. Enable the write operations by setting the PG_OPT bit in FLASH_OPTCR.
3. Write the desired new option byte values in the corresponding option byte word register (FLASH_xSRP).
4. Wait until the QW bit is cleared in FLASH_SR register. Once cleared corresponding FLASH_xSR register has been updated, if security allows it (see next section).

Note: If a reset or a power-down occurs while the option byte words modification is ongoing, the original option byte value are kept. A new option byte modification sequence is required to program the new value.
Changing security option bytes

On top of OPTLOCK bit, there is a second level of protection for security-sensitive option byte words. Note that the option byte words defined in Section 5.4.5 do not have any special protection.

Option byte words with specific protections are described hereafter.

- **Sector write protection (WRPS)**
  Those user options managing group of sector write protection can be changed using FLASH_WRPSRP register, if application is RSS or the immutable root of trust.

- **Non-volatile state (NVSTATE)**
  A detailed description of NVSTATE option bits is given in Section 5.5.3. The following rules must be respected to modify NVSTATE using FLASH_NVSRP register.
  - Writes to FLASH_NVSRP register are ignored if HDPL is different from 0 or 1 in SBS_HDPLSR register.
  - NVSTATE option change is triggered only after the RAM erase signal has confirmed that Backup RAM and PKA RAM have been successfully erased.
  - When NVSTATE=OPEN, option byte change to CLOSE is allowed. Writing any other value than 0x51 triggers an OPTERRF flag, without option change.
  - When NVSTATE=CLOSE, option byte change to OPEN is allowed, triggering a global erase explained in Section 5.5.3. Writing any other value than 0xB4 triggers an OPTERRF flag, without option change.

- **OEM provisioned (OEM_PROVD)**
  As defined in Table 36: Boot level and HDP area protections (non STiRoT case), OEM_PROVD defines the protection of the HDP area. OEM_PROVD can only be changed by RSS in FLASH_ROTSPR.

- **iRoT selection (IROT_SELECT)**
  As defined in Table 37: Boot level and HDP area protections (STiRoT case), IROT_SELECT defines where the immutable root of trust code is stored, for STM32H7S devices only. IROT_SELECT can only be changed when the device is opened by RSS in FLASH_ROTSPR.

- **Debug authentication method (DBG_AUTH)**
  DBG_AUTH defines the method used to open up the device debug. It has no hardware effect in embedded flash memory.
  DBG_AUTH can only be changed by RSS in FLASH_ROTSPR.

- **Secure storage counter (EPOCH)**
  This 24-bit non-volatile value is directly send by embedded flash to the SAES peripheral. As soon as this value changes all current keys encrypted with a derived hardware unique key (DHUK) are lost. For more details on the DHUK, refer to SAES chapter. EPOCH can only be changed by RSS.

- **Hide protection area size (HDP_AREA_START and HDP_AREA_END)**
  These user options configure the size of the user flash area that can be accessed while HDPL equals to the value defined in Section 5.5.5. Writes to FLASH_HDPSRP register are ignored if HDPL is different from 0 or 1 in the SBS_HDPLSR register.

*Note:* For all user option bytes in this section: default values are loaded when a double ECC error occurs. OBLERRF error flag is also raised.

Hide protection area end address in system flash is fixed by STMicroelectronics.
5.4.4 Option byte key management

Option byte key programming

Following sequence is required to program an option byte key in embedded flash memory:

1. Unlock FLASH_OPTCR register as described in Section 5.5.1: FLASH configuration protection (only if the register is not already unlocked).

2. Enable the write operation by setting the PG_OPT bit in FLASH_OPTCR, and make sure the KTEF and KVEF bits are cleared in FLASH_OPTISR.

3. Write the key value in the FLASH_OBKDRx registers. Key[31:0] goes in OBKDR0[31:0], Key[63:32] to OBKDR1[31:0], Key[95:64] to OBKDR2[31:0], Key[127:96] to OBKDR3[31:0], Key[159:128] to OBKDR4[31:0], Key[191:160] to OBKDR5[31:0], Key[223:192] to OBKDR6[31:0] and Key[255:224] to OBKDR7[31:0].

4. Fill the following information to FLASH_OBKCR:
   - OBKINDEX[4:0]: index of the key for this hide protection level
   - OBKSIZE[1:0]: size of the key (see bitfield description)
   - NEXTKL[1:0]: when HDPL=1 in SBS_HDPLSR register RoT application can set those bit to 01 to provision a key for the next HDPL level (2).
   - Set both KEYSTART and KEYPROG bits to start the programming sequence.

5. Read back the key to verify its value (recommended). See Option byte key loading.

Note: When HDPL value in SBS peripheral changes FLASH_OBKDR register is cleared to 0x0.

For a given hide protection level, if authorized the application writes to an OBKINDEX that has already been successfully used before the old key is overwritten with the new value.

Like for any option change, if an error occurs OPTERRF is set in FLASH_OPTISR. It must be cleared, like KTEF and KVEF, before initiating another option byte key programming (otherwise the setting of KEYSTART bit is ignored).

All key error flags (KVEF, KTEF) must be cleared before application reads or write an option byte key.

Note: Option byte key integrity could fail when a reset is issued while programming it. When this happens the previously written key is kept, and no key is returned if it was the first programming. The OBLERRF error flag is also raised.

Option byte key loading

If OBKINDEX[4:0] is or greater than or equal to 0x8, the following sequence is required to read an option byte key stored in embedded flash memory:

1. Fill the following information to FLASH_OBKCR:
   - OBKINDEX[4:0]: index of the key for this hide protection level. Size of the key is automatically recovered from the flash memory.
   - NEXTKL[1:0]: when HDPL=1 in SBS_HDPLSR register RoT application can set those bit to 01 to read a key provisioned for the next HDPL level (2).
   - Set KEYSTART bit with KEYPROG bit cleared to start the read sequence.

2. Wait until QW bit is cleared in FLASH_SR register.

3. Read the value of the key using FLASH_OBKDRx registers

If OBKINDEX[4:0] is less than 0x8, the following sequence is required to load to the SAES peripheral an option byte key stored in embedded flash.
1. In the SAES peripheral, set the correct KEYSIZE and write KEYSEL[2:0] =011 or 101 in the SAES_CR register.

2. Perform the same sequence as a normal option byte key read, with the exception of reading back the FLASH_OBKDRx registers. In this case, key data are automatically transferred from embedded flash memory to the SAES key registers, while the BUSY bit is set in the SAES_SR register.

3. Once the transfer is completed the BUSY bit is cleared and the KEYVALID bit is set in the SAES_SR register. If KEYVALID is not set when the BUSY bit is cleared, or if a key error flag (KEIF) is set in SAES, this means that an unexpected event occurred during the transfer. In this unlikely event the IPRST bit must be set then cleared in the SAES_CR register, then sequence can be restarted from Step 1 above.

During option byte key loading two errors can happen:
- Key valid error (see Section 5.7.10)
- Key transfer error (see Section 5.7.11)

All key error flags (KVEF, KTEF) must be cleared before application reads or writes an option byte key.

Note: When the HDPL value in the SBS peripheral changes, the FLASH_OBKDR register is cleared to 0x0.

5.4.5 Option byte user words overview

Table 32 lists all the user option bytes managed through the embedded flash memory registers, as well as their default values before the first option byte change (default factory value). They are configured by the end-user depending on the application requirements. Some option bytes might have been initialized by STMicroelectronics during manufacturing stage.

Embedded flash memory (FLASH)
5.4.6 Description of user option byte word

The general-purpose option bytes that can be used by the application are listed below. They are accessed through the FLASH_OBWSRx registers.

- **Watchdog management**
  - IWDG_FZ_STOP: independent watchdog IWDG counter active in Stop mode if 1 (stop counting or freeze if 0)
  - IWDG_FZ_SDBY: independent watchdog IWDG counter active in Standby mode if 1 (stop counting or freeze if 0)
  - IWDG_HW: hardware (0) or software (1) IWDG watchdog control selection

*Note:* If the hardware watchdog “control selection” feature is enabled (set to 0), the watchdog is automatically enabled at power-on, thus generating a reset unless the watchdog key register is written to or the down-counter is reloaded before the end-of-count is reached. Depending on the configuration of IWDG_STOP and IWDG_STBY options, the IWDG can continue counting (1) or not (0) when the device is in Stop or Standby mode respectively. When the IWDG is kept running during Stop or Standby mode, it can wake up the device from these modes.

- **Reset management**
  - BOR_LEV: Brownout level option, indicating the supply level threshold that activates/releases the reset
  - NRST_STDBY: Independent watchdog generates a reset when entering Standby mode if cleared to 0
  - NRST_STOP: Independent watchdog generates a reset when entering Stop mode if cleared to 0.

*Note:* Whenever a Standby (respectively Stop) mode entry sequence is successfully executed, the device is reset instead of entering Standby (respectively Stop) mode if NRST_STDBY (respectively NRST_STOP) is cleared to 0.

- **Device options**
  - VDDIO_HSLV: enables the configuration of pads below 2.5 V for VDDIO power rail if set to 1.
  - XSPI1_HSLV: enable I/O XSPIM_P1 high-speed option if set to 1.
  - XSPI2_HSLV: enable I/O XSPIM_P2 high-speed option if set to 1.

When STMicroelectronics delivers the device, the values programmed in the general-purpose option bytes are the following:

- **Watchdog management**
  - IWDG reset active in Standby and Stop modes (option value = 0x1)
  - IWDG not automatically enabled at power-on (option byte value = 0x1)

- **Reset management:**
  - BOR: brownout level option (reset level) equals 2.1 V (option byte value = 0x0). A reset is not generated when the device enters Standby or Stop low-power mode (option byte value = 0x1)

- The speed of the device I/Os are optimized when device voltage is low (VDDIO_HSLV= XSPI1_HSLV= XSPI2_HSLV= 1)

Refer to *[Section 5.9: FLASH registers]* for details.
5.4.7 Description of security option bytes

The option bytes that are use by root of trust application to enhance security are listed below:

- NVSTATE[7:0]: Non-volatile state (see Section 5.5.3 for details).
- IROT_SELECT[7:0]: Selection of ST iRoT (STM32H7S only).
- WRPS[7:0]: Write protection option of user flash sectors. It is active low. Refer to Section 5.9.26 for details.
- OTPL[15:0]: Write protection option of OTP blocks. It is active high. Refer to Section 5.3.11 for details.
- HDP_AREA: Hide protection user flash area definitions. Refer to Section 5.5.5.
  - HDP_AREA_START (respectively HDP_AREA_END) contains the first (respectively last) 256-byte block of the HDP area.
Usage of above options are summarized in Table 33.

Table 33. STM32H7Rx/7Sx device lifecycle table

</tr>
</tbody>
</table>

1. A “closed” product with incorrect or non-defined debug certificate is equivalent to a “locked” product.

When STMicroelectronics delivers the device, the values programmed in the security option bytes are the following:

- OPEN device (NVSTATE value = 0xB4)
- iRoT selection (only on H7S part)
  - OEM iRoT (IROT_SELECT value = 0x6A)
  - ST iRoT (IROT_SELECT value = 0xB4)
- Swap is locked deactivated, with all user flash sector are allocated to bank A.
- HDP area protection disabled (start addresses higher than end addresses)
- Write protection disabled (all option byte bits set to 1)
- All OTP blocks are writable, as they are virgin (all option byte bits set to 0)

Refer to Section 5.9: FLASH registers for details.
5.5 **FLASH protection mechanisms**

Since sensitive information are stored in the flash memory, it is important to protect it against unwanted operations such as reading confidential areas, illegal programming of immutable sectors, or malicious flash memory erasing.

For this purpose FLASH implements the following protection mechanisms:

- Configuration protection
- User flash write protection
- Device non-volatile security life cycle and application temporal isolation management
- OTP locking

This section provides a detailed description of all these security mechanisms.

5.5.1 **FLASH configuration protection**

The embedded flash memory uses hardware mechanisms to protect the following assets against unwanted or spurious modifications (e.g. software bugs):

- Option bytes change
- Write operations
- Erase commands
- Interrupt masking

More specifically, write operations to embedded flash memory control registers (FLASH_CR and FLASH_OPTCR) are not allowed after reset.

The following sequence must be used to unlock FLASH_CR register:

1. Program KEY1 to 0x45670123 in FLASH_KEYR key register.
2. Program KEY2 to 0xCDEF89AB in FLASH_KEYR key register.
3. LOCK bit is now cleared and FLASH_CR is unlocked.

The following sequence must be used to unlock FLASH_OPTCR register:

1. Program OPTKEY1 to 0x08192A3B in FLASH_OPTKEYR option key register.
2. Program OPTKEY2 to 0x4C5D6E7F in FLASH_OPTKEYR option key register.
3. OPTLOCK bit is now cleared and FLASH_OPTCR register is unlocked.

Any wrong sequence locks up the corresponding register/bit until the next system reset, and generates a bus error.

The above registers can be locked again by software by setting the LOCK bit in the corresponding control register.

The FLASH_CR register remains locked and a bus error is generated when the following operations are executed:

- Programming a third key value
- Writing to a different register than FLASH_KEYR before FLASH_CR has been completely unlocked (KEY1 programmed but KEY2 not yet programmed)
- Writing less than 32 bits to KEY1 or KEY2.
Similarly the FLASH_OPTCR register remains locked and a bus error is generated when the following operations are executed:

- Programming a third key value
- Writing to a different register before FLASH_OPTCR has been completely unlocked (OPTKEY1 programmed but OPTKEY2 not yet programmed)
- Writing less than 32 bits to OPTKEY1 or OPTKEY2.

The embedded flash memory configuration registers protection is summarized in Table 34. Registers not present in this table are not protected by any key.

2. Once set, the OTP Block Lock bits cannot be reset by the application.

### 5.5.2 Write protection

The purpose of embedded flash memory write protection is to prevent unwanted modifications to embedded non-volatile code and/or data.

Any 8 Kbyte sector can be independently write-protected or unprotected by clearing/setting the corresponding WRPS bit in the FLASH_WRPSR register.

A write-protected sector can neither be erased nor programmed. As a result, a full bank erase cannot be performed if one sector is write-protected, unless a NVSTATE transition to OPEN is triggered.

The embedded flash memory write-protection user option bits can be modified when HDPL=0 or 1 in SBS_HDPLSR register, using FLASH_WRPSRP.

**Note:** The HDP are in user flash is write and erase protected, while system flash cannot be erased by user application.

Write protection errors are documented in Section 5.7: FLASH error management.
5.5.3 Life cycle management

Introduction

Figure 18 shows how embedded flash manages the non-volatile security life cycle of the device.

Figure 18. Life cycle management scheme

</tr>
</tbody>
</table>

1. Enforced outside flash.
2. Includes STMicroelectronics engineering test modes. Those are disabled in CLOSE state, by hardware.
3. User can attempt to unlock debug features, if allowed by DEBUG_AUTH option bits.

Flash opening

When requesting a change of NVSTATE to OPEN, writing 0xB4 to FLASH_NVSRP register, flash performs an automatic erase of the following information:

- The whole user flash (write protected or not)
- The write protection data in FLASH_WRPSR.
- The option byte register defining the hide protection area is reset to their default manufacturing values (disabled).
- The option byte keys, excluding hide protection level 0 keys
- Root of trust option byte registers: FLASH_ROTSR and FIXEDSR

Note: The FLASH_EPOCHSR setting is kept when opening the flash memory

NVSTATE option change is triggered only after the RAM erase signal has confirmed that Backup RAM and PKA RAM have been successfully erased.
The system flash memory and the read-only region are not affected by flash opening and remain unchanged.

**Flash closing**

Writing 0x51 to the FLASH_NVSRP register triggers a change of NVSTATE from OPEN to CLOSE, confirmed when NVSTATE=0x51 in FLASH_NVSR register.

### 5.5.4 Hide protected system flash area

System flash sectors included between 0x1FF0 0000 and SEC_AREA_END addresses can be used to store STMicroelectronics secure firmware install (SFI) code, or the STM32 immutable root of trust code and data, with the associated encrypted keys stored in option byte keys.

Embedded flash system area can only be accessed by Cortex M7 in read or execute. The hide protected area can only be accessed when NVSTATE is CLOSE and when hide protection level in SBS_HDPLSR is 0 or 1 for ST iRoT products (default), or just 0 for OEM iROT products.

In all other cases one of the following events is triggered:

- Data read transactions return zero. Data write transactions are ignored. No bus error is generated but an error flag is raised (RDSERR for read, WRPERR for write).
- Read instruction transactions generate a bus error and the RDSERR error flag is raised.

Embedded flash system area is immutable, that is, it cannot be erased by any application code.

*Note:* When FLASH transition from CLOSE to OPEN state, embedded flash system area is kept.

### 5.5.5 Hide protected user flash area

**Overview**

User flash sectors included between HDP_AREA_START and HDP_AREA_END addresses are used to store the root of trust code and data, with the associated keys stored in embedded flash option byte keys.

Embedded flash hide protected (HDP) user area can only be accessed:

- by Cortex M7 in read, write or execute
- according to the conditions defined in following tables. *Table 36* concerns STM32H7R parts, or STM32H7S parts with IROT_SELECT different from 0xB4. STM32H7S parts with ST iRoT (IROT_SELECT=0xB4) are described in *Table 37*.

</table>

1. In FLASH_NVSR and FLASH_ROTTSR registers
2. Level for which hide protection is activated.

For more details on HDPL level following a reset, refer to Section 8: System configuration, boot and security (SBS).

Note: IROT_SELECT is stored in the FLASH_ROTTSR register.
Hide protection area in user flash programming

HDP user flash area is programmed in FLASH_HDPSRP by setting the HDP_AREA_START and HDP_AREA_END so that the END address is strictly higher than the START address.

HDP_AREA_START and HDP_AREA_END are defined with a granularity of 256 bytes. This means that the actual HDP user flash area size (in bytes) is defined by:

\[(HDP\_AREA\_END - HDP\_AREA\_START + 1) \times 256\]

As an example, to set the HDP user flash area on the first 8 Kbytes (that is, from address 0x0800 0000 to address 0x0800 1FFF, both included), the embedded flash memory must be configured as follows:

\[
\begin{align*}
HDP\_AREA\_START[15:0] &= 0x0 \\
HDP\_AREA\_END[15:0] &= 0x001F
\end{align*}
\]

The HDP user flash area size defined above is equal to:

\[(HDP\_AREA\_END - HDP\_AREA\_START + 1) \times 256 = 32 \times 256 \text{ bytes} = 8 \text{ Kbytes}.\]

The minimum HDP user flash area that can be set is 32 flash words (or 512 bytes). The maximum area is the whole user flash memory bank, configured by setting HDP\_AREA\_START= HDP\_AREA\_END.

Note: It is recommended to align the HDP user area size with 8 Kbytes flash sector granularity to always be able to erase non-HDP code and data.

It is possible to disable HDP protections by setting HDP\_AREA\_END lower than HDP\_AREA\_START.

Hide protection area in user flash properties

- Embedded flash hide protected user area can only be accessed in the conditions described in Overview. In all other cases one of the following events is triggered:
  - Data read transactions return zero. Data write transactions are ignored. No bus error is generated but an error flag is raised (RDSERR for read, WRPERR for write).
  - Read instruction transactions generate a bus error and the RDSERR error flag is raised.
- HDP user flash area is erase-protected. As a result:
  - No erase operations to a sector located in this area are possible (including the sector containing the area end address), unless HDPL=0 or 1.
  - In HDPL=2 or 3 the only possibility to fully erase user flash bank is to perform a device opening sequence (see Section 5.5.3).
- Rules to change the HDP user flash area are detailed in Changing option byte words in Section 5.4.3.
- When FLASH transition from CLOSE to OPEN state, the whole user flash (hide protected or not) is automatically erased, with the HDP area disabled (see Section 5.5.3).

For more information on HDP user flash area errors, refer to Section 5.7: FLASH error management.
5.6 FLASH low-power modes

5.6.1 Introduction

Table 38 summarizes the behavior of the embedded flash memory in microcontroller low-power modes. The embedded flash memory belongs to the Core domain.

Table 38. Effect of low-power modes on the embedded flash memory

<table>
<thead>
<tr>
<th>Power mode</th>
<th>Core domain voltage range</th>
<th>Allowed if FLASH busy</th>
<th>FLASH power mode (in Core domain)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run</td>
<td>VOS low / high</td>
<td>Yes</td>
<td>Run</td>
</tr>
<tr>
<td>Stop</td>
<td>SVOS low / high</td>
<td>No</td>
<td>Clock gated or Stopped</td>
</tr>
<tr>
<td>Standby</td>
<td>Off</td>
<td>No</td>
<td>Off</td>
</tr>
</tbody>
</table>

When the system state changes, or within a given system state, the embedded flash memory might be subjected to a different voltage supply range (VOS) depending on the application. The procedure to switch the embedded flash memory into various power modes (run, clock gated, stopped, off) is described below.

Note: For more information on microcontroller power states, refer to the Power control section (PWR).

5.6.2 Managing the FLASH domain switching to Stop or Standby

As explained in Table 38, if the embedded flash memory informs the reset and clock controller (RCC) that it is busy (that is, BUSY, QW, WBNE is set), the microcontroller cannot switch the Core domain to Stop or Standby mode.

Note: CRC_BUSY is not taken into account.

There are two ways to release the embedded flash memory:

- Reset the WBNE busy flag in the FLASH_SR register by any of the following actions:
  - Complete the write buffer with missing data.
  - Force the write operation without filling-in the missing data, by activating the FW bit in the FLASH_CR register. This forces all missing data “high”.
  - Reset the PG bit in FLASH_CR register. This disables the write buffer and consequently leads to the loss of its content.

- Poll the QW busy bits in the FLASH_SR register until they are cleared. This indicates that all recorded write, erase and option change operations are complete.

The microcontroller can then switch the domain to Stop or Standby mode.
5.7 FLASH error management

5.7.1 Introduction

The embedded flash memory automatically reports when an error occurs during a read, program or erase operation. A wide range of errors are reported:

- Write protection error (WRPERRF)
- Programming sequence error (PGSERRF)
- Strobe error (STRBERRF)
- Inconsistency error (INCERRF)
- Error correction code error (SNECCERRF/DBECCERRF)
- Read secure error (RDSERRF)
- CRC read error (CRCRDERRF)
- Option byte change error (OPTERRF)
- Key valid error (KVEF)
- Key transfer error (KTEF)
- Option byte loading error (OBLERRF)

The application software can individually enable the interrupt for each error, as detailed in Section 5.8: FLASH interrupts.

Note: For some errors, the application software must clear the error flag before attempting a new operation.

Note: General purpose errors (e.g. INCERRF) are taken into account when queues are loaded. Temporal isolation and other protection errors (for example WRPERRF, RDSERRF) are taken into account at FSM level, in front of the flash bank interface controller.

5.7.2 Write protection error (WRPERRF)

When an illegal erase/program operation is attempted to the non-volatile memory, the embedded flash memory sets the write protection error flag WRPERRF in FLASH_ISR register.

An erase operation is rejected and flagged as illegal if it targets one of the following memory areas:

- a sector belonging to a valid HDP user flash area (even partially), except if HDPL=0 or 1 in SBS_HDPLSR register.
- a sector write-locked with WRPS
- the read-only/OTP area

An program operation is ignored and flagged as illegal if it targets one of the following memory areas:

- a protected user flash sector belonging to a valid HDP user flash area (see Section 5.5.5)
- a user sector write-locked with WRPS
- an OTP block, locked with OTPL
- a read-only section
- the system flash memory
- a reserved area
When the WRPERRF flag is raised, the operation is rejected and nothing is changed. If a write burst operation was ongoing, WRPERRF is raised each time a flash word write operation is processed by the embedded flash memory.

**Note:** The WRPERRF flag does not block any new erase/program operation.

Not clearing the WRPERRF flag does not generate a programming sequence error (see below).

WRPERRF flag is cleared by setting the corresponding bit in FLASH_ICR register.

If WRPERRIE bit in FLASH_IER register is set, an interrupt is generated when the WRPERRF flag is raised (see Section 5.8: FLASH interrupts for details).

### 5.7.3 Programming sequence error (PGSERRF)

When the programming sequence is incorrect, the embedded flash memory sets the programming sequence error flag PGSERRF in FLASH_ISR register.

More specifically, the PGSERRF flag is set if one of the conditions below is met:

- A write operation is requested but the program enable bit (PG or PG_OTP) has not been set in the FLASH_CR register prior to the request. This program enable bit must stay at 1 until write is added to operation queue (QW rises).
- The inconsistency error (INCERRF) has not been cleared before requesting a new write operation.

When THE PGSERRF flag is raised, the current program operation is aborted and nothing is changed in flash. The corresponding write data buffer is also flushed. If a write burst operation was ongoing, PGSERRF is raised at the end of the burst.

**Note:** When the PGSERRF flag is raised, there is a risk that the last write operation performed by the application has been lost because of the above protection mechanism. Hence it is recommended to generate interrupts on PGSERRF and verify in the interrupt handler if the last write operation has been successful by reading back the value in the flash memory.

The PGSERRF flag also blocks any new program operation. This means that PGSERRF must be cleared before starting a new program operation.

The PGSERRF flag is cleared by setting the corresponding bit in the FLASH_ICR register.

If the PGSERRIE bit in FLASH_IER register is set, an interrupt is generated when the PGSERRF flag is raised. See Section 5.8: FLASH interrupts for details.

### 5.7.4 Strobe error (STRBERRF)

When the application software writes several times to the same byte write buffer, the embedded flash memory sets the strobe error flag STRBERRF in the FLASH_ISR register.

When the STRBERRF flag is raised, the current program operation is not aborted and new byte data replaces the old data. The application can ignore the error, proceed with the current write operation and request new write operations. If a write burst was ongoing, STRBERRF is raised at the end of the burst.

The STRBERRF flag is cleared by setting corresponding bit in the FLASH_ICR register.

If the STRBERRIE bit in FLASH_IER register is set, an interrupt is generated when the STRBERRF flag is raised. See Section 5.8: FLASH interrupts for details.
5.7.5 Inconsistency error (INCERRF)

When a programming inconsistency is detected, the embedded flash memory sets the inconsistency error flag INCERRF in the FLASH_ISR register.

More specifically, the INCERRF flag is set when one of the following conditions is met:

- A write operation is attempted before completion of the previous write operation, for example:
  - The application software starts a write operation to fill the 128-bit write buffer, but sends a new write burst request to a different flash memory address before the buffer is full.
  - One master starts a write operation, but before the buffer is full, another master starts a new write operation to the same address or to a different address.
- A wrap burst request issued by a master overlaps two or more 128-bit flash-word addresses, that is, wrap bursts must be done within 128-bit flash-word address boundaries.

Following the sequence below is recommended to avoid losing data when an inconsistency error occurs:

1. Execute a handler routine when the INCERRF flag is raised.
2. Stop all write requests to embedded flash memory.
3. Verify that the write operations that have been requested just before the INCERRF event have been successful by reading back the programmed values from the memory.
4. Clear the INCERRF bit in the FLASH_ICR register.
5. Restart the write operations where they have been interrupted.

Note: INCERRF flag must be cleared before starting a new write operation, otherwise a sequence error (PGSERRF) is raised.

Any write triggering inconsistency error is discarded by embedded flash memory.

5.7.6 Error correction code error (SNECCERRF/DBECCERRF)

When a single error correction is detected during a read the embedded flash memory sets the single error correction flag SNECCERRF in the FLASH_ISR register.

When two ECC errors are detected during a read, the embedded flash memory sets the double error detection flag DBECCERRF in the FLASH_ISR register.

When the SNECCERRF flag is raised, the corrected read data are returned. Hence the application can ignore the error and request new read operations.

If a read burst operation was ongoing, the SNECCERRF or DBECCERRF flag is raised each time a new data is sent back to the requester through the corresponding system bus.

When the SNECCERRF (or DBECCERRF respectively) flag is raised, the address of the flash word that generated the error is saved in the FLASH_ECCSFAR (or FLASH_ECCDFAR respectively) register. This register is automatically cleared when the associated flag that generated the error is cleared.

Note: In the case of successive single correction (or double detection respectively) errors, only the address corresponding to the first error is stored in the FLASH_ECCSFAR (or FLASH_ECCDFAR respectively) register.
When the DBECCERRF flag is raised reading the user flash memory, a bus error is generated. In the case of successive double error detections, a bus error is generated each time a new data is sent back to the requester through the AXI interface.

**Note:** It is not mandatory to clear the SNECCERRF or DBECCERRF flags before starting a new read operation.

The SNECCERRF and DBECCERRF flags are cleared by setting corresponding bit in the FLASH_ICR register.

If the SNECCERRIE (or respectively DBECCERRIE) bit in the FLASH_ISR register is set, an interrupt is generated when the SNECCERRF (or respectively DBECCERRF) flag is raised. See Section 5.8: FLASH interrupts for details.

### 5.7.7 Read secure error (RDSERRF)

When an illegal read or execute operation is attempted to a hide protected area, the embedded flash memory sets the read secure the error flag RDSERRF in the FLASH_ISR register. For more information on illegal access definition, refer to Section 5.5.4: Hide protected system flash area and Section 5.5.5: Hide protected user flash area.

When the RDSERRF flag is raised, the current read operation is aborted and the application can request new read operations. If a read burst was ongoing, RDSERRF is raised each time a data is sent back to the requester through the AXI interface.

**Note:** The bus error is raised only if the illegal access is due to an instruction fetch.

RDSERRF flag is cleared by setting corresponding bit in the FLASH_ICR register.

If the RDSERRIE bit in the FLASH_IER register is set, an interrupt is generated when the RDSERRF flag is raised (see Section 5.8: FLASH interrupts for details).

### 5.7.8 CRC read error (CRCRDERRF)

After a CRC computation, the embedded flash memory sets the CRC read error flag CRCERR in the FLASH_ISR register when one or more address belonging to a protected area was read by the CRC module. A protected area corresponds to a valid HDP area in user flash, for which any read is currently illegal (see Section 5.5.5 for details).

The CRCRDERRF flag is raised when the CRCEND bit is set (end of CRC calculation). In this case, it is likely that the CRC result is wrong since illegal read operations to protected areas return null values.

The CRCRDERRF flag is cleared by setting corresponding bit in the FLASH_ICR register.

If the CRCRDERRIE bit in the FLASH_IER register is set, an interrupt is generated when the CRCRDERRF flag is raised together with the CRCEND bit (see Section 5.8: FLASH interrupts for details).

### 5.7.9 Option byte change error (OPTERRF)

When the embedded flash memory finds an error during an option change operation, it aborts the operation and sets the option byte change the error flag OPTERRF in the FLASH_OPTISR register.

The OPTERRF flag is cleared by setting corresponding bit in the FLASH_OPTICR register.
If the OPTERRIE bit in the FLASH_OPTCR register is set, an interrupt is generated when the OPTERRF flag is raised (see Section 5.8: FLASH interrupts for details).

It is mandatory to clear the OPTERRF flag before starting a new option byte change, or an option byte key programming.

### 5.7.10 Key valid error (KVEF)

KVEF error flag is set in the FLASH_OPTISR register in two cases:

- Embedded flash did not find an option byte key that corresponds to the given OBKINDEX[4:0] and the requested HDPL (optionally modified by NEXTKL[1:0]). It can happen for example when requested key has not being provisioned.
- A double error detection was found when loading the requested option byte key. In this case, if this key is provisioned again the error should disappear.

It is mandatory to clear the KVEF flag before doing any operation on option byte keys because when KVEF is set, writes to the START bit in the FLASH_OBKCR are ignored.

The KVEF flag is cleared by setting corresponding bit in FLASH_OPTICR register.

If the KVEIE bit in the FLASH_OPTCR register is set, an interrupt is generated when the KVEF flag is raised (see Section 5.8: FLASH interrupts for details).

### 5.7.11 Key transfer error (KTEF)

The KTEF error flag is set in the FLASH_OPTISR register when embedded flash signals an error to the SAES peripheral. This happens when:

- the key size (128-bit or 256-bit) is not matching between embedded flash OBKSIZE[1:0] and KEYSIZE bit in SAES_CR register.
- an ECC dual error detection occurred while embedded flash loaded an option byte key for the SAES peripheral. In this case KVEF is also set.

It is mandatory to clear the KTEF flag before doing any operation on option byte keys. Because when KTEF is set write to the START bit in the FLASH_OBKCR is ignored.

The KTEF flag is cleared by setting corresponding bit in the FLASH_OPTICR register.

If the KTEIE bit in the FLASH_OPTCR register is set, an interrupt is generated when the KTEF flag is raised (see Section 5.8: FLASH interrupts for details).

While flash memory loads the option byte key to share with the SAES peripheral no other flash operation should be started until the key is transferred to the SAES. Otherwise the key transfer may fail (BUSY=KEYVALID=0 in the SAES_SR register) or the BUSY bit in the SAES_SR register stays at 1, until IPRST bit is used to clear it.

*Note:* When KTEF is cleared by the application the error signal to SAES is cleared.

### 5.7.12 Option byte loading error (OBLERRF)

When the embedded flash memory finds one of the following error during an option byte loading sequence (see Section 5.4.2) it sets the option byte change error flag OBLERRF in the FLASH_ISR register.

- ECC double error detection on one or more option byte (data or metadata)
- ECC double error detection on one or more option byte key (data or metadata)
In the case of an OBLERRF event the application should verify the correctness of the option byte information described in Section 5.4.

The OBLERRF flag is cleared by setting the corresponding bit in the FLASH_ICR register. If the OBLERRIE bit in the FLASH_IER register is set, an interrupt is generated when the OBLERRF flag is raised (see Section 5.8: FLASH interrupts for details).

### 5.7.13 Miscellaneous HardFault errors

The following events generate a bus error on the corresponding bus interface:

- On the AXI system bus:
  - illegal instruction fetch to HDP protected area because of the lifecycle (e.g. protected system flash when NVSTATE=OPEN).
- On AHB configuration or system bus:
  - wrong key input to FLASH_KEYR or FLASH_OPTKEYR
  - 8-bit accesses to system AHB interface

### 5.8 FLASH interrupts

The embedded flash memory can generate a maskable interrupt to signal the following events:

- Read and write errors (see Section 5.7: FLASH error management)
  - Single ECC error correction during read operation
  - Double ECC error detection during read operation
  - Write inconsistency error
  - Bad programming sequence
  - Strobe error during write operations
  - Option change error
  - Option byte keys error
- Security errors (see Section 5.7: FLASH error management)
  - Write protection error
  - Read security error
  - CRC computation on HDP area error
  - Option byte loading error
  - Key valid or key transfer errors
- Miscellaneous events (described below)
  - End of programming
  - CRC computation complete

These multiple sources are combined into a single interrupt signal, flash_it, which is the only interrupt signal from the embedded flash memory that drives the NVIC (nested vectored interrupt controller).

You can individually enable or disable embedded flash memory interrupt sources by changing the mask bits in the FLASH_IER register. Setting the appropriate mask bit enables the interrupt.
Note: Prior to writing, FLASH_IER register must be unlocked as explained in Section 5.5.1: FLASH configuration protection

Table 39 gives a summary of the available embedded flash memory interrupt features.

Note: Some flags need to be cleared before a new operation is triggered.

1. AXI bus only
2. Set in FLASH_OPTISR register, cleared in FLASH_OPTICR register.

The status of the individual maskable interrupt sources described in Table 39 (except for option byte error) can be read from the FLASH_ISR register. They can be cleared by setting the corresponding bit in the FLASH_ICR register.

No unlocking mechanism is required to clear an interrupt.

**End-of-program event**

Setting the end-of-operation interrupt enable bit (EOPIE) in the FLASH_IER register enables the generation of an interrupt at the end of an erase operation, a program operation or an option byte change. The EOPF bit in the FLASH_ISR register is also set when one of these events occurs.

Setting the EOPF bit in FLASH_ICR register clears the EOPF flag in the FLASH_ISR register.
### CRC end of calculation event

Setting the CRC end-of-calculation interrupt enable bit (CRCENDIE) in the FLASH_IER register enables the generation of an interrupt at the end of a CRC operation. The CRCENDF bit in the FLASH_ISR register is also set when this event occurs.

Setting the CRCENDF bit in the FLASH_ICR register clears the CRCENDF flag in the FLASH_ISR register.

### 5.9 FLASH registers

#### 5.9.1 FLASH access control register (FLASH_ACR)

Address offset: 0x000  
Reset value: 0x0000 0013

</tbody>
</table>

Bits 31:6  Reserved, must be kept at reset value.

Bits 5:4 **WRHIGHFREQ[1:0]:** Flash signal delay  
These bits are used to control the delay between non-volatile memory signals during programming operations. Application software has to program them to the correct value depending on the embedded flash memory interface frequency. Refer to Table 29 for details.

*Note: Embedded flash does not verify that the configuration is correct.*

Bits 3:0 **LATENCY[3:0]:** Read latency  
These bits are used to control the number of wait states used during read operations on both non-volatile memory banks. The application software has to program them to the correct value depending on the embedded flash memory interface frequency and voltage conditions. Refer to Table 29 for details.

- 0000: zero wait state used to read a word from non-volatile memory  
- 0001: one wait state used to read a word from non-volatile memory  
- 0010: two wait states used to read a word from non-volatile memory  
- 0011: seven wait states used to read a word from non-volatile memory  
- 1111: fifteen wait states used to read from non-volatile memory  

*Note: Embedded flash does not verify that the configuration is correct.*
5.9.2 **FLASH control key register (FLASH_KEYR)**

Address offset: 0x004

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>CUKEY[31:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>w w w w w w w w w w w w w w</td>
</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

Bits 31:0 **CUKEY[31:0]**: Control unlock key

Following values must be written to FLASH_KEYR consecutively to unlock FLASH_CR register:

1st key = 0x4567 0123

2nd key = 0xCDEF 89AB

Reads to this register returns zero. If above sequence is wrong or performed twice, the FLASH_CR register is locked until the next system reset, and access to it generates a bus error.

5.9.3 **FLASH control register (FLASH_CR)**

Address offset: 0x010

Reset value: 0x0000 0001

When LOCK bit in this register is set writes to all other bits are ignored.

Write access to this register is controlled by FLASH_KEYR.

<table>
<thead>
<tr>
<th>Bits 31:25 Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 24 <strong>ALL_BANKS</strong>: All banks select bit</td>
</tr>
<tr>
<td>When this bit is set the erase is done on all flash memory sectors.</td>
</tr>
<tr>
<td>ALL_BANKS is used only if a bank erase is required (BER=1). In all others operations, this control bit is ignored.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bits 23:18 Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 17 <strong>CRC_EN</strong>: CRC enable</td>
</tr>
<tr>
<td>Setting this bit enables the CRC calculation. CRC_EN does not start CRC calculation but enables CRC configuration through FLASH_CRCRR register.</td>
</tr>
<tr>
<td>When CRC calculation is performed it can be disabled by clearing CRC_EN bit. Doing so sets CRCDATA to 0x0, clears CRC configuration and resets the content of FLASH_CRCDDAT register.</td>
</tr>
</tbody>
</table>
Bit 16 **PG_OTP**: Program Enable for OTP Area
Set this bit to enable write operations to OTP area.

Bits 15:9 Reserved, must be kept at reset value.

Bits 8:6 **SSN[2:0]**: Sector erase selection number
These bits are used to select the target sector for an erase operation (they are unused otherwise).
- 000: Sector 0
- 001: Sector 1
- ...
- 111: Sector 7

Bit 5 **START**: Erase start control bit
This bit is used to start a sector erase or a bank erase operation. The embedded flash memory resets START when the corresponding operation has been acknowledged. The user application cannot access any embedded flash memory register until the operation is acknowledged.

Bit 4 **FW**: Force write
This bit forces a write operation even if the write buffer is not full. In this case all bits not written are set by hardware. The embedded flash memory resets FW when the corresponding operation has been acknowledged.

*Note: Using a force-write operation prevents the application from updating later the missing bits with something other than 1, because this would likely to lead to a permanent ECC error.*

Write forcing is effective only if the write buffer is not empty (in particular, FW does not start several write operations when the force-write operations are performed consecutively).

Bit 3 **BER**: Bank erase request
Setting this bit requests a bank erase operation (user flash memory only).

- 0: Bank erase is not requested
- 1: Bank erase is requested. Actual erase is started setting START bit in this register.

Write protection error is triggered when a bank erase is required and some sectors are protected.

BER has a higher priority than SER: if both are set, the embedded flash memory executes a bank erase.
Bit 2  **SER**: Sector erase request
   Setting this bit requests a sector erase.
   0: Sector erase not requested
   1: Sector erase requested
   Write protection error is triggered when a sector erase is required on at least one protected sector.
   BER has a higher priority than SER: if both bits are set, the embedded flash memory executes a bank erase.

Bit 1  **PG**: Internal buffer control bit
   Setting this bit enables internal buffer for write operations. This allows preparing program operations even if a sector or bank erase is ongoing. When PG is cleared, the internal buffer is disabled for write operations, and all the data stored in the buffer but not sent to the operation queue are lost.
   0: Internal buffer disabled for write operations
   1: Internal buffer enabled for write operations

Bit 0  **LOCK**: Configuration lock bit
   When this bit is set write to all other bits in this register, and to FLASH_IER register, are ignored.
   0: FLASH_CR and FLASH_IER registers are unlocked
   1: Writes to FLASH_IER, and to other bits than LOCK in FLASH_CR, are ignored
   Clearing this bit requires the correct write sequence to FLASH_KEYR register (see this register for details). If a wrong sequence is executed, or if the unlock sequence is performed twice, this bit remains locked until the next system reset.
   During the write access to set LOCK bit from 0 to 1, it is possible to change the other bits of this register.
### 5.9.4 FLASH status register (FLASH_SR)

Address offset: 0x014  
Reset value: 0x0000 0000

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:7 Reserved, must be kept at reset value.

**Bit 6 IS_OPTCHANGE:** Is an option change  
This bit is set together with BUSY when an option change operation is ongoing. It is cleared when BUSY is cleared.  
This flag can also raise with IS_PROGRAM or IS_ERASE, because a program or erase step is ongoing during option change.

**Bit 5 IS_ERASE:** Is an erase  
This bit is set together with BUSY when an erase operation is ongoing. It is cleared when BUSY is cleared.  
This flag can also raise with IS_OPTCHANGE, because an erase operation can happen during an option change.

**Bit 4 IS_PROGRAM:** Is a program  
This bit is set together with BUSY when a program operation is ongoing. It is cleared when BUSY is cleared.  
This flag can also raise with IS_OPTCHANGE, because a program operation can happen during an option change.

**Bit 3 CRC_BUSY:** CRC busy flag  
This bit is set when a CRC calculation is ongoing. This bit cannot be forced to 0. The user must wait until the CRC calculation has completed or disable CRC computation using CRC_EN bit in FLASH_CR register.  
0: No CRC calculation ongoing  
1: CRC calculation ongoing
Bit 2  **QW**: Wait queue flag
This bit is set when a write, erase or option byte change operation is pending in the command queue buffer. It is not possible to know what type of programming operation is present in the queue.
This flag is reset by hardware when all write, erase or option byte change operations have been executed and thus removed from the waiting queue(s). This bit cannot be forced to 0. It is reset after a deterministic time if no other operations are requested.
0: No write, erase or option byte change operations waiting in the operation queues
1: At least one write, erase or option byte change operation is waiting in the operation queue

Bit 1  **WBNE**: Write buffer not empty flag
This bit is set when the embedded flash memory is waiting for new data to complete the write buffer. In this state, the write buffer is not empty. WBNE is reset by hardware each time the write buffer is complete or the write buffer is emptied following one of the event below:
- the application software forces the write operation using FW bit in FLASH_CR
- the embedded flash memory detects an error that involves data loss
- the application software has disabled write operations
This bit cannot be forced to 0. To reset it, clear the write buffer by performing any of the above listed actions, or send the missing data.
0: Write buffer empty or full
1: Write buffer waiting data to complete

Bit 0  **BUSY**: Busy flag
This bit is set when an effective write, erase or option byte change operation is ongoing. It is possible to know what type of operation is being executed reading the flags IS_PROGRAM, IS_ERASE and IS_OPTCHANGE.
BUSY cannot be cleared by application. It is automatically reset by hardware every time a step in a write, erase or option byte change operation completes. It is not recommended to do software polling on BUSY to know when one operation completed because, depending of operation, more pulses are possible for one only operation. For software polling it is therefore better to use QW flag or to check the EOPF flag.
0: No programming, erase or option byte change operation are being executed
1: Programming, erase or option byte change operation are being executed. See flags IS_PROGRAM, IS_ERASE and IS_OPTCHANGE for details.
5.9.5  FLASH interrupt enable register (FLASH_IER)

Address offset: 0x020
Reset value: 0x0000 0000

Writes to this register are ignored if LOCK bit is set in FLASH_CR register.

</tr>
</tbody>
</table>

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **CRCRDERRF**: CRC read error flag
This bit is set when a word is found read protected during a CRC operation. An interrupt is generated if CRCRDIE is set. Setting CRCRDERRF bit in FLASH_ICR register clears this bit.
0: No protected area detected inside addresses read by CRC
1: At least one protected area has been detected inside address read by CRC. As a result CRC result is very likely incorrect.
This flag is valid only when CRCEND bit is set.

Bit 27 **CRCENDF**: CRC end flag
This bit is set when the CRC computation has completed. An interrupt is generated if CRCENDIE is set. It is not necessary to reset CRCEND before restarting CRC computation.
Setting CRCENDF bit in FLASH_ICR register clears this bit.
0: CRC computation not complete
1: CRC computation complete

Bit 26 **DBECCERRF**: ECC double error flag
This bit is set when an ECC double detection error occurs during a read operation. An interrupt is generated if DBECCERRIE is set. Setting DBECCERRF bit in FLASH_ICR register clears this bit.
0: No ECC double detection error occurred
1: ECC double detection error occurred
Embedded flash memory (FLASH)  

Bit 25  **SNECCERRF**: ECC single error flag  
This bit is set when an ECC single correction error occurs during a read operation. An interrupt is generated if SNECCERRIE is set. Setting SNECCERRF bit in FLASH_ICR register clears this bit.  
0: No ECC single correction error occurred  
1: ECC single correction error occurred  

Bit 24  **RDSERRF**: Read security error flag  
This bit is set when a read security error occurs (read access to hide protected area with incorrect hide protection level). An interrupt is generated if RDSERRIE is set. Setting RDSERRF bit in FLASH_ICR register clears this bit.  
0: No security error occurred  
1: A security error occurred  

Bits 23:22  Reserved, must be kept at reset value.  

Bit 21  **INCERRF**: Inconsistency error flag  
This bit is set when a inconsistency error occurs. An interrupt is generated if INCERRIE is set. Setting INCERRF bit in the FLASH_ICR register clears this bit.  
0: No inconsistency error occurred  
1: A inconsistency error occurred  

Bit 20  **OBLERRF**: Option byte loading error flag  
This bit is set when an error is found during the option byte loading sequence. An interrupt is generated if OBLERRIE is set. Setting OBLERRF bit in the FLASH_ICR register clears this bit.  
0: No error found during option byte loading sequence  
1: Some errors found during option byte loading sequence  

Bit 19  **STRBERRF**: Strobe error flag  
This bit is set when a strobe error occurs (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if the STRBERRIE bit is set. Setting STRBERRF bit in FLASH_ICR register clears this bit.  
0: No strobe error occurred  
1: A strobe error occurred  

Bit 18  **PGSERRF**: Programming sequence error flag  
This bit is set when a sequence error occurs. An interrupt is generated if the PGSERRIE bit is set. Setting PGSERRF bit in FLASH_ICR register clears this bit.  
0: No sequence error occurred  
1: A sequence error occurred  

Bit 17  **WRPERRF**: Write protection error flag  
This bit is set when a protection error occurs during a program operation. An interrupt is also generated if the WRPERRIE is set. Setting WRPERRF bit in FLASH_ICR register clears this bit.  
0: No write protection error occurred  
1: A write protection error occurred  

Bit 16  **EOPF**: End-of-program flag  
This bit is set when a programming operation completes. An interrupt is generated if the EOPIE is set. It is not necessary to reset EOPF before starting a new operation. Setting EOPF bit in FLASH_ICR register clears this bit.  
0: No programming operation completed  
1: A programming operation completed  

Bits 15:0  Reserved, must be kept at reset value.
5.9.7 **FLASH interrupt clear register (FLASH_ICR)**

Address offset: 0x028  
Reset value: 0x0000 0000

| 27   | **CRCENDF**: CRC end flag clear   
Setting this bit clears CRCENDF flag in FLASH_ISR register. |
| 26   | **DBECCERRF**: ECC double error flag clear  
Setting this bit clears DBECCERRF flag in FLASH_ISR register. If the SNECCERRF flag of FLASH_ISR register is also cleared, FLASH_ECCFAR register is reset to zero as well. |
| 25   | **SNECCERRF**: ECC single error flag clear  
Setting this bit clears SNECCERRF flag in FLASH_ISR register. If the DBECCERRF flag of FLASH_ISR register is also cleared, FLASH_ECCFAR register is reset to zero as well. |
| 24   | **RDSERRF**: Read security error flag clear  
Setting this bit clears RDSERRF flag in FLASH_ISR register. |
| 23:22 | Reserved, must be kept at reset value. |
| 21   | **INCERRF**: Inconsistency error flag clear  
Setting this bit clears INCERRF flag in FLASH_ISR register. |
| 20   | **OBLERRF**: Option byte loading error flag clear  
Setting this bit clears OBLERRF flag in FLASH_ISR register. |
| 19   | **STRBERRF**: Strobe error flag clear  
Setting this bit clears STRBERRF flag in FLASH_ISR register. |
| 18   | **PGSERRF**: Programming sequence error flag clear  
Setting this bit clears PGSERRF flag in FLASH_ISR register. |
| 17   | **WRPERRF**: Write protection error flag clear  
Setting this bit clears WRPERRF flag in FLASH_ISR register. |
| 16   | **EOPF**: End-of-program flag clear  
Setting this bit clears EOPF flag in FLASH_ISR register. |
| 15:0 | Reserved, must be kept at reset value. |
5.9.8 FLASH CRC control register (FLASH_CRCCR)

Address offset: 0x030
Reset value: 0x001C 0000

Writes to this register are ignored if CRC_EN bit is cleared in FLASH_CR register.

</tbody>
</table>
Bit 10 **ADD_SECT**: CRC sector select bit
When this bit is set the sector whose number is written in CRC_SECT is added to the list of sectors on which the CRC is calculated.

Bit 9 **CRC_BY_SECT**: CRC sector mode select bit
When this bit is set the CRC calculation is performed at sector level, on the sectors present in the list of sectors. To add a sector to this list, use ADD_SECT and CRC_SECT bits. To clean the list, use CLEAN_SECT bit.
When CRC_BY_SECT is cleared the CRC calculation is performed on all addresses defined between start and end addresses defined in FLASH_CRCSADDR and FLASH_CRCEADDR registers.

Bits 8:3 Reserved, must be kept at reset value.

Bits 2:0 **CRC_SECT[2:0]**: CRC sector number
CRC_SECT is used to select one user flash sectors to be added to the list of sectors on which the CRC is calculated. The CRC can be computed either between two addresses (using registers FLASH_CRCSADDR and FLASH_CRCEADDR) or on a list of sectors using this register. If this latter option is selected, it is possible to add a sector to the list of sectors by programming the sector number in CRC_SECT and then setting ADD_SECT bit.
The list of sectors can be erased either by setting CLEAN_SECT bit or by disabling the CRC computation.
000: sector 0 for CRC
001: sector 1 for CRC
... 111: sector 7 for CRC

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:6 **CRC_START_ADDR[10:0]**: CRC start address
This register is used when CRC_BY_SECT is cleared. It must be programmed to the address of the first flash word to use for the CRC calculation, done burst by burst.
CRC computation starts at an address aligned to the burst size defined in CRC_BURST of FLASH_CRCCCR register. Hence least significant bits [5:0] of the address are set by hardware to 0 (minimum burst size = 64 bytes).
The address is relative to the flash bank.

Bits 5:0 Reserved, must be kept at reset value.
5.9.10 FLASH CRC end address register (FLASH_CRCEADDR)

Address offset: 0x038
Reset value: 0x0000 0000

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:6 CRC_END_ADDR[10:0]: CRC end address

This register is used when CRC_BY_SECT is cleared. It must be programmed to the address of the flash word starting the last burst of the CRC calculation. The burst size is defined in CRC_BURST of FLASH_CRCCR register.

The least significant bits [5:0] of the address are set by hardware to 0 (minimum burst size=64 bytes). The address is relative to the flash bank.

Bits 5:0 Reserved, must be kept at reset value.

5.9.11 FLASH CRC data register (FLASH_CRCDATAR)

Address offset: 0x03C
Reset value: 0x0000 0000

Bits 31:0 CRC_DATA[31:0]: CRC result

This bitfield contains the result of the last CRC calculation. The value is valid only when CRC calculation completed (CRCENDF is set in FLASH_ISR register).

CRC_DATA is cleared when CRC_EN is cleared in FLASH_CR register (CRC disabled), or when CLEAN_CRC bit is set in FLASH_CRCCR register.
5.9.12  FLASH ECC single error fail address (FLASH_ECCSFADDR)

Address offset: 0x040
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>SEC_FADD[31:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>r r r r r r r r r r r r r r r</td>
</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

Bits 31:0  SEC_FADD[31:0]: ECC single error correction fail address
- When a single ECC error correction occurs during a read operation, the SEC_FADD bitfield contains the system bus address that generated the error.
- This register is automatically cleared when SNECCERRF flag that generated the error is cleared.
- Note that only the first address that generated an ECC single error correction error is saved in this register.

5.9.13  FLASH ECC double error fail address (FLASH_ECCDFADDR)

Address offset: 0x044
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>DED_FADD[31:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>r r r r r r r r r r r r r r r</td>
</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

Bits 31:0  DED_FADD[31:0]: ECC double error detection fail address
- When a double ECC detection occurs during a read operation, the DED_FADD bitfield contains the system bus address that generated the error.
- This register is automatically cleared when the DBECCERRF flag that generated the error is cleared.
- Note that only the first address that generated an ECC double error detection error is saved in this register.
5.9.14  **FLASH options key register (FLASH_OPTKEYR)**

Address offset: 0x100  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>OCUKKEY[31:16]</th>
<th>w</th>
<th>w</th>
<th>w</th>

<td>w</td>
<td>w</td>
<td>w</td>
<td>w</td>
<td>w</td>
<td>w</td>
</tr>
</tbody>
</table>

Bits 31:0  **OCUKKEY[31:0]**: Options configuration unlock key  
Following values must be written to FLASH_OPTKEYR consecutively to unlock FLASH_OPTCR register:  
1st key = 0x0819 2A3B  
2nd key = 0x4C5D 6E7F  
Reads to this register returns zero. If above sequence is performed twice locks up the corresponding register/bit until the next system reset, and generates a bus error.

5.9.15  **FLASH options control register (FLASH_OPTCR)**

Address offset: 0x104  
Reset value: 0x0000 0001

When OPTLOCK bit in this register is set writes to all other bits are ignored.  
Write access to this register is controlled by FLASH_OPTKEYR register.

</tbody>
</table>

Bit 31  **Reserved, must be kept at reset value.**

Bit 30  **OPTERRIE**: Option byte change error interrupt enable bit  
This bit controls if an interrupt has to be generated when an error occurs during an option byte change.  
0: no interrupt is generated when an error occurs during an option byte change  
1: an interrupt is generated when and error occurs during an option byte change

Bit 29  **Reserved, must be kept at reset value.**

Bit 28  **KTEIE**: Key transfer error interrupt enable bit  
This bit controls if an interrupt has to be generated when KTEF is set in FLASH_OPTISR.  
0: no interrupt is generated when a key transfer error occurs  
1: an interrupt is generated when a key transfer error occurs
Bit 27  **KVEIE**: Key valid error interrupt enable bit
This bit controls if an interrupt has to be generated when KVEF is set in FLASH_OPTISR.
0: no interrupt is generated when a key valid error occurs
1: an interrupt is generated when a key valid error occurs

Bits 26:2  Reserved, must be kept at reset value.

Bit 1  **PG_OPT**: Program options
0: Update operations to user option bytes and option byte keys do not start
1: Write operation to user option bytes and option byte keys is enabled

Bit 0  **OPTLOCK**: Options lock
When this bit is set write to all other bits in this register, and write to OTP words, option bytes and option bytes keys control registers, are ignored.
0: OTP words, FLASH_OPTCR, FLASH_OBKCR and FLASH_xxSRP registers are unlocked
1: Writes to OTP words, FLASH_OBKCR, FLASH_xxSRP and to other bits than OPTLOCK in FLASH_OPTCR, are ignored
Clearing this bit requires the correct write sequence to FLASH_OPTKEYR register (see this register for details). If a wrong sequence is executed, or the unlock sequence is performed twice, this bit remains locked until next system reset.
During the write access to set LOCK bit from 0 to 1, it is possible to change the other bits of this register.

### 5.9.16  FLASH options interrupt status register (FLASH_OPTISR)
Address offset: 0x108
Reset value: 0xXXXX XXXX

<table>

</tr>
</tbody>
</table>

Bit 31  Reserved, must be kept at reset value.

Bit 30  **OPTERRF**: Option byte change error flag
When OPTERRF is set, the option byte change operation did not successfully complete. An interrupt is generated when this flag is raised if the OPTERRIE bit of FLASH_OPTCR register is set. Setting OPTERRF of register FLASH_OPTCR clears this bit.
0: No option byte change errors occurred
1: One or more errors occurred during an option byte change operation.

Bit 29  Reserved, must be kept at reset value.
Bit 28  **KTEF**: Key transfer error flag
This bit is set when embedded flash signals an error to the SAES peripheral. It happens when the key size (128-bit or 256-bit) is not matching between embedded flash OBKSIZE[1:0] and KEYSIZE bit in SAES_CR register. It also happen when an ECC dual error detection occurred while embedded flash loaded an option byte key for the SAES peripheral.

When KTEF is set write to START bit in FLASH_OBKCR is ignored.
An interrupt is generated when this flag is raised if the KTEIE bit of FLASH_OPTCR register is set. Setting KTEF bit of register FLASH_OPTICR clears this bit.

Bit 27  **KVEF**: Key valid error flag
This bit is set when loading an unknown or corrupted option byte key. More specifically:

- Embedded flash did not find an option byte key that corresponds to the given OBKINDEX[4:0] and the requested HDPL (optionally modified by NEXTKL[1:0]). It can happen for example when requested key has not being provisioned.
- A double error detection was found when loading the requested option byte key. In this case, if this key is provisioned again the error should disappear.

When KVEF is set write to START bit in FLASH_OBKCR is ignored.
An interrupt is generated when this flag is raised if the KVEIE bit of FLASH_OPTCR register is set. Setting KVEF bit of register FLASH_OPTICR clears this bit.

Bits 26:0  Reserved, must be kept at reset value.

</tr>
</tbody>
</table>

Bits 31:16  Reserved, must be kept at reset value.

Bit 15  KEYSTART: Key option start
This bit is used to start the option byte key operation defined by the PROG bit.
The embedded flash memory resets START when the corresponding operation has been acknowledged.

Bit 14  KEYPROG: Key program
This bit must be set to write option byte keys (keys are read otherwise).
0: Read key. Result of the operation is stored in FLASH_OBKDRx registers, if applicable.
1: Program key if PG_OPT is set in FLASH_OPTCR register, and KDREF flag is cleared in
FLASH_OPTISR register. Correct key information must be stored in FLASH_OBKDRx
register before setting PROG and START bits.

Bits 13:12  Reserved, must be kept at reset value.

Bits 11:10  OBKSIZE[1:0]: Option byte key size
Application must use this bitfield to specify how many bits must be used for the new key.
Embedded flash ignores OBKSIZE during read of option keys because size is stored with the
key.
00: Key size is 32 bits
01: Key size is 64 bits
10: Key size is 128 bits
11: Key size is 256 bits

Bits 9:8  NEXTKL[1:0]: Next key level
00: OBKINDEX represents the index of the option byte key stored for the hide protection level
indicated in SBS_HDPLSR.
01: OBKINDEX represents the index of the option byte key stored for the hide protection level
indicated in SBS_HDPLSR plus one (e.g. if HDPL=1 in SBS_HDPLR the key of level 2 is
selected).
10 or 11: reserved

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0  OBKINDEX[4:0]: Option byte key index
This bitfield represents the index of the option byte key in a given hide protection level.
Reading keys with index lower that 8, the value is not be available in OBKDRx registers. It is
instead sent directly to SAES peripheral. All others keys can be read using OBKDRx registers.
Up to 32 keys can be provisioned per hide protection level (0, 1 or 2), provided there is enough
space left in the flash to store them.
5.9.19  FLASH option bytes key data register x (FLASH_OBKDRx)

Address offset: 0x118 + 0x4 * x (x=0 to 7)
Reset value: 0x0000 0000
Writes are ignored if KDREF is set in FLASH_OPTISR register.

<table>
<thead>
<tr>
<th>Bits 31:0</th>
<th>OBKDATA[31:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>rw rw rw rw rw</td>
</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td>rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 31:0  OBKDATA[31:0]: option byte key data, bits [31+x:0+x]
Data register used in conjunction with FLASH_OBKCR register.
Reading this register (read value once), or incrementing HDPL value in SBS peripheral
automatically clears OBKDATA to 0x0. Writing this register prevents reading OBKDATA until option
byte key programming sequence is completed.

5.9.20  FLASH non-volatile status register (FLASH_NVSR)

Address offset: 0x200
Reset value: 0x0000 XXXX
This read-only register reflects the current values of corresponding option bits.

<table>
<thead>
<tr>
<th>Bits 31:0</th>
<th>NVSTATE[7:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>r r r r r r</td>

<td>r r r r</td>
</tr>
</tbody>
</table>

Bits 31:8  Reserved, must be kept at reset value.
Bits 7:0  NVSTATE[7:0]: Non-volatile state
0xB4: OPEN device
0x51: CLOSED device
others: invalid configuration.
5.9.21 FLASH security status register programming (FLASH_NVSRP)

Address offset: 0x204

Reset value: 0x0000 XXXX (same as FLASH_NVSR)

Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OPTCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR register.

Write are ignored if HDPL is different from 0 or 1 in SBS_HDPLSR register.

<table>
<thead>

- **Bits 31:24 IROT_SELECT[7:0]:** iRoT selection
  - This option is ignored for STM32H7R device's (user firmware is always selected).
  - For STM32H7S devices there are two options:
    - 0xB4: ST iRoT is selected at boot
    - 0x6A (default): OEM iRoT is selected at boot.

- **Bits 23:16 Reserved, must be kept at reset value.**

- **Bits 15:8 DBG_AUTH[7:0]:** Debug authentication method
  - 0xB4: Locked device (no debug allowed)
  - 0x51: Authentication method using ECDSA signature (NIST P256)
  - 0x8A: Authentication method using password
  - Any other value: no authentication method selected (different to 0xB4, 0x51, 0x8A).

- **Bits 7:0 OEM_PROVD[7:0]:** OEM provisioned device
  - 0xB4: Device has been provisioned by the OEM
  - Any other value: device is not provisioned by the OEM.
5.9.23  FLASH RoT status register programming (FLASH_ROTSRP)

Address offset: 0x20C
Reset value: 0x0000 XXXX (same as FLASH_ROTSR)

Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OPTCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR.

Writes are ignored if HDPL is different from 0 in SBS_HDPLSR register.

Bits 31:24  IROT_SELECT[7:0]: iRoT selection
This option is ignored for STM32H7R devices.
Write to change corresponding bits in FLASH_ROTSR register.

Bits 23:16  Reserved, must be kept at reset value.

Bits 15:8  DBG_AUTH[7:0]: Debug authentication method programming
Write to change corresponding bits in FLASH_ROTSR register.

Bits 7:0  OEM_PROVD[7:0]: OEM provisioned device
Write to change corresponding bits in FLASH_ROTSR register.

5.9.24  FLASH OTP lock status register (FLASH_OTPLSR)

Address offset: 0x210
Reset value: 0x0000 XXXX

|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  OTPL[15:0]: OTP lock n (n=0 to 15)
Block n corresponds to OTP 16-bit word 32 x n to 32 x n + 31.
OTPL[n] = 1 indicates that all OTP 16-bit words in OTP Block n are locked and can no longer be programmed.
OTPL[n] = 0 indicates that all OTP 16-bit words in OTP Block n are not locked and can still be modified.
5.9.25 **FLASH OTP lock status register programming (FLASH_OTPLSRP)**

Address offset: 0x214  
Reset value: 0x0000 XXXX (same as for FLASH_OTPLSR)

Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OPTCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR.

**OTPL[15:0]**

Bits 31:16 Reserved, must be kept at reset value.  
Bits 15:0 **OTPL[15:0]:** OTP lock n programming (n=0 to 15)  
Write to change corresponding option byte bit in FLASH_OTPLSR.  
OTPL bits can be only be set, not cleared.

5.9.26 **FLASH write protection status register (FLASH_WRPSR)**

Address offset: 0x218  
Reset value: 0x0000 XXXX

This read-only register reflects the current values of corresponding option bits.

**WRPS[7:0]**

Bits 31:8 Reserved, must be kept at reset value.  
Bits 7:0 **WRPS[7:0]:** Write protection for sector n (n=0 to 7)  
This bit reflects the write protection status of user flash sector n  
0: sector n is write protected  
1: sector n is not write protected
5.9.27  **FLASH write protection status register programming (FLASH_WRPSRP)**

Address offset: 0x21C

Reset value: 0x0000 XXXX

Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OPTCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR.

Writes are ignored if HDPL is different from 0 or 1 in SBS_HDPLSR register.

(The reset value is the same as for FLASH_WRPSR)

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 HDP_AREA_END[8:0]: Hide protection user flash area end programming
Write to change corresponding option byte bits in FLASH_HDPSR.
If HDP_AREA_END=HDP_AREA_START all the sectors are protected.
If HDP_AREA_END<HDP_AREA_START no sectors are protected.

Bits 15:9 Reserved, must be kept at reset value.

Bits 8:0 HDP_AREA_START[8:0]: Hide protection user flash area start programming
Write to change corresponding option byte bits in FLASH_HDPSR.
If HDP_AREA_END=HDP_AREA_START all the sectors are protected.
If HDP_AREA_END<HDP_AREA_START no sectors are protected.
5.9.30  **FLASH epoch status register (FLASH_EPOCHSR)**

Address offset: 0x250  
Reset value: 0x0000 XXXX  
This read-only register reflects the current values of corresponding option bits.

![Epoch Status Register Bit Diagram]

Bits 31:24  Reserved, must be kept at reset value.  
Bits 23:0  **EPOCH[23:0]**: Epoch  
This value is distributed by hardware to the SAES peripheral.

5.9.31  **FLASH RoT status register programming (FLASH_EPOCHSRP)**

Address offset: 0x254  
Reset value: 0x0000 XXXX  
Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OPTCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR.  
Writes are ignored if HDPL is different from 0 in SBS_HDPLSR register.  
(The reset value is the same as for FLASH_EPOCHSR.)

![Epoch Programming Register Bit Diagram]

Bits 31:24  Reserved, must be kept at reset value.  
Bits 23:0  **EPOCH[23:0]**: Epoch programming  
Write to change corresponding bits in FLASH_EPOCHSR register.
5.9.32 FLASH option byte word 1 status register (FLASH_OBW1SR)

Address offset: 0x260
Reset value: 0xXXXX XXXX (see Option byte user words organization)

This register reflects the current values of corresponding option bits.

</table>

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **VDDIO_HSLV**: I/O High-Speed at Low-Voltage
This bit indicates that the product operates below 2.5 V.
0: Product working in the full voltage range, I/O speed optimization at low-voltage disabled
1: Product operating below 2.5 V, I/O speed optimization at low-voltage feature allowed

Bit 28 **PERSO_OK**: Personalization OK
This bit is set on STMicroelectronics production line.

Bits 27:19 Reserved, must be kept at reset value.

Bit 18 **IWDG_FZ_SDBY**: IWDG standby mode freeze
When set the independent watchdog IWDG is frozen in system Standby mode.
0: Independent watchdog frozen in Standby mode
1: Independent watchdog keep running in Standby mode

Bit 17 **IWDG_FZ_STOP**: IWDG stop mode freeze
When set the independent watchdog IWDG is frozen in system Stop mode.
0: Independent watchdog frozen in Stop mode
1: Independent watchdog keep running in Stop mode

Bits 16:10 Reserved, must be kept at reset value.

Bit 9 **XSPI2_HSLV**: XSPIM_P2 High-Speed at Low-Voltage
0: I/O XSPIM_P2 High-Speed option disabled
1: I/O XSPIM_P2 High-Speed option enabled

Bit 8 **XSPI1_HSLV**: XSPIM_P1 High-Speed at Low-Voltage
0: I/O XSPIM_P1 High-Speed option disabled
1: I/O XSPIM_P1 High-Speed option enabled

Bit 7 **NRST_STBY**: Reset on standby mode
0: Independent WDG generates a reset if STANDBY mode is requested
1: Independent WDG does not generate a reset if STANDBY mode is requested
5.9.33 **FLASH option byte word 1 status register programming (FLASH_OBW1SRP)**

Address offset: 0x264

Reset value: 0xFFFF XXXX (same as for FLASH_OBW1SR)

Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OPTCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR.

### Bits Descriptions:

- **Bit 9** XSPI2_HSLV: XSPI_M_P2 High-Speed at Low-Voltage programming
  Write to change corresponding bit in FLASH_OBW1SR register.

- **Bit 8** XSPI1_HSLV: XSPI_M_P1 High-Speed at Low-Voltage
  Write to change corresponding bit in FLASH_OBW1SR register.

- **Bit 7** NRST_STBY: Reset on standby mode programming
  Write to change corresponding bit in FLASH_OBW1SR register.

- **Bit 6** NRST_STOP: Reset on stop mode programming
  Write to change corresponding bit in FLASH_OBW1SR register.

- **Bit 5** Reserved, must be kept at reset value.

- **Bit 4** IWDG_HW: Independent watchdog HW Control
  Write to change corresponding bit in FLASH_OBW1SR register.

- **Bits 3:2** BOR_LEV[1:0]: Brownout level
  Write to change corresponding bits in FLASH_OBW1SR register.

- **Bits 1:0** Reserved, must be kept at reset value.

6 Power control (PWR)

6.1 Introduction

The power control section (PWR) provides an overview of the supply architecture for the different power domains and of the supply configuration controller.

It also describes the features of the power supply supervisors and explains how the $V_{\text{CORE}}$ supply domain is configured depending on the operating modes, the selected performance (clock frequency) and the voltage scaling.

6.2 PWR main features

- Power supplies and supply domains
  - Core domains ($V_{\text{CORE}} = V_{\text{CAP}}$)
  - $V_{\text{DD}}$ domain
  - Backup domain ($V_{\text{SW}}$, $V_{\text{BKP}}$)
  - Analog domain ($V_{\text{DDA}}$)

- System supply voltage regulation
  - Switched-mode power supply power-efficient voltage down-converter (SMPS step-down converter)
  - Voltage regulator (LDO)

- Peripheral supply regulation
  - USB regulator

- Power supply supervision
  - POR/PDR monitor
  - BOR monitor
  - PVD monitor
  - AVD monitor
  - $V_{\text{BAT}}$ thresholds
  - Temperature thresholds

- Power management
  - $V_{\text{BAT}}$ battery charging
  - Operating modes
  - Voltage scaling control
  - Low-power modes

6.4 Power supplies

The device requires $V_{DD}$ and $V_{DDSMPS}$ power supplies as well as independent supplies for $V_{DDLDO}$, $V_{DDA}$, $V_{DDUSB}$, and $V_{CAP}$. It also provides regulated supplies for specific functions (step-down converter, voltage regulator, USB regulator).

- $V_{DD}$: external power supply for I/Os and system analog blocks such as reset, power management and oscillators
- $V_{DDxspi1}, V_{DDxspi2}$: external power supply for dedicated I/Os (Octo SPI and Hexa Deca SPI memories)
- $V_{BAT}$: optional external power supply for backup domain when $V_{DD}$ is not present ($V_{BAT}$ mode)
  This power supply must be connected to VDD when no battery is used.
- $V_{DDSMPS}$: external power supply for the SMPS step-down converter
  VDDSMS must be connected to VDD or tied to VSS when the SMPS is not used.
- $V_{LXSMPS}$: step-down converter supply output
- $V_{FBSMPS}$: step-down converter sense feedback
- $V_{SSSMPS}$: separate step-down converter ground
- $V_{DDLDO}$: external power supply for voltage regulator
- $V_{CAP}$: digital core domain supply
  This power supply is independent from all the other power supplies:
  – When the voltage regulator is enabled, $V_{CORE}$ is delivered by the internal voltage regulator.
  – When the voltage regulator is disabled, $V_{CORE}$ is delivered by an external power supply through VCAP pin, or by the SMPS step-down converter.
- $V_{DDA}$: external analog power supply for ADCs and voltage reference buffers
  This power supply is independent from all the other power supplies.
- $V_{REF+}$: external reference voltage for ADC.
  – When the voltage reference buffer is enabled, $V_{REF+}$ and $V_{REF-}$ are delivered by the internal voltage reference buffer.
  – When the voltage reference buffer is disabled, $V_{REF+}$ is delivered by an independent external reference supply.
- $V_{SSA}$: separate analog and reference voltage ground.
- $V_{DD50USB}$: external power supply for USB regulator.
- $V_{DD33USB}$: USB regulator supply output for USB interface.
  – When the USB regulator is enabled, $V_{DD33USB}$ is delivered by the internal USB regulator.
  – When the USB regulator is disabled, $V_{DD33USB}$ is delivered by an independent external supply input.
- $V_{SS}$: common ground for all supplies except for step-down converter and analog peripherals.

Note: Depending on the operating power supply range, some peripherals might be used with limited features and performance. For more details, refer to section “General operating conditions” of the device datasheets.
Figure 20. Power supply overview(a)

a. Refer to application note AN5935 "Getting started hardware with STM32H7Rx/7Sx MCUs" for the possible power scheme and connected capacitors.
By configuring the SMPS step-down converter and LDO voltage regulator, the supply configurations shown in Figure 21 are supported for the V\textsubscript{CORE} core domain and an external supply. For the different configuration available per package refer to the product datasheet.

Note: The SMPS step-down converter is not available on all packages, and the Bypass mode is available only when the SMPS is available.
The different supply configurations are controlled through the LDOEN, SDEN, SMPSEXTHP, SDHILEVEL and BYPASS bits in the PWR control register 2 (PWR_CSR2) register according to Table 44.

In the following table HP refers to High power, LP refers to Low Power and off refers to no supply.

### Table 44. Supply configuration control

- SMPS step-down converter enabled according to SDHILEVEL used to supply external circuits.  
- SMPS step-down converter forced ON in HP mode. |
| 4  | SMPS step-down converter supplies external and LDO Bypass | 1         | 1         | 1    | 0     | 1      | - \( V_{\text{CORE}} \) supplied from external source  
- SMPS step-down converter enabled according to SDHILEVEL used to supply external circuits and may supply the external source for \( V_{\text{CORE}} \).  
- SMPS step-down converter forced ON in HP mode. |
| 5  | SMPS step-down converter disabled and LDO Bypass | x         | x         | 0    | 0     | 1      | - \( V_{\text{CORE}} \) supplied from external source  
- SMPS step-down converter disabled and LDO bypassed, voltage monitoring still active. |
6.4.1 System supply startup

The system startup sequence from power-on in different supply configurations is the following (see *Figure 22* and *Figure 23* for LDO supply and Direct SMPS supply, respectively):

1. When the system is powered on, the POR monitors \( V_{DD} \) supply. Once \( V_{DD} \) is above the POR threshold level, the SMPS step-down converter and voltage regulator are enabled in the default supply configuration:
   - The SMPS step-down converter output level is set at 1.35 V.
   - The voltage regulator LDO output level is set at 1.11 V.
   - Depending on the package and configuration the SMPS provides the voltage to internal power domain and/or LDO or external supply.
2. The system is kept in reset mode as long as \( V_{CORE} \) is not stable.
3. Once \( V_{CORE} \) is stable, the system is taken out of reset and the HSI oscillator is enabled.
4. Once the oscillator is stable, the system is initialized: Flash memory is ready, option bytes are loaded and the CPU starts in limited run mode (Run*).
5. The software must then initialize the system including supply configuration programming in *PWR control register 2 (PWR_CSR2)*. Once the supply configuration has been configured, the ACTVOSRDY bit in the *PWR control status register 1 (PWR_SR1)* must be checked to guarantee valid voltage levels:
   a) As long as ACTVOSRDY indicates that voltage levels are invalid, the system is in Run* mode, write accesses to the RAMs are not permitted and VOS must not be changed.
   b) Once ACTVOSRDY indicates that voltage levels are valid, the system is in normal Run mode, write accesses to RAMs are allowed and VOS can be changed.

</tbody>
</table>
VCORE directly supplied from the SMPS step-down converter

When VCORE is directly supplied from the SMPS step-down converter, the VCORE voltage first settles at VFBSMPS default level (1.36 V). Due to a too high supply compared to the VOS level, the ACTVOSRDY bit in the PWR control status register 1 (PWR_SR1) indicates invalid voltage levels. VCORE settles at VOS low and ACTVOSRDY indicates valid voltage levels only when the supply configuration has been programmed in PWR control register 2 (PWR_CSR2) (see Figure 22).

**Figure 22. Device startup with VCORE supplied directly from SMPS step-down converter**

1. In Run* mode, write operations to RAM are not allowed.
2. Write operations to RAM are allowed and VOS can be changed only when ACTVOSRDY is valid.
When exiting from Standby mode, the supply configuration is known by the system since the content of **PWR control register 2 (PWR_CSR2)** is retained. However the software must still wait for the **ACTVOSRDY** bit to be set in **PWR control status register 1 (PWR_SR1)** to indicate V\textsubscript{CORE} voltage levels are valid, before performing write accesses to RAM or changing VOS.

**V\textsubscript{CORE} supplied in Bypass mode (LDO and SMPS OFF)**

The devices that feature the SMPS can also be used in Bypass mode. When V\textsubscript{CORE} is supplied in Bypass mode (LDO and SMPS OFF), the V\textsubscript{CORE} voltage must first settles at a default level higher than 1.2 V. Due to the LDO default state after power-up (enabled by default), the external V\textsubscript{CORE} voltage must remain higher than 1.2 V until the LDO is disabled by software.

When the LDO is disabled, the external V\textsubscript{CORE} voltage can be adjusted according to the user application needs (refer to section **General operating conditions** of the datasheet for details on V\textsubscript{CORE} level versus the maximum operating frequency).

![Figure 23. Device startup with V\textsubscript{CORE} supplied in Bypass mode from external regulator](MSv53472V1)
6.4.2 Core domain

The $V_{\text{CORE}}$ core domain supply can be provided by the SMPS step-down converter, LDO voltage regulator or by an external supply ($V_{\text{CAP}}$). $V_{\text{CORE}}$ supplies all the digital circuitries except for the backup domain and the Standby circuitry. When a system reset occurs, the voltage regulator is enabled and supplies $V_{\text{CORE}}$. The SMPS step-down converter is also enabled to deliver 1.36 V. This allows the system to start up in any supply configurations (see Figure 21).

After a system reset, the software must configure the used supply configuration in $PWR$ control register 2 ($PWR\_CSR2$) register before changing VOS in the $PWR$ control status register 4 ($PWR\_CSR4$) or the RCC sys_ck frequency. The different system supply configurations are controlled as shown in Table 44.

Note: The SMPS step-down converter and the LDO are not available on all packages.

LDO voltage regulator

The embedded voltage regulator (LDO) requires external capacitors to be connected to VCAP pins.

The voltage regulator provides three different operating modes: High Power (HP), Low-power (LP) or Off. These modes are used depending on the system operating modes (Run, Stop and Standby).

- Run modes
  The LDO regulator is in Main mode and provides full power to the $V_{\text{CORE}}$ domain (core, memories and digital peripherals). The regulator output voltage can be scaled by software to different voltage levels (VOS low and VOS high) that are configured through the VOS bit in the $PWR$ control status register 4 ($PWR\_CSR4$). The VOS voltage scaling allows optimizing the power consumption when the system is clocked below the maximum frequency. By default VOS low is selected after system reset. VOS can be changed on-the-fly to adapt to the required system performance.

- Stop mode
  The voltage regulator supplies the $V_{\text{CORE}}$ domain to retain the content of registers and internal memories, and must be set in LP mode.
  In LP mode the regulator mode is selected through the SVOS bit in the $PWR$ control register 1 ($PWR\_CR1$). Due to a lower voltage level for SVOS low scaling, the Stop mode consumption can be further reduced.

- Standby mode
  The voltage regulator is OFF and the $V_{\text{CORE}}$ domains are powered down. The content of the registers and memories is lost except for the Standby circuitry and the backup domain.

For more details, refer to the voltage regulator section in the datasheets.
SMPS step-down converter regulator

The SMPS step-down converter requires an external coil to be connected between the dedicated VLXSMPS pin and, via a capacitor, to VSS.

The SMPS step-down converter can be used in internal supply mode or external supply mode. The internal supply mode is used to directly supply the V_CORE domain, while the external supply mode is used to generate an intermediate supply level (V_DDExtern at 1.8 V) which can supply the voltage regulator and optionally an external circuitry.

The SMPS step-down converter works in three different power modes: High Power (HP), Low-power (LP) or Off.

When the SMPS step-down converter is used in internal supply mode, the converter operating modes depend on the system modes (Run, Stop, Standby) and are configured through the associated VOS and SVOS levels:

- **Run mode**
  The SMPS step-down converter operates in HP mode and provides full power to the V_CORE domain (core, memories and digital peripherals). The regulator output voltage can be scaled by software to different voltage levels (VOS low and VOS high) that are configured through the VOS bit in the PWR control status register 4 (PWR_CSR4). The VOS voltage scaling allows optimizing the power consumption when the system is clocked below the maximum frequency. By default VOS low is selected after system reset. VOS can be changed on-the-fly to adapt to the required system performance.

- **Stop mode**
  The SMPS step-down converter supplies the V_CORE domain to retain the content of registers and internal memories, and must be set in LP mode. The voltage regulator mode is selected through the SVOS in the PWR control register 1 (PWR_CR1). In LP mode only SVOS low and SVOS high scaling are allowed. Due to a lower voltage level for these scaling, the Stop mode consumption can be further reduced.

- **Standby mode**
  The SMPS step-down converter is OFF and the V_CORE domains are powered down. The content of the registers and memories are lost except for the Standby circuitry and the backup domain.

When the SMPS step-down converter supplies an external circuitry by generating an intermediate voltage level, the converter is forced ON and operates in HP mode. The intermediate voltage level is selected through SDHILEVEL bits in the PWR control register 2 (PWR_CSR2). V_DDExtern is supplied at all times with full power whatever the system modes (Run, Stop, Standby).

**Note:** The SMPS step-down converter is not available on all packages, the SMPS supplies the voltage regulator and optionally an external circuitry. The LDO may not be used in some configuration.
6.4.3 PWR external supply

When \( V_{\text{CORE}} \) is supplied from an external source (Bypass mode), different operating modes can be used depending on the system operating modes (Run, Stop or Standby):
- **In Run modes**
  The external source supplies full power to the \( V_{\text{CORE}} \) domain (core, memories and digital peripherals). The external source output voltage is scalable through different voltage levels (VOS low and VOS high). The externally applied voltage level must be reflected in the VOS bit of PWR_CSR4 register. The RAMs must only be accessed for write operations when the external applied voltage level matches VOS settings.
- **In Stop mode**
  The external \( V_{\text{CORE}} \) supply should be maintained at the VOS level or at least over 0.95 V to ensure proper internal wakeup.
- **In Standby mode**
  The wake mechanism should be monitored externally. Refer to the datasheet for the proper \( V_{\text{CORE}} \) ramp time.

6.4.4 Backup domain

To retain the content of the backup domain (RTC, backup registers and backup RAM) when \( V_{\text{DD}} \) is turned off, VBAT pin can be connected to an optional voltage which is supplied from a battery or from another source.

The switching to VBAT is controlled by the power-down reset embedded in the Reset block that monitors the \( V_{\text{DD}} \) supply.

---

**Warning:** During \( t_{\text{RSTTEMPO}} \) (temporization at \( V_{\text{DD}} \) startup) or after a PDR is detected, the power switch between VBAT and \( V_{\text{DD}} \) remains connected to VBAT.

During the startup phase, if \( V_{\text{DD}} \) is established in less than \( t_{\text{RSTTEMPO}} \) (see the datasheet for the value of \( t_{\text{RSTTEMPO}} \)) and \( V_{\text{DD}} > V_{\text{BAT}} + 0.6 \) V, a current may be injected into VBAT through an internal diode connected between \( V_{\text{DD}} \) and the power switch (VBAT).

If the power supply/battery connected to the VBAT pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the VBAT pin.
When the $V_{DD}$ supply is present, the backup domain is supplied from $V_{DD}$. This allows saving $V_{BAT}$ power supply battery life time.

If no external battery is used in the application, it is recommended to connect $V_{BAT}$ externally to $V_{DD}$, and add a a 100 nF external ceramic capacitor between $V_{BAT}$ and $V_{SS}$.

When the $V_{DD}$ supply is present and higher than the PDR threshold, the backup domain is supplied by $V_{DD}$ and the following functions are available:

- PC14 and PC15 can be used either as GPIO or as LSE pins.
- PC13 can be used either as GPIO or as RTC_OUT1, RTC_TS, TAMP_IN1, TAMP_OUT2 pin assuming they have been configured by the RTC or the TAMPER registers (see Section 49.3.3: GPIOs controlled by the RTC and TAMP).
- PB9/TAMP_IN2, PE1/TAMP_IN3 when configured by the RTC as tamper pins.

*Note:* Since the switch only sinks a limited amount of current, the use of PC13 and PC15 GPIOs is restricted: only one I/O can be used as an output at a time. These I/Os must not be used as current sources (for example to drive an LED). Refer to the DS.

In $V_{BAT}$ mode, when the $V_{DD}$ supply is absent and a supply is present on $V_{BAT}$, the backup domain is supplied by $V_{BAT}$ and the following functions are available:

- PC14 and PC15 can be used as LSE pins only.
- PC13 can be used as RTC_OUT1, RTC_TS, TAMP_IN1, TAMP_OUT2 pin assuming they have been configured by the RTC or the TAMPER registers (see Section 49.3.3: GPIOs controlled by the RTC and TAMP).
- PB9/TAMP_IN2, PE1/TAMP_IN3 when configured by the RTC as tamper pins.

**Accessing the backup domain**

After reset, the backup domain (RTC registers and RTC backup registers) is protected against possible unwanted write accesses. To enable access to the backup domain, set the DBP bit in the **PWR control register 1 (PWR_CR1)**.

For more detail on RTC and backup RAM access, refer to Section 7: Reset and clock control (RCC).

**Backup RAM**

The backup domain includes 4 Kbytes of backup RAM accessible in 32-bit, 16-bit or 8-bit data mode. The backup RAM is supplied from the backup regulator in the backup domain. When the backup regulator is enabled through BREN bit in the **PWR control status register 1 (PWR_CSR1)**, the backup RAM content is retained even in Standby and/or $V_{BAT}$ mode (it can be considered as an internal EEPROM if $V_{BAT}$ is always present.)

The backup regulator can be ON or OFF depending whether the application needs the backup RAM function in Standby or $V_{BAT}$ modes.
After a tamper event, if the RTC flag is set, the backup RAM cannot be used until an erase is explicitly requested. When a tamper event is generated, reading the backup RAM returns 0x0, and any write different from 0 is not effective. The backup RAM can be erased:

- through the Flash memory interface when a regression from nvstate closed to nvstate open is requested. See also Section 4: System security.
  
or
- by performing a simple dummy write with zero as data to any address of the backup RAM (this action resets the whole backup RAM when it is performed after a tamper event).

**Figure 24. Backup domain**

### 6.4.5 V\textsubscript{BAT} battery charging

When \( V_{DD} \) is present, the external battery connected to \( V_{BAT} \) can be charged through an internal resistance.

\( V_{BAT} \) charging can be performed either through a 5 k\( \Omega \) resistor or through a 1.5 k\( \Omega \) resistor, depending on the VBRS bit value in *PWR control register 2 (PWR_CSR2)*.

The battery charging is enabled by setting the VBE bit in the *PWR control register 2 (PWR_CSR2)*. It is automatically disabled in \( V_{BAT} \) mode.
6.4.6 **Analog supply**

**Separate \( V_{DDA} \) analog supply**

The analog supply domain is powered by dedicated \( V_{DDA} \) and \( V_{SSA} \) pads that allow the supply to be filtered and shielded from noise on the PCB, thus improving ADC conversion accuracy:

- The analog supply voltage input is available on a separate \( V_{DDA} \) pin.
- An isolated supply ground connection is provided on \( V_{SSA} \) pin.
Analog reference voltage $V_{\text{REF+}}/V_{\text{REF-}}$

To achieve better accuracy low-voltage signals, the ADC also has a separate reference voltage, available on $V_{\text{REF+}}$ pin. The user can connect a separate external reference voltage on $V_{\text{REF+}}$.

The $V_{\text{REF+}}$ controls the highest voltage, represented by the full scale value, the lower voltage reference ($V_{\text{REF-}}$) being connected to VSSA.

When enabled by ENVR bit in the VREFBUF control and status register (see Section 29: Voltage reference buffer (VREFBUF)), $V_{\text{REF+}}$ is provided from the internal voltage reference buffer. The internal voltage reference buffer can also deliver a reference voltage to external components through $V_{\text{REF+}}/V_{\text{REF-}}$ pins.

When the internal voltage reference buffer is disabled by ENVR, $V_{\text{REF+}}$ is delivered by an independent external reference supply voltage.

**Note:** $V_{\text{REF+}}$ and $V_{\text{REF-}}$ pins are not available on all packages (in this case they are connected internally respectively to VDDA and VSSA). **Do not** enable the internal voltage reference buffer when an external power supply is applied to the $V_{\text{REF+}}$ pin.

### 6.4.7 USB regulator

The USB transceivers are supplied from a dedicated $V_{\text{DD33USB}}$ supply that can be provided either by the integrated USB regulator, or by an external USB supply.

When enabled by USBREGEN bit in the PWR control register 2 (PWR_CSR2), the $V_{\text{DD33USB}}$ is provided from the USB regulator, which is powered through the VDD50USB pin generally connect to the USB VBUS line. Before using $V_{\text{DD33USB}}$, check that it is available by monitoring USB33RDY bit in the PWR control register 2 (PWR_CSR2). The $V_{\text{DD33USB}}$ supply level detector must be enabled through USB33DEN bit in the PWR_CSR2 register.

When the USB regulator is disabled through USBREGEN bit, VDD33USB can be provided from an external supply. In this case VDD33USB and VDD50USB must be connected together. The VDD33USB supply level detector must be enabled through USB33DEN bit in the PWR_CSR2 register before using the USB transceivers.

For more information on the USB regulator (see Section 62: USB on-the-go high-speed (OTG_HS)).

**Figure 25. USB supply configurations**
6.5 Power supply supervision

Power supply level monitoring is available on the following supplies:

- \( V_{DD} (V_{DDSMPS}) \) can be monitored via POR/PDR (see Section 6.5.1), BOR (see Section 6.5.2) and PVD monitor (see Section 6.5.3)
- \( V_{DDA} \) can be monitored via AVD monitor (see Section 6.5.4)
- \( V_{BAT} \) can be monitored via VBAT threshold (see Section 6.5.5)
- \( V_{SW} \) can be monitored via rst_vsw, which keeps \( V_{SW} \) domain in Reset mode as long as the level is not OK.
- \( V_{BKP} \) can be monitored via a BRRDY bit in the \textit{PWR control status register 1 (PWR_CSR1)}.
- \( V_{FBSMPS} \) can be monitored via a SDEXTRDY bit in the \textit{PWR control register 2 (PWR_CSR2)}.
- \( V_{DD33USB} \) can be monitored via the USB33RDY bit in the \textit{PWR control register 2 (PWR_CSR2)}.  

6.5.1 Power-on reset (POR)/power-down reset (PDR)

The system has an integrated POR/PDR circuitry that ensures proper startup operation.

The system remains in Reset mode when \( V_{DD} \) is below a specified \( V_{POR} \) threshold, without the need for an external reset circuit. Once the \( V_{DD} \) supply level is above the \( V_{POR} \) threshold, the system is taken out of reset (see Figure 26). For more details concerning the power-on/power-down reset threshold, refer to the electrical characteristics section of the datasheets.

By default the PDR is enabled.

![Figure 26. Power-on reset/power-down reset waveform](image)

1. For thresholds and hysteresis values, refer to the datasheets.
6.5.2 Brownout reset (BOR)

During power-on, the Brownout reset (BOR) keeps the system under reset until the $V_{DD}$ supply voltage reaches the specified $V_{BOR}$ threshold.

The $V_{BOR}$ threshold is configured through system option bytes. By default, BOR is OFF. The following programmable $V_{BOR}$ thresholds can be selected:

- BOR OFF ($V_{BOR0}$)
- BOR Level 1 ($V_{BOR1}$)
- BOR Level 2 ($V_{BOR2}$)
- BOR Level 3 ($V_{BOR3}$)

For more details on the brown-out reset thresholds, refer to the section “Electrical characteristics” of the product datasheets.

A system reset is generated when the BOR is enabled and $V_{DD}$ supply voltage drops below the selected $V_{BOR}$ threshold.

BOR can be disabled by programming the system option bytes. To disable the BOR function, $V_{DD}$ must have been higher than $V_{BOR0}$ to start the system option byte programming sequence. The power-down is then monitored by the PDR (see Section 6.5.1).

1. For thresholds and hysteresis values, refer to the datasheets.
6.5.3 Programmable voltage detector (PVD)

The PVD can be used to monitor the \( V_{DD} \) power supply by comparing it to a threshold selected by the PLS[2:0] bits in the PWR control register 1 (PWR.CR1). The PVD can also be used to monitor a voltage level on the PVD_IN pin. In this case PVD_IN voltage is compared to the internal \( V_{REFINT} \) level.

The PVD is enabled by setting the PVDE bit in the PWR control register 1 (PWR.CR1).

A PVDO flag is available in the PWR control status register 1 (PWR_SR1) to indicate if \( V_{DD} \) or PVD_IN voltage is higher or lower than the PVD threshold. This event is internally connected to the EXTI and can generate an interrupt, assuming it has been enabled through the EXTI registers. The PVDO output interrupt can be generated when \( V_{DD} \) or PVD_IN voltage drops below the PVD threshold and/or when \( V_{DD} \) or PVD_IN voltage rises above the PVD threshold depending on EXTI rising/falling edge configuration. As an example the service routine could perform emergency shutdown tasks.

**Figure 28. PVD thresholds**

![PVD thresholds diagram](MSv40342V2)

1. For thresholds and hysteresis values, refer to the datasheets.
6.5.4 **Analog voltage detector (AVD)**

The AVD can be used to monitor the $V_{DDA}$ supply by comparing it to a threshold selected by the ALS[1:0] bits in the *PWR control register 1 (PWR_CR1)*.

The AVD is enabled by setting the AVDEN bit in the *PWR control register 1 (PWR_CR1)*.

An AVDO flag is available in the *PWR control status register 1 (PWR_SR1)* to indicate whether $V_{DDA}$ is higher or lower than the AVD threshold. This event is internally connected to the EXTI and can generate an interrupt if enabled through the EXTI registers. The AVDO interrupt can be generated when $V_{DDA}$ drops below the AVD threshold and/or when $V_{DDA}$ rises above the AVD threshold depending on EXTI rising/falling edge configuration. As an example the service routine could indicate when the $V_{DDA}$ supply drops below a minimum level.

**Figure 29. AVD thresholds**

1. For thresholds and hysteresis values, refer to the datasheets.
### 6.5.5 Battery voltage thresholds

The battery voltage supply monitors the backup domain $V_{SW}$ level. $V_{SW}$ is monitored by comparing it with two threshold levels: $V_{BAT_{high}}$ and $V_{BAT_{low}}$. $VBATH$ and $VBATL$ flags in the PWR control status register 1 ($PWR_{CSR1}$) indicate if $V_{SW}$ is higher or lower than the threshold.

The $V_{BAT}$ supply monitoring can be enabled/disabled via MONEN bit in the PWR control status register 1 ($PWR_{CSR1}$). When it is enabled, the battery voltage thresholds increase power consumption. As an example the $V_{SW}$ levels monitoring could be used to trigger a tamper event for an over or under voltage of the RTC power supply domain (available in VBAT mode).

$VBATH$ and $VBATL$ are connected to RTC tamper signals (see Section 49: Real-time clock (RTC)).

**Note:** Battery voltage monitoring is only available when the backup regulator is enabled (BREN bit set in the PWR control status register 1 ($PWR_{CSR1}$)).

When the device does not operate in VBAT mode, the battery voltage monitoring checks $V_{DD}$ level. When $V_{DD}$ is available, $V_{SW}$ is connected to $V_{DD}$ through the internal power switch (see Section 6.4.4: Backup domain).

**Figure 30. VBAT thresholds**

![VBAT thresholds diagram](MSv40344V1)

1. For thresholds and hysteresis values, refer to the datasheets.
### 6.5.6 Temperature thresholds

The junction temperature can be monitored by comparing it with two threshold levels, \( \text{TEMP}_{\text{high}} \) and \( \text{TEMP}_{\text{low}} \). TEMPH and TEMPL flags, in the PWR control status register 1 (PWR_CSR1), indicate whether the device temperature is higher or lower than the threshold. The temperature monitoring can be enabled/disabled via MONEN bit in the PWR control status register 1 (PWR_CSR1). When enabled, the temperature thresholds increase power consumption. As an example the levels could be used to trigger a routine to perform temperature control tasks.

The temperature thresholds are available only when the backup regulator is enabled (BREN bit set in the PWR_CSR1 register).

TEMPH and TEMPL wakeup interrupts are available on the RTC tamper signals (see Section 49: Real-time clock (RTC)).

![Figure 31. Temperature thresholds](image)

1. For thresholds and hysteresis values, refer to the datasheets.
6.5.7 \textit{V} \textsubscript{CORE} maximum voltage level detector

\( \text{V}_{\text{CORE}} \) is protected against too high voltages in the direct SMPS step-down converter supply configuration. \( \text{V}_{\text{CORE}} \) overvoltage protection is enabled at startup by hardware once the SMPS step-down converter configuration has been programmed into \textit{PWR control register 2 (PWR_CSR2)}:

- \( \text{V}_{\text{CORE}} \) voltage level stays within range:
  - ACTVOSRDY bit in the \textit{PWR control status register 1 (PWR_SR1)} indicate valid voltage levels.
  - The system operates normally and \( \text{V}_{\text{CORE}} \) overvoltage protection is disabled.
- \( \text{V}_{\text{CORE}} \) overvoltage (due to a wrongly programmed SMPS step-down converter configuration):
  - The hardware forces the SMPS step-down converter voltage level to 1.0 V.
  - The ACTVOSRDY goes on indicating invalid voltage levels. In this case the software must be corrected and re-loaded to program a correct SMPS step-down converter configuration that matches the application supply connections. The system must then be power cycled.

\begin{figure}
\centering
\includegraphics[width=\textwidth]{msv55525v1.png}
\caption{\textit{V} \textsubscript{CORE} overvoltage protection}
\end{figure}
6.6 Power management

The power management block controls the $V_{\text{CORE}}$ supply in accordance with the system operation modes (see Section 6.6.1).

The device power domains can operate in one of the following operating modes:

- Run (power ON, clock ON)
- Sleep (power ON, core clock stopped, peripherals keep running)
- Stop (power ON, clock OFF)
- Standby (Power OFF, clock OFF).

The $V_{\text{CORE}}$ supply level follows the system operating mode (Run, Stop, Standby).

The following voltage scaling features allow controlling the power with respect to the required system performance (see Section 6.6.2: Voltage scaling):

- To obtain a given system performance, the corresponding voltage scaling must be set in accordance with the system clock frequency. To do this, configure the VOS bits to the Run mode voltage scaling.
- To obtain the best trade-off between power consumption and exit-from-Stop mode latency, configure the SVOS bit to Stop mode voltage scaling.

6.6.1 Operating modes

Several system operating modes are available to tune the system according to the performance required, that is, when the CPU does not need to execute code and are waiting for an external event. It is up to the user to select the operating mode that gives the best compromise between low power consumption, short startup time and available wakeup sources.

The operating modes allow controlling the clock distribution to the different system blocks and powering them.

In Run mode, power consumption can be reduced by one of the following means:

- Lowering the system performance by slowing down the system clocks and reducing the $V_{\text{CORE}}$ supply level through VOS voltage scaling bit.
- Gating the clocks to the APBx and AHBx peripherals when they are not used, through PERxEN bits.
The VCORE domain is supplied from a single voltage regulator supporting voltage scaling with the following features:

- **Run mode voltage scaling**
  - VOS low
  - VOS high
- **Stop mode voltage scaling**
  - SVOS low
  - SVOS high

For more details on voltage scaling values, refer to the product datasheets.

After reset, the system starts on the lowest Run mode voltage scaling (VOS low). The voltage scaling can then be changed on-the-fly by software by programming the VOS bit in the `PWR control status register 4 (PWR_CSR4)` according to the required system performance. When exiting from Stop mode or Standby mode, the Run mode voltage scaling is reset to the default VOS low value.

Before entering Stop mode, the software can preselect the SVOS level in `PWR control register 1 (PWR_CR1)`. The Stop mode voltage scaling for SVOS low and SVOS high also sets the voltage regulator in Low-power (LP) mode to further reduce power consumption.

In Standby mode the VCORE supply is switched off.
6.6.3 Power management examples

- Figure 34 shows $V_{\text{CORE}}$ voltage scaling behavior in Run mode.
- Figure 35 shows $V_{\text{CORE}}$ voltage scaling behavior in Stop mode.
- Figure 36 shows $V_{\text{CORE}}$ voltage regulator and voltage scaling behavior in Standby mode.

Example of $V_{\text{CORE}}$ voltage scaling behavior in Run mode

Figure 34 illustrates the following system operation sequence example:

1. After reset, the system starts from HSI with VOS low.
2. The system performance is then increased to a high-speed clock from the PLL with voltage scaling VOS high. To do this:
   a) Program the voltage scaling to VOS high.
   b) Once the $V_{\text{CORE}}$ supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.
3. The next step is to reduce the system performance to HSI clock with voltage scaling VOS low. To do this:
   a) Switch the clock to HSI.
   b) Disable the PLL.
   c) Decrease the voltage scaling to VOS low.
4. The system performance can then be increased to high-speed clock from the PLL. To do this:
   a) Program the voltage scaling to VOS high.
   b) Once the $V_{\text{CORE}}$ supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.

When the system performance (clock frequency) is changed, VOS must be set accordingly, otherwise the system might be unreliable.

**Figure 34. Dynamic voltage scaling in Run mode**

1. The status of the register bits at each step is shown in blue.

**Example of $V_{\text{CORE}}$ voltage scaling behavior in Stop mode**

*Figure 35* illustrates the following system operation sequence example:
1. The system is running from the PLL in high-performance mode (VOS high voltage scaling).
2. First the CPU subsystem deallocates all the peripheral, in a second step, the CPU subsystem enters Stop mode and the system enters Stop mode. The system clock is stopped and the hardware lowers the voltage scaling to the software preselected SVOS low.
3. The CPU subsystem is then woken up. The system exits from Stop mode and the CPU subsystem exits from Stop mode. The hardware always sets the voltage scaling to VOS low after exiting from Stop mode and waits for the requested supply level to be reached before enabling the HSI clock. Once the HSI clock is stable, the system clock is enabled and switch in run mode under HSI clock.

4. The system performance could then be increased. To do this:
   a) The software first sets the voltage scaling to VOS high.
   b) Once the $V_{\text{CORE}}$ supply has reached the required level indicated by VOSRDY, the clock frequency can be increased by enabling the PLL.
   c) Once the PLL is locked, the system clock can be switched.

**Figure 35. Dynamic voltage scaling behavior in Stop mode**

1. The status of the register bits at each step is shown in blue.

**Example of $V_{\text{CORE}}$ voltage regulator and voltage scaling behavior in Standby mode**

**Figure 36** illustrates the following system operation sequence example:

1. The system is running from the PLL in high-performance mode (VOS high voltage scaling).
2. The CPU subsystem deallocates all the peripherals and the power is switched off. The system enter in standby mode.
3. The system is then woken up by a wakeup source. The system exits from Standby mode. The hardware sets the voltage scaling to the default VOS low and waits for the requested supply level to be reached before enabling the default HSI oscillator. Once
the HSI clock is stable, the system clock is enabled. The software must then check the
ACTVOSRDKY is valid before changing the system performance.

4. In a next step, increase the system performance. To do this:
   a) The software first increases the voltage scaling to VOS high
   b) Before enabling the PLL, it waits for the requested supply level to be reached by
      monitoring VOSRDY bit.
   c) Once the PLL is locked, the system clock can be switched.

Figure 36. Dynamic voltage scaling from Standby mode

1. The status of the register bits at each step is shown in blue.

6.7 Low-power modes

Several low-power modes are available to save power when the CPU does not need to
execute code (i.e. when waiting for an external event). It is up to the user application to
select the mode that gives the best compromise between low power consumption, short
startup time and available wakeup sources:

- Slowing down system clocks (see Section 7.5.6: System clock (sys_clk))
- Controlling individual peripheral clocks (see Section 7.5.12: Peripheral clock gating
  control)
- Low-power modes
  - Sleep (CPU clock stopped and still in RUN mode)
  - Stop (System clock stopped)
  - Standby (System powered down)
6.7.1 **Slowing down system clocks**

In Run mode, the speed of the system clock sys_ck can be reduced. For more details refer to Section 7.5.6: System clock (sys_ck).

6.7.2 **Controlling peripheral clocks**

In Run mode, the HCLKx and PCLKx for individual peripherals can be stopped by configuring at any time PERxEN bit in RCC_xxxxENR to reduce power consumption.

To reduce power consumption in CSleep mode, the individual peripheral clocks can be disabled by configuring PERxLPEN bit in RCC_xxxxLPENR. For the peripherals still receiving a clock in Sleep mode, their clock can be slowed down before entering Sleep mode.

Example: for APB2 peripherals: the RCC registers is named: RCC_APB2ENR, this register contains SPI4EN, SAI1EN, and so on.

6.7.3 **Entering low-power modes**

CPU subsystem Sleep and Stop low-power modes are entered by the MCU when executing the WFI (Wait For Interrupt) or WFE (Wait for Event) instructions, or when the SLEEPONEXIT bit in the Cortex®-M System Control register is set on Return from ISR.

The system can enter Stop or Standby low-power mode when all EXTI wakeup sources are cleared.

6.7.4 **Exiting from low-power modes**

The CPU subsystem exits from Sleep mode through any interrupt or event depending on how the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter to low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the system.
- If the WFE instruction is used to enter to low-power mode, the CPU exits from low-power mode as soon as an event occurs. The wakeup event can be generated either by:
  - An NVIC IRQ interrupt.
    
    **When SEVONPEND = 0** in the Cortex®-M7 System Control register, the interrupt must be enabled in the peripheral control register and in the NVIC.
    
    When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit in the NVIC interrupt clear pending register have to be cleared. Only NVIC interrupts with sufficient priority wakes up and interrupts the MCU.

    **When SEVONPEND = 1** in the Cortex®-M7 System Control register, the interrupt must be enabled in the peripheral control register and optionally in the NVIC.
    
    When the MCU resumes from WFE, the peripheral interrupt pending bit and, when
enabled, the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

All NVIC interrupts wakeup the MCU, even the disabled ones.
Only enabled NVIC interrupts with sufficient priority wakeup and interrupt the MCU.

– An event

An EXTI line must be configured in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set. It might be necessary to clear the interrupt flag in the peripheral.

The CPU subsystem exits from Stop modes by enabling an EXTI interrupt or event depending on how the low-power mode was entered (see above).

The CPU subsystem exits from Standby mode by enabling an EXTI interrupt or event. Program execution restarts from CPU local reset (such as a reset vector fetched from the system configuration boot and security block (SBS).

The CPU subsystem exits from Standby mode by enabling an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC event. Program execution restarts in the same way as after a system reset (such as boot pin sampling, option bytes loading or reset vector fetched).
6.7.5 Sleep mode

The Sleep mode applies only to the CPU subsystem. In Sleep mode, the CPU clock is stopped. The CPU subsystem peripheral clocks operate according to the values of PERxLPEN bits in RCC_xxxxENR.

Entering Sleep mode

The Sleep mode is entered according to Section 6.7.3: Entering low-power modes, when the SLEEPDEEP bit in the Cortex®-M System Control register is cleared.

Refer to Table 46 for details on how to enter to Sleep mode.

Exiting from Sleep mode

The Sleep mode is exited according to Section 6.7.4: Exiting from low-power modes.

Refer to Table 46 for more details on how to exit from Sleep mode.

<table>
<thead>
<tr>
<th>Sleep mode</th>

|           | – Any event: Refer to Section 20.5.3: EXTI CPU wakeup procedure |
|           | If WFE was used for entry and SEVONPEND = 1: |
|           | – Any Interrupt even when disabled in NVIC: refer to Table 142: NVIC or any event: refer to Section 20.5.3: EXTI CPU wakeup procedure |

| Wakeup latency | None |

6.7.6 Stop mode

The Stop mode applies to the MCU. In Stop mode, the CPU clock is stopped. All CPU subsystem peripheral clocks are stopped too and.

In Stop mode, CPU subsystem peripherals having a kernel clock request can still request their kernel clock.

The Flash memory can enter low-power Stop mode when it is enabled through FLPS in PWR_CR1 register. This allows a trade-off between domain Stop restart time and low power consumption.

The HSI or CSI can remain enabled in system Stop mode (HSIKERON and CSIKERON set in RCC_CR register). After exiting Stop mode, the clock is quickly available as kernel clock.
for peripherals. Other system oscillator sources are stopped in Stop mode and require a starting time after exiting Stop mode.

In Stop mode and SVOS high, peripherals using the LSI or LSE clock and peripherals having a kernel clock request are still able to operate.

In system Stop mode, the following features can be selected to remain active by programming individual control bits:

- **Independent watchdog (IWDG)**
  The IWDG is started by writing to its key register or by hardware option. Once started it cannot be stopped except by a reset (see Section 48.3 in Section 48: Independent watchdog (IWDG)).

- **Real-time clock (RTC)**
  This is configured via the RTCEN bit in the RCC Backup domain control register (RCC_BDCR).

- **Internal RC oscillator (LSI RC)**
  This is configured via the LSION bit in the RCC clock control and status register (RCC_CSR).

- **External 32.768 kHz oscillator (LSE OSC)**
  This is configured via the LSEON bit in the RCC Backup domain control register (RCC_BDCR).

- **Peripherals capable of running on the LSI or LSE clock.**

- **Peripherals having a kernel clock request.**

- **Internal RC oscillators (HSI and CSI)**
  This is configured via the HSIKERON and CSIKERON bits in the RCC source control register (RCC_CR).

- **The ADC can also consume power during Stop mode, unless they are disabled before entering this mode. To disable them, the ADON bit in the ADC_CR2 register must be written to 0.**

The selected SVOS low levels add an additional startup delay when exiting from system Stop mode (see Table 47).

<table>
<thead>
<tr>
<th>SVOS</th>
<th>Stop mode Voltage regulator operation</th>
<th>Wake-up Latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>SVOS high</td>
<td>LP</td>
<td>Voltage Regulator wakeup time from SVOS high LP mode to VOS low</td>
</tr>
<tr>
<td>SVOS low</td>
<td>LP</td>
<td>Voltage Regulator wakeup time from SVOS low LP mode to VOS low</td>
</tr>
</tbody>
</table>
**Entering Stop mode**

The Stop mode is entered according to Section 6.7.3: Entering low-power modes, when the SLEEPDEEP bit in the Cortex®-M System Control register is set.

If Flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to the domain bus matrix is ongoing, the Stop mode entry is delayed until the domain bus matrix access is complete.

See Table 48 below for details on how to enter to Stop mode.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
To allow peripherals having a kernel clock request to operate in Stop mode, the system must use SVOS high.

**Note:** *Use a DSB instruction to ensure that outstanding memory transactions complete before entering stop mode.*

**Exiting from Stop mode**

The Stop mode is exited according to *Section 6.7.4: Exiting from low-power modes.*

Refer to *Table 48: Stop mode* for more details on how to exit from Stop mode.

When exiting from Stop mode, the system clock, bus matrix clocks and voltage scaling are reset.

STOPF status flag in the *PWR CPU control register 3 (PWR_CSR3)* indicates that the system has exited from Stop mode.

**I/O states in Stop mode**

I/O pin configuration remain unchanged in Stop mode.

### 6.7.7 Standby mode

The Standby mode allows achieving the lowest power consumption. Like Stop mode, it is based on CPU subsystem Stop mode. However the \( V_{CORE} \) supply regulator is powered off.

When the system enters in Standby mode, the voltage regulator is disabled. The complete \( V_{CORE} \) domain is consequently powered off. The PLLs, HSI oscillator, CSI oscillator, HSI48 and the HSE oscillator are also switched off. SRAM and register contents are lost except for backup domain registers (RTC registers, RTC backup register and backup RAM), and Standby circuitry (see *Section 6.4.4: Backup domain*).

In system Standby mode, the following features can be selected by programming individual control bits:

- **Independent watchdog (IWDG)**
  
  The IWDG is started by programming its Key register or by hardware option. Once started, it cannot be stopped except by a reset (see *Section 48.3 in Section 48: Independent watchdog (IWDG).*

- **Real-time clock (RTC)**
  
  This is configured via the RTCEN bit in the backup domain control register (RCC_BDCR).

- **Internal RC oscillator (LSI RC)**
  
  This is configured by the LSION bit in the Control/status register (RCC_CSR).

- **External 32.768 kHz oscillator (LSE OSC)**
  
  This is configured by the LSEON bit in the backup domain control register (RCC_BDCR).
Entering Standby mode

The Standby mode is entered according to Section 6.7.3: Entering low-power modes, when the PDDS bits in the PWR CPU control register 3 (PWR_CSR3) is set to one.

If Flash memory programming is ongoing, the Standby mode entry is delayed until the memory access is finished.

Refer to Table 50 for more details on how to enter to Standby mode.

Exiting from Standby mode

The Standby mode is exited according to Section 6.7.4: Exiting from low-power modes.

The system exits from Standby mode when an external Reset (NRST pin), an IWDG Reset, a WKUP pin event, a RTC alarm, a tamper event, or a time stamp event is detected. All registers are reset after waking up from Standby except for power control and status registers (PWR control register 2 (PWR_CSR2), PWR CPU control register 3 (PWR_CSR3)), SBF bit in the PWR CPU control register 3 (PWR_CSR3), PWR wakeup flag register (PWR_WKUPFR), and PWR wakeup enable and polarity register (PWR_WKUPEPR).

After waking up from Standby mode, the program execution restarts in the same way as after a system reset (boot option sampling, boot vector reset fetched, etc.). The SBF status flags in the PWR CPU control register 3 (PWR_CSR3) registers indicate from which mode the system has exited (refer to Table 50).

Table 49. Standby and Stop flags

Table 50. Standby mode

<table>
<thead>
<tr>
<th>Standby mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| Mode entry   | – The CPU subsystem is in Stop mode, and there is no active EXTI Wakeup source.  
                 – PDDS bit for select Standby.  
                 – All WKUPF bits in the Power Control/Status register (PWR_WKUPFR) are cleared. |
| Mode exit    | – WKUP pins rising or falling edge, RTC alarm (Alarm A and Alarm B), RTC wakeup, tamper event, time stamp event, external reset in NRST pin, IWDG reset. |
| Wakeup latency | System reset phase (see Section 7.4.2: The system and application resets (sys_rst and nreset)) |
I/O states in Standby mode

In Standby mode, all I/O pins are high impedance without pull, except for:
- Reset pad (still available)
- RTC_AF1 pin if configured for tamper, time stamp, RTC Alarm out, or RTC clock calibration out
- WKUP pins (if enabled). The WKUP pin pull configuration can be defined through WKUPPUPD register bits in the PWR wakeup enable and polarity register (PWR_WKUPEPR)
- I2C pin-pull configuration if enabled through the register PWR_APCR.

6.7.8 Monitoring low-power modes

The devices feature state monitoring pins to monitor the state transition to low-power mode (refer to Table 51 for the list of pins and their description). The GPIO pin corresponding to each monitoring signal has to be programmed in alternate function mode.

This feature is not available in Standby mode since these I/O pins are switched to high impedance.

<table>
<thead>
<tr>
<th>Power state monitoring pins</th>

1. The CPU is powered off.
6.8 **PWR registers**

The PWR registers can be accessed in word, half-word and byte format, unless otherwise specified.

### 6.8.1 PWR control register 1 (PWR_CR1)

Address offset: 0x000

Reset value: 0x0000 0001

| Bit 31-16 | Reserved, must be kept at reset value. |
| Bit 15-14 | ALS[1:0]: Analog voltage detector level selection |
| | These bits select the voltage threshold detected by the AVD. |
| | 00: AVD level 1 |
| | 01: AVD level 2 |
| | 10: AVD level 3 |
| | 11: AVD level 4 |
| Bit 13 | AVDEN: Peripheral voltage monitor on VDDA enable |
| | 0: Peripheral voltage monitor on VDDA disabled |
| | 1: Peripheral voltage monitor on VDDA enabled |
| Bit 12 | AVDREADY: analog voltage ready |
| | This bit is only used when the analog switch boost needs to be enabled (see BOOSTE bit). |
| | It must be set by software when the expected VDDA analog supply level is available. |
| | The correct analog supply level is indicated by the AVDO bit (PWR_CSR1 register) after setting the AVDEN bit and selecting the supply level to be monitored (ALS bits). |
| | 0: peripheral analog voltage VDDA not ready (default) |
| | 1: peripheral analog voltage VDDA ready |
| Bit 11 | BOOSTE: analog switch VBoost control |
| | This bit enables the booster to guarantee the analog switch AC performance when the VDD supply voltage is below 2.7 V (reduction of the total harmonic distortion to have the same switch performance over the full supply voltage range) |
| | The VDD supply voltage can be monitored through the PVD and the PLS bits. |
| | 0: booster disabled (default) |
| | 1: booster enabled if analog voltage ready (AVD_READY = 1) |
| Bit 10 | Reserved, must be kept at reset value. |
Bit 9  **FLPS**: Flash low-power mode in Stop mode
This bit allows to obtain the best trade-off between low-power consumption and restart time when exiting from Stop mode.
When it is set, the Flash memory enters low-power mode when device is in Stop mode.
0: Flash memory remains in normal mode when device enters Stop (quick restart time).
1: Flash memory enters low-power mode when device enters Stop mode (low-power consumption).

Bit 8  **DBP**: Disable backup domain write protection
In reset state, the RCC_BDCR register, the RTC registers (including the backup registers), BREN and MOEN bits in the PWR_CSR1 register, are protected against parasitic write access.
This bit must be set to enable write access to these registers.
0: Access to RTC, RTC backup registers and backup SRAM disabled
1: Access to RTC, RTC backup registers and backup SRAM enabled

Bits 7:5  **PLS[2:0]**: Programmable voltage detector level selection
These bits select the voltage threshold detected by the PVD.
000: PVD level 1
001: PVD level 2
010: PVD level 3
011: PVD level 4
100: PVD level 5
101: PVD level 6
110: PVD level 7
111: External voltage level on PVD_IN pin
111: External voltage level on PVD_IN pin, compared to internal VREFINT level.

*Note: Refer to Section "Electrical characteristics" of the product datasheet for more details.*

Bit 4  **PVDE**: Programmable voltage detector enable
0: Programmable voltage detector disabled.
1: Programmable voltage detector enabled

Bits 3:1  Reserved, must be kept at reset value.

Bit 0  **SVOS**: System Stop mode voltage scaling selection.
0: SVOS low
1: SVOS high (default)
### 6.8.2 PWR control status register 1 (PWR_SR1)

Address offset: 0x004  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:14</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bit 13    | AVDO: Analog voltage detector output on VDDA  
This bit is set and cleared by hardware. It is valid only if AVD on VDDA is enabled by the AVDEN bit.  
0: VDDA is equal or higher than the AVD threshold selected with the ALS[1:0] bits.  
1: VDDA is lower than the AVD threshold selected with the ALS[1:0] bits  
**Note:** Since the AVD is disabled in Standby mode, this bit is equal to 0 after Standby or reset until the AVDEN bit is set |
| Bit 12:5  | Reserved, must be kept at reset value. |
| Bit 4     | PVDO: Programmable voltage detect output  
This bit is set and cleared by hardware. It is valid only if the PVD has been enabled by the PVDE bit.  
0: VDD or PVD_IN voltage is equal or higher than the PVD threshold selected through the PLS[2:0] bits.  
1: VDD or PVD_IN voltage is lower than the PVD threshold selected through the PLS[2:0] bits.  
**Note:** Since the PVD is disabled in Standby mode, this bit is equal to 0 after Standby or reset until the PVDE bit is set |
| Bit 3:2   | Reserved, must be kept at reset value. |
| Bit 1     | ACTVOSRDY: Voltage levels ready bit for currently used ACTVOS and SDHILEVEL  
This bit is set to 1 by hardware when the voltage regulator and the SMPS step-down converter are both disabled and Bypass mode is selected in PWR control register 2 (PWR_CSR2).  
0: Voltage level invalid, above or below current ACTVOS and SDHILEVEL selected levels.  
1: Voltage level valid, at current ACTVOS and SDHILEVEL selected levels. |
| Bit 0     | ACTVOS: VOS currently applied for VCORE voltage scaling selection.  
These bit reflect the last VOS value applied to the PMU.  
0: VOS low level  
1: VOS high level |
6.8.3 PWR control status register 1 (PWR_CSR1)

Address offset: 0x008
Reset value: 0x0000 0000

This register is not reset by wakeup from Standby mode, RESET signal and V_DD POR. It is only reset by V_SW POR and VSWRST reset.

This register must not be accessed when VSWRST bit in the RCC_BDCR register resets the V_SW domain.

After reset, the PWR_CSR1 register is write-protected. Prior to modifying its content, the DBP bit in the PWR_CR1 register must be set to disable the write protection.

</tbody>
</table>

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 TEMPH: Temperature level monitoring versus high threshold
0: Temperature below high threshold level.
1: Temperature equal or above high threshold level.

Bit 22 TEMPL: Temperature level monitoring versus low threshold
0: Temperature above low threshold level.
1: Temperature equal or below low threshold level.

Bit 21 VBATL: V_BAT level monitoring versus low threshold
0: V_BAT level above low threshold level.
1: V_BAT level equal or below low threshold level.

Bits 20:17 Reserved, must be kept at reset value.

Bit 16 BRRDY: Backup regulator ready
0: Backup regulator not ready.
1: Backup regulator ready.

Bits 15:5 Reserved, must be kept at reset value.
Bit 4 **MONEN**: V\textsubscript{BAT} and temperature monitoring enable

- When set, the V\textsubscript{BAT} supply and temperature monitoring is enabled.
- 0: V\textsubscript{BAT} and temperature monitoring disabled.
- 1: V\textsubscript{BAT} and temperature monitoring enabled.

*Note:* V\textsubscript{BAT} and temperature monitoring are only available when the backup regulator is enabled (BREN bit set to 1).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **BREN**: Backup regulator enable

- When set, the backup regulator (used to maintain the backup RAM content in Standby and V\textsubscript{BAT} modes) is enabled.
- If BREN is reset, the backup regulator is switched off. The backup RAM can still be used in Run and Stop modes. However, its content is lost in Standby and V\textsubscript{BAT} modes.
- If BREN is set, the application must wait till the backup regulator ready flag (BRRDY) is set to indicate that the data written into the SRAMs is maintained in Standby and V\textsubscript{BAT} modes.
- 0: Backup regulator disabled.
- 1: Backup regulator enabled.
6.8.4 PWR control register 2 (PWR_CSR2)

Address offset: 0x00C
Reset value: 0x0000 0006

This register is reset only by a power-on reset (POR). It is not reset by a wakeup from Standby mode or RESET signal.

The lower byte of this register is written once after POR and must be written before entering low power mode, changing VOS level.

The lower byte of this register should be written as soon as possible after device start and the regulator state should be verified by reading ACTVOSRDY before entering the low power mode or changing VOS level.

No limitation applies to the upper bytes.

Programming data corresponding to an invalid combination of SDHILEVEL, SMPSEXTHP, SDEN, LDOEN and BYPASS bits (see Table 44: Supply configuration control) is ignored; data is not written because the written-once mechanism locks the register and any further write access is ignored.

The default supply configuration is kept, and the ACTVOSRDY bit in the PWR control status register 1 (PWR_SR1) continues to indicate invalid voltage levels. The system must be power cycled before writing a new value.

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **USBHSRGEN**: USB HS regulator enable.
0: USB HS PHY regulator disabled (default)
1: USB HS PHY regulator enabled

*Note:* This bit should only be set if USB HS is used

Bit 26 **USB33RDY**: USB supply ready.
0: USB33 supply not ready
1: USB33 supply ready.

Bit 25 **USBRGEN**: USB regulator enable.
0: USB regulator disabled
1: USB regulator enabled.

Bit 24 **USB33DEN**: VDD33USB voltage level detector enable
0: VDD33USB voltage level detector disabled
1: VDD33USB voltage level detector enabled.

*Note:* This bit should be set if USB HS, FS, or a GPIO on PMx is used

Bits 23:17 Reserved, must be kept at reset value.
Bit 16 **SDEXT RDY**: SMPS step-down converter external supply ready
   This bit is set by hardware to indicate that the external supply from the SMPS step-down converter is ready.
   0: External supply not ready.
   1: External supply ready.

Bit 15 **EN_XSPIM2**: this bit allows the SW to enable the XSPI interface, when available. The XSPIM_P2 supply must be stable prior to setting this bit. It should also be set when FMC is used.
   0: XSPIM2 interface is not enabled
   1: XSPIM2 interface is enabled
   **CAUTION**: Not respecting this condition could damage the device.

Bit 14 **EN_XSPIM1**: this bit allow the SW to enable the XSPI interface. The XSPIM_P1 supply must be stable prior to setting this bit.
   0: XSPIM1 interface is not enabled
   1: XSPIM1 interface is enabled
   **CAUTION**: not respecting this condition could damage the device.

Bits 13:12 **XSPICAP2[1:0]**: XSPI port 2 capacitor control bits
   00: XSPI Capacitor OFF (default)
   01: XSPI Capacitor set to 1/2
   10: XSPI Capacitor set to 1/2
   11: XSPI Capacitor set to full capacitance
   see the product datasheet for more details

Bits 11:10 **XSPICAP1[1:0]**: XSPI port 1 capacitor control bits
   00: XSPI Capacitor OFF (default)
   01: XSPI Capacitor set to 1/2
   10: XSPI Capacitor set to 1/2
   11: XSPI Capacitor set to full capacitance
   see the product datasheet for more details

Bit 9 **VBRS**: VBAT charging resistor selection
   0: Charge VBAT through a 5 kΩ resistor.
   1: Charge VBAT through a 1.5 kΩ resistor.

Bit 8 **VBE**: VBAT charging enable
   0: VBAT battery charging disabled.
   1: VBAT battery charging enabled.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SDHILEVEL**: SMPS step-down converter voltage output for external supply.
   This bit is used when SMPSEXTHP is enabled. In this case SDHILEVEL has to be set to 1 to confirm the regulator settings.
   0: Reset value
   1: 1.8V

Bit 3 **SMPSEXTHP**: SMPS external power delivery selection
   0: SMPS normal operating mode, no power delivery to external circuits
   1: SMPS external operating mode, power delivery to external circuits

**Note**: Illegal combinations of SDHILEVEL, SMPSEXTHP, SDEN, LDOEN and BYPASS are described in Table 44.
Bit 2  **SDEN**: SMPS step-down converter enable  
   0: SMPS step-down converter disabled  
   1: SMPS step-down converter enabled. (Default)  

   **Note:**  Illegal combinations of SDHILEVEL, SMPSEXTHP, SDEN, LDOEN and  
   BYPASS are described in Table 44.

Bit 1  **LDOEN**: Low drop-out regulator enable  
   0: Low drop-out regulator disabled.  
   1: Low drop-out regulator enabled (default)  

   **Note:**  Illegal combinations of SDHILEVEL, SMPSEXTHP, SDEN, LDOEN and  
   BYPASS are described in Table 44.

Bit 0  **BYPASS**: Power management unit bypass  
   0: Power management unit normal operation.  
   1: Power management unit bypassed, voltage monitoring still active.  

   **Note:**  Illegal combinations of SDHILEVEL, SMPSEXTHP, SDEN, LDOEN and  
   BYPASS are described in Table 44.
6.8.5  PWR CPU control register 3 (PWR_CSR3)

This register allows controlling the CPU power.

Address offset: 0x010
Reset value: 0x0000 0000
After Standby Reset value: 0x0000 0200

<table>
<thead>
<tr>

</table>

Bits 31:10  Reserved, must be kept at reset value.

Bit 9  **SBF**: System Standby flag
This bit is set by hardware and cleared only by a POR (Power-on Reset) or by setting the CPU CSSF bit.
0: System has not been in Standby mode
1: System has been in Standby mode

Bit 8  **STOPF**: STOP flag
This bit is set by hardware and cleared only by any reset or by setting the CPU CSSF bit.
0: System has not been in Stop mode
1: System has been in Stop mode

Bits 7:2  Reserved, must be kept at reset value.

Bit 1  **CSSF**: Clear Standby and Stop flags (always read as 0)
This bit is cleared to 0 by hardware.
0: No effect.
1: flags (STOPF, SBF) are cleared.

Bit 0  **PDDS**: Power Down Deepsleep.
This bit allows CPU to define the Deepsleep mode
0: Stop mode when device enters Deepsleep.
1: Standby mode when device enters Deepsleep.
6.8.6 PWR control status register 4 (PWR_CSR4)

Address offset: 0x014
Reset value: 0x0000 0002

</table>

Bits 31:2 Reserved, must be kept at reset value.

**Bit 1 VOSRDY**: VOS Ready bit for VCORE voltage scaling output selection.
When an internal regulator is used, this bit indicates that all the features allowed by the selected VOS can be used.*

*Note*: When Bypass mode is selected in the PWR control register (PWR_CSR2), VOSRDY bit is set to 1 by hardware whatever the VCORE level.

- 0: Not ready, voltage level below VOS selected level.
- 1: Ready, voltage level at or above VOS selected level.

**Bit 0 VOS**: Voltage scaling selection according to performance
These bits control the VCORE voltage level and allow to obtains the best trade-off between power consumption and performance:

- When increasing the performance, the voltage scaling must be changed before increasing the system frequency.
- When decreasing performance, the system frequency must first be decreased before changing the voltage scaling.

- 0: VOS low level (default)
- 1: VOS high level

*Note*: Refer to Section "Electrical characteristics" of the product datasheet for more details.

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 WKUPC4: Clear Wakeup pin flag for WKUP4
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF4 Wakeup pin flag (bit is cleared to 0 by hardware)

Bit 2 WKUPC3: Clear Wakeup pin flag for WKUP3
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF3 Wakeup pin flag (bit is cleared to 0 by hardware)

Bit 1 WKUPC2: Clear Wakeup pin flag for WKUP2
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF2 Wakeup pin flag (bit is cleared to 0 by hardware)

Bit 0 WKUPC1: Clear Wakeup pin flag for WKUP1
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF1 Wakeup pin flag (bit is cleared to 0 by hardware)
### 6.8.8 PWR wakeup flag register (PWR_WKUPFR)

Bits 31:4 Reserved, must be kept at reset value.

**Bit 3 WKUPF4**: Wakeup pin WKUP4 flag.  
This bit is set by hardware and cleared only by a Reset pin or by setting the WKUPC4 bit in the PWR wakeup clear register (PWR_WKUPCR).  
0: No wakeup event occurred  
1: A wakeup event was received from WKUP4 pin

**Bit 2 WKUPF3**: Wakeup pin WKUP3 flag.  
This bit is set by hardware and cleared only by a Reset pin or by setting the WKUPC3 bit in the PWR wakeup clear register (PWR_WKUPCR).  
0: No wakeup event occurred  
1: A wakeup event was received from WKUP3 pin

**Bit 1 WKUPF2**: Wakeup pin WKUP2 flag.  
This bit is set by hardware and cleared only by a Reset pin or by setting the WKUPC2 bit in the PWR wakeup clear register (PWR_WKUPCR).  
0: No wakeup event occurred  
1: A wakeup event was received from WKUP2 pin

**Bit 0 WKUPF1**: Wakeup pin WKUP1 flag.  
This bit is set by hardware and cleared only by a Reset pin or by setting the WKUPC1 bit in the PWR wakeup clear register (PWR_WKUPCR).  
0: No wakeup event occurred  
1: A wakeup event was received from WKUP1 pin
### 6.8.9 PWR wakeup enable and polarity register (PWR_WKUPEPR)

Address offset: 0x028  
Reset value: 0x0000 0000

(Reset value after Standby: the value of the register is kept in Standby mode.)

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **WKUPPUPDn[1:0]**: Wakeup pin pull configuration for WKUPn, (n = 4 to 1)  
These bits define the I/O pad pull configuration used when WKUPENn = 1. The associated GPIO port pull configuration must be set to the same value or to 00.  
The Wakeup pin pull configuration is kept in Standby mode.  
00: No pull-up  
01: Pull-up  
10: Pull-down  
11: Reserved

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **WKUPP[4:1]**: Wakeup pin polarity bit for WKUPn, (n = 4, 3, 2, 1)  
These bits define the polarity used for event detection on WKUPn external wakeup pin.  
0: Detection on high level (rising edge)  
1: Detection on low level (falling edge)

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **WKUPEN[4:1]**: Enable Wakeup Pin WKUPn, (n = 4, 3, 2, 1)  
Each bit is set and cleared by software.  
0: An event on WKUPn pin does not wakeup the system from Standby mode.  
1: A rising or falling edge on WKUPn pin wakes-up the system from Standby mode.  
*Note: An additional wakeup event is detected if WKUPn+1 pin is enabled (by setting the WKUPENn bit) when WKUPn pin level is already high when WKUPn+1 selects rising edge, or low when WKUPn selects falling edge.*
6.8.10  PWR USB Type-C and Power Delivery register (PWR_UCPDR)

Address offset: 0x02C
Reset value: 0x0000 0002

(Reset value after Standby: the value of the register is kept in Standby mode.)

<table>

</tr>
</thead>
</table>

Bits 31:2  Reserved, must be kept at reset value.

**Bit 1 UCPD_STBY**: UCPD Standby mode
When set, this bit is used to memorize the UCPD configuration in Standby mode.
This bit must be written to 1 just before entering Standby mode when using UCPD.
It must be written to 0 after exiting the Standby mode and before writing any UCPD registers.

**Bit 0 UCPD_DBDIS**: UCPD dead battery disable
After exiting reset, the USB Type-C “dead battery” behavior is enabled, which may have a pull-down effect on CC1 and CC2 pins. It is recommended to disable it in all cases, either to stop this pull-down or to handover control to the UCPD (the UCPD must be initialized before doing the disable).
0: UCPD dead battery pull-down behavior enabled on UCPDx_CC1 and UCPDx_CC2 pins
1: UCPD dead battery pull-down behavior disabled on UCPDx_CC1 and UCPDx_CC2 pins
6.8.11 PWR apply pull configuration register (PWR_APCR)

Address offset: 0x030
Reset value: 0x0003 0000

(Reset value after Standby: the value of the register is kept in Standby mode.)

<table>
<thead>
<tr>
<th>Bit 31</th>

<tr>
<td>Bit 16</td>
<td>PN7_PUPD: Port N bit 7 pull-up/down configuration</td>
</tr>
</tbody>
</table>

Bits 27:18 Reserved, must be kept at reset value.

Bit 17 PO5_PUPD: Port O bit 5 pull-up/down configuration
When this bit is set, a weak pull-up or pull down resistor is applied on PO5 following inverse logic applied on PO4.
If the PUO4 bit in PWR_PUCRO register is set and APC bit is set the week pull-down is applied on PO5.
If the PDO4 bit in PWR_PDCRO register is set and APC bit is set the week pull-up is applied on PO5.

Bit 16 PN7_PUPD: Port N bit 7 pull-up/down configuration
When this bit is set, a weak pull-up or pull-down resistor is applied on PN7 following inverse logic applied on PN6.
If the PUN6 bit in PWR_PUCRN register is set and APC bit is set the week pull-down is applied on PN7.
If the PDN6 bit in PWR_PDCRN register is set and APC bit is set the week pull-up is applied on PN7.

Bits 15:1 Reserved, must be kept at reset value.
Bit 0  **APC**: Apply pull-up and pull-down configuration

When this bit is set, the I/O pull-up and pull-down configurations defined in PO5_PUPD, PN7_PUPD bits and PUCRx, PDCRx registers are applied in Standby mode even after wakeup until APC bit is reset to 0.

When this bit is cleared, the I/O pull-up or pull-down configurations defined in PO5_PUPD, PN7_PUPD bits and PUCRx and PDCRx registers are not applied in Standby mode and IO becomes Hi-Z.
### 6.8.12 PWR port N pull-up control register (PWR_PUCRN)

Address offset: 0x034

Reset value: 0x0000 0000 (POR and System Reset)

(Reset value after Standby: the value of the register is kept in Standby mode.)

</table>

Bits 31:13 Reserved, must be kept at reset value.

**Bit 12** PUN12: Port N pull-up bit 12

When set, each bit activates the pull-up on PN12 when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PD12 bit is also set.

Bits 11:7 Reserved, must be kept at reset value.

**Bit 6** PUN6: Port N pull-up bit 6

When set activates the pull-up on PN6 when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PDN6 bit is also set.

Bits 5:2 Reserved, must be kept at reset value.

**Bit 1** PUN1: Port N pull-up bit 1

When set, each bit activates the pull-up on PN1 when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PD1 bit is also set.

**Bit 0** Reserved, must be kept at reset value.
### 6.8.13 PWR port N pull-down control register (PWR_PDCRN)

Address offset: 0x038  
Reset value: 0x0000 0000  
(Reset value after Standby: the value of the register is kept in Standby mode.)

Bits 31:13 Reserved, must be kept at reset value.

- **Bit 12** **PDN12**: Port N pull-down bit 12  
  When set activates the pull-down on PN12 when the APC bit is set in PWR_APCR.

Bits 11:9 Reserved, must be kept at reset value.

- **Bit 8** **PDN8N11**: Port N - PN8 to PN11 pull-down activation  
  When set, four pull-down resistors are activated on PN8 to PN11 when the APC bit is set in PWR_APCR.

- **Bit 7** Reserved, must be kept at reset value.

- **Bit 6** **PDN6**: Port N pull-down bit 6  
  When set activates the pull-down on PN6 when the APC bit is set in PWR_APCR.

Bits 5:3 Reserved, must be kept at reset value.

- **Bit 2** **PDN2N5**: Port N PN2 to PN5 pull-down activation  
  When set, four pull-down resistors are activated on PN2 to PN5 when the APC bit is set in PWR_APCR.

- **Bit 1** **PDN1**: Port N pull-down bit 1  
  When set activates the pull-down on PN1 when the APC bit is set in PWR_APCR.

- **Bit 0** **PDN0**: Port N pull-down bit 0  
  When set activates the pull-down on PN0 when the APC bit is set in PWR_APCR.
### 6.8.14 PWR port O pull-up control register (PWR_PUCRO)

Address offset: 0x03C  
Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

**Bit 4 PUO4**: Port O pull-up bit 4  
When set activates the pull-up on PO4 when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding bits PDO4 in PWR_PDCRO is also set.

Bits 3:2 Reserved, must be kept at reset value.

**Bits 1:0 PUOn**: (n = 1 to 0) Port O pull-up bits  
When set, each bit activates the pull-up on POy when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding bits in PWR_PDCRO is also set.
### 6.8.15 PWR port O pull-down control register (PWR_PDCRO)

Address offset: 0x040  
Reset value: 0x0000 0000

Refer to Section 2.3 on page 149 for the register boundary addresses.
7 Reset and clock control (RCC)

The RCC block manages the clock and reset generation for the whole microcontroller. The operating modes to which this section refers are defined in Section 6.6.1: Operating modes of the PWR block.

7.1 RCC main features

AHB-Lite bus interface

Reset block:
- Generation of local and system reset
- Bidirectional pin reset allowing to reset the microcontroller or external devices
- WWDG and IWDG reset supported
- Power-on (POR) and Brownout (BOR) resets initiated by the power control (PWR)

Clock generation block:
- Generation and dispatching of clocks for the complete device
- 3 separate PLLs using integer or fractional ratios
- Possibility of changing the PLL fractional ratios on-the-fly
- Smart clock gating to reduce power dissipation
- System clock protection
- 2 external oscillators:
  - High-speed external oscillator (HSE) supporting a wide range of crystals from 4 to 50 MHz frequency \(^{(a)}\)
  - Low-speed external oscillator (LSE) for the 32 kHz crystals
- 4 internal oscillators
  - High-speed internal oscillator (HSI)
  - 48 MHz RC oscillator (HSI48)
  - Low-power internal oscillator (CSI)
  - Low-speed internal oscillator (LSI)
- Buffered clock outputs for external devices
- Generation of two types of interrupts lines:
  - Dedicated interrupt lines for clock security management
  - One general interrupt line for other events
- Clock generation handling in Stop and Standby mode

\(^{(a)}\) Note that when the USBHSPHY is used, the HSE frequency must be 16, 19.2, 20, 24, 26 or 32 MHz.

7.4 RCC reset block functional description

The RCC handles the reset generation for the complete product, using events coming from different sources:
- assertion of the NRST pin from an external device
- a failure on the supply voltage applied to VDD, VBAT
- an exit from Standby
- a watchdog timeout
- a software command

The reset scope depends on the source that generates the reset.

7.4.1 Reset from PWR block

The PWR block provides several reset signals to the RCC:
- The power-on/off reset signal (**pwr_por_rst**), which is asserted when the VDD supply is lower than the VPOR threshold.
- The brown-out reset signal (**pwr_bor_rst**), which is asserted when the VDD supply is lower than the VBOR threshold.
- The core reset signal (**pwr_vcore_ok**), which is asserted when the VDDCORE supply is not valid or available. Note that the VDDCORE voltage is switched off, when the product is in Standby. So when the system exits from Standby mode, the **pwr_vcore_ok** signal is asserted as long the VDDCORE voltage provided by the internal regulator is not valid. Note that when VDD supply is not valid, **pwr_vcore_ok** is asserted as well.
- The VSW domain reset signal (**pwr_vsw_rst**), which is asserted when the VSW supply is lower than the expected threshold.

*Note:* The **rcc_vcore_rst** is generated from the **pwr_vcore_ok** signal, the main difference between these two signals is that **rcc_vcore_rst** remains asserted until the option byte loading operation is completed.

Refer to *Table 56: Reset coverage summary* for details.
Figure 38. Simplified reset circuit
7.4.2 The system and application resets (sys_rst and nreset)

A system reset (sys_rst) resets most of the registers to their default values unless otherwise specified in the register description.

A system reset can be generated from one of the following sources:

- an assertion of the NRST pin (external reset)
- a reset from the power-on/off reset block (pwr_por_rst)
- a reset from the brownout reset block (pwr_bor_rst)

Refer to Section 6.5.2: Brownout reset (BOR) for a detailed description of the BOR function.

- a reset from the independent watchdogs (iwdg_out_rst)
- an exit from Standby (rcc_vcore_rst).
- a reset from the window watchdogs depending on WWDG configuration (wwdg_out_rst)
- a software reset from the Cortex®-M7 core
  It is generated via the SYSRESETREQ signal issued by the Cortex®-M7 core. This signal is also named SFTRESET in this document.
- A reset from the low-power mode security reset, depending on option byte configuration (lpwr_rst).
- An option byte reload request from the flash interface (obl_rst)

The application reset (nreset) is similar to the system reset, but is not asserted when the system exits from Standby.

Note: The SYSRESETREQ bit in Cortex®-M7 through the FPU application interrupt and reset control register, must be set to force a software reset on the device. Refer to the Cortex®-M7 with FPU technical reference manual for more details (see http://infocenter.arm.com).

7.4.3 The NRST reset

The NRST is active low. A pulse stretcher guarantees a minimum reset pulse duration of 20 μs (Refer to datasheet for details). In addition it is possible to extend the NRST assertion thanks to $C_R$ capacitor. It is not recommended to let the NRST pin unconnected.

When it is not used, connect this pin to ground via a 10 to 100 nF capacitor (CR in Figure 38). As shown in Figure 38, a filter is also present in order to suppress spurs coming from NRST PAD.

7.4.4 Low-power mode security reset (lpwr_rst)

To prevent critical applications from mistakenly enter a low-power mode, two low-power mode security resets are available. When enabled through nRST_STOP and nRST_STANDBY option bytes, a system reset is generated if the following conditions are met:

- The CPU accidentally enters Stop mode.
  This type of reset is enabled by resetting nRST_STOP user option byte. In this case, whenever the Stop mode entry sequence is successfully executed, a system reset is generated.
- The system accidentally enter Standby mode.
  This type of reset is enabled by resetting nRST_STANDBY user option byte. In this case,
case, whenever a Standby mode entry sequence is successfully executed, a system reset is generated. When the Standby mode is entered, a flag is also set in the power controller.

LPWRRSTF bit in the **RCC Reset status register (RCC_RSR)** indicates that a low-power mode security reset occurred (see line #7 in **Table 57**).

lpwr_rst is activated when a low-power mode security reset due to CPU occurred. Refer to **Section 5.4: FLASH option bytes** for additional information.

Refer to **Section 6: Power control (PWR)** for additional information and **Table 45: Operating mode summary** for the overview of the existing power modes.

### 7.4.5 Backup domain reset

A backup domain reset (pwr_vsw_rst) is generated when one of the following events occurs:

- Software reset, triggered by setting the VSWRST bit in the **RCC Backup domain control register (RCC_BDCR)**. All RTC registers and the RCC_BDCR register are set to their reset values, with the exception of LSEDRV, which is not changed if LSEON=1. The BKPSRAM is not affected.
- When the VSW voltage is outside the operating range. All RTC registers and the RCC_BDCR register are set to their reset values. In this case the content of the BKPSRAM is no longer valid.

Refer to **Section 6.4.4: Backup domain section of PWR block** and to section “System security” for additional information.

### 7.4.6 Coresight debug reset

The coresight debug components can be reset in different ways:

- Over the DAP by setting to 1 the bit CDBGRSTREQ of the control/status register of the debug port. This action asserts the debug reset request signal cdbgreq to the RCC. Then the RCC activates the debug reset (rcc_dbg_rst), a handshake signal cdbgreq is provided to the DAP request. The debug reset remains as long as the cdbgreq is to 1, refer to **Figure 38** for details.
- When VDDCORE power-on reset occurs (rcc_vcore_rst). This reset is activated after a power-on reset, or when the product exits from Standby.

Refer to **Section 1.7.1: CoreSight Debug Reset** for details.
7.4.7 Option bytes loading

As shown in Figure 38, the option bytes loading (OBL) sequence is triggered under the following conditions:

- After a power-on, or
- When the system exits from Standby
- When the flash interface requested a reload of option bytes

The system reset (sys_rst) can be released only when the option byte loading (OBL) is completed.

7.4.8 Peripheral resets

The application can individually reset any peripheral whenever requested. This can be done via the RCC_xxxxRSTR registers where “xxxx” is the name of the bus to which the peripheral is connected.

In order to reset a peripheral, the corresponding reset bit must be set to 1, and then set back to 0. There is no need to enable the peripheral clock in order to reset a peripheral.

Note also that the CRYP, SAES and HASH blocks can be reset in the case of a tamper event.

7.4.9 Reset coverage summary

Table 56: Reset coverage summary gives a detailed view of the reset coverage of the most important reset sources.

Note: When $V_{DD}$ is not valid, $V_{DDCORE}$ is also not valid.
### Table 56. Reset coverage summary\(^{(1)}\)

1. The 'x' means that the function is reset by the corresponding reset line, the '-' means that the function is not reset by the corresponding reset line.
2. The \(\text{pwr\_por\_rst}\) is asserted when the voltage applied to VDD is not valid. When \(\text{pwr\_por\_rst}\) is asserted, the \(\text{rcc\_vcore\_rst}\), \(\text{nrst}\), \(\text{sys\_rst}\) and the \(\text{reset}\), are asserted as well.
3. The rcc_vcore_rst is asserted when the voltage applied to VDD is not valid, or when the system exits from Standby (because VDDCORE was switched off). When rcc_vcore_rst is asserted, the sys_rst, and the pwr_dbg_rst are asserted as well.

4. When nreset is asserted, the sys_rst is also asserted.

### 7.4.10 Reset source identification

The CPU can identify the reset source by checking the reset flags in the RCC_RSR register. The CPU can reset the flags by setting RMVF bit.

*Table 57* shows how the status bits of the RCC_RSR register behave according to the situation that generated the reset. For example, when an IWDG timeout occurs (line #6), if the CPU is reading the RCC_RSR register during the boot phase, both PINRSTF and IWDGRSTF bits are set, indicating that the IWDG also generated a pin reset.

1. Grayed cells highlight the register bits that are set.
2. The SBF bit is located into the PWR_CSR3 register of the PWR block

### 7.4.11 Power-on and wakeup sequences

For detailed diagrams refer to *Section 6.4.1: System supply startup* in the PWR section.

The time interval between the event that exits the product from a low-power and the moment where the CPU is able to execute code, depends on the system state and on its configuration. *Figure 39* shows the most usual examples.

**Power-on wakeup sequence**

The power-on wakeup sequence shown in *Figure 39* gives the most significant phases of the power-on sequence. It is the longest sequence since the circuit was not powered. Note that this sequence remains unchanged, whatever V_{BAT} was present or not.
Boot from pin reset

When a pin reset occurs, \( V_{DD} \) is still present. As a result:
- The regulator settling time is faster since the reference voltage is already stable.
- The HSI restart delay may be needed if the HSI was not enabled when the NRST occurred, otherwise this restart delay phase is skipped.
- The Flash memory power recovery delay can also be skipped if the Flash memory was enabled when the NRST occurred.

**Note:** The boot sequence is similar for `pwr_bor_rst`, `lpwr_rst`, `STFRESET`, `iwdg_out_rst` and `wwdg_out_rst`.

Boot from system Standby

When waking up from system Standby, the reference voltage is stable since \( V_{DD} \) has not been removed. As a result, the regulator settling time is fast. Since \( V_{CORE} \) was not present, the restart delay for the HSI, the Flash memory power recovery and the option byte reloading cannot be skipped.

Restart from system Stop

When restarting from Stop, \( V_{DD} \) is still present. As a result, the sequence is mainly composed of two steps:
1. Regulator settling time to reach VOS low (default voltage).
2. HSI/CSI restart delay. This step can be skipped if HSIKERON or CSIKERON bit is set to 1 in the **RCC register map**.

**Figure 39. Boot sequences versus system states**
7.5 RCC clock block functional description

The RCC provides a wide choice of clock generators:

- HSI (high-speed internal oscillator) clock: ~ 8, 16, 32 or 64 MHz
- HSE (high-speed external oscillator) clock: 4 to 50 MHz
- LSE (low-speed external oscillator) clock: 32 kHz
- LSI (low-speed internal oscillator) clock: ~ 32 kHz
- CSI (low-power internal oscillator) clock: ~4 MHz
- HSI48 (high-speed internal oscillator) clock: ~48 MHz

The RCC offers a high flexibility for the application to select the appropriate clock for CPU and peripherals, in particular for peripherals that require a specific clock such as SPI/I2S and SAI.

To optimize the power consumption, each clock source can be switched ON or OFF independently.

The RCC provides up to 3 PLLs; each of them can be configured in integer, with or without SSCG, or fractional mode.

As shown in the Figure 40, the RCC offers two clock outputs (MCO1 and MCO2), with a great flexibility on the clock selection and frequency adjustment.

The SCGU block (system clock generation unit) contains several prescalers used to configure the CPU and bus matrix clock frequencies.

The PKSU block (peripheral kernel clock selection unit) provides several dynamic switches allowing a large choice of kernel clock distribution to peripherals.

The PKEU (peripheral kernel clock enable unit) and SCEU (system clock enable unit) blocks perform the peripheral kernel clock gating, and the bus interface/cores/bus matrix clock gating, respectively.
Figure 40. Top-level clock tree

The selected input can be changed on-the-fly without spurs on the output signal.

* Represents the selected mux input after a system reset.
7.5.1 Clock naming convention

The RCC provides clocks to the complete circuit. To avoid misunderstanding, the following terms are used in this document:

- **Peripheral clocks**
  
The peripheral clocks are the clocks provided by the RCC to the peripherals. Two kinds of clock are available:
  - bus interface clocks
  - kernel clocks

A peripheral receives from the RCC a bus interface clock in order to access its registers, and thus control the peripheral operation. This clock is generally the AHB, APB or AXI clock depending on which bus the peripheral is connected to. Some peripherals only need a bus interface clock (such as RNG, TIMx).

Some peripherals also require a dedicated clock to handle the interface function. This clock is named kernel clock. As an example, peripherals such as SAI must generate specific and accurate master clock frequencies, which require dedicated kernel clock frequencies. Another advantage of decoupling the bus interface clock from the specific interface needs, is that the bus clock can be changed without reprogramming the peripheral.

- **CPU clock**
  
The CPU clock is the clock provided to the CPU. It is derived from the system clock (\(sys_{\text{ck}}\)).

- **Bus matrix clocks**
  
The bus matrix clocks are the clocks provided to the different bridges (APB, AHB or AXI). These clocks are derived from the system clock (\(sys_{\text{ck}}\)).

7.5.2 Oscillators description

The table hereafter shows the oscillator states versus system modes, when the oscillators are enabled via registers. The term “available” means that the resource can be used if activated via registers.

1. If STOPWUCK = 0 or STOPKERWUCK = 0
2. If STOPWUCK = 1 or STOPKERWUCK = 1
3. HSI can remain activated in Stop if HSIKERON = 1, or if a peripheral selecting HSI, generates a kernel clock request.
4. CSI can remain activated in Stop if CSIKERON = 1, or if the peripheral selecting CSI, generates a kernel clock request.
HSE oscillator

The HSE block allows the application to provide a very accurate high-speed clock for the product. The HSE can generate an internal clock from two possible sources:
- external clock source
- external crystal/ceramic resonator

**Figure 41. HSE/LSE clock source**

External clock source (HSE bypass)

In this mode the oscillator is not used, and an external clock source must be provided to OSC_IN pin. The external clock can be low swing (analog) or digital. The OSC_OUT pin must be left HI-Z (see Figure 41).

The external clock signal can be digital or analog (square, sinus or triangle). An analog clock signal with a reduced amplitude, is supported thanks to an internal clock squarer. The input signal must have a duty cycle close to 50%. Refer to the datasheet for additional information.

This mode is selected when HSEBYP = 1, and HSEON = 1. In case of an analog clock input (low swing) the HSEEXT must be set to 0, for a digital clock input, HSEEXT bits must be set to 1.

**Figure 42. HSE clock generation**
External crystal/ceramic resonator

A crystal/resonator can be connected as shown in Figure 41: the crystal/resonator and the load capacitors must be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The oscillator mode is enabled by setting the HSEBYP bit to 0 and HSEON bit to 1.

HSE ready logic

The HSERDY flag indicates when a valid clock is available at HSE output (hse_ck). When the HSE is enabled (HSEON set to '1'), the HSERDY flag goes to '1' when 256 valid cycles of HSE have been detected. The hse_ck clock is not released until HSERDY goes to 1.

An interrupt can be generated if enabled in the RCC clock source interrupt enable register (RCC_CIER).

HSE controls

The HSE can be switched ON and OFF through the HSEON bit.

The hardware does not allow modifying HSEON bit if one of the condition is met:

- The HSE is used directly (via SW switch) as system clock.
- The HSE is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via SW switch).
- The bit XSPICKP is set to 1.
- The bit FMCKCP is set to 1.

The hardware does not allow changing the values of HSEBYP, and HSEEXT when HSEON = 1. Bits HSEBYP, HSEEXT and HSEON are located into the RCC register map.

The HSE is automatically disabled by hardware when the system enters Stop or Standby mode (See Table 58: Oscillator states versus system modes).

In addition, the HSE clock can be driven to the MCO1 and MCO2 outputs and used as clock source for other application components.
**Programming sequence**

In order to initialize the HSE, the application must follow the sequence hereafter:

- Make sure the HSE is not directly or indirectly used as system clock, if it is the case, use HSI or CSI as clock source for system clock.
- Make sure that XSPICKP and FMCCKP are set to 0
- Disable the HSE by writing to 0 the HSEON bit,
- Check that the HSE is disabled by waiting that the bit HSERDY is set to 0,
- If the oscillator mode is needed:
  - Select the oscillator mode by setting HSEBYP to 0,
- If an external clock is connected to OSC_IN:
  - Select the bypass mode by setting HSEBYP to 1,
  - If the input clock is a full-swing digital signal, set HSEEXT to 1
  - If the input clock is a low-swing signal, set HSEEXT to 0
- Enable again the HSE by writing the HSEON bit to 1,
- Wait for HSERDY = 1, then the HSE is ready for use.

**LSE oscillator**

The LSE block allows the application to provide a very accurate low-frequency clock for the product. The LSE can generate an internal clock from two possible sources:

- external user clock
- external crystal/ceramic resonator

**External clock source (LSE bypass)**

In this mode, the oscillator is not used, and an external clock source must be provided to OSC32_IN pin. The OSC32_OUT pin must be left Hi-Z (see [Figure 41](#)).

The external clock signal can have a frequency up to 1 MHz and be digital or analog (square, sinus or triangle). An analog clock signal with a reduced amplitude is supported thanks to an internal clock squarer. The input signal must have a duty cycle close to 50%. Refer to the datasheet for additional information.

This mode is selected by setting the LSEBYP and LSEON bits to 1. In case of an analog clock input (low swing) the LSEEXT must be set to 0, for a digital clock input, LSEEXT bits must be set to 1.

![Figure 43. LSE clock generation](#)
External crystal/ceramic resonator source (LSE crystal)

The LSE clock is generated from a 32.768 kHz crystal or ceramic resonator. It has the advantage to provide a low-power highly accurate clock source to the real-time clock (RTC) for clock/calendar or other timing functions. A crystal/resonator can be connected as shown in Figure 41: the crystal/resonator and the load capacitors must be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The oscillator mode is selected by setting LSEBYP bit to 0 and LSEON bit to 1.

The LSE also offers a programmable driving capability (LSEDRV[1:0]) that can be used to modulate the amplifier driving capability. This driving capability is chosen according to the external crystal/ceramic component requirement to insure a stable oscillation.

The driving capability must be set before enabling the LSE oscillator.

---

**Warning:** It is not allowed to change the driving capability when the LSE is enabled. The LSE behavior is not guaranteed in that case.

---

LSE ready logic

The LSE offers a LSERDY flag which indicates whether the LSE clock is available or not. When the LSE is enabled (LSEON set to 1) the LSERDY flag goes to 1 when certain amount of valid cycles of LSE clock have been detected. The lse_ck clock is not released until LSERDY goes to 1.

When LSEBYP = 0, the RCC waits 4096 clocks cycles before activating the LSERDY flag, when LSEBYP = 1, the RCC waits 8 clocks cycles.

An interrupt, can be generated if enabled in the RCC clock source interrupt enable register (RCC_CIER).

LSERDY bit is located into the RCC Backup domain control register (RCC_BDCR).

LSE controls

The LSE control bits LSEBYP, LSEEXT, LSEDRV[1:0] and LSEON are located into the RCC Backup domain control register (RCC_BDCR). This register is write-protected by DBP bit of PWR_CR1 register. In order to modify the RCC_BDCR register, the bit DBP must be set 1.

The LSE oscillator is switched ON and OFF using the LSEON bit.

The LSE remains enabled when the system enters Stop, Standby or VBAT mode (See Table 58: Oscillator states versus system modes).

The hardware does not allow changing the values of LSEBYP, and LSEEXT when LSEON = 1.

In addition, the LSE clock can be driven to the MCO1 output and used as clock source for external components.
LSE Programming sequence

In order initialize the LSE, the application must follow the sequence hereafter:

- Set DBP bit of PWR.CR1 to 1 in order to allow write accesses to RCC.BDCR register.
- Disable the LSE by writing to 0 the LSEON bit.
- Check that the LSE is disabled by waiting that the bit LSERDY is set to 0,
- if the oscillator mode is needed:
  - Select the oscillator mode by setting LSEBYP to 0,
  - Configure LSEDRV[1:0],
- if an external clock is connected to OSC32_IN:
  - Select the bypass mode by setting LSEBYP to 1,
  - If the input clock is a full-swing digital signal, set LSEEXT to 1
  - If the input clock is a low-swing signal, set LSEEXT to 0
- Enable again the LSE by writing the LSEON bit to 1,
- Wait for LSERDY = 1, then the LSE is ready for use.
- If RCC_BDCR register no longer need to be changed, set DBP bit of PWR.CR1 to 0 in order to write-protect accesses.

If the RTC is used, the LSE bypass must not be configured in digital mode but in low swing analog mode (default value after reset).
HSI oscillator

The HSI block provides the default clock to the product. The HSI is a high-speed internal RC oscillator that can be used directly as system clock, peripheral clock, or as PLL input. A predivider allows the application to select an HSI output frequency of 8, 16, 32 or 64 MHz. This predivider is controlled by the HSIDIV.

The HSI advantages are the following:
- low-cost clock source since no external crystal is required
- faster startup time than HSE (a few microseconds)

The HSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

HSI controls

The HSI can be switched ON and OFF using the HSION bit.

The hardware does not allow modifying HSION bit if one of the condition is met:
- The HSI is used directly (via software mux) as system clock.
- The HSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).
- The bit XSPICKP is set to 1.
- The bit FMCCKP is set to 1.

Note that the HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set to 1). In that case the hardware does not update the HSIDIV with the new value. However it is possible to change the HSIDIV if the HSI is used directly as system clock.

The HSIRDY flag indicates if the HSI is stable or not. At startup, the HSI output clock is not released until this bit is set by hardware.

The HSI clock can also be used as a backup source (auxiliary clock) if the HSE fails (refer to Section: CSS on HSE).

The HSI can be disabled or not when the system enters Stop mode (See Table 58: Oscillator states versus system modes).

In addition, the HSI clock can be driven to the MCO1 output and used as clock source for other application components.

Care must be taken when the HSI is used as kernel clock for communication peripherals, the application must take into account the following parameters:
- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- the frequency accuracy.

HSION, HSIRDY and HSIDIV bits are located in the RCC register map.

HSI calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations. That is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of ACC_\text{HSI} (refer to the product datasheet for more information).

After a power-on reset, or at the exit of Standby mode, the factory calibration value is loaded in the HSICAL[11:0] bits.
If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the HSI frequency using the HSITRIM[6:0] bits.

*Note:* HSICAL[11:0] and HSITRIM[6:0] bits are located in the RCC HSI calibration register (RCC_HSICFGR).

**CSI oscillator**

The CSI is a low-power RC oscillator that can be used directly as system clock, peripheral clock, or PLL input.

The CSI advantages are the following:

- low-cost clock source since no external crystal is required
- faster startup time than HSE (a few microseconds)
- very low-power consumption.

The CSI provides a clock frequency of about 4 MHz, while the HSI is able to provide a clock up to 64 MHz.

CSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

**CSI controls**

The CSI can be switched ON and OFF through the CSION bit. The CSIRDY flag indicates whether the CSI is stable or not. At startup, the CSI output clock is not released until this bit is set by hardware.

The hardware does not allow modifying CSION bit if one of the condition is met:

- The CSI is used directly (via software mux) as system clock.
- The CSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).
- The bit XSPICKP is set to 1.
- The bit FMCCKP is set to 1.

The CSI can be disabled or not when the system enters Stop mode (See Table 58: Oscillator states versus system modes).

In addition, the CSI clock can be driven to the MCO2 output and used as clock source for other application components.
Even if the CSI settling time is faster than the HSI, care must be taken when the CSI is used as kernel clock for communication peripherals: the application must take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- the frequency precision.

**Note:** CSION and CSIRDY bits are located in the RCC register map.

### CSI calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by STMicroelectronics to achieve accuracy of ACCCSI (refer to the product datasheet for more information).

After a power-on reset, or at the exit of Standby mode, the factory calibration value is loaded in the CSICAL[7:0] bits.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the CSI frequency using the CSITRIM[5:0] bits.

**Note:** Bits CSICAL[7:0] and CSITRIM[5:0] are located into the RCC CSI calibration register (RCC_CSICFRG).

![Figure 45. CSI calibration flow](MSv48152V1)

### HSI48 oscillator

The HSI48 is an RC oscillator delivering a 48 MHz clock that can be used directly as kernel clock for some peripherals.

The HSI48 oscillator mainly aims at providing an accurate clock to the USB Full-Speed peripherals by means of a special clock recovery system (CRS) circuitry. The CRS can use the USB SOF signal, the LSE or an external signal to automatically adjust the oscillator frequency on-the-fly, with a very small granularity. It is possible to read the calibration value provided to the HSI48 via RCC clock recovery RC register (RCC_CRRCR). The HSI48TRIM value can be adjusted through the CRS block, for more details, refer to Section 9: Clock recovery system (CRS).
The HSI48 oscillator is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, this oscillator is free running and thus subject to manufacturing process variations. This is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of $\text{ACC}_{\text{HSI48}}$ (refer to the product datasheet for more information).

The HSI48RDY flag indicates whether the HSI48 oscillator is stable or not. At startup, the HSI48 output clock is not released until this bit is set by hardware.

After a power-on reset, or at the exit of Standby mode, the factory calibration value is loaded into the HSI48.

The HSI48 can be switched ON and OFF using the HSI48ON bit.

The HSI48 clock can also be driven to the MCO1 multiplexer and used as clock source for other application components.

Note: HSI48ON and HSI48RDY bits are located in the RCC register map.

**LSI oscillator**

The LSI acts as a very-low-power clock source that can be kept running when the system is in Stop or Standby mode for the independent watchdog (IWDG) and auto-wakeup unit (AWU). The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the datasheet.

The LSI can be switched ON and OFF using the LSION bit. The LSIRDY flag indicates whether the LSI oscillator is stable or not. If an independent watchdog is started either by hardware or software, the LSI is forced ON and cannot be disabled.

The LSI remains enabled when the system enters Stop or Standby mode (See *Table 58: Oscillator states versus system modes*).

At LSI startup, the clock is not provided until the hardware sets the LSIRDY bit. An interrupt can be generated if enabled in the RCC clock source interrupt enable register (RCC_CIER).

In addition, the LSI clock can be driven to the MCO2 output and used as a clock source for other application components.

Note: Bits LSION and LSIRDY bits are located into the RCC clock control and status register (RCC_CSR).
7.5.3 Clock security system (CSS)

The RCC offers a clock security system for the HSE and LSE oscillators. The clock security systems are capable of detecting a failure on HSE and LSE oscillators. The figure hereafter shows how this function interact with other blocks.

Figure 47. LSE and HSE CSS function

CSS on HSE

The clock security system can be enabled by software via the HSECSSON bit. The HSECSSON bit can be enabled even when the HSEON is set to 0.

The CSS on HSE is activated when the HSE is enabled and ready, and the software sets the HSECSSON bit to 1. The CSS on HSE is no longer working when the HSE is disabled. For example, this function does not work when the system is in Stop mode.

It is not possible to clear directly the HSECSSON bit by software. The HSECSSON bit is cleared by hardware when a system reset occurs or when the system enters Standby mode (see Section 7.4.2: The system and application resets (sys_rst and nreset)).
When the CSS on HSE is enabled, the following actions are done by the RCC if a failure is detected:

- The signal `rcc_hsecss_fail` is asserted.
- If the STOPWUCK = 0, the HSI clock is enabled and the SW switch automatically selects HSI as system clock.
- If the STOPWUCK = 1, the CSI clock is enabled and the SW switch automatically selects CSI as system clock.
- The HSE is then automatically disabled.
- If the HSE output was used as clock source for PLLs, the PLLs are also disabled.
- The XSPI[2:1]SEL switches go to recovery position.
- The FMCSEL switch goes to recovery position:
  - if PLL1 has been disabled and FMCSEL is in position 1.
  - if PLL2 has been disabled and FMCSEL is in position 2.
  See details on Section : Clock distribution for SDMMCs, FMC, and XSPIs.
- The clock failure event (`rcc_hsecss_fail`) is also sent to the break inputs of advanced-control timers (TIM1, TIM15, TIM16 and TIM17).
- A NMI interrupt is generated to inform the software about the failure (CSS interrupt: `rcc_hsecss_it`), thus allowing the MCU to perform rescue operations. The CSS interrupt is asserted until the HSECSSF bit is cleared. The HSECSSF flag can be cleared by setting the HSECSSC bit in the RCC clock source interrupt clear register (`RCC_CICR`).
- A tamper event can also be triggered, in order to clear content of the backup registers, and backup RAM.

CSS on LSE

A clock security system on the LSE oscillator can be enabled by software by programming the LSECSSON bit in the `RCC Backup domain control register (RCC_BDCR)`. This bit is disabled by hardware if one of the following condition is met:

- After a VSW hardware reset (`pwr_vsw_rst`),
- After a VSW software reset via VSWRST bit

The software can also disable the clock security system after a LSE failure detection. The CSS on LSE works in all modes (Run, Stop and Standby) including VBAT.

The LSECSS provides a re-arm feature, offering to the software the possibility to re-arm the LSECSS and re-enable the LSE clock when a failure has been detected. This feature allows the application to decide if the LSE is to be provided again to the RTC even if a failure occurred, or if another action must be performed. For example the application can decide to reset the VSW domain only if a certain amount of consecutive LSE failures occurred, within a time window.

The LSECSS offers two flag signals:

- The LSECSSD, capable of retaining an LSE failures even in VBAT mode.
- The LSECSSF used to generate interrupt in case of LSE failure. This flag is not affected by a failure detected when the product is in VBAT mode.
The sequence hereafter describes the LSE enabling sequence with the clock security system enabled.

- Follow the LSE enable procedure given in the section LSE Programming sequence, except the last step
- Select the LSE clock via RTCSEL[1:0]
- Set the LSECSSON bit to 1
- If RCC_BDCR register no longer needs to be changed, set DBP bit of PWR_CR1 to 0 in order to write-protect accesses.

Note: The LSECSSON bit must be enabled after the LSE is enabled (LSEON bit set by software) and ready (LSERDY set by hardware), and after the RTC clock has been selected through the RTCSEL bit.

If a failure is detected on the LSE, the hardware does the following:

- The LSE clock is no more delivered to the RTC.
- The values of RTCSEL, LSECSSON and LSEON bits are not changed by the hardware.
- A failure event is generated (rcc_lsecss_fail). This event allows the system to wake-up from Standby, but also to protect the backup registers and BKPSRAM via TAMP block. This event is also generated in VBAT mode.
- The interrupt flag LSECSSF is activated (except in VBAT mode) in order to generate an interrupt (rcc_lsecss_it).
- The LSECSSD flag is activated as well, retaining the first LSE failure even in VBAT.

In the software side, different actions can be taken according to the application requirements. Three different cases are described hereafter in order to illustrate the hardware behavior, they can also be combined. The application can also decide to handle LSE failure differently.

Case A:

The application no longer wants to use LSE when a failure is detected:

- Unlock RCC_BDCR register by setting the DBP bit of PWR_CR1 to 1
- Disable the CSS function (this step is mandatory)
  - Clear the LSECSSF bit, if interrupt was enabled for this event
  - Set the LSECSSON bit to 0
  - Set the LSEON bit to 0, in order to disable the LSE
- Change the clock source for the RTC if needed:
  - Set the RTCEN bit to 0 to disable the RTC clock
  - Enable the new clock source for the RTC
  - Select the proper clock source via RTCSEL
  - Set the RTCEN bit to 1 to enable the RTC clock
- The application must perform specific actions consecutive to TAMPER events if enabled
- Lock RCC_BDCR register by setting the DBP bit of PWR_CR1 to 0

Case B:
The application wants to re-initialize the VSW domain:
- Unlock RCC_BDCR register by setting the DBP bit of PWR_CR1 to 1
- Perform a VSW reset by setting VSWRST bit to 1, then back to 0 (it is in reality a pulse of one period of sys_ck)
- The application must perform specific actions consecutive to TAMPER events if enabled
- Re-initialize all components of the VSW domain.
- Lock RCC_BDCR register by setting the DBP bit of PWR_CR1 to 0

**Case C:**
The application tries to re-use LSE when a failure is detected:
- If the number of failures in a given time window is higher than a given threshold then go to case A or B. Otherwise continue to next step.
- Unlock RCC_BDCR register by setting the DBP bit of PWR_CR1 to 1
- Clear the LSECSSF bit if interrupt was enabled for this event.
- The application must perform specific actions consecutive to TAMPER events if enabled
- Set the LSECSSON bit to 0.
- Re-arm the LSECSS function by writing the LSECSSRA bit to 1, then back to 0.
- Wait for LSERDY set 1. The LSERDY flag must go to 1 after the oscillator settling time delay plus, 4096 periods of LSE clock. If this is not the case, it probably means that the LSE failure is permanent. It is not possible to set LSECSSON to 1, it is recommended to execute case A or B.
- Set the LSECSSON bit to 1.
- When LSECSSON is seen to 1, the LSE is enabled, and protected by LSECSS.
- Lock RCC_BDCR register by setting the DBP bit of PWR_CR1 to 0

All bits used in this sequences (except DBP) are located into **RCC Backup domain control register (RCC_BDCR)**.

### 7.5.4 Clock output generation (MCO1/MCO2)

Two microcontroller clock output pins MCO1 and MCO2, are available. A clock source can be selected for each output. The selected clock can be divided thanks to configurable prescaler (refer to **Figure 40** for additional information on signal selection).

MCO1 and MCO2 outputs are controlled via MCO1PRE[3:0], MCO1SEL[2:0], MCO2PRE[3:0] and MCO2SEL[2:0] located in the **RCC clock configuration register (RCC_CFGR)**.

The GPIO port corresponding to each MCO pin must be programmed in alternate function mode.

The dividers MCO1PRE and MCO2PRE, provide a clock with a duty cycle of 50% for even divisions values. More generally the duty cycle is given by the following formula:

\[
DC(\%) = \frac{\text{FLOOR}\left(\frac{\text{MCOxPRE}}{2}\right)}{\text{MCOxPRE}} \times 100
\]
For MCOxPRE = 2 to 15.

Note that the MCO1 and MCO2 outputs are available in Run and Stop modes.

**Caution:** The clock provided to the MCOs outputs must not exceed the maximum PAD speed, refer to the product datasheet for information about the supported PAD speed.

The table hereafter show the signals available on each MCO output.

Table 59. Oscillator states versus system modes
7.5.5 PLL description

The RCC features three PLLs:
- PLL1, generally used to provide clocks to the CPU, busses, and some peripherals
- PLL2, generally used to provide clocks to XSPI and SDMMC, and some peripherals
- PLL3, dedicated to the kernel clock generation for peripherals

The PLLs integrated into the RCC are completely independent. They offer the following features:
- A VCO supporting two modes:
  - a wide-range
  - a low-range used for instance in audio application cases
- Input frequency range:
  - 2 to 16 MHz for the VCO in wide-range mode
  - 1 to 2 MHz for the VCO in low-range mode
- VCO frequency range:
  - 384 to 1672 MHz for the VCO in high-range mode (VCOH), before the divider.
  - 150 to 420 MHz for the VCO in low-range mode (VCOL)
- Capability to work either in integer with or without SSGC, or in fractional mode
- 13-bit sigma-delta modulator, allowing to fine-tune the VCO frequency by steps of 10 to 0.3 ppm
- The sigma-delta modulator can be updated on-the-fly without generating frequency overshoots on PLLs outputs.
- PLLs offer up to 5 outputs with post-dividers.

For better flexibility, all PLLs offer two VCOs (VCOH and VCOL), the application can select the wanted VCO via PLLxVCOSEL bit.

The frequency of the reference clock provided to the PLLs (refx_ck) must range from 1 to 16 MHz. The DIVMx dividers of the RCC PLLs clock source selection register (RCC_PLLCKSELR) must be properly programmed in order to match this condition. In addition, the PLLxRGE[1:0] field of the RCC PLLs configuration register (RCC_PLLCFGR) must be set according to the reference input frequency to guarantee an optimal performance of the PLL.

The user application can then configure the proper VCO. VCOL must be chosen when the reference clock frequency is lower than 2 MHz.

To reduce the power consumption, it is recommended to configure the VCO output to the smaller range.
The PLLs can be enabled by setting PLLxON to 1. The PLLxRDY bits indicate that the PLL is ready (means locked).

The DIVN loop divider must be programmed to achieve the expected frequency at VCO output. The VCO output range must be respected.

PLLs have a divider-by-2, at VCOH output, insuring that the clock provided to the post-dividers has a duty-cycle of 50%.

The frequency of the clocks provided by the PLLs can also be adjusted thanks to post-dividers DIVP, DIVQ, DIVR, DIVS and DIVT. The post-divider values can be changed without disabling the PLLs, if their respective enable bits are set to 0.

The post-dividers provide clocks with 50% duty-cycle in the following conditions:
- When the post-dividers are dividing the clock by an even value.
- When VCOH is used and post-dividers are bypassed.
- When VCOH is selected and post-dividers DIVS and DIVT are used.

PLL programming recommendations

This section is providing a list of recommendations to follow in order to guarantee a good usage of the PLLs. Note that programming examples are given in Section 1.6.2: PLL programming.

- Before enabling the PLLs, the user must ensure that the reference frequency \( \text{refx}_\text{ck} \) provided to the PLL is stable and in the good range.
- When one or several PLL outputs are not used, the application must set the corresponding enable bit DIV[y]ENx and the divider value DIV[y]x to 0 (with x = 1, 2 or 3, and y = P, Q, R, S or T).
- In order to ensure the good behavior of the PLL, the bits PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN and PLLxTEN must be set to 0 before disabling the corresponding PLL. In the same way, the bits PLLxPEN, PLLxQEN, PLLxREN,
PLLxSEN and PLLxTEN can be set to 1 only if the corresponding bit PLLON is already set to 1 and the PLL is ready.

Refer to section *Section 7.7.1: PLL programming procedure* for additional information.

**PLL protections**

- The RCC hardware does not allow changing DIVMx, DIVN, PLLxRGE, PLLxVCOSEL when the corresponding PLLx is ON and it is also not possible to change PLLSRC when one of the PLL is ON.
- The RCC hardware does not allow changing of the post-dividers’ DIVy when the corresponding PLLxyEN bit is set to 1 (with x = 1, 2 or 3, and y = P, Q, R, S or T).
- The hardware prevents writing PLL1ON or PLL1PEN to 0 if the PLL1 is currently used to deliver the system clock. There are other hardware protections on the clock generators (refer to *Section 7.5.7: Clock protection*).

The PLLs are disabled by hardware when the system enters Stop or Standby mode.

PLLs using HSE as reference clock are also disabled by hardware if an HSE failure is detected.

*Note: The refx_ck clock is provided to the PLLx when the corresponding PLLON bit is set to 1.*

The PLLs can work in 3 different modes:

- In integer mode
- In fractional mode
- In spread spectrum mode

**Using the PLLs in integer mode**

The PLL is working in integer mode when the sigma-delta modulator (SDM) is loaded with a 0, and the bit PLLxSSCGEN = 0.

In order to load 0 into the SDM, the user has to perform the following sequence:

- Write PLLxFRACLE of *RCC PLLs configuration register (RCC_PLLCFGR)* to 0
- Write FRACN[12:0] to 0,
- Write PLLxFRACLE to 1
- Wait at least 5 µs

The bits FRACN[12:0] are located in the RCC_PLLxFRACR registers.

The VCO frequency ($F_{VCO}$) and output frequencies expressions are given by the following table:
Using the PLLs in fractional mode

The fractional mode is activated when the value loaded into the SDM is different from 0, and the bit PLLxSSCGEN = 0.

The SDM value can be updated at anytime by the application by executing the following sequence:
- Write PLLxFRACLE bit to ‘0’
- Write into FRACN[12:0] the new fractional value,
- Write PLLxFRACLE to ‘1’. The new FRACN value is loaded into the SDM when PLLxFRACLE bit goes from 0 to 1.
- Wait at least 5 µs

The sigma delta modulator is designed in order to minimize the jitter impact while allowing very small frequency steps.

When the PLL is used in fractional mode, the DIVN divider must be initialized before enabling the PLL.
This feature can be used either to generate a specific frequency, with a good accuracy from any crystal value, or to perform a fine tuning of the frequency on-the-fly.

---

<td>( F_{VCO} = F_{ref_ck} \times (DIVN + 1) )</td>
</tr>
<tr>
<td>( F_{\text{pll}<em>y_ck} = \frac{F</em>{VCO}}{2 \times (DIVy + 1)} )</td>
<td>( F_{\text{pll}<em>y_ck} = \frac{F</em>{VCO}}{(DIVy + 1)} )</td>
</tr>
</tbody>
</table>

with \( y = P, Q, R, S \) or \( T \)

Refer to section *Section 7.7.1: PLL programming procedure* for additional information.
The VCO frequency (F_{VCO}) and output frequencies expressions are given by the following table:

<table>
<thead>
<tr>
<th>Table 61. VCO frequency and output frequency in fractional mode</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PLLxVCOSEL = 0</strong></td>
</tr>
<tr>
<td>F_{VCO} = 2 \times \frac{F_{ref_ck} \times (DIVN + 1 + \frac{FRACN}{2^{13}})}{y}</td>
</tr>
<tr>
<td>F_{pll_y_ck} = \frac{F_{VCO}}{2 \times (DIVy + 1)}</td>
</tr>
<tr>
<td>with y = P, Q, R, S or T</td>
</tr>
</tbody>
</table>

Refer to section **Section 7.7.1: PLL programming procedure** for additional information.

**Using the PLLs in spread spectrum mode**

The spread spectrum mode is activated when the SDM loaded with 0, and the bit PLLxSSCGEN = 1. This feature is available on all PLLs.

The VCOH must be selected when the spread spectrum mode is activated. VCOH is selected by setting PLLxVCOSEL to 0. PLLxVCOSEL are located into the **RCC clock configuration register (RCC_CFGR)**.

The spread spectrum technique consist of modulating the VCO frequency with a low-frequency signal (in our case a triangular signal), in order to spread the clock energy into a wider frequency band. As a consequence, the amount of emitted EMI peaks is reduced.

The parameters of the spread spectrum modulation are adjusted via the following fields:

- MODPER[12:0]: used to adjust the modulation frequency
- INCSTEP[14:0]: used to adjust the modulation depth (or modulation index)
- SPREADSEL: used to define if the modulation is centered around the VCO frequency (center-spread) or if it is lowered with respect to VCO frequency (down-spread).

The bits MODPER[12:0], INCSTEP[14:0] and SPREADSEL are located into the RCC_PLLxSSCSR registers with x=1, 2 or 3.

**Figure 49** shows the signal modulating the nominal frequency (F_N), when SPREADSEL = 0 (center-spread) and SPREADSEL = 1 (down-spread). The nominal frequency is the frequency output by the PLL in integer mode, when no clock spreading is applied.

Setting the SPREADSEL bit to ‘1’ (down-spread) guarantees that the PLL output frequency does not exceed the programmed frequency value when the SSCG is enabled.
The peak modulation depth (in percentage) is given by the following formula:

\[ M_D (\%) = \frac{\text{MODPER} \times \text{INCSTEP} \times 100 \times 5}{(2^{15} - 1) \times (\text{DIVN} + 1)} \]

Note that MODPER x INCSTEP must not exceed \((2^{15}-1)\).

The modulation frequency (\(F_{mod}\)) is given by:

\[ F_{mod} = \frac{F_{\text{ck\_ref}}}{4 \times \text{MODPER}} \]

**Note:** Refer to the datasheet of the product for the recommended modulation frequency range.

In order to use the spread spectrum feature, the user has to do the following:

- Program the PLL as explained into **Section : Using the PLLs in integer mode** in order to adjust the nominal frequency (\(F_N\)) according to the targeted by the application.
- Compute the MODPER value according to the wanted modulation frequency (\(F_{\text{mod}}\)):

\[ \text{MODPER} = \text{ROUND} \left( \frac{F_{\text{ck\_ref}}}{4 \times F_{\text{mod}}} \right) \]

- Compute the INCSTEP value according to the wanted modulation depth (\(M_D\)):

\[ \text{INCSTEP} = \text{ROUND} \left( \frac{(2^{15} - 1) \times M_D \times (\text{DIVN} + 1)}{100 \times 5 \times \text{MODPER}} \right) \]

Check that MODPER x INCSTEP does not exceed \((2^{15}-1)\).
- Then DIVP, Q, R, S or T can be adjusted, and the bit PLLxSSCGEN can be set to 1, and the PLL enabled.
The user can check \( F_{\text{MIN}} \), \( F_{\text{MAX}} \), and \( F_C \) as follow:

- If \( \text{SSCG\_MODE} = '0' \) (centered-spread)
  
  \[
  F_C = \frac{F_{\text{PLL}}}{} \times (1 - \frac{M_D}{100})
  \]
  
  \[
  F_{\text{MIN}} = F_C \times (1 - \frac{M_D}{100})
  \]
  
  \[
  F_{\text{MAX}} = F_C \times (1 + \frac{M_D}{100})
  \]

- If \( \text{SSCG\_MODE} = '1' \) (down-spread)
  
  \[
  F_{\text{MAX}} = \frac{F_{\text{PLL}}}{1 - 2 \times \frac{M_D}{100}}
  \]
  
  \[
  F_{\text{MIN}} = F_{\text{MAX}} \times (1 - \frac{M_D}{100})
  \]
  
  \[
  F_C = F_{\text{MAX}} \times (1 - \frac{M_D}{100})
  \]

\text{Figure 50} shows the digital signal generated by Triangular Waveform Generator (TWG block), and the way of MODPER and INCSTEP are changing the triangular waveform.

\text{Refer to section Section 7.7.1: PLL programming procedure for additional information.}

\textbf{7.5.6 System clock (sys\_ck)}

\textbf{System clock selection}

After a system reset, the HSI is selected as system clock and all PLLs are switched OFF. When a clock source is used for the system clock, it is not possible for the software to disable the selected source via the xxxON bits.

Of course, the system clock can be stopped by the hardware when the system enters Stop or Standby mode.

When the system is running, the user application can select the system clock (\texttt{sys\_ck}) among the 4 following sources:

- HSE
- HSI
- CSI
- pll1_p\_ck

This function is controlled by programming the \texttt{RCC clock configuration register (RCC\_CFGR)}. A switch from one clock source to another occurs only if the target clock...
source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source is ready.

The SWS status bits in the RCC clock configuration register (RCC_CFGR) indicate which clock is currently used as system clock. The other status bits in the RCC_CR register indicate which clock(s) is (are) ready.

System clock generation

Figure 51 shows a simplified view of the clock distribution for the CPU and busses. All the dividers shown in the block diagram can be changed on-the-fly without generating timing violations. This feature is a very simple solution to adapt the busses frequencies to the application needs, thus optimizing the power consumption.

The CPRE divider can be used to adjust the CPU clock. However this also impacts the clock frequency of all bus matrix. CPRE is controlled via RCC_CDCFG register.

In the same way, BMPRE divider can be used to adjust the clock for the bus matrix (AHB and AXI), but this also impacts the clock frequency of APB busses. BMPRE is controlled via RCC_BMCFG register.

Most of the prescalers are controlled via RCC_CDCFG and RCC_SRDCFG registers.
Dividers values can be changed on-the-fly. All dividers provide have 50% duty-cycles.

Note that the application must respect the maximum allowed frequencies: \( F_{\text{CPU Max}} \) and \( F_{\text{BUS Max}} \). \( F_{\text{BUS}} \) represents the maximum allowed frequency for the AHB and AXI busses. Refer to the product datasheet for maximum values.

Note as well that the trace clock (\( \text{trace}_{\text{ck}} \)) is generated from \( \text{sys}_{\text{cpu}_{\text{ck}}} \) clock, divided by 3. For additional information refer to Section: Clock distribution for Debug and Trace.
7.5.7 Clock protection

The RCC does not allow to disable the system clock (sys_ck). Several protections are implemented in order to prevent actions disabling accidentally the system clock.

In addition, protection bits are available in order to prevent accidental disabling of FMC and XSPI block activities.

The protections consist on ignoring the invalid write operations. It is recommended to read back registers having protection to insure that the clock configuration expected by the software is accepted by the RCC.

The table hereafter shows the protections handled by the RCC.

<table>

<td>Changing these fields is allowed only if LSEON = 0.</td>
</tr>
</tbody>
</table>

There is also clock protection mechanism in case of HSE failure, refer to Section : CSS on HSE.
Clock generation in Stop and Standby modes

When the whole system enters Stop mode, all the clocks (system and kernel clocks) are stopped and the following clock sources are disabled as well:

- CSI, HSI (depending on HSIKERON, and CSIKERON bits)
- HSE
- PLL1, PLL2 and PLL3
- HS48

The content of the RCC registers is not altered except for PLL1ON, PLL2ON, PLL3ON HSEON and HS48ON that are set to 0.

HSION and CSION bits are also affected depending on STOPWUCK and STOPKERWUCK bits (see Table 63).

When the CPU requested to go in Stop mode, the RCC first stop all the requested clocks, and inform the PWR that all clocks have been properly stopped. As shown in Figure 52, three main signals are used to control power transitions:

- The rcc_pwrds is used to indicate to the PWR that the RCC has stopped all the clocks, and thus the PWR can go to Stop or Standby.
- The pwr_wkup is used to indicate to the RCC to re-enable the clocks.
- The exti_wkup is used to indicate to the PWR that an event requests to exit the system from Stop mode.

Exiting Stop mode

When the microcontroller exits system Stop mode via a wakeup event, the application can select which oscillator (HSI and/or CSI) is used to restart. The STOPWUCK bit selects the oscillator used as system clock. The STOPKERWUCK bit selects the oscillator used as kernel clock for peripherals. The STOPKERWUCK bit is useful if after a system Stop, a peripheral needs a kernel clock generated by an oscillator different from the one used for the system clock.

All these bits belong to the RCC clock configuration register (RCC_CFGR).

Table 63 gives a detailed description of their behavior.
During Stop mode

There are two specific cases where the HSI or CSI can be enabled during system Stop mode:

- when a dedicated peripheral requests the kernel clock
  The peripheral receives the HSI or CSI according to the kernel clock source selected for this peripheral (via PERxSRC).
- when the HSIKERON or CSIKERON bits are set the HSI and CSI are kept running during Stop mode but the outputs are gated. The clock is then available immediately when the system exits Stop mode or when a peripheral requests the kernel clock (see Table 64 for details).

HSIKERON and CSIKERON bits belong to RCC register map. Table 64 gives a detailed description of their behavior.

Table 64. HSIKERON and CSIKERON behavior

<table>
<thead>
<tr>
<th>HSIKERON (CSIKERON)</th>
<th>-</th>
<th>HSI (CSI) state during Stop mode</th>
<th>HSI (CSI) setting time</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>→</td>
<td>OFF</td>
<td>( t_{su(HSI)} ) ( t_{su(CSI)} ) (^{(1)})</td>
</tr>
<tr>
<td>1</td>
<td>→</td>
<td>Running and gated</td>
<td>Immediate</td>
</tr>
</tbody>
</table>

1. \( t_{su(HSI)} \) and \( t_{su(CSI)} \) are the startup times of the HSI and CSI oscillators (refer to the product datasheet for values of these parameters).

When the microcontroller exists Standby mode, the HSI is selected as system and kernel clock. The RCC registers are reset to their initial values except for the RCC_RSR and RCC_BDCR registers.

Note that the HSI and CSI outputs provide two clock paths (see Figure 40):

- one path for the system clock (hsi_ck or csi_ck)
- one path for the peripheral kernel clock (hsi_ker_ck or csi_ker_ck).

When a peripheral requests the kernel clock in system Stop mode, only the path providing the hsi_ker_ck or csi_ker_ck is activated.

Caution: The CPU does not get automatically the same clock frequencies when leaving Stop mode: it is up to the application to restore the previous clock settings if needed.
### 7.5.9 Peripheral clock distribution

Some peripherals are designed to work with two different clock domains that operate asynchronously:

- a clock domain synchronous with the register and bus interface (`ckg_bus_perx` clock)
- a clock domain generally synchronous with the peripheral (kernel clock)

The benefit of having peripherals supporting these two clock domains is that the user application has more freedom to choose optimized clock frequency for the CPU, bus matrix and for the kernel part of the peripheral.

As a consequence, the user application can change the bus frequency without reprogramming the peripherals. As an example an on-going transfer with UART is not disturbed if its APB clock is changed on-the-fly.

*Table 65* shows the clocks the RCC delivers to the peripherals. Note as well that the clock named `per_ck`, is the output of a mux which allows the application to select:

- `hsi_ker_ck`, or
- `csi_ker_ck`, or
- `hse_ker_ck`

</table>
Figure 53 to Figure 68 provide a more detailed description of kernel clock distribution. Refer to Section 7.5.12: Peripheral clock gating control for more details.

To reduce the amount of switches, some peripherals share the same kernel clock source. Nevertheless, all peripherals have their dedicated enable signal.

**Clock distribution for ADF, SAIs, and SPDIFRX**

The audio peripherals generally need specific accurate frequencies, except for SPDIFRX. As shown in Figure 53 and Figure 56, the kernel clock of the SAIs or SPI(I2S)s can be generated by:

- PLL1 when the amount of active PLLs must be reduced (for SAIs and SPI/I2S1 to 3)
- APB2 peripheral clock (for SPI/I2S4 and 5)
- APB4 peripheral clock (for SPI/I2S6)
- PLL2 or 3 for optimal flexibility in frequency generation
- HSE, HSI or CSI for use-cases where the current consumption is critical
- I2S_CKIN when an external clock reference needs to be used
The SPDIFRX does not require a specific kernel clock frequency but only a frequency high enough to sample properly the incoming stream. Refer to the SPDIFRX description for more details.

The SPDIFRX also provides a symbol clock (spdifrx_symb_ck) which is 64 times faster than the received samples. The symbol clock is proposed as kernel clock for SAI2 in order to ease bridging from SPDIFRX to SAI2.

The audio blocks also have common kernel clocks in order to ease data exchange.

The ADF can work even in Stop mode as long as the bus clock is not requested. Working in Stop mode is possible only if the application selected csi_ker_ck or hsi_ker_ck as kernel clock sources. The ADF asserts the adf_ker_ckreq when the kernel clock is requested.

The kernel clock mechanism works only if the kernel clock source is provided by an RC oscillator (hsi_ker_ck or csi_ker_ck).
1. **X** represents the selected mux input after a system reset.

**Clock distribution for SPIs, SPI/I2Ss**

SPI peripherals do not need an accurate kernel clock frequency but a clock fast enough for the serial interface. The SPI/I2S peripherals may request accurate kernel clock frequency when using the I2S function. For that purpose the source can be selected among the following ones:

- The bus clock (for SPIs)
- PLL1 when the amount of active PLLs must be reduced
- PLL2 or PLL3 if better flexibility is required. As an example, this solution allows changing the frequency bus via PLL1 without affecting the speed of some serial interfaces.
- HSI or CSI or per_ck for low-power use-cases.
The SPI/I2S also have common kernel clocks with audio blocks in order to ease data exchange.

Figure 54. Clock distribution for SPIs and SPI/I2S

1. X represents the selected switch input after a system reset.

Clock distribution for I2C[3:2], and I2C1/I3C1

I2Cs and I3C1 peripherals do not need an accurate kernel clock frequency but a clock fast enough to handle properly the serial interface. The following kernel clock sources are proposed:

- The bus clock
- PLL3 in the case were the bus clock cannot be used
- HSI or CSI for low-power use-cases

The I2Cs and I3C1 can work even in Stop mode as long as the bus clock is not requested. Working in Stop mode is possible only if the application selected csi_ker_ck or hsi_ker_ck as kernel clock sources. The I2Cs and I3C1 assert the i2c_ker_ckreq or i3c_ker_ckreq signals, when the kernel clock is requested.
The kernel clock mechanism works only if the kernel clock source is provided by an RC oscillator (hsi_ker_ck or csi_ker_ck).

Figure 55. Clock distribution for I2C[3:2] and I2C1/I3C1

1. X represents the selected switch input after a system reset
Clock distribution for UARTs and USARTs

UARTs need kernel clock frequency allowing the adjustment of the baud rate with an acceptable accuracy (generally less than +/−2%). For that purpose the source can be selected among the following ones:

- The bus clock
- PLL3 in the case were the bus clock cannot be used
- HSI, CSI or LSE for low-power use-cases

The UARTs can work even in Stop mode as long as the bus clock is not requested. Working in Stop mode is possible only if the application selected csi_ker_ck or hsi_ker_ck as kernel clock sources. The UARTs assert the uartx_ker_ckreq signal, when the kernel clock is requested. The kernel clock mechanism works only if the kernel clock source is provided by an RC oscillator (hsi_ker_ck or csi_ker_ck).

UARTs can also work in Stop mode using the LSE clock when high baud rates are not required.

Figure 56. Clock distribution for UARTs, LPUART1 and USARTs

1. X represents the selected switch input after a system reset.
Clock distribution for FDCAN

The switch is dynamic: the transition between two inputs is glitch-free.

1. X represents the selected switch input after a system reset.
Clock distribution for graphic blocks (GPU2D, LTDC, DCMIPP and PSSI)

Figure 58. Clock distribution for GPU2D

1. X represents the selected switch input after a system reset.

Figure 59. Clock distribution for LTDC and DCMIPP

1. X represents the selected switch input after a system reset.

The PSSI receives an AHB clock and a kernel clock (pxclk).

The pxclk can be provided either by an external device via PSSI_PIXCK pad, or by the RCC. Note that the clock generated by the RCC is provided to pxclk input by the feedback path of the PSSI_PIXCK pad. The drive of the PSSI_PIXCK is controlled by the PSSI block.
Clock distribution for SDMMCs, FMC, and XSPIs

The FMC kernel clock can be chosen between 4 different sources, giving good flexibility.

For each XSPI, a clock switch allows the selection between 3 different sources, giving good flexibility. It is possible to enable independently each XSPI block.

The switches FMCSEL, XSPI[2:1]SEL, also embeds several protections:

- In case of HSE failure detected by the HSECSS function, the XSPI[2:1]SEL switches and the FMCSEL switch go to recovery position in order to provide a default clock.
- A protection bit: FMCKP prevents the application to accidentally change the FMCSEL value. Refer to Section 7.5.7: Clock protection for details.
- A protection bit: XSPICKP prevents the application to accidentally change the XSPI[2:1]SEL values. Refer to Section 7.5.7: Clock protection for details.
- Status fields (FMCSWP, XSPI[2:1]SWP) located into RCC clock protection register (RCC_CKPROTR) allows the application to check the effective position of the switches.
- If one of the switch is selecting an input with an invalid clock, the switch outputs a recovery clock preventing a memory crash and allowing the application to log or correct the issue. The RCC provides hclk5/4 as recovery clock. In order to work fine, the
application must ensure that the recovery clock frequency is supported by the external device.

- For the XSPI[2:1]SEL switches:
  - Going to position 1 is allowed if PLL2ON = PLL2SEN = 1. If the application switches to position 1 when these conditions are not met, the switch generates the recovery clock.
  - Going to position 2 is allowed if PLL2ON = PLL2TEN = 1. If the application switches to position 2 when these conditions are not met, the switch generates the recovery clock.

- For the FMCSEL switch:
  - Going to position 1 is allowed if PLL1ON = PLL1QEN = 1. If the application switches to position 1 when these conditions are not met, the switch generates the recovery clock.
  - Going to position 2 is allowed if PLL2ON = PLL2REN = 1. If the application switches to position 2 when these conditions are not met, the switch generates the recovery clock.
  - Going to position 3 is allowed if HSION = 1. If the application switches to position 3 when this condition is not met, the switch generates the recovery clock.

How to handle properly XSPI switches:

- Switch on the wanted clock source,
- Ensure the clock source is ready, and conditions described above are met,
- Set XSPI1SEL to the wanted position,
- Enable the XSPI clock (XSPIxEN = 1),
- Read XSPIISWP field from RCC_CKPROTR register,
- If the position given by XSPIISWP is the same as the wanted, it means that the XSPIx kernel clock is as expected.
- If the position given by XSPIISWP is 000, it means that there is no clock present at the selected input.

The XSPIs must provide a clock to the external memory, with a duty cycle distortion generally lower than 5%. In order to reach this requirement, the kernel clock provided to the XSPIs has a typical duty cycle of 50%. In addition, the XSPIs embed prescaler allowing clock division by even ratios.
1. \( \times \) represents the selected switch input after a system reset.

The SDMMC1 and SDMMC2 share the same kernel clock. A clock switch allows the selection between 2 different sources. It is possible to enable independently each SDMMC block. Note that when one of the SDMMC is enabled via its SDMMC[2:1]EN bit, the associated delay block is enabled as well.

The application must take care about the duty-cycle of the kernel clock provided to the SDMMC blocks.

### Table 66. SDMMC interface clock constraints

<table>
<thead>
<tr>
<th>SDMMC mode</th>
<th>Mode name</th>
<th>Interface clock frequency</th>
<th>Duty cycle constraint</th>
</tr>
</thead>
<tbody>
<tr>
<td>SDIO</td>
<td>SDR12</td>
<td>25 MHz or less</td>
<td>30 - 70%</td>
</tr>
<tr>
<td></td>
<td>SDR25</td>
<td>50 MHz or less</td>
<td>30 - 70%</td>
</tr>
<tr>

<td>45 - 55%</td>
</tr>
<tr>
<td></td>
<td>SDR50</td>
<td>100 MHz or less</td>
<td>30 - 70%</td>
</tr>
</tbody>
</table>
For example, if the SDMMC works in SDR50, then a kernel clock of 50 MHz, with a duty cycle better than 30-70% is enough. If the SDMMC works in DDR50, then it is recommended to provide a kernel clock of 100 MHz, and divide the frequency of the kernel clock by two, using the SDMMC divider in order to insure a duty-cycle very close to 50% for the SDMMC_CK.

Figure 62. Clock distribution for SDMMC[2:1] and DB_SDMMC[2:1]

1. X represents the selected switch input after a system reset.
Clock distribution for OTGFS, OTGHS and UCPD

*Figure 63* shows the clock distribution for the USB blocks.

- The USB type-C power delivery block (UCPD), uses ucpd_ker_ck as kernel clock. The ucpd_ker_ck is directly generated from the HSI output divided by 4.
- The USBPHYC, embeds a PLL accepting a reference input frequency of 16, 19.2, 20, 24, 26 or 32 MHz. The reference clock can be selected among:
  - hse.osc_ck
  - hse.ker_ck/2 or
  - pll3_q_ck

  The USBPHYC provides a 60 MHz clock to the OTGHS block, and a 48 MHz clock to the OTGFS block. The clock hse.osc_ck is the direct output of the HSE oscillator.

- The OTGHS receives the 60 MHz clock from the USBPHYC (phy60m_ck), when working in HS or FS mode.
- The OTGFS receives a 48 MHz clock. The application can select:
  - the clk48mohci (from USBPHYC)
  - the hsi48_ker_ck for crystal-less applications
  - hse.ker_ck or
  - pll3_q_ck

The selection of the reference clock for the USBPHYC is performed by a simple MUX. In order to change the clock source, the application must follow the sequence hereafter:

- Disable the USBPHYC clock by setting USBPHYCEN to 0
- Change the clock source selector (USBPHYCSEL) to the wanted value
- Enable the USBPHYC clock by setting USBPHYCEN to 1.
Figure 63. Clock distribution for USB and UCPD

1. \( \times \) represents the selected switch input after a system reset.
Clock distribution for ETH1

The Ethernet clocks provided by the RCC are available on ETH_CLK pad. The application can select if the ETH_CLK is generated from the HSE kernel clock or from the pll3_s_ck.

The RCC also provides the bus clock and the reference clock for the PTP function.

Note that the bus and PTP clocks generation are controlled via ETH1MACEN and ETH1MACLPEN bits.

Figure 64. Clock distribution for ETH1

1. \( X \) represents the selected switch input after a system reset.

The signal ETH_SEL is provided by the SBS block and defines the interface type used:

In MII mode (orange path):
- The transmit clock is received from the external PHY via the pad ETH_MII_TX_CLK.
- The receive clock is received from the external PHY via the pad ETH_MII_RX_CLK.
- The clock frequency is 2.5 MHz for Ethernet at 10 Mbps or 25 MHz for Ethernet at 100 Mbps.
In RMII mode (blue path):

- The reference clock (50 MHz) can be selected between several sources:
  - The ETH_RMII_REF_CLK pad, if the reference clock is provided by the PHY
  - The hse_ker_clk in case the Ethernet PHY is providing a reference clock connected to OSC_IN
  - The ETH_CLK feedback clock (eth_clk_fb) if the RCC is providing the reference clock to the PHY. This selection is controlled via ETH1REFCKSEL[1:0].

- The ETH_SEL must be set to 1,
  - a clock must be provided to clk_rx_i and clk_tx_i inputs
  - The clock frequency at clk_rx_i and clk_tx_i inputs is 2.5 MHz (division by 20) for Ethernet at 10 Mbps, and 25 MHz (division by 2) for Ethernet at 100 Mbps.
  - The transmit and receive clock frequency can be adjusted dynamically to 2.5 or 25 MHz according to the signal mac_speed_o[0] provided by the ETH block.

Note that the ETH1REFCKSEL mux position cannot be changed when a clock is provided to the ETH1 block. In order to select the wanted mux position the following sequence must be respected:

- Set bits ETH1TXEN, ETH1RXEN and ETH1MACEN to 0,
- Set ETH1REFCKSEL to the wanted position,
- Set bits ETH1TXEN, ETH1RXEN and ETH1MACEN to 1

The RCC can generate a reference clock of 25 or 50 MHz to the external PHY, via ETH_CLK pad. The figure hereafter shows the possible clock configurations.

The ETH_CLK is generated only if:

- ETH1TXEN or ETH1RXEN are enabled, and
- the system is in Run or Sleep, and
- the clock source selected by ETH1PHYCKSEL is available.

The bits ETH1REFCKSEL[1:0] and ETH1PHYCKSEL are located into the RCC AHB peripheral kernel clock selection register (RCC_CCIPR1).

**Figure 65. ETH clock configuration**

![Figure 65. ETH clock configuration](image)

The ETH1 block provides information on the MAC speed (mac_speed_o[1:0]), which may change dynamically:

- mac_speed_o[1:0] = 0b10: for 10 Mbps
- mac_speed_o[1:0] = 0b11 or 0b0x: for 100 Mbps
Clock distribution for ADC1-2

Figure 66. Clock distribution For ADCs

1. \( X \) represents the selected switch input after a system reset.

Clock distribution for SAES and RNG

Figure 67. Clock distribution for SAES and RNG

1. \( X \) represents the selected switch input after a system reset.

The RNG block is using the hsi48_ker_ck as kernel clock. The logic handling controlling the clock of the RNG is different from standard peripherals. When enabled, the RNG has to assert its kernel clock request, in order to get a kernel clock. For example, if the SAES needs the RNG resource, the RNG must also be enabled. Refer to Section 7.5.12: Peripheral clock gating control for details.
Clock distribution for HDMI-CEC

Figure 68. Clock distribution for HDMI-CEC

1. X represents the selected switch input after a system reset

Clock distribution for TIM and LPTIM

The TIMs timers are using kernel clocks (tim_ker_ck) phase aligned with the bus interface clock.

The working frequency of the timers clock depends on:
- The APB prescaler corresponding to the bus where the timer is connected, and
- The bit TIMPRE

Figure 69. Clock distribution for TIMs

1. X represents the selected switch input after a system reset
2. Can be changed on the fly
The Table 67 shows how to select the timer clock frequency.

</tr>
</tbody>
</table>

1. PPRE1 and PPRE2 are the prescaler for the APB1 and APB2 clocks.
2. TIMPRE belongs to RCC clock configuration register (RCC_CFGR).

The LPTIMs timers have a kernel clocks fully asynchronous with respect to their bus interface clock. The kernel clock can be selected among up to 6 clock sources.

The LPTIMs also use lse_ck and lsi_ck as kernel clock, allowing them to work even when the system is in Stop mode.
Figure 70. Clock distribution for LPTIMs

The switch is dynamic: the transition between two inputs is glitch-free.

The **rtc_ck** clock source can be one of the following:

- the **hse_rtc_ck** (**hse_ker_ck** divided by a programmable prescaler)
- the **lse_ck**
- the **lsi_ck** clock

The source clock is selected by programming the RTCSEL[1:0] bits in the **RCC Backup domain control register (RCC_BDCR)** and the RTCPRE[5:0] bits in the **RCC clock configuration register (RCC_CFGR)**.

This selection cannot be modified without resetting the Backup domain.
1. X represents the selected switch input after a system reset

If the LSE is selected as RTC clock, the RTC works normally even if the backup or the V_DD supply disappears.

The LSE clock is in the Backup domain, whereas the other oscillators are not. As a consequence:

- If LSE is selected as RTC clock, the RTC continues working even if the V_DD supply is switched OFF, provided the V_BAT supply is maintained.
- If LSI is selected as the RTC clock, the AWU state is not guaranteed if the V_DD supply is powered off.
- If the HSE clock is used as RTC clock, the RTC state is not guaranteed if the V_DD supply is powered off or if the V_CORE supply is powered off. In addition the HSE is not available if the system goes to Stop.

The rtc_ck clock is enabled through RTCEN bit located in the RCC Backup domain control register (RCC_BDCR).

The RTC bus interface clock (APB clock) is enabled through RTCAPBEN and RTCAPBLPEN bits located in RCC_APB4ENR/LPENR registers.

**Note:** To read the RTC calendar register when the APB clock frequency is less than seven times the RTC clock frequency (F_APB < 7 x F_RTCLOCK), the software must read the calendar time and date registers twice. The data are correct if the second read access to RTC_TR gives the same result than the first one. Otherwise a third read access must be performed.

**Clock distribution for watchdog**

The RCC provides the clock for the two watchdog blocks available on the circuit. The independent watchdog (IWDG) is connected to the LSI. The window watchdog (WWWDG) is connected to the APB clock.

If an independent watchdog is started by either hardware option or software access, the LSI is forced ON and cannot be disabled. After the LSI oscillator setup delay, the clock is provided to the IWDG.

The window watchdog clock (pclk1) can be enabled by setting the WWWDGEN bit in RCC_APB1ENR register. The software cannot stop WWWDG down-counting by setting WWWDGEN bit to ‘0’.
The WWDG block is frozen when the MCU goes to Stop mode.

**Figure 72. Clock distribution for WWDG and IWDG**

![Clock distribution diagram](image)

1. X represents the selected switch input after a system reset

**Clock distribution for Debug and Trace**

The clock generation for the trace and debug is controlled by the DBGMCU block. The DBGCKEN bit allows the application to provide a clock to the debug components. It is also possible to enable this clock via the Debug Access Port.

The trace clock generation is controlled via TRACECKEN bit.

**Figure 73. Clock distribution for DBG and trace**

![Clock distribution diagram](image)

1. X represents the selected switch input after a system reset

**Clock frequency measurement using TIMx**

Most of the clock source generator frequencies can be measured by means of the input capture of TIMx.

- Calibrating the HSI or CSI with the LSE:

The primary purpose of having the LSE connected to a TIMx input capture is to be able to accurately measure the HSI or CSI. This requires to use the HSI or CSI as system clock source either directly or via PLL1. The number of system clock counts between...
consecutive edges of the LSE signal gives a measurement of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm) we can determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process and/or temperature- and voltage-related frequency deviations.

The basic concept consists in providing a relative measurement (e.g. HSI/LSE ratio). The precision is therefore tightly linked to the ratio between the two clock sources. The greater the ratio is, the more accurate the measurement is.

The HSI and CSI oscillators have dedicated user-accessible calibration bits for this purpose (see **RCC CSI calibration register (RCC_CSICFGR)**). When HSI or CSI is used via the PLLx, the system clock can also be fine-tuned by using the fractional divider of the PLLs.

- Calibrating the LSI with the HSI:

  The LSI frequency can also be measured: this is useful for applications that do not have a crystal. The ultra-low-power LSI oscillator has a large manufacturing process deviation. The LSI clock frequency can be measured using the more precise HSI clock source. Using this measurement, a more accurate RTC time base timeouts (when LSI is used as the RTC clock source) and/or an IWDG timeout with an acceptable accuracy can be obtained.

### 7.5.10 General clock concept overview

The RCC handles the distribution of the CPU, bus interface and peripheral clocks for the system, according to the CPU operating mode (refer to **Section 7.5.1: Clock naming convention** for details on clock definitions).

For each peripheral, the application can control the activation/deactivation of its kernel and bus interface clock. Prior to use a peripheral, the CPU must enable it (by setting PERxEN to 1), and define if this peripheral remains active in Sleep mode (by setting PERxLPEN to 1). This is called ‘allocation’ of a peripheral by the CPU (refer to **Section 7.5.11: Peripheral allocation** for more details).

The peripheral allocation is used:
- by the RCC to automatically control the clock gating according to the CPU modes, and
- by the PWR to control the supply voltages of VCORE.

#### Memory handling

The CPU can access all the memory areas available in the product:

- AXISRAM1, AXISRAM2, AXISRAM3, AXISRAM4, ITCM, DTCM1, DTCM2 and FLASH
- AHBSRAM1 and AHBSRAM2
- BKPRAM

The BKPRAM, AHBSRAM1 and AHBSRAM2 have dedicated enable bits in order to gate the bus interface clock. The CPU needs to enable them prior to use these memories.

*Note:* The memory interface clocks (Flash memory and RAM interfaces) can be stopped by software during Sleep mode (via SRAMyLPEN bits).

Refer to **Section 7.5.12: Peripheral clock gating control** and **Section 7.5.13: CPU and bus matrix clock gating control** sections for details on clock enabling.
7.5.11 Peripheral allocation

The CPU can allocate a peripheral and hence control its kernel and bus interface clock.

The CPU can allocate a peripheral by setting the dedicated PERxEN bit to 1.

The CPU can control the peripheral clocks gating when it is in Sleep mode via the PERxLPEN bits.

Refer to for additional information.

The peripheral allocation bits (PERxEN bits) are used by the hardware to provide the kernel and bus interface clocks to the peripherals. However they are also used to link peripherals to the CPU. In this way, the hardware is able to safely gate the peripheral clocks and bus matrix clocks according to CPU states.

Clock switches and gating

- Clock switching delays

  The input selected by the clock switches can be changed dynamically without generating spurs or timing violation. For example, if PERxSEL (in Figure 74) goes from 0 to 1, the switch first disables the clock output using the currently selected clock (in0_ck), and enables again the clock output using the new selected clock (in1_ck). The disable and enable commands are re-synchronized to their respective clocks. If one of the two clocks are not present, the sequence cannot be completed, and no clock is output. To recover from this situation, the user must either provide a valid clock to in1_ck input or set back PERxSEL to 0.

  During the transition from one input to another, the kernel clock provided to the peripheral is gated, in the worst case, during 2 or 3 clock cycles of the new selected clock. As shown in Figure 74, both input clocks must be present during transition time.

- Clock enabling delays

  In the same way, the clock gating logic synchronizes the enable command (coming generally from a kernel clock request or PERxEN bits) with the selected clock, in order to avoid generation of spurs.

  - A maximum delay of two periods of the enabled clock may occur between the enable command and the first rising edge of the clock. The enable command can
be the rising edge of the PERxEN bits of RCC_xxxxENR registers, or a kernel clock request asserted by a peripheral.

– A maximum delay of 1.5 periods of the disabled clock may occur between the disable command and the last falling edge of the clock. The disable command can be the falling edge of the PERxEN bits of RCC_xxxxENR registers, or a kernel clock request released by a peripheral.

Note: Both the kernel and bus interface clocks are affected by this re-synchronization delay.

7.5.12 Peripheral clock gating control

As mentioned previously, each peripheral requires one or several bus interface clock, named rcc_perx_bus_ck (for peripheral ‘x’). These clocks can be an APB, AHB or AXI clock, according to which bus or busses, the peripheral is connected.

The clocks used as bus interface for peripherals, can be aclk, hclk[5:1], pclk[5:4], or pclk[2:1], depending on the bus connected to each peripheral.

Some peripherals also require dedicated clocks for their communication interface. These clocks are generally asynchronous with respect to the bus interface clock. They are named kernel clocks (perx_ker_ck). Both bus interface and kernel clocks can be gated according to several conditions detailed hereafter.

As shown in Figure 75, enabling the kernel and bus interface clocks of each peripheral depends on several input signals:

- PERxEN and PERxLPEN bits,
  PERxEN represents the peripheral enable (allocation) bit for the CPU. The CPU can write these bits to 1 via the RCC_xxxxENR registers.
- CPU state (cpu_sleep and cpu_deepsleep signals)
- Kernel clock request (perx_ker_ckreq) of the peripheral itself, when the feature is available

Refer to Section 7.5.11: Peripheral allocation for more details.

Figure 75. Peripheral kernel clock enable logic details
Table 68 gives a detailed description of the enabling logic of the peripheral clocks for peripherals located in the CPU domain and allocated by the CPU.

Table 68. Peripheral clock enabling

</tbody>
</table>

As a summary, we can state that the kernel clock is provided to the peripherals when the following conditions are met:
1. The CPU is in Run mode, and the peripheral is enabled.
2. The CPU is in Sleep mode and the peripheral is enabled with PERxLPEN = 1.
3. The CPU is in Stop mode, the peripheral is enabled with PERxLPEN = 1, the peripheral generates a kernel clock request and the selected clock is hsi_ker_ck or csi_ker_ck.
4. The CPU is in Stop mode, the peripheral is enabled with PERxLPEN = 1 and the kernel source clock of the peripheral is lse_ck or lsi_ck.

The bus interface clock is provided to the peripherals only when conditions 1 or 2 are met.
The RNG block is not clocked as other peripherals, the table hereafter shows the way RNG is clocked.

7.5.13  CPU and bus matrix clock gating control

The clocks of the CPU, AHB and AXI bridges and APB busses are enabled according to the rules hereafter:

- The CPU clock (rcc_cpu_ck) is enabled when the CPU is in Run or Sleep mode.
- The AXI bridge clock is enabled when the CPU is in Run or Sleep mode.
- Each AXI master and slave has an independent clock gating activated by default, to further reduce the power consumption. When activated the clock is automatically enabled on bus transaction request. The RCC AXI clocks gating disable register (RCC_CKGDISR) allows the application to control this behavior.
- The AHB bus matrix clock is enabled if one of the following conditions is met:
  - The CPU is in Run mode
  - The CPU is in Sleep mode, and at least one peripheral connected to this bridge have both its PERxEN and PERxLPEN set to 1.
  - The CPU is in Sleep mode, and AHB1, AHB2, AHB3, AHB4 or AHB5 has its clock enabled
- The clocks of the bridges AHB1, 2, 3, 4, 5 are enabled when one of the following conditions is met:
  - The CPU is in Run mode.
  - The CPU is in Sleep mode with at least one peripheral connected to this bus having both its PERxEN and PERxLPEN set to 1.
  - The CPU is in Sleep mode and the APB bus connected to the AHB bridge has its clock enabled.
- The APB1, 2, 4, 5 clock busses are enabled when one of the following conditions is met:
  - The CPU is in Run mode.
  - When the CPU is in Sleep mode with at least one peripheral connected to this bus having both its PERxEN and PERxLPEN set to 1.
7.5.14 Low-power emulation modes

In order to ease the debugging of the circuit, the RCC is able to handle an emulation mode for Stop and Standby modes.

Sleep emulation mode

The Sleep emulation mode is controlled by the DBG_SLEEP bit of the DBGMCU_CR register. When the processor goes to Sleep with DBG_SLEEP = 1, then the processor clock, the clocks of all enabled peripherals, debug parts, and interconnect are maintained activated.

Stop emulation mode

The Stop emulation mode is controlled by the DBG_STOP bit of DBGMCU_CR register. When the processor goes to Stop with DBG_STOP = 1, then:

- The PWR and the RCC remains activated.
- The VDDCORE voltage is set to the minimum VOS value.
- The RCC selects HSI or CSI as system clock, depending on STOPWUCK bit.
- The processor clock is gated (rcc_cpu_ck, see Figure 51),
- The free-running clock is generated (rcc_fclk, see Figure 51), and all the debug parts remain clocked.
- All peripheral clocks are gated. Peripherals can still receive a kernel clock if they request it, and if the kernel clock source is an RC oscillator. They also receive the kernel clock if the kernel clock source is LSI or LSE.
- The interconnect clocks are gated.

When a wakeup event occurs:

- The VDDCORE voltage remains to the minimum VOS value.
- The peripheral waking up the system sends the interrupt to the NVIC via the EXTI.
- The CPU exits from STOP and the RCC provide the processor clock and interconnect clocks.

Standby emulation mode

The Standby emulation mode is controlled by the DBG_STANDBY bit of the DBGMCU_CR register.

When the system goes to Standby with DBG_STANDBY = ‘1’, then:

- The VDDCORE voltage is not switched-off, but remains to the minimum VOS value.
- All the VDDCORE domain is under reset except the debug part.
- The debug part is clocked.
- Peripherals on VBat or VDD domains are not reset.

When the system exits from Standby, then:

- Option bytes are reloaded.
- The reset of the VDDCORE domain is released.
- The Standby flag is updated as well.
7.6 RCC interrupts

The RCC provides three interrupt lines:

- **rcc_it**: general interrupt line providing events when the PLLs are ready or when the oscillators are ready
- **rcc_hsecss_it**: interrupt line dedicated to the failure detection of the HSE CSS (clock security system)
- **rcc_lsecss_it**: interrupt line dedicated to the failure detection of the LSE CSS

The interrupt enable is controlled via **RCC clock source interrupt enable register** (*RCC_CIER*), except for the HSE CSS failure. When the HSE CSS feature is enabled, it is not possible to mask the interrupt generation.

The interrupt flags can be checked via **RCC clock source interrupt flag register** (*RCC_CIFR*), and these flags can be cleared via **RCC clock source interrupt clear register** (*RCC_CICR*).

**Note:** The interrupt flags are not relevant if the corresponding interrupt enable bit is not set.

**Table 70** gives a summary of the interrupt sources and the way to control them.

</tr>
</tbody>
</table>

1. The security system feature must also be enabled (LSECSSON = 1), in order to generate interrupts.
2. It is not possible to mask this interrupt when the security system feature is enabled (HSECSSON = 1).
7.7 RCC Programming examples

7.7.1 PLL programming procedure

PLL initialization procedure

The recommended initialization sequence of the PLLs for the integer and fractional mode is given hereafter:

- The PLL is supposed to be disabled: PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN, PLLxTEN, PLLxON, and PLLxRDY set to '0', if it is not the case, refer to PLL disabling procedure.
- Enable the wanted clock source (HSE, HSI, or CSI) and wait for the ready flag.
- Select the clock source via PLLSCR into RCC PLLs clock source selection register (RCC_PLLCKSELR).
- Initialize the pre-dividers (DIVMx) in order to provide to the PLL, a valid reference clock. DIVMx are located into RCC PLLs clock source selection register (RCC_PLLCKSELR).
- Configure the PLL:
  - In integer or clock spreading mode the application must ensure that a 0 is loaded into the SDM. This can be done as follows:
    - Set PLLxFRACLE to 0
    - Write FRACN to 0
    - Set PLLxFRACLE to 1
    - Write FRACN to 0
    - Wait at least 5 µs
  - In fractional mode, the application must load the SDM with the wanted value (FracInitValue) by executing a sequence similar to the integer mode, but with FRACN = FracInitValue.
    - Program the fields PLLxRGE, PLLxVCOSEL, SSCG_CTRL, DIVxN, DIVxP, DIVxQ, DIVxR, DIV2S and DIV2T.
    - If the clock spreading mode is used, program also the fields MODPER, INCSTEP, SPREADSEL, TPDFNDIS, RPDFNDIS, and set PLLxSSCGEN to 1.
    - If the clock spreading mode is not used, set PLLxSSCGEN to 0.
  - Enable the PLL:
    - Set the corresponding PLLxON bit to 1, and wait for PLLxRDY bit set to 1.
    - If the PLL is in fractional mode, the FRACLE bit must not be set back to 0 as long as PLLxRDY = 0.
  - When the PLLxRDY bit is equal to 1, the application can enable the wanted outputs by setting PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN, PLLxTEN to 1.
  - If the application intends to tune the PLL frequency on-the-fly (only possible in fractional mode), then:
    - Set PLLxFRACLE to ‘0’,
      When FRACLE = ‘0’, the sigma delta modulator is still operating with the current value,
    - Write the new value into FRACN[12:0] (FracValue(n)),
    - Set PLLxFRACLE to 1, in order to latch the content of FRACN[12:0] into the SDM.
– Wait at least 5 µs.

**Note:** When the PLLxRDY goes to 1, it means that the PLLx output frequency is within 2% of its target value.

### Reprogramming post-dividers

When the PLLs are enabled, it is possible to change the values of a post-dividers (DIVP, DIVQ, DIVR, DIVS or DIVT) without disabling the corresponding PLLx, by performing the following sequence:

- Disable the wanted output by setting the bit PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN or PLLxTEN to 0,
- Change the value of the corresponding post-divider (DIVP, DIVQ, DIVR, DIVS or DIVT),
- Re-enable this output by setting the bit PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN or PLLxTEN to 1.

### PLL disabling procedure

The recommended disabling sequence is given hereafter:

- Disable all the post-dividers by setting PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN and PLLxTEN bits of PLLx to 0,
- Disable the PLL: set PLLxON bit of PLLx to 0,
- Wait for PLLxRDY = 0.

### Using the SSCG block

For example, if an application needs to generate with the PLL2, a clock signal having the following characteristics:

- A frequency at DIVS output \((F_{pll2\_s\_ck})\) of 200 MHz Max,
- With a modulation depth of 0.5% peak \((M_D)\),
- With a frequency modulation of 28 kHz \((F_{MOD})\).

The assumption is that the crystal oscillator is 8 MHz \((F_{hse\_ck})\).

DIVM2 is programmed to 0 in order to provide a reference clock of 8 MHz to the PLL2 \((F_{ref2\_ck})\). The VCOH must be selected when SSCG is used.

From a 8 MHz reference clock, it is possible to generate 200 MHz, by programming the PLL2 as follow: \((DIVN+1) = 50\), \((F_{vco} = 800\text{ MHz})\), \((DIVS+1) = 4\).

The application has to compute the following parameters:

**Computing MODPER:**

\[
MODPER = \text{ROUND}\left(\frac{F_{ref\_ck}}{4 \times F_{MOD}}\right) = \text{ROUND}\left(\frac{8 \times 10^6}{4 \times 28 \times 10^3}\right) = 71
\]

**Computing INCSTEP:**

\[
\text{INCSTEP} = \text{ROUND}\left(\frac{(2^{15} - 1) \times M_D \times (DIVN + 1)}{100 \times 5 \times \text{MODPER}}\right) = \text{ROUND}\left(\frac{32767 \times 0.5 \times (49 + 1)}{100 \times 5 \times 71}\right) = 23
\]
Check that $\text{MODPER} \times \text{INCSTEP}$ is lower than $2^{15} - 1$.

In the example, $\text{MODPER} \times \text{INCSTEP} = 1633 \Rightarrow \text{OK}$

Due to rounding operations, the modulation period and the modulation depth does not completely match the target. The real modulation depth is:

$$M_D(\%) = \frac{\text{MODPER} \times \text{INCSTEP} \times 100 \times 5}{(2^{15} - 1) \times (\text{DIVN} + 1)} = \frac{71 \times 23 \times 100 \times 5}{(2^{15} - 1) \times (49 + 1)} = 0.498 \%$$

And the modulation frequency ($F_{\text{mod}}$) is:

$$F_{\text{mod}} = \frac{F_{\text{ck_ref}}}{4 \times \text{MODPER}} = \frac{8 \times 10^6}{4 \times 80} = 28.2 \text{ kHz}$$

The down-spread modulation must be used ($\text{SPREADSEL} = 1$) to keep the maximum frequency to a value lower than 200 MHz.

### 7.7.2 Frequency configuration examples

This section gives various frequency settings for CPU and XSPI interfaces, combined with audio constraints. The case without audio constraints is not shown as it is obvious that PLL1 and PLL2 can provide the expected frequency. If audio applications are required, several options are offered to the user:

- Generate the kernel clock with PLL1, PLL2 or PLL3
- Use the external audio clock input (I2S_CKIN)
- Use oscillators

In this section, we explore the cases where PLL1 or PLL2 are used for audio.

Note as well that PLL2 is also used for XSPIs, if it is shared for audio application, it is not recommended to activate the SSCG.

The configurations listed in the tables hereafter are not exhaustive, many other setting are available. For example if the clock provided to the SAI must be shared with FDCAN, then the application would like to generate a clock around 100 MHz to insure good working conditions for FDCAN. These considerations are not taken into account in these tables.

Note also that in order to get the best clock quality at PLL output, $F_{\text{REF}}$ must be as close as possible to 16 MHz. This is not always easy to do for PLLs in integer mode, but can be done easily when the PLLs are in fractional mode (as shown in the tables).

</tr>
<tr>
<td></td>
<td>0: PLL1 unlocked (default after reset)</td>
</tr>
<tr>
<td></td>
<td>1: PLL1 locked</td>
</tr>
</tbody>
</table>
Bit 24 **PLL1ON**: PLL1 enable
Set and cleared by software to enable PLL1.
Cleared by hardware when entering Stop or Standby mode. Note that the hardware prevents writing this bit to 0, if the PLL1 output is used as the system clock (SW=3) or if FMCKP = 1, or if XSPICKP = 1.
0: PLL1 OFF (default after reset)
1: PLL1 ON

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **HSECSSON**: HSE clock security system enable
Set by software to enable clock security system on HSE.
This bit is "set only" (disabled by a system reset or when the system enters in Standby mode).
When HSECSSON is set, the clock detector is enabled by hardware when the HSE is ready and disabled by hardware if an oscillator failure is detected.
0: CSS on HSE OFF (clock detector OFF) (default after reset)
1: CSS on HSE ON (clock detector ON if the HSE oscillator is stable, OFF if not).

Bit 19 **HSEEXT**: external high speed clock type in Bypass mode
Set and reset by software to select the external clock type (analog or digital).
The external clock must be enabled with the HSEON bit to be used by the device.
The HSEEXT bit can be written only if the HSE oscillator is disabled.
0: HSE in analog mode (default after reset)
1: HSE in digital mode

Bit 18 **HSEBYP**: HSE clock bypass
Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit to be used by the device.
The HSEBYP bit can be written only if the HSE oscillator is disabled.
0: HSE oscillator not bypassed (default after reset)
1: HSE oscillator bypassed with an external clock

Bit 17 **HSERDY**: HSE clock ready flag
Set by hardware to indicate that the HSE oscillator is stable.
0: HSE clock is not ready (default after reset)
1: HSE clock is ready

Bit 16 **HSEON**: HSE clock enable
Set and cleared by software.
Cleared by hardware to stop the HSE when entering Stop or Standby mode.
This bit cannot be cleared if the HSE is used directly (via SW mux) as system clock, or if the HSE is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1) or if FMCKP = 1, or if XSPICKP = 1.
0: HSE is OFF (default after reset)
1: HSE is ON

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **HSI48RDY**: HSI48 clock ready flag
Set by hardware to indicate that the HSI48 oscillator is stable.
0: HSI48 clock is not ready (default after reset)
1: HSI48 clock is ready
Bit 12  **HSI48ON**: HSI48 clock enable
    Set by software and cleared by software or by the hardware when the system enters to Stop or Standby mode.
    0: HSI48 is OFF (default after reset)
    1: HSI48 is ON

Bits 11:10 Reserved, must be kept at reset value.

Bit 9  **CSIKERON**: CSI clock enable in Stop mode
    Set and reset by software to force the CSI to ON, even in Stop mode, in order to be quickly available as kernel clock for some peripherals. This bit has no effect on the value of CSION.
    0: no effect on CSI (default after reset)
    1: CSI is forced to ON even in Stop mode

Bit 8  **CSIRDY**: CSI clock ready flag
    Set by hardware to indicate that the CSI oscillator is stable. This bit is activated only if the RC is enabled by CSION (it is not activated if the CSI is enabled by CSIKERON or by a peripheral request).
    0: CSI clock is not ready (default after reset)
    1: CSI clock is ready

Bit 7  **CSION**: CSI clock enable
    Set and reset by software to enable/disable CSI clock for system and/or peripheral.
    Set by hardware to force the CSI to ON when the system leaves Stop mode, if STOPWUCK = 1 or STOPKERWUCK = 1.
    This bit cannot be cleared if the CSI is used directly (via SW mux) as system clock, or if the CSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1) or if FMCCKP = 1, or if XSPICKP = 1.
    0: CSI is OFF (default after reset)
    1: CSI is ON

Bit 6  Reserved, must be kept at reset value.

Bit 5  **HSIDIVF**: HSI divider flag
    Set and reset by hardware.
    As a write operation to HSIDIV has not an immediate effect on the frequency, this flag indicates the current status of the HSI divider. HSIDIVF goes immediately to 0 when HSIDIV value is changed, and is set back to 1 when the output frequency matches the value programmed into HSIDIV.
    0: new division ratio not yet propagated to *hsi(_ker)_ck* (default after reset)
    1: *hsi(_ker)_ck* clock frequency reflects the new HSIDIV value (default register value when the clock setting is completed)

Bits 4:3  **HSIDIV[1:0]**: HSI clock divider
    Set and reset by software.
    These bits allow selecting a division ratio in order to configure the wanted HSI clock frequency. The HSI48 cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set to 1). In that case, the new HSIDIV value is ignored.
    00: division by 1, *hsi(_ker)_ck* = 64 MHz (default after reset)
    01: division by 2, *hsi(_ker)_ck* = 32 MHz
    10: division by 4, *hsi(_ker)_ck* = 16 MHz
    11: division by 8, *hsi(_ker)_ck* = 8 MHz
Bit 2  HSIRDY: HSI clock ready flag
    Set by hardware to indicate that the HSI oscillator is stable.
    0: HSI clock is not ready (default after reset)
    1: HSI clock is ready

Bit 1  HSIKERON: HSI clock enable in Stop mode
    Set and reset by software to force the HSI to ON, even in Stop mode, in order to be quickly available
    as kernel clock for peripherals. This bit has no effect on the value of HSION.
    0: no effect on HSI (default after reset)
    1: HSI is forced to ON even in Stop mode

Bit 0  HSION: HSI clock enable
    Set and cleared by software.
    Set by hardware to force the HSI to ON when the product leaves Stop mode, if STOPWUCK = 0 or
    STOPKERWUCK = 0.
    Set by hardware to force the HSI to ON when the product leaves Standby mode or in case of a
    failure of the HSE which is used as the system clock source.
    This bit cannot be cleared if the HSI is used directly (via SW switch) as system clock, or if the HSI is
    selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1) or if FMCCKP = 1, or
    if XSPICKP = 1.
    0: HSI is OFF
    1: HSI is ON (default after reset)

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **HSITRIM[6:0]**: HSI clock trimming

Set by software to adjust calibration.

HSITRIM field is added to the engineering option bytes loaded during reset phase (FLASH_HSI_opt) in order to form the calibration trimming value.

HSICAL = HSITRIM + FLASH_HSI_opt.

**Note:** The reset value of the field is 0x40.

Bits 23:12 Reserved, must be kept at reset value.

Bits 11:0 **HSICAL[11:0]**: HSI clock calibration

Set by hardware by option byte loading.

Adjusted by software through trimming bits HSITRIM.

This field represents the sum of engineering option byte calibration value and HSITRIM bits value.

Bits 31:30  Reserved, must be kept at reset value.

Bits 29:24  CSITRIM[5:0]: CSI clock trimming  
Set by software to adjust calibration.  
CSITRIM field is added to the engineering option bytes loaded during reset phase  
(FLASH_CSI_opt) in order to form the calibration trimming value.  
CSICAL = CSITRIM + FLASH_CSI_opt.  
*Note:* The reset value of the field is 0x20.

Bits 23:8  Reserved, must be kept at reset value.

Bits 7:0  CSICAL[7:0]: CSI clock calibration  
Set by hardware by option byte loading.  
Adjusted by software through trimming bits CSITRIM.  
This field represents the sum of engineering option byte calibration value and CSITRIM bits value.
7.8.6 RCC clock configuration register (RCC_CFGR)

Address offset: 0x010
Reset value: 0x0000 0000

Bits 31:29 **MCO2SEL[2:0]**: microcontroller clock output 2
Set and cleared by software. Clock source selection may generate glitches on MCO2.
It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.
- 000: system clock selected (**sys_ck**) (default after reset)
- 001: PLL2 oscillator clock selected (**pll2_p_ck**)
- 010: HSE clock selected (**hse_ck**)
- 011: PLL1 clock selected (**pll1_p_ck**)
- 100: CSI clock selected (**csi_ck**)
- 101: LSI clock selected (**lsi_ck**)
- others: reserved

Bits 28:25 **MCO2PRE[3:0]**: MCO2 prescaler
Set and cleared by software to configure the prescaler of the MCO2. Modification of this prescaler may generate glitches on MCO2. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.
- 0000: prescaler disabled (default after reset)
- 0001: division by 1 (bypass)
- 0010: division by 2
- 0011: division by 3
- 0100: division by 4
- ...
- 1111: division by 15

Bits 24:22 **MCO1SEL[2:0]**: Microcontroller clock output 1
Set and cleared by software. Clock source selection may generate glitches on MCO1.
It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.
- 000: HSI clock selected (**hsi_ck**) (default after reset)
- 001: LSE oscillator clock selected (**lse_ck**)
- 010: HSE clock selected (**hse_ck**)
- 011: PLL1 clock selected (**pll1_q_ck**)
- 100: HSI48 clock selected (**hsi48_ck**)
- others: reserved
Bits 21:18  **MCO1PRE[3:0]**: MCO1 prescaler
   Set and cleared by software to configure the prescaler of the MCO1. Modification of this prescaler may generate glitches on MCO1. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.
   0000: prescaler disabled (default after reset)
   0001: division by 1 (bypass)
   0010: division by 2
   0011: division by 3
   0100: division by 4
   ...
   1111: division by 15

Bits 17:16  Reserved, must be kept at reset value.

Bit 15  **TIMPRE**: timers clocks prescaler selection
   This bit is set and reset by software to control the clock frequency of all the timers connected to APB1 and APB2 domains.
   0: The timers kernel clock is equal to \( \text{rcc}_\text{hclk1} \) if \( \text{CDPPREx} \) is corresponding to division by 1 or 2, else it is equal to \( 2 \times \text{rcc}_\text{pclkx}_\text{d2} \) (default after reset)
   1: The timers kernel clock is equal to \( \text{rcc}_\text{hclk1} \) if \( \text{CDPPREx} \) is corresponding to division by 1, 2 or 4, else it is equal to \( 4 \times \text{rcc}_\text{pclkx}_\text{d2} \)
   Refer to  Table 67: Ratio between clock timer and pclk for more details.

Bit 14  Reserved, must be kept at reset value.

Bits 13:8  **RTCPRE[5:0]**: HSE division factor for RTC clock
   Set and cleared by software to divide the HSE to generate a clock for RTC.
   Caution: The software must set these bits correctly to ensure that the clock supplied to the RTC is lower than 1 MHz. These bits must be configured if needed before selecting the RTC clock source.
   000000: no clock (default after reset)
   000001: no clock
   000010: HSE/2
   000011: HSE/3
   000100: HSE/4
   ...
   111110: HSE/62
   111111: HSE/63

Bit 7  **STOPKERWUCK**: kernel clock selection after a wake up from system Stop
   Set and reset by software to select the kernel wakeup clock from system Stop.
   0: HSI selected as wake up clock from system Stop (default after reset)
   1: CSI selected as wake up clock from system Stop
   See  Section 1.: Dividers values can be changed on-the-fly. All dividers provide have 50% duty-cycles. for details.
Bit 6 STOPWUCK: system clock selection after a wake up from system Stop
  Set and reset by software to select the system wakeup clock from system Stop.
The selected clock is also used as emergency clock for the clock security system (CSS) on HSE.
  0: HSI selected as wake up clock from system Stop (default after reset)
  1: CSI selected as wake up clock from system Stop
  See Section 1.: Dividers values can be changed on-the-fly. All dividers provide have 50% duty-cycles. for details.
  Caution: STOPWUCK must not be modified when CSS is enabled (by HSECSSON bit) and the system clock is HSE (SWS = 10) or a switch on HSE is requested (SW =10).

Bits 5:3 SWS[2:0]: system clock switch status
  Set and reset by hardware to indicate which clock source is used as system clock.
  000: HSI used as system clock (hsi_ck) (default after reset)
  001: CSI used as system clock (csi_ck)
  010: HSE used as system clock (hse_ck)
  011: PLL1 used as system clock (pll1_p_ck)
  others: reserved

Bits 2:0 SW[2:0]: system clock switch
  Set and reset by software to select system clock source (sys_ck).
  Set by hardware in order to force the selection of the HSI or CSI (depending on STOPWUCK selection) when leaving a system Stop mode or in case of failure of the HSE when used directly or indirectly as system clock.
  000: HSI selected as system clock (hsi_ck) (default after reset)
  001: CSI selected as system clock (csi_ck)
  010: HSE selected as system clock (hse_ck)
  011: PLL1 selected as system clock (pll1_p_ck)
  others: reserved
7.8.7 RCC CPU domain clock configuration register (RCC_CDCFGR)

Address offset: 0x018
Reset value: 0x0000 0000

Caution:
Care must be taken when using the voltage scaling. Due to the propagation delay of the new division factor, after a prescaler factor change and before lowering the VCORE voltage, this register must be read in order to check that the new prescaler value has been taken into account.

Depending on the clock source frequency and the voltage range, the software application must program a correct value in BMPRE to make sure that the system frequency does not exceed the maximum frequency.
### 7.8.8 RCC AHB clock configuration register (RCC_BMCFGR)

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:12 **PPRE5[2:0]**: CPU domain APB5 prescaler
- Set and reset by software to control the division factor of rcc_pclk5.
- The clock is divided by the new prescaler factor from 1 to 16 cycles of sys_bus_ck after PPRE5 write.
  - 0xx: rcc_pclk5 = sys_bus_ck (default after reset)
  - 100: rcc_pclk5 = sys_bus_ck / 2
  - 101: rcc_pclk5 = sys_bus_ck / 4
  - 110: rcc_pclk5 = sys_bus_ck / 8
  - 111: rcc_pclk5 = sys_bus_ck / 16

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **PPRE4[2:0]**: CPU domain APB4 prescaler
- Set and reset by software to control the division factor of rcc_pclk4.
- The clock is divided by the new prescaler factor from 1 to 16 cycles of sys_bus_ck after PPRE4 write.
  - 0xx: rcc_pclk4 = sys_bus_ck (default after reset)
  - 100: rcc_pclk4 = sys_bus_ck / 2
  - 101: rcc_pclk4 = sys_bus_ck / 4
  - 110: rcc_pclk4 = sys_bus_ck / 8
  - 111: rcc_pclk4 = sys_bus_ck / 16

Bit 7 Reserved, must be kept at reset value.
Bits 6:4  **PPRE2[2:0]**: CPU domain APB2 prescaler
   Set and reset by software to control the division factor of **rcc_pclk2**.
   The clock is divided by the new prescaler factor from 1 to 16 cycles of **sys_bus_ck** after PPRE2 write.
   
   0xx: `rcc_pclk2 = sys_bus_ck` (default after reset)
   100: `rcc_pclk2 = sys_bus_ck / 2`
   101: `rcc_pclk2 = sys_bus_ck / 4`
   110: `rcc_pclk2 = sys_bus_ck / 8`
   111: `rcc_pclk2 = sys_bus_ck / 16`

   Bit 3  Reserved, must be kept at reset value.

Bits 2:0  **PPRE1[2:0]**: CPU domain APB1 prescaler
   Set and reset by software to control the division factor of **rcc_pclk1**.
   The clock is divided by the new prescaler factor from 1 to 16 cycles of **sys_bus_ck** after PPRE1 write.
   
   0xx: `rcc_pclk1 = sys_bus_ck` (default after reset)
   100: `rcc_pclk1 = sys_bus_ck / 2`
   101: `rcc_pclk1 = sys_bus_ck / 4`
   110: `rcc_pclk1 = sys_bus_ck / 8`
   111: `rcc_pclk1 = sys_bus_ck / 16`
7.8.10 RCC PLLs clock source selection register (RCC_PLLCKSELR)

Address offset: 0x028
Reset value: 0x0202 0200

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:20 **DIVM3[5:0]**: prescaler for PLL3
Set and cleared by software to configure the prescaler of the PLL3.
The hardware does not allow any modification of this prescaler when PLL3 is enabled (PLL3ON = 1).
In order to save power when PLL3 is not used, the value of DIVM3 must be set to 0.
000000: prescaler disabled
000001: division by 1 (bypass)
000010: division by 2
000011: division by 3
... 100000: division by 32 (default after reset)
... 111111: division by 63

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:12 **DIVM2[5:0]**: prescaler for PLL2
Set and cleared by software to configure the prescaler of the PLL2.
The hardware does not allow any modification of this prescaler when PLL2 is enabled (PLL2ON = 1).
In order to save power when PLL2 is not used, the value of DIVM2 must be set to 0.
000000: prescaler disabled
000001: division by 1 (bypass)
000010: division by 2
000011: division by 3
... 100000: division by 32 (default after reset)
... 111111: division by 63

Bits 11:10 Reserved, must be kept at reset value.
Bits 9:4 **DIVM1[5:0]**: prescaler for PLL1
Set and cleared by software to configure the prescaler of the PLL1.
The hardware does not allow any modification of this prescaler when PLL1 is enabled (PLL1ON = 1).
In order to save power when PLL1 is not used, the value of DIVM1 must be set to 0.
000000: prescaler disabled
000001: division by 1 (bypass)
000010: division by 2
000011: division by 3
...
100000: division by 32 (default after reset)
...
111111: division by 63

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **PLLSRC[1:0]**: DIVMx and PLLs clock source selection
Set and reset by software to select the PLL clock source.
These bits can be written only when all PLLs are disabled.
In order to save power, when no PLL is used, PLLSRC must be set to ‘11’.
00: HSI selected as PLL clock (**hsi_ck**)(default after reset)
01: CSI selected as PLL clock (**csi_ck**)
10: HSE selected as PLL clock (**hse_ck**)
11: no clock send to DIVMx divider and PLLs

**Bit 31** Reserved, must be kept at reset value.

**Bit 30 PLL3SEN:** PLL3 DIVS divider output enable  
Set and reset by software to enable the PLL3.  
To save power, PLL3SEN must be set to 0 when the PLL3 is not used.  
0: PLL3 output disabled (default after reset)  
1: PLL3 output enabled

**Bit 29 PLL3REN:** PLL3 DIVR divider output enable  
Set and reset by software to enable the PLL3.  
To save power, PLL3REN and DIVR bits must be set to 0 when the PLL3 is not used.  
0: PLL3 output disabled (default after reset)  
1: PLL3 output enabled

**Bit 28 PLL3QEN:** PLL3 DIVQ divider output enable  
Set and reset by software to enable the PLL3.  
To save power, PLL3REN and DIVQ bits must be set to 0 when the PLL3 is not used.  
0: PLL3 output disabled (default after reset)  
1: PLL3 output enabled

**Bit 27 PLL3PEN:** PLL3 DIVP divider output enable  
Set and reset by software to enable the PLL3.  
To save power, PLL3REN and DIVP bits must be set to 0 when the PLL3 is not used.  
0: PLL3 output disabled (default after reset)  
1: PLL3 output enabled

**Bits 26:25 PLL3[3:0]:** PLL3 input frequency range  
Set and reset by software to select the proper reference frequency range used for PLL3.  
These bits must be written before enabling the PLL3.  
00: PLL3 input (ref3_ck) clock range frequency between 1 and 2 MHz (default after reset)  
01: PLL3 input (ref3_ck) clock range frequency between 2 and 4 MHz  
10: PLL3 input (ref3_ck) clock range frequency between 4 and 8 MHz  
11: PLL3 input (ref3_ck) clock range frequency between 8 and 16 MHz
Bit 24 **PLL3SSCGEN**: PLL3 SSCG enable
Set and reset by software to enable the Spread Spectrum Clock Generator of PLL3, in order to reduce the amount of EMI peaks.
0: SSCG disabled (default after reset)
1: SSCG enabled

Bit 23 **PLL3VCOSEL**: PLL3 VCO selection
Set and reset by software to select the proper VCO frequency range used for PLL3.
This bit must be written before enabling the PLL3. It allows the application to select the VCO range:
- VCOH: working from 384 to 1672 MHz (Fref2_ck must be between 2 and 16 MHz)
- VCOL: working from 150 to 420 MHz (Fref2_ck must be between 1 and 2 MHz)
0: VCOH selected (default after reset)
1: VCOL selected

Bit 22 **PLL3FRACEN**: PLL3 fractional latch enable
Set and reset by software to latch the content of FRACN into the sigma-delta modulator.
In order to latch the FRACN value into the sigma-delta modulator, PLL3FRACEN must be set to 0, then set to 1. The transition 0 to 1 transfers the content of FRACN into the modulator.
Refer to **PLL initialization procedure on page 418** for additional information.
PLL3FRACEN must remain at 0 for at least 5 µs

Bit 21 Reserved, must be kept at reset value.

Bit 20 **PLL2TEN**: PLL2 DIVT divider output enable
Set and reset by software to enable the pll2_t_ck output of the PLL2.
To save power, PLL2TEN must be set to 0 when the pll2_t_ck is not used.
The hardware prevents writing this bit if XSPICKP = 1.
0: pll2_t_ck output disabled (default after reset)
1: pll2_t_ck output enabled

Bit 19 **PLL2SEN**: PLL2 DIVS divider output enable
Set and reset by software to enable the pll2_s_ck output of the PLL2.
To save power, PLL2SEN must be set to 0 when the pll2_s_ck is not used.
The hardware prevents writing this bit if XSPICKP = 1.
0: pll2_s_ck output disabled (default after reset)
1: pll2_s_ck output enabled

Bit 18 **PLL2REN**: PLL2 DIVR divider output enable
Set and reset by software to enable the pll2_r_ck output of the PLL2.
The hardware prevents writing this bit if FMCCKP = 1.
To save power, PLL3REN and DIVR bits must be set to 0 when the pll3_r_ck is not used.
0: pll2_r_ck output disabled (default after reset)
1: pll2_r_ck output enabled

Bit 17 **PLL2QEN**: PLL2 DIVQ divider output enable
Set and reset by software to enable the pll2_q_ck output of the PLL2.
To save power, PLL3QEN and DIVQ bits must be set to 0 when the pll3_q_ck is not used.
0: pll2_q_ck output disabled (default after reset)
1: pll2_q_ck output enabled

Bit 16 **PLL2PEN**: PLL2 DIVP divider output enable
Set and reset by software to enable the pll2_p_ck output of the PLL2.
To save power, PLL2PEN and DIVP bits must be set to 0 when the pll2_p_ck is not used.
0: pll2_p_ck output disabled (default after reset)
1: pll2_p_ck output enabled
Bits 15:14  **PLL2RGE[1:0]**: PLL2 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL2.
These bits must be written before enabling the PLL2.
00: PLL3 input (ref2_ck) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL3 input (ref2_ck) clock range frequency between 2 and 4 MHz
10: PLL3 input (ref2_ck) clock range frequency between 4 and 8 MHz
11: PLL3 input (ref2_ck) clock range frequency between 8 and 16 MHz

Bit 13  **PLL2SSCGEN**: PLL2 SSCG enable
Set and reset by software to enable the Spread Spectrum Clock Generator of PLL2, in order to reduce the amount of EMI peaks.
0: SSCG disabled (default after reset)
1: SSCG enabled

Bit 12  **PLL2VCOSEL**: PLL2 VCO selection
Set and reset by software to select the proper VCO frequency range used for PLL2.
This bit must be written before enabling the PLL2. It allows the application to select the VCO range:
- **VCOH**: working from 384 to 1672 MHz (F_{ref2_ck} must be between 2 and 16 MHz)
- **VCOL**: working from 150 to 420 MHz (F_{ref2_ck} must be between 1 and 2 MHz)
0: VCOH selected (default after reset)
1: VCOL selected

Bit 11  **PLL2FRACLEN**: PLL2 fractional latch enable
Set and reset by software to latch the content of FRACN into the sigma-delta modulator.
In order to latch the FRACN value into the sigma-delta modulator, PLL2FRACLEN must be set to 0, then set to 1. The transition 0 to 1 transfers the content of FRACN into the modulator.
Refer to **PLL initialization procedure on page 418** for additional information.
PLL2FRACLEN must remain at 0 for at least 5 µs.

Bits 10:9 Reserved, must be kept at reset value.

Bit 8  **PLL1SEN**: PLL1 DIVS divider output enable
Set and reset by software to enable the pll1_s_ck output of the PLL1.
To save power, PLL1SEN must be set to 0 when the pll1_s_ck is not used.
0: pll1_s_ck output disabled (default after reset)
1: pll1_s_ck output enabled

Bit 7 Reserved, must be kept at reset value.

Bit 6  **PLL1QEN**: PLL1 DIVQ divider output enable
Set and reset by software to enable the pll1_q_ck output of the PLL1.
The hardware prevents writing this bit if FMCCKP = 1.
In order to save power, when the pll1_q_ck output of the PLL1 is not used, the pll1_q_ck must be disabled.
0: pll1_q_ck output disabled (default after reset)
1: pll1_q_ck output enabled

Bit 5  **PLL1PEN**: PLL1 DIVP divider output enable
Set and reset by software to enable the pll1_p_ck output of the PLL1.
The hardware prevents writing this bit to 0, if the PLL1 output is used as the system clock (SW=3).
In order to save power, when the pll1_p_ck output of the PLL1 is not used, the pll1_p_ck must be disabled.
0: pll1_p_ck output disabled (default after reset)
1: pll1_p_ck output enabled
**7.8.12 RCC PLL1 dividers configuration register 1 (RCC_PLL1DIVR1)**

| Bit 23  | Reserved, must be kept at reset value. |

![Image of table showing register configuration](image-url)
Bits 22:16 **DIVQ[6:0]**: PLL1 DIVQ division factor
Set and reset by software to control the frequency of the \(\text{pll1\_q\_ck} \) clock.
These bits can be written only when the PLL1QEN = 0.
0000000: \(\text{pll1\_q\_ck} = vco1\_ck\)
0000001: \(\text{pll1\_q\_ck} = vco1\_ck \div 2\) (default after reset)
0000010: \(\text{pll1\_q\_ck} = vco1\_ck \div 3\)
0000011: \(\text{pll1\_q\_ck} = vco1\_ck \div 4\)
... 1111111: \(\text{pll1\_q\_ck} = vco1\_ck \div 128\)

Bits 15:9 **DIVP[6:0]**: PLL1 DIVP division factor
Set and reset by software to control the frequency of the \(\text{pll1\_p\_ck} \) clock.
These bits can be written only when the PLL1PEN = 0.
0000000: \(\text{pll1\_p\_ck} = vco1\_ck\)
0000001: \(\text{pll1\_p\_ck} = vco1\_ck \div 2\) (default after reset)
0000010: not allowed
0000011: \(\text{pll1\_p\_ck} = vco1\_ck \div 4\)
... 1111111: \(\text{pll1\_p\_ck} = vco1\_ck \div 128\)

Bits 8:0 **DIVN[8:0]**: multiplication factor for PLL1 VCO
Set and reset by software to control the multiplication factor of the VCO.
These bits can be written only when the PLL is disabled (PLL1ON = PLL1RDN = 0).
.........: not used
0x006: wrong configuration
0x007: DIVN = 8
...
0x080: DIVN = 129 (default after reset)
...
0x1A3: DIVN = 420
Others: wrong configurations

**Caution:** The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:
- 128 to 544MHz if PLL1VCOSEL = 0
- 150 to 420 MHz if PLL1VCOSEL = 1

VCO output frequency = \(F_{\text{ref1\_ck}} \times \text{DIVN}\), when fractional value 0 has been loaded into FRACN, with:
- DIVN between 8 and 420
- The input frequency \(F_{\text{ref1\_ck}}\) must be between 1 and 16 MHz.

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:3  **FRACN[12:0]**: fractional part of the multiplication factor for PLL1 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO.

These bits can be written at any time, allowing dynamic fine-tuning of the PLL1 VCO.

**Caution:** The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

- 128 to 544 MHz if PLL1VCOSEL = 0
- 150 to 420 MHz if PLL1VCOSEL = 1

VCO output frequency = \( F_{ref1,ck} \times (DIVN + (FRACN / 2^{13})) \), with
- \( DIVN \) between 8 and 420
- \( FRACN \) can be between 0 and \( 2^{13} - 1 \)
- The input frequency \( F_{ref1,ck} \) must be between 1 and 16 MHz.

To change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

- Set the bit PLL1FRACEN to 0.
- Write the new fractional value into FRACN.
- Set the bit PLL1FRACEN to 1
- Wait at least 5 \( \mu s \).

Bits 2:0  Reserved, must be kept at reset value.

- 111111: \texttt{pll2_q_ck} = \texttt{vco2_ck} / 128

Bits 15:9 **DIVP[6:0]**: PLL2 DIVP division factor
Set and reset by software to control the frequency of the \texttt{pll2_p_ck} clock.
These bits can be written only when the PLL2PEN = 0.
- 000000: \texttt{pll2_p_ck} = \texttt{vco2_ck}
- 000001: \texttt{pll2_p_ck} = \texttt{vco2_ck} / 2 (default after reset)
- 000010: \texttt{pll2_p_ck} = \texttt{vco2_ck} / 3
- 000011: \texttt{pll2_p_ck} = \texttt{vco2_ck} / 4
- ...
- 111111: \texttt{pll2_p_ck} = \texttt{vco2_ck} / 128

Bits 8:0 **DIVN[8:0]**: multiplication factor for PLL2 VCO
Set and reset by software to control the multiplication factor of the VCO.
These bits can be written only when the PLL is disabled (PLL2ON = PLL2RDY = 0).
- ..........: not used
- 0x006: wrong configuration
- 0x007: DIVN = 8
- ...
- 0x080: DIVN = 129 (default after reset)
- ...
- 0x1A3: DIVN = 420
- Others: wrong configurations

**Caution:** The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:
- 128 to 544 MHz if PLL2VCOSSEL = 0
- 150 to 420 MHz if PLL2VCOSSEL = 1

VCO output frequency = \(F_{\text{ref2}} \times \text{DIVN}\), when fractional value 0 has been loaded into FRACN, with
- \text{DIVN} between 8 and 420
- The input frequency \(F_{\text{ref2}}\) must be between 1 and 16MHz.
7.8.17 **RCC PLL2 dividers configuration register 2 (RCC_PLL2DIVR2)**

Address offset: 0x0C4

Reset value: 0x0000 0101

<table>

<tr>
<th>Bits 10:8</th>
<th>DIVT[2:0]: PLL2 DIVT division factor</th>
</tr>
</thead>
</table>

Set and reset by software to control the frequency of the pll2_t_ck clock.
This post-divider performs divisions with 50% duty-cycle.
The duty-cycle of 50% is guaranteed only in the following conditions:
- With VCOL, if (DIVT+1) is even,
- With VCOH, for all DIVT values

These bits can be written only when the PLL2TEN = 0.

7.8.18  RCC PLL2 fractional divider register (RCC_PLL2FRACR)

Address offset: 0x03C
Reset value: 0x0000 0000

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:3  **FRACN[12:0]**: fractional part of the multiplication factor for PLL2 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO. These bits can be written at any time, allowing dynamic fine-tuning of the PLL2 VCO.

**Caution:** The software must correctly set these bits to ensure that the VCO output frequency is within its valid frequency range, that is:

- 128 to 544 MHz if PLL2VCOSEL = 0
- 150 to 420 MHz if PLL2VCOSEL = 1

VCO output frequency = \( F_{\text{ref2,ck}} \times (\text{DIVN} + \frac{\text{FRACN}}{2^{13}}) \), with

- DIVN between 8 and 420
- FRACN can be between 0 and \( 2^{13} - 1 \)
- The input frequency \( F_{\text{ref2,ck}} \) must be between 1 and 16 MHz.

In order to change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

- Set the bit PLL2FRACLEN to 0.
- Write the new fractional value into FRACN.
- Set the bit PLL2FRACLEN to 1
- Wait at least 5 µs.

Bits 2:0  Reserved, must be kept at reset value.
### 7.8.19 RCC PLL2 Spread Spectrum Clock Generator register (RCC_PLL2SSCGR)

</tbody>
</table>

- **INCSTEP[14:0]**: Modulation Depth Adjustment for PLL2
  - Set and reset by software to adjust the modulation depth of the clock spreading generator.

- **SPREADSEL**: Spread spectrum clock generator mode for PLL2
  - Set and reset by software to select the clock spreading mode.
  - 0: Center-spread modulation selected (default after reset)
  - 1: Down-spread modulation selected

- **RPDFNDIS**: Dithering RPDF noise control for PLL2
  - Set and reset by software.
  - This bit is used to enable or disable the injection of a dithering noise into the SSCG modulator. This dithering noise is generated using a rectangular probability density function.
  - 0: Dithering noise injection enabled (default after reset)
  - 1: Dithering noise injection disabled

- **TPDFNDIS**: Dithering TPDF noise control for PLL2
  - Set and reset by software.
  - This bit is used to enable or disable the injection of a dithering noise into the SSCG modulator. This dithering noise is generated using a triangular probability density function.
  - 0: Dithering noise injection enabled (default after reset)
  - 1: Dithering noise injection disabled

- **MODPER[12:0]**: Modulation Period Adjustment for PLL2
  - Set and reset by software to adjust the modulation period of the clock spreading generator.
7.8.20  RCC PLL3 dividers configuration register 1 (RCC_PLL3DIVR1)

Address offset: 0x040
Reset value: 0x0101 0280

Bit 31  Reserved, must be kept at reset value.

Bits 30:24  DIVR[6:0]: PLL3 DIVR division factor
- Set and reset by software to control the frequency of the pll3_r_ck clock.
- These bits can be written only when the PLL3REN = 0.
  0000000: pll3_r_ck = vco3_ck
  0000001: pll3_r_ck = vco3_ck / 2 (default after reset)
  0000010: pll3_r_ck = vco3_ck / 3
  0000011: pll3_r_ck = vco3_ck / 4
  ...
  1111111: pll3_r_ck = vco3_ck / 128

Bit 23  Reserved, must be kept at reset value.
Bits 22:16 **DIVQ[6:0]**: PLL3 DIVQ division factor
Set and reset by software to control the frequency of the `pll3_q_ck` clock.
These bits can be written only when the PLL3QEN = 0.
- **0000000**: \( \text{pll3}_q\_ck = \text{vco3}_ck \)
- **0000001**: \( \text{pll3}_q\_ck = \text{vco3}_ck / 2 \) (default after reset)
- **0000010**: \( \text{pll3}_q\_ck = \text{vco3}_ck / 3 \)
- **0000011**: \( \text{pll3}_q\_ck = \text{vco3}_ck / 4 \)
- ... 
- **1111111**: \( \text{pll3}_q\_ck = \text{vco3}_ck / 128 \)

Bits 15:9 **DIVP[6:0]**: PLL3 DIVP division factor
Set and reset by software to control the frequency of the `pll3_p_ck` clock.
These bits can be written only when the PLL3PEN = 0.
- **0000000**: \( \text{pll3}_p\_ck = \text{vco3}_ck \)
- **0000001**: \( \text{pll3}_p\_ck = \text{vco3}_ck / 2 \) (default after reset)
- **0000010**: \( \text{pll3}_p\_ck = \text{vco3}_ck / 3 \)
- **0000011**: \( \text{pll3}_p\_ck = \text{vco3}_ck / 4 \)
- ... 
- **1111111**: \( \text{pll3}_p\_ck = \text{vco3}_ck / 128 \)

Bits 8:0 **DIVN[8:0]**: Multiplication factor for PLL3 VCO
Set and reset by software to control the multiplication factor of the VCO.
These bits can be written only when the PLL is disabled (PLL3ON = PLL3RDY = 0).
- ..........: not used
- **0x006**: wrong configuration
- **0x007**: DIVN = 8
- ... 
- **0x080**: DIVN = 129 (default after reset)
- ... 
- **0x1A3**: DIVN = 420
- Others: wrong configurations

**Caution:** The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:
- 128 to 544 MHz if PLL3VCOSSEL = 0
- 150 to 420 MHz if PLL3VCOSSEL = 1

VCO output frequency = \( F_{\text{ref3}} \_ck \times \text{DIVN} \), when fractional value 0 has been loaded into FRACN, with:
- DIVN between 8 and 420
- The input frequency \( F_{\text{ref3}} \_ck \) must be between 1 and 16 MHz
### 7.8.21 RCC PLL3 dividers configuration register 2 (RCC_PLL3DIVR2)

**Address offset:** 0x0C8

**Reset value:** 0x0000 0101

#### Bits 31:3
Reserved, must be kept at reset value.

#### Bits 2:0 **DIVS[2:0]**: PLL3 DIVS division factor

- Set and reset by software to control the frequency of the pll3_s_ck clock.
- This post-divider performs divisions with 50% duty-cycle.
- The duty-cycle of 50% is guaranteed only in the following conditions:
  - With VCOL, if (DIVS+1) is even,
  - With VCOH, for all DIVS values

These bits can be written only when the PLL3SEN = 0.

- 000: \( \text{pll3}_\_s\_ck = \text{vco3}_\_ck \)
- 001: \( \text{pll3}_\_s\_ck = \text{vco3}_\_ck / 2 \) (default after reset)
- 010: \( \text{pll3}_\_s\_ck = \text{vco3}_\_ck / 3 \)
- 011: \( \text{pll3}_\_s\_ck = \text{vco3}_\_ck / 4 \)
- 100: \( \text{pll3}_\_s\_ck = \text{vco3}_\_ck / 5 \)
- 101: \( \text{pll3}_\_s\_ck = \text{vco3}_\_ck / 6 \)
- 110: \( \text{pll3}_\_s\_ck = \text{vco3}_\_ck / 7 \)
- 111: \( \text{pll3}_\_s\_ck = \text{vco3}_\_ck / 8 \)

### 7.8.22 RCC PLL3 fractional divider register (RCC_PLL3FRACCR)

**Address offset:** 0x044

**Reset value:** 0x0000 0000

#### Bits 31:16
Bits 15:13 Reserved, must be kept at reset value.

#### Bits 12:0 **FRACN[12:0]**

- These bits can be written only when the PLL3SEN = 0.
Bits 31:16  Reserved, must be kept at reset value.

Bits 15:3  **FRACN[12:0]**: fractional part of the multiplication factor for PLL3 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO.

These bits can be written at any time, allowing dynamic fine-tuning of the PLL3 VCO.

**Caution:** The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

- 128 to 544 MHz if PLL3VCOSEL = 0
- 150 to 420 MHz if PLL3VCOSEL = 1

VCO output frequency = \( F_{\text{ref3,ck}} \times (\text{DIVN} + (\text{FRACN} / 2^{13})) \), with

- DIVN between 8 and 420
- FRACN can be between 0 and \( 2^{13} - 1 \)
- The input frequency \( F_{\text{ref3,ck}} \) must be between 1 and 16 MHz.

In order to change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

- Set the bit PLL1FRACEN to 0.
- Write the new fractional value into FRACN.
- Set the bit PLL1FRACEN to 1
- Wait at least 5 \( \mu \)s.

Bits 2:0  Reserved, must be kept at reset value.

  Set and reset by software to adjust the modulation period of the clock spreading generator.
### 7.8.24 RCC AHB peripheral kernel clock selection register (RCC_CCIPR1)

Address offset: 0x04C

Reset value: 0x0000 0A00

Changing the clock source on-the-fly is allowed (except for CKPERSEL and ETH1REFCKSEL[1:0]) and does not generate any timing violation. However, the user must make sure that both the previous and the new clock sources are present during the switching, and during the whole transition time. Refer to *Clock switches and gating*.

![Register Table](image)

Bits 31:30: Reserved, must be kept at reset value.

Bits 29:28: **CKPERSEL[1:0]: per_ck clock source selection**

- 00: `hsi_ker_ck` selected as `per_ck` clock (default after reset)
- 01: `csi_ker_ck` selected as `per_ck` clock
- 10: `hse_ker_ck` selected as `per_ck` clock
- 11: reserved, the `ck_per` clock is disabled

Bit 27: **PSSISEL**: PSSI kernel clock source selection

Set and reset by software.

- 0: `pll3_r_ck` selected as kernel peripheral clock (default after reset)
- 1: `per_ck` selected as kernel peripheral clock

Bit 26: Reserved, must be kept at reset value.

Bits 25:24: **ADCSEL[1:0]: SAR ADC kernel clock source selection**

Set and reset by software.

- 00: `pll2_p_ck` selected as kernel peripheral clock (default after reset)
- 01: `pll3_r_ck` selected as kernel peripheral clock
- 10: `per_ck` selected as kernel peripheral clock
- others: reserved, the kernel clock is disabled

Bit 23: Reserved, must be kept at reset value.
Bits 22:20  ADF1SEL[2:0]: ADF kernel clock source selection
   Set and reset by software.
   0: hclk1 selected as ADF kernel clock (default after reset)
   1: pll2_p_ck selected as ADF kernel clock
   2: pll3_p_ck selected as ADF kernel clock
   3: I2S_CKIN selected as ADF kernel clock
   4: csi_ker_ck selected as ADF kernel clock
   5: hsi_ker_ck selected as ADF kernel clock
   Note: I2S_CKIN is an external clock taken from a pin.

Bit 19  Reserved, must be kept at reset value.

Bit 18  ETH1PHYCKSEL: Clock source selection for external Ethernet PHY
   Set and reset by software.
   0: hse_ker_ck selected as clock source (default after reset)
   1: pll3_s_ck selected clock source

Bits 17:16  ETH1REFCKSEL[1:0]: Ethernet reference clock source selection
   Set and reset by software.
   00: PAD ETH_RMII_REF_CLK selected as kernel peripheral clock (default after reset)
   01: hse_ker_ck selected as kernel peripheral clock
   10: eth_clk_fb selected as kernel peripheral clock
   others: reserved, the kernel clock is disabled

Bits 15:14  OTGFSSEL[1:0]: OTGFS kernel clock source selection
   Set and reset by software.
   00: hsi48_ker_ck (default after reset)
   01: pll3_q_ck
   10: hse_ker_ck
   11: clk48mohci

Bits 13:12  USBPHYCSEL[1:0]: USBPHYC kernel clock source selection
   Set and reset by software.
   00: hse_ker_ck (default after reset)
   01: hse_ker_ck / 2
   10: pll3_q_ck
   11: reserved, the kernel clock is disabled

Bits 11:8  USBREFCKSEL[3:0]: USBPHYC kernel clock frequency selection
   Set and reset by software.
   This field is used to indicate to the USBPHYC, the frequency of the reference kernel clock provided
   to the USBPHYC.
   0011: The kernel clock frequency provided to the USBPHYC is 16 MHz
   1000: The kernel clock frequency provided to the USBPHYC is 19.2 MHz
   1001: The kernel clock frequency provided to the USBPHYC is 20 MHz
   1010: The kernel clock frequency provided to the USBPHYC is 24 MHz (default after reset)
   1110: The kernel clock frequency provided to the USBPHYC is 32 MHz
   others: reserved

Bits 7:6  XSPI2SEL[1:0]: XSPI2 kernel clock source selection
   Set and reset by software.
   00: hclk5 selected as kernel peripheral clock (default after reset)
   01: pll2_s_ck selected as kernel peripheral clock
   1x: pll2_t_ck selected as kernel peripheral clock
Bits 5:4  **XSPI1SEL[1:0]**: XSPI1 kernel clock source selection  
Set and reset by software.  
- 00: **hclk5** selected as kernel peripheral clock (default after reset)  
- 01: **pll2_s_ck** selected as kernel peripheral clock  
- 1x: **pll2_t_ck** selected as kernel peripheral clock

Bit 3  Reserved, must be kept at reset value.

Bit 2  **SDMMC12SEL**: SDMMC1 and SDMMC2 kernel clock source selection  
Set and reset by software.  
- 0: **pll2_s_ck** selected as kernel peripheral clock (default after reset)  
- 1: **pll2_t_ck** selected as kernel peripheral clock

Bits 1:0  **FMCSEL[1:0]**: FMC kernel clock source selection  
Set and reset by software.  
- 00: **hclk5** selected as kernel peripheral clock (default after reset)  
- 01: **pll1_q_ck** selected as kernel peripheral clock  
- 10: **pll2_r_ck** selected as kernel peripheral clock  
- 11: **hsi_ker_ck** selected as kernel peripheral clock
7.8.25 RCC APB1 peripherals kernel clock selection register (RCC_CCIPR2)

Address offset: 0x050
Reset value: 0x0000 0000

Changing the clock source on-the-fly is allowed and does not generate any timing violation. However the user must make sure that both the previous and the new clock sources are present during the switching, and during the whole transition time. Refer to *Clock switches and gating*.

- 100: lsi_ck selected as kernel peripheral clock
- 101: per_ck selected as kernel peripheral clock
others: reserved, the kernel clock is disabled

Bits 15:14  Reserved, must be kept at reset value.

Bits 13:12  **I2C1_I3C1SEL[1:0]**: I2C1 or I3C1 kernel clock source selection
Set and reset by software.
- 00: pclk1 selected as kernel peripheral clock (default after reset)
- 01: pll3_r_ck selected as kernel peripheral clock
- 10: hsi_ker_ck selected as kernel peripheral clock
- 11: csi_ker_ck selected as kernel peripheral clock

Bits 11:10  Reserved, must be kept at reset value.

Bits 9:8  **I2C23SEL[1:0]**: I2C2, I2C3 kernel clock source selection
Set and reset by software.
- 00: pclk1 selected as kernel clock (default after reset)
- 01: pll3_r_ck selected as kernel clock
- 10: hsi_ker_ck selected as kernel clock
- 11: csi_ker_ck selected as kernel clock

Bit 7  Reserved, must be kept at reset value.

Bits 6:4  **SPI23SEL[2:0]**: SPI/I2S2 and SPI/I2S3 kernel clock source selection
Set and reset by software.
Caution: If the selected clock is the external clock and this clock is stopped, it is not be possible to switch to another clock. Refer to Clock switches and gating on page 411 for additional information.
- 000: pll1_q_ck selected as kernel clock (default after reset)
- 001: pll2_p_ck selected as kernel clock
- 010: pll3_p_ck selected as kernel clock
- 011: I2S_CKIN selected as kernel clock
- 100: per_ck selected as kernel clock
others: reserved, the kernel clock is disabled
Note: I2S_CKIN is an external clock taken from a pin.

Bits 5:3  Reserved, must be kept at reset value.

Bits 2:0  **UART234578SEL[2:0]**: USART2,3, UART4,5,7,8 (APB1) kernel clock source selection
Set and reset by software.
- 000: pclk1 selected as kernel clock (default after reset)
- 001: pll2_q_ck selected as kernel clock
- 010: pll3_q_ck selected as kernel clock
- 011: hsi_ker_ck selected as kernel clock
- 100: csi_ker_ck selected as kernel clock
- 101: lse_ck selected as kernel clock
others: reserved, the kernel clock is disabled
7.8.26 RCC APB2 peripherals kernel clock selection register (RCC_CCIPR3)

Address offset: 0x054
Reset value: 0x0000 0000

Changing the clock source on-the-fly is allowed and does not generate any timing violation. However the user must make sure that both the previous and the new clock sources are present during the switching, and during the whole transition time. Refer to Clock switches and gating.

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:20 **SAI2SEL[2:0]**: SAI2 kernel clock source selection
Set and reset by software.

**Caution:** If the selected clock is the external clock and this clock is stopped, it is not possible to switch to another clock. Refer to Clock switches and gating on page 411 for additional information.

- 000: pll1_q_ck selected as SAI2 kernel clock (default after reset)
- 001: pll2_p_ck selected as SAI2 kernel clock
- 010: pll3_p_ck selected as SAI2 kernel clock
- 011: I2S_CKIN selected as SAI2 kernel clock
- 100: per_ck selected as SAI2 kernel clock
- 101: spdifrx_symb_ck selected as SAI2 kernel clock
- Others: reserved, the kernel clock is disabled

**Note:** I2S_CKIN is an external clock taken from a pin. spdifrx_symb_ck is the symbol clock generated by the spdifrx (see Figure 53).

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **SAI1SEL[2:0]**: SAI1 kernel clock source selection
Set and reset by software.

**Caution:** If the selected clock is the external clock and this clock is stopped, it is not possible to switch to another clock. Refer to Clock switches and gating on page 411 for additional information.

- 000: pll1_q_ck selected as SAI1 kernel clock (default after reset)
- 001: pll2_p_ck selected as SAI1 kernel clock
- 010: pll3_p_ck selected as SAI1 kernel clock
- 011: I2S_CKIN selected as SAI1 kernel clock
- 100: per_ck selected as SAI1 kernel clock
- Others: reserved, the kernel clock is disabled

**Note:** I2S_CKIN is an external clock taken from a pin.

Bits 15:11 Reserved, must be kept at reset value.
Bits 10:8 **SPI1SEL[2:0]**: SPI/I2S1 kernel clock source selection
Set and reset by software.

**Caution:** If the selected clock is the external clock and this clock is stopped, it is not be possible to switch to another clock. Refer to Clock switches and gating on page 411 for additional information.

000: **pll1_q_ck** selected as SPI/I2S1 and 7 kernel clock (default after reset)
001: **pll2_p_ck** selected as SPI/I2S1 and 7 kernel clock
010: **pll3_p_ck** selected as SPI/I2S1 and 7 kernel clock
011: **I2S_CKIN** selected as SPI/I2S1 and 7 kernel clock
100: **per_ck** selected as SPI/I2S1, and 7 kernel clock
others: reserved, the kernel clock is disabled

*Note: I2S_CKIN is an external clock taken from a pin.*

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **SPI45SEL[2:0]**: SPI4 and 5 kernel clock source selection
Set and reset by software.

000: **pclk2** selected as kernel clock (default after reset)
001: **pll2_q_ck** selected as kernel clock
010: **pll3_q_ck** selected as kernel clock
011: **hsi_ker_ck** selected as kernel clock
100: **csi_ker_ck** selected as kernel clock
101: **hse_ker_ck** selected as kernel clock
others: reserved, the kernel clock is disabled

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **USART1SEL[2:0]**: USART1 kernel clock source selection
Set and reset by software.

000: **pclk2** selected as kernel clock (default after reset)
001: **pll2_q_ck** selected as kernel clock
010: **pll3_q_ck** selected as kernel clock
011: **hsi_ker_ck** selected as kernel clock
100: **csi_ker_ck** selected as kernel clock
101: **lse_ck** selected as kernel clock
others: reserved, the kernel clock is disabled
7.8.27 RCC APB4,5 peripherals kernel clock selection register (RCC_CCIPR4)

Address offset: 0x058
Reset value: 0x0000 0000

Changing the clock source on-the-fly is allowed and does not generate any timing violation. However the user must make sure that both the previous and the new clock sources are present during the switching, and during the whole transition time. Refer to Clock switches and gating.

Bits 31:11 Reserved, must be kept at reset value.

**Bit 10 HSECSSF:** HSE clock security system interrupt flag  
- Reset by software by writing HSECSSC bit.  
- Set by hardware in case of HSE clock failure.  
  0: no clock security interrupt caused by HSE clock failure (default after reset)  
  1: clock security interrupt caused by HSE clock failure

**Bit 9 LSECSSF:** LSE clock security system interrupt flag  
- Reset by software by writing LSECSSC bit.  
- Set by hardware when a failure is detected on the external 32 kHz oscillator and LSECSSIE is set.  
  0: no failure detected on the external 32 kHz oscillator (default after reset)  
  1: failure detected on the external 32 kHz oscillator

**Bit 8 PLL3RDYF:** PLL3 ready interrupt flag  
- Reset by software by writing PLL3RDYC bit.  
- Set by hardware when the PLL3 locks and PLL3RDYIE is set.  
  0: no clock ready interrupt caused by PLL3 lock (default after reset)  
  1: clock ready interrupt caused by PLL3 lock
Bit 7  **PLL2RDYF**: PLL2 ready interrupt flag
Reset by software by writing PLL2RDYC bit.
Set by hardware when the PLL2 locks and PLL2RDYIE is set.
0: no clock ready interrupt caused by PLL2 lock (default after reset)
1: clock ready interrupt caused by PLL2 lock

Bit 6  **PLL1RDYF**: PLL1 ready interrupt flag
Reset by software by writing PLL1RDYC bit.
Set by hardware when the PLL1 locks and PLL1RDYIE is set.
0: no clock ready interrupt caused by PLL1 lock (default after reset)
1: clock ready interrupt caused by PLL1 lock

Bit 5  **HSI48RDYF**: HSI48 ready interrupt flag
Reset by software by writing HSI48RDYC bit.
Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set.
0: no clock ready interrupt caused by the HSI48 oscillator (default after reset)
1: clock ready interrupt caused by the HSI48 oscillator

Bit 4  **CSIRDYF**: CSI ready interrupt flag
Reset by software by writing CSIRDYC bit.
Set by hardware when the CSI clock becomes stable and CSIRDYIE is set.
0: no clock ready interrupt caused by the CSI (default after reset)
1: clock ready interrupt caused by the CSI

Bit 3  **HSERDYF**: HSE ready interrupt flag
Reset by software by writing HSERDYC bit.
Set by hardware when the HSE clock becomes stable and HSERDYIE is set.
0: no clock ready interrupt caused by the HSE (default after reset)
1: clock ready interrupt caused by the HSE

Bit 2  **HSIRDYF**: HSI ready interrupt flag
Reset by software by writing HSIRDYC bit.
Set by hardware when the HSI clock becomes stable and HSIRDYIE is set.
0: no clock ready interrupt caused by the HSI (default after reset)
1: clock ready interrupt caused by the HSI

Bit 1  **LSERDYF**: LSE ready interrupt flag
Reset by software by writing LSERDYC bit.
Set by hardware when the LSE clock becomes stable and LSERDYIE is set.
0: no clock ready interrupt caused by the LSE (default after reset)
1: clock ready interrupt caused by the LSE

Bit 0  **LSIRDYF**: LSI ready interrupt flag
Reset by software by writing LSIRDYC bit.
Set by hardware when the LSI clock becomes stable and LSIRDYIE is set.
0: no clock ready interrupt caused by the LSI (default after reset)
1: clock ready interrupt caused by the LSI

       Set by software to clear LSIRDYF.
       Reset by hardware when clear done.
       0: LSIRDYF no effect (default after reset)
       1: LSIRDYF cleared
### 7.8.31 RCC Backup domain control register (RCC_BDCR)

Address offset: 0x070  
Reset value: 0x0000 0010  
Reset by Backup domain reset.

Access: $0 \leq \text{wait state} \leq 7$, word, half-word and byte access. Wait states are inserted in case of successive accesses to this register.

After a system reset, the RCC_BDCR register is write-protected. To modify this register, the DBP bit in the PWR control register 1 (PWR_CR1) must be set to 1. RCC_BDCR bits are only reset after a Backup domain reset (see Section 7.4.5: Backup domain reset). Any other internal or external reset does not have any effect on these bits.

#### Table: RCC_BDCR register

</tbody>
</table>

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **VSWRST**: VSwitch domain software reset  
Set and reset by software.  
To generate a VSW reset, it is recommended to write this bit to 1, then back to 0.  
0: reset not activated (default after Backup domain reset)  
1: generates a reset pulse, resetting the entire VSW domain.

Bit 15 **RTCEN**: RTC clock enable  
Set and reset by software.  
0: rtc_ck disabled (default after Backup domain reset)  
1: rtc_ck enabled

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LSECSSRA**: Re-Arm the LSECSS function  
Set by software.  
After a LSE failure detection, the software application can re-enable the LSECSS by writing this bit to 1. Reading this bit returns the written value. Prior to set this bit to 1, LSECSSON must be set to 0. Refer to Section 7.4.4: CSS on LSE for details.  
0: Writing 0 has no effect (default after Backup domain reset)  
1: Writing 1 generates a re-arm pulse for the LSECSS function

Bits 11:10 Reserved, must be kept at reset value.
Bits 9:8 RTCSEL[1:0]: RTC clock source selection
- Set by software to select the clock source for the RTC. These bits can be written only one time (except in case of failure detection on LSE). These bits must be written before LSECSSON is enabled. The VSWRST bit can be used to reset them, then it can be written one time again. If HSE is selected as RTC clock, this clock is lost when the system is in Stop mode or in case of a pin reset (NRST).
  - 00: no clock (default after Backup domain reset)
  - 01: LSE selected as RTC clock
  - 10: LSI selected as RTC clock
  - 11: HSE divided by RTCPRE value selected as RTC clock

Bit 7 LSEEXT: low-speed external clock type in Bypass mode
- Set and reset by software to select the external clock type (analog or digital).
- The external clock must be enabled with the LSEON bit, to be used by the device.
- The LSEEXT bit can be written only if the LSE oscillator is disabled.
  - 0: LSE in analog mode (default after Backup domain reset)
  - 1: LSE in digital mode (do not use if RTC is active)

Bit 6 LSECSSD: LSE clock security system failure detection
- Set by hardware to indicate when a failure has been detected by the clock security system on the external 32 kHz oscillator.
  - 0: no failure detected on 32 kHz oscillator (default after Backup domain reset)
  - 1: failure detected on 32 kHz oscillator

Bit 5 LSECSSON: LSE clock security system enable
- Set by software to enable the clock security system on 32 kHz oscillator.
- LSECSSON must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware) and after RTCSEL is selected.
- Once enabled, this bit can only be disabled,
  - After a LSE failure detection (LSECSSD = 1). In that case the software must disable LSECSSON.
  - After a back-up domain reset
  - 0: CSS on 32 kHz oscillator OFF (default after Backup domain reset)
  - 1: CSS on 32 kHz oscillator ON

Bits 4:3 LSEDRV[1:0]: LSE oscillator driving capability
- Set by software to select the driving capability of the LSE oscillator.
  - 00: lowest drive
  - 01: medium-low drive
  - 10: medium-high drive (default after backup domain if LSEON=0)
  - 11: highest drive
### 7.8.32 RCC clock control and status register (RCC_CSR)

Address offset: 0x074

Reset value: 0x0000 0000

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

<table>

</thead>
<tbody>
<tr>
<td>Reserved</td>
<td>LSIRDY</td>
<td>LSION</td>
</tr>
</tbody>
</table>

**Bit 31:2** Reserved, must be kept at reset value.

**Bit 1** **LSIRDY**: LSI oscillator ready
- Set and reset by hardware to indicate when the low-speed internal RC oscillator is stable.
- This bit needs 3 cycles of lsi_ck clock to fall down after LSION has been set to 0.
- This bit can be set even when LSION is not enabled if there is a request for LSI clock by the clock security system on LSE or by the low-speed watchdog or by the RTC.
- 0: LSI clock is not ready (default after reset)
- 1: LSI clock is ready

**Bit 0** **LSION**: LSI oscillator enable
- Set and reset by software.
- 0: LSI is OFF (default after reset)
- 1: LSI is ON

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **CORDICRST**: CORDIC reset
   Set and reset by software.
   0: does not reset CORDIC block (default after reset)
   1: resets CORDIC block

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **SDMMC2RST**: SDMMC2 and SDMMC2 delay blocks reset
   Set and reset by software.
   0: does not reset SDMMC2 and SDMMC2 delay blocks (default after reset)
   1: resets SDMMC2 and SDMMC2 delay blocks

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **PSSIRST**: PSSI block reset
   Set and reset by software.
   0: does not reset PSSI block (default after reset)
   1: resets PSSI block

Bit 0 Reserved, must be kept at reset value.
7.8.35 RCC AHB3 peripheral reset register (RCC_AHB3RSTR)

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **PKARST**: PKA block reset
Set and reset by software.
0: does not reset PKA block (default after reset)
1: resets PKA block

Bit 5 Reserved, must be kept at reset value.

Bit 4 **SAESRST**: SAES block reset
Set and reset by software.
0: does not reset SAES block (default after reset)
1: resets SAES block

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CRYPRST**: CRYP block reset
Set and reset by software.
0: does not reset CRYP block (default after reset)
1: resets CRYP block

Bit 1 **HASHRST**: HASH block reset
Set and reset by software.
0: does not reset HASH block (default after reset)
1: resets HASH block

Bit 0 **RNGRST**: random number generator block reset
Set and reset by software.
0: does not reset RNG block (default after reset)
1: resets RNG block
### 7.8.36  RCC AHB4 peripheral reset register (RCC_AHB4RSTR)

Bit 6  **GPIOGRST**: GPIOG block reset
       Set and reset by software.
       0: does not reset the GPIOG block (default after reset)
       1: resets the GPIOG block

Bit 5  **GPIOFRST**: GPIOF block reset
       Set and reset by software.
       0: does not reset the GPIOF block (default after reset)
       1: resets the GPIOF block

Bit 4  **GPIOERST**: GPIOE block reset
       Set and reset by software.
       0: does not reset the GPIOE block (default after reset)
       1: resets the GPIOE block

Bit 3  **GPIODRST**: GPIOD block reset
       Set and reset by software.
       0: does not reset the GPIOD block (default after reset)
       1: resets the GPIOD block

Bit 2  **GPIOCRST**: GPIOC block reset
       Set and reset by software.
       0: does not reset the GPIOC block (default after reset)
       1: resets the GPIOC block

Bit 1  **GPIOBRST**: GPIOB block reset
       Set and reset by software.
       0: does not reset the GPIOB block (default after reset)
       1: resets the GPIOB block

Bit 0  **GPIOARST**: GPIOA block reset
       Set and reset by software.
       0: does not reset the GPIOA block (default after reset)
       1: resets the GPIOA block
7.8.37  RCC AHB5 peripheral reset register (RCC_AHB5RSTR)

Address offset: 0x07C
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:21 Reserved, must be kept at reset value.

Bit 20  **GPU2DRST**: GPU2D block reset
Set and reset by software.
0: reset is released (default after reset)
1: reset is asserted

Bit 19  **GFXMMURST**: GFXMMU block reset
Set and reset by software.
0: reset is released (default after reset)
1: reset is asserted

Bits 18:15 Reserved, must be kept at reset value.

Bit 14  **XSPIMRST**: XSPIM reset
Set and reset by software.
0: reset is released (default after reset)
1: reset is asserted

Bit 13 Reserved, must be kept at reset value.

Bit 12  **XSPI2RST**: XSPI2 and MCE2 blocks reset
Set and reset by software.
The hardware prevents writing this bit if XSPICKP = 1.
0: reset is released (default after reset)
1: reset is asserted

Bits 11:9 Reserved, must be kept at reset value.

Bit 8  **SDMMC1RST**: SDMMC1 and DB_SDMMC1 blocks reset
Set and reset by software.
0: reset is released (default after reset)
1: reset is asserted

Bits 7:6 Reserved, must be kept at reset value.
Bit 5 **XSPI1RST**: XSPI1 and MCE1 blocks reset
   Set and reset by software.
   The hardware prevents writing this bit if XSPICKP = 1.
   0: reset is released (default after reset)
   1: reset is asserted

Bit 4 **FMCRST**: FMC and MCE3 blocks reset
   Set and reset by software.
   The hardware prevents writing this bit if FMCCKP = 1.
   0: reset is released (default after reset)
   1: reset is asserted

Bit 3 **JPEGRST**: JPEG block reset
   Set and reset by software.
   0: reset is released (default after reset)
   1: reset is asserted

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DMA2DRST**: DMA2D block reset
   Set and reset by software.
   0: reset is released (default after reset)
   1: reset is asserted

Bit 0 **HPDMA1RST**: HPDMA1 block reset
   Set and reset by software.
   0: reset is released (default after reset)
   1: reset is asserted

  - 0: does not reset the I2C1/I3C1 block (default after reset)
  - 1: resets the I2C1/I3C1 block
Bit 20 **UART5RST**: UART5 block reset
Set and reset by software.
0: does not reset the UART5 block (default after reset)
1: resets the UART5 block

Bit 19 **UART4RST**: UART4 block reset
Set and reset by software.
0: does not reset the UART4 block (default after reset)
1: resets the UART4 block

Bit 18 **USART3RST**: USART3 block reset
Set and reset by software.
0: does not reset the USART3 block (default after reset)
1: resets the USART3 block

Bit 17 **USART2RST**: USART2 block reset
Set and reset by software.
0: does not reset the USART2 block (default after reset)
1: resets the USART2 block

Bit 16 **SPDIFRXRST**: SPDIFRX block reset
Set and reset by software.
0: does not reset the SPDIFRX block (default after reset)
1: resets the SPDIFRX block

Bit 15 **SPI3RST**: SPI2S3 block reset
Set and reset by software.
0: does not reset the SPI2S3 block (default after reset)
1: resets the SPI2S3 block

Bit 14 **SPI2RST**: SPI2S2 block reset
Set and reset by software.
0: does not reset the SPI2S2 block (default after reset)
1: resets the SPI2S2 block

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1RST**: LPTIM1 block reset
Set and reset by software.
0: does not reset the LPTIM1 block (default after reset)
1: resets the LPTIM1 block

Bit 8 **TIM14RST**: TIM14 block reset
Set and reset by software.
0: does not reset the TIM14 block (default after reset)
1: resets the TIM14 block

Bit 7 **TIM13RST**: TIM13 block reset
Set and reset by software.
0: does not reset the TIM13 block (default after reset)
1: resets the TIM13 block

Bit 6 **TIM12RST**: TIM12 block reset
Set and reset by software.
0: does not reset the TIM12 block (default after reset)
1: resets the TIM12 block
Bit 5 **TIM7RST**: TIM7 block reset
Set and reset by software.
0: does not reset the TIM7 block (default after reset)
1: resets the TIM7 block

Bit 4 **TIM6RST**: TIM6 block reset
Set and reset by software.
0: does not reset the TIM6 block (default after reset)
1: resets the TIM6 block

Bit 3 **TIM5RST**: TIM5 block reset
Set and reset by software.
0: does not reset the TIM5 block (default after reset)
1: resets the TIM5 block

Bit 2 **TIM4RST**: TIM4 block reset
Set and reset by software.
0: does not reset the TIM4 block (default after reset)
1: resets the TIM4 block

Bit 1 **TIM3RST**: TIM3 block reset
Set and reset by software.
0: does not reset the TIM3 block (default after reset)
1: resets the TIM3 block

Bit 0 **TIM2RST**: TIM2 block reset
Set and reset by software.
0: does not reset the TIM2 block (default after reset)
1: resets the TIM2 block
## 7.8.39 RCC APB1 peripheral reset register 2 (RCC_APB1RSTR2)

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **UCPD1RST**: UCPD block reset  
Set and reset by software.  
0: does not reset the UCPD block (default after reset)  
1: resets the UCPD block

Bits 26:9 Reserved, must be kept at reset value.

Bit 8 **FDCANRST**: FDCAN block reset  
Set and reset by software.  
0: does not reset the FDCAN block (default after reset)  
1: resets the FDCAN block

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **MDIOSRST**: MDIOS block reset  
Set and reset by software.  
0: does not reset the MDIOS block (default after reset)  
1: resets the MDIOS block

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CRSRST**: clock recovery system reset  
Set and reset by software.  
0: does not reset CRS (default after reset)  
1: resets CRS

Bit 0 Reserved, must be kept at reset value.

**Bits 31:24**  Reserved, must be kept at reset value.

**Bit 23**  **SAI2RST**: SAI2 block reset  
Set and reset by software.  
0: does not reset the SAI2 (default after reset)  
1: resets the SAI2

**Bit 22**  **SAI1RST**: SAI1 block reset  
Set and reset by software.  
0: does not reset the SAI1 (default after reset)  
1: resets the SAI1

**Bit 21**  Reserved, must be kept at reset value.

**Bit 20**  **SPI5RST**: SPI5 block reset  
Set and reset by software.  
0: does not reset the SPI5 block (default after reset)  
1: resets the SPI5 block

**Bit 19**  **TIM9RST**: TIM9 block reset  
Set and reset by software.  
0: does not reset the TIM9 block (default after reset)  
1: resets the TIM9 block

**Bit 18**  **TIM17RST**: TIM17 block reset  
Set and reset by software.  
0: does not reset the TIM17 block (default after reset)  
1: resets the TIM17 block

**Bit 17**  **TIM16RST**: TIM16 block reset  
Set and reset by software.  
0: does not reset the TIM16 block (default after reset)  
1: resets the TIM16 block

**Bit 16**  **TIM15RST**: TIM15 block reset  
Set and reset by software.  
0: does not reset the TIM15 block (default after reset)  
1: resets the TIM15 block
Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4RST**: SPI4 block reset
Set and reset by software.
0: does not reset the SPI4 block (default after reset)
1: resets the SPI4 block

Bit 12 **SPI1RST**: SPI2S1 block reset
Set and reset by software.
0: does not reset the SPI2S1 block (default after reset)
1: resets the SPI2S1 block

Bits 11:5 Reserved, must be kept at reset value.

Bit 4 **USART1RST**: USART1 block reset
Set and reset by software.
0: does not reset the USART1 block (default after reset)
1: resets the USART1 block

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **TIM1RST**: TIM1 block reset
Set and reset by software.
0: does not reset the TIM1 block (default after reset)
1: resets the TIM1 block
7.8.41 RCC APB4 peripheral reset register (RCC_APB4RSTR)

Address offset: 0x09C
Reset value: 0x0000 0000

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 DTSRST: DTS block reset
Set and reset by software.
0: does not reset the DTS block (default after reset)
1: resets the DTS block

Bits 25:16 Reserved, must be kept at reset value.

Bit 15 VREFRST: VREF block reset
Set and reset by software.
0: does not reset the VREF block (default after reset)
1: resets the VREF block

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 LPTIM5RST: LPTIM5 block reset
Set and reset by software.
0: does not reset the LPTIM5 block (default after reset)
1: resets the LPTIM5 block

Bit 11 LPTIM4RST: LPTIM4 block reset
Set and reset by software.
0: does not reset the LPTIM4 block (default after reset)
1: resets the LPTIM4 block

Bit 10 LPTIM3RST: LPTIM3 block reset
Set and reset by software.
0: does not reset the LPTIM3 block (default after reset)
1: resets the LPTIM3 block

Bit 9 LPTIM2RST: LPTIM2 block reset
Set and reset by software.
0: does not reset the LPTIM2 block (default after reset)
1: resets the LPTIM2 block

Bits 8:6 Reserved, must be kept at reset value.
Bit 5  **SPI6RST**: SPI/I2S6 block reset
   Set and reset by software.
   0: does not reset the SPI/I2S6 block (default after reset)
   1: resets the SPI/I2S6 block

Bit 4  Reserved, must be kept at reset value.

Bit 3  **LPUART1RST**: LPUART1 block reset
   Set and reset by software.
   0: does not reset the LPUART1 block (default after reset)
   1: resets the LPUART1 block

Bit 2  Reserved, must be kept at reset value.

Bit 1  **SBSRST**: SBS block reset
   Set and reset by software.
   0: does not reset the SBS block (default after reset)
   1: resets the SBS block

Bit 0  Reserved, must be kept at reset value.
### 7.8.42 RCC APB5 peripheral reset register (RCC_APB5RSTR)

| 4 | GFTXIMRST | GFXTIM block reset  
Set and reset by software.  
0: does not reset the GFXTIM block (default after reset)  
1: resets the GFXTIM block |
| 3 | Reserved | Must be kept at reset value. |
| 2 | DCMIPPRST | DCMIPP block reset  
Set and reset by software.  
0: does not reset the DCMIPP block (default after reset)  
1: resets the DCMIPP block |
| 1 | LTDCRST | LTDC block reset  
Set and reset by software.  
0: does not reset the LTDC block (default after reset)  
1: resets the LTDC block |
| 0 | Reserved | Must be kept at reset value. |
### 7.8.43 RCC AXI clocks gating disable register (RCC_CKGDISR)

Address offset: 0x0B0  
Reset value: 0x8000 0000

The dynamic power consumption can be optimized by enabling the functional clock gating.

**Bit 31 JTAGCKG**: JTAG automatic clock gating disabling  
This bit is set and reset by software.  
0: The clock gating is enabled. The clock is disabled except if a JTAG connection has been detected  
1: The clock gating is disabled. The clock is always enabled. (default after reset)

**Bit 30 EXTICKG**: EXTI clock gating disable  
This bit is set and reset by software.  
0: The clock gating is enabled. The clock is enabled after an event detection and stopped again when the event flag is cleared. (default after reset)  
1: The clock gating is disabled. The clock is always enabled.

**Bits 29:22 Reserved**, must be kept at reset value.

**Bit 21 FLASHCKG**: AXI slave Flash interface (FLIFT) clock gating disable  
This bit is set and reset by software.  
0: The clock gating is enabled. The clock of the AXI slave port connected to the FLASH is enabled on bus transaction request. (default after reset)  
1: The clock gating is disabled. The clock is always enabled.

**Bit 20 AXISRAM1CKG**: AXI slave SRAM1 / error code correction (ECC) clock gating disable  
This bit is set and reset by software.  
0: The clock gating is enabled. The clock of the AXI slave port connected to the SRAM1 is enabled on bus transaction request. (default after reset)  
1: The clock gating is disabled. The clock is always enabled.

**Bit 19 AXISRAM2CKG**: AXI slave SRAM2 clock gating disable  
This bit is set and reset by software.  
0: The clock gating is enabled. The clock of the AXI slave port connected to the SRAM2 is enabled on bus transaction request. (default after reset)  
1: The clock gating is disabled. The clock is always enabled.
Bit 18 **AXISRAM3CKG**: AXI matrix slave SRAM3 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the SRAM3 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 17 **AXISRAM4CKG**: AXI matrix slave SRAM4 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the SRAM4 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 16 **XSPI2CKG**: AXI slave XSPI2 and MCE2 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the XSPI2 and MCE2 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 15 **XSPI1CKG**: AXI slave XSPI1 and MCE1 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the XSPI1 and MCE1 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 14 **FMCCKG**: AXI slave FMC and MCE3 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the FMC and MCE3 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 13 **AHBSCKG**: AXI slave AHB clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The AXI matrix slave AHB clock is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 12 **GFXMMUMCKG**: AXI master GFXMMU clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the GFXMMU is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 11 **LTDCCKG**: AXI master LTDC clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the LTDC is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 10 **GFXMMUSCKG**: AXI matrix slave GFXMMU clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the GFXMMU is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled
Bit 9 **DMA2DCKG**: AXI master DMA2D clock gating disable  
This bit is set and reset by software.  
0: The clock gating is enabled. The clock of the AXI master port connected to the DMA2D is enabled on bus transaction request. (default after reset)  
1: The clock gating is disabled. The clock is always enabled

Bit 8 **DCMIPPCKG**: AXI master DCMIPP clock gating disable  
This bit is set and reset by software.  
0: The clock gating is enabled. The clock of the AXI master port connected to the DCMIPP is enabled on bus transaction request. (default after reset)  
1: The clock gating is disabled. The clock is always enabled.

Bit 7 **GPU2DCLCKG**: AXI master cache GPU2D clock gating disable  
This bit is set and reset by software.  
0: The clock gating is enabled. The clock of the AXI master port connected to the GPU2D I-Cache is enabled on bus transaction request. (default after reset)  
1: The clock gating is disabled. The clock is always enabled.

Bit 6 **GPU2D$S1CKG**: AXI master 1 GPU2D clock gating disable  
This bit is set and reset by software.  
0: The clock gating is enabled. The clock of the AXI master port connected to the GPU2D port 1 is enabled on bus transaction request. (default after reset)  
1: The clock gating is disabled. The clock is always enabled.

Bit 5 **GPU2D$S0CKG**: AXI master 0 GPU2D clock gating disable  
This bit is set and reset by software.  
0: The clock gating is enabled. The clock of the AXI master port connected to the GPU2D port 0 is enabled on bus transaction request. (default after reset)  
1: The clock gating is disabled. The clock is always enabled.

Bit 4 **CPUCKG**: AXI master CPU clock gating disable  
This bit is set and reset by software.  
0: The clock gating is enabled. The clock of the AXI master port connected to the CPU is enabled on bus transaction request. (default after reset)  
1: The clock gating is disabled. The clock is always enabled.

Bit 3 **HPDMA1CKG**: AXI master HPDMA1 clock gating disable  
This bit is set and reset by software.  
0: The clock gating is enabled. The clock of the AXI master port connected to the HPDMA1 is enabled on bus transaction request. (default after reset)  
1: The clock gating is disabled. The clock is always enabled.
Bit 2  **SDMMC1CKG**: AXI master SDMMC1 clock gating disable
   This bit is set and reset by software.
   0: The clock gating is enabled. The clock of the AXI master port connected to SDMMC1 is enabled on bus transaction request. (default after reset)
   1: The clock gating is disabled. The clock is always enabled.

Bit 1  **AHBMCKG**: AXI master AHB clock gating disable
   This bit is set and reset by software.
   0: The clock gating is enabled. The clock of the AXI master port connected to the AHB interconnect is enabled on bus transaction request. (default after reset)
   1: The clock gating is disabled. The clock is always enabled.

Bit 0  **AXICKG**: AXI interconnect matrix clock gating disable
   This bit is set and reset by software.
   0: The clock gating is enabled. The AXI interconnect matrix clock is enabled on bus transaction request. (default after reset)
   1: The clock gating is disabled. The clock is always enabled
## 7.8.44 RCC Reset status register (RCC_RSR)

Address offset: 0x130  
Reset value: 0x00E0 0000  
Reset by power-on reset only.

Access: $0 \leq$ wait state $\leq 7$, word, half-word and byte access. Wait states are inserted in case of successive accesses to this register.

### Bit Descriptions

#### Bit 31 Reserve, must be kept at reset value.

#### Bit 30 LPWRRSTF: reset due to illegal Stop or Standby flag \(^{(1)}\)
- Reset by software by writing the RMVF bit.
- Set by hardware when the CPU goes erroneously in Stop or Standby mode,
  - 0: no illegal reset occurred (default after power-on reset)
  - 1: illegal Stop or Standby reset occurred

#### Bit 29 Reserve, must be kept at reset value.

#### Bit 28 WWDGRSTF: window watchdog reset flag \(^{(1)}\)
- Reset by software by writing the RMVF bit.
- Set by hardware when a window watchdog reset occurs.
  - 0: no window watchdog reset occurred from WWDG (default after power-on reset)
  - 1: window watchdog reset occurred from WWDG

#### Bit 27 Reserve, must be kept at reset value.

#### Bit 26 IWGRSTF: independent watchdog reset flag \(^{(1)}\)
- Reset by software by writing the RMVF bit.
- Set by hardware when an independent watchdog reset occurs.
  - 0: no independent watchdog reset occurred (default after power-on reset)
  - 1: independent watchdog reset occurred

#### Bit 25 Reserve, must be kept at reset value.

#### Bit 24 SFTRSTF: system reset from CPU reset flag \(^{(1)}\)
- Reset by software by writing the RMVF bit.
- Set by hardware when the system reset is due to CPU. The CPU can generate a system reset by writing SYSRESETREQ bit of AIRCR register of the core M7.
  - 0: no CPU software reset occurred (default after power-on reset)
  - 1: a system reset has been generated by the CPU

Bit 23 **PORRSTF**: POR/PDR reset flag (1)
- Reset by software by writing the RMVF bit.
- Set by hardware when a POR/PDR reset occurs.
  - 0: no POR/PDR reset occurred
  - 1: POR/PDR reset occurred (default after power-on reset)

Bit 22 **PINRSTF**: pin reset flag (NRST) (1)
- Reset by software by writing the RMVF bit.
- Set by hardware when a reset from pin occurs.
  - 0: no reset from pin occurred
  - 1: reset from pin occurred (default after power-on reset)

Bit 21 **BORRSTF**: BOR reset flag (1)
- Reset by software by writing the RMVF bit.
- Set by hardware when a BOR reset occurs (pwr_bor_rst).
  - 0: no BOR reset occurred
  - 1: BOR reset occurred (default after power-on reset)

Bits 20:18 Reserved, must be kept at reset value.

Bit 17 **OBLRSTF**: Option byte loading reset flag (1)
- Reset by software by the RMVF bit.
- Set by hardware when a reset from the option byte loading occurs.
  - 0: No reset from option byte loading occurred
  - 1: Reset from option byte loading occurred

Bit 16 **RMVF**: remove reset flag
- Set and reset by software to reset the value of the reset flags.
  - 0: reset of the reset flags not activated (default after power-on reset)
  - 1: resets the value of the reset flags

Bits 15:0 Reserved, must be kept at reset value.

1. Refer to *Table 57: Reset source identification (RCC_RSR)* for details on flag behavior.

Bit 15 **ETH1MACEN**: ETH1 MAC peripheral clock enable
  Set and reset by software.
  0: ETH1 MAC peripheral clock disabled (default after reset)
  1: ETH1 MAC peripheral clock enabled

Bits 14:6 Reserved, must be kept at reset value.

Bit 5 **ADC12EN**: ADC1 and 2 peripheral clocks enable
  Set and reset by software.
  0: ADC1 and 2 peripheral clocks disabled (default after reset)
  1: ADC1 and 2 peripheral clocks enabled
  The peripheral clocks of the ADC1 and 2 are the kernel clock selected by ADCSEL and provided to
  ADCx_CK input, and the **hclk1** bus interface clock.

Bit 4 **GPDMA1EN**: GPDMA1 clock enable
  Set and reset by software.
  0: GPDMA1 clock disabled (default after reset)
  1: GPDMA1 clock enabled

Bits 3:0 Reserved, must be kept at reset value.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SRAM2EN**: SRAM2 clock enable
Set and reset by software.
0: SRAM2 clock disabled (default after reset)
1: SRAM2 clock enabled

Bit 29 **SRAM1EN**: SRAM1 clock enable
Set and reset by software.
0: SRAM1 clock disabled (default after reset)
1: SRAM1 clock enabled

Bits 28:15 Reserved, must be kept at reset value.

Bit 14 **CORDICEN**: CORDIC clock enable
Set and reset by software.
0: CORDIC clock disabled (default after reset)
1: CORDIC clock enabled

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **SDMMC2EN**: SDMMC2 and SDMMC2 delay clock enable
Set and reset by software.
0: SDMMC2 and SDMMC2 delay clock disabled (default after reset)
1: SDMMC2 and SDMMC2 delay clock enabled

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **PSSIEN**: PSSI peripheral clocks enable
Set and reset by software.
0: PSSI peripheral clocks disabled (default after reset)
1: PSSI peripheral clocks enabled

Bit 0 Reserved, must be kept at reset value.

Bits 31:7 Reserved, must be kept at reset value.

**Bit 6 PKAEN**: PKA peripheral clock enable
- Set and reset by software.
  - 0: PKA peripheral clock disabled (default after reset)
  - 1: PKA peripheral clock enabled

**Bit 5** Reserved, must be kept at reset value.

**Bit 4 SAESEN**: SAES peripheral clock enable
- Set and reset by software.
  - This bit controls the enable of the clock delivered to the SAES.
  - 0: The SAES peripheral clocks are disabled (default after reset)
  - 1: The SAES peripheral clocks are enabled

**Bit 3** Reserved, must be kept at reset value.

**Bit 2 CRYPEN**: CRYP peripheral clock enable
- Set and reset by software.
  - 0: CRYP peripheral clock disabled (default after reset)
  - 1: CRYP peripheral clock enabled

**Bit 1 HASHEN**: HASH peripheral clock enable
- Set and reset by software.
  - 0: HASH peripheral clock disabled (default after reset)
  - 1: HASH peripheral clock enabled

**Bit 0 RNGEN**: RNG peripheral clocks enable
- Set and reset by software.
  - 0: RNG peripheral clocks disabled (default after reset)
  - 1: RNG peripheral clocks enabled.

Bits 31:29  Reserved, must be kept at reset value.

Bit 28  BKPRA: Backup RAM clock enable
Set and reset by software.
0: Backup RAM clock disabled (default after reset)
1: Backup RAM clock enabled

Bits 27:20  Reserved, must be kept at reset value.

Bit 19  CRCEN: CRC clock enable
Set and reset by software.
0: CRC clock disabled (default after reset)
1: CRC clock enabled

Bits 18:16  Reserved, must be kept at reset value.

Bit 15  GPIOPEN: GPIOP peripheral clock enable
Set and reset by software.
0: GPIOP peripheral clock disabled (default after reset)
1: GPIOP peripheral clock enabled

Bit 14  GPIOOEN: GPIOO peripheral clock enable
Set and reset by software.
0: GPIOO peripheral clock disabled (default after reset)
1: GPIOO peripheral clock enabled

Bit 13  GPIONEN: GPION peripheral clock enable
Set and reset by software.
0: GPION peripheral clock disabled (default after reset)
1: GPION peripheral clock enabled

Bit 12  GPIOMEN: GPIOM peripheral clock enable
Set and reset by software.
0: GPIOM peripheral clock disabled (default after reset)
1: GPIOM peripheral clock enabled

Bits 11:8  Reserved, must be kept at reset value.
Bit 7  **GPIOHEN**: GPIOH peripheral clock enable
Set and reset by software.
0: GPIOH peripheral clock disabled (default after reset)
1: GPIOH peripheral clock enabled

Bit 6  **GPIOGEN**: GPIOG peripheral clock enable
Set and reset by software.
0: GPIOG peripheral clock disabled (default after reset)
1: GPIOG peripheral clock enabled

Bit 5  **GPIOFEN**: GPIOF peripheral clock enable
Set and reset by software.
0: GPIOF peripheral clock disabled (default after reset)
1: GPIOF peripheral clock enabled

Bit 4  **GPIOEEN**: GPIOE peripheral clock enable
Set and reset by software.
0: GPIOE peripheral clock disabled (default after reset)
1: GPIOE peripheral clock enabled

Bit 3  **GPIODEN**: GPIOD peripheral clock enable
Set and reset by software.
0: GPIOD peripheral clock disabled (default after reset)
1: GPIOD peripheral clock enabled

Bit 2  **GPIOCEN**: GPIOC peripheral clock enable
Set and reset by software.
0: GPIOC peripheral clock disabled (default after reset)
1: GPIOC peripheral clock enabled

Bit 1  **GPIOBEN**: GPIOB peripheral clock enable
Set and reset by software.
0: GPIOB peripheral clock disabled (default after reset)
1: GPIOB peripheral clock enabled

Bit 0  **GPIOAEN**: GPIOA peripheral clock enable
Set and reset by software.
0: GPIOA peripheral clock disabled (default after reset)
1: GPIOA peripheral clock enabled

Bits 31:21 Reserved, must be kept at reset value.

**Bit 20 GPU2DEN**: GPU2D peripheral clock enable  
Set and reset by software.  
0: GPU2D peripheral clock disabled (default after reset)  
1: GPU2D peripheral clock enabled

**Bit 19 GFXMMUEN**: GFXMMU peripheral clock enable  
Set and reset by software.  
0: GFXMMU peripheral clock disabled (default after reset)  
1: GFXMMU peripheral clock enabled

Bits 18:15 Reserved, must be kept at reset value.

**Bit 14 XSPIMEN**: XSPIM peripheral clock enable  
Set and reset by software.  
0: XSPIM peripheral clock disabled (default after reset)  
1: XSPIM peripheral clock enabled

**Bit 13 Reserved, must be kept at reset value.**

**Bit 12 XSPI2EN**: XSPI2 and MCE2 peripheral clocks enable  
Set and reset by software.  
The hardware prevents writing this bit if XSPICKP = 1.  
0: XSPI2 and MCE2 peripheral clocks disabled (default after reset)  
1: XSPI2 and MCE2 peripheral clocks enabled

Bits 11:9 Reserved, must be kept at reset value.

**Bit 8 SDMMC1EN**: SDMMC1 and DB_SDMMC1 peripheral clocks enable  
Set and reset by software.  
0: SDMMC1 and DB_SDMMC1 peripheral clocks disabled (default after reset)  
1: SDMMC1 and DB_SDMMC1 peripheral clocks enabled

Bits 7:6 Reserved, must be kept at reset value.
Bit 5 **XSPI1EN**: XSPI1 and MCE1 peripheral clocks enable
- Set and reset by software.
  - The hardware prevents writing this bit if XSPICKP = 1.
  - 0: XSPI1 and MCE1 peripheral clocks disabled (default after reset)
  - 1: XSPI1 and MCE1 peripheral clocks enabled

Bit 4 **FMCEN**: FMC and MCE3 peripheral clocks enable
- Set and reset by software.
  - The hardware prevents writing this bit if FMCCKP = 1.
  - 0: FMC and MCE3 peripheral clocks disabled (default after reset)
  - 1: FMC and MCE3 peripheral clocks enabled
  - The peripheral clocks of the FMC are the kernel clock selected by FMCSEL, and the **hclk5** bus interface clock.

Bit 3 **JPEGEN**: JPEG peripheral clock enable
- Set and reset by software.
  - 0: JPEG peripheral clock disabled (default after reset)
  - 1: JPEG peripheral clock enabled

Bit 2 **Reserved**, must be kept at reset value.

Bit 1 **DMA2DEN**: DMA2D peripheral clock enable
- Set and reset by software.
  - 0: DMA2D peripheral clock disabled (default after reset)
  - 1: DMA2D peripheral clock enabled

Bit 0 **HPDMA1EN**: HPDMA1 peripheral clock enable
- Set and reset by software.
  - 0: HPDMA1 peripheral clock disabled (default after reset)
  - 1: HPDMA1 peripheral clock enabled

**Bit 31** **UART8EN**: UART8 peripheral clocks enable  
- Set and reset by software.  
- 0: UART8 peripheral clocks disabled (default after reset)  
- 1: UART8 peripheral clocks enabled

**Bit 30** **UART7EN**: UART7 peripheral clocks enable  
- Set and reset by software.  
- 0: UART7 peripheral clocks disabled (default after reset)  
- 1: UART7 peripheral clocks enabled

**Bits 29:28** **Reserved**, must be kept at reset value.

**Bit 27** **CECEN**: HDMI-CEC peripheral clock enable  
- Set and reset by software.  
- 0: HDMI-CEC peripheral clock disabled (default after reset)  
- 1: HDMI-CEC peripheral clock enabled

**Bits 26:24** **Reserved**, must be kept at reset value.

**Bit 23** **I2C3EN**: I2C3 peripheral clocks enable  
- Set and reset by software.  
- 0: I2C3 peripheral clocks disabled (default after reset)  
- 1: I2C3 peripheral clocks enabled

**Bit 22** **I2C2EN**: I2C2 peripheral clocks enable  
- Set and reset by software.  
- 0: I2C2 peripheral clocks disabled (default after reset)  
- 1: I2C2 peripheral clocks enabled

**Bit 21** **I2C1/I3C1EN**: I2C1/I3C1 peripheral clocks enable  
- Set and reset by software.  
- 0: I2C1/I3C1 peripheral clocks disabled (default after reset)  
- 1: I2C1/I3C1 peripheral clocks enabled

**Bit 20** **UART5EN**: UART5 peripheral clocks enable  
- Set and reset by software.  
- 0: UART5 peripheral clocks disabled (default after reset)  
- 1: UART5 peripheral clocks enabled
Bit 19 **UART4EN**: UART4 peripheral clocks enable
- Set and reset by software.
- 0: UART4 peripheral clocks disabled (default after reset)
- 1: UART4 peripheral clocks enabled
  The peripheral clocks of the UART4 are the kernel clock selected by USART234578SEL and provided to UCLK input, and the \texttt{rcc\_pclk1} bus interface clock.

Bit 18 **USART3EN**: USART3 peripheral clocks enable
- Set and reset by software.
- 0: USART3 peripheral clocks disabled (default after reset)
- 1: USART3 peripheral clocks enabled
  The peripheral clocks of the USART3 are the kernel clock selected by USART234578SEL and provided to UCLK input, and the \texttt{rcc\_pclk1} bus interface clock.

Bit 17 **USART2EN**: USART2 peripheral clocks enable
- Set and reset by software.
- 0: USART2 peripheral clocks disabled (default after reset)
- 1: USART2 peripheral clocks enabled
  The peripheral clocks of the USART2 are the kernel clock selected by USART234578SEL and provided to UCLK input, and the \texttt{rcc\_pclk1} bus interface clock.

Bit 16 **SPDIFRXEN**: SPDIFRX peripheral clocks enable
- Set and reset by software.
- 0: SPDIFRX peripheral clocks disabled (default after reset)
- 1: SPDIFRX peripheral clocks enabled
  The peripheral clocks of the SPDIFRX are the kernel clock selected by SPDIFRXSEL and provided to SPDIFRX\_CLK input, and the \texttt{rcc\_pclk1} bus interface clock.

Bit 15 **SPI3EN**: SPI3 peripheral clocks enable
- Set and reset by software.
- 0: SPI3 peripheral clocks disabled (default after reset)
- 1: SPI3 peripheral clocks enabled
  The peripheral clocks of the SPI3 are the kernel clock selected by I2S123SRC and provided to \texttt{com\_clk} input, and the \texttt{rcc\_pclk1} bus interface clock.

Bit 14 **SPI2EN**: SPI2 peripheral clocks enable
- Set and reset by software.
- 0: SPI2 peripheral clocks disabled (default after reset)
- 1: SPI2 peripheral clocks enabled
  The peripheral clocks of the SPI2 are the kernel clock selected by I2S123SRC and provided to \texttt{com\_clk} input, and the \texttt{rcc\_pclk1} bus interface clock.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WWDGEN**: WWDG clock enable
- Set by software, and reset by hardware when a system reset occurs.
- 0: WWDG peripheral clock disable (default after reset)
- 1: WWDG peripheral clock enabled

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1EN**: LPTIM1 peripheral clocks enable
- Set and reset by software.
- 0: LPTIM1 peripheral clocks disabled (default after reset)
- 1: LPTIM1 peripheral clocks enabled
  The peripheral clocks of the LPTIM1 are the kernel clock selected by LPTIM1SEL and provided to \texttt{clk\_lpt} input, and the \texttt{rcc\_pclk1} bus interface clock.
Bit 8 **TIM14EN**: TIM14 peripheral clock enable
   Set and reset by software.
   0: TIM14 peripheral clock disabled (default after reset)
   1: TIM14 peripheral clock enabled

Bit 7 **TIM13EN**: TIM13 peripheral clock enable
   Set and reset by software.
   0: TIM13 peripheral clock disabled (default after reset)
   1: TIM13 peripheral clock enabled

Bit 6 **TIM12EN**: TIM12 peripheral clock enable
   Set and reset by software.
   0: TIM12 peripheral clock disabled (default after reset)
   1: TIM12 peripheral clock enabled

Bit 5 **TIM7EN**: TIM7 peripheral clock enable
   Set and reset by software.
   0: TIM7 peripheral clock disabled (default after reset)
   1: TIM7 peripheral clock enabled

Bit 4 **TIM6EN**: TIM6 peripheral clock enable
   Set and reset by software.
   0: TIM6 peripheral clock disabled (default after reset)
   1: TIM6 peripheral clock enabled

Bit 3 **TIM5EN**: TIM5 peripheral clock enable
   Set and reset by software.
   0: TIM5 peripheral clock disabled (default after reset)
   1: TIM5 peripheral clock enabled

Bit 2 **TIM4EN**: TIM4 peripheral clock enable
   Set and reset by software.
   0: TIM4 peripheral clock disabled (default after reset)
   1: TIM4 peripheral clock enabled

Bit 1 **TIM3EN**: TIM3 peripheral clock enable
   Set and reset by software.
   0: TIM3 peripheral clock disabled (default after reset)
   1: TIM3 peripheral clock enabled

Bit 0 **TIM2EN**: TIM2 peripheral clock enable
   Set and reset by software.
   0: TIM2 peripheral clock disabled (default after reset)
   1: TIM2 peripheral clock enabled

[RM0477 Rev 6] 509/3791
Bits 31:27  Reserved, must be kept at reset value.

  Bit 26  **DTSEN**: Temperature Sensor peripheral clock enable
  Set and reset by software.
  0: DTS peripheral clock disabled (default after reset)
  1: DTS peripheral clock enabled

Bits 25:17  Reserved, must be kept at reset value.

  Bit 16  **RTCAPBEN**: RTC APB clock enable
  Set and reset by software.
  0: The register clock interface of the RTC (APB) is disabled
  1: The register clock interface of the RTC (APB) is enabled (default after reset)

  Bit 15  **VREFEN**: VREF peripheral clock enable
  Set and reset by software.
  0: VREF peripheral clock disabled (default after reset)
  1: VREF peripheral clock enabled

Bits 14:13  Reserved, must be kept at reset value.

  Bit 12  **LPTIM5EN**: LPTIM5 peripheral clocks enable
  Set and reset by software.
  0: LPTIM5 peripheral clocks disabled (default after reset)
  1: LPTIM5 peripheral clocks enabled
  The LPTIM5 kernel clock can be selected by LPTIM45SEL.

  Bit 11  **LPTIM4EN**: LPTIM4 peripheral clocks enable
  Set and reset by software.
  0: LPTIM4 peripheral clocks disabled (default after reset)
  1: LPTIM4 peripheral clocks enabled
  The LPTIM4 kernel clock can be selected by LPTIM45SEL.

  Bit 10  **LPTIM3EN**: LPTIM3 peripheral clocks enable
  Set and reset by software.
  0: LPTIM3 peripheral clocks disabled (default after reset)
  1: LPTIM3 peripheral clocks enabled
  The LPTIM3 kernel clock can be selected by LPTIM23SEL.

  Bit 9  **LPTIM2EN**: LPTIM2 peripheral clocks enable
  Set and reset by software.
  0: LPTIM2 peripheral clocks disabled (default after reset)
  1: LPTIM2 peripheral clocks enabled
  The LPTIM2 kernel clock can be selected by LPTIM23SEL.

Bits 8:6  Reserved, must be kept at reset value.

  Bit 5  **SPI6EN**: SPI/I2S6 peripheral clocks enable
  Set and reset by software.
  0: SPI/I2S6 peripheral clocks disabled (default after reset)
  1: SPI/I2S6 peripheral clocks enabled
  The peripheral clocks of the SPI/I2S6 are the kernel clock selected by SPI6SEL and provided to `com_clk` input, and the `pclk4` bus interface clock.

  Bit 4  Reserved, must be kept at reset value.
Bit 3 **LPUART1EN**: LPUART1 peripheral clocks enable
   Set and reset by software.
   0: LPUART1 peripheral clocks disabled (default after reset)
   1: LPUART1 peripheral clocks enabled
   The peripheral clocks of the LPUART1 are the kernel clock selected by LPUART1SEL and provided
to UCLK input, and the **pclk4** bus interface clock.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SBSEN**: SBS peripheral clock enable
   Set and reset by software.
   0: SBS peripheral clock disabled (default after reset)
   1: SBS peripheral clock enabled

Bit 0 Reserved, must be kept at reset value.

Bit 14 **XSPIMLPEN**: XSPIM low-power peripheral clock enable
Set and reset by software.
0: XSPIM interface peripheral clock disabled in low-power mode
1: XSPIM interface peripheral clock enabled in low-power mode (default after reset)

Bit 13 Reserved, must be kept at reset value.

Bit 12 **XSPI2LPEN**: XSPI2 and MCE2 low-power peripheral clock enable
Set and reset by software.
The hardware prevents writing this bit if XSPICKP = 1.
0: XSPI2 and MCE2 peripheral clock disabled in low-power mode
1: XSPI2 and MCE2 peripheral clock enabled in low-power mode (default after reset)

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC1LPEN**: SDMMC1 and SDMMC1 delay low-power peripheral clock enable
Set and reset by software.
0: SDMMC1 and SDMMC1 delay peripheral clock disabled in low-power mode
1: SDMMC1 and SDMMC1 delay peripheral clock enabled in low-power mode (default after reset)

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **XSPI1LPEN**: XSPI1 and MCE1 low-power peripheral clock enable
Set and reset by software.
The hardware prevents writing this bit if XSPICKP = 1.
0: XSPI1 and MCE1 peripheral clock disabled in low-power mode
1: XSPI1 and MCE1 peripheral clock enabled in low-power mode (default after reset)

Bit 4 **FMCLPEN**: FMC and MCE3 peripheral clocks enable in low-power mode
Set and reset by software.
The hardware prevents writing this bit if FMCCKP = 1.
0: FMC and MCE3 peripheral clocks disabled in low-power mode
1: FMC and MCE3 peripheral clocks enabled in low-power mode (default after reset):
The peripheral clocks of the FMC are the kernel clock selected by FMCSEL, and the hclk5 bus interface clock.

Bit 3 **JPEGLPEN**: JPEG clock enable in low-power mode
Set and reset by software.
0: JPEG peripheral clock disabled in low-power mode
1: JPEG peripheral clock enabled in low-power mode (default after reset)

Bit 2 **FLASHLPEN**: FLASH low-power peripheral clock enable
Set and reset by software.
0: FLASH peripheral clock disabled in low-power mode
1: FLASH peripheral clock enabled in low-power mode (default after reset)

Bit 1 **DMA2DLPEN**: DMA2D low-power peripheral clock enable
Set and reset by software.
0: DMA2D peripheral clock disabled in low-power mode
1: DMA2D peripheral clock enabled in low-power mode (default after reset)

Bit 0 **HPDMA1LPEN**: HPDMA1 low-power peripheral clock enable
Set and reset by software.
0: HPDMA1 peripheral clock disabled in low-power mode
1: HPDMA1 peripheral clock enabled in low-power mode (default after reset)

- **Bit 31** **ADF1LPEN**: ADF clock enable in low-power mode
  - Set and reset by software.
  - 0: ADF peripheral clock disabled in low-power mode
  - 1: ADF peripheral clock enabled in low-power mode (default after reset)

- **Bits 30:28** Reserved, must be kept at reset value.

- **Bit 27** **OTGFSLPEN**: OTGFS clock enable in low-power mode
  - Set and reset by software.
  - 0: OTGFS peripheral clock disabled in low-power mode
  - 1: OTGFS peripheral clock enabled in low-power mode (default after reset)

- **Bit 26** **USBPHYCLPEN**: USBPHYC peripheral clock enable in low-power mode
  - Set and reset by software.
  - 0: USBPHYC peripheral clock disabled in low-power mode
  - 1: USBPHYC peripheral clock enabled in low-power mode (default after reset)

- **Bit 25** **OTGHSLPEN**: OTGHS peripheral clock enable in low-power mode
  - Set and reset by software.
  - 0: OTGHS peripheral clock disabled in low-power mode
  - 1: OTGHS peripheral clock enabled in low-power mode (default after reset)

- **Bit 24** **UCPDCTRL**: USBPHYC common block power-down control
  - Set and reset by software.
  - 0: In SUSPEND, PHY state machine, bias and USBPHYC PLL remain powered (default after reset).
  - 1: In SUSPEND, PHY state machine, bias and USBPHYC PLL are powered down.

- **Bits 23:18** Reserved, must be kept at reset value.

- **Bit 17** **ETH1RXLPEN**: ETH1 reception peripheral clock enable in low-power mode
  - Set and reset by software.
  - 0: ETH1 reception peripheral clock disabled in low-power mode
  - 1: ETH1 reception peripheral clock enabled in low-power mode (default after reset)
Bit 16  **ETH1TXLPEN**: ETH1 transmission peripheral clock enable in low-power mode
   Set and reset by software.
   0: ETH1 transmission peripheral clock disabled in low-power mode
   1: ETH1 transmission peripheral clock enabled in low-power mode (default after reset)

Bit 15  **ETH1MACLPEN**: ETH1 MAC peripheral clock enable in low-power mode
   Set and reset by software.
   0: ETH1 MAC peripheral clock disabled in low-power mode
   1: ETH1 MAC peripheral clock enabled in low-power mode (default after reset)

Bits 14:6  Reserved, must be kept at reset value.

Bit 5  **ADC12LPEN**: ADC1 and 2 peripheral clocks enable in low-power mode
   Set and reset by software.
   0: ADC1 and 2 peripheral clocks disabled in low-power mode
   1: ADC1 and 2 peripheral clocks enabled in low-power mode (default after reset)
   The peripheral clocks of the ADC1 and 2 are the kernel clock selected by ADCSEL and provided to
   ADCx_CK input, and the **rcc_hclk1** bus interface clock.

Bit 4  **GPDMA1LPEN**: GPDMA1 clock enable in low-power mode
   Set and reset by software.
   0: GPDMA1 clock disabled in low-power mode
   1: GPDMA1 clock enabled in low-power mode (default after reset)

Bits 3:0  Reserved, must be kept at reset value.

</tbody>
</table>
Bit 10 LPTIM3LPEN: LPTIM3 peripheral clocks enable in low-power mode
   Set and reset by software.
   0: LPTIM3 peripheral clocks disabled in low-power mode
   1: LPTIM3 peripheral clocks enabled in low-power mode (default after reset)
   The peripheral clocks of the LPTIM3 are the kernel clock selected by LPTIM23SEL and provided to clk_lpt input, and the pclk4 bus interface clock.

Bit 9 LPTIM2LPEN: LPTIM2 peripheral clocks enable in low-power mode
   Set and reset by software.
   0: LPTIM2 peripheral clocks disabled in low-power mode
   1: LPTIM2 peripheral clocks enabled in low-power mode (default after reset)
   The peripheral clocks of the LPTIM2 are the kernel clock selected by LPTIM23SEL and provided to clk_lpt input, and the pclk4 bus interface clock.

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 SPI6LPEN: SPI/I2S6 peripheral clocks enable in low-power mode
   Set and reset by software.
   0: SPI/I2S6 peripheral clocks disabled in low-power mode
   1: SPI/I2S6 peripheral clocks enabled in low-power mode (default after reset)
   The peripheral clocks of the SPI/I2S6 are the kernel clock selected by SPI6SEL and provided to com_ck input, and the rcc_pclk4 bus interface clock.

Bit 4 Reserved, must be kept at reset value.

Bit 3 LPUART1LPEN: LPUART1 peripheral clocks enable in low-power mode
   Set and reset by software.
   0: LPUART1 peripheral clocks disabled in low-power mode
   1: LPUART1 peripheral clocks enabled in low-power mode (default after reset)
   The peripheral clocks of the LPUART1 are the kernel clock selected by LPUART1SEL and provided to UCLK input, and the rcc_pclk4 bus interface clock.

Bit 2 Reserved, must be kept at reset value.

Bit 1 SBSLPEN: SBS peripheral clock enable in low-power mode
   Set and reset by software.
   0: SBS peripheral clock disabled in low-power mode
   1: SBS peripheral clock enabled in low-power mode (default after reset)

Bit 0 Reserved, must be kept at reset value.
### 7.8.64 RCC APB5 low-power clock enable register (RCC_APB5LPENR)

Reset and clock control (RCC)
Refer to Section 2.3 on page 149 for the register boundary addresses.
8 System configuration, boot and security (SBS)

8.1 SBS introduction

The STM32H7Rx/7Sx devices feature a set of configuration registers located in the SBS. On top of various device configurations, this SBS peripheral controls key boot and security features, including debug.

8.2 SBS main features

- Boot control
  - Upon system reset, configure the Cortex-M7 boot address and the hide protection level (HDPL) depending on the device life cycle (open or close).
- Debug control
  - Control the opening of the device debug interface, ensuring the sequencing of events that guarantee the device security
- System configuration
  - Analog switch configuration management
  - I2C Fast-mode Plus configuration
  - Selection of the Ethernet PHY interface
  - I/O compensation cell management
  - Selection of source input to the EXTI inputs used for external interrupt/event detection
  - Configuration for Cortex-M7 FPU interrupts
  - Enable/disable the divider by 32 on ADC12 clock
  - Optional one wait-state added to all AXI RAMs when ECC = 0
- Security status
  - BKPRAM and PKA SRAM erase
- RSSCMD[15:0] in SBS_RSSCMR for applications to pass on a command to the RSS (root secure services) executed at the next reset
8.3 SBS functional description

</tr>
</tbody>
</table>

8.3.3 SBS reset and clocks

The SBS configuration port is clocked by the APB bus clock. There is a general reset and a debug configuration reset controlled in DBGMCU.
### 8.3.4 SBS hide protection management

The HDPL is a monotonic counter incremented during the boot stages. It is reset to its default value only following a power-on reset or a system reset. This default value (0 or 1) depends on the device lifecycle, as defined in Table 76: SBS boot control.

The device uses HDPL information to automatically isolate code and its associated secrets (like keys) during the boot process. Incrementing HDPL ensures that private code and data for one boot stage cannot be directly accessible from later boot stages.

**Note:** The use of HDPL in the embedded Flash memory is detailed in Section 5: Embedded flash memory (FLASH).

The HDPL can take a 0 to 3 value. When reaching the value 3, HDPL keeps this value until reset. The current HDPL value is readable in HDPL bitfield in SBS_HDPLSR register.

**Incrementing HDPL**

The application must write 0x6A to INCR_HDPL bitfield in SBS_HDPLCR register to increment the HDPL by one.

After such increment, and before doing any subsequent action, the application must check if the HDPL has effectively been incremented, by reading SBS_HDPLSR.

### 8.3.5 SBS boot control

The figure below and Table 76 shows how the SBS uses multiple information to define the Cortex-M7 boot address (INITVTOR) and the HDPL before the CPU reset is released.

**Figure 77. SBS boot control**

![SBS boot control diagram](MSv55532V2)
The BOOT value coming from the external pin is latched upon reset release. This pin is in input mode during the complete reset phase, and then switches automatically in analog mode after reset is released.

The NVSTATE value comes from the Flash memory interface, following an automatic option-byte load sequence (see Section 5: Embedded flash memory (FLASH) for details).

### 8.3.6 SBS debug management

Device debug is allowed or not depending on the lifecycle of the device:
- For open devices (NVSTATE = OPEN), the debug is always allowed.
- For close devices (NVSTATE = CLOSE), the debug is disabled at boot but can be reopened during the boot after an authenticated debug sequence.

When debug is forbidden, mailbox access port, CM7 access port, and CPU debug interface are locked. In this situation, the debugger cannot access the CPU and no effective debug can be done. Refer to Section 66: Debug infrastructure for more details.

#### Authenticated debug sequence

1. External host requests to launch the debug authentication protocol, via the DBGMCU access port mailbox. The rest of the device is kept under reset.
2. SBS selects the ST RSS boot address and requests the CPU to be released from reset.
3. CPU running RSS library executes the debug authentication library in system Flash memory. If the device is closed, the access port mailbox is closed until RSS acknowledges the authentication sequence start request.
4. As soon as a debug certificate is accepted by the device, RSS programs the opening of the Cortex-M7 access port by writing to AP_UNLOCK bitfield in SBS_DBGCR register. RSS also programs the opening of the CPU debug interface by writing to DBG_UNLOCK bitfield in SBS_DBGCR register.
5. Above re-openings are effective only when the HDPL in SBS_HDPLSR register has a value equal or superior to the value programmed in DBG_AUTH_HDPL in SBS_DBGCR register. If DBG_AUTH_HDPL bitfield is kept at 0x0, the debug never opens (forbidden value).
Note: The debug authentication library in system Flash memory is only available when HDPL = 0 in SBS_HDPLSR. Only this code can perform the above steps 3 and 4.

At any time, the application via DBGMCU can reset the debug configuration in SBS_DBGCR register. See dedicated sections for details (TBC).

**Debug locking**

To ensure the debug configuration is not modified by an unauthorized code, any application can lock it by writing to DBGCFG_LOCK bitfield in SBS_DBGLOCKR register. Once the debug configuration is locked, the application can unlock it using DBGMCU (TBC).

### 8.3.7 SBS voltage booster for I/O analog switches

By setting BOOSTEN in SBS_PMCR, the application reduces the total harmonic distortion (THD) of the I/O analog switches when the supply voltage is below 2.7 V, to guarantee the same performance as with the full voltage range.

To avoid current consumption due to booster activation when \( V_{DDA} < 2.7 \) V and \( V_{DD} > 2.7 \) V, \( V_{DD} \) can be selected as supply voltage for the analog switches, by setting BOOSTVDDSEL in SBS_PMCR.

In this case, BOOSTEN must be cleared to avoid unexpected power consumption.

#### Table 77. Analog switches recommended configuration

<table>
<thead>
<tr>

<td>0</td>
<td>( V_{DDA} )</td>
</tr>
</tbody>
</table>

### 8.3.8 SBS I/O compensation cell management

The I/O compensation cell generates an 8-bit value for the I/O buffer (4 bits for N-MOS and 4 bits for P-MOS), that depends on PVT operating conditions (process, voltage, temperature). These bits are used to control the output impedance in the I/O buffer, and the slew rate of the I/O commutation (the \( t_{fall} \) and \( t_{rise} \) time), in order to reduce the I/O noise on power supply.

The CSI is used by the compensation cells and must be enabled before enabling the compensation cells.

As shown in *Figure 78*, the compensation cell is split into two blocks: one block to provide an optimal code for the current PVT, and one block to drive the block controlled by the software.
The compensation cell value can be read when the READY flag is set in SBS_CCCSR. With CODESEL in SBS_CCCSR, the application can select the value to apply between two options: the code from the cell or the code from SBS_CCSWVALR.

Three compensation cells are embedded in STM32H7Rx/7Sx devices:

- one for the I/Os supplied by VDD or VDDA (see Section 8.3.7)
- one for the dedicated I/Os of the XSPI1
- one for the dedicated I/Os of the XSPI2

By default, the compensation cells are disabled, and a fixed code is applied to all the I/Os.

**Note:** The compensation cell can be used only when 2.7 V ≤ VDDIOx ≤ 3.6 V or 1.71 V ≤ VDDIOx ≤ 2 V (see the figure below).

### 8.3.9 SBS registers access control

Some SBS registers can be accessed only if HDPL = 0 in SBS_HDPLSR (hence only accessible by the ST RSS code).

Some bitfields in SBS are security critical, reset in non-secure state (coded as 0xB4) or in secure state (any other values). For bitfields reset in non-secure state, when the secure state is selected writing any value but 0xB4, the bitfield is no more writable until a reset occurs.
As a general rule, it is recommended to write 0xC3 to select a secure state and read back 0x6A to acknowledge the write is effective.

Protected fields are the following:
- INCR_HDPL
- DBGCFG_LOCK

### 8.3.10 SBS error management

The SBS does not manage errors.

### 8.4 SBS interrupts

The SBS does not support interrupts.

### 8.5 SBS registers

#### 8.5.1 SBS boot status register (SBS_BOOTSR)

Address offset: 0x000

**DBG_AUTH_HDPL[7:0]**

Bits 31:24 Reserved, must be kept at reset value.
Bits 23:16 **DBG_AUTH_HDPL[7:0]:** authenticated debug hide protection level

Writing to this bitfield defines at which HDPL the authenticated debug opens.

- 0x51: HDPL1
- 0x8A: HDPL2
- 0x6F: HDPL3

*Note: Writing any other values is ignored. Reading any other value means the authenticated debug always fails.*

Bits 15:8 **DBG_UNLOCK[7:0]:** debug unlock

Write 0xB4 to this bitfield to open the debug when HDPL in SBS_HDPLSR equals to DBG_AUTH_HDPL in this register.

Bits 7:0 **AP_UNLOCK[7:0]:** access port unlock

Write 0xB4 to this bitfield to open the device access port.

8.5.5 SBS debug lock register (SBS_DBGLOCKR)

Address offset: 0x024
Reset value: 0x0000 00B4

This register is reset when sbs_dbgcrst is asserted.

</tr>
</tbody>
</table>

Bits 31:19 Reserved, must be kept at reset value.
Bit 18 **XSPI2_IOHSLV**: XSPIM_P2 I/O high speed at low voltage

When this bit is set, the speed of the XSPIM_P2 I/Os is optimized when the device voltage is low.

This bit is active only if XSPI2_HSLV user option bit is set in FLASH. This bit must be used only if the device supply voltage is below 2.7 V. Setting this bit when $V_{DD}$ is higher than 2.7 V may be destructive.

0: No XSPIM_P2 I/O speed optimization when device voltage is low
1: XSPIM_P2 I/O speed optimized when device voltage is low, if XSPI2_HSLV user option is set (no effect otherwise)

Bit 17 **XSPI1_IOHSLV**: XSPIM_P1 I/O high speed at low voltage

When this bit is set, the speed of the XSPIM_P1 I/Os is optimized when the device voltage is low.

This bit is active only if XSPI1_HSLV user option bit is set in FLASH. This bit must be used only if the device supply voltage is below 2.7 V. Setting this bit when $V_{DD}$ is higher than 2.7 V may be destructive.

0: No XSPIM_P1 I/O speed optimization when device voltage is low
1: XSPIM_P1 I/O speed optimized when device voltage is low, if XSPI1_HSLV user option is set (no effect otherwise)

Bit 16 **IOHSLV**: I/O high speed at low voltage

When this bit is set, the speed of the I/Os is optimized when the device voltage is low.

This bit is active only if VDDIO_HSLV user option bit is set in FLASH. It must be used only if the device supply voltage is below 2.7 V. Setting this bit when $V_{DD}$ is higher than 2.7 V may be destructive.

0: No I/O speed optimization when device voltage is low
1: I/O speed optimized when device voltage is low, if VDDIO_HSLV user option is set (no effect otherwise)

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **XSPI2_COMP_RDY**: XSPIM_P2 compensation cell ready

This bit provides the status of the XSPIM_P2 compensation cell.

0: XSPIM_P2 I/O compensation cell not ready
1: XSPIM_P2 I/O compensation cell ready. The code value provided by the cell can be used

*Note*: The CSI clock is required for the compensation cell to work properly. The compensation cell ready bit (XSPI2_COMP_RDY) is not set if the CSI clock is not enabled.

Bit 9 **XSPI1_COMP_RDY**: XSPIM_P1 compensation cell ready

This bit provides the status of the XSPIM_P1 compensation cell.

0: XSPIM_P1 I/O compensation cell not ready
1: XSPIM_P1 I/O compensation cell ready. The code value provided by the cell can be used

*Note*: The CSI clock is required for the compensation cell to work properly. The compensation cell ready bit (XSPI1_COMP_RDY) is not set if the CSI clock is not enabled.

Bit 8 **COMP_RDY**: Compensation cell ready

This bit provides the status of the compensation cell.

0: I/O compensation cell not ready
1: I/O compensation cell ready. The code value provided by the cell can be used.

*Note*: The CSI clock is required for the compensation cell to work properly. The compensation cell ready bit (COMP_RDY) is not set if the CSI clock is not enabled.

Bits 7:6 Reserved, must be kept at reset value.
Bit 5  **XSPI2_COMP_CODESEL**: XSPIM_P2 compensation cell code selection  
This bit selects the code to be applied for the XSPIM_P2 I/O compensation cell.  
0: Code from the cell (available in the SBS_CCVALR)  
1: Code from the SBS software value register (SBS_CCSWVALR)

Bit 4  **XSPI2_COMP_EN**: XSPIM_P2 compensation cell enable  
Set this bit to enable the XSPIM_P2 compensation cell.  
0: XSPIM_P2 compensation cell disabled  
1: XSPIM_P2 compensation cell enabled

Bit 3  **XSPI1_COMP_CODESEL**: XSPIM_P1 compensation cell code selection  
This bit selects the code to be applied for the XSPIM_P1 I/O compensation cell.  
0: Code from the cell (available in the SBS_CCVALR)  
1: Code from the SBS software value register (SBS_CCSWVALR)

Bit 2  **XSPI1_COMP_EN**: XSPIM_P1 compensation cell enable  
Set this bit to enable the XSPIM_P1 compensation cell.  
0: XSPIM_P1 compensation cell disabled  
1: XSPIM_P1 compensation cell enabled

Bit 1  **COMP_CODESEL**: Compensation cell code selection  
This bit selects the code to be applied for the I/O compensation cell.  
0: Code from the cell (available in the SBS_CCVALR)  
1: Code from the SBS software value register (SBS_CCSWVALR)

Bit 0  **COMP_EN**: Compensation cell enable  
Set this bit to enable the compensation cell.  
0: Compensation cell disabled  
1: Compensation cell enabled
8.5.11  SBS compensation cell for I/Os value register (SBS_CCVALR)

Address offset: 0x114
Reset value: 0x0000 0088
Reset: system reset

For more details on this register, refer to Section 8.3.8.

| Bits 31:24 | Reserved, must be kept at reset value. |
| Bits 23:20 | **XSPI2_PSRC[3:0]**: XSPIM_P2 PMOS transistors slew-rate compensation |
| Bits 19:16 | **XSPI2_NSRC[3:0]**: XSPIM_P2 NMOS transistors slew-rate compensation |
| Bits 15:12 | **XSPI1_PSRC[3:0]**: XSPIM_P1 PMOS transistors slew-rate compensation |
| Bits 11:8 | **XSPI1_NSRC[3:0]**: XSPIM_P1 NMOS transistors slew-rate compensation |
| Bits 7:4 | **PSRC[3:0]**: PMOS transistors slew-rate compensation |
| Bits 3:0 | **NSRC[3:0]**: NMOS transistors slew-rate compensation |

This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P2 to compensate the PMOS transistors slew rate in the functional range if XSPI2_COMP_CODESEL = 0 in SBS_CCCSR register.

This bitfield returns the NMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P2 to compensate the NMOS transistors slew rate in the functional range if XSPI2_COMP_CODESEL = 0 in SBS_CCCSR register.

This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P1 to compensate the PMOS transistors slew rate in the functional range if XSPI1_COMP_CODESEL = 0 in SBS_CCCSR register.

This bitfield returns the NMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P1 to compensate the NMOS transistors slew rate in the functional range if XSPI1_COMP_CODESEL = 0 in SBS_CCCSR register.

This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted to compensate the PMOS transistors slew rate in the functional range if COMP_CODESEL = 0 in SBS_CCCSR register.

This bitfield returns the NMOS transistors slew-rate compensation value computed by the cell. It is interpreted to compensate the NMOS transistors slew rate in the functional range if COMP_CODESEL = 0 in SBS_CCCSR register.
8.5.12 SBS compensation cell for I/Os software value register (SBS_CCSWVALR)

Address offset: 0x118
Reset value: 0x0000 0088

For more details on this register, refer to Section 8.3.8.

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:20  **XSPI2_SW_PSRC[3:0]**: XSPIM_P2 software PMOS transistors slew-rate compensation
This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P2 to compensate the PMOS transistors slew rate in the functional range if XSPI2_COMP_CODESEL = 1 in SBS_CCCSR register.

Bits 19:16  **XSPI2_SW_NSRC[3:0]**: XSPIM_P2 software NMOS transistors slew-rate compensation
This bitfield returns the NMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P2 to compensate the NMOS transistors slew rate in the functional range if XSPI2_COMP_CODESEL = 1 in SBS_CCCSR register.

Bits 15:12  **XSPI1_SW_PSRC[3:0]**: XSPIM_P1 software PMOS transistors slew-rate compensation
This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P1 to compensate the PMOS transistors slew rate in the functional range if XSPI1_COMP_CODESEL = 1 in SBS_CCCSR register.

Bits 11:8  **XSPI1_SW_NSRC[3:0]**: XSPIM_P1 software NMOS transistors slew-rate compensation
This bitfield returns the NMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P1 to compensate the NMOS transistors slew rate in the functional range if XSPI1_COMP_CODESEL = 1 in SBS_CCCSR register.

Bits 7:4  **SW_PSRC[3:0]**: Software PMOS transistors slew-rate compensation
This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted to compensate the PMOS transistors slew rate in the functional range if COMP_CODESEL = 1 in SBS_CCCSR register.

Bits 3:0  **SW_NSRC[3:0]**: Software NMOS transistors slew-rate compensation
This bitfield returns the NMOS transistors slew-rate compensation value computed by the cell. It is interpreted to compensate the NMOS transistors slew rate in the functional range if COMP_CODESEL = 1 in SBS_CCCSR register.
8.5.13 SBS break lockup register (SBS_BKLOCKR)

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 ARAMECC_BL: AXISRAM1 ECC error break lock
Set this bit to enable and lock the connection between AXISRAM1 ECC double error detection flag and break inputs of TIM1/15/16/17 peripherals.
Once set, this bit is cleared only by a system reset.
0: AXISRAM1 ECC double error detection flag disconnected from TIM1/15/16/17 break inputs
1: AXISRAM1 ECC double error detection flag connected to TIM1/15/16/17 break inputs

Bit 22 Reserved, must be kept at reset value.

Bit 21 ARAMECC_BL: AXISRAM3 ECC error break lock
Set this bit to enable and lock the connection between AXISRAM3 ECC double error detection flag and break inputs of TIM1/15/16/17 peripherals.
Once set this bit is cleared only by a system reset.
0: AXISRAM3 ECC double error detection flag disconnected from TIM1/15/16/17 break inputs
1: AXISRAM3 ECC double error detection flag connected to TIM1/15/16/17 break inputs

Bits 20:15 Reserved, must be kept at reset value.

Bit 14 ITCMECC_BL: ITCM ECC error break lock
Set this bit to enable and lock the connection between ITCM ECC double error detection flag and break inputs of TIM1/15/16/17 peripherals.
Once set, this bit is cleared only by a system reset.
0: ITCM ECC double error detection flag disconnected from TIM1/15/16/17 break inputs
1: ITCM ECC double error detection flag connected to TIM1/15/16/17 break inputs

Bit 13 DTMECC_BL: DTCM ECC error break lock
Set this bit to enable and lock the connection between DTCM ECC double error detection flag and break inputs of TIM1/15/16/17 peripherals.
Once set, this bit is cleared only by a system reset.
0: DTCM ECC double error detection flag disconnected from TIM1/15/16/17 break inputs
1: DTCM ECC double error detection flag connected to TIM1/15/16/17 break inputs

Note: The DTCM0 and DTCM1 are Or’ed to give DTMECC
Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **BKRAMECC_BL**: Backup RAM ECC error break lock
Set this bit to enable and lock the connection between backup RAM ECC double error detection flag and break inputs of TIM1/15/16/17 peripherals.
Once set, this bit is cleared only by a system reset.
0: Backup RAM ECC double error detection flag disconnected from TIM1/15/16/17 break inputs.
1: Backup RAM ECC double error detection flag connected to TIM1/15/16/17 break inputs.

Bit 6 **CM7LCKUP_BL**: Cortex-M7 lockup break lock
Set this bit to enable and lock the connection between the Cortex-M7 lockup (HardFault) output and break inputs of TIM1/15/16/17 peripherals.
Once set, this bit is cleared only by a system reset.
0: Cortex-M7 lockup output disconnected from TIM1/15/16/17 break inputs
1: Cortex-M7 lockup output connected to TIM1/15/16/17 break inputs

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **FLASH_ECC_BL**: Flash ECC error break lock
Set this bit to enable and lock the connection between embedded flash memory ECC double error detection flag and break inputs of TIM1/15/16/17 peripherals.
Once set, this bit is cleared only by a system reset.
0: FLASH ECC double error detection flag disconnected from TIM1/15/16/17 break inputs
1: FLASH ECC double error detection flag connected to TIM1/15/16/17 break inputs

Bit 2 **PVD_BL**: PVD break lock
This bit is set by SW and cleared only by a system reset. It can be used to enable and lock the connection to TIM1/8/15/16/17 break input as well as the PVDE and PLS[2:0] bitfields in the PWR_CR1 register.
Once set, this bit is cleared only by a system reset.
0: PVD interrupt disconnected from TIM1/8/15/16/17 break inputs. PVDE and PLS[2:0] bitfields can be programmed by the application.
1: PVD output connected to TIM1/8/15/16/17 break input. PVDE and PLS[2:0] bits are read only.

Bits 1:0 Reserved, must be kept at reset value.

Refer to Section 2.3 for the register boundary addresses.
Clock recovery system (CRS)

9.1 CRS introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means to evaluate the oscillator output frequency, based on comparison with a selectable synchronization signal. The CRS can perform automatic trimming adjustments based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In this case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from the LSE oscillator output, or generated by user software.

9.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity:
  - External pin
  - LSE oscillator output
  - USB SOF packet reception
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster startup convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

9.5.1 Synchronization input

The CRS synchronization (SYNC) source, selectable through the CRS_CFGR register, can be the signal from an external signal (SYNC), the LSE clock, or the OTG HS SOF signal. This source signal also has a configurable polarity and can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to Section 9.8.2.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.

9.5.2 Frequency error measurement

The frequency error counter is a 16-bit down/up counter, reloaded with the RELOAD value on each SYNC event. It starts counting down until it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit, where it eventually stops (if no SYNC event is received), and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the down-counting phase (before reaching the zero value), it means that the actual frequency is lower than the target (the TRIM value must be incremented). When it is detected during the up-counting phase, it means that the actual frequency is higher (the TRIM value must be decremented).
9.5.3 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:
- **TOLERANCE LIMIT**, given directly in the FELIM field of the CRS_CFGR register
- **WARNING LIMIT**, defined as $3 \times FELIM$ value
- **OUTRANGE** (error limit), defined as $128 \times FELIM$ value

The result of this comparison is used to generate the status indication and also to control the automatic trimming, which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:
- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode
- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated
  - TRIM value adjusted by one trimming step in AUTOTRIM mode
- When the frequency error is above or equal to the warning limit but below the error limit, a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode
- When the frequency error is above or equal to the error limit, the frequency is out of the trimming range. This can also happen when the SYNC input is not clean, or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCFMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

**Note:**
If the actual value of the TRIM field is close to its limits and the automatic trimming can force it to overflow or underflow, the TRIM value is set to the limit, and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

### 9.5.4 CRS initialization and configuration

**RELOAD value**

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. This value is decreased by 1, to reach the expected synchronization on the zero value. The formula is the following:

\[
\text{RELOAD} = \left( \frac{f_{TARGET}}{f_{SYNC}} \right) - 1
\]

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).

**FELIM value**

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of oscillator clock ticks. The following formula can be used:

\[
\text{FELIM} = \left( \frac{f_{TARGET}}{f_{SYNC}} \right) \times \text{STEP} \% / 100 \% / 2
\]

The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to \( \left( \frac{f_{TARGET}}{f_{SYNC}} \right) = 48000 \), and to a typical trimming step size of 0.14%.

**Note:**
The trimming step size depends upon the product, check the datasheet for accurate setting.

**Caution:**
There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields, this can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).
9.6 CRS in low-power modes

Table 82. Effect of low-power modes on CRS

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. CRS interrupts cause the device to exit the Sleep mode.</td>

9.8 CRS registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed only by words (32-bit).

9.8.1 CRS control register (CRS_CR)

Address offset: 0x00
Reset value: 0x0000 2000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-14</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
Bits 13:8 **TRIM[5:0]**: HSI48 oscillator smooth trimming

These bits provide a user-programmable trimming value to the HSI48 oscillator. They can be programmed to adjust to variations in voltage and temperature that influence the oscillator frequency.

The default value is 32, corresponding to the middle of the trimming interval. The trimming step is specified in the product datasheet. A higher TRIM value corresponds to a higher output frequency.

When the AUTOTRIMEN bit is set, this field is controlled by hardware and is read-only.

Bit 7 **SWSYNC**: Generate software SYNC event

This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.

0: No action
1: A software SYNC event is generated.

Bit 6 **AUTOTRIMEN**: Automatic trimming enable

This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to Section 9.5.3 for more details.

0: Automatic trimming disabled, TRIM bits can be adjusted by the user.
1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 **CEN**: Frequency error counter enable

This bit enables the oscillator clock for the frequency error counter.

0: Frequency error counter disabled
1: Frequency error counter enabled

When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **ESYNCE**: Expected SYNC interrupt enable

0: Expected SYNC (ESYNCF) interrupt disabled
1: Expected SYNC (ESYNCF) interrupt enabled

Bit 2 **ERRIE**: Synchronization or trimming error interrupt enable

0: Synchronization or trimming error (ERRF) interrupt disabled
1: Synchronization or trimming error (ERRF) interrupt enabled

Bit 1 **SYNCEWANIE**: SYNC warning interrupt enable

0: SYNC warning (SYNCWARNF) interrupt disabled
1: SYNC warning (SYNCWARNF) interrupt enabled

Bit 0 **SYNCKIE**: SYNC event OK interrupt enable

0: SYNC event OK (SYNCOKF) interrupt disabled
1: SYNC event OK (SYNCOKF) interrupt enabled
9.8.2 CRS configuration register (CRS_CFGR)

This register can be written only when the frequency error counter is disabled (the CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04

Reset value: 0x2022 BB7F

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>SYNCPOL: SYNC polarity selection</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This bit is set and cleared by software to select the input polarity for the SYNC signal source.</td>
</tr>
<tr>
<td>0</td>
<td>SYNC active on rising edge (default)</td>
</tr>
<tr>
<td>1</td>
<td>SYNC active on falling edge</td>
</tr>
</tbody>
</table>

| Bit 30 | Reserved, must be kept at reset value. |

<table>
<thead>
<tr>
<th>Bits 29:28</th>
<th>SYNCSRC[1:0]: SYNC signal source selection</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>CRS_SYNC pin selected as SYNC signal source</td>
</tr>
<tr>
<td>01</td>
<td>LSE selected as SYNC signal source</td>
</tr>
<tr>
<td>10</td>
<td>OTG FS SOF selected as SYNC signal source (default)</td>
</tr>
<tr>
<td>11</td>
<td>OTG HS SOF selected as SYNC signal source</td>
</tr>
</tbody>
</table>

**Note:** When using USB LPM (link power management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the HSI48 oscillator on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE clock or the SYNC pin must be used as SYNC signal.

| Bit 27 | Reserved, must be kept at reset value. |

<table>

<td>FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to Section 9.5.3 for more details about FECAP evaluation.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bits 15:0</th>
<th>RELOAD[15:0]: Counter reload value</th>
</tr>
</thead>
<tbody>
<tr>
<td>RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to Section 9.5.2 for more details about counter behavior.</td>
<td></td>
</tr>
</tbody>
</table>
**9.8.3 CRS interrupt and status register (CRS_ISR)**

Address offset: 0x08  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:16</th>
<th>FECAP[15:0]</th>
<th>Frequency error capture</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:16</td>
<td>r</td>
<td>Frequency error capture</td>
</tr>
</tbody>
</table>

FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to Section 9.5.3 for more details about FECAP usage.

<table>
<thead>
<tr>
<th>Bit 15</th>
<th>FEDIR</th>
<th>Frequency error direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>r</td>
<td>Up-counting direction, the actual frequency is above the target</td>
</tr>
</tbody>
</table>

0: Up-counting direction, the actual frequency is above the target  
1: Down-counting direction, the actual frequency is below the target

<table>
<thead>
<tr>
<th>Bit 14:11</th>
<th>TRIMOVF</th>
<th>Trimming overflow or underflow</th>
</tr>
</thead>
<tbody>
<tr>
<td>14:11</td>
<td>r</td>
<td>Trimming overflow or underflow</td>
</tr>
</tbody>
</table>

This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

<table>
<thead>
<tr>
<th>Bit 9</th>
<th>SYNCMISS</th>
<th>SYNMC missed</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>r</td>
<td>SYNMC missed</td>
</tr>
</tbody>
</table>

This flag is set by hardware when the frequency error counter reaches value FELIM * 128 and no SYNC is detected, meaning either that a SYNC pulse was missed, or the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, hence some other action must be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC), and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

<table>
<thead>
<tr>
<th>Bit 8</th>
<th>SYNCERR</th>
<th>SYNC error</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>r</td>
<td>SYNC error</td>
</tr>
</tbody>
</table>

This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

<table>
<thead>
<tr>
<th>Bit 7:4</th>
<th>Reserved</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>7:4</td>
<td>r</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

Reserved, must be kept at reset value.

</tbody>
</table>

Bits 31:4 Reserved, must be kept at reset value.

**Bit 3 ESYNCC**: Expected SYNC clear flag
Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register.

**Bit 2 ERRC**: Error clear flag
Writing 1 to this bit clears TRIMOVF, SYNCMISS, and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register.

Refer to Section 2.3 for the register boundary addresses.
10 General-purpose I/Os (GPIO)

10.1 Introduction
Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR), a 16 bits reset register (GPIOx_BRR) and a 32-bit set/reset register (GPIOx_BSRR).

In addition, all GPIOs have a 32-bit locking register (GPIOx_LCKR), two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL).

10.2 GPIO main features
- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_BSRR) for bitwise write access to GPIOx_ODR
- Lock mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

10.3 GPIO functional description
Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:
- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers must be accessed as 32-bit words, half-words or bytes. The GPIOx_BSRR and GPIOx_BRR registers allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.
The figure below shows the basic structure of a three-volt or five-volt tolerant GPIO (TT or FT). The Table 85 gives the possible port bit configurations.

**Figure 82. Structure of three-volt or five-volt tolerant GPIO (TT or FT)**

![Figure 82. Structure of three-volt or five-volt tolerant GPIO (TT or FT)](MSv46873V1)

Note: On a TT GPIO, the analog switch is not present and replaced by a direct connection. The analog bloc parasitic circuitry does not allow five-volt tolerance.

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

#### 10.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in analog mode.

The debug pins are in AF pull-up/pull-down after reset:
- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDIO in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO/TRACESWO in floating state no pull-up/pull-down

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, that can be activated or not depending on the value in the GPIOx_PUPDR register.
10.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there is no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to 16 alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:

- After reset, the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages. The I/O pins on Port P and port O do not have alternate functions as these are dedicated for xSPI interface.

To use an I/O in a given configuration, the user must proceed as follows:

- **Debug function**: after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host.
- **GPIO**: configure the desired I/O as output, input or analog in the GPIOx_MODER register.
- **Peripheral alternate function**:
  - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  - Select the type, pull-up/pull-down and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDR registers respectively.
  - Configure the desired I/O as an alternate function in the GPIOx_MODER register.
- **Additional functions**:
  - For all ADCs, configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC registers.
  - For the additional functions like RTC, WKUPx and oscillators, configure the required function in the related RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

10.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.
10.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIO port input data register (GPIOx_IDR) (x = A to G, M to P) and GPIO port output data register (GPIOx_ODR) (x = A to G, M to P)).

GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register.

10.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register that allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, BS(i) sets the corresponding ODR(i) bit. When written to 1, BR(i) resets the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: one or more bits can be modified in a single atomic AHB write access.

10.3.6 GPIO locking mechanism

The GPIO control registers can be frozen by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL, GPIOx_AFRH.

To write the GPIOx_LCKR register, a specific write/read sequence must be applied. When the right LOCK sequence is applied to the bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence is applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

The LOCK sequence can only be performed using a word (32-bit long) access to the GPIOx_LCKR register due to the fact that GPIOx_LCKR bit 16 must be set at the same time as the [15:0] bits.

10.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can
thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.

### 10.3.8 External interrupt/wakeup lines

All ports have external interrupt capability. To use external interrupt lines, the port can be configured in input, output or alternate function mode (the port must not be configured in analog mode). Refer to Section 20: Extended interrupt and event controller (EXTI).

### 10.3.9 Input configuration

When the I/O port is programmed as input:
- The output buffer is disabled.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register provides the I/O state.

The figure below shows the input configuration of the I/O port bit.

![Input floating/pull-up/pull-down configurations](https://example.com/input-config-diagram.png)

**Figure 83. Input floating/pull-up/pull-down configurations**
10.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open-drain mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register leaves the port in Hi-Z (the P-MOS is never activated).
  - Push-pull mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register activates the P-MOS.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.
- A read access to the output data register gets the last written value.

The figure below shows the output configuration of the I/O port bit.

Figure 84. Output configuration

10.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode.
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data).
- The Schmitt trigger input is activated.
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.
10.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled.
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled by hardware.
- Read access to the input data register gets the value 0.

The figure below shows the high-impedance, analog-input configuration of the I/O port bits.

10.3.13 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched off (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched on (by setting the HSEON or LSEON bit in the RCC_CSR register), the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.
When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input, and the OSC.OUT or OSC32_OUT pin can still be used as normal GPIO.

10.3.14 **Using the GPIO pins in the RTC supply domain**

The PC13/PC14/PC15 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to **Section 49.3: RTC functional description**

10.3.15 **Privileged and unprivileged modes**

All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or non-secure).

10.3.16 **High-speed low-voltage mode (HSLV)**

The I/Os can increase their maximum speed at low voltage by configuring them in HSLV mode. The I/O HSLV bit controls whether the I/O output speed is optimized to operate at 3.3 V (default setting) or at 1.8 V (HSLV = 1). The CSI must be enabled in order to configure the I/Os in HSLV mode.

Procedure to set the HSLV mode for the XSPIx interface:
1. Set the user option byte for the targeted interface (XSPI1_HSLV, XSPI2_HSLV) in the **FLASH option byte word 1 status register (FLASH_OBW1SR)**.
2. Enable the target interface EN_XSPIM1, EN_XSPIM2 in the **PWR control register 2 (PWR_CSR2)**.
3. Activate the HSLV on the targeted i/f (XSPI1_IOHSLV, XSPI2_IOHSLV) in the **SBS I/O compensation cell control and status register (SBS_CCCSR)**.

Procedure to set the HSLV mode for the FMC interface:
1. Set the user option byte for the GPIO and the shared XSPI interface (VDDIO_HSLV, XSPI2_HSLV) in the **FLASH option byte word 1 status register (FLASH_OBW1SR)**.
2. Enable the target interface EN_XSPIM2 in the **PWR control register 2 (PWR_CSR2)**.
3. Activate the HSLV on the targeted i/f (IOHSLV, XSPI2_IOHSLV) in the **SBS I/O compensation cell control and status register (SBS_CCCSR)**.

**Caution:** The I/O HSLV configuration bit must not be set if the I/O supply (VDD) is above 2.7 V. Setting it while the voltage is higher than 2.7 V can damage the device.

**Caution:** The GPIOs are all programed with the same HSLV setting, except those from dedicated power rail (OCTO, HEXA and USB):
- XSPIM2 rail: PN[0:12]
- XSPIM1 rail: PO[0:5], PP[0:15]
- USB no software compensation setting

GPIOs that are shared with the USB are limited in terms of frequency, to hundreds of kHz for UCPD-based GPIOs, and up to 1 MHz for USBHS and USBFS-based GPIOs. Refer to the datasheet for the exact values. In order to be used the IO supply must be above 2.7 V for the USBHS/FS.
Note: When using an FMC with HSLV both the XSPIM2 and GPIO must be set to HSLV and on the same supply, still respecting the HSLV I/O supply limitation.

10.3.17 I/O compensation cell

The I/O commutation slew rate (fall / rise) can be adapted by software depending on process, voltage and temperature conditions, in order to reduce the I/O noise on the power supply.

10.4 GPIO registers

This section gives a detailed description of the GPIO registers.

The peripheral registers can be written in word, half word or byte mode.

10.4.1 GPIO port mode register (GPIOx_MODER) (x = A to G, M to P)

Address offset: 0x00
Reset value: 0xABFF FFFF (port A)
Reset value: 0xFFFF FEBF (port B)
Reset value: 0xFFFF FFFF (ports C...H and M...P)

10.4.5 GPIO port input data register (GPIOx_IDR) (x = A to G, M to P)

Address offset: 0x10
Reset value: 0x0000 XXXX

<table>
<thead>
<tr>
<th>Bits 31:16</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>

Bits 15:0 IDy: Port x input data I/O pin y (y = 15 to 0)
These bits are read-only. They contain the input value of the corresponding I/O port.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.
10.4.6 GPIO port output data register (GPIOx_ODR) (x = A to G, M to P)

Address offset: 0x14
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 ODy: Port output data I/O pin y (y = 15 to 0)
These bits can be read and written by software.

Note: For atomic bit set/reset, the OD bits can be individually set and/or reset by writing to the GPIOx_BSRR or GPIOx_BRR registers (x = A to G) (x = M to P).
The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

10.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to G, M to P)

Address offset: 0x18
Reset value: 0x0000 0000

Bits 31:16 BRy: Port x reset I/O pin y (y = 15 to 0)
These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit
1: Resets the corresponding ODy bit

Note: If both BSy and BRy are set, BSy has priority.
The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Bits 15:0 BSy: Port x set I/O pin y (y = 15 to 0)
These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit
1: Sets the corresponding ODy bit

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.
10.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to G, M to P)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

Note: A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:17 Reserved, must be kept at reset value.</th>
<th>Bit 16 LCKK: Lock key</th>
</tr>
</thead>
<tbody>
<tr>
<td>This bit can be read any time. It can only be modified using the lock key write sequence.</td>
<td>This bit can be read any time. It can only be modified using the lock key write sequence.</td>
</tr>
<tr>
<td>0: Port configuration lock key not active</td>
<td>0: Port configuration lock key not active</td>
</tr>
<tr>
<td>1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.</td>
<td>1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.</td>
</tr>
<tr>
<td>- LOCK key write sequence:</td>
<td>- LOCK key write sequence:</td>
</tr>
<tr>
<td>- LOCK key read</td>
<td>- LOCK key read</td>
</tr>
<tr>
<td>RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)</td>
<td>RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)</td>
</tr>
</tbody>
</table>

Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.

Any error in the lock sequence aborts the LOCK.

After the first LOCK sequence on any bit of the port, any read access on the LCKK bit returns 1 until the next MCU reset or peripheral reset.

Bits 15:0 LCKy: Port x lock I/O pin y (y = 15 to 0)

These bits are read/write but can only be written when the LCKK bit is 0

0: Port configuration not locked
1: Port configuration locked

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.
### 10.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to G, M to P)

Refer to Section 2.3 for the register boundary addresses.
11 Peripheral interconnect

11.1 Introduction

Several peripherals have direct connections between them. This allows autonomous communication and or synchronization between peripherals, saving CPU resources, thus power supply consumption.

In addition, these hardware connections remove software latency and allow design of predictable system.

Depending on peripherals, these interconnections can operate in various power modes: Run, Sleep or Stop modes.

11.2 Connection summary

1. Letters in the table correspond to the type of connection described in Section 11.2: Connection summary
2. The "-" symbol in a gray cell means no interconnect.
11.3 Interconnection details

11.3.1 Master to slave interconnection for timers

From timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM9/TIM12/TIM13/TIM14/TIM15/TIM16/TIM17) to timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM9/TIM12/TIM13/TIM14/TIM15/TIM16/TIM17)

Purpose

Some of the TIMx timers are linked together internally for timer synchronization or chaining. When one timer is configured in master mode, it can reset, start, stop or clock the counter of another timer configured in slave mode.

Timer synchronization

The synchronization modes are detailed in:
- Section 41.3.30: Timer synchronization for advanced-control timers TIM1
- Section 42.4.23: Timer synchronization for general-purpose timers TIM2/TIM3/TIM4/TIM5
- Section 44.4.20: Timer synchronization (TIM9/TIM12 only) for the general-purpose timer (Lite no DT) TIM9/TIM12
- Section 45.4.26: Timer synchronization (TIM15 only) for the general-purpose timer (Lite) TIM15

Triggering signals

The output (from master) is on signal TIMx_TRGO (and TIMx_TRGO2 for TIM1) following a configurable timer event. It can be also from signals tim16_oc1 and tim17_oc1 in case of TIM16/TIM17. The input (to slave) is on signals TIMx_ITR0/ITR1/ITR2/ITR3.

The possible master/slave connections are given in:
- Table 408: Internal trigger connection for advanced-control timers TIM1
- Table 431: TIMx internal trigger connection for the general-purpose timers TIM2/TIM3/TIM4/TIM5
- Table 452: TIMx internal trigger connection for general-purpose timers TIM9/TIM12
- Table 464: TIMx internal trigger connection for general-purpose timers TIM15

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:
- Table 420: Effect of low-power modes on TIM1
- Table 445: Effect of low-power modes on TIM6/TIM7
- Table 438: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5
- Table 454: Effect of low-power modes on TIM9/TIM12/TIM13/TIM14
- Table 470: Effect of low-power modes on TIM15/TIM16/TIM17
11.3.2 **Triggers to ADCs**

From EXTI, timers (TIM1/TIM2/TIM3/TIM4/TIM6/TIM9/TIM12/TIM15) and LP timers (LPTIM1/ LPTIM2/LPTIM3) to ADC1

**Purpose**

A conversion, or a sequence of conversions, can be triggered either by software or by an external event (such as timer capture or input pins). For ADC1, if the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events can trigger a conversion with the selected polarity. More details in:

- *Section 27.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN,JEXTSEL, JEXTEN)*
- *ADC configuration register (ADC_CFGR)*
- *ADC injected sequence register (ADC_JSQR)*

General-purpose timers (TIM2/TIM3/TIM4), basic timer (TIM6), advanced-control timers (TIM1) and general-purpose timer (TIM9/TIM12/TIM15) can be used to generate the ADC triggering event through the timer outputs tim_oc and tim_trgo.

Low-power timers (LPTIM1/ LPTIM2/LPTIM3) can be used to generate the ADC triggering event through the LPTIM channels (TIMx synchronization described in *Section 41.3.30: Timer synchronization* for TIM1) in addition to the EXTI on channels 11 and 15.

**Triggering signals**

For ADC1, the input triggering signals and the description of the interconnection between ADC1, and timers, are given in:

- *Table 229: ADC interconnection*
- *Section 27.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN,JEXTSEL, JEXTEN)*
- *Section 27.4.25: Timing diagrams example (single/continuous modes, hardware/software triggers)*

**Active power mode**

This interconnection is active in Run and Sleep modes for all ADCs. The timers are active in Run and Sleep mode only. The effects of low-power modes are given in:

- *Table 420: Effect of low-power modes on TIM1*
- *Table 438: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
- *Table 454: Effect of low-power modes on TIM9/TIM12/TIM13/TIM14*
- *Table 476: STM32H7Rx/7Sx LPTIM features*
11.3.3 ADC analog watchdogs as triggers to timers

From ADC1/ADC2 to TIM1

**Purpose**

The internal analog watchdog output signals coming from ADC1, are connected to on-chip timers. ADC1 can provide trigger event through analog watchdog signals to advanced-control timers (TIM1) in order to reset, start, stop or clock the counter.

Settings description of the ADC analog watchdog and timer trigger, are provided in:

- *Section 41.3.6: External trigger input*
- *Table 409: Interconnect to the tim_etr input multiplexer* for the internal ADC1 sources connected to TIM1 (tim_etr) input multiplexer
- *Table 228: ADC internal input/output signals* for the ADC_AWDx

**Triggering signals**

The output (from ADC) is on signals ADCn_AWDx_OUT, with n being the ADC instance and x = 1, 2, 3 (three watchdogs per ADC). The input (to timer) is on signal TIMx_ETR (external trigger).

**Active power mode**

ADC1 are active in Run and Sleep modes.

11.3.4 Triggers on ADF1

From EXTI to ADF1

**Purpose**

EXTI (EXTI15) can be used to generate a triggering event on ADF1 module and start an A/C conversion.

A description is given in:

- *Section 27.4.2: ADC pins and internal signals*
- *Section 30.4.9: Start-up sequence examples*

**Triggering signals**

The adf_trgi trigger input is the triggering input signal. The ADF trigger inputs connections are detailed in:

- *Table 257: ADF trigger connections*

**Active power mode**

This interconnection remains active down to Stop (SVOS high) for ADF1, assuming the trigger source remains active.

11.3.5 Internal input and clock sources to timers

From HSE, LSE, HSI CSI and MCO to TIM (TIM9, TIM12), LP timers (LPTIM1/LPTIM2/LPTIM3/LPTIM4/LPTIM5) and RTC
Purpose

A timer input or timer counter can receive different clock sources and can be used to calibrate internal oscillator on a reference clock for example.

Internal clocks (CSI, HSI) and microcontroller output clock (MCO) can be used as input to timers:

- HSI and CSI are assigned to general purpose timers TIM12 as external inputs signals. This allows the calibration. HSI/CSI can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in). Inputs assignment and clock selection description are detailed in:
  - Section 44.4.5: Clock selection for TIM12
  - External clock mode1: Table 442: TIM internal input/output signals for TIM12, tim_ti1_in2 (HSI) and tim_ti1_in3(CSI)
- Microcontroller output clock (MCO) is connected as external input to general-purpose timers TIM9. This allows the calibration or clock measurement. When the low-speed external (LSE) oscillator is used, no additional hardware connections are required. This feature is given in Table 450: Interconnect to the tim_ti1 input multiplexer
- LSI and LSE can be selected as input capture 2 to LPTIM1 as described in Table 485: LPTIM1 input capture 2 connection
- HSI/1024 CSI/128 can be selected as input capture 2 to LPTIM2 as described in Table 486: LPTIM2 input capture 2 connection.

Triggering signals

lptim_ic2_mux1 LPTIM input capture selection can be set in the LPTIM configuration register 2 (LPTIM_CFGR2). For timers, the internal clock signal can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in) and mode2 (external trigger input tim_etr_in).

Active power mode

This feature is available under Run and Sleep modes.

11.3.6 Triggers to low-power timers

From EXTI, TAMP and RTC alarm to LP timers (LPTIM1/LPTIM2/LPTIM3/LPTIM4/LPTIM5)

Purpose

LPTIM1/LPTIM2/LPTIM3/LPTIM4/LPTIM5 counters may be started either by software or after the detection of an active edge on one of the eight trigger inputs.

GPIO can also be selected as LPTIM input capture selection or LPTIM input selection, according to the LPTIM configuration register 2 (LPTIM_CFGR2).

Triggering signals

This trigger feature is described in Table 46.4.7: Trigger multiplexer and the following sections. The input selection is described in Table 481: LPTIM1/2/3/4/5 external trigger connection.

Active power mode

This interconnection remains active down to Stop mode.
11.3.7 RTC wakeup as inputs to timers
From RTC to timers (TIM16)

**Purpose**
RTC wakeup interrupt can be used as input to general-purpose timers (TIM16) channel 1.

**Triggering signals**
RTC wakeup signal is connected to tim_ti1_in3 signal as described in *Table 450: Interconnect to the tim_ti1 input multiplexer* for TIM15.

**Active power mode**
This interconnection is active down to Stop. Timers are not active but the count is performed at wakeup.

11.3.8 USB OTG SOF as trigger to timers
From USB OTG SOF to TIM2

**Purpose**
USB OTG SOF (start-of-frame) can generate a trigger to the general-purpose timer TIM2/TIM5. The USB connection to TIM2/TIM5 are described in *Table 431: TIMx internal trigger connection*.

**Triggering signals**
The tim_itr13 internal signal is generated by OTG HS SOF, the tim_itr14 internal signal is generated by OTG FS SOF.

**Active power mode**
This interconnection is active in Run and Sleep modes.

11.3.9 System errors as break signals to timers
The following system-level errors can trigger a timer break event: Cortex-M7 lockup, PVD low threshold, CSS, double ECC errors in AXISRAM1, AXISRAM3, ITCM, DTCM, backup RAM and flash memory.

The purpose of the break event is to disable the timer outputs to protect the power transistors they control.

System errors apply in RUN and Sleep modes.

**Active power mode**
Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:
- *Table 420: Effect of low-power modes on TIM1*
- *Table 470: Effect of low-power modes on TIM15/TIM16/TIM17*
11.3.10 **Triggers to GPDMA/HPDMA**

From EXTI, RTC (wakeup), timers (TIM1/TIM2/TIM3/TIM4/TIM5/TIM6/TIM7/TIM9/TIM12/TIM15), LP timers (LPTIM1/LPTIM3/LPTIM4/LPTIM5), HP/GPDMA1 transfer complete (gpdma1_chx_tcf/lhdma1_chx_tcf), SPI6, LPUART,

**Purpose**

A HP/GPDMA trigger can be assigned to a HP/GPDMA channel x. A programmed HP/GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event. The trigger mode can also be programmed to condition the LLI link transfer. More details are given in the sections below:

- Section 12.3.6: GPDMA triggers and Section 13.3.6: HPDMA triggers
- Section 12.4.12: GPDMA triggered transfer and Section 13.4.12: HPDMA triggered transfer
- Section 12.8.9: GPDMA channel x transfer register 2 (GPDMA_CxTR2) and Section 13.8.9: HPDMA channel x transfer register 2 (HPDMA_CxTR2) for more details on:
  - Trigger selection TRIGSEL[5:0] field
  - Trigger mode (LLI) defined by TRIGM[1:0].
  - Trigger polarity as defined by TRIGPOL[1:0]

**Triggering signals**

GPDMA trigger mapping is specified in Table 94: Programmed GPDMA1 trigger, according to GPDMA_CxTR2.TRIGSEL[5:0].

HPDMA trigger mapping is specified in Table 106: Programmed HPDMA1 trigger, according to HPDMA_CxTR2.TRIGSEL[5:0].

**Active power mode**

Assuming sources are active down to Stop modes, this interconnection remains functional in Stop.

Refer to:
- Section 12.6: GPDMA in low-power modes
- Section 13.6: HPDMA in low-power modes

11.3.11 **Internal analog signals to analog peripherals**

From internal analog source to ADC (ADC1)

**Purpose**

The internal reference voltage (VREFINT), the internal temperature sensor (VSENSE) monitoring channel are connected to ADC (ADC1) input channels. In addition, the internal
digital core voltage (VCORE) and VBAT are connected to input channels. This is according to:

- Section 27.4.32: Temperature sensor
- Section 27.4.33: VBAT supply monitoring
- Section 27.4.34: Monitoring the internal voltage reference
- Section 27.4.35: Monitoring the supply voltage

Active power mode
These interconnections remain in Stop modes if the selected peripheral is kept active. Refer to Section 27.5: ADC in low-power modes

11.3.12 ADC data filtering by the ADF1
From ADC1 to ADF1

Purpose
The ADF1 allows the connection of up to two ADCs to the filter path. For each filter, the DATSRC[1:0] field in the ADF digital filter configuration register x (ADF_DFLTxCICR) is used to select either data from the ADCs in:

- Section 27.4.4: ADC connectivity
- Table 229: ADC interconnection
  - mdf_adcitf1_dat[15:0] to adc_da
- Table 268: Effect of low-power modes on ADF

Active power mode
This feature remains available down to Sleep mode.

11.3.13 Internal tamper sources
From internal peripherals, clocks or monitoring to tamper.

Purpose
In order to detect any abnormal activity or tentative to corrupt the device, tampers are introduced and alert the system of such undesired event. Different actions can be taken in consequences.

List of tamper sources can be found in Table 21: Internal tampers in TAMP

Active power mode
This interconnection is active in all power modes if the tamper source is activated.
11.3.14 Output from tamper to RTC

From TAMP to RTC

Purpose

The RTC can timestamp a tamper event in order to retrieve history in time of such detection. The RTC can also control GPIOs and set a signal based on tamp or alarm status outside the MCU.

Refer to Section 49.3.3: GPIOs controlled by the RTC and TAMP for more details.

Active power mode

This interconnection remain active in all power modes.

11.3.15 Encryption keys to AES/SAES

From TAMP backup registers, system Flash memory to and in between SAES and AES

Purpose

The encryption mechanism requires an hardware key that must be stored in a protected non-volatile memory. Different approaches are implemented in order to load them in a non-readable way. Tamper backup registers or system Flash can be used to store respectively BHK or RHUK, and to implement a dedicated bus to pass it to the SAES.

Refer to Section 36.4.14: SAES operation with wrapped keys for more details.

The AES encryption mechanism (faster than the SAES) can benefit from the sharing key of the SAES. Refer to Section 36.4.15: SAES operation with shared keys for more details.

Active power mode

AES and SAES are operating under Run and Sleep modes.
12 General purpose direct memory access controller (GPDMA)

12.1 GPDMA introduction

The general purpose direct memory access (GPDMA) controller is a bus master and system peripheral.

The GPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

12.2 GPDMA main features

- Dual bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral
- Autonomous data transfers during low-power modes (see Section 12.3.2)
  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 16 concurrent GPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see Section 12.3.1)
  - Intra-channel GPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel GPDMA transfers chaining via programmable GPDMA input triggers connection to GPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level
- Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive burst transfers
- 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see Section 12.3.1)
- Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
- Programmable GPDMA request and trigger selection
- Programmable GPDMA half transfer and transfer complete events generation
- Pointer to the next linked-list item and its data structure in memory, with automatic update of the GPDMA linked-list control registers

- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- Privileged/unprivileged support:
  - Support for privileged and unprivileged GPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

### 12.3 GPDMA implementation

#### 12.3.1 GPDMA channels

A given GPDMA channel x is implemented with the following features and intended usage. To make the best use of the GPDMA performances, the table below lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested GPDMA transfer.

<table>
<thead>
<tr>
<th>Channel x</th>
<th>Hardware parameters</th>
<th>Features</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>dma_fifo_size[x]</td>
<td></td>
</tr>
<tr>
<td></td>
<td>dma_addressing[x]</td>
<td></td>
</tr>
<tr>
<td>x = 0 to 11</td>
<td>2</td>
<td></td>
</tr>
<tr>
<td>x = 12 to 15</td>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>

Channel x (x = 0 to 11) is implemented with:
- a FIFO of 8 bytes, 2 words
- fixed/contiguously incremented addressing

These channels must be typically allocated for GPDMA transfers between an APB or AHB peripheral and AHB SRAM.

Channel x (x = 12 to 15) is implemented with:
- a FIFO of 32 bytes, 8 words
- 2D addressing

These channels may be also used for GPDMA transfers, between a demanding AHB peripheral and AHB SRAM, or for transfers from/to AXI SRAM or external AXI memories.
12.3.2 GPDMA autonomous mode in low-power modes

The GPDMA autonomous mode and wake-up feature are implemented in the device low-power modes as per the table below.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Low-power modes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wake-up</td>
<td>GPDMA1 in Sleep mode</td>
</tr>
</tbody>
</table>

12.3.3 GPDMA requests

A GPDMA request from a peripheral can be assigned to a GPDMA channel x, via REQSEL[6:0] in GPDMA_CxTR2, provided that SWREQ = 0.

The GPDMA requests mapping is specified in the table below.

<table>
<thead>
<tr>
<th>GPDMA_CxTR2.REQSEL[6:0]</th>
<th>Selected GPDMA request</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

</tbody>
</table>
### 12.3.4 GPDMA block requests

Some GPDMA requests must be programmed as a block request, and not as a burst request. Then BREQ in GPDMA_CxTR2 must be set for a correct GPDMA execution of the requested peripheral transfer at the hardware level.

#### Table 91. Programmed GPDMA1 request as a block request

<table>
<thead>
<tr>
<th>GPDMA block requests</th>
</tr>
</thead>
<tbody>
<tr>
<td>lptim1_ue_dma</td>
</tr>
<tr>
<td>lptim2_ue_dma</td>
</tr>
<tr>
<td>lptim3_ue_dma</td>
</tr>
</tbody>
</table>
### 12.3.5 GPDMA channels with peripheral early termination

A GPDMA channel, if implemented with this feature, can support the early termination of
the data transfer from the peripheral which does also support this feature.

<table>
<thead>
<tr>
<th>GPDMA channel x with peripheral early termination</th>
</tr>
</thead>
<tbody>
<tr>
<td>x = 0 and x = 15</td>
</tr>
</tbody>
</table>

This GPDMA support is activated when the channel x is programmed with
GPDMA_CxTR2.PFREQ = 1. Then, the peripheral itself can initiate and request a data
transfer completion, before that the GPDMA has transferred the whole block
(see Section 12.4.14 for more details).

### 12.3.6 GPDMA triggers

A GPDMA trigger can be assigned to a GPDMA channel x, via TRIGSEL[5:0]
in GPDMA_CxTR2, provided that TRIGPOL[1:0] defines a rising or a falling edge of the
selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

(1) Refer to the device implementation table for the number of channels.
12.4.2 GPDMA channel state and direct programming without any linked-list

After a GPDMA reset, a GPDMA channel x is in idle state. When the software writes 1 in GPDMA_CxCR.EN, the channel takes into account the value of the different channel configuration registers (GPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

After enabling/starting a GPDMA channel transfer by writing 1 in GPDMA_CxCR.EN, a GPDMA channel interrupt on a complete transfer notifies the software that the GPDMA channel is back in idle state (EN is then deasserted by hardware) and that the channel is ready to be reconfigured then enabled again.

The figure below illustrates this GPDMA direct programming without any linked-list (GPDMA_CxLLR = 0).

Figure 88. GPDMA channel direct programming without linked-list (GPDMA_CxLLR = 0)
12.4.3 GPDMA channel suspend and resume

The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.

Note that an ongoing GPDMA transfer can be a data transfer (a source/destination burst transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to GPDMA_CxCR.SUSP.

Figure 89. GPDMA channel suspend and resume sequence

Note: A suspend and resume sequence does not impact the GPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

12.4.4 GPDMA channel abort and restart

Alternatively, like for aborting a continuous GPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the
channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.

3. The software resets the channel by writing 1 to GPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the GPDMA_CxCR.EN bit, and the reset of the GPDMA_CxCR.SUSP bit.

4. The software safely reconfigures the channel. The software must reprogram the hardware-modified GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR registers.

5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the GPDMA_CxCR.EN bit.

**Figure 90. GPDMA channel abort and restart sequence**

12.4.5 **GPDMA linked-list data structure**

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.
The base address in memory of the data structure of a next LLI_{n+1} of a channel \(x\) is the sum of the following:

- the link base address of the channel \(x\) (in GPDMA_CxLBAR)
- the link address offset (LA[15:2] field in GPDMA_CxLLR). The linked-list register GPDMA_CxLLR is the updated result from the data structure of the previous LLI_{n} of the channel \(x\).

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the UT1, UT2, UB1, USA, UDA and ULL bits, plus UB2 and UT3, in GPDMA_CxLLR.

In linked-list mode, each GPDMA linked-list register (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3 or GPDMA_CxBR2) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the GPDMA_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

**Static linked-list data structure**

For example, when the update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3) in GPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel \(x\) (\(x = 0\) to \(11\)) contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR (see Figure 91) and including the first linked-list register file (LLI_{0}) and the next LLIs (such as LLI_{1}, LLI_{2}) in the memory
- channel \(x\) (\(x = 12\) to \(15\)), contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2 (see Figure 92), and including the first linked-list register file (LLI_{0}) and the next LLIs (such as LLI_{1}, LLI_{2}) in the memory
Figure 91. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x
Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register GPDMA_CxLLR is pointing to the updated value of the GPDMA_CxTR2 instead of the GPDMA_CxTR1 which is not to be modified (see Figure 93).

Example: if UT1 = UB1 = USA = 0 and if UT3 = UDA = ULL = 1, when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for GPDMA_CxTR1, nor GPDMA_CxBR1, nor GPDMA_CxSAR, nor GPDMA_CxDAR, nor GPDMA_CxTR3, nor GPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for GPDMA_CxTR2, GPDMA_CxDAR, and GPDMA_CxLLR, as shown in Figure 94.
The user must program GPDMA_CxLLR for each LLI to be 32-bit aligned and not to exceed the 64-Kbyte addressable space pointed by GPDMA_CxLBAR.

12.4.6 Linked-list item transfer execution

A LLI transfer is the sequence of:

1. a data transfer: GPDMA executes the data transfer as described by the GPDMA internal register file (this data transfer can be void/null for LLI_0)
2. a conditional link transfer: GPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI+1, as defined by the GPDMA_CxLLR value of the LLI.

Note: The initial data transfer as defined by the internal register file (LLI_0) can be null (GPDMACxBR1.BNDT[15:0] = 0 and GPDMACxTR2.PFREQ = 0) provided that the conditional update bit UB1 in GPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI in the memory to be executed).

Depending on the intended GPDMA usage, a GPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, GPDMA_CxCxCR.LSM = 0) or a GPDMA channel x can be programmed for a single execution of a LLI (link step mode, GPDMA_CxCxCR.LSM = 1), as described in the next sections.
12.4.7 GPDMA channel state and linked-list programming in run-to-completion mode

When GPDMA_CxCR.LSM = 0 (in full list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), a GPDMA channel x is initially programmed, started by writing 1 to GPDMA_CxCR.EN, and after completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI₀, internal linked-list register file: GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2
  - the last LLIₙ₋₁, described by the linked-list data structure in memory, as defined by the GPDMA_CxLLR reflecting the before last LLIN-1
- completed when GPDMA_CxLLR[31:0] = 0, GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLIN-1 transfer

GPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:
- The 16 low significant bits GPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits GPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3).

The channel may never be completed when GPDMA_CxLLR.LSM = 0:
- If the last LLIN is recursive, pointing to itself as a next LLI:
  - either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value
  - or GPDMA_CxLLR.ULL = 0
- If LLIN is pointing to a previous LLI

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see Section 12.4.14 for more details).

In the typical run-to-completion mode, the allocation of a GPDMA channel, including its fine programming, is done once during the GPDMA initialization. In order to have a reserved data communication link and GPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

Figure 95 depicts the GPDMA channel execution and its registers programming in run-to-completion mode.

Note: Figure 95 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

In Figure 95, BNDT ≠ 0 is the typical condition for starting the first data transfer in this figure. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 12.3.5).
Figure 95. GPDMA channel execution and linked-list programming in run-to-completion mode (GPDMA_CxCR.LSM = 0)

- Setting USEF = 1 Disabling DMA channel
- Setting USEF = 1 Disabling DMA channel
- Setting USEF = 1 Disabling DMA channel

End
Run-time inserting a LLIₙ via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLIₙ₋₁ (start of the LLIₙ loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the GPDMA_CxTR2 in the data structure of the LLIₙ₋₁:

- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[5:0] (see Section 12.3.6 for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLIₙ in the memory and to generate a transfer complete event gpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLIₙ₋₁ of the channel x, the software can pause the primary channel x after its LLIₙ₋₁ data transfer, until it is indeed written the LLIₙ.

The figure below depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLIₙ₋₁ data transfer that does not need a trigger. The triggering mode of this LLIₙ₋₁ is used to load the next LLIₙ.
12.4.8 GPDMA channel state and linked-list programming in link step mode

When GPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

A GPDMA channel transfer can be programmed at LLI level, started by writing 1 into GPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI transfer is described with:
  - GPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - GPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]) and, for channel x (x = 12 to 15), the number of blocks at a 2D/repeated block level (BRC[10:0]+1) and the incrementing/decrementing mode for address offsets.
- GPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
- GPDMA_CxSAR/GPDMA_CxDAR define the source/destination transfer start address.
- GPDMA_CxTR3 for channel x (x = 12 to 15) defines the source/destination additional address offset between burst transfers.
- GPDMA_CxBR2 for channel x (x = 12 to 15) defines the source/destination additional address offset between blocks at a 2D/repeated block level.
- GPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when \( GPDMA_CxBR1.BRC[10:0] = 0 \), and \( GPDMA_CxBR1.BNDT[15:0] = 0 \))
  - after the (conditional) update of the GPDMA link register file from the data structure of the next LLI_{n+1} in memory

**Note:** If a LLI is recursive (pointing to itself as a next LLI, either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value, or GPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see Section 12.4.14 for more details).

The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of GPDMA_CxLLR have a static value, LLI_{n}.LLR.LA = LLI_{n-1}.LLR.LA + constant).

**Figure 97** depicts the GPDMA channel execution mode, and its programming in link step mode.

**Note:** **Figure 97** is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In **Figure 97**, BNDT \( \neq 0 \) is the typical condition for starting the first data transfer. This condition becomes (BNDT \( \neq 0 \) and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 12.3.5).
Figure 97. GPDMA channel execution and linked-list programming in link step mode (GPDMA_CxCR.LSM = 1)

  - N: Disabling DMA channel

End
Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after GPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_{n} from the memory, as shown in the figure below.

**Figure 98. Building LLI_{n+1}: GPDMA dynamic linked-lists in link step mode**

Run-time replacing a LLI_{n} with a new LLI_{n'} in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI_{n'}, after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_{n} from the memory by overwriting directly the linked-list register file with the new LLI_{n'}, as shown in the figure below.
Figure 99. Replace with a new LLI_{n'} in register file in link step mode

Run-time replacing a LLI_{n} with a new LLI_{n'} in link step mode (in the memory)

The software can build and insert a new LLI_{n'} and LLI_{n'+1}' in the memory, after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_{n} from the memory, by overwriting partly the linked-list register file (GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new LLI_{n'}) as shown in the figure below.
Figure 100. Replace with a new LLI_{n} and LLI_{n+1}' in memory in link step mode (option 1)

LSM = 1 with 1-stage linked-list programming:
Overwriting the (pre)loaded LLI_{n} linked-list register file with a new LLI_{n}' and LLI_{n+1}' in memory and
overwrite partly linked-list register file
(DMA_CxBR1.BNDT = 0 and DMA_CxLLR to point to new LLI_{n}')
DMA executes LLI_{n-1} and load LLI_{n} then CPU builds (LLI_{n}' and LLI_{n+1}') and overwrite (BR1 and LLR)

DMA Channel

✅ Executing LLI_{n-1} data transfer

Loading LLI_{n}

Transfer complete interrupt

CPU

Build LLI_{n}' and LLI_{n+1}' in memory

Write DMA_CxBR1.BNDT = 0
Write DMA_CxLLR to point to new LLI_{n}'

Enable DMA channel

✅ Loading LLI_{n}'

Transfer complete interrupt

✅ Executing LLI_{n+1}' data transfer

Loading LLI_{n+1}'

Transfer complete interrupt
Run-time replacing a \( LLIn \) with a new \( LLIn' \) in link step mode

Other software implementations exist. Meanwhile GPDMA executes the transfer from the \( LLIn-1 \) and loads a formerly elaborated \( LLIn \) from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new \( LLIn' \) and a new \( LLIn_{n+1}' \).
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for \( LLIn_{n-1} \) is then restricted to overwrite \( GPDMA\_CxBR1.BNDT[15:0] = 0 \) and \( GPDMA\_CxLLR \) to point to new \( LLIn' \), as shown in the figure below.

Figure 101. Replace with a new \( LLIn' \) and \( LLIn_{n+1}' \) in memory in link step mode (option 2)

- LSM = 1 with 1-stage linked-list programming:
  - Overwriting the (pre)loaded \( LLIn \), linked-list register file by building new \( LLIn' \) and \( LLIn_{n+1}' \) in memory while disabling (temporary) channel interrupt at NVIC level, and overwriting \( DMA\_CxBR1.BNDT = 0 \) and \( DMA\_CxLLR \) to point to new \( LLIn' \).
  - DMA executes \( LLIn_{n-1} \) and loading \( LLIn \) while CPU builds \( (LLIn' \) and \( LLIn_{n+1}' \)), then CPU overwrites \( (BR1 \) and \( LLR) \).
12.4.9 GPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (GPDMA_CxCR.EN = 0) and update the execution mode (GPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLIn+1 in the memory to finally complete the channel by this LLIn+1 (clear the GPDMA_CxLLR of this LLIn+1), before that this LLIn+1 is loaded/used by the GPDMA channel
- abort and reconfigure the channel with a LSM update (see Section 12.4.4.)

In link step mode, the software can clear LSM after each a single execution of any LLI, during LLIn-1.

*Figure 102* shows the overall and unified GPDMA linked-list programming, whatever is the execution mode.

**Note:** *Figure 102 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.*

In *Figure 102*, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 12.3.5).

        - Disabling DMA channel

End
12.4.10 GPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see Section 12.3.1 for more details).

GPDMA burst

A programmed transfer at the lowest level is a GPDMA burst.

A GPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by the field SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by the field SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in the GPDMA_CxTR1 register.

The addressing mode after each data (named beat) of a GPDMA burst is defined by SINC and DINC in GPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a GPDMA source/destination burst (defined by GPDMA_CxSAR and GPDMA_CxDAR) must be aligned with the respective data width.

The table below lists the main characteristics of a GPDMA burst.

<table>
<thead>
<tr>
<th>Table 95. Programmed GPDMA source/destination burst</th>
</tr>
</thead>
<tbody>
<tr>
<td>SDW_LOG2[1:0]</td>
</tr>
<tr>
<td>----------------</td>
</tr>
<tr>
<td>00</td>
</tr>
<tr>
<td>01</td>
</tr>
<tr>
<td>10</td>
</tr>
<tr>
<td>00</td>
</tr>
<tr>
<td>01</td>
</tr>
<tr>
<td>10</td>
</tr>
<tr>
<td>11</td>
</tr>
</tbody>
</table>

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.

The next burst address in the above table is the next source/destination default address pointed by GPDMA_CxSAR or GPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.
GPDMA burst with 2D addressing (channel x = 12 to 15)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by GPDMA_CxTR2.SAO[12:0]/DAO[12:0] and GPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by GPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and GPDMA_CxBR1.BRSDEC/BRDDEC

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by the figure below with a 2D destination buffer.
Programmable address jumps 1) after burst and 2) after block.
Example:
burst: \( I \times \text{words} \) (DBL=1; DDW_LOG2=\( \text{b}10 \))
block: \( J \times \text{bursts} \) (BNDT=\( J^*4 \))
LLI: \( K \times \text{blocks} \) (BRC=K-1)
**GPDMA FIFO-based burst**

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- one burst from the source to the FIFO over the allocated source master port, as defined by GPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by GPDMA_CxTR1.DAP

**GPDMA source burst**

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

\[
\text{when } \text{FIFO level } \leq 2^{\text{dma_fifo_size}[x]} - (SBL_1[5:0]+1) \times 2^{\text{SDW_LOG2}[1:0]}
\]

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- \(2^{\text{dma_fifo_size}[x]}\) is the half of the FIFO size of the channel x, in bytes (see *Section 12.3.1* for the implementation details and dma_fifo_size[x] value).
- \((SBL_1[5:0]+1) \times 2^{\text{SDW_LOG2}[1:0]}\) is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (GPDMA_CxCR.PRIOR[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

**GPDMA destination burst**

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

\[
\text{when } \text{FIFO level } \geq (DBL_1[5:0]+1) \times 2^{\text{DDW_LOG2}[1:0]}
\]

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- \((DBL_1[5:0]+1) \times 2^{\text{DDW_LOG2}[1:0]}\) is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

**GPDMA burst vs source block size, 1-Kbyte address boundary and FIFO size**

The programmed source/destination GPDMA burst is implemented with an AHB burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel x is lower than the programmed source/destination burst size, the programmed source/destination GPDMA burst is implemented with a series of singles or bursts of a lower size, each transfer being of a size that is lower or equal than half of the FIFO size, without any user constraint.
- if the source block size (GPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (GPDMA_CxTR1.SDW_LOG2[1:0]), the GPDMA modifies and shortens bursts into singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.
- If the source/destination burst transfer have crossed the 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.
- If the source/destination burst length exceeds 16 on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.

In any case, the GPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in GPDMA_CxSR) is compared to and updated with the effective transfer size, and the GPDMA re-arbitrates between each AHB single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

**Note:** In linked-list mode, the GPDMA read transfers related to the update of the linked-list parameters from the memory to the internal GPDMA registers, are scheduled over the link allocated port, as programmed by GPDMA_CxCR.LAP.

**GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment**

The data handling is controlled by GPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word or word, as per the SDW_LOG2[1:0] and DDW_LOG2[1:0] fields (see Table 96).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. **Byte-based source reordering**
   - If SBX = 1 and if source data width is a word, the two bytes of the unaligned half-word at the middle of each source data word are exchanged.

2. **Data width conversion by packing, unpacking, padding or truncation,** if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.

3. **Byte-based destination re-ordering:**
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.

**Note:** Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding and a destination byte-based re-ordering.
The table below lists the possible data handling from the source to the destination.

12.4.11 GPDMA transfer request and arbitration

GPDMA transfer request

As defined by GPDMA_CxTR2, a programmed GPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory-mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the GPDMA hardware peripheral request is driven by the REQSEL[6:0] field (see Section 12.3.3). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in GPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control registers update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory

1. Data stream is timely ordered starting from the byte with the lowest index (B0).
2. RA = right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.
Caution:  The user must not assign a same input hardware peripheral GPDMA request via GPDMA_CxTR.REQSEL[6:0] to two different channels, if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

GPDMA transfer request for arbitration

A ready FIFO-based GPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (GPDMA_CxTR1.SAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRI0[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

A ready FIFO-based GPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (GPDMA_CxTR1.DAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRI0[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

An arbitrated GPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in memory to one of the linked-list registers (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3, GPDMA_CxBR2). Each 32-bit read from memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (GPDMA_CxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to-memory transfer (GPDMA_CxTR2.SWREQ = 1), or with a hardware request (GPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (GPDMA_CxTR2.SWREQ = 0 and GPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

GPDMA arbitration

The GPDMA arbitration is directed from the 4-grade assigned channel priority (GPDMA_CxCR.PRI0[1:0]). The arbitration policy, as illustrated in Figure 104, is defined by:

- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels
  
  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.

- three low-priority traffic classes (queues 0, 1 or 2) for non time-sensitive channels with priority 0, 1 or 2
  
  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.
Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.

Any queue 0, 1 or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.

Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1 and queue 2.

**Figure 104. GPDMA arbitration policy**

GPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as BQ3) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive GPDMA requests: req0 and req1. There are the following programming possibilities:
  - If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (Breq0) is equal to the allocated bandwidth to req1 (Breq1).
    \[ B_{req0} = B_{req1} = \frac{1}{2} \times (1 - B_{Q3}) \]
  - If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (BP0) is 3 times less than the allocated bandwidth to req1 (BP1).  
    \[ B_{req0} = B_{P0} = \frac{1}{2} \times \frac{1}{2} \times (1 - B_{Q3}) = \frac{1}{4} \times (1 - B_{Q3}) \]
    \[ B_{req1} = B_{P1} = \frac{1}{2} + 1 \times \frac{1}{2} \times (1 - B_{Q3}) = \frac{3}{4} \times (1 - B_{Q3}) \]
  - If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (BP0) is 5 times less than the allocated bandwidth to req1 (BP2).  
    \[ B_{req0} = B_{P0} = \frac{1}{2} \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{1}{6} \times (1 - B_{Q3}) \]
    \[ B_{req1} = B_{P2} = \frac{1}{2} + 1 + 1 \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{5}{6} \times (1 - B_{Q3}) \]

The above computed bandwidth calculation is based on a theoretical input request, always active for any GPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one GPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.
Example 2: application where the user distributes a same non-null N number of GPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:

- The allocated bandwidth to the set of requests of priority 0 (B_P0) is
  \[ B_{P0} = \frac{1}{3} \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{1}{9} \times (1 - B_{Q3}) \]

- The allocated bandwidth to the set of requests of priority 1 (B_P1) is
  \[ B_{P1} = \left(\frac{1}{3} + \frac{1}{2}\right) \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{5}{18} \times (1 - B_{Q3}) \]

- The allocated bandwidth to the set of requests of priority 2 (B_P2) is
  \[ B_{P2} = \left(\frac{1}{3} + \frac{1}{2} + 1\right) \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{11}{18} \times (1 - B_{Q3}) \]

- The allocated bandwidth to any request n (B_n) among the N requests of that priority P_i (i = 0 to 2) is
  \[ B_n = \frac{1}{N} \times B_{P_i} \]

- The allocated bandwidth to any request n of priority 0 (B_n, P_0) is
  \[ B_{n, P0} = \frac{1}{N} \times \frac{1}{9} \times (1 - B_{Q3}) \]

  \[ B_{n, P1} = \frac{1}{N} \times \frac{5}{18} \times (1 - B_{Q3}) \]

  \[ B_{n, P2} = \frac{1}{N} \times \frac{11}{18} \times (1 - B_{Q3}) \]

In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I \geq 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.

- J requests (J \geq 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.

- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1

- L requests (L \geq 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- \[ B_l = B_{Q3} / L \text{ for } L > 0 \text{ (else: } B_l = 0) \]

The bandwidth for each non-time sensitive queue is:

- B_{Q0} = \frac{1}{3} \times (1 - B_{Q3})
- B_{Q1} = \frac{1}{3} \times (1 - B_{Q3})
- B_{Q2} = \frac{1}{3} \times (1 - B_{Q3})

The bandwidth for the set of requests with priority 0 is:

- B_{P0} = I / (I + J + K) \times B_{Q0}

The bandwidth for each request i with priority 0 is:

- B_i = B_{P0} / I \text{ for } L > 0 \text{ (else } B_{P0} = 0)\]

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- B_{P1,Q0} = J / (I + J + K) \times B_{Q0}
The bandwidth for the set of requests with priority 1 and routed to queue 1 is:
• $B_{P1,Q1} = J / (J + K) \cdot B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:
• $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request $j$ with priority 1 is:
• $B_j = B_{P1} / J$ for $J > 0$ (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:
• $B_{P2,Q0} = K / (I + J + K) \cdot B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:
• $B_{P2,Q1} = K / (J + K) \cdot B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:
• $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:
• $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request $k$ with priority 2 is:
• $B_k = B_{P2} / K$ (for $K > 0$ in the general case)

Thus finally the maximum allocated residual bandwidths for any $i$, $j$, $k$ non-time sensitive request are:
• in the general case (when there is at least one request $k$ with a priority 2 ($K > 0$)):
  - $B_i = 1/l * 1/3 * l/(l + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(l + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(l + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
• in the specific case (when there is no request $k$ with a priority 2 ($K = 0$)):
  - $B_i = 1/l * 1/2 * l/(l + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(l + J) + 1] * (1 - B_{Q3})$

Consequently, the GPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

### 12.4.12 GPDMA triggered transfer

A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGSEL[5:0] (see Section 12.3.6 for the trigger selection).

The triggered transfer, as defined by the trigger mode in GPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block for channel $x$ ($x = 12$ to $15$), or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see TRIGM[1:0] in GPDMA_CxTR2 for more details).
Trigger hit memorization and trigger overrun flag generation

The GPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[5:0] are not modified, and the channel is enabled.

Transferring a next LLI\textsubscript{n+1}, that updates the GPDMA\_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI\textsubscript{n} trigger.

**Caution:** After a first new trigger hit\textsubscript{n+1} is memorized, if another trigger hit\textsubscript{n+2} is detected and if the hit\textsubscript{n} triggered transfer is still not completed, hit\textsubscript{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA\_CxSR.TOF = 1) and an interrupt is generated if enabled (if GPDMA\_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

The figure below illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

**Figure 105. Trigger hit, memorization and overrun waveform**

Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

12.4.13 GPDMA circular buffering with linked-list programming

GPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel

For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half transfer and complete transfer
events/interrupts generation (GPDMA_CxCR.HTIE = 1 and GPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI0 is configured for the first block transfer with the linear addressing channel. A continuously-executed LLI1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). GPDMA automatically reloads the initially programmed GPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore GPDMA_CxBR1.

The figure below illustrates this programming with a linear addressing GPDMA channel and a source circular buffer.

**Figure 106. GPDMA circular buffer programming: update of the memory start address with a linear addressing channel**

Note: With a 2D addressing channel, the user may use a single LLI with GPDMA_CxBR1.BRC[10:0] = 1, and program a negative memory block address offset with GDMA_CxBR2 and GDMA_CxBR1, in order to jump back to the memory source or the destination start address.

If circular buffering must be executed after some other transfers over the shared GPDMA channel x, the before-last LLI\textsubscript{N-1} in memory is needed to configure the first block transfer. And the last LLI\textsubscript{N} restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).
The figure below illustrates this programming with a linear addressing shared GPDMA channel, and a source circular buffer.

**Figure 107. Shared GPDMA channel with circular buffering: update of the memory start address with a linear addressing channel**

### 12.4.14 GPDMA transfer in peripheral flow-control mode

A peripheral with the peripheral flow-control mode feature can decide to early terminate a GPDMA block transfer, provided that the allocated channel is implemented with this feature (see Section 12.3.5).

If the related GPDMA channel x is also programmed in peripheral flow-control mode (GPDMA_CxTR2.PFREQ = 1):

- The GPDMA block transfer starts as follows:
  - If GPDMA_CxBR1.BNDT[15:0] ≠ 0, the programmed value is internally taken into account by the GPDMA hardware.
  - If GPDMA_CxBR1.BNDT[15:0] = 0, the GPDMA hardware internally considers a 64-Kbyte value for the maximum source block size to be transferred.

- The GPDMA block transfer is completed as soon as the first occurrence of one of the following condition occurs:
  - when GPDMA_CxBR1.BNDT[15:0] = 0
  - when the peripheral early terminates the block. The complete transfer event is generated if programmed, depending on GPDMA_CxTR2 (see GPDMA channel x transfer register 2 (GPDMA_CxTR2)). Then the software can read the current number of transferred bytes from the source (GPDMA_CxBR1.BNDT[15:0]), and/or read the current source or destination address of the buffer in memory (GPDMA_CxSAR[31:0] or GPDMA_CxDAR[31:0]).
In peripheral flow-control mode:
- a destination peripheral with a hardware requested transfer is not supported:
  memory-to-peripheral transfer is not supported.
- Data packing from a source peripheral is not supported.
- 2D/repeated block is not supported.
- GPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source
  (peripheral) burst size.

12.4.15 GPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a
privileged agent via GPDMA_PRIVCFGFR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following
access control rules are applied:
- An unprivileged read access to a register field of this channel is forced to return 0,
  except for GPDMA_PRIVCFGFR and GPDMA_RCFGLOCKR that are readable by an
  unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and
destination data transfers are privileged (respectively unprivileged) transfers over the AHB
master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode,
the loading of the next linked-list data structure from the GPDMA memory into its register
file, is automatically performed with privileged (respectively unprivileged) transfers, via the
GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a privileged bus that reflects GPDMA_PRIVCFGFR, to keep the
other peripherals informed of the privileged/unprivileged state of each GPDMA channel x.

When the privileged software must switch a channel from a privileged state to
an unprivileged state, the privileged software must abort the channel or wait until that the
privileged channel is completed before switching. This is needed to dynamically re-allocate
a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so,
and must have GPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the
GPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x
(GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

12.4.16 GPDMA error management

The GPDMA is able to manage and report to the user a transfer error, as follows, depending
on the root cause.

Data transfer error

on a bus access (as a AHB single or a burst) to the source or the destination
- The source or destination target reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the
  GPDMA hardware). The channel status register reports an idle state
  (GPDMA_CxSR.IDLEF = 1) and the data error (GPDMA_CxSR.DTEF = 1).
- After a GPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After a GPDMA data transfer error, the user must issue a channel reset (set GPDMA_CxCR.RESET) to reset the hardware GPDMA channel data path and the content of the FIFO, before the user enables again the same channel for a next transfer.

**Link transfer error**

on a tentative update of a GPDMA channel register from the programmed LLI in the memory

- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware), the channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the link error (GPDMA_CxSR.ULEF = 1).
- After a GPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (GPDMA_CxLBAR and GPDMA_CxLLR), including the protection attributes.
- After a GPDMA link error, the user must explicitly write the linked-list register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2), before the user enables again the same channel for a next transfer.

**User setting error**

on a tentative execution of a GPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (GPDMA_CxCR.EN forced and cleared by the GPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and a user setting error (GPDMA_CxSR.USEF = 1).
- After a GPDMA user setting error, the user must perform a debug session, taking care of the GPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI1 (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - when in packing/unpacking mode (if PAM[1] = 1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed unaligned source start address, being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxSAR[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 12 to 15): a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxTR3.SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
– for channel x (x = 12 to 15): a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR2.BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
– a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxDAR[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
– for channel x (x = 12 to 15): a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxTR3.DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
– for channel x (x = 12 to 15): a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR2.BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
– a programmed double-word source data width (GPDMA_CxTR1.SDW_LOG2[1:0] = 11)
– a programmed double-word destination data width (GPDMA_CxTR1.DDW_LOG2[1:0] = 11)
– a programmed linked-list item LLI_{n+1} with a null data transfer (GPDMA_CxLLR.UB1 = 1 and GPDMA_CxBR1.BNDT = 0)

12.4.17 GPDMA autonomous mode

To save dynamic power consumption while the GPDMA executes the programmed linked-list transfers, the GPDMA hardware automatically manages its own clock gating and generates a clock request output signal to the RCC, whenever the device is in Run or low-power modes, provided that the RCC is programmed with the corresponding GPDMA enable control bits.

For more details about the RCC programming, refer to the RCC section of the reference manual.

For mode details about the availability of the GPDMA autonomous feature vs the device low-power modes, refer to Section 12.3.2.

The user can program and schedule the execution of a given GPDMA transfer at a LLI_{n} level of a GPDMA channel x, with GPDMA_CxTR2 as follows:

- The software controls and conditions the input of a transfer with TRIGM[1:0], TRIGPOL[1:0], TRIGSEL[5:0], SWREQ and REQSEL[6:0] for the input trigger and request.
- The software controls and signals the output of a transfer with TCEM[1:0] for generating or not a transfer complete event, and generating or not an associated half data transfer event).

See GPDMA channel x transfer register 2 (GPDMA_CxTR2) for more details.

When used in low-power modes, this functionality enables a CPU wake-up on a specific transfer completion by the enabled GPDMA transfer complete interrupt (GPDMA_CxCR.TCIE = 1) or/and enables to continue with the autonomous GPDMA for operating another LLI_{n+1} transfer over the same channel.

The output channel x transfer complete event, gpdma_chx_tc, can be programmed as a selected input trigger for a channel if this event is looped-back and connected at the
GPDMA level (see Section 12.3.6), allowing autonomous and fine GPDMA inter-channel transfer scheduling, without needing a cleared transfer complete flag (TCF).

A given GPDMA channel x asserts its clock request in one of the following conditions:
- if the next transfer to be executed is programmed as conditioned by a trigger (GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGM[1:0]), only when the trigger hit occurs.
- if the next transfer to be executed is not conditioned by a trigger:
  - if GPDMA_CxTR2.SWREQ = 0, only when the hardware request is asserted by the selected peripheral
  - if GPDMA_CxTR2.SWREQ = 1 (memory-to-memory, GPIO to/from memory), as soon as the GPDMA is enabled

The GPDMA channel x releases its clock request as soon as all the following conditions are met:
- The transfer to be executed is completed.
- The GPDMA channel x is not immediately ready and requested to execute the next transfer.
- If a channel x interrupt was raised, all the flags of the status register that can cause this interrupt, are cleared by a software agent.

When one channel asserts its clock request, the GPDMA asserts its clock request to the RCC. When none channel asserts its clock request, the GPDMA releases its clock request to the RCC.

### 12.5 GPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

*Note:* In debug mode, GPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, GPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

### 12.6 GPDMA in low-power modes

<table>
<thead>

<td>GPDMA_CxSR.TOF</td>
<td>Write 1 to GPDMA_CxFCR.TOF</td>
</tr>
</tbody>
</table>

A GPDMA channel x event may be:
- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

**Note:** When a channel x transfer complete event occurs, the output signal gpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:
- the corresponding interrupt event xx is enabled (GPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (GPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into GPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by GPDMA_CxTR2.TCEM[1:0] as follows:
- A transfer complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].
• A half transfer event is an half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].
A half-block transfer occurs when half of the source block size bytes (rounded-up integer of GPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.
A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2) is transferred to the destination.

See GPDMA channel x transfer register 2 (GPDMA_CxTR2) for more details.

A transfer error rises in one of the following situations:
• during a single/burst data transfer from the source or to the destination (DTEF)
• during an update of a GPDMA channel register from the programmed LLI in memory (ULEF)
• during a tentative execution of a GPDMA channel with an unauthorized setting (USEF)
The user must perform a debug session to correct the GPDMA channel programming versus the USEF root causes list (see Section 12.4.16).

A trigger overrun is described in Trigger hit memorization and trigger overrun flag generation.

12.8 GPDMA registers

The GPDMA registers must be accessed with an aligned 32-bit word data access.

12.8.1 GPDMA privileged configuration register (GPDMA_PRIVCFGR)

Address offset: 0x04
Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (GPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

Bits 31:16 Res. must be kept at reset value.

Bits 15:0 PRIVx: privileged state of channel x (x = 15 to 0)
0: unprivileged
1: privileged
12.8.2  GPDMA configuration lock register (GPDMA_RCFGLOCKR)

Address offset: 0x08
Reset value: 0x0000 0000

This register can be written by a software agent with privileged attributes in order to individually lock, for example at boot time, the privileged attributes of any GPDMA channel/resource (to lock the setting of GPDMA_CxPRIVCFGR for any channel x, for example at boot time).

A read access may be privileged or unprivileged.

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **LOCKx**: lock the configuration of GPDMA_PRIVCFGR.PRIVx, until a global GPDMA reset (x = 15 to 0)

This bit is cleared after reset and, once set, it cannot be reset until a global GPDMA reset.
0: privilege configuration of the channel x is writable.
1: privilege configuration of the channel x is not writable.

12.8.3  GPDMA masked interrupt status register (GPDMA_MISR)

Address offset: 0x0C
Reset value: 0x0000 0000

This is a read register.

This register contains the masked interrupt status bit MISx for each channel x. It is a logical OR of all the GPDMA_CxSR flags, each source flag being enabled by the corresponding GPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when writing 1 to the corresponding GPDMA_CxFCR flag clear bit.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full interrupt status. An unprivileged software is restricted to read the status of unprivileged channels, other privileged bit fields returning zero.

12.8.4 GPDMA channel x linked-list base address register (GPDMA_CxLBAR)

Address offset: 0x50 + 0x80 * x (x = 0 to 15)
Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x GPDMA_PRIVCFGR.PRIVx.

This register must be written when GPDMA_CxCR.EN = 0.
This register is read-only when GPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the GPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit GPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:0 MISx: masked interrupt status of channel x (x = 15 to 0)
0: no interrupt occurred on channel x
1: an interrupt occurred on channel x

12.8.5 GPDMA channel x flag clear register (GPDMA_CxFCR)

Address offset: 0x5C + 0x80 * x (x = 0 to 15)
Reset value: 0x0000 0000

This is a write register privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:0 Reserved, must be kept at reset value.
Bit 14 **TOF**: trigger overrun flag clear  
0: no effect  
1: corresponding TOF flag cleared  

Bit 13 **SUSPF**: completed suspension flag clear  
0: no effect  
1: corresponding SUSPF flag cleared  

Bit 12 **USEF**: user setting error flag clear  
0: no effect  
1: corresponding USEF flag cleared  

Bit 11 **ULEF**: update link transfer error flag clear  
0: no effect  
1: corresponding ULEF flag cleared  

Bit 10 **DTEF**: data transfer error flag clear  
0: no effect  
1: corresponding DTEF flag cleared  

Bit 9 **HTF**: half transfer flag clear  
0: no effect  
1: corresponding HTF flag cleared  

Bit 8 **TCF**: transfer complete flag clear  
0: no effect  
1: corresponding TCF flag cleared  

Bits 7:0 Reserved, must be kept at reset value.

### 12.8.6 GPDMA channel x status register (GPDMA_CxSR)

Address offset: 0x60 + 0x80 * x (x = 0 to 15)  
Reset value: 0x0000 0001  

This is a read register, reporting the channel status.

This register is privileged or non-privileged, depending on the privileged state of the channel (GPDMA_PRIVCFG.RPRIVx).

</tbody>
</table>

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **FIFOL[7:0]**: monitored FIFO level  
Number of available write beats in the FIFO, in units of the programmed destination data width (see GPDMA_CxTR1.DDW_LOG2[1:0], in units of bytes, half-words, or words).

**Note:** After having suspended an active transfer, the user may need to read FIFOL[7:0], additionally to GPDMA_CxBR1.BDNT[15:0] and GPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (GPDMA_CxSR.SUSPF = 1).
Bit 15  Reserved, must be kept at reset value.

Bit 14  **TOF**: trigger overrun flag
        0: no trigger overrun event
        1: a trigger overrun event occurred

Bit 13  **SUSPF**: completed suspension flag
        0: no completed suspension event
        1: a completed suspension event occurred

Bit 12  **USEF**: user setting error flag
        0: no user setting error event
        1: a user setting error event occurred

Bit 11  **ULEF**: update link transfer error flag
        0: no update link transfer error event
        1: a master bus error event occurred while updating a linked-list register from memory

Bit 10  **DTEF**: data transfer error flag
        0: no data transfer error event
        1: a master bus error event occurred on a data transfer

Bit 9   **HTF**: half transfer flag
        0: no half transfer event
        1: a half transfer event occurred
        A half transfer event is either a half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).
        A half block transfer occurs when half of the bytes of the source block size (rounded up integer of GPDMA_CxBR1.BNDT[15:0]/2) has been transferred to the destination.
        A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2)) has been transferred to the destination.

Bit 8   **TCF**: transfer complete flag
        0: no transfer complete event
        1: a transfer complete event occurred
        A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).

Bits 7:1  Reserved, must be kept at reset value.

Bit 0   **IDLEF**: idle flag
        0: channel not in idle state
        1: channel in idle state
        This idle flag is deasserted by hardware when the channel is enabled (GPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).
        This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).
12.8.7 GPDMA channel x control register (GPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

</table>

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 PRIO[1:0]: priority level of the channel x GPDMA transfer versus others
- 00: low priority, low weight
- 01: low priority, mid weight
- 10: low priority, high weight
- 11: high priority

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 LAP: linked-list allocated port

This bit is used to allocate the master port for the update of the GPDMA linked-list registers from the memory.
- 0: port 0 (AHB) allocated
- 1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 16 LSM: Link step mode

0: channel executed for the full linked-list and completed at the end of the last LLI (GPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0). Then GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0.
1: channel executed once for the current LLI

First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by GPDMA_CxLLR. Then channel execution is completed.

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 TOIE: trigger overrun interrupt enable

0: interrupt disabled
1: interrupt enabled
Bit 13 **SUSPIE**: completed suspension interrupt enable  
  0: interrupt disabled  
  1: interrupt enabled  

Bit 12 **USEIE**: user setting error interrupt enable  
  0: interrupt disabled  
  1: interrupt enabled  

Bit 11 **ULEIE**: update link transfer error interrupt enable  
  0: interrupt disabled  
  1: interrupt enabled  

Bit 10 **DTEIE**: data transfer error interrupt enable  
  0: interrupt disabled  
  1: interrupt enabled  

Bit 9 **HTIE**: half transfer complete interrupt enable  
  0: interrupt disabled  
  1: interrupt enabled  

Bit 8 **TCIE**: transfer complete interrupt enable  
  0: interrupt disabled  
  1: interrupt enabled  

Bits 7:3 Reserved, must be kept at reset value.  

Bit 2 **SUSP**: suspend  
  Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:  
  Software must write 1 in order to suspend an active channel (channel with an ongoing GPDMA transfer over its master ports).  
  The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in Figure 89.  
  0: write: resume channel, read: channel not suspended  
  1: write: suspend channel, read: channel suspended.  

Bit 1 **RESET**: reset  
  This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0).  
  The reset is effective when the channel is in steady state, meaning one of the following:  
  - active channel in suspended state (GPDMA_CxSR.SUSPF = 1 and GPDMA_CxSR.IDLEF = 0 and GPDMA_CxCR.EN = 1)  
  - channel in disabled state (GPDMA_CxSR.IDLEF = 1 and GPDMA_CxCR.EN = 0).  
  After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR) before enabling again the channel (see the programming sequence in Figure 90).  
  0: no channel reset  
  1: channel reset
Bit 0  **EN**: enable
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:
this bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).
Else, this bit can be asserted by software.
Writing 0 into this EN bit is ignored.
0: write: ignored, read: channel disabled
1: write: enable channel, read: channel enabled

### 12.8.8 GPDMA channel x transfer register 1 (GPDMA_CxTR1)

Address offset: 0x90 + 0x80 * x (x = 0 to 15)
Reset value: 0x0000 0000

This register is privileged or non-privileged, depending on the privileged state of the channel x in GPDMA_PRIVCFG.PRIVx.
This register controls the transfer of a channel x.
This register must be written when GPDMA_CxCR.EN = 0.
This register is read-only when GPDMA_CxCR.EN = 1.
This register must be written when the channel is completed. Then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.
In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UT1 = 1.

| Bit 31 | Res. DAP Res. DHX DBX DBL_1[5:0] DINC Res. DDW_LOG2[1:0] |
|--------|----------------|----------------|----------------|----------------|----------------|
| rw     | rw             | rw             | rw             | rw             | rw             |
| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |

| rw     | rw             | rw             | rw             | rw             | rw             |

- **Bit 31**  Reserved, must be kept at reset value.
- **Bit 30**  **DAP**: destination allocated port
  This bit is used to allocate the master port for the destination transfer
  0: port 0 (AHB) allocated
  1: port 1 (AHB) allocated
  *Note*: This bit must be written when EN = 0. This bit is read-only when EN = 1.
- **Bits 29:28**  Reserved, must be kept at reset value.
- **Bit 27**  **DHX**: destination half-word exchange
  If the destination data size is shorter than a word, this bit is ignored.
  If the destination data size is a word:
  0: no halfword-based exchanged within word
  1: the two consecutive (post PAM) half-words are exchanged in each destination word.
Bit 26  **DBX**: destination byte exchange  
If the destination data size is a byte, this bit is ignored.  
If the destination data size is not a byte:  
0: no byte-based exchange within half-word  
1: the two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20  **DBL_1[5:0]**: destination burst length minus 1, between 0 and 63  
The burst length unit is one data named beat within a burst. If DBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width DDW_LOG2[1:0].

**Note:** If a burst transfer crossed a 1-Kbyte address boundary on an AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

**If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.**

Bit 19  **DINC**: destination incrementing burst  
0: fixed burst  
1: contiguously incremented burst  
The destination address, pointed by GPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18  Reserved, must be kept at reset value.

Bits 17:16  **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a burst, in bytes  
00: byte  
01: half-word (2 bytes)  
10: word (4 bytes)  
11: user setting error reported and no transfer issued

**Note:** Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.  
A destination burst transfer must have an aligned address with its data width (start address GPDMA_CxDAR[2:0] and address offset GPDMA_CxTR3.DAO[2:0], versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.

Bit 15  Reserved, must be kept at reset value.

Bit 14  **SAP**: source allocated port  
This bit is used to allocate the master port for the source transfer  
0: port 0 (AHB) allocated  
1: port 1 (AHB) allocated

**Note:** This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 13  **SBX**: source byte exchange within the unaligned half-word of each source word  
If the source data width is shorter than a word, this bit is ignored.  
If the source data width is a word:  
0: no byte-based exchange within the unaligned half-word of each source word  
1: the two consecutive bytes within the unaligned half-word of each source word are exchanged.
Bits 12:11 **PAM[1:0]:** padding/alignment mode

If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.

Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when source data width is higher than destination data width.

**Condition: PAM_1**
- 00: source data is transferred as right aligned, padded with 0s up to the destination data width
- 01: source data is transferred as right aligned, sign extended up to the destination data width
- 10-11: successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer

**Condition: PAM_2**
- 00: source data is transferred as right aligned, left-truncated down to the destination data width
- 01: source data is transferred as left-aligned, right-truncated down to the destination data width
- 10-11: source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

**Note:** If the transfer from the source peripheral is configured with peripheral flow-control mode (SWREQ = 0 and PFREQ = 1 and DREQ = 0), and if the destination data width > the source data width, packing is not supported.

Bit 10 Reserved, must be kept at reset value.

Bits 9:4 **SBL_1[5:0]:** source burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If SBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width SDW_LOG2[1:0].

**Note:** If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3 **SINC:** source incrementing burst

- 0: fixed burst
- 1: contiguously incremented burst

The source address, pointed by GPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2 Reserved, must be kept at reset value.
12.8.9 **GPDMA channel x transfer register 2 (GPDMA_CxTR2)**

Address offset: \(0x94 + 0x80 \times x (x = 0 \text{ to } 15)\)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory, if GPDMA_CxLLR.UT2 = 1.

Note: Setting a 8-byte data width causes a user setting error to be reported and no transfer is issued.

A source block size must be a multiple of the source data width (GPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source burst transfer must have an aligned address with its data width (start address GPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.
Bits 31:30  **TCEM[1:0]:** transfer complete event mode

These bits define the transfer granularity for the transfer complete and half transfer complete events generation.

00: at block level (when GPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

**Note:** If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

01: channel x (x = 0 to 11), same as 00, channel x (x =12 to 15), at 2D/repeated block level (when GPDMA_CxBR1.BRC[10:0] = 0 and GPDMA_CxBR1.BNDT[15:0] = 0). The complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

**Note:** If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer The LLI data transfer is a block transfer or a 2D/repeated block transfer for channel x (x =12 to 15), if any data transfer.

**Note:** If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address GPDMA_CxLLR.LA[15:2] to zero and clears all the GPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26  Reserved, must be kept at reset value.

Bits 25:24  **TRIGPOL[1:0]:** trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[5:0].

00: no trigger (masked trigger event)
01: trigger on the rising edge
10: trigger on the falling edge
11: same as 00

Bits 23:22  Reserved, must be kept at reset value.

Bits 21:16  **TRIGSEL[5:0]:** trigger event input selection

These bits select the trigger event input of the GPDMA transfer (as per Section 12.3.6), with an active trigger event if TRIGPOL[1:0] ≠ 00.
Bits 15:14 **TRIGM[1:0]: trigger mode**

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (GPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, a GPDMA transfer is conditioned by at least one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x (x = 12 to 15), for each block if a 2D/repeated block is configured with GPDMA_CxBR1.BRC[10:0] ≠ 0).

01: channel x (x = 0 to 11), same as 00; channel x (x = 12 to 15), at 2D/repeated block level. The first burst read of a 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger.

– If the peripheral is programmed as a source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is programmed as a destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and the first trigger hit.

The GPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled.

Transferring a next LLI_{n+1} that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_{n} trigger.

After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_{n} triggered transfer is still not completed, hit_{n+2} is lost and not memorized.

A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

**Note:** When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ = 0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1-Kbyte boundary address crossing): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bit 13 Reserved, must be kept at reset value.
Bit 12 **PFREQ**: Hardware request in peripheral flow control mode

*Important: If a given channel x is not implemented with this feature, this bit is reserved and PFREQ is not present (see Section 12.3.1 for the list of the implemented channels with this feature).*

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in GPDMA control mode. The GPDMA is programmed with GPDMA_CxTR1.BNDT[15:0] and this is internally used by the hardware for the block transfer completion.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in peripheral control mode. The GPDMA block transfer can be early completed by the peripheral itself (see Section 12.3.5 for more details).

**Note:** In peripheral flow control mode, there are the following restrictions:
- no 2D/repeated block support (GPDMA_CxBR1.BRC[10:0] must be set to 0)
- the peripheral must be set as the source of the transfer (DREQ = 0).
- data packing to a wider destination width is not supported (if destination width > source data width, GPDMA_CxTR1.PAM[1] must be set to 0).
- GPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

Bit 11 **BREQ**: Block hardware request

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see Section 12.3.3).

Bit 10 **DREQ**: destination hardware request

This bit is ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: selected hardware request driven by a source peripheral (request signal taken into account by the GPDMA transfer scheduler over the source/read port)

1: selected hardware request driven by a destination peripheral (request signal taken into account by the GPDMA transfer scheduler over the destination/write port)

**Note:** If the channel x is activated (GPDMA_CxCR.EN is asserted) with SWREQ = 0 and PFREQ = 1 (peripheral hardware request with peripheral flow-control mode), any software assertion to this DREQ bit is ignored: in peripheral flow-control mode, only a peripheral-to-memory transfer is supported.

Bit 9 **SWREQ**: software request

This bit is internally taken into account when GPDMA_CxCR.EN is asserted.

0: no software request. The selected hardware request REQSEL[6:0] is taken into account.

1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[6:0] is ignored.

Bits 8:7 Reserved, must be kept at reset value.
12.8.10 GPDMA channel x block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the field BNDT[15:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

BNDT[15:0]

Bits 31:16  Reserved, must be kept at reset value.
12.8.11 **GPDMA channel x alternate block register 1 (GPDMA_CxBR1)**

Address offset: 0x98 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGx.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored to the programmed value (finite/continuous last LLI).

Note: **A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.**

When configured in packing mode (GPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.
automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0] after each execution of this final LLI.

- If GPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

Bit 31  **BRDDEC**: Block repeat destination address decrement
0: at the end of a block transfer, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxBR2.BRDAO to the current GPDMA_CxDAR value (current destination address)
1: at the end of a block transfer, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRDAO from the current GPDMA_CxDAR value (current destination address)

**Note:** On top of this increment/decrement (depending on BRDDEC), GPDMA_CxDAR is in the same time also updated by the increment/decrement (depending on DDEC) of the GPDMA_CxTR3.DAO value, as it is usually done at the end of each programmed burst transfer.

Bit 30  **BRSDEC**: Block repeat source address decrement
0: at the end of a block transfer, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxBR2.BRSAO to the current GPDMA_CxSAR value (current source address)
1: at the end of a block transfer, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRSAO from the current GPDMA_CxSAR value (current source address)

**Note:** On top of this increment/decrement (depending on BRSDEC), GPDMA_CxSAR is in the same time also updated by the increment/decrement (depending on SDEC) of the GPDMA_CxTR3.SAO value, as it is done after any programmed burst transfer.

Bit 29  **DDEC**: destination address decrement
0: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)
1: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

Bit 28  **SDEC**: source address decrement
0: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)
1: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

Bit 27  **Reserved:** must be kept at reset value.
Bits 26:16 **BRC[10:0]**: Block repeat counter

This field contains the number of repetitions of the current block (0 to 2047).

- When the channel is enabled, this field becomes read-only. After decrements, this field indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.
- Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):
  - If GPDMA_CxLLR.UB1 = 1, all GPDMA_CxBR1 fields are updated by the next LLI in the memory.
  - If GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.
  - If all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
  - If GPDMA_CxLLR = 0, this field is kept as zero following the last LLI and data transfer.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

- Once the last data transfer is completed (BNDT[15:0] = 0):
  - if GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.
  - if GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.
  - if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
  - if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

*Note:* A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (GPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.
12.8.12 GPDMA channel x source address register (GPDMA_CxSAR)

Address offset: 0x9C + 0x80 * x (x = 0 to 15)
Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.USA = 1.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
SA[31:16]
rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
SA[15:0]

Bits 31:0 SA[31:0]: source address
This field is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (GPDMA_CxTR1.SINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

– the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.SBL_1[5:0] and GPDMA_CxTR1.SDW_LOG2[1:0]
– the additional source incremented/decremented offset value as programmed by GPDMA_CxBR1.SDEC and GPDMA_CxTR3.SAO[12:0].
– once/if completed source block transfer, for a channel x with 2D addressing capability (x = 12 to 15). additional block repeat source incremented/decremented offset value as programmed by GPDMA_CxBR1.BRSDEC and GPDMA_CxBR2.BRSAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source burst (SA[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.
12.8.13 GPDMA channel x destination address register (GPDMA_CxDAR)

Address offset: 0xA0 + 0x80 * x (x = 0 to 15)
Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UDA = 1.

Bits 31:0 \textbf{DA}[31:0]: destination address

This field is the pointer to the address from which the next data is written.
During the channel activity, depending on the destination addressing mode (GPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.DDW_LOG2[1:0]) after each burst destination data, reflecting the next address from which data is written.
During the channel activity, this address is updated after each completed destination burst, consequently to:

– the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.DBL_1[5:0] and GPDMA_CxTR1.DDW_LOG2[1:0]
– the additional destination incremented/decremented offset value as programmed by GPDMA_CxBR1.DDEC and GPDMA_CxTR3.DAO[12:0].
– once/if completed destination block transfer, for a channel x with 2D addressing capability (x = 12 to 15), the additional block repeat destination incremented/decremented offset value as programmed by GPDMA_CxBR1.BRDDEC and GPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.UDA = 1.

\textbf{Note}: A destination address must be aligned with the programmed data width of a destination burst (DA[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.
12.8.14 GPDMA channel x transfer register 3 (GPDMA_CxTR3)

Address offset: 0xA4 + 0x80 * x (x = 12 to 15)
Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGER.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UT3 = 1.

| Bits 31:29 | Reserved, must be kept at reset value. |
| Bits 28:16 | DAO[12:0]: destination address offset increment |
| The destination address, pointed by GPDMA_CxDAR, is incremented or decremented (depending on GPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.DINC = 1). |
| Note: A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued. |
| Bits 15:13 | Reserved, must be kept at reset value. |
| Bits 12:0 | SAO[12:0]: source address offset increment |
| The source address, pointed by GPDMA_CxSAR, is incremented or decremented (depending on GPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.SINC = 1). |
| Note: A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued. |
| When the source block size is not a multiple of the destination burst size, and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied. |
### 12.8.15 GPDMA channel x block register 2 (GPDMA_CxBR2)

Address offset: \(0xA8 + 0x80 \times x\) (\(x = 12\) to \(15\))

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel \(x\) (GPDMA_PRIVCFGx.PRIVx).

This register controls the transfer of a channel \(x\) at a 2D/repeated block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UB2 = 1.

#### BRDAO[15:0]

**Bits 31:16** **BRDAO[15:0]:** Block repeated destination address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRDDEC) the current destination address (GPDMA_CxDAR) at the end of a block transfer.

**Note:** A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

BRDAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

#### BRSAO[15:0]

**Bits 15:0** **BRSAO[15:0]:** Block repeated source address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRSDEC) the current source address (GPDMA_CxSAR) at the end of a block transfer.

**Note:** A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

BRSAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).
12.8.16  GPDMA channel x linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

### Bit 31 UT1: Update GPDMA_CxTR1 from memory
- This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.
- 0: no GPDMA_CxTR1 update
- 1: GPDMA_CxTR1 update

### Bit 30 UT2: Update GPDMA_CxTR2 from memory
- This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.
- 0: no GPDMA_CxTR2 update
- 1: GPDMA_CxTR2 update

### Bit 29 UB1: Update GPDMA_CxBR1 from memory
- This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
- If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
- GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
- 0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
- 1: GPDMA_CxBR1 update

### Bit 28 USA: Update GPDMA_CxSAR from memory
- This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.
- 0: no GPDMA_CxSAR update
- 1: GPDMA_CxSAR update
Bit 27  **UDA**: Update GPDMA\_CxDAR register from memory
This bit is used to control the update of GPDMA\_CxDAR from the memory during the link transfer.
0: no GPDMA\_CxDAR update
1: GPDMA\_CxDAR update

Bits 26:17  Reserved, must be kept at reset value.

Bit 16  **ULL**: Update GPDMA\_CxLLR register from memory
This bit is used to control the update of GPDMA\_CxLLR from the memory during the link transfer.
0: no GPDMA\_CxLLR update
1: GPDMA\_CxLLR update

Bits 15:2  **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA\_CxTR1, GPDMA\_CxTR2, GPDMA\_CxBR1, GPDMA\_CxSAR, GPDMA\_CxDAR, and GPDMA\_CxLLR).

Note:  *The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.*

Bits 1:0  Reserved, must be kept at reset value.
## 12.8.17 GPDMA channel x alternate linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFG.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

Refer to Section 2.3 for the register boundary addresses.
13 High-performance direct memory access controller (HPDMA)

13.1 HPDMA introduction

The high-performance direct memory access (HPDMA) controller is a bus master and system peripheral.

The HPDMA is used to perform programmable data transfers between memory-mapped peripherals, and/or memories via linked-lists, upon the control of an off-loaded CPU.

13.2 HPDMA main features

- Single bidirectional AXI master and single bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral
- Autonomous data transfers during low-power modes (Section 13.3.2)
  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 16 concurrent HPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see Section 13.3.1)
  - Intra-channel HPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel HPDMA transfers chaining via programmable HPDMA input triggers connection to HPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level
- Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at block level, between successive burst transfers
- 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see Section 13.3.1)
- Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
- Selection of programmable HPDMA request and trigger
- Generation of programmable HPDMA half-transfer and transfer-complete event
- Pointer to the next linked-list item and its data structure in memory, with automatic update of the HPDMA linked-list control registers
- Channel abort and restart

- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- Privileged/unprivileged support:
  - Support for privileged and unprivileged HPDMA transfers, independently at channel level
  - Privileged-aware AHB slave port

### 13.3 HPDMA implementation

#### 13.3.1 HPDMA channels

A given HPDMA channel \( x \) is implemented with the following features and intended use.

To make the best use of the HPDMA performance, the following table lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested HPDMA transfer.

<table>
<thead>
<tr>
<th>Channel ( x )</th>
<th>Hardware parameters</th>
<th>Features</th>
</tr>
</thead>
</table>
| \( x = 0 \) to \( 11 \) | \( \text{dma}_\text{fifo}_\text{size}[x] \) 3 \( \text{dma}_\text{addressing}[x] \) 0 | Channel \( x \) (\( x = 0 \) to 11) is implemented with:
- a FIFO of 16 bytes, 4 words, 2 double-words
- fixed/contiguously incremented addressing
These channels can be used for HPDMA transfers between an APB or AHB peripheral, an AHB/AXI SRAM, or CPU TCM. |
Table 100. Implementation of HPDMA1 channels (continued)

<table>
<thead>
<tr>
<th>Channel x</th>
<th>dma_fifo_size[x]</th>
<th>dma_addressing[x]</th>
<th>Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>x = 12 to 15</td>
<td>5</td>
<td>1</td>
<td>Channel x (x = 12 to 15) is implemented with:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>– a FIFO of 64 bytes, 8 double-words</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>– 2D addressing</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>These channels can be also used for HPDMA transfers, including AXI external memories.</td>
</tr>
</tbody>
</table>

13.3.2 HPDMA autonomous mode in low-power modes

The HPDMA autonomous mode and wake-up feature are implemented in the device low-power modes as per the table below.

Table 101. HPDMA1 in low-power modes

<table>
<thead>
<tr>
<th>Feature</th>
<th>Low-power modes</th>
</tr>
</thead>
<tbody>
<tr>
<td>wake-up</td>
<td>HPDMA1 in Sleep mode</td>
</tr>
</tbody>
</table>

13.3.3 HPDMA requests

An HPDMA request from a peripheral can be assigned to a HPDMA channel x, via REQSEL[4:0] in HPDMA_CxTR2, provided that SWREQ = 0.

The HPDMA requests mapping is specified in the table below.

Table 102. Programmed HPDMA1 request

<table>
<thead>
<tr>
<th>HPDMA_CxTR2.REQSEL[4:0]</th>
<th>Selected HPDMA request</th>
</tr>
</thead>
<tbody>
<tr>

<td>xspi1_rx_dma</td>
</tr>
<tr>
<td>3</td>
<td>xspi2_rx_dma</td>
</tr>
<tr>
<td>4</td>
<td>spi3_rx_dma</td>
</tr>
<tr>
<td>5</td>
<td>spi3_tx_dma</td>
</tr>
<tr>
<td>6</td>
<td>spi4_rx_dma</td>
</tr>
<tr>
<td>7</td>
<td>spi4_tx_dma</td>
</tr>
<tr>
<td>8</td>
<td>adc1_dma</td>
</tr>
<tr>
<td>9</td>
<td>adc2_dma</td>
</tr>
<tr>
<td>10</td>
<td>adf1_flt0_dma</td>
</tr>
<tr>
<td>11</td>
<td>uart4_rx_dma</td>
</tr>
<tr>
<td>12</td>
<td>uart4_tx_dma</td>
</tr>
</tbody>
</table>
13.3.4 HPDMA block requests

Some HPDMA requests must be programmed as a block request, and not as a burst request. Then BREQ in HPDMA_CxTR2 must be set for a correct HPDMA execution of the requested peripheral transfer at the hardware level.

Table 103. Programmed HPDMA1 request as a block request

<table>
<thead>
<tr>
<th>HPDMA block requests</th>
</tr>
</thead>
<tbody>
<tr>
<td>lptim2_ue_dma</td>
</tr>
</tbody>
</table>

13.3.5 HPDMA channels with peripheral early termination

An HPDMA channel, if implemented with this feature, can support the early termination of the data transfer from the peripheral which does also support this feature.

Table 104. HPDMA channel with peripheral early termination

<table>
<thead>
<tr>
<th>HPDMA channel x with peripheral early termination</th>
</tr>
</thead>
<tbody>
<tr>
<td>x = 15</td>
</tr>
</tbody>
</table>

This HPDMA support is activated when the channel x is programmed with HPDMA_CxTR2.PFREQ = 1. Then, the peripheral itself can initiate and request a data transfer completion, before that the HPDMA has transferred the whole block (see Section 13.4.14 for more details).

Table 105. Programmed HPDMA request with peripheral early termination

<table>
<thead>
<tr>
<th>Programmed HPDMA channel x request with peripheral early termination</th>
</tr>
</thead>
<tbody>
<tr>
<td>jpeg_tx_dma</td>
</tr>
</tbody>
</table>

13.3.6 HPDMA triggers
An HPDMA trigger can be assigned to an HPDMA channel x, via TRIGSEL[5:0] in HPDMA_CxTR2, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

Table 106. Programmed HPDMA1 trigger

13.4 **HPDMA functional description**

13.4.1 **HPDMA block diagram**

Figure 108. HPDMA block diagram

13.4.2 **HPDMA channel state and direct programming without any linked-list**

After an HPDMA reset, an HPDMA channel x is in idle state. When the software writes 1 into the HPDMA_CxCR.EN enable control bit, the channel takes into account the value of the different channel configuration registers (HPDMA_CxXXX), switches to the active/non-idle state, and starts to execute the corresponding requested data transfers.

After enabling/starting an HPDMA channel transfer by writing 1 into HPDMA_CxCR.EN, an HPDMA channel interrupt on a complete transfer notifies the software that the HPDMA channel is back in idle state (EN is then deasserted by hardware), and that the channel is ready to be reconfigured then enabled again.
13.4.3 HPDMA channel suspend and resume

The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the HPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag HPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to HPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing HPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or bitfield that is hardware modifiable.
Note: An ongoing HPDMA transfer can be a data transfer (a source/destination burst transfer,) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to HPDMACxCR.SUSP.

**Figure 110. HPDMA channel suspend and resume sequence**

![Diagram showing channel states and suspend/resume sequence]

Note: A suspend and resume sequence does not impact the HPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

### 13.4.4 HPDMA channel abort and restart

Alternatively, like for aborting a continuous HPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the HPDMA_CxCR.SUSP bit.
2. The software polls suspended flag HPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to HPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing HPDMA transfer over its master port.
3. The software resets the channel by writing 1 to HPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the HPDMA_CxCR.EN bit, and the reset of the HPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram hardware-modified HPDMA_CxBR1, HPDMA_CxSAR, and HPDMA_CxDAR.
5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the HPDMA_CxCR.EN bit.

**Figure 111. HPDMA channel abort and restart sequence**

13.4.5 HPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

For a channel x, the base address in memory of the data structure of a next LLI_{n+1} is the sum of the following:
- the link base address of the channel x (in HPDMA_CxLBAR)
- the link address offset LA[15:2] bitfield in HPDMA_CxLLR, that is the updated result from the data structure of the previous LLIn of the channel x

The data structure for each LLI can be specific.

A linked-list data structure is addressed following the value of UT1, UT2, UB1, USA, UDA, and ULL bits, plus UB2 and UT3 when present, in HPDMA_CxLLR.

In linked-list mode, each HPDMA linked-list register (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR or HPDMA_CxLLR,
plus HPDMA_CxTR3 or HPDMA_CxBR2 when present) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of HPDMA_CxLLR that was conditionally updated from the linked-list data structure of the previous LLI.

**Static linked-list data structure**

For example, when the update bits (UT1, UT2, UB1, USA, UDA, and ULL, plus UB2 and UT3 when present) in HPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel x, x = 0 to 11, six contiguous 32-bit locations, including HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR (see **Figure 112**) and including the first linked-list register file (LLI0), and the next LLI0s (LLI1, LLI2,...) in the memory
- channel x, x = 12 to 15, eight contiguous 32-bit locations, including HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR, plus HPDMA_CxTR3 and HPDMA_CxBR2 (see **Figure 113**), including the first linked-list register file (LLI0), and the next LLI0s (LLI1, LLI2,...) in the memory

**Figure 112. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x**
Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of HPDMA_CxLLR points to the updated value of HPDMA_CxTR2, instead of HPDMA_CxTR1 which is not to be modified (see Figure 114).

Example: if UT1 = UB1 = USA = 0, and if UT3 = UB2 = 0 when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for HPDMA_CxTR1, nor HPDMA_CxBR1, nor HPDMA_CxSAR, nor HPDMA_CxTR3, nor HPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for HPDMA_CxTR2, HPDMA_CxDAR, and HPDMA_CxLLR, as shown in Figure 115.
The user must program HPDMA_CxLLR for each LLI_n to be 32-bit aligned, and not to exceed the 64-Kbyte addressable space pointed by HPDMA_CxLBAR.

### 13.4.6 Linked-list item transfer execution

An LLI_n transfer is the sequence of:

1. a data transfer: the HPDMA executes the data transfer as described by the HPDMA internal register file (this data transfer can be void/null for LLI_0).
2. a conditional link transfer: the HPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_{n+1}, as defined by the HPDMA_CxLLR value of the LLI_n.

**Note:** The initial data transfer, as defined by the internal register file (LLI_0), can be null (HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxTR2.PFREQ = 0), provided that UB1 is set in HPDMA_CxLLR (meaning there is a non-null data transfer described by the next LLI_1 in the memory to be executed).

Depending on the intended HPDMA use, an HPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, HPDMA_CxCR.LSM = 0), or can be programmed for a single execution of a LLI (link step mode, HPDMA_CxCR.LSM = 1), as described in the next sections.
13.4.7 HPDMA channel state and linked-list programming in run-to-completion mode

When HPDMA_CxCR.LSM = 0 (in full-list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), an HPDMA channel x is initially programmed, started by writing 1 to HPDMA_CxCR.EN, and after completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI0, internal linked-list register file: HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR, plus HPDMA_CxTR3 and HPDMA_CxBR2 when present
  - the last LLI_{N-1} described by the linked-list data structure in memory, as defined by HPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when HPDMA_CxLLR[31:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0, if BRC[10:0] is present and HPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last transfer

HPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion, and means the following:

- The 16 low significant bits HPDMA_CxLLR.LA[15:0] of the next link address are null.
- All bits HPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA,UDA, and ULL, plus UB2 and UT3 when present).

The channel may never be completed when HPDMA_CxLLR.LSM = 0:

- If the last LLI_{N-1} is recursive, pointing to itself as a next LLI, in one of the following:
  - HPDMA_CxLLR.ULL = 1 and HPDMA_CxLLR.LA[15:2] is updated by the same value.
  - HPDMA_CxLLR.ULL = 0
- If LLI_{N} points to a previous LLI

In the regular data transfer completion at a block level, HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see Section 13.4.14 for more details).

In the typical run-to-completion mode, the allocation of an HPDMA channel, including its fine programming, is done once during the HPDMA initialization. In order to have a reserved data communication link and HPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

Figure 116 depicts the HPDMA channel execution and its registers programming in run-to-completion mode.

Note: Figure 116 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in HPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel...
In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

In Figure 116, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 13.3.5).
Figure 116. HPDMA channel execution and linked-list programming in run-to-completion mode (HPDMA_CxCR.LSM = 0)

  - No: Setting USEF = 1

End
Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following bitfields of HPDMA_CxTR2 in the data structure of the LLI_{n-1}:

- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[5:0] (see Section 13.3.6 for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory, and to generate a transfer complete event hpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

Figure 117 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

**Caution:** This use case is restricted to an application with an LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.
13.4.8 HPDMA channel state and linked-list programming in link step mode

When HPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

An HPDMA channel transfer can be programmed at an LLI level, started by writing 1 into HPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI\(_n\) transfer is described with the following:
  - HPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - HPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]), for channel \(x = 12\) to \(15\), the number of blocks at a 2D/repeated block level (BRC[10:0]+1), and the incrementing/decrementing mode for address offsets.
- HPDMA_CxTR2 defines the input control (request, trigger), and the output control (transfer-complete event) of the transfer.
- HPDMA_CxSAR and HPDMA_CxDAR define the source/destination transfer start address.
- HPDMA_CxTR3 (for channel x = 12 to 15) defines the source/destination additional address offset between burst transfers.
- HPDMA_CxBR2 (for channel x = 12 to 15) defines the source/destination additional address offset between blocks at a 2D/repeated block level.
- HPDMA_CxLLR defines the data structure, and the address offset of the next LLI_{n+1} in the memory.

- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when HPDMA_CxBR1.BRC[10:0] = 0 if BRC[10:0] is present, and HPDMA_CxBR1.BNDT[15:0] = 0)
  - after the (conditional) update of the HPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If an LLI is recursive (pointing to itself as a next LLI, either HPDMA_CxLLR.ULL = 1 and HPDMA_CxLLR.LA[15:2] is updated by the same value, or HPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

In the regular data transfer completion at a block level, HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer can be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see Section 13.4.14 for more details).

The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of HPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Figure 118 depicts the HPDMA channel execution mode, and its programming in link step mode.

Note: Figure 118 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in HPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 118, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes BNDT ≠ 0 and PFREQ = 1 if the peripheral requests a data transfer with early termination (see Section 13.3.5).
Figure 118. HPDMA channel execution and linked-list programming in link step mode (HPDMA_CxCR.LSM = 1)

    - End
Run-time adding a $\text{LLI}_{n+1}$ in link step mode

During run-time, the software can defer the elaboration of the $\text{LLI}_{n+1}$ (and next LLIs), until/after the HPDMA executed the transfer from the $\text{LLI}_{n-1}$ and loaded the $\text{LLI}_n$ from the memory, as shown in the figure below.

**Figure 119. Building $\text{LLI}_{n+1}$: HPDMA dynamic linked-lists in link step mode**

Run-time replacing an $\text{LLI}_n$ with a new $\text{LLI}_n'$ in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new $\text{LLI}_n'$, after the HPDMA executed the transfer from the $\text{LLI}_{n-1}$, and loaded a formerly elaborated $\text{LLI}_n$ from the memory by overwriting directly the linked-list register file with the new $\text{LLI}_n'$, as shown in **Figure 120**.
LSM = 1 with 1-stage linked-list programming:
Overwriting the (pre)loaded LLIₙ linked-list register file with
a new LLIₙ', directly in linked-list register file.
DMA executes LLIₙ₋₁ and load LLIₙ, then CPU builds and overwrites LLIₙ'.

Figure 120. Replace with a new LLIₙ' in register file in link step mode
Run-time replacing an LLI_n with a new LLI_n' in link step mode (in the memory)

The software can build and insert a new LLI_n' and LLI_{n+1}' in the memory, after HPDMA executed the transfer from the LLI_{n-1}, and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (HPDMA_CxBR1.BNDT[15:0] to be null, and HPDMA_CxLLR to point to new LLI_n) as shown in Figure 121.

Figure 121. Replace with a new LLI_n' and LLI_{n+1}' in memory in link step mode (option 1)
Run-time replacing a $\text{LLI}_n$ with a new $\text{LLI}_{n'}$ in link step mode

Other software implementations exist. Meanwhile the HPDMA executes the transfer from the $\text{LLI}_{n-1}$ and loads a formerly elaborated $\text{LLI}_n$ from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $\text{LLI}_n$ and a new $\text{LLI}_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for $\text{LLI}_{n-1}$ is then restricted to overwrite HPDMA_CxBR1.BNDT[15:0] to be null and HPDMA_CxLLR to point to new $\text{LLI}_{n'}$, as shown in the figure below.

Figure 122. Replace with a new $\text{LLI}_{n'}$ and $\text{LLI}_{n+1'}$ in memory in link step mode (option 2)

---

LSM = 1 with 1-stage linked-list programming:
Overwriting the (pre)loaded $\text{LLI}_n$ linked-list register file by building new $\text{LLI}_{n'}$ and $\text{LLI}_{n+1'}$ in memory while disabling (temporary) channel interrupt at NVIC level, and overwriting DMA_CxBR1.BNDT = 0 and DMA_CxLLR to point to new $\text{LLI}_{n'}$

DMA executes $\text{LLI}_{n-1}$ and loading $\text{LLI}_n$ while CPU builds ($\text{LLI}_{n'}$ and $\text{LLI}_{n+1'}$), then CPU overwrites (BR1 and LLR)
13.4.9 HPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (HPDMA_CxCR.EN = 0), and update the execution mode (HPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the HPDMA_CxLLR of this LLI_{n+1}), before this LLI_{n+1} is loaded/used by the HPDMA channel
- abort and reconfigure the channel with an LSM update (see Section 13.4.4.)

In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

*Figure 123* shows the overall and unified HPDMA linked-list programming, whatever is the execution mode.

*Note:* *Figure 123* is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in HPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

*In Figure 123, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes BNDT ≠ 0 and PFREQ = 1 if the peripheral requests a data transfer with early termination (see Section 13.3.5).*

End
13.4.10 HPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel $x$ is implemented with a dedicated FIFO whose size is defined by $\text{dmafifo}_x$ (see Section 13.3.1 for more details).

HPDMA burst

A programmed transfer at the lowest level is an HPDMA burst.

An HPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by $\text{SBL}_1[5:0]$ (respectively $\text{DBL}_1[5:0]$), and with a data width defined by $\text{SDW}_2[1:0]$ (respectively $\text{DDW}_2[1:0]$) in HPDMA_CxTR1.

The addressing mode after each data (named beat) of an HPDMA burst is defined by SINC and DINC in HPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of an HPDMA source/destination burst (defined by HPDMA_CxSAR and HPDMA_CxDAR) must be aligned with the respective data width.

The table below lists the main characteristics of an HPDMA burst.

<table>
<thead>
<tr>
<th>SAP/DAP (allocated port)</th>
<th>SDW_LOG2[1:0]</th>
<th>Data width (bytes)</th>

</tbody>
</table>

1. When $\text{S/DBL}_1[5:0] = 0$, burst is of length 1. Then burst can be also named as single.

The next burst address in the above table is the next source/destination default address pointed by HPDMA_CxSAR or HPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.
HPDMA burst with 2D addressing (channel x = 12 to 15)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by HPDMA_CxTR2.SAO[12:0]/DAO[12:0] and HPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by HPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and HPDMA_CxBR1.BRSDEC/BRDDEC)

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by Figure 124 with a 2D destination buffer.
Programmable address jumps 1) after burst and 2) after block.

Example:
burst: \( I \) * words (DBL_1=I-1; DDW_LOG2='b10)
block: \( J \) * bursts (BNDT=J\(^4\))
LLI: \( K \) * blocks (BRC=K-1)
HPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- one burst from the source to the FIFO over the allocated source master port, as defined by HPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by HPDMA_CxTR1.DAP

HPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

\[
\text{when FIFO level} \leq 2^{\text{dma_fifo_size}[x]} - (\text{SBL}_1[5:0]+1) \times 2^{\text{SDW_LOG2}[1:0]}
\]

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- \(2^{\text{dma_fifo_size}[x]}\) is the channel x FIFO size, in bytes (see Section 13.3.1 for the implementation details and dma_fifo_size[x] value).
- \((\text{SBL}_1[5:0]+1) \times 2^{\text{SDW_LOG2}[1:0]}\) is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (HPDMA_CxCR.PRI0[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

HPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

\[
\text{when FIFO level} \geq (\text{DBL}_1[5:0]+1) \times 2^{\text{DDW_LOG2}[1:0]}
\]

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- \((\text{DBL}_1[5:0]+1) \times 2^{\text{DDW_LOG2}[1:0]}\) is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

HPDMA burst versus source block size, 1- or 4-Kbyte address boundary and FIFO size

The programmed source/destination HPDMA burst is implemented with an AHB/AXI burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel x is lower than the programmed source/destination burst size, the programmed source/destination HPDMA burst is implemented with a series of singles or bursts of a lower size, each transfer being of a size that is lower or equal than half of the FIFO size, without any user constraint.
- if the source block size (HPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (HPDMA_CxTR1.SDW_LOG2[1:0]), the HPDMA modifies and shortens bursts into
singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.

- if the source/destination burst transfer have crossed the 1- or 4-Byte address boundary on, respectively, an AHB or AXI transfer, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB/AXI protocol, without any user constraint.

- If the source/destination burst length exceeds 16 on an AHB transfer, or if the source/destination burst on an AXI transfer is both with fixed addressing and with a burst length which exceeds 16, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB/AXI protocol, without any user constraint.

In any case, the HPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in HPDMA_CxSR) is compared to and updated with the effective transfer size, and the HPDMA re-arbitrates between each AHB/AXI single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

Note: In linked-list mode, the HPDMA read transfers related to the update of the linked-list parameters from the memory to the internal HPDMA registers, are scheduled over the link allocated port, as programmed by HPDMA_CxCR.LAP.

HPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension, and left/right alignment

The data handling is controlled by HPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word, word, or double-word, as per SDW_LOG2[1:0] and DDW_LOG2[1:0] (see Table 108).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. Byte-based source reordering
   - If SBX = 1 and if the source data width is a word or a double-word (for AXI source bus, SAP = 0), the two bytes of the unaligned half-word at the middle of each source data word are exchanged.

2. Data-width conversion by packing, unpacking, padding, or truncation, if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.
3. Byte-based destination re-ordering:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.
   - If DWX = 1 and if the destination data width is a double-word and the destination bus is AXI (DAP = 0), the two aligned words are exchanged within aligned (post PAM[1:0]) double-words.

Note: Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding, and a destination byte-based re-ordering.

The table below lists the possible data handling from the source to the destination.

\(^{(1)}\) Depending on the source data type.

\(^{(2)}\) Depending on the destination data type.

\(^{(3)}\) 00 is the default value.

\(^{(4)}\) 01 is the default value.

\(^{(5)}\) \(x\) indicates that any data can be used.

1x (PACK) indicates that the data is packed.

SDW and DDW are logic 2 bits that represent the number of data words.

PAM[1:0] represents the programmed access mode.

DBX, DHX, and DWX are logic 3 bits that represent the data type.

Destination data stream represents the destination data stream that can be selected.

Source data stream represents the source data stream that can be selected.

</table>

1. Data stream is timely ordered starting from the byte with the lowest index (B0).
2. RA = right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.
3. RA = right aligned, LA = left aligned, RT = right truncated, LT = left truncated.
4. 0P = zero-bit padding up to the destination data width, SE = sign bit extended up to the destination data width.
5. If DDW\_LOG2[1:0] = 11 and if DAP = 0 (destination allocated port is AXI). Else if DDW\_LOG2[1:0] = 11 and DAP = 1 (AHB), a user setting error (USEF) is reported.
6. If SDW\_LOG2[1:0] = 11 and if SAP = 0 (source allocated source port is AXI). Else if SDW\_LOG2[1:0] = 11 and SAP = 1 (AHB), a user setting error (USEF) is reported.
13.4.11 HPDMA transfer request and arbitration

HPDMA transfer request

As defined by HPDMA_CxTR2, a programmed HPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the HPDMA hardware peripheral request is driven by REQSEL[4:0] (see Section 13.3.4). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in HPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control register update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign the same input hardware peripheral HPDMA request via HPDMA_CxTR.REQSEL[4:0] to two different channels, if at a given time this request is asserted by the peripheral, and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

HPDMA transfer request for arbitration

A ready FIFO-based HPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (HPDMA_CxTR1.SAP) is arbitrated based on the channel priority (HPDMA_CxCR.PRIOR[1:0]) versus the other simultaneous requested HPDMA transfers to the same master port.

A ready FIFO-based HPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (HPDMA_CxTR1.DAP) is arbitrated based on the channel priority (HPDMA_CxCR.PRIOR[1:0]) versus the other simultaneous requested HPDMA transfers to the same master port.

An arbitrated HPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in the memory to one of the linked-list registers (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CsAR, HPDMA_CsAR, HPDMA_CxTR3, HPDMA_CxBR2 or HPDMA_CxLLR). Each 32-bit read from the memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (HPDMA_CxCR.LAP).

Whenever the requested data transfer is programmed with a software request for a memory-to-memory transfer (HPDMA_CxTR2.SWREQ = 1), or with a hardware request (HPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (HPDMA_CxTR2.SWREQ = 0 and HPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request
to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

HPDMA arbitration

The HPDMA arbitration is directed from the 4-grade assigned channel priority (HPDMA_CxCR.PRIOR[1:0]). The arbitration policy, as illustrated in Figure 125, is defined by:

- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels.
  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.

- three low-priority traffic classes (queues 0, 1 or 2) for non time-sensitive channels with priority 0, 1 or 2.
  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.
  - Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
  - Any queue 0, 1 or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
  - Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1 and queue 2.

**Figure 125. HPDMA arbitration policy**

HPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- equal maximum bandwidth between requests with same priority
- reserved bandwidth (noted as BQ3) to the time-sensitive requests (with priority 3)
- residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).
The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive HPDMA requests: req0 and req1. There are the following programming possibilities:
  - If they are assigned with same priority, the allocated bandwidth by the arbiter to req0\(B_{\text{req0}}\) is equal to the allocated bandwidth to req1\(B_{\text{req1}}\).
    \[ B_{\text{req0}} = B_{\text{req1}} = \frac{1}{2} \cdot (1 - B_{Q3}) \]
  - If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0\(B_{P0}\) is 3 times less than the allocated bandwidth to req1\(B_{P1}\).
    \[ B_{\text{req0}} = B_{P0} = \frac{1}{2} \cdot \frac{1}{2} \cdot (1 - B_{Q3}) = \frac{1}{4} \cdot (1 - B_{Q3}) \]
    \[ B_{\text{req1}} = B_{P1} = (\frac{1}{2} + 1) \cdot \frac{1}{2} \cdot (1 - B_{Q3}) = \frac{3}{4} \cdot (1 - B_{Q3}) \]
  - If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0\(B_{P0}\) is 5 times less than the allocated bandwidth to req1\(B_{P2}\).
    \[ B_{\text{req0}} = B_{P0} = \frac{1}{2} \cdot \frac{1}{3} \cdot (1 - B_{Q3}) = \frac{1}{6} \cdot (1 - B_{Q3}) \]
    \[ B_{\text{req1}} = B_{P2} = (\frac{1}{2} + 1 + 1) \cdot \frac{1}{3} \cdot (1 - B_{Q3}) = \frac{5}{6} \cdot (1 - B_{Q3}) \]

The above computed bandwidth calculation is based on a theoretical input request, always active for any HPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one HPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.

- **Example 2**: application where the user distributes a same non-null N number of HPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0\(B_{P0}\) is
    \[ B_{P0} = \frac{1}{3} \cdot \frac{1}{3} \cdot (1 - B_{Q3}) = \frac{1}{9} \cdot (1 - B_{Q3}) \]
  - The allocated bandwidth to the set of requests of priority 1\(B_{P1}\) is
    \[ B_{P1} = \left(\frac{1}{3} + \frac{1}{2}\right) \cdot \frac{1}{3} \cdot (1 - B_{Q3}) = \frac{5}{18} \cdot (1 - B_{Q3}) \]
  - The allocated bandwidth to the set of requests of priority 2\(B_{P2}\) is
    \[ B_{P2} = \left(\frac{1}{3} + \frac{1}{2} + 1\right) \cdot \frac{1}{3} \cdot (1 - B_{Q3}) = \frac{11}{18} \cdot (1 - B_{Q3}) \]
  - The allocated bandwidth to any request n\(B_{n}\) among the N requests of that priority Pi (i = 0 to 2) is
    \[ B_{n} = \frac{1}{N} \cdot B_{Pi} \]
    \[ B_{n, P0} = \frac{1}{N} \cdot \frac{1}{9} \cdot (1 - B_{Q3}) \]
    \[ B_{n, P1} = \frac{1}{N} \cdot \frac{5}{18} \cdot (1 - B_{Q3}) \]
    \[ B_{n, P2} = \frac{1}{N} \cdot \frac{11}{18} \cdot (1 - B_{Q3}) \]

In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.
More generally, assume that the following requests are present:

- I requests \((I \geq 0)\) assigned to priority 0
  
  If \(I > 0\), these requests are noted from \(i = 0\) to \(I-1\).

- J requests \((J \geq 0)\) assigned to priority 1
  
  If \(J > 0\), these requests are noted from \(j = 0\) to \(J-1\).

- K requests \((K > 0)\) assigned to priority 2
  
  These requests are noted from \(k = 0\) to \(K-1\).

- L requests \((L \geq 0)\) assigned to priority 3
  
  If \(L > 0\), these requests are noted from \(l = 0\) to \(L-1\).

As \(B_Q3\) is the reserved bandwidth to time-sensitive requests, the bandwidth for each request \(L\) with priority 3 is:

- \(B_L = B_Q3 / L\) for \(L > 0\) (else: \(B_L = 0\))

The bandwidth for each non-time sensitive queue is:

- \(B_Q0 = 1/3 \ast (1 - B_Q3)\)
- \(B_Q1 = 1/3 \ast (1 - B_Q3)\)
- \(B_Q2 = 1/3 \ast (1 - B_Q3)\)

The bandwidth for the set of requests with priority 0 is:

- \(B_{P0} = I / (I + J + K) \ast B_Q0\)

The bandwidth for each request \(i\) with priority 0 is:

- \(B_i = B_{P0} / I\) for \(L > 0\) (else \(B_i = 0\))

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- \(B_{P1,Q0} = J / (I + J + K) \ast B_Q0\)

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- \(B_{P1,Q1} = J / (J + K) \ast B_Q1\)

The total bandwidth for the set of requests with priority 1 is:

- \(B_P1 = B_{P1,Q0} + B_{P1,Q1}\)

The bandwidth for each request \(j\) with priority 1 is:

- \(B_j = B_P1 / J\) for \(J > 0\) (else \(B_j = 0\))

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- \(B_{P2,Q0} = K / (I + J + K) \ast B_Q0\)

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- \(B_{P2,Q1} = K / (J + K) \ast B_Q1\)

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- \(B_{P2,Q2} = B_Q2\)

The total bandwidth for the set of requests with priority 2 is:

- \(B_P2 = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}\)

The bandwidth for each request \(k\) with priority 2 is:

- \(B_k = B_P2 / K\) (K>0 in the general case)
Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 (K > 0)):
  - \( B_i = \frac{1}{I} \times \frac{1}{3} \times \frac{I}{I + J + K} \times (1 - B_{Q3}) \)
  - \( B_j = \frac{1}{J} \times \frac{1}{3} \times \left[\frac{J}{I + J + K} + \frac{J}{J + K}\right] \times (1 - B_{Q3}) \)
  - \( B_k = \frac{1}{K} \times \frac{1}{3} \times \left[\frac{K}{I + J + K} + \frac{K}{J + K} + 1\right] \times (1 - B_{Q3}) \)
- in the specific case (when there is no request k with a priority 2 (K = 0)):
  - \( B_i = \frac{1}{I} \times \frac{1}{2} \times \frac{I}{I + J} \times (1 - B_{Q3}) \)
  - \( B_j = \frac{1}{J} \times \frac{1}{2} \times \left[\frac{J}{I + J} + 1\right] \times (1 - B_{Q3}) \)

Consequently, the HPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

### 13.4.12 HPDMA triggered transfer

A programmed HPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by HPDMA_CxTR2.TRIGPOL[1:0] and HPDMA_CxTR2.TRIGSEL[5:0] (see Section 13.3.6 for the trigger selection).

The triggered transfer, as defined by the trigger mode in HPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block (for channel \( x = 12 \) to 15), or each programmed burst read/write. The trigger mode can also be programmed to condition the LLI link transfer (see TRIGM[1:0] in HPDMA channel x transfer register 2 (HPDMA_CxTR2) for more details).

#### Trigger hit memorization and trigger overrun flag generation

The HPDMA monitoring of a trigger for a channel \( x \) is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[5:0] are not modified, and the channel is enabled.

Transferring a next LLI\(_{n+1}\) that updates HPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI\(_n\) trigger.

**Caution:** After a first new trigger, hit\(_{n+1}\) is memorized. If another trigger hit\(_{n+2}\) is detected, and if the hit\(_n\) triggered transfer is still not completed, hit\(_{n+2}\) is lost and not memorized. A trigger overrun flag is reported (HPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if HPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.
The figure below illustrates the trigger hit, memorization, and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

**Figure 126. Trigger hit, memorization and overrun waveform**

**Note:** The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

---

### 13.4.13 HPDMA circular buffering with linked-list programming

**HPDMA circular buffering for memory-toPeripheral and peripheral-to-memory transfers, with a linear addressing channel**

For a circular buffering, with a continuous memory-toPeripheral (or peripheral-to-memory) transfer, the software must set up a channel with half-transfer and complete-transfer event/interrupt generation (HPDMA_CxCR.HTIE = 1 and HPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI0 is configured for the first block transfer with the linear addressing channel. A continuously-executed LLI1 is needed to restore the memory source (or destination) start address for the memory-toPeripheral transfer (respectively the peripheral-to-memory).

The HPDMA automatically reloads the initially programmed HPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore HPDMA_CxBR1.
The figure below illustrates this programming with a linear addressing HPDMA channel and a source circular buffer.

**Figure 127. HPDMA circular buffer programming: update of the memory start address with a linear addressing channel**

**Note:** With a 2D addressing channel, a single LLI can be used with HPDMA_CxBR1.BRC[10:0] = 1. The user can program a negative memory block address offset with HDMA_CxBR2 and HDMA_CxBR1, in order to jump back to the memory source or destination start address.

If the circular buffering must be executed after some other transfers over the shared HPDMA channel x, the before-last LLI\(_{N-1}\) in the memory is needed to configure the first block transfer. The last LLI\(_N\) restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory).
The figure below illustrates this programming with a linear addressing shared HPDMA channel, and a source circular buffer.

**Figure 128. Shared HPDMA channel with circular buffering: update of the memory start address with a linear addressing channel**

### 13.4.14 HPDMA transfer in peripheral flow-control mode

A peripheral with the peripheral flow-control mode feature can decide to early terminate an HPDMA block transfer, provided that the allocated channel is implemented with this feature (see **Section 13.3.5**).

If the related HPDMA channel x is also programmed in peripheral flow-control mode (HPDMA_CxTR2.PFREQ = 1):

- The HPDMA block transfer starts as follows:
  - If HPDMA_CxBR1.BNDT[15:0] ≠ 0, the programmed value is internally taken into account by the HPDMA hardware.
  - If HPDMA_CxBR1.BNDT[15:0] = 0, the HPDMA hardware internally considers a 64-Kbyte value for the maximum source block size to be transferred.

- The HPDMA block transfer is completed as soon as the first occurrence of any of the following condition occurs:
  - when HPDMA_CxBR1.BNDT[15:0] = 0
  - when the peripheral early terminates the block. The complete transfer event is generated if programmed, depending on HPDMA_CxTR2. Then the software can read the current number of transferred bytes from the source (HPDMA_CxBR1.BNDT[15:0]), and/or read the current source or destination address of the buffer in memory (HPDMA_CxSAR[31:0] or HPDMA_CxDAR[31:0]).
In peripheral flow-control mode:
- a destination peripheral with an hardware requested transfer is not supported: memory-to-peripheral transfer is not supported.
- Data packing from a source peripheral is not supported.
- 2D/repeated block is not supported.
- HPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

13.4.15 HPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via HPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:
- An unprivileged read access to a bitfield of this channel is forced to return 0, except for HPDMA_PRIVCFGR that is readable by an unprivileged agent.
- An unprivileged write access to a bitfield of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB/AXI master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the HPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the HPDMA_CxCR.LAP allocated master port.

The HPDMA generates a privileged bus that reflects HPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each HPDMA channel x.

13.4.16 HPDMA error management

The HPDMA can manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

On a bus access (as an AHB/AXI single or a burst) to the source or the destination
- The source or destination target reports an AHB/AXI error.
- The programmed channel transfer is stopped (HPDMA_CxCR.EN cleared by the HPDMA hardware). The channel status register reports an idle state (HPDMA_CxSR.IDLEF = 1) and the data error (HPDMA_CxSR.DTEF = 1).
- After an HPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After an HPDMA data transfer error, the user must issue a channel reset (set HPDMA_CxCR.RESET) to reset the hardware HPDMA channel data path and the FIFO content, before the user enables again the same channel for a next transfer.
Link transfer error

On a tentative update of a HPDMA channel register from the programmed LLI in the memory:

- The linked-list memory reports an AHB/AXI error.
- The programmed channel transfer is stopped (HPDMA_CxCR.EN cleared by the HPDMA hardware), the channel status register reports an idle state (HPDMA_CxSR.IDLEF = 1), and the link error (HPDMA_CxSR.ULEF = 1).
- After an HPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (HPDMA_CxLBAR and HPDMA_CxLLR), including the protection attributes.
- After an HPDMA link error, the user must explicitly write the linked-list register file (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR, plus HPDMA_CxTR3 and HPDMA_CxBR2 when present), before the user enables again the same channel for a next transfer.

User setting error

On a tentative execution of an HPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (HPDMA_CxCR.EN forced and cleared by the HPDMA hardware), preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (HPDMA_CxSR.IDLEF = 1), and a user setting error (HPDMA_CxSR.USEF = 1).
- After an HPDMA user setting error, the user must perform a debug session, taking care of the HPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI (HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxBR1.BNDT[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0])
  - when in packing/unpacking mode (if PAM[1] = 1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxBR1.BNDT[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
  - when in packing/unpacking mode (if PAM[1] = 1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxBR1.BNDT[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed unaligned source start address being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxSAR[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x = 12 to 15, a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxTR3.SAO[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x = 12 to 15, a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxBR2.BRSAO[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0])
  - a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxDAR[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
– for channel x = 12 to 15, a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxTR3.DAO[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
– for channel x = 12 to 15, a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxBR2.BRDAO[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
– a programmed double-word source data width and a programmed AHB source allocated port (HPDMA_CxTR1.SDW_LOG2[1:0] = 11 and HPDMA_CxTR1.SAP = 1)
– a programmed double-word destination data width and a programmed AHB destination allocated port (HPDMA_CxTR1.DDW_LOG2[1:0] = 11 and HPDMA_CxTR1.DAP = 1)
– a programmed linked-list item LLI_{n+1} with a null data transfer (HPDMA_CxLLR.UB1 = 1 and HPDMA_CxBR1.BNDT = 0)

13.4.17 HPDMA autonomous mode

To save dynamic power consumption while the HPDMA executes the programmed linked-list transfers, the HPDMA hardware automatically manages its own clock gating, and generates a clock request output signal to the RCC, whenever the device is in Run, Sleep, or Stop mode, provided that the RCC is programmed with the corresponding HPDMA enable control bits.

For more details about the RCC programming, refer to the RCC section of the reference manual.

For mode details about the availability of the HPDMA autonomous feature versus the device low-power modes, see Section 13.3.2.

The user can program and schedule the execution of a given HPDMA transfer at a LLI_{n} level of an HPDMA channel x, with HPDMA_CxTR2 as follows:

- The software controls and conditions the input of a transfer with TRIGM[1:0], TRIGPOL[1:0], TRIGSEL[5:0], SWREQ, and REQSEL[4:0] for the input trigger and request.
- The software controls and signals the output of a transfer with TCEM[1:0] for generating or not a transfer-complete event, and generating or not an associated half-transfer event).

See HPDMA channel x transfer register 2 (HPDMA_CxTR2) for more details.

When used in low-power modes, this functionality enables a CPU wake-up on a specific transfer completion by the enabled the HPDMA transfer complete interrupt (HPDMA_CxCR.TCIE = 1), or/and enables to continue with the autonomous HPDMA for operating another LLI_{n+1} transfer over the same channel.

The output channel x transfer complete event, hpdma_chx TC, can be programmed as a selected input trigger for a channel if this event is looped-back and connected at HPDMA level (see Section 13.3.6), allowing autonomous and fine HPDMA inter-channel transfer scheduling, without needing a cleared transfer complete flag (TCF).

A given HPDMA channel x asserts its clock request in one of the following conditions:
• if the next transfer to be executed is programmed as conditioned by a trigger (HPDMA_CxTR2.TRIGPOL[1:0] and HPDMA_CxTR2.TRIGM[1:0]), only when the trigger hit occurs
• if the next transfer to be executed is not conditioned by a trigger:
  – if HPDMA_CxTR2.SWREQ = 0, only when the hardware request is asserted by the selected peripheral
  – if HPDMA_CxTR2.SWREQ = 1 (memory-to-memory, GPIO to/from memory), as soon as the HPDMA is enabled

The HPDMA channel x releases its clock request as soon as all the following conditions are met:
• The transfer to be executed is completed.
• The HPDMA channel x is not immediately ready and requested to execute the next transfer.
• If a channel x interrupt was raised, all the flags of the status register that can cause this interrupt, are cleared by a software agent.

When one channel asserts its clock request, the HPDMA asserts its clock request to the RCC. When none channel asserts its clock request, the HPDMA releases its clock request to the RCC.

13.5 HPDMA in debug mode

When the device enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, HPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, HPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

13.6 HPDMA in low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. HPDMA interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop(^1)</td>
<td>The content of HPDMA registers is kept when entering Stop mode. The content of HPDMA registers can be autonomously updated by a next linked-list item from the memory, to perform autonomous data transfers. HPDMA interrupts can cause the device to exit Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The HPDMA is powered down, and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

\(^1\) Refer to Section 13.3.2 to know which Stop mode is supported.
13.7 HPDMA interrupts

There is one HPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 110. HPDMA interrupt requests

<table>
<thead>

<tr>
<td></td>
<td>Trigger overrun</td>
<td>HPDMA_CxCR.TOFIE</td>
<td>HPDMA_CxSR.TOF</td>
<td>Writes 1 to HPDMA_CxFCR.TOF</td>
</tr>
</tbody>
</table>

An HPDMA channel x event can be:
- a transfer complete
- an half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal hpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:
- the corresponding interrupt event xx is enabled (HPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (HPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into HPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by HPDMA_CxTR2.TCEM[1:0] as follows:
- A transfer-complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode HPDMA_CxTR2.TCEM[1:0].
- A half-transfer event is an half-block transfer, or a half 2D/repeated block transfer, depending on the transfer complete event mode HPDMA_CxTR2.TCEM[1:0].
An half-block transfer occurs when half of the source block size bytes (rounded-up integer of \( \text{HPDMA}_\text{CxBR1.BNDT}[15:0] / 2 \)) is transferred to the destination.

An half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of \( \text{HPDMA}_\text{CxBR1.BRC}[10:0] + 1 / 2 \)) is transferred to the destination.

See **HPDMA channel x transfer register 2 (HPDMA_CxTR2)** for more details.

Note: The interrupt mode must be used (not the polling mode) to be notified on an half transfer when the write data transaction has been completed over the AXI destination allocated port (written at the destination memory-mapped address), and not just before when has been issued, at HPDMA level, this AXI burst transaction.

A transfer error rises in one of the following situations:
- during a single/burst data transfer from the source or to the destination (DTEF)
- during an update of an HPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of an HPDMA channel with an unauthorized setting (USEF)

The user must perform a debug session to correct the HPDMA channel programming versus the USEF root causes list (see [Section 13.4.16](#)).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

## 13.8 HPDMA registers

The HPDMA registers must be accessed with an aligned 32-bit word data access.

### 13.8.1 HPDMA privileged configuration register (HPDMA_PRIVCFGR)

Address offset: 0x004

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a HPDMA channel (HPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.
13.8.2 **HPDMA configuration lock register (HPDMA_RCFGLOCKR)**

Address offset: 0x008

Reset value: 0x0000 0000

This register can be written by a software agent with privileged attributes in order to individually lock, for example at boot time, the privileged attributes of any HPDMA channel/resource (to lock the setting of HPDMA_PRIVCFGR for any channel x at, for example at boot time).

A read access may be privileged or unprivileged.

<table>
<thead>
<tr>
<th>bits 31:16</th>
<th>reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>bits 15:0</td>
<td>lockx: lock of the configuration of HPDMA_PRIVCFGR.PRIVx until a global HPDMA reset (x = 15 to 0)</td>

<td></td>
</tr>
<tr>
<td>1: privilege configuration of the channel x is not writable.</td>
<td></td>
</tr>
</tbody>
</table>

13.8.3 **HPDMA masked interrupt status register (HPDMA_MISR)**

Address offset: 0x0C

Reset value: 0x0000 0000

This is a read register.

This register contains the masked interrupt status bit MISx for each channel x. It is a logical OR of all the HPDMA_CxSR flags, each source flag being enabled by the corresponding HPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when writing 1 to the corresponding HPDMA_CxFCR flag clear bit.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel HPDMA_PRIVCFGR.PRIVx. A privileged software can read the full interrupt status. An unprivileged software is restricted to read the status of unprivileged channels, other privileged bitfields returning zero.
13.8.4 HPDMA channel x linked-list base address register (HPDMA_CxLBAR)

Address offset: 0x050 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x HPDMA_PRIVCFGR.PRIVx.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the HPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit HPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

Bits 31:16 LBA[31:16]: Linked-list base address of HPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.
13.8.5 HPDMA channel x flag clear register (HPDMA_CxFCR)

Address offset: 0x05C+ 0x80 * x (x = 0 to 15)
Reset value: 0x0000 0000

This is a write register privileged or unprivileged, depending on the privileged state of the channel x (HPDMA_PRIVCFG.RIVx).

Bits 7:0 Reserved, must be kept at reset value.
13.8.6 HPDMA channel x status register (HPDMA_CxSR)

Address offset: 0x060 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is privileged or unprivileged, depending on the privileged state of the channel (HPDMA_PRIVCFGR.PRIVx).

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 **FIFOL[8:0]**: Monitored FIFO level

Number of available write beats in the FIFO, in units of the programmed destination data width (see Section 13.8.8: HPDMA channel x transfer register 1 (HPDMA_CxTR1) DDW_LOG2[1:0], in units of bytes, half-words, words or double-words).

Note: After having suspended an active transfer, the user may need to read FIFOL[8:0], additionally to HPDMA_CxBR1.BDNT[15:0] and HPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (HPDMA_CxSR.SUSPF = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOF**: Trigger overrun flag
0: No trigger overrun event
1: A trigger overrun event occurred.

Bit 13 **SUSPF**: Completed suspension flag
0: No completed suspension event
1: A completed suspension event occurred.

Bit 12 **USEF**: User setting error flag
0: No user setting error event
1: A user setting error event occurred.

Bit 11 **ULEF**: Update link transfer error flag
0: No update link transfer error event
1: A master bus error event occurred while updating a linked-list register from memory.

Bit 10 **DTEF**: Data transfer error flag
0: No data transfer error event
1: A master bus error event occurred on a data transfer.
13.8.7 **HPDMA channel x control register (HPDMA_CxCR)**

Address offset: 0x064 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of the channel x (HPDMA_PRIVCFGx.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

Bits 31:24 Reserved, must be kept at reset value.
Bits 23:22 PRIOR[1:0]: Priority level of the channel x HPDMA transfer versus others
   00: Low priority, low weight
   01: Low priority, mid weight
   10: Low priority, high weight
   11: High priority

   Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 LAP: Linked-list allocated port
   This bit is used to allocate the master port for the update of the HPDMA linked-list registers
   from the memory.
   0: Port 0 (AXI) allocated
   1: Port 1 (AHB) allocated

   Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 16 LSM: Link step mode
   0: Channel executed for the full linked-list and completed at the end of the last LLI
      (HPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0)
      and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and
      UT3 = UB2 = 0 if present). Then HPDMA_CxBR1.BNDT[15:0] = 0 and
      HPDMA_CxBR1.BRC[10:0] = 0 if present.
   1: Channel executed once for the current LLI
      First the (possible 1D/repeated) block transfer is executed as defined by the current internal
      register file until HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0, if present.
      Secondly the next linked-list data structure is conditionally uploaded from memory
      as defined by HPDMA_CxLLR. Then channel execution is completed.

   Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 TOIE: Trigger overrun interrupt enable
   0: Interrupt disabled
   1: Interrupt enabled

Bit 13 SUSP: Cmpleted suspension interrupt enable
   0: Interrupt disabled
   1: Interrupt enabled

Bit 12 USE: User setting error interrupt enable
   0: Interrupt disabled
   1: Interrupt enabled

Bit 11 ULE: Update link transfer error interrupt enable
   0: Interrupt disabled
   1: Interrupt enabled

Bit 10 DTE: Data transfer error interrupt enable
   0: Interrupt disabled
   1: Interrupt enabled

Bit 9 HTIE: Half transfer complete interrupt enable
   0: Interrupt disabled
   1: Interrupt enabled

Bit 8 TCIE: Transfer complete interrupt enable
   0: Interrupt disabled
   1: Interrupt enabled
Bits 7:3  Reserved, must be kept at reset value.

Bit 2  **SUSP**: Suspend

Writing 1 to RESET in this register causes the hardware to deassert this SUSP bit, whatever is written into this SUSP. Else:

Software must write 1 in order to suspend an active channel (a channel with an ongoing HPDMA transfer over its master ports).

The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in Figure 110.

0: Write: resume channel, read: channel not suspended
1: Write: suspend channel, read: channel suspended

Bit 1  **RESET**: Reset

This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0).

The reset is effective when the channel is in steady state, meaning one of the following:
- active channel in suspended state (HPDMA_CxSR.SUSPF = 1 and HPDMA_CxSR.IDLEF = HPDMA_CxCR.EN = 1)
- channel in disabled state (HPDMA_CxSR.IDLEF = 1 and HPDMA_CxCR.EN = 0).

After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (HPDMA_CxBR1, HPDMA_CxSAR and HPDMA_CxDAR) before enabling again the channel (see the programming sequence in Figure 111).

0: No channel reset
1: Channel reset

Bit 0  **EN**: Enable

Writing 1 to RESET in this register causes the hardware to deassert this EN bit, whatever is written into this bit 0. Else:

This bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).

Else, this bit can be asserted by software.

Writing 0 into this EN bit is ignored.

0: Write: ignored, read: channel disabled
1: Write: enable channel, read: channel enabled
13.8.8 **HPDMA channel x transfer register 1 (HPDMA_CxTR1)**

Address offset: 0x090 + 0x80 * x (x = 0 to 15)
Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of the channel x in HPDMA_PRIVCFGPR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has de-asserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by HPDMA from the memory if HPDMA_CxLLR.UT1 = 1.

</table>
Bits 25:20 **DBL_1[5:0]**: Destination burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If DBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width **DDW_LOG2[1:0]**.

**Note:** If a burst transfer crossed a 1- or 4-Byte address boundary on respectively an AHB or AXI transfer, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB/AXI protocol.

If the burst length exceeds 16 on an AHB transfer, or if the burst on an AXI transfer is both with fixed addressing (DINC = 0) and with a burst length which exceeds 16, the HPDMA modifies and shortens the programmed burst into bursts of lower length, to be compliant with the AHB or AXI protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with HPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19 **DINC**: Destination incrementing burst

0: Fixed burst
1: Contiguously incremented burst

The destination address, pointed by HPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: Binary logarithm of the destination data width of a burst, in bytes

00: Byte
01: Half-word (2 bytes)
10: Word (4 bytes)
11: If DAP = 0 (AXI), double-word (8 bytes)

if DAP = 1, user setting error reported and no transfer issued

**Note:** A destination burst transfer must have an aligned address with its data width (start address HPDMA_CxDAR[2:0] and address offset HPDMA_CxTR3.DAO[2:0], versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.

When configured in packing mode (PAM[1] = 1 and destination data width different from source data width), a source block size must be a multiple of the destination data width (see HPDMA_CxBR1.BNDT[2:0] versus DDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

A destination burst transfer must have an aligned address with its data width (start address HPDMA_CxDAR[2:0] versus DDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

A burst with a double-word data width must be allocated to the AXI master port, else a user setting error is reported and none transfer is issued.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **SAP**: Source allocated port

This bit is used to allocate the master port for the source transfer

0: Port 0 (AXI) allocated
1: Port 1 (AHB) allocated

**Note:** This bit must be written when EN = 0. This bit is read-only when EN = 1.
Bit 13 **SBX**: Source byte exchange within the unaligned half-word of each source word

If the source data width is shorter than a word, this bit is ignored.

If the source data width is a word or a double-word, and if source bus is AXI (SAP = 0):
- 0: No byte-based exchange within the unaligned half-word of each source word
- 1: The two consecutive bytes within the unaligned half-word of each source word are exchanged.

Bits 12:11 **PAM[1:0]**: Padding/alignment mode

If \(DDW\_LOG2[1:0] = SDW\_LOG2[1:0]\): if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.

Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when source data width is higher than destination data width.

**Condition: PAM_1**
- 00: Source data is transferred as right aligned, padded with 0s up to the destination data width
- 01: Source data is transferred as right aligned, sign extended up to the destination data width
- 10-11: Successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer

**Condition: PAM_2**
- 00: Source data is transferred as right aligned, left-truncated down to the destination data width
- 01: Source data is transferred as left-aligned, right-truncated down to the destination data width
- 10-11: Source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

**Note**: If the transfer from the source peripheral is configured with peripheral flow-control mode (SWREQ = 0 and PFREQ = 1 and DREQ = 0), and if the destination data width > the source data width, packing is not supported.

Bit 10 Reserved, must be kept at reset value.

Bits 9:4 **SBL_1[5:0]**: Source burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If \(SBL\_1[5:0] = 0\), the burst can be named as single. Each data/beat has a width defined by the destination data width \(SDW\_LOG2[1:0]\).

**Note**: If a burst transfer crossed a 1- or 4-Kbyte address boundary on respectively an AHB or an AXI transfer, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If the burst length exceeds 16 on an AHB transfer, or if the burst on an AXI transfer is both with fixed addressing \((SINC = 0)\) and with a burst length which exceeds 16, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with HPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3 **SINC**: Source incrementing burst

- 0: Fixed burst
- 1: Contiguously incremented burst

The source address, pointed by HPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2 Reserved, must be kept at reset value.
Bits 1:0 **SDW_LOG2[1:0]**: Binary logarithm of the source data width of a burst in bytes

- 00: Byte
- 01: Half-word (2 bytes)
- 10: Word (4 bytes)
- 11: If SAP = 0 (AXI), double-word (8 bytes)
  
  if SAP = 1, user setting error reported and no transfer issued

**Note:** A source block size must be a multiple of the source data width (HPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source burst transfer must have an aligned address with its data width (start address HPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

A source burst transfer must have an aligned address with its data width (start address HPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

A burst with a double-word data width must be allocated to the AXI master port, else a user setting error is reported and none transfer is issued.

### 13.8.9 HPDMA channel x transfer register 2 (HPDMA_CxTR2)

Address offset: 0x094 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by HPDMA from the memory, if HPDMA_CxLLR.UT2 = 1.

**Note:** A source block size must be a multiple of the source data width (HPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source burst transfer must have an aligned address with its data width (start address HPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

A source burst transfer must have an aligned address with its data width (start address HPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

A burst with a double-word data width must be allocated to the AXI master port, else a user setting error is reported and none transfer is issued.
Bits 31:30  **TCEM[1:0]**: Transfer complete event mode

These bits define the transfer granularity for the transfer complete and half transfer complete events generation.

00: At block level (when HPDMA_CxBR1.BNDT[15:0] = 0): The complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

**Note:** If the initial LLI₀ data transfer is null/void (directly programmed by the internal register file with HPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

01: Channel x = 0 to 11, same as 00; channel x = 12 to 15, at 2D/repeated block level (when HPDMA_CxBR1.BRC[10:0] = 0 and HPDMA_CxBR1.BNDT[15:0] = 0), the complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

**Note:** If the initial LLI₀ data transfer is null/void (directly programmed by the internal register file with HPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

10: At LLI level: The complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer (the LLI data transfer being a block transfer or a 2D/repeated block transfer for channel x = 12 to 15), if any data transfer.

**Note:** If the initial LLI₀ data transfer is null/void (directly programmed by the internal register file with HPDMA_CxBR1.BNDT[15:0] = 0), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI₁.

11: At channel level: The complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address HPDMA_CxLLR.LA[15:2] to zero and clears all the HPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2 if present). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26  Reserved, must be kept at reset value.

Bits 25:24  **TRIGPOL[1:0]**: Trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[5:0].

00: No trigger (masked trigger event)

01: Trigger on the rising edge

10: Trigger on the falling edge

11: Same as 00

Bits 23:22  Reserved, must be kept at reset value.

Bits 21:16  **TRIGSEL[5:0]**: Trigger event input selection

These bits select the trigger event input of the HPDMA transfer (as per Section 13.3.6), with an active trigger event if TRIGPOL[1:0] # 00.
Bits 15:14 **TRIGM[1:0]:** Trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (HPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, an HPDMA transfer is conditioned by at least one trigger hit:
- **00:** at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x = 12 to 15, for each block if a 2D/repeated block is configured with HPDMA_CxBR1.BRC[10:0] ≠ 0).
- **01:** channel x = 0 to 11, same as 00; channel x = 12 to 15, at 2D/repeated block level, the first burst read of a 2D/repeated block transfer is conditioned by one hit trigger.
- **10:** at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.
- **11:** at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger.
  - If the peripheral is programmed as a source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.
  - If the peripheral is programmed as a destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and the first trigger hit.

The HPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled.

Transferring a next LLI_{n+1} that updates the HPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_{n} trigger.

After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_{n} triggered transfer is still not completed, hit_{n+2} is lost and not memorized.

A trigger overrun flag is reported (HPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (HPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

**Note:** When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ = 0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1/4-Kbyte boundary address crossing maximum burst length versus AHB/AXI protocol): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bit 13 **Reserved, must be kept at reset value.**
Bit 12 **PFREQ**: Hardware request in peripheral flow control mode

*Important: If a given channel x is not implemented with this feature, this bit is reserved and PFREQ is not present (see Section 13.3.5 for the list of the implemented channels with this feature.)*

If the channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in HPDMA control mode. The HPDMA is programmed with HPDMA_CxCB1.BNDT[15:0] and this is internally used by the hardware for the block transfer completion.

1: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in peripheral control mode. The HPDMA block transfer can be early completed by the peripheral itself (see Section 13.3.5 for more details).

Note: In peripheral flow control mode, there are the following restrictions:

- no 2D/repeated block support (HPDMA_CxB1.BRC[10:0] must be set to 0 if present)
- the peripheral must be set as the source of the transfer (DREQ = 0).
- data packing to a wider destination width is not supported (if destination width > source data width, HPDMA_CxTR1.PAM[1] must be set to 0).
- HPDMA_CxB1.BNDT[15:0] must be set as a multiple of the source (peripheral) burst size.

Bit 11 **BREQ**: Block hardware request

If the channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.

1: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see Section 13.3.4).

Bit 10 **DREQ**: Destination hardware request

This bit is ignored if channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: Selected hardware request driven by a source peripheral (request signal taken into account by the HPDMA transfer scheduler over the source/read port)

1: Selected hardware request driven by a destination peripheral (request signal taken into account by the HPDMA transfer scheduler over the destination/write port)

Note: If the channel x is activated (HPDMA_CxCR.EN is asserted) with SWREQ = 0 and PFREQ = 1 (peripheral hardware request with peripheral flow-control mode), any software assertion to this DREQ bit is ignored: in peripheral flow-control mode, only a peripheral-to-memory transfer is supported.

Bit 9 **SWREQ**: Software request

This bit is internally taken into account when HPDMA_CxCR.EN is asserted.

0: No software request. The selected hardware request REQSEL[4:0] is taken into account.

1: Software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[4:0] is ignored.

Bits 8:5 Reserved, must be kept at reset value.
Bits 4:0 **REQSEL[4:0]:** Hardware request selection

These bits are ignored if channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per Section 13.3.3.

**Caution:** The user must not assign a same input hardware request (same REQSEL[4:0] value) to different active HPDMA channels (HPDMA_CxCR.EN = 1 and HPDMA_CxTR2.SWREQ = 0 for these channels). The HPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

### 13.8.10 HPDMA channel x block register 1 (HPDMA_CxBR1)

**Address offset:** 0x098 + 0x80 * x (x = 0 to 11)

**Reset value:** 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGPR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has de-asserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer:

- if HPDMA_CxLLR.UB1 = 1, this register is automatically updated by the HPDMA from the next LLI in memory.
- If HPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the bitfield BNDT[15:0].
- If all the update bits HPDMA_CxLLR.Uxx are null and if HPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI.
- If HPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

<table>

<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

**Bits 31:16** Reserved, must be kept at reset value.
Bits 15:0  **BDNT[15:0]:** Block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this bitfield becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. **BDNT[15:0]** is programmed in number of bytes, maximum source block size is 64 Kbytes - 1.

Once the last data transfer is completed (**BDNT[15:0] = 0**):
- if HPDMA_CxLLR.UB1 = 1, this bitfield is updated by the LLI in the memory.
- if HPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this bitfield is internally restored to the programmed value.
- if all HPDMA_CxLLR.Uxx = 0 and if HPDMA_CxLLR.LA[15:0] = 0, this bitfield is internally restored to the programmed value (infinite/continuous last LLI).
- if HPDMA_CxLLR = 0, this bitfield is kept as zero following the last LLI data transfer.

**Note:** A non-null source block size must be a multiple of the source data width (**BDNT[2:0]** versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (**HPDMA_CxTR1.PAM[1] = 1** and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (**BDNT[2:0]** versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

13.8.11 **HPDMA channel x alternate block register 1 (HPDMA_CxBR1)**

Address offset: 0x098 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has de-asserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer:
- if HPDMA_CxLLR.UB1 = 1, this register is automatically updated by the HPDMA from the next LLI in memory.
- If HPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the bitfields **BDNT[15:0]** and **BRC[10:0]**.
- If all the update bits HPDMA_CxLLR.Uxx are null and if HPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for the bitfields **BDNT[15:0]** and **BRC[10:0]** after each execution of this final LLI.
- If HPDMA_CxLLR = 0, **BDNT[15:0]** and **BRC[10:0]** are kept as null, channel x is completed.
**High-performance direct memory access controller (HPDMA)**

### Bit 31: BRDDEC
- **Block repeat destination address decrement**
  - 0: At the end of a block transfer, the HPDMA_CxDAR register is updated by adding the programmed offset HPDMA_CxBR2.BRDAO to the current HPDMA_CxDAR value (current destination address)
  - 1: At the end of a block transfer, the HPDMA_CxDAR register is updated by subtracting the programmed offset HPDMA_CxBR2.BRDAO from the current HPDMA_CxDAR value (current destination address)

**Note:** On top of this increment/decrement (depending on BRDDEC), HPDMA_CxDAR is in the same time also updated by the increment/decrement (depending on DDEC) of the HPDMA_CxTR3.DAO value, as it is usually done at the end of each programmed burst transfer.

### Bit 30: BRSDEC
- **Block repeat source address decrement**
  - 0: At the end of a block transfer, the HPDMA_CxSAR register is updated by adding the programmed offset HPDMA_CxBR2.BRSAO to the current HPDMA_CxSAR value (current source address)
  - 1: At the end of a block transfer, the HPDMA_CxSAR register is updated by subtracting the programmed offset HPDMA_CxBR2.BRSAO from the current HPDMA_CxSAR value (current source address)

**Note:** On top of this increment/decrement (depending on BRSDEC), HPDMA_CxSAR is in the same time also updated by the increment/decrement (depending on SDEC) of the HPDMA_CxTR3.DAO value, as it is done after any programmed burst transfer.

### Bit 29: DDEC
- **Destination address decrement**
  - 0: At the end of a programmed burst transfer to the destination, the HPDMA_CxDAR register is updated by adding the programmed offset HPDMA_CxTR3.DAO to the current HPDMA_CxDAR value (current destination address)
  - 1: At the end of a programmed burst transfer to the destination, the HPDMA_CxDAR register is updated by subtracting the programmed offset HPDMA_CxTR3.DAO from the current HPDMA_CxDAR value (current destination address)

### Bit 28: SDEC
- **Source address decrement**
  - 0: At the end of a programmed burst transfer from the source, the HPDMA_CxSAR register is updated by adding the programmed offset HPDMA_CxTR3.SAO to the current HPDMA_CxSAR value (current source address)
  - 1: At the end of a programmed burst transfer from the source, the HPDMA_CxSAR register is updated by subtracting the programmed offset HPDMA_CxTR3.SAO from the current HPDMA_CxSAR value (current source address)

### Bit 27: Reserved
- Must be kept at reset value.
**Bits 26:16**  
**BRC[10:0]: Block repeat counter**

This bitfield contains the number of repetitions of the current block (0 to 2047). When the channel is enabled, this bitfield becomes read-only. After decrements, this bitfield indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):

- If HPDMA_CxLLR.UB1 = 1, all HPDMA_CxBR1 bitfields are updated by the next LLI in the memory.
- If HPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this bitfield is internally restored to the programmed value.
- If all HPDMA_CxLLR.Uxx = 0 and if HPDMA_CxLLR.LA[15:0] ≠ 0, this bitfield is internally restored to the programmed value (infinite/continuous last LLI).
- If HPDMA_CxLLR = 0, this bitfield is kept as zero following the last LLI and data transfer.

**Bits 15:0**  
**BNDT[15:0]: Block number of data bytes to transfer from the source**

Block size transferred from the source. When the channel is enabled, this bitfield becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred.

BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1. Once the last data transfer is completed (BNDT[15:0] = 0):

- If HPDMA_CxLLR.UB1 = 1, this bitfield is updated by the LLI in the memory.
- If HPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this bitfield is internally restored to the programmed value.
- If all HPDMA_CxLLR.Uxx = 0 and if HPDMA_CxLLR.LA[15:0] ≠ 0, this bitfield is internally restored to the programmed value (infinite/continuous last LLI).
- If HPDMA_CxLLR = 0, this bitfield is kept as zero following the last LLI data transfer.

**Note:** A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (HPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.
13.8.12 HPDMA channel x source address register (HPDMA_CxSAR)

Address offset: 0x09C + 0x80 * x (x = 0 to 15)
Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.USA = 1.

Bits 31:0 \texttt{SA}[31:0]: Source address

This bitfield is the pointer to the address from which the next data is read. During the channel activity, depending on the source addressing mode (HPDMA_CxTR1.SINC), this bitfield is kept fixed or incremented by the data width (HPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

– the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (HPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by HPDMA_CxTR1.SBL_1[5:0] and HPDMA_CxTR1.SDW_LOG2[1:0]

– the additional source incremented/decremented offset value as programmed by HPDMA_CxBR1.SDEC and HPDMA_CxTR3.SAO[12:0]

– once/if completed source block transfer, for a channel x with 2D addressing capability (x = 12 to 15). additional block repeat source incremented/decremented offset value as programmed by HPDMA_CxBR1.BRSDEC and HPDMA_CxBR2.BRSAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by HPDMA from the memory, provided the LLI is set with HPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source burst (\texttt{SA}[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional HPDMA_CxTR3.SAO[12:0] is not applied.
13.8.13  HPDMA channel x destination address register (HPDMA_CxDAR)

Address offset: 0x0A0 + 0x80 * x (x = 0 to 15)
Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGPR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when HPDMA_CxCREN = 0.

This register is read-only when HPDMA_CxCREN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCREN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by HPDMA from the memory if HPDMA_CxLLR.UDA = 1.

Bits 31:0  DA[31:0]: destination address

This bitfield is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (HPDMA_CxTR1.DINC), this bitfield is kept fixed or incremented by the data width (HPDMA_CxTR1.DDW_LOG2[1:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:
– the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (HPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by HPDMA_CxTR1.DBL_1[5:0] and HPDMA_CxTR1.DDW_LOG2[1:0]
– the additional destination incremented/decremented offset value as programmed by HPDMA_CxBR1.DDEC and HPDMA_CxTR3.DAO[12:0]
– once/if completed destination block transfer, for a channel x with 2D addressing capability (x = 12 to 15), the additional block repeat destination incremented/decremented offset value as programmed by HPDMA_CxBR1.BRDDEC and HPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the HPDMA from the memory, provided the LLI is set with HPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst [DA[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]]. Else, a user setting error is reported and no transfer is issued.
### 13.8.14 HPDMA channel x transfer register 3 (HPDMA_CxTR3)

Address offset: 0x0A4 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFG.PRIVx).

This register controls the transfer of a channel x.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.UT3 = 1.

</table>

**Bits 31:29** Reserved, must be kept at reset value.

**Bits 28:16** DAO[12:0]: Destination address offset increment

The destination address, pointed by HPDMA_CxDAR, is incremented or decremented (depending on HPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (HPDMA_CxTR1.DINC = 1).

**Note:** A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

**Bits 15:13** Reserved, must be kept at reset value.

**Bits 12:0** SAO[12:0]: Source address offset increment

The source address, pointed by HPDMA_CxSAR, is incremented or decremented (depending on HPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (HPDMA_CxTR1.SINC = 1).

**Note:** A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shortened to match the block size. In this case, the additional HPDMA_CxTR3.SAO[12:0] is not applied.
13.8.15 HPDMA channel x block register 2 (HPDMA_CxBR2)

Address offset: 0x0A8 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.UB2 = 1.

</tbody>
</table>

Bits 31:16 **BRDAO[15:0]**: Block repeated destination address offset

For a channel with 2D addressing capability, this bitfield is used to update (by addition or subtraction depending on HPDMA_CxBR1.BRDDEC) the current destination address (HPDMA_CxDAR) at the end of a block transfer.

*Note:* A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

**BRDAO[15:0] must be set to 0 in peripheral flow-control mode (if HPDMA_CxTR2.PFREQ = 1).**

</tr>
<tr>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **BRSAO[15:0]**: Block repeated source address offset

For a channel with 2D addressing capability, this bitfield is used to update (by addition or subtraction depending on HPDMA_CxBR1.BRSDEC) the current source address (HPDMA_CxSAR) at the end of a block transfer.

*Note:* A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

**BRSAO[15:0] must be set to 0 in peripheral flow-control mode (if HPDMA_CxTR2.PFREQ = 1).**
**13.8.16 HPDMA channel x linked-list address register (HPDMA_CxLLR)**

Address offset: 0x0CC + 0x80 * x (x = 0 to 11)
Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGx.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.ULL = 1.

Bit 31 **UT1**: Update HPDMA_CxTR1 from memory
This bit controls the update of HPDMA_CxTR1 from the memory during the link transfer.
0: No HPDMA_CxTR1 update
1: HPDMA_CxTR1 update

Bit 30 **UT2**: Update HPDMA_CxTR2 from memory
This bit controls the update of HPDMA_CxTR2 from the memory during the link transfer.
0: No HPDMA_CxTR2 update
1: HPDMA_CxTR2 update

Bit 29 **UB1**: Update HPDMA_CxBR1 from memory
This bit controls the update of HPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if HPDMA_CxLLR ≠ 0, the linked-list is not completed.
HPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: No HPDMA_CxBR1 update from memory (HPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: HPDMA_CxBR1 update

Bit 28 **USA**: Update HPDMA_CxSAR from memory
This bit controls the update of HPDMA_CxSAR from the memory during the link transfer.
0: No HPDMA_CxSAR update
1: HPDMA_CxSAR update
Bit 27  **UDA**: Update HPDMA_CxDAR register from memory
   This bit is used to control the update of HPDMA_CxDAR from the memory during the link transfer.
   0: No HPDMA_CxDAR update
   1: HPDMA_CxDAR update

Bits 26:17  Reserved, must be kept at reset value.

Bit 16  **ULL**: Update HPDMA_CxLLR register from memory
   This bit is used to control the update of HPDMA_CxLLR from the memory during the link transfer.
   0: No HPDMA_CxLLR update
   1: HPDMA_CxLLR update

Bits 15:2  **LA[15:2]**: Pointer (16-bit low-significant address) to the next linked-list data structure
   If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list HPDMA register file.
   Else, this bitfield is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list HPDMA internal register file (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR).
   
   **Note**: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0  Reserved, must be kept at reset value.
### 13.8.17 HPDMA channel x alternate linked-list address register (HPDMA_CxLLR)

Address offset: 0x0CC + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.ULL = 1.

#### Bit 31  **UT1**: Update HPDMA_CxTR1 from memory
This bit controls the update of HPDMA_CxTR1 from the memory during the link transfer.
0: No HPDMA_CxTR1 update
1: HPDMA_CxTR1 update

#### Bit 30  **UT2**: Update HPDMA_CxTR2 from memory
This bit controls the update of HPDMA_CxTR2 from the memory during the link transfer.
0: No HPDMA_CxTR2 update
1: HPDMA_CxTR2 update

#### Bit 29  **UB1**: Update HPDMA_CxBR1 from memory
This bit controls the update of HPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if HPDMA_CxLLR ≠ 0, the linked-list is not completed.
HPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: No HPDMA_CxBR1 update from memory (HPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: HPDMA_CxBR1 update

#### Bit 28  **USA**: Update HPDMA_CxSAR from memory
This bit controls the update of HPDMA_CxSAR from the memory during the link transfer.
0: No HPDMA_CxSAR update
1: HPDMA_CxSAR update
Bit 27 **UDA**: Update HPDMA_CxDAR register from memory
   This bit is used to control the update of HPDMA_CxDAR from the memory during the link transfer.
   0: No HPDMA_CxDAR update
   1: HPDMA_CxDAR update

Bit 26 **UT3**: Update HPDMA_CxTR3 from memory
   This bit controls the update of HPDMA_CxTR3 from the memory during the link transfer.
   0: No HPDMA_CxTR3 update
   1: HPDMA_CxTR3 update

Bit 25 **UB2**: Update HPDMA_CxBR2 from memory
   This bit controls the update of HPDMA_CxBR2 from the memory during the link transfer.
   0: No HPDMA_CxBR2 update
   1: HPDMA_CxBR2 update

Bits 24:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update HPDMA_CxLLR register from memory
   This bit is used to control the update of HPDMA_CxLLR from the memory during the link transfer.
   0: No HPDMA_CxLLR update
   1: HPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: Pointer (16-bit low-significant address) to the next linked-list data structure
   If UT1 = UT2 = UB1 = USA = UDA = ULL= 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list HPDMA register file.
   Else, this bitfield is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list HPDMA internal register file (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR and HPDMA_CxLLR).
   **Note:** The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

### 13.8.18 HPDMA register map

**Table 111. HPDMA register map and reset values**

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

Refer to Section 2.3 for the register boundary addresses.
14 Chrom-GRC (GFXMMU)

14.1 Introduction

The Chrom-GRC (GFXMMU) is a graphical oriented memory management unit aimed to optimize memory usage according to the display shape.

14.2 GFXMMU main features

- Fully programmable display shape to physically store only the visible pixel
- Up to 4 virtual buffers
- Each virtual buffer have 3072 or 4096 bytes per line and 1024 lines
- Each virtual buffer can be physically mapped to any system memory
- Packing and unpacking operation to store 32-bit pixel data into 24-bit packed
- Interrupt in case of buffer overflow (1 per buffer)
- Interrupt in case of memory transfer error

14.3 GFXMMU functional and architectural description

The GFXMMU is responsible of address resolution to convert the virtual buffer address into the physical buffer address.

14.3.3 Virtual memory

The GFXMMU provides a virtual memory space seen by the system masters. This virtual memory space is divided into four virtual buffers.

Virtual buffer

A virtual buffer is seen by any system master as a continuous memory space representing a virtual frame buffer of 1024 lines.

Each line is divided into 256 12-byte or 16-byte blocks depending on the BS bit of the GFXMMU configuration register (GFXMMU_CR).

When the address translation is enabled setting the address translation enable (ATE) bit of the graphic MMU configuration register (GFXMMU_CR), each line can be configured individually to be mapped onto a physical memory.

Depending on the display shape and size, only the necessary blocks are mapped to a physical memory location. This mapping is done programming the LUT entry for each line:

- The enable of the line
- The number of the first “visible” block
- The number of the last “visible” block
- The address offset of the line within the physical buffer

The “visible” blocks can be arranged in the physical buffer in a continuous way programming the address offset of each line.

The LUT is common to all the buffers i.e. all the buffers have the same “shape”.
Virtual buffer overview

For a frame buffer coded in 32 bpp or 16 bpp, the virtual buffer can be configured to have 12-byte or 16-byte blocks. This results in a virtual frame buffer of 768 x 1024 or 1024 x 1024 pixels for 32 bpp and 1536 x 1024 or 2048 x 1024 for 16 bpp.

For a frame buffer coded in 24 bpp, the virtual buffer must be configured to have 12-byte blocks to have an integer number of pixel per line. This results in a virtual frame buffer of 1024 x 1024 pixels for 24 bpp.

Each buffer can be physically mapped anywhere in the physical memory thanks to:

- The physical buffer base address (PBA) field of the GFXMMU buffer x configuration register (GFXMMU_BxCR). It configures the physical location of the 8-Mbyte area where the buffer is mapped.
- The physical buffer location respective to the physical buffer base address is defined by the physical buffer offset (PBO) field of the GFXMMU buffer x configuration register (GFXMMU_BxCR).
The buffer can not overflow the 8-Mbyte boundary of the zone defined by its base address. In case of overflow, the buffer x overflow flag (BxOF) of the GFXMMU status register (GFXMMU_SR) is set and an interrupt is generated if the buffer x overflow interrupt enable (BxOIE) bit of the GFXMMU configuration register (GFXMMU_CR) is set.

**Virtual buffer application use case**

As the physical locations are independently configurable, the four virtual buffers can be physically mapped to non continuous locations. This would allow for example to have the four buffers mapped on to four different SDRAM banks and avoid extra precharge cycles accessing the SDRAM.

As a consequence, one buffer must be used by the CPU/Graphic accelerator for frame buffer calculation while an other one must be used by the LTDC.

The two remaining buffers can be used as a graphical library requiring extra drawing buffers.

**14.3.4 Packing and unpacking**

When addressing 24bpp frame buffers, the virtual buffer must be configured in 12-byte block mode to have an integer number of pixel per block.
Nevertheless, it is possible to access these 24-bit data as if they where unpacked in a 32-bit word.

The packing mode is enabled, per buffer setting the buffer x packing enable (BxPE) bit of the graphic MMU configuration register (GFXMMU_CR).

When the packing mode is enabled and the 12-byte mode is selected, the access to the buffer are done as in 16-byte mode, but either the most significant byte or the less significant byte is ignored to transform each 32-bit word into a 24-bit word.

The ignored byte is selected with the buffer x packing mode (BxPM) bit of the graphic MMU configuration register (GFXMMU_CR).

During write operation MSB or LSB is ignored. During read operation, the ignored MSB or LSB is replaced by the 8-bit default value programmed in the default alpha (DA) field of the graphic MMU default alpha register (GFXMMU_DAR).

The buffer x packing enable (BxPE) bit has no effect when the graphic MMU is configured in 16-byte block.

14.3.5 MMU architecture

The MMU block is responsible of the address resolution. It receives the 24-bit address and returns the physical 23-bit address and a valid signal to indicate the address is physically mapped or not. The MMU also checks overflow of a area boundary.

The MMU LUT is implemented as a 1024 x 35-bit RAM

![MMU block diagram](image)

**Figure 132. MMU block diagram**

**Line block decoder**

The line block decoder is generating the block number and the line number according the address.
Look up RAM

The look up RAM is a 1024 x 35-bit RAM with the following fields:
- 1-bit line enable
- 8-bit first valid block
- 8-bit last valid block
- 18-bit for line offset

As the RAM is bigger than a word, each entry is split into two words on the memory map. The write access are done in two steps:
1. Write the first word with enable/first valid block/last valid block in the GFXMMU_LUTxL memory location (internally buffered).
2. Write the second word with line offset in the GFXMMU_LUTxH memory location (effective write into the memory together with the internally buffered value).

A write in the LUT can happen any time but it can lead to inconsistencies if a master is using the MMU at the same time. As the CPU has the priority during LUT programming, this may slow down MMU calculation.

There is no restriction during read operations, but this may slow down CPU as the MMU has the priority on LUT accesses.

Block validation/comparator

This block is checking if the block is valid.

A block is considered as valid (physically mapped) when:
- Line is enable.
- The block number is greater or equal to the first valid block.
- The block number is lower or equal to the last valid block.

When the block is valid, the physical address generated is considered as correct.

If the result of the MMU evaluation is not valid, the write operations are ignored, and read operations return the default 32-bit value stored in the default value (DV) field of the GFXMMU default value register (GFXMMU_DVR).

Block offset address calculation within the buffer

The block number is added to the line offset to get the offset of the block within the physical buffer.

As a consequence, the line offset stored in the LUT is given by the following formula:

\[
\text{Line offset} = ([\text{Number of visible blocks already used}] - (1^{\text{st}} \text{ visible block}))
\]

with:
- The maximum value for the line offset is when all the block of all the line are used. As the consequence the line offset for the last line can be maximum: \(1023 \times 256 = 0x3:FF00\)
- The minimum value for the line offset is when the last block of the first line is the first valid block: \(-255 = -0xFF\ i.e\ 0x3:FF01\)

As the consequence the full range of the line offset entry of the LUT is used.
Chrom-GRC (GFXMMU)  

Carry is not taken into account as this stage to be able to perform negative offset calculations (values from 0x3:FF01 to 0x3:FFFF)

As the block offset is within a 4-Mbyte buffer, the address generated is 22-bit wide.

**Block offset address calculation**

Once the offset of the block within the buffer as been calculated, this value is added to the offset of the block respective to the physical buffer base address.

The offset of the blocks are defined in registers as shown in *Figure 133*:

![Figure 133. Block validation/comparator implementation](image)

The resulting address and the buffer offset address must be on 23-bit.

The carry is taken into account to trigger address overflow. The carry is propagated to the GFXMMU status register (GFXMMU_S$) to set the buffer x overflow flag (BxOF).

**Example of calculation**

Consider the following configuration for virtual buffer 0:

- 16-byte block mode
- First visible block of line 0: block 7
- Number of visible block in line 0: 10
- First visible block of line 1: block 6
- Number of visible block in line 1: 12
- Address of the physical buffer: 0xC020:0000

The configuration must be:

- The base address of the physical buffer 0: 0xC000:0000
- The offset of buffer 0: 0x20:0000
- First visible block of line 0: block 7
- Last visible block of line 0: block 16
- Block 0 offset of line 0: (0 - 7) = -0x7 = 0x3:FFF9
- First visible block of line 1: block 6
- Last visible block of line 1: block 17
- Block 0 offset of line 1: (10 - 6) = (0xA - 0x6) = 0x4
As a consequence:
- the physical address of block 7 of line 0 is:
  \[0xC000:0000 + 0x20:0000 + (0x3:FFF9 + 0x7 \text{ without carry}) \times 0x10 = 0xC020:0000\]
- the physical address of block 16 of line 0 is:
  \[0xC000:0000 + 0x20:0000 + (0x3:FFF9 + 0x10 \text{ without carry}) \times 0x10 = 0xC020:0090\]
- the physical address of block 6 of line 1 is:
  \[0xC000:0000 + 0x20:0000 + (0x4 + 0x6 \text{ without carry}) \times 0x10 = 0xC020:00A0\]
- the physical address of block 17 of line 1 is:
  \[0xC000:0000 + 0x20:0000 + (0x4 + 0x11 \text{ without carry}) \times 0x10 = 0xC020:0150\]

For the same example in 12-byte mode, the user has the same configuration regarding the offsets by the addresses are different in the physical buffer:
- the physical address of block 7 of line 0 is:
  \[0xC000:0000 + 0x20:0000 + (0x3:FFF9 + 0x7 \text{ without carry}) \times 0x0C = 0xC020:0000\]
- the physical address of block 16 of line 0 is:
  \[0xC000:0000 + 0x20:0000 + (0x3:FFF9 + 0x10 \text{ without carry}) \times 0x0C = 0xC020:006C\]
- the physical address of block 6 of line 1 is:
  \[0xC000:0000 + 0x20:0000 + (0x4 + 0x6 \text{ without carry}) \times 0x0C = 0xC020:0078\]
- the physical address of block 17 of line 1 is:
  \[0xC000:0000 + 0x20:0000 + (0x4 + 0x11 \text{ without carry}) \times 0x0C = 0xC020:00FC\]

### 14.4 GFXMMU interrupts

An interrupt can be produced on the following events:
- Buffer 0 overflow
- Buffer 1 overflow
- Buffer 2 overflow
- Buffer 3 overflow
- AXI master error

Separate interrupt enable bits are available for flexibility.

<table>

# 14.5 GFXMMU registers

## 14.5.1 GFXMMU configuration register (GFXMMU_CR)

Address offset: 0x0000  
Reset value: 0x0000 0000

| Bit 31 | B3PM: Buffer 3 packing mode  
This bit selects the byte to be removed during packing operations on buffer 3  
0: MSB is removed  
1: LSB is removed  

Bit 30 | B3PE: Buffer 3 packing enable  
This bit enables the packing on buffer 3.  
The packing is functional only if the block size is configured in 12-byte mode. In 16-byte mode, this bit is ignored.  
0: Packing is disabled  
1: Packing is enable  

Bit 29 | B2PM: Buffer 2 packing mode  
This bit selects the byte to be removed during packing operations on buffer 2  
0: MSB is removed  
1: LSB is removed  

Bit 28 | B2PE: Buffer 2 packing enable  
This bit enables the packing on buffer 2.  
The packing is functional only if the block size is configured in 12-byte mode. In 16-byte mode, this bit is ignored.  
0: Packing is disabled  
1: Packing is enable  

Bit 27 | B1PM: Buffer 1 packing mode  
This bit selects the byte to be removed during packing operations on buffer 1  
0: MSB is removed  
1: LSB is removed  

Bit 26 | B1PE: Buffer 1 packing enable  
This bit enables the packing on buffer 1.  
The packing is functional only if the block size is configured in 12-byte mode. In 16-byte mode, this bit is ignored.  
0: Packing is disabled  
1: Packing is enable  

Bit 25 | B0PM: Buffer 0 packing mode  
This bit selects the byte to be removed during packing operations on buffer 0  
0: MSB is removed  
1: LSB is removed |
Bit 24  **B0PE**: Buffer 0 packing enable  
This bit enables the packing on buffer 0.  
The packing is functional only if the block size is configured in 12-byte mode. In 16-byte mode, this bit is ignored.  
0: Packing is disabled  
1: Packing is enable

Bits 23:16  Reserved, must be kept at reset value.

Bit 15  **ATE**: Address translation enable  
This bit enables the address translation based on the values programmed in the LUT.  
0: Address translation is disable  
1: Address translation is enable

Bits 14:7  Reserved, must be kept at reset value.

Bit 6  **BS**: Block size  
This bit defines the size of the blocks  
0: 16-byte blocks  
1: 12-byte blocks

Bit 5  Reserved, must be kept at reset value.

Bit 4  **AMEIE**: AXI master error interrupt enable  
This bit enables the AXI master error interrupt.  
0: Interrupt disable  
1: Interrupt enabled

Bit 3  **B3OIE**: Buffer 3 overflow interrupt enable  
This bit enables the buffer 3 overflow interrupt.  
0: Interrupt disable  
1: Interrupt enabled

Bit 2  **B2OIE**: Buffer 2 overflow interrupt enable  
This bit enables the buffer 2 overflow interrupt.  
0: Interrupt disable  
1: Interrupt enabled

Bit 1  **B1OIE**: Buffer 1 overflow interrupt enable  
This bit enables the buffer 1 overflow interrupt.  
0: Interrupt disable  
1: Interrupt enabled

Bit 0  **B0OIE**: Buffer 0 overflow interrupt enable  
This bit enables the buffer 0 overflow interrupt.  
0: Interrupt disable  
1: Interrupt enabled
14.5.2 **GFXMMU status register (GFXMMU_SR)**

Address offset: 0x0004
Reset value: 0x0000 0000

![Table showing GFXMMU status register](image)

Bits 31:5 Reserved, must be kept at reset value.

- **Bit 4 AMEF**: AXI master error flag
  - This bit is set when an AXI error happens during a transaction. It is cleared by writing 1 to CAMEF.

- **Bit 3 B3OF**: Buffer 3 overflow flag
  - This bit is set when an overflow occurs during the offset calculation of the buffer 3. It is cleared by writing 1 to CB3OF.

- **Bit 2 B2OF**: Buffer 2 overflow flag
  - This bit is set when an overflow occurs during the offset calculation of the buffer 2. It is cleared by writing 1 to CB2OF.

- **Bit 1 B1OF**: Buffer 1 overflow flag
  - This bit is set when an overflow occurs during the offset calculation of the buffer 1. It is cleared by writing 1 to CB1OF.

- **Bit 0 B0OF**: Buffer 0 overflow flag
  - This bit is set when an overflow occurs during the offset calculation of the buffer 0. It is cleared by writing 1 to CB0OF.

14.5.3 **GFXMMU flag clear register (GFXMMU_FCR)**

Address offset: 0x0008
Reset value: 0x0000 0000

![Table showing GFXMMU flag clear register](image)

Bits 31:5 Reserved, must be kept at reset value.

- **Bit 4 CAMEF**: Clear AXI master error flag
  - Writing 1 clears the AXI master error flag in the GFXMMU_SR register.

- **Bit 3 CB3OF**: Clear buffer 3 overflow flag
  - Writing 1 clears the buffer 3 overflow flag in the GFXMMU_SR register.
Bit 2 **CB2OF**: Clear buffer 2 overflow flag
   Writing 1 clears the buffer 2 overflow flag in the GFXMMU_SR register.

Bit 1 **CB1OF**: Clear buffer 1 overflow flag
   Writing 1 clears the buffer 1 overflow flag in the GFXMMU_SR register.

Bit 0 **CB0OF**: Clear buffer 0 overflow flag
   Writing 1 clears the buffer 0 overflow flag in the GFXMMU_SR register.

### 14.5.4 GFXMMU default value register (GFXMMU_DVR)

- **Address offset**: 0x0010
- **Reset value**: 0x0000 0000

15 Chrom-ART Accelerator controller (DMA2D)

15.1 DMA2D introduction

The Chrom-ART Accelerator (DMA2D) is a specialized DMA dedicated to image manipulation. It can perform the following operations:

- Filling a part or the whole of a destination image with a specific color
- Copying a part or the whole of a source image into a part or the whole of a destination image
- Copying a part or the whole of a source image into a part or the whole of a destination image with a pixel format conversion
- Blending a part and/or two complete source images with different pixel format and copy the result into a part or the whole of a destination image with a different color format

All the classical color coding schemes are supported from 4-bit up to 32-bit per pixel with indexed or direct color mode, including block based YCbCr to handle JPEG decoder output. The DMA2D has its own dedicated memories for CLUTs (color look-up tables).

15.2 DMA2D main features

The main DMA2D features are:

- Single AXI master bus architecture
- AHB slave programming interface supporting 8-, 16-, 32-bit accesses (except for CLUT accesses which are 32-bit)
- User-programmable working area size
- User-programmable offset for sources and destination areas expressed in pixels or bytes
- User-programmable sources and destination addresses on the whole memory space
- Up to two sources with blending operation
- Alpha value that can be modified (source value, fixed value, or modulated value)
- User programmable source and destination color format
- Up to 12 color formats supported from 4-bit up to 32-bit per pixel with indirect or direct color coding
- Block based (8x8) YCbCr support with 4:4:4, 4:2:2 and 4:2:0 chroma sub-sampling factors
- 2 internal memories for CLUT storage in indirect color mode
- Automatic CLUT loading or CLUT programming via the CPU
- User programmable CLUT size
- Internal timer to control AXI bandwidth
- 6 operating modes: register-to-memory, memory-to-memory, memory-to-memory with pixel format conversion, memory-to-memory with pixel format conversion and blending, memory-to memory with pixel format conversion, blending and fixed color foreground, and memory-to memory with pixel format conversion, blending and fixed color background.
- Area filling with a fixed color
• Copy from an area to another
• Copy with pixel format conversion between source and destination images
• Copy from two sources with independent color format and blending
• Output buffer byte swapping to support refresh of displays through parallel interface
• Abort and suspend of DMA2D operations
• Watermark interrupt on a user programmable destination line
• Interrupt generation on bus error or access conflict
• Interrupt generation on process completion

15.3 DMA2D functional description

15.3.1 General description

The DMA2D controller performs direct memory transfer. As an AXI master, it can take the control of the AXI bus matrix to initiate AXI transactions.

The DMA2D can operate in the following modes:
• Register-to-memory
• Memory-to-memory
• Memory-to-memory with pixel format conversion
• Memory-to-memory with pixel format conversion and blending
• Memory-to-memory with pixel format conversion, blending and fixed color foreground
• Memory-to-memory with pixel format conversion, blending and fixed color background

The AHB slave port is used to program the DMA2D controller.

The block diagram of the DMA2D is shown in Figure 134.
15.3.2 DMA2D internal signals

The internal signals of the DMA2D are given in the table below:

<table>
<thead>

</tbody>
</table>
15.3.3 DMA2D control

The DMA2D controller is configured through DMA2D_CR. The user application can perform the following operations:

- Select the operating mode.
- Enable/disable the DMA2D interrupt.
- Start/suspend/abort ongoing data transfers.

15.3.4 DMA2D foreground and background FIFOs

The DMA2D foreground (FG) FG FIFO and background (BG) FIFO fetch the input data to be copied and/or processed.

The FIFOs fetch the pixels according to the color format defined in their respective pixel format converter (PFC).

They are programmed through the following control registers:

- DMA2D foreground memory address register (DMA2D_FGMAR)
- DMA2D foreground offset register (DMA2D_FGOR)
- DMA2D background memory address register (DMA2D_BGMAR)
- DMA2D background offset register (DMA2D_BGBOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

When the DMA2D operates in register-to-memory mode, none of the FIFOs is activated.

When the DMA2D operates in memory-to-memory mode (no pixel format conversion nor blending operation), only the FG FIFO is activated, and acts as a buffer.

When the DMA2D operates in memory-to-memory operation with pixel format conversion (no blending operation), the BG FIFO is not activated.

15.3.5 DMA2D foreground and background PFC

DMA2D foreground pixel format converter (PFC) and background pixel format converter perform the pixel format conversion to generate a 32-bit per pixel value. The PFC can also modify the alpha channel.

The first PFC stage converts the color format. The original color format of the foreground and background pixels are configured through CM[3:0] in DMA2D_FGPFCR and DMA2D_BGPFCR, respectively.

The supported input formats are given in the table below.

<table>
<thead>
<tr>
<th>CM[3:0]</th>
<th>Color mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>ARGB8888</td>
</tr>
<tr>
<td>0001</td>
<td>RGB888</td>
</tr>
<tr>
<td>0010</td>
<td>RGB565</td>
</tr>
<tr>
<td>0011</td>
<td>ARGB1555</td>
</tr>
<tr>
<td>0100</td>
<td>ARGB4444</td>
</tr>
<tr>
<td>0101</td>
<td>L8</td>
</tr>
</tbody>
</table>

Table 117. Supported color mode in input
The color format are coded as follows:

- **Alpha value field**: transparency
  - 0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.
- **R field** for Red
- **G field** for Green
- **B field** for Blue
- **L field**: luminance
  - This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format was direct color mode (ARGB/RGB), the extension to 8-bit per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

If the original format is indirect color mode (L/AL), a CLUT is required, and each pixel format converter is associated with a 256 entry 32-bit CLUT.

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and defined in DMA2D_FGCOLR for foreground pixels, and in DMA2D_BGCOLR for background pixels.

The order of the fields in the system memory is defined in the table below.

### Table 117. Supported color mode in input (continued)

<table>
<thead>
<tr>
<th>CM[3:0]</th>
<th>Color mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0110</td>

</tr>
<tr>
<td>1010</td>
<td>A4</td>
</tr>
<tr>
<td>1011</td>
<td>YCbCr (only for foreground)</td>
</tr>
</tbody>
</table>

The color format are coded as follows:

- **Alpha value field**: transparency
  - 0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.
- **R field** for Red
- **G field** for Green
- **B field** for Blue
- **L field**: luminance
  - This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format was direct color mode (ARGB/RGB), the extension to 8-bit per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

If the original format is indirect color mode (L/AL), a CLUT is required, and each pixel format converter is associated with a 256 entry 32-bit CLUT.

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and defined in DMA2D_FGCOLR for foreground pixels, and in DMA2D_BGCOLR for background pixels.

The order of the fields in the system memory is defined in the table below.

### Table 118. Data order in memory

<table>
<thead>
<tr>
<th>Color mode</th>

</tr>
<tr>
<td>L8</td>
<td>L₃[7:0]</td>
<td>L₂[7:0]</td>
<td>L₁[7:0]</td>
<td>L₀[7:0]</td>
</tr>
</tbody>
</table>
The 24-bit RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

Once the 32-bit value is generated, the alpha channel can be modified according to AM[1:0] in DMA2D_FGPFCCR or DMA2D_BGPFCCR, as shown in Table 119.

One of the following happens for the alpha channel:
- It is kept as it is (no modification).
- It is replaced by ALPHA[7:0] value in DMA2D_FGPFCCR/DMA2D_BGPFCCR.
- It is replaced by the original alpha value multiplied by the value in DMA2D_FGPFCCR/DMA2D_BGPFCCR divided by 255.

Table 119. Alpha mode configuration

<td>Replaced by original value multiplied by the value in DMA2D_xxPFCCR / 255</td>
</tr>
<tr>
<td>11</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

Note: To support the alternate format, the incoming alpha value can be inverted setting AI in DMA2D_FGPFCCR or DMA2D_BGPFCCR. This applies also to the Alpha value stored in the DMA2D_FGPFCCR or DMA2D_BGPFCCR, and in the CLUT.

The R and B fields can also be swapped setting RBS in DMA2D_FGPFCCR or DMA2D_BGPFCCR. This applies also to the RGB order used in the CLUT, and in DMA2D_FGCOLOR or DMA2D_BGCOLOR.

15.3.6 DMA2D foreground and background CLUT interface

The CLUT interface manages the CLUT memory access and the automatic loading of the CLUT.

Three kinds of accesses are possible:
- CLUT read by the PFC during pixel format conversion operation
- CLUT accessed through the AHB slave port when the CPU is reading or writing data into the CLUT
- CLUT written through the AXI master port when an automatic loading of the CLUT is performed

The CLUT memory loading can be done in two different ways:
- Automatic loading
  The following sequence must be followed to load the CLUT:
a) Program the CLUT address into DMA2D_FGCMAR (foreground CLUT) or DMA2D_BGCMAR (background CLUT).

b) Program the CLUT size with CS[7:0] field in DMA2D_FGPFCCR (foreground CLUT), or DMA2D_BGPFCCR (background CLUT).

c) Set START in DMA2D_FGPFCCR (foreground CLUT) or DMA2D_BGPFCCR (background CLUT) to start the transfer. During this automatic loading process, the CLUT is not accessible by the CPU. If a conflict occurs, a CLUT access error interrupt is raised assuming CAEIE = 1 in DMA2D_CR.

- Manual loading

The application has to program the CLUT manually through the DMA2D AHB slave port to which the local CLUT memory is mapped. The foreground CLUT (FGCLUT) is located at address offset 0x0400 and the background CLUT (BGCLUT) at address offset 0x0800.

The CLUT format can be 24 or 32 bits. It is configured through CCM in DMA2D_FGPFCCR (foreground CLUT) or DMA2D_BGPFCCR (background CLUT) as shown in table below.

### Table 120. Supported CLUT color mode

<table>
<thead>

</table>
15.3.7 DMA2D blender

The DMA2D blender blends the source pixels by pair to compute the resulting pixel.
The blending is performed according to the following equation:

\[
\alpha_{\text{Mult}} = \frac{\alpha_{\text{FG}} \cdot \alpha_{\text{BG}}}{255}
\]

\[
\alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \alpha_{\text{Mult}}
\]

\[
C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{BG}} \cdot \alpha_{\text{Mult}}}{\alpha_{\text{OUT}}}
\]

with \( C = R \) or \( G \) or \( B \)

Division is rounded to the nearest lower integer

No configuration register is required by the blender. The blender use depends on the DMA2D operating mode defined by \( \text{MODE}[2:0] \) in DMA2D\_CR.

15.3.8 DMA2D output PFC

The output PFC performs the pixel format conversion from 32 bits to the output format defined by \( \text{CM}[2:0] \) in DMA2D\_OPFCCR.

Supported output formats are given in the table below

<table>
<thead>
<tr>
<th>CM[2:0]</th>
<th>Color mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>ARGB8888</td>
</tr>
<tr>
<td>001</td>
<td>RGB888</td>
</tr>
<tr>
<td>010</td>
<td>RGB565</td>
</tr>
<tr>
<td>011</td>
<td>ARGB1555</td>
</tr>
<tr>
<td>100</td>
<td>ARGB4444</td>
</tr>
</tbody>
</table>

Table 122. Supported color mode in output

Note: To support the alternate format, the calculated alpha value can be inverted setting AI bit in DMA2D\_OPFCCR. This applies also to the Alpha value used in DMA2D\_OCOLR. The \( R \) and \( B \) fields can also be swapped setting RBS in DMA2D\_OPFCCR. This applies also to the RGB order used in DMA2D\_OCOLR.

15.3.9 DMA2D output FIFO

The output FIFO programs the pixels according to the color format defined in the output PFC.

The destination area is defined through the following registers:
- DMA2D output memory address register (DMA2D\_OMAR)
- DMA2D output offset register (DMA2D\_OOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D\_NLR)
If the DMA2D operates in register-to-memory mode, the configured output rectangle is filled by the color specified in DMA2D_OCOLR which contains a fixed 32-, 24-, or 16-bit value. The format is selected by CM[2:0] in DMA2D_OPFCCR.

The data are stored into the memory in the order defined in the table below.

### Table 123. Data order in memory

<table>
<thead>
<tr>
<th>Color mode</th>
<th>@ + 3</th>
<th>@ + 2</th>
<th>@ + 1</th>
<th>@ + 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>G₂[7:0]</td>
<td>B₂[7:0]</td>
<td>R₁[7:0]</td>
<td>G₁[7:0]</td>
<td></td>
</tr>
<tr>
<td>R₃[7:0]</td>
<td>G₃[7:0]</td>
<td>B₃[7:0]</td>
<td>R₂[7:0]</td>
<td></td>
</tr>
</tbody>
</table>

The RGB888 aligned on 32 bits is supported through the ARGB8888 mode.

### 15.3.10 DMA2D output FIFO byte reordering

The output FIFO bytes can be reordered to support display frame buffer update through a parallel interface (F(S)MC) directly from the DMA2D.

The reordering of bytes can be done using:
- **RBS** bit to swap red and blue component
- **SB** bit to swap byte two by two in the output FIFO

When the byte swapping is activated (SB = 1 in DMA2D_OPFCR), the number of pixel per line (PL field in DMA2D_NLR) must be even, and the output memory address (MA field in DMA2D_OMAR) must be even. The output line offset computed in bytes (resulting from LOM field in DMA2D_CR and LO field in DMA2D_OOR values) must also be even. If not a configuration error is detected.

### Table 124. Standard data order in memory

<table>
<thead>
<tr>

<td>G₃[7:0]</td>
<td>B₃[7:0]</td>
<td>R₂[7:0]</td>
<td></td>
</tr>
</tbody>
</table>

### 16-bit mode (RGB565)

This mode is supported without byte reordering by the DMA2D.
18/24-bit mode (RGB888)

This mode needs data reordering:
1. The red and the blue have to be swapped (setting the RBS bit).
2. MSB and the LSB bytes of a half-word must be swapped (setting SB bit).

**Table 125. Output FIFO byte reordering steps**

</table>
15.3.11 DMA2D AXI master port timer

An 8-bit timer is embedded into the AXI master port to provide an optional limitation of the bandwidth on the crossbar. This timer is clocked by the AXI clock and counts a dead time between two consecutive accesses. This limits the bandwidth usage.

The timer enabling and dead time value are configured through DMA2D_AMPTCR.

15.3.12 DMA2D transactions

DMA2D transactions consist of a sequence of a given number of data transfers. Number of data and width can be programmed by software.

Each DMA2D data transfer is composed of up to four steps:
1. Data loading from the memory location pointed by DMA2D_FGMAR and pixel format conversion as defined in DMA2D_FGCR
2. Data loading from a memory location pointed by DMA2D_BGMAR and pixel format conversion as defined in DMA2D_BGCR
3. Blending of all retrieved pixels according to the alpha channels resulting of PFC operation on alpha values
4. Pixel format conversion of resulting pixels according to DMA2D_OCR and programming of data to the memory location addressed through DMA2D_OMAR

15.3.13 DMA2D configuration

Both source and destination data transfers can target peripherals and memories in the whole 4-Byte memory area, at addresses ranging between 0x0000 0000 and 0xFFFF FFFF.

The DMA2D can operate in any of the following modes selected through MODE[2:0] in DMA2D_CR: 
- Register-to-memory
- Memory-to-memory
- Memory-to-memory with PFC
- Memory-to-memory with PFC and blending
- Memory-to-memory with PFC, blending and fixed FG color
- Memory-to-memory with PFC, blending and fixed BG color

Register-to-memory

The register-to-memory mode is used to fill a user defined area with a predefined color. The color format is set in DMA2D_OPFCCR.

Table 125. Output FIFO byte reordering steps (continued)

</table>
The DMA2D does not perform any data fetching from any source. It just writes the color defined in DMA2D_OCOLR to the area located at the address pointed by DMA2D_OMAR and defined in DMA2D_NLR and DMA2D_OOR.

**Memory-to-memory**

In memory-to-memory mode, the DMA2D does not perform any graphical data transformation. The foreground input FIFO acts as a buffer, and data are transferred from the source memory location defined in DMA2D_FGMAR, to the destination memory location pointed by DMA2D_OMAR.

The color mode programmed by CM[3:0] in DMA2D_FGPFCR defines the number of bits per pixel for both input and output.

The size of the area to be transferred is defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.

**Memory-to-memory with PFC**

In this mode, the DMA2D performs a pixel format conversion of the source data, and stores them in the destination memory location.

The size of the areas to be transferred are defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.

Data are fetched from the location defined in DMA2D_FGMAR, and processed by the foreground PFC. The original pixel format is configured through DMA2D_FGPFCR.

If the original pixel format is direct-color mode, the color channels are all expanded to 8 bits.

If the pixel format is indirect color mode, the associated CLUT has to be loaded into the CLUT memory.

The CLUT loading can be done automatically by following the sequence below:

1. Set the CLUT address into DMA2D_FGCMAR.
2. Set the CLUT size with CS[7:0] in DMA2D_FGPFCR.
3. Set the CLUT format (24 or 32 bits) with CCM in DMA2D_FGPFCR.
4. Start the CLUT loading by setting START in DMA2D_FGPFCR.

Once the CLUT loading is complete, CTCIF flag in DMA2D_IFR is raised, and an interrupt is generated if CTCIE is set in DMA2D_CR. The automatic CLUT loading process cannot work in parallel with classical DMA2D transfers.

The CLUT can also be filled by the CPU or by any other master through the AHB port. The access to the CLUT is not possible when a DMA2D transfer is ongoing, and uses the CLUT (indirect color format).

In parallel to the color conversion process, the alpha value can be added or changed depending on the value programmed in DMA2D_FGPFCR. If the original image does not have an alpha channel, a default alpha value of 0xFF is automatically added to obtain a fully opaque pixel.

The alpha value is modified as follows according to AM[1:0] in DMA2D_FGPFCR:

- It is unchanged.
- It is replaced by ALPHA[7:0] value in DMA2D_FGPFCR.
- It is replaced by the original value multiplied by ALPHA[7:0] value in DMA2D_FGPFCR divided by 255.
The resulting 32-bit data are encoded by the output PFC into the format specified by CM[2:0] in DMA2D_OPFCCR. The output pixel format cannot be the indirect mode since no CLUT generation process is supported.

Processed data are written into destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC and blending**

In this mode, two sources are fetched in the foreground and background FIFOs from the memory locations defined by DMA2D_FGMAR and DMA2D_BGMAR respectively.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory.

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended according to the equation below:

$$\alpha_{OUT} = \alpha_{FG} + \alpha_{BG} - \alpha_{Mult}$$

$$C_{OUT} = \frac{C_{FG}\alpha_{FG} + C_{BG}\alpha_{BG} - C_{BG}\alpha_{Mult}}{\alpha_{OUT}}$$

with $\alpha = \text{R or G or B}$

Division are rounded to the nearest lower integer

The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and data are written into the destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC, blending and fixed color FG**

In this mode, only one source is fetched in the background FIFO from the memory location defined by DMA2D_BGMAR.

The value of the foreground color is given by DMA2D_FGCOLR, and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_FGPFCCR.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory.

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended together. The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format. Data are written into the destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC, blending and fixed color BG**

In this mode, only open source is fetched in the foreground FIFO from the memory location defined by DMA2D_FGMAR.
The value of the background color is given by DMA2D_BGCOLR, and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_BGPFCR.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory.

Once each pixel has been converted into 32 bits by their respective PFCs, all pixels are blended together. The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format. Data are written into the destination memory location pointed by DMA2D_OMAR.

Configuration error detection

The DMA2D checks that the configuration is correct before any transfer. The configuration error interrupt flag is set by hardware when a wrong configuration is detected when a new transfer/automatic loading starts. An interrupt is then generated if CEIE = 1 in DMA2D_CR.

The wrong configurations that can be detected are listed below:

- Foreground CLUT automatic loading: MA bits in DMA2D_FGCMAR are not aligned with CCM in DMA2D_FGPFCR.
- Background CLUT automatic loading: MA bits in DMA2D_BGCMAR are not aligned with CCM in DMA2D_BGPFCR.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): MA bits in DMA2D_FGMAR are not aligned with CM in DMA2D_FGPFCR.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): CM bits in DMA2D_FGPFCR are invalid.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): PL bits in DMA2D_NLR are odd while CM is DMA2D_FGPFCR is A4 or L4.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): LO bits in DMA2D_FGOR are odd while CM in DMA2D_FGPFCR is A4 or L4, and LOM in DMA2D_CR is pixel mode.
- Memory transfer (only in blending mode, except in memory-to-memory with blending and fixed color FG): MA bits in DMA2D_BGMAR are not aligned with the CM in DMA2D_BGPFCR.
- Memory transfer (only in blending and blending with fixed color FG): CM bits in DMA2D_BGPFCR are invalid.
- Memory transfer (only in blending and blending with fixed color FG mode): PL bits in DMA2D_NLR odd while CM in DMA2D_BGPFCR is A4 or L4.
- Memory transfer (only in blending and blending with fixed color FG): LO bits in DMA2D_BGOR are odd while CM in DMA2D_BGPFCR is A4 or L4, and LOM in DMA2D_CR is pixel mode.
- Memory transfer (except in memory-to-memory): MA bits in DMA2D_OMAR are not aligned with CM in DMA2D_OPFCCR.
- Memory transfer (except in memory-to-memory): CM bits in DMA2D_OPFCCR are invalid.
• Memory transfer with byte swapping: PL bits in DMA2D_NLR are odd, or MA bits in DMA2D_OMAR are odd, or LO in bytes (resulting from LOM in DMA2D_CR and LO in DMA2D_OOR) are odd while SB = 1 in DMA2D_OPFCCR.

• Memory transfer: NL bits in DMA2D_NLR are all zeros.

• Memory transfer: PL bits in DMA2D_NLR are all zeros.

• Memory transfer: MODE bits in DMA2D_CR are invalid.

• YCbCr format: when a CLUT loading starts setting START in DMA2D_FGPFCCR

• YCbCr format: when memory-to-memory mode is selected

• YCbCr format: when YCbCr4:4:4 is selected, and the sum of number of pixel (PL) and line offset LO is not a multiple of 8 pixels

• YCbCr format: when YCbCr4:2:2 or YCbCr4:2:0 is selected, and the sum of number of pixel (PL) and line offset LO is not a multiple of 16 pixels

15.3.14 YCbCr support

The DMA2D foreground plane can support 8x8 block-based YCbCr as output by the JPEG decoder with different chroma subsampling factors.

The memory organization follows the standard JFIF rules:
• Each of the three color components must be coded on 8-bit.
• Each component must be arranged by blocks of 8x8 (64 bytes) called MCU.

Depending of the chroma subsampling factor, the MCU must be arranged in the memory as described in the table below.

<table>
<thead>
<tr>
<th>Sub-sampling</th>
<th>@</th>
<th>@ + 64</th>
<th>@ + 128</th>
<th>@ +192</th>
<th>@+256</th>
<th>@ + 320</th>
</tr>
</thead>
<tbody>
<tr>
<td>4:4:4</td>
<td>Y1</td>
<td>Cb1</td>
<td>Cr1</td>
<td>Y2</td>
<td>Cb2</td>
<td>Cr2</td>
</tr>
<tr>
<td>4:2:2</td>
<td>Y1</td>
<td>Y2</td>
<td>Cb12</td>
<td>Cr12</td>
<td>Y3</td>
<td>Y4</td>
</tr>
<tr>
<td>4:2:0</td>
<td>Y1</td>
<td>Y2</td>
<td>Y3</td>
<td>Y4</td>
<td>Cb1234</td>
<td>Cr1234</td>
</tr>
</tbody>
</table>

The chroma subsampling factor is configured through CSS in DMA2D_FGPFCCR.

Once the DMA2D has started with the foreground configured in YCbCr color mode, the first two chroma MCUs are loaded in the foreground CLUT. Once the chroma MCUs are loaded, the DMA2D performs the loading of the Y MCU as for a classical color mode.

15.3.15 DMA2D transfer control (start, suspend, abort, and completion)

Once the DMA2D is configured, the transfer can be launched by setting START in DMA2D_CR. Once the transfer is completed, START is automatically reset, and TCIF flag is raised in DMA2D_ISR. An interrupt can be generated if TCIE is set in DMA2D_CR.

The user application can suspend the DMA2D at any time by setting SUSP in DMA2D_CR. The transaction can be aborted by setting ABORT in DMA2D_CR, or can be restarted by resetting SUSP in DMA2D_CR.

The user application can abort at any time an ongoing transaction by setting ABORT in DMA2D_CR. In this case, the TCIF flag is not raised.
Automatic CLUT transfers can also be aborted or suspended by using their own START bits in DMA2D_FGPFCCR and DMA2D_BGPFCCR.

### 15.3.16 Watermark

A watermark can be programmed to generate an interrupt when the last pixel of a given line has been written to the destination memory area.

The line number is defined in LW[15:0] in DMA2D_LWR.

When the last pixel of this line has been transferred, TWIF flag is raised in DMA2D_ISR, and an interrupt is generated if TWIE is set in DMA2D_CR.

### 15.3.17 Error management

Two kinds of errors can be triggered:

- AXI master port errors signaled by TEIF flag in DMA2D_ISR
- Conflicts caused by CLUT access (CPU trying to access the CLUT while a CLUT loading or a DMA2D transfer is ongoing) signaled by CAEIF flag in DMA2D_ISR

Both flags are associated to their own interrupt enable flag in DMA2D_CR to generate an interrupt if need be (TEIE and CAEIE).

### 15.3.18 AXI dead time

To limit the AXI bandwidth use, a dead time between two consecutive AXI accesses can be programmed. This feature can be enabled by setting EN in DMA2D_AMTCR.

The dead-time value is stored in DT[7:0] in DMA2D_AMTCR. This value represents the guaranteed minimum number of cycles between two consecutive transactions on AXI bus.

The update of the dead-time value while the DMA2D is running is taken into account for the next AXI transfer.

### 15.4 DMA2D interrupts

An interrupt can be generated on the following events:

- Configuration error
- CLUT transfer complete
- CLUT access error
- Transfer watermark reached
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

Table 127. DMA2D interrupt requests (continued)

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **MODE[2:0]:** DMA2D mode

This bit is set and cleared by software. It cannot be modified while a transfer is ongoing.

000: Memory-to-memory (FG fetch only)
001: Memory-to-memory with PFC (FG fetch only with FG PFC active)
010: Memory-to-memory with blending (FG and BG fetch with PFC and blending)
011: Register-to-memory (no FG nor BG, only output stage active)
100: Memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active)
101: Memory-to-memory with blending and fixed color BG (FG fetch only with FG and BG PFC active)
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **CEIE:** Configuration error (CE) interrupt enable

This bit is set and cleared by software.
0: CE interrupt disabled
1: CE interrupt enabled

Bit 12 **CTCIE:** CLUT transfer complete (CTC) interrupt enable

This bit is set and cleared by software.
0: CTC interrupt disabled
1: CTC interrupt enabled
Bit 11 **CAEIE**: CLUT access error (CAE) interrupt enable  
This bit is set and cleared by software.  
0: CAE interrupt disabled  
1: CAE interrupt enabled

Bit 10 **TWIE**: Transfer watermark (TW) interrupt enable  
This bit is set and cleared by software.  
0: TW interrupt disabled  
1: TW interrupt enabled

Bit 9 **TCIE**: Transfer complete (TC) interrupt enable  
This bit is set and cleared by software.  
0: TC interrupt disabled  
1: TC interrupt enabled

Bit 8 **TEIE**: Transfer error (TE) interrupt enable  
This bit is set and cleared by software.  
0: TE interrupt disabled  
1: TE interrupt enabled

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LOM**: Line offset mode  
This bit configures how the line offset is expressed (pixels or bytes) for the foreground, background and output.  
This bit is set and cleared by software. It can not be modified while a transfer is ongoing.  
0: Line offsets expressed in pixels  
1: Line offsets expressed in bytes

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **ABORT**: Abort  
This bit can be used to abort the current transfer. This bit is set by software, and is automatically reset by hardware when START = 0.  
0: No transfer abort requested  
1: Transfer abort requested

Bit 1 **SUSP**: Suspend  
This bit can be used to suspend the current transfer. This bit is set and reset by software. It is automatically reset by hardware when START = 0.  
0: Transfer not suspended  
1: Transfer suspended

Bit 0 **START**: Start  
This bit can be used to launch the DMA2D according to parameters loaded in the various configuration registers. This bit is automatically reset by the following events:  
– at the end of the transfer  
– when the data transfer is aborted by the user by setting ABORT in this register  
– when a data transfer error occurs  
– when the data transfer has not started due to a configuration error, or another transfer operation already ongoing (automatic CLUT loading)
15.5.2 DMA2D interrupt status register (DMA2D_ISR)

Address offset: 0x004
Reset value: 0x0000 0000

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CEIF**: Configuration error interrupt flag
This bit is set when START is set in DMA2D_CR, DMA2DFGPFCCR or DMA2D_BGPFCR, and a wrong configuration has been programmed.

Bit 4 **CTCIF**: CLUT transfer complete interrupt flag
This bit is set when the CLUT copy from a system memory area to the internal DMA2D memory is complete.

Bit 3 **CAEIF**: CLUT access error interrupt flag
This bit is set when the CPU accesses the CLUT while the CLUT is being automatically copied from a system memory to the internal DMA2D.

Bit 2 **TWIF**: Transfer watermark interrupt flag
This bit is set when the last pixel of the watermarked line has been transferred.

Bit 1 **TCIF**: Transfer complete interrupt flag
This bit is set when a DMA2D transfer operation is complete (data transfer only).

Bit 0 **TEIF**: Transfer error interrupt flag
This bit is set when an error occurs during a DMA transfer (data transfer or automatic CLUT loading).

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CCEIF**: Clear configuration error interrupt flag
Programming this bit to 1 clears the CEIF flag in DMA2D_ISR.
Bit 4 **CCTCIF**: Clear CLUT transfer complete interrupt flag  
Programming this bit to 1 clears the CTCIF flag in DMA2D_ISR.

Bit 3 **CAECIF**: Clear CLUT access error interrupt flag  
Programming this bit to 1 clears the CAEIF flag in DMA2D_ISR.

Bit 2 **CTWIF**: Clear transfer watermark interrupt flag  
Programming this bit to 1 clears the TWIF flag in DMA2D_ISR.

Bit 1 **CTCIF**: Clear transfer complete interrupt flag  
Programming this bit to 1 clears the TCIF flag in DMA2D_ISR.

Bit 0 **CTEIF**: Clear transfer error interrupt flag  
Programming this bit to 1 clears the TEIF flag in DMA2D_ISR.

### 15.5.4 DMA2D foreground memory address register (DMA2D_FGMAR)

Address offset: 0x00C  
Reset value: 0x0000 0000  
This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

LO[15:0]
```

Bits 31:16 Reserved, must be kept at reset value.
15.5.6 DMA2D background memory address register (DMA2D_BGMAR)

Address offset: 0x014
Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

Bits 15:0 LO[15:0]: Line offset
This field gives the line offset used for the foreground image, expressed:
– in pixels when LOM = 0 in DMA2D_CR. Only LO[13:0] bits are considered, LO[15:14] bits are ignored.
– in bytes when LOM = 1
This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.
If the image format is 4-bit per pixel, the line offset must be even.

Bits 31:0 MA[31:0]: Memory address, address of the data used for the background image
The address alignment must match the image format selected: a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

15.5.7 DMA2D background offset register (DMA2D_BGOR)

Address offset: 0x018
Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

Bits 31:16 Reserved, must be kept at reset value.
15.5.8 DMA2D foreground PFC control register (DMA2D_FGPFCCR)

Address offset: 0x01C
Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

</table>

Bits 31:24 **ALPHA[7:0]:** Alpha value
These bits define a fixed alpha channel value which can replace the original alpha value, or be multiplied by the original alpha value, according to the alpha mode selected through AM[1:0] in this register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RBS:** Red/Blue swap
This bit allows to swap Red and Blue to support BGR or ABGR color formats.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 **AI:** Alpha inverted
This bit inverts the alpha value.
0: Regular alpha
1: Inverted alpha

Bits 19:18 **CSS[1:0]:** Chroma subsampling
These bits define the chroma subsampling mode for YCbCr color mode.
00: 4:4:4 (no chroma subsampling)
01: 4:2:2
10: 4:2:0
Others: Reserved
Bits 17:16  AM[1:0]: Alpha mode
   These bits select the alpha channel value to be used for the foreground image.
   00: No modification of the foreground image alpha channel value
   01: Replace original foreground image alpha channel value by ALPHA[7:0]
   10: Replace original foreground image alpha channel value by ALPHA[7:0] multiplied with
       original alpha channel value
   Others: Reserved

Bits 15:8  CS[7:0]: CLUT size
   These bits define the size of the CLUT used for the foreground image.
   The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6  Reserved, must be kept at reset value.

Bit 5  START: Start
   This bit can be set to start the automatic loading of the CLUT. It is automatically reset:
   – at the end of the transfer
   – when the transfer is aborted by the user by setting ABORT in DMA2D_CR
   – when a transfer error occurs
   – when the transfer has not started due to a configuration error or another transfer
     operation already ongoing (data transfer or automatic background CLUT transfer)

Bit 4  CCM: CLUT color mode
   This bit defines the color format of the CLUT.
   0: ARGB8888
   1: RGB888

Bits 3:0  CM[3:0]: Color mode
   These bits define the color format of the foreground image.
   0000: ARGB8888
   0001: RGB888
   0010: RGB565
   0011: ARGB1555
   0100: ARGB4444
   0101: L8
   0110: AL44
   0111: AL88
   1000: L4
   1001: A8
   1010: A4
   1011: YCbCr
   Others: Reserved
15.5.9 DMA2D foreground color register (DMA2D_FGCOLR)

Address offset: 0x020
Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

GREEN[7:0] BLUE[7:0]

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 RED[7:0]: Red value for the A4 or A8 mode of the foreground image
Used also for fixed color FG in memory-to-memory mode with blending and fixed color FG (BG fetch only with FG and BG PFC active).

Bits 15:8 GREEN[7:0]: Green value for the A4 or A8 mode of the foreground image
Used also for fixed color FG in memory-to-memory mode with blending and fixed color FG (BG fetch only with FG and BG PFC active).

Bits 7:0 BLUE[7:0]: Blue value for the A4 or A8 mode of the foreground image
Used also for fixed color FG in memory-to-memory mode with blending and fixed color FG (BG fetch only with FG and BG PFC active).

15.5.10 DMA2D background PFC control register (DMA2D_BGPFCCR)

Address offset: 0x024
Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

CS[7:0] START CCM CM[3:0]

Bits 31:24 ALPHA[7:0]: Alpha value
These bits define a fixed alpha channel value which can replace the original alpha value, or be multiplied with the original alpha value according to the alpha mode selected with AM[1:0].

Bits 23:22 Reserved, must be kept at reset value.
Bit 21  **RBS**: Red/Blue swap  
This bit allows to swap Red and Blue to support BGR or ABGR color formats.  
0: Regular mode (RGB or ARGB)  
1: Swap mode (BGR or ABGR)  

Bit 20  **AI**: Alpha Inverted  
This bit inverts the alpha value.  
0: Regular alpha  
1: Inverted alpha  

Bits 19:18  Reserved, must be kept at reset value.  

Bits 17:16  **AM[1:0]**: Alpha mode  
These bits define which alpha channel value to be used for the background image.  
00: No modification of the foreground image alpha channel value  
01: Replace original background image alpha channel value by ALPHA[7:0]  
10: Replace original background image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value  
Others: Reserved  

Bits 15:8  **CS[7:0]**: CLUT size  
These bits define the size of the CLUT used for the BG.  
The number of CLUT entries is equal to CS[7:0] + 1.  

Bits 7:6  Reserved, must be kept at reset value.  

Bit 5  **START**: Start  
This bit is set to start the automatic loading of the CLUT. This bit is automatically reset:  
– at the end of the transfer  
– when the transfer is aborted by the user by setting ABORT bit in DMA2D_CR  
– when a transfer error occurs  
– when the transfer has not started due to a configuration error or another transfer operation already on going (data transfer or automatic background CLUT transfer)  

Bit 4  **CCM**: CLUT color mode  
These bits define the color format of the CLUT.  
0: ARGB8888  
1: RGB888  

Bits 3:0  **CM[3:0]**: Color mode  
These bits define the color format of the foreground image.  
0000: ARGB8888  
0001: RGB888  
0010: RGB565  
0011: ARGB1555

Bits 31:24 Reserved, must be kept at reset value.
Bits 23:16 **RED[7:0]**: Red value for the A4 or A8 mode of the background
Used also for fixed color BG in memory-to-memory mode with blending and fixed color BG (FG fetch only with FG and BG PFC active).

Bits 15:8 **GREEN[7:0]**: Green value for the A4 or A8 mode of the background
Used also for fixed color BG in memory-to-memory mode with blending and fixed color BG (FG fetch only with FG and BG PFC active).

Bits 7:0 **BLUE[7:0]**: Blue value for the A4 or A8 mode of the background
Used also for fixed color BG in memory-to-memory mode with blending and fixed color BG (FG fetch only with FG and BG PFC active).

15.5.12 DMA2D foreground CLUT memory address register (DMA2D_FGCMAR)

Address offset: 0x02C
Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

Bits 31:0 **MA[31:0]**: Memory address
Address of the data used for the CLUT address dedicated to the foreground image.
If the foreground CLUT format is 32-bit, the address must be 32-bit aligned.
15.5.13 DMA2D background CLUT memory address register (DMA2D_BGCMAR)

Address offset: 0x030
Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

Bits 31:0 **MA[31:0]**: Memory address
Address of the data used for the CLUT address dedicated to the background image.
If the background CLUT format is 32-bit, the address must be 32-bit aligned.

15.5.14 DMA2D output PFC control register (DMA2D_OPFCCR)

Address offset: 0x034
Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red/Blue swap
This bit allows to swap Red and Blue to support BGR or ABGR color formats.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted
This bit inverts the alpha value.
0: Regular alpha
1: Inverted alpha

Bits 19:9 Reserved, must be kept at reset value.
Bit 8  **SB**: Swap bytes  
When this bit is set, the bytes in the output FIFO are swapped two by two. The number of pixels per line (PL) must be even, and the output memory address (OMAR) must be even.  
0: Bytes in regular order in the output FIFO  
1: Bytes swapped two by two in the output FIFO  

Bits 7:3  Reserved, must be kept at reset value.  

Bits 2:0  **CM[2:0]**: Color mode  
These bits define the color format of the output image.  
000: ARGB8888  
001: RGB888  
010: RGB565  
011: ARG8155  
100: ARGB4444  
Others: Reserved  

### 15.5.15 DMA2D output color register (DMA2D_OCOLR)

Address offset: 0x038  
Reset value: 0x0000 0000  
The same register is used to show the color values, with different formats depending on the color mode.  
This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.  

**ARGB8888 or RGB888 color mode**

Bits 14:10 RED[4:0]: Red value of the output image in ARGB1555 mode

Bits 9:5 GREEN[4:0]: Green value of the output image in ARGB1555 mode

Bits 4:0 BLUE[4:0]: Blue value of the output image in ARGB1555 mode
15.5.18 DMA2D output color register [alternate] (DMA2D_OCOLR)

Address offset: 0x038
Reset value: 0x0000 0000

The same register is used to show the color values, with different formats depending on the color mode.

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

ARGB4444 color mode

15.5.19 DMA2D output memory address register (DMA2D_OMAR)

Address offset: 0x03C
Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.
15.5.20 DMA2D output offset register (DMA2D_OOR)

Address offset: 0x040
Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

LO[15:0]

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 LO[15:0]: Line offset

This field gives the line offset used for the output, expressed:

- in pixels when LOM = 0 in DMA2D_CR. Only LO[13:0] bits are considered, LO[15:14] bits are ignored.
- in bytes when LOM = 1

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

15.5.21 DMA2D number of line register (DMA2D_NLR)

Address offset: 0x044
Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

PL[13:0]

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:16 PL[13:0]: Pixel per lines per lines of the area to be transferred
If any of the input image format is 4-bit per pixel, pixel per lines must be even.

Bits 15:0 NL[15:0]: Number of lines of the area to be transferred.
### 15.5.22 DMA2D line watermark register (DMA2D_LWR)

Address offset: 0x048

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

16 Neo-Chrom graphic processor (GPU2D)

16.1 GPU2D introduction

The GPU2D is a dedicated graphics processing unit accelerating numerous 2.5D graphics applications such as graphical user interface (GUI), menu display or animations.

The GPU2D works together with an optimized software stack designed for state of the art graphic rendering.

16.2 GPU2D main features

Main features
- Multi-threaded fragment (pixel) processing core with a VLIW (very-long instruction word) instruction set
- Fixed point functional units
- Command list based DMAs to minimize CPU overhead
- Two 64-bit AXI master interfaces for texture and framebuffer access
- Dedicated 64-bit AXI master interface for command list
- 32-bit AHB slave interface for register bank access
- Up to 4 general-purpose flags for system-level synchronization
- Texture decompression unit with TSC™4 and TSC™6/TSC™6a support

2D drawing features
- Pixel/line drawing
- Filled rectangles
- Triangles, quadrilateral drawing
- Anti-aliasing 8xMSAA (multi-sample anti-aliasing)

Image transformations
- 3D perspective correct projections
- Texture mapping with bilinear filtering or point sampling

Blit support
- Rotation, mirroring, stretching (independently on x and y axis)
- Source and/or destination color keying
- Pixel format conversions

Text rendering support
- A1, A2, A4, and A8 bitmap anti-aliased
- Subsampled anti-aliased
Color formats
- ABGR8888, ARGB8888, BGRA8888, RGBA8888
- xBGR8888, xRGB8888, BGRx8888, RGBx8888, RGB888, BGR888
- BGR565, RGB565
- RGB322, BGR322
- TSC4, TSC6, TSC6A
- L1, L2, L4, L8 (grayscale)
- A1, A2, A4, A8

Full alpha blending with hardware blender
- Programmable blending modes
- Source/destination color keying

16.3 GPU2D general description

17 Texture cache (ICACHE)

17.1 ICACHE introduction

The texture cache (ICACHE) is introduced on the AXI read-only texture port of the GPU to improve performance when reading texture data from internal and external memories.

The texture cache is an assembly of ICACHE (a peripheral with AHB ports) and an AXI-to-AHB bus bridge plugged on ICACHE AHB slave port, providing an AXI interface on the texture cache slave port.

The following sections only describe the AHB ICACHE peripheral itself.

Some specific features like hit-under-miss, and critical-word-first refill policy, allow close to zero-wait-state performance in most use cases.

17.2 ICACHE main features

The main features of ICACHE are described below:

- **Bus interface**
  - One 64-bit AHB slave port, the read port (input from GPU texture read interface)
  - One 64-bit AHB master port: master1 port (output to texture bus of main AXI/AHB bus matrix)
  - One 32-bit AHB slave port for control (input from AHB peripherals interconnect, for ICACHE registers access)

- **Cache access**
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Optimal cache line refill thanks to WRAPw bursts of the size of the cache line (32-bit word size, w, aligned on cache line size)
  - n-way set-associative default configuration with possibility to configure as 1-way, means direct mapped cache, for applications needing very-low-power consumption profile

- **the Replacement and refill**
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Critical-word-first refill policy, minimizing processor stalls

- **Performance counters**
  The ICACHE implements two performance counters:
  - Hit monitor counter (32-bit)
  - Miss monitor counter (16-bit)

- **Error management**
  - Possibility to detect an unexpected cacheable write access, to flag an error and optionally to raise an interrupt

- **Maintenance operation**
  - Cache invalidate: full cache invalidation, fast command, noninterruptible
17.3 ICACHE implementation

The purpose of the texture cache is to cache GPU read accesses to texture data. As such, the ICACHE only manages cacheable read transactions and does not manage cacheable write transactions.

The noncacheable transactions (both read and write ones) bypass the ICACHE.

For the error management purpose, in case a write cacheable transaction is presented (this only happens in case of bad software programming), the ICACHE sets an error flag and, if enabled, raises an interrupt to the processor.

17.4 ICACHE functional description

The purpose of the texture cache is to cache GPU read accesses to texture data. As such, the ICACHE only manages cacheable read transactions and does not manage cacheable write transactions.

The noncacheable transactions (both read and write ones) bypass the ICACHE.

For the error management purpose, in case a write cacheable transaction is presented (this only happens in case of bad software programming), the ICACHE sets an error flag and, if enabled, raises an interrupt to the processor.

</tbody>
</table>
17.4.1 ICACHE block diagram

Figure 138. ICACHE block diagram

17.4.2 ICACHE reset and clocks

The ICACHE is clocked on the texture AHB bus clock.

When the ICACHE reset signal is released, a cache invalidate procedure is automatically launched, making the ICACHE busy (ICACHE_SR = 0x0000 0001).

When this procedure is finished:

- the ICACHE is invalidated: “cold cache”, with all cache line valid bits = 0 (ICACHE must be filled up)
- ICACHE_SR = 0x0000 0002 (reflecting the cache is no longer busy)
- the ICACHE is disabled: the EN bit in ICACHE_CR holds its reset state (=0).

Note: When disabled, the ICACHE is bypassed: slave input requests are just forwarded to the master port.
17.4.3 ICACHE TAG memory

The ICACHE TAG memory contains:
- address tags that indicate which data are contained in the cache data memories
- validity bits

There is one valid bit per cache line (per way).

The valid bit is set when a cache line is refilled (after a miss).

Valid bits are reset in any of the below cases:
- after the ICACHE reset is released
- when the cache is disabled, by setting EN = 0 in ICACHE_CR (by software)
- when executing an ICACHE invalidate command, by setting CACHEINV = 1 in ICACHE_CR (by software)

When a cacheable transaction is received at the execution input port, its AHB address (HADDR_in) is split into the following fields (see Table 132 for B and W definitions):
- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to the TAG memory address to check if the requested data is already available (meaning valid) inside the ICACHE.

The following table gives a summary of the ICACHE main parameters for TAG memory dimensioning. Figure 139 shows the functional view of TAG and data memories, for an n-way set associative ICACHE.

Table 132. TAG memory dimensioning parameters for n-way set associative operating mode (default)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache size</td>
<td>S Kbytes = s bytes (s = 1024 x S)</td>
<td>8 Kbytes = 8192 bytes</td>
</tr>
<tr>

<td>n</td>
<td>2</td>
</tr>
<tr>
<td>Cache line size</td>
<td>L-byte = l-bit (l = 8 x L)</td>
<td>16-byte = 128-bit</td>
</tr>
<tr>
<td>Number of cache lines (per way)</td>
<td>LpW = s / (n x L) lines / way</td>
<td>256 lines / way</td>
</tr>
<tr>
<td>Address byte offset size</td>
<td>B = log2(L) bit</td>
<td>4-bit</td>
</tr>
<tr>
<td>Address way index size</td>
<td>W = log2(LpW) bit</td>
<td>8-bit</td>
</tr>
<tr>
<td>TAG address size</td>
<td>T = (32 - W - B) bit</td>
<td>20-bit</td>
</tr>
</tbody>
</table>
17.4.4 Direct-mapped ICACHE (1-way cache)

The default configuration (at reset) is an n-way set associative cache (WAYSEL = 1 in ICACHE_CR), but the user can configure the ICACHE as direct mapped by writing WAYSEL = 0 (only possible when the cache is disabled, EN = 0 in ICACHE_CR).

The following table gives a summary of ICACHE main parameters for TAG memory when the direct-mapped cache operating mode is selected.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache size</td>
<td>$S$ Kbytes $= s$ bytes ($s = 1024 \times S$)</td>
<td>8 Kbytes = 8192 bytes</td>
</tr>
<tr>
<td>Cache number of ways</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Cache line size</td>
<td>$L$-byte $= l$-bit ($l = 8 \times L$)</td>
<td>16-byte $= 128$-bit</td>
</tr>
<tr>
<td>Number of cache lines</td>
<td>$LpW = s / L$ lines</td>
<td>512 lines</td>
</tr>
<tr>
<td>Address byte offset size</td>
<td>$B = \log_2(L)$ bit</td>
<td>4-bit</td>
</tr>
<tr>
<td>Address way index size</td>
<td>$W = \log_2(LpW)$ bit</td>
<td>9-bit</td>
</tr>
<tr>
<td>TAG address size</td>
<td>$T = (32 - W - B)$ bit</td>
<td>19-bit</td>
</tr>
</tbody>
</table>
All cache operations (such as read, refill, invalidation) remain the same in the direct-mapped configuration. The only difference is the absence of a replacement algorithm in case of line eviction (as explained in Section 17.4.7): only one way (the unique one) is possible for any data refill.

### 17.4.5 ICACHE enable

To activate the ICACHE, the EN bit must be set to 1 in ICACHE_CR.

When the ICACHE is disabled, it is bypassed and all transactions are copied from the slave port to the master port in the same clock cycle.

It is recommended to initialize or modify the main memory content (region to be later cached) with the ICACHE disabled, and to enable the ICACHE only when this region remains unchanged (an enabled ICACHE detects cacheable write transactions as errors).

To ensure performance determinism, it is recommended to wait for the end of a potential cache invalidate procedure before enabling the ICACHE. This invalidate procedure occurs when the hardware reset signal is released, when CACHEINV is set, or when EN is cleared in ICACHE_CR. During the procedure, BUSYF is set in ICACHE_SR, and once finished, BUSYF is cleared and BSYENDF is set in the same register (raising the ICACHE interrupt if enabled on such a busy end condition).

The software must test BUSYF and/or BSYENDF values before enabling the ICACHE. Else, if the ICACHE is enabled before the end of an invalidate procedure, any cache access (while BUSYF = 1) is treated as noncacheable, and its performance depends on the main memory access time.

The ICACHE is by default disabled at boot.

### 17.4.6 Cacheable and noncacheable traffic

The ICACHE is placed on the GPU texture bus, and thus caches all internal and external memory regions (ranging from address 0x0000 0000 to 0x3FFF FFFF, respectively 0x6000 0000 to 0x9FFF FFFF, of the memory map).

An incoming memory request to the ICACHE is defined as cacheable according to its AHB transaction memory lookup attribute, as shown in Table 134. This AHB attribute depends on the GPU setting for the addressed region.

**Table 134. ICACHE cacheability for AHB transaction**

<table>
<thead>
<tr>
<th>AHB lookup attribute</th>
<th>Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Cacheable</td>
</tr>
<tr>
<td>0</td>
<td>Noncacheable</td>
</tr>
</tbody>
</table>

In the case of a noncacheable access (either a noncacheable read or a noncacheable write), the ICACHE is bypassed, meaning that the AHB transaction is propagated unchanged to the master output port.

The bypass does not increase the latency of the access to the targeted memory.

In the case of a cacheable access, the ICACHE behaves as explained in Section 17.4.7.
17.4.7 Cacheable accesses

When the ICACHE receives a cacheable transaction from the GPU, the ICACHE checks if the address requested is present in its TAG memory, and if the corresponding cache line is valid.

There are then three alternatives:

- The address is present inside the TAG memory, the cache line is valid: **cache hit**, the data is read from the cache and provided to the processor in the same cycle.
- The address is not present in the TAG memory: **cache miss**, the data is read from the main memory and provided to the processor, and a cache line refill is performed.
  - The critical-word-first policy insures minimum wait cycles for the processor, since read data can be provided while the cache still performs a cache line refill (associated latency is the latency of fetching one word from the main memory).
  - The burst generated on the ICACHE master bus is WRAPw (w being the cache line width, in words).
  - The AHB transaction attributes are also propagated to the main AHB bus matrix on the master port.
- The address is not present in TAG memory, but belongs to the refill burst from the main memory that is currently ongoing: **cache hit** (hit-under-miss feature).
  - This happens during cache-line refill. The ICACHE can provide the requested data as soon as the data is available at its master interface, thus avoiding a miss (fetching data from the main memory).

In the case of cache refill (due to cache miss), the ICACHE selects which cache line is written with the refill data:

- In direct map (1-way) mode, only one line can be used to store the refill data: the line pointed by the index of the input address.
- In n-way set associative mode, one line among n can be used (the line pointed by the address index, in each of the n ways). The way selection is based on a pLRU-t replacement algorithm that points, for each index, on the way candidate for the next refill.

If ever the cache line where the refill data must be written is already valid, the targeted cache line must be invalidated first. This is true whatever the direct map or n-way set associative cache mode.

17.4.8 ICACHE maintenance

The software can invalidate the whole content of the ICACHE by programming CACHEINV in the ICACHE_CR register.

When CACHEINV = 1, the ICACHE control logic sets the BUSYF flag in ICACHE_SR and launches the invalidate cache operation, resetting each TAG valid bit to 0 (one valid bit per cache line). CACHEINV is automatically cleared.

Once the invalidate operation is finished (all valid bits reset to 0), the ICACHE automatically clears BUSYF, and sets BSYENDF in the ICACHE_SR register.

If enabled on this flag condition (BSYENDIE = 1 in ICACHE_IER), the ICACHE interrupt is raised. Then, the (empty) cache is available again.
17.4.9 **ICACHE performance monitoring**

The ICACHE provides the following monitors for performance analysis:

- The 32-bit hit monitor counts the cacheable AHB-transactions on the slave cache port that hits the ICACHE content.
  
  It also takes into account all accesses whose address is present in the TAG memory or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from the cache master port) (see Section 17.4.7).

- The 16-bit miss monitor counts the cacheable AHB-transactions on the slave cache port that misses the ICACHE content.
  
  It also takes into account all accesses whose address is not present neither in the TAG memory nor in the refill buffer.

Upon reaching their maximum values, these monitors do not wrap over.

Hit and miss monitors can be enabled and reset by software allowing the analysis of specific pieces of code.

The software can perform the following tasks:

- Enable/stop the hit monitor through HITMEN in ICACHE_CR.
- Reset the hit monitor by setting HITMRST in ICACHE_CR.
- Enable/stop the miss monitor through MISSMEN in ICACHE_CR.
- Reset the miss monitor by setting MISSMRST in ICACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

17.4.10 **ICACHE boot**

The ICACHE is disabled (EN = 0 in ICACHE_CR) at boot.

Once the boot is finished, the ICACHE can be enabled (software setting EN = 1 in CACHE_CR).

17.5 **ICACHE low-power modes**

At device level, using the ICACHE reduces the power consumption by reading textures from the internal ICACHE most of the time, rather than from the bigger and then more-power-consuming main memories. This reduction is even higher if the cached main memories are external.

Applications with a lower-performance profile (in terms of hit ratio) and stringent low-power consumption constraints may benefit from the lower power consumption of an ICACHE configured as direct mapped. This single-way cache configuration is obtained by programming WAYSEL = 0 in ICACHE_CR (see Figure 139). The power consumption is then reduced by accessing, for each request, only the necessary cut of TAG and data memories. Meanwhile, the cache effect still improves memory access performance. Even if for most texture accesses, it is a little less efficient than with an n-way set associative cache mode.
17.6 ICACHE error management and interrupts

In case an unsupported cacheable write request is detected (functional error), the ICACHE generates an error by setting the ERRF flag in ICACHE_SR. An interrupt is then generated if the corresponding interrupt enable bit is set (ERRIE = 1 in ICACHE_IER).

The other possible interrupt generation is at the end of a cache invalidation operation. When the cache-busy state is finished, the ICACHE sets the BSYENDF flag in ICACHE_SR. An interrupt is then generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in ICACHE_IER).

All ICACHE interrupt sources raise the same and unique interrupt signal, icache_it, and then use the same interrupt vector.

<table>
<thead>
<tr>
<th>Interrupt vector</th>

<td>End of busy state (invalidate finished)</td>
<td>BSYENDF in ICACHE_SR</td>
<td>BSYENDIE in ICACHE_IER</td>
<td>Set CBSYENDF to 1 in ICACHE_FCR</td>
</tr>
</tbody>
</table>

The ICACHE also propagates all AHB bus errors (such as address decoding issues) from the master1 port back to the slave read port.

17.7 ICACHE registers

17.7.1 ICACHE control register (ICACHE_CR)

Address offset: 0x000

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **MISSMRST**: miss monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache miss monitor

Bit 18 **HITMRST**: hit monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache hit monitor
Bit 17 **MISSMEN**: miss monitor enable  
0: cache miss monitor switched off. Stopping the monitor does not reset it.  
1: cache miss monitor enabled  

Bit 16 **HITMEN**: hit monitor enable  
0: cache hit monitor switched off. Stopping the monitor does not reset it.  
1: cache hit monitor enabled  

Bits 15:3 Reserved, must be kept at reset value.  

Bit 2 **WAYSEL**: cache associativity mode selection  
This bit allows user to choose ICACHE set-associativity. It can be written by software only when cache is disabled (EN = 0).  
0: direct mapped cache (1-way cache)  
1: n-way set associative cache (reset value)  

Bit 1 **CACHEINV**: cache invalidation  
Set by software and cleared by hardware when the BUSYF flag is set (during cache maintenance operation). Writing 0 has no effect.  
0: no effect  
1: invalidate entire cache (all cache lines valid bit = 0)  

Bit 0 **EN**: enable  
0: cache disabled  
1: cache enabled

18 Graphic timer (GFXTIM)

18.1 Introduction

The graphic timer (GFXTIM) is a graphic oriented timer allowing smart management of graphical events for frame or line counting.

18.2 GFXTIM main features

- Integrated frame and line clock generation
- One absolute frame counter with one compare channel
- Two auto-reload relative frame counters
- One line timer with two compare channels
- External tearing-effect line management and synchronization
- Four programmable event generators with external trigger generation
- One watchdog counter

18.3 GFXTIM functional description

18.3.1 Block diagram

The graphic timer is split into six functional blocks
- Clock generator
- Absolute timers
- Relative timers
- Tearing-effect detection
- Event generators
- Watchdog timer
**18.3.2 GFXTIM pins and internal signals**

### 18.3.3 Clock generator

Two clocks are generated internally to fed the absolute and relative timers:
- the frame clock: clocking frame counters
- the line clock: clocking line counters

#### Internal counter for time base generation

The GFXTIM embeds a two-clock generation counter:
- a 22-bit auto-reload down-counter on the system clock
- a 12-bit auto-reload down-counter on selectable internal or external event
Figure 141. Clock generator

Line clock counter

The line clock counter is a 22-bit auto-reload down-counter on the system clock.

The line clock counter is enabled selecting its clock source with LCCCS (line clock counter clock source) in GFXTIM_CGCR (clock generator control register).

The line clock counter can be reloaded automatically when one of the following event occurs:

- frame clock counter underflows
- VSYNC edge (with control of polarity)
- HSYNC edge (with control of polarity)
- TE edge (with control of polarity)

The hardware reload function and source can be selected with LCCHRS (line clock counter hardware reload source) in GFXTIM_CGCR (clock generator control register).

The line clock counter can be reloaded by software, setting LCCFR (line clock counter force reload) in GFXTIM_CGCR (clock generator control register).

The reload value is programmed in GFXTIM_LCCRR (line clock counter reload register).

Frame clock counter

The frame clock counter if an 12-bit auto-reload down-counter clocked by either, TE, HYSNC, VSYNC or a line clock counter underflow.

The frame clock counter is enabled selecting its clock source with FCCCS in GFXTIM_CGCR.

The frame clock counter can be reloaded automatically when one of the following event occurs:

- line clock counter underflow
- VSYNC edge (with control of polarity)
- HSYNC edge (with control of polarity)
- TE edge (with control of polarity)

The hardware reload function and source can be selected with FCCHRS in GFXTIM_CGCR.

The frame clock counter can be reloaded by software, setting FCCFR in GFXTIM_CGCR.
The reload value is programmed in GFXTIM_FCCRR.

**Clock generation**

The line clock source can be one of the following:
- underflow flag of the internal 22-bit down-counter
- underflow flag of the internal 12-bit down-counter
- HSYNC, VSYNC or TE pin (with control of polarity)

The frame clock source can be one of the following:
- underflow flag of the internal 22-bit down-counter
- underflow flag of the internal 12-bit down-counter
- HSYNC, VSYNC or TE pin (with control of polarity)

**Clock calibration output**

For calibration/debug purpose, the frame clock and line clock can be output on a specific I/O.

The frame clock calibration output is enabled by setting FCCOE (frame clock calibration output enable) in GFXTIM_CR (configuration register).

The line clock calibration output is enabled by setting LCCOE in GFXTIM_CR.

**Synchronization and tearing-effect sources**

The GFXTIM can be connected to peripherals providing HSYNC and/or VSYNC synchronization signals, like the LCD-TFT controller or the camera interface.

The source of HSYNC and/or VSYNC is selected through SYNCS (synchronization source) in GFXTIM_CR.

The tearing-effect source can be an external pin or can be provided by the MIPI® DSI Host on system embedding this interface. To extend the orthogonality versus the synchronization signals, the tearing-effect source can be also the selected HSYNC or VSYNC input.

The tearing-effect source can be selected with TES (TE source) in GFXTIM_CR.

### 18.3.4 Example of clock generator configuration

The clock generator can have several configuration to work:
- in standalone (without any external synchronization)
- with external HSYNC and VSYNC
- with external HSYNC only
- with external VSYNC only
- with external CSYNC (TE) only

The synchronization signals, HSYNC, VSYNC and TE, are symmetrical in the implementation and can be exchanged if needed.

The set of examples detailed below are given for reference, but other combinations can be programmed into the clock generator.
Standalone

In standalone configuration, the clock generator provides to the GFXTIM, the frame clock and the line clock without any external signals.

Figure 142. Waveforms in standalone

The LCCUF (line-clock counter underflow) event acts as line clock and the FCCUF (frame-clock counter underflow) acts as frame clock.

The clock generator can be synchronized by one of the following ways:
- by software reload, setting the FCCFR in GFXTIM_CGCR.
- by hardware reload on an external VSYNC (or TE)

Figure 143. Active counters and signals in standalone

External HSYNC and VSYNC

When using external HSYNC and VSYNC, the counters are not used for the line and frame clock generation. The clock generator copy directly HSYNC to the line clock and VSYNC to the frame clock.

Figure 144. Waveforms with external HSYNC and VSYNC
HSYNC acts as line clock and VSYNC acts as frame clock.

**External HSYNC only**

With external HSYNC only, the clock generator provides to the GFXTIM, the frame clock and the line clock based only on HSYNC.

**Figure 145. Waveforms with external HSYNC only**

![Waveforms with external HSYNC only](image1)

HSYNC acts as line clock and FCCUF acts as frame clock.

The clock generator can be synchronized by one of the following ways:
- by software reload, setting FCCFR in GFXTIM_CGCR
- by hardware reload on an external VSYNC (or TE)

**Figure 146. Active counters and signals with external HSYNC only**

![Active counters and signals with external HSYNC only](image2)

**External VSYNC only**

With external VSYNC only, the clock generator provides to the GFXTIM, the frame clock and the line clock based only on VSYNC.

**Figure 147. Waveforms with external VSYNC only**

![Waveforms with external VSYNC only](image3)

LCCUF (line clock counter underflow) acts as line clock and VSYNC acts as frame clock.
The line clock counter generating the line clock is reloaded on VSYNC event.

**Figure 148. Active counters with external VSYNC only**

The line clock counter can also act as a prescaler for the frame clock counter to have a wider range of counting. FCCUF acts as line clock.

**Figure 149. Prescaling when external VSYNC only**

**External CSYNC only**

With external CSYNC only, the clock generator provides to the GFXTIM, the frame clock and the line clock based only on CSYNC (in the following figures, CSYNC is input on TE).

**Figure 150. Waveforms with external CSYNC only**

The CSYNC (on TE pin in this example) acts as line clock and LCCUF acts as frame clock. The line clock counter generating the frame clock is reloaded on CSYNC event.
The line-clock counter can also act as a prescaler for the frame clock counter to have a wider range of counting. FCCUF acts as frame clock.

18.3.5 Absolute timers

Absolute time

The absolute time 32-bit value can be read directly in GFXTIM_ATR (absolute time register) to provide a global time and to generate absolute time accurate event to synchronize the graphical software.

The absolute time is generated by the combination of:
- the absolute frame counter
- the absolute line counter

Absolute frame counter

The absolute frame counter is a 20-bit free running up-counter with a software controlled reset.

It can be enabled by writing 1 in AFCEN (absolute-frame counter enable) of GFXTIM_TCR (timers configuration register).
The counter is incremented at each rising edge of the frame clock and is reset by setting FAFCR (force absolute-frame counter reset) in GFXTIM_TCR.

In case of overflow of the absolute frame counter, AFCOF (overflow flag) is set in GFXTIM_ISR (interrupt status register), and an interrupt is generated if AFCOIE (overflow interrupt enable) is set in (interrupt enable register).

A 20-bit compare register can generate an absolute-frame counter compare event when the counter value matches the compare value. When a compare event occurs, AFCC1F (compare 1 flag) is set in GFXTIM_ISR, and an interrupt is generated if AFCC1IE (compare 1 interrupt enable) is set in GFXTIM_IER.

The absolute frame counter can be disabled by writing 1 in AFCDIS (counter disable) of GFXTIM_TDR (timers disable register).

The status (enabled/disabled) can be monitored through AFCS (counter status) in GFXTIM_TSR (timers status register).

### Absolute line counter

The absolute line counter is 12-bit free running-up counter with an hardware controlled reset.

It can be enabled by writing 1 in ALCEN of GFXTIM_TCR.

The counter is incremented at each rising edge of the line clock an is reset at each rising edge of the frame clock or setting FALCR in GFXTIM_TCR).

In case of overflow of the absolute line counter, ALCOF is set in GFXTIM_ISR, and an interrupt is generated if ALCOIE is set in GFXTIM_IER.

Two 12-bit compare registers can generate an absolute line counter compare events when the counter value matches the compare value. When a compare event occurs, ALCC1F or ALCC2F is set in GFXTIM_ISR, and an interrupt is generated if ALCC1IE or ALCC2IE is set in GFXTIM_IER.

The absolute line counter can be disabled writing 1 in ALCDIS of GFXTIM_TDR.

The status (enabled/disabled) can be monitored through ALCS in GFXTIM_TSR.

### 18.3.6 Relative timers

The relative timers can generate periodic events to synchronize the graphical tasks at frame level.

The relative frame counters are 12-bit down-counting auto-reload timers that are decremented at each rising edge of the frame clock. The counter is started by writing 1 in RFCxEN (relative frame counter x enable) of GFXTIM_TCR. The starting value is automatically loaded from GFXTIM_RFCxRR (relative frame counter x reload register).

The current relative frame counter value can be read directly in GFXTIM_RFCxR.

Once the counter reaches zero, it is automatically reloaded with the value of GFXTIM_RFCxRR. RFCxRF (reload flag) is set in GFXTIM_ISR is set, and an interrupt is generated if RFCxRIE (interrupt enable) is set in GFXTIM_IER.

Once the reload operation occurs, the timer can be disabled automatically or continue counting if RFCxCM (continuous mode) is set in GFXTIM_TCR.

The status (enabled/disabled) can be monitored through RFCxS in GFXTIM_TSR.
The counter can be reloaded on the fly by setting FRFCRx in GFXTIM_TCR. This force reload neither stop the timer (even if RFCxCM = 0 in GFXTIM_TCR), nor set RFCxRF (reload flag) in GFXTIM_ISR.

The relative frame counter can be disabled by setting RFCxDIS (disable) in GFXTIM_TDR.

18.3.7 **Tearing-effect detection**

A tearing-effect line can work in one of the two configurations shown in the figure below.

**Figure 153. Tearing-effect configurations**

A tearing-effect event can be generated on rising or falling edge depending on TEPOL (tearing-effect polarity) in GFXTIM_CR.

When a tearing-effect event is detected, TEF (tearing-event flag) is set in GFXTIM_ISR, and an interrupt is generated if TEIE (interrupt enable) is set in GFXTIM_IER.

18.3.8 **Event generator**

The event generator can combine timer events into complex events. Up to four combined events can be generated.

The events can be used for:
- interrupt generation
- watchdog clocking
- external trigger generation

A complex event is a combination between a frame event and a line event.

Once a frame event occurs, the GFXTIM waits for the line event to occur before generating the complex event.

The frame event is selected by the corresponding FESx (frame event selection x) in GFXTIM_EVSR (events selection y register). The line event is selected by the corresponding LESx in GFXTIM_EVSR.

The complex event generation is enabled by setting the corresponding EVxEN (event x enable) in GFXTIM_EVCR (event control register).

It is recommended to disable the event generation prior to any event configuration to avoid spurious complex event generation.

When a complex event occurs, the corresponding EVxF (event x flag) is set in GFXTIM_ISR, and an interrupt is generated if EVxIE (event x interrupt enable) is set in GFXTIM_IER.

Each of the events can be connected to another peripherals (such as DMA) to generate hardware triggers.
18.3.9 Watchdog timer

The watchdog timer is a 16-bit auto-reload down-counter with a programmable clock source.

**Clock source**

The watchdog clock source can be selected through WDGCS (clock source) in GTXTIM_WDGTCR (watchdog timer configuration register), between one of the following:
- line clock
- frame clock
- HSYNC
- VSYNC
- TE
- event 1
- event 2
- event 3
- event 4

**Startup**

The watchdog is started by setting WDGEN in GFXTIM_WDGTCR and stops automatically when reaching 0.

On start, the watchdog counter is automatically loaded with the auto-reload value programmed in GFXTIM_WDGRR (watchdog reload register).

The current watchdog value can be read through GFXTIM_WDGCR.

**Auto-reload**

The auto-reload can be forced in one of the following ways:
- by software, setting FWDGR (force watchdog reload) in GTXTIM_WDGTCR (watchdog timer configuration register)
- by hardware through an external trigger (gfxtim_wrld signal)

The polarity of the trigger is configured by WDGHRC (watchdog hardware reload configuration) in GFXTIM_WDGTCR.
Event and interrupt generation

The watchdog can generate two events:
- an alarm when the watchdog down-counter reaches 0
  The watchdog counter is automatically stopped, and WDGAF (alarm flag) is set in GFXTIM_ISR. An interrupt is generated if WDGAIE (alarm interrupt enable) is set in GFXTIM_IER.
- a pre-alarm when the watchdog counter matches the pre-alarm register value in GFXTIM_WDGPAR (watchdog pre-alarm register)
  WDGPF (pre-alarm flag) is set in GFXTIM_ISR, and an interrupt is generated if WDGPIE (pre-alarm interrupt enable) is set in GFXTIM_IER.

18.4 GFXTIM interrupts

An interrupt can be produced on the following events:
- absolute frame counter compare event
- absolute frame counter overflow
- absolute line counter compare events
- absolute line counter overflow
- relative frame counter reload events
- external tearing effect
- combined events
- watchdog alarm event
- watchdog pre-alarm event

Separate interrupt enable bits are available for flexibility.

- 001: Absolute line counter overflow
- 010: Tearing effect
- 100: Absolute line counter 1 compare
- 101: Absolute line counter 2 compare
- Others: Reserved

Bit 23  Reserved, must be kept at reset value.

Bits 22:20  **FES3[2:0]:** Frame-event selection 3
This bitfield defines the frame-event selection for complex event 3 generation.
- 000: No frame event
- 001: Absolute frame counter overflow
- 010: Absolute frame counter compare
- 100: Relative frame counter 1 reload
- 101: Relative frame counter 2 reload
- Others: Reserved

Bit 19  Reserved, must be kept at reset value.

Bits 18:16  **LES3[2:0]:** Line-event selection 3
This bitfield defines the line-event selection for complex event 3 generation.
- 000: No line event
- 001: Absolute line counter overflow
- 010: Tearing effect
- 100: Absolute line counter 1 compare
- 101: Absolute line counter 2 compare
- Others: Reserved

Bit 15  Reserved, must be kept at reset value.

Bits 14:12  **FES2[2:0]:** Frame-event selection 2
This bitfield defines the frame-event selection for complex event 2 generation.
- 000: No frame event
- 001: Absolute frame counter overflow
- 010: Absolute frame counter compare
- 100: Relative frame counter 1 reload
- 101: Relative frame counter 2 reload
- Others: Reserved

Bit 11  Reserved, must be kept at reset value.
Bits 10:8 **LES2[2:0]:** Line-event selection 2
This bitfield defines the line-event selection for complex event 2 generation.
- 000: No line event
- 001: Absolute line counter overflow
- 010: Tearing effect
- 100: Absolute line counter 1 compare
- 101: Absolute line counter 2 compare
- Others: Reserved

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **FES1[2:0]:** Frame-event selection 1
This bitfield defines the frame-event selection for complex event 1 generation.
- 000: No frame event
- 001: Absolute frame counter overflow
- 010: Absolute frame counter compare
- 100: Relative frame counter 1 reload
- 101: Relative frame counter 2 reload
- Others: Reserved

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **LES1[2:0]:** Line-event selection 1
This bitfield defines the line-event selection for complex event 1 generation.
- 000: No line event
- 001: Absolute line counter overflow
- 010: Tearing effect
- 100: Absolute line counter 1 compare
- 101: Absolute line counter 2 compare
- Others: Reserved

18.5.7 **GFXTIM watchdog timer configuration register**
*(GFXTIM_WDGTCR)*

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **FWDGR:** Force watchdog reload
This bit forces the reload of the graphic watchdog.
- 0: No effect
- 1: Graphic watchdog reload forced

Bits 15:12 Reserved, must be kept at reset value.
Bits 11:8  **WDGCS[3:0]**: Watchdog clock source
This bitfield selects the watchdog clock source.
0000: Line clock
0001: Frame clock
0010: HSYNC rising edge
0011: HSYNC falling edge
0100: VSYNC rising edge
0101: VSYNC falling edge
0110: TE rising edge
0111: TE falling edge
1000: Event 1
1001: Event 2
1010: Event 3
1011: Event 4
Others: Reserved

Bits 7:6  Reserved, must be kept at reset value.

Bits 5:4  **WDGHR[1:0]**: Watchdog hardware reload configuration
This bitfield configures the watchdog hardware reload.
00: Watchdog hardware reload disabled
01: Watchdog reloaded a rising edge of gfxtim_wrld
10: Watchdog reloaded a falling edge of gfxtim_wrld
11: Reserved

Bit 3  Reserved, must be kept at reset value.

Bit 2  **WDGS**: Watchdog status
This bit returns the status of the graphic watchdog.
0: Graphic watchdog disabled
1: Graphic watchdog enabled

Bit 1  **WDGDIS**: Watchdog disable
This bit disables the graphic watchdog.
0: No effect
1: Graphic watchdog disabled

Bit 0  **WDGEN**: Watchdog enable
This bit enables the graphic watchdog.
0: No effect
1: Graphic watchdog enabled
# GFXTIM interrupt status register (GFXTIM_ISR)

**Address offset:** 0x030  
**Reset value:** 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:26</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>

**Bit 25** WDGPF: Watchdog pre-alarm flag  
This bit indicates that a graphic watchdog pre-alarm occurred.  
0: No graphic watchdog pre-alarm occurred.  
1: A graphic watchdog pre-alarm occurred.

**Bit 24** WDGAF: Watchdog alarm flag  
This bit indicates that a graphic watchdog alarm occurred.  
0: No graphic watchdog alarm occurred.  
1: A graphic watchdog alarm occurred.

**Bits 23:20** Reserved, must be kept at reset value.

**Bit 19** EV4F: Event 4 flag  
This bit indicates a complex event 4 occurred.  
0: No complex event 4 occurred.  
1: A complex event 4 occurred.

**Bit 18** EV3F: Event 3 flag  
This bit indicates a complex event 3 occurred.  
0: No complex event 3 occurred.  
1: A complex event 3 occurred.

**Bit 17** EV2F: Event 2 flag  
This bit indicates a complex event 2 occurred.  
0: No complex event 2 occurred.  
1: A complex event 2 occurred.

**Bit 16** EV1F: Event 1 flag  
This bit indicates a complex event 1 occurred.  
0: No complex event 1 occurred.  
1: Complex event 1 occurred.

**Bits 15:14** Reserved, must be kept at reset value.

**Bit 13** RFC2RF: Relative frame counter 2 reload flag  
This bit indicates relative frame counter 2 has been reloaded.  
0: No reload occurred on relative frame counter 2.  
1: A reload on relative frame counter 2 occurred.
Bit 12 **RFC1RF**: Relative frame counter 1 reload flag
This bit indicates relative frame counter 1 has been reloaded.
0: No reload occurred on relative frame counter 1.
1: A reload on relative frame counter 1 occurred.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **ALCC2F**: Absolute line counter compare 2 flag
This bit indicates match on compare 2 of the absolute line counter.
0: No match occurred on compare 2 of the absolute line counter.
1: A match on compare 2 of the absolute line counter occurred.

Bit 8 **ALCC1F**: Absolute line counter compare 1 flag
This bit indicates match on compare 1 of the absolute line counter.
0: No match occurred on compare 1 of the absolute line counter.
1: A match on compare 1 of the absolute line counter occurred.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **AFCC1F**: Absolute frame counter compare 1 flag
This bit indicates match on compare 1 of the absolute frame counter.
0: No match occurred on compare 1 of the absolute frame counter.
1: A match on compare 1 of the absolute frame counter occurred.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TEF**: Tearing-effect flag
This bit indicates a tearing effect event occurred.
0: No tearing effect occurred.
1: A tearing effect occurred.

Bit 1 **ALCOF**: Absolute line counter overflow flag
This bit indicates an overflow occurred on the absolute line counter.
0: No overflow occurred on the absolute line counter.
1: A overflow on the absolute line counter occurred.

Bit 0 **ACFOF**: absolutely frame counter overflow flag
This bit indicates an overflow occurred on the absolute frame counter.
0: No overflow occurred on the absolute frame counter.
1: An overflow on the absolute frame counter occurred.

Bits 31:26 Reserved, must be kept at reset value.
Bit 25  **CWDGPF**: Clear watchdog pre-alarm flag
        This bit clears WDGPF in GXFXTIM_ISR.
        0: No effect
        1: WDGPF cleared

Bit 24  **CWDGAF**: Clear watchdog alarm flag
        This bit clears WDGA in GXFXTIM_ISR.
        0: No effect
        1: WDGA cleared

Bits 23:20  **Reserved**, must be kept at reset value.

Bit 19  **CEV4F**: Clear event 4 flag
        This bit clears EV4F in GXFXTIM_ISR.
        0: No effect
        1: EV4F cleared

Bit 18  **CEV3F**: Clear event 3 flag
        This bit clears EV3F in GXFXTIM_ISR.
        0: No effect
        1: EV3F cleared

Bit 17  **CEV2F**: Clear event 2 flag
        This bit clears EV2F in GXFXTIM_ISR.
        0: No effect
        1: EV2F cleared

Bit 16  **CEV1F**: Clear event 1 flag
        This bit clears EV1F in GXFXTIM_ISR.
        0: No effect
        1: EV1F cleared

Bits 15:14  **Reserved**, must be kept at reset value.

Bit 13  **CRFC2RF**: Clear relative frame counter 2 reload flag
        This bit clears RFC2RF in GXFXTIM_ISR.
        0: No effect
        1: RFC2RF cleared

Bit 12  **CRFC1RF**: Clear relative frame counter 1 reload flag
        This bit clears RFC1RF in GXFXTIM_ISR.
        0: No effect
        1: RFC1RF cleared

Bits 11:10  **Reserved**, must be kept at reset value.

Bit 9  **CALCC2F**: Clear absolute line counter compare 2 flag
        This bit clears ALCC2F in GXFXTIM_ISR.
        0: No effect
        1: ALCC2F cleared

Bit 8  **CALCC1F**: Clear absolute line counter compare 1 flag
        This bit clears ALCC1F in GXFXTIM_ISR.
        0: No effect
        1: ALCC1F cleared

Bits 7:5  **Reserved**, must be kept at reset value.
Bit 4 **CAFCC1F**: Clear absolute frame counter compare 1 flag
This bit clears AFCC1F in GXTIM_ISR.
0: No effect
1: AFCC1F cleared

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CTEF**: Clear tearing-effect flag
This bit clears TEF in GXTIM_ISR.
0: No effect
1: TEF cleared

Bit 1 **CALCOF**: Clear absolute line counter overflow flag
This bit clears ALCOF in GXTIM_ISR.
0: No effect
1: ALCOF cleared

Bit 0 **CAFCOF**: Clear absolute frame counter overflow flag
This bit clears AFCOF in GXTIM_ISR.
0: No effect
1: AFCOF cleared

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **WDGPIE**: Watchdog pre-alarm interrupt enable
This bit enables the watchdog pre-alarm interrupt generation.
0: Watchdog pre-alarm interrupt disabled
1: Watchdog pre-alarm interrupt enabled

Bit 24 **WDGAIE**: Watchdog alarm interrupt enable
This bit enables the watchdog alarm interrupt generation.
0: Watchdog alarm interrupt disabled
1: Watchdog alarm interrupt enabled

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **EV4IE**: Event 4 interrupt enable
This bit enables the complex event 4 interrupt generation.
0: Event 4 interrupt disabled
1: Event 4 interrupt enabled
Bit 18  **EV3IE**: Event 3 interrupt enable  
This bit enables the complex event 3 interrupt generation.  
0: Event 3 interrupt disabled  
1: Event 3 interrupt enabled  

Bit 17  **EV2IE**: Event 2 interrupt enable  
This bit enables the complex event 2 interrupt generation.  
0: Event 2 interrupt disabled  
1: Event 2 interrupt enabled  

Bit 16  **EV1IE**: Event 1 interrupt enable  
This bit enables the complex event 1 interrupt generation.  
0: Event 1 interrupt disabled  
1: Event 1 interrupt enabled  

Bits 15:14 Reserved, must be kept at reset value.  

Bit 13  **RFC2RIE**: Relative frame counter 2 reload interrupt enable  
This bit enables the relative frame counter 2 reload interrupt generation.  
0: Relative frame counter 2 reload interrupt disabled  
1: Relative frame counter 2 reload interrupt enabled  

Bit 12  **RFC1RIE**: Relative frame counter 1 reload interrupt enable  
This bit enables the relative frame counter 1 reload interrupt generation.  
0: Relative frame counter 1 reload interrupt disabled  
1: Relative frame counter 1 reload interrupt enabled  

Bits 11:10 Reserved, must be kept at reset value.  

Bit 9  **ALCC2IE**: Absolute line counter compare 2 interrupt enable  
This bit enables the absolute line counter compare 2 interrupt generation.  
0: Absolute line counter compare 2 interrupt disabled  
1: Absolute line counter compare 2 interrupt enabled  

Bit 8  **ALCC1IE**: Absolute line counter compare 1 interrupt enable  
This bit enables the absolute line counter compare 1 interrupt generation.  
0: Absolute line counter compare 1 interrupt disabled  
1: Absolute line counter compare 1 interrupt enabled  

Bits 7:5 Reserved, must be kept at reset value.  

Bit 4  **AFCC1IE**: Absolute frame counter compare 1 interrupt enable  
This bit enables the absolute frame counter compare 1 interrupt generation.  
0: Absolute frame counter compare 1 interrupt disabled  
1: Absolute frame counter compare 1 interrupt enabled  

Bit 3 Reserved, must be kept at reset value.  

Bit 2  **TEIE**: Tearing-effect interrupt enable  
This bit enables the Tearing Effect interrupt generation.  
0: Tearing-effect interrupt disabled  
1: Tearing-effect interrupt enabled  

Bit 1  **ALCOIE**: Absolute line counter overflow interrupt enable  
This bit enables the absolute line counter overflow interrupt generation.  
0: Absolute line counter overflow interrupt disabled  
1: Absolute line counter overflow interrupt enabled
Bit 0  **AFCOIE**: Absolute frame counter overflow interrupt enable
This bit enables the absolute frame counter overflow interrupt generation.
0: Absolute frame counter overflow interrupt disabled
1: Absolute frame counter overflow interrupt enabled

**Bits 31:12**  **Reserved, must be kept at reset value.**

**Bits 11:0**  **LINE[11:0]: Line number**

Current value of the absolute line counter.

**Note:** This bitfield can only be written when the absolute line counter is disabled.
### 18.5.17 GFXTIM absolute frame counter compare 1 register (GFXTIM_AFCC1R)

- **Address offset:** 0x060
- **Reset value:** 0x0000 0000

#### Bits 31:20
Reserved, must be kept at reset value.

#### Bits 19:0
- **FRAME[19:0]:** Frame number
  - Compare 1 value for the absolute frame counter.

### 18.5.18 GFXTIM absolute line counter compare 1 register (GFXTIM_ALCC1R)

- **Address offset:** 0x070
- **Reset value:** 0x0000 0000

#### Bits 31:12
Reserved, must be kept at reset value.

#### Bits 11:0
- **LINE[11:0]:** Line number
  - Compare value 1 for the absolute line counter.

### 18.5.19 GFXTIM absolute line counter compare 2 register (GFXTIM_ALCC2R)

- **Address offset:** 0x074
- **Reset value:** 0x0000 0000

#### Bits 31:12
Reserved, must be kept at reset value.

#### Bits 11:0
- **LINE[11:0]:** Line number
  - Compare value 1 for the absolute line counter.
18.5.20  GFXTIM relative frame counter 1 register (GFXTIM_RFC1R)

Address offset: 0x080
Reset value: 0x0000 0000

Bits 31:12  Reserved, must be kept at reset value.
Bits 11:0  **LINE[11:0]:** Line number
Compare value 2 for the absolute line counter.

18.5.21  GFXTIM relative frame counter 1 reload register (GFXTIM_RFC1RR)

Address offset: 0x084
Reset value: 0x0000 0000

Bits 31:12  Reserved, must be kept at reset value.
Bits 11:0  **FRAME[11:0]:** Frame number
Current value of the relative frame counter 1.
### 18.5.22 GFXTIM relative frame counter 2 register (GFXTIM_RFC2R)

Address offset: 0x088  
Reset value: 0x0000 0000

Refer to Section 2.3 for the register boundary addresses.
19 Nested vectored interrupt controller (NVIC)

19.1 NVIC features

The NVIC includes the following features:

- up to 140 maskable interrupt channels for STM32H7xxx (not including the 10 interrupt lines of Cortex®-M7 with FPU)
- 16 programmable priority levels (4 bits of interrupt priority are used)
- low-latency exception and interrupt handling
- power management control
- implementation of system control registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late-arriving interrupts.

All interrupts, including the core exceptions, are managed by the NVIC.

For more information on exceptions and NVIC programming, refer to PM0253 programming manual for Cortex®-M7.

19.1.1 SysTick calibration value register

The SysTick calibration value (SYST_CALIB) is fixed to 0x3E8. It provides a reference timebase of 1 ms based when the SysTick clock frequency is 1 MHz. To match the 1 ms timebase whatever the application frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- If the SysTick clock source is the 100 MHz CPU clock (HCLK):
  \[
  \text{reload value} = (F_{\text{HCLK}} \times \text{SYST_CALIB}) - 1
  \]

- If the SysTick clock source is an external clock:
  \[
  \text{reload value} = \left(\frac{F_{\text{HCLK}}}{8}\right) \times \text{SYST_CALIB} - 1
  \]

where \( F_{\text{HCLK}} \) refers to the AHB frequency expressed in MHz.

For example, to achieve a timebase of 1 ms when the SysTick clock source is the 100 MHz HCLK:

\[
\text{reload value} = (100 \times \text{SYST_CALIB}) - 1 = 0x1869F
\]
### 19.1.2 Interrupt and exception vectors

The exception vectors connected to the NVIC are the following: reset, NMI, HardFault, MemManage, Bus Fault, UsageFault, SVCall, DebugMonitor, PendSV, SysTick.

When different signals are connected to the same NVIC interrupt line, they are OR-ed.
20 Extended interrupt and event controller (EXTI)

The extended interrupt and event controller (EXTI) manages wakeup through configurable and direct event inputs. It provides wakeup requests to the power control, and generates interrupt requests to the CPU NVIC and events to the CPU event input.

The EXTI wakeup requests allow the system to be woken up from Stop mode, and the CPU to be woken up from CStop mode.

Both the interrupt request and event request generation can also be used in Run modes.

20.1 EXTI main features

The EXTI main features are as follows:

- All event inputs allow the CPU to wakeup and to generate a CPU interrupt and/or CPU event

The asynchronous event inputs are classified in 2 groups:

- Configurable events (signals from I/Os or peripherals able to generate a pulse) that feature:
  - Selectable active trigger edge
  - Interrupt pending status register bit
  - Individual interrupt and event generation mask
  - SW trigger possibility

- Direct events (interrupt and wakeup sources from other peripherals, requiring to be cleared in the peripheral) that feature:
  - Fixed rising edge active trigger
  - No interrupt pending status register bit in the EXTI (the interrupt pending status is provided by the peripheral generating the event)
  - Individual interrupt and event generation mask
  - No SW trigger possibility.

20.2 EXTI block diagram

As shown in Figure 155, the EXTI consists of a register block accessed via an APB interface, an event input Trigger block, and a masking block.

The register block contains all EXTI registers.

The event input trigger block provides event input edge triggering logic.

The masking block provides the event input distribution to the different wakeup, interrupt and event outputs, and their masking.
20.2.1 EXTI connections between peripherals and CPU

The peripherals able to generate wakeup events when the system is in Stop mode or the CPU is in CStop mode are connected to an EXTI configurable event input or direct event input:

- Peripheral signals that generate a pulse are connected to an EXTI configurable event input. For these events the EXTI provides a CPU status pending bit that has to be cleared.
- Peripheral interrupt and wakeup sources that have to be cleared in the peripheral are connected to an EXTI direct event input. There is no CPU status pending bit within the EXTI. The interrupt or wakeup is cleared by the CPU in the peripheral.

The CPU interrupts are connected to their respective CPU NVIC, and, similarly, the CPU event is connected to the CPU rxev input.

The EXTI wakeup signals are connected to the PWR block, and are used to wakeup the CPU.
20.3 EXTI functional description

Depending on the EXTI event input type and wakeup target(s), different logic implementations are used. The applicable features are controlled from register bits:

- Active trigger edge enable, by EXTI rising trigger selection register (EXTI_RTSR1), EXTI rising trigger selection register (EXTI_RTSR2), EXTI interrupt mask register (EXTI_IMR1), and EXTI falling trigger selection register (EXTI_FTSR1), EXTI falling trigger selection register (EXTI_FTSR2), EXTI interrupt mask register (EXTI_IMR1)
- Software trigger, by EXTI software interrupt event register (EXTI_SWIER1), EXTI software interrupt event register (EXTI_SWIER2), EXTI interrupt mask register (EXTI_IMR1)
- CPU interrupt enable, by EXTI interrupt mask register (EXTI_IMR1), EXTI interrupt mask register (EXTI_IMR2), EXTI interrupt mask register (EXTI_IMR3)
- CPU event enable, by EXTI event mask register (EXTI_EMR1), EXTI interrupt mask register (EXTI_IMR2), EXTI event mask register (EXTI_EMR3)

1. X indicates that functionality is available.
20.3.1 EXTI configurable event input - CPU wakeup

*Figure 20.3.2* is a detailed representation of the logic associated with configurable event inputs which always wake up the CPU.

*Figure 156. Configurable event triggering logic CPU wake up*

The software interrupt event register allows the system to trigger configurable events by software, writing the EXTI software interrupt event register (EXTI_SWIER1), the EXTI software interrupt event register (EXTI_SWIER2), or the EXTI interrupt mask register (EXTI_IMR1) register bit.

The rising edge EXTI rising trigger selection register (EXTI_RTSR1), EXTI rising trigger selection register (EXTI_RTSR2), EXTI interrupt mask register (EXTI_IMR1), and falling edge EXTI falling trigger selection register (EXTI_FTSR1), EXTI falling trigger selection register (EXTI_FTSR2), EXTI interrupt mask register (EXTI_IMR1) selection registers allow the system to enable and select the configurable event active trigger edge or both edges.

The devices feature dedicated interrupt mask registers, namely EXTI interrupt mask register (EXTI_IMR1) and EXTI interrupt mask register (EXTI_IMR2), EXTI interrupt mask register (EXTI_IMR3), and EXTI pending register (EXTI_PR1), EXTI pending register (EXTI_PR2), for configurable event pending request registers. The CPU pending register is only set for an unmasked CPU interrupt. Each event provides a individual CPU interrupt to the CPU NVIC. The configurable event interrupts need to be acknowledged by software in the EXTI_PR register.
The devices feature dedicated event mask registers, i.e. EXTI event mask register (EXTI_EMR1), EXTI interrupt mask register (EXTI_IMR2), and EXTI event mask register (EXTI_EMR3). The enabled event then generates an event on the CPU. All events for a CPU are OR-ed together into a single CPU event signal. The CPU pending register (EXTI_PR) is not set for an unmasked CPU event.

When a CPU interrupt or CPU event is enabled, the asynchronous edge detection circuit is reset by the clocked delay and rising edge detect pulse generator. This guarantees that the CPU clock is woken up before the asynchronous edge detection circuit is reset.

Note: A detected configurable event, enabled by the CPU, is only cleared when the CPU wakes up.

20.3.2 EXTI direct event input - CPU wakeup

Figure 157 is a detailed representation of the logic associated with direct event inputs waking up the CPU.

Direct events only provide CPU interrupt enable and CPU event enable functionality.

1. The CPU interrupt for asynchronous direct event inputs (peripheral Wakeup signals) is synchronized with the CPU clock. The synchronous direct event inputs (peripheral interrupt signals), after the asynchronous edge detection, are directly sent to the CPU interrupt without resynchronization.
20.4 EXTI event input mapping

For the sixteen GPIO event inputs the associated IPORT pin has to be selected in the SBS register SBS_EXTICRn. The same pin from each IPORT maps to the corresponding EXTI event input.

The wakeup capabilities of each event input are detailed in Table 144. An event input can wake up the CPU.

The EXTI event inputs with a connection to the CPU NVIC are indicated in the Connection to NVIC column. For the EXTI events not having a connection to the NVIC, the peripheral interrupt is directly connected to the NVIC in parallel with the connection to the EXTI.

All EXTI event inputs are OR-ed together and connected to the CPU event input (rxev).

20.5 **EXTI functional behavior**

The direct event inputs are enabled in the respective peripheral generating the event. The configurable events are enabled by enabling at least one of the trigger edges.

An event only wakes up the CPU when the event-associated CPU interrupt is unmasked and/or the CPU event is unmasked.

For configurable event inputs, when the enabled edge(s) occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding pending PRx bit in EXTI_PR is set and the CPU interrupt signal is activated. EXTI_PR PRx pending bit must be cleared by software writing it to ‘1’. This clears the CPU interrupt.

For direct event inputs, when enabled in the associated peripheral, an event request is generated on the rising edge only. There is no corresponding CPU pending bit. When the associated CPU interrupt is unmasked the corresponding CPU interrupt signal is activated.

The CPU event has to be unmasked to generate an event. When the enabled edge(s) occur on the event input a CPU event pulse is generated. There is no CPU event pending bit.

Both a CPU interrupt and a CPU event may be enabled on the same event input. They both trigger the same event input condition(s).

For the configurable event inputs an event input request can be generated by software when writing a ‘1’ in the software interrupt/event register EXTI_SWIER.
20.5.1 EXTI CPU interrupt procedure

- Unmask the event input interrupt by setting the corresponding mask bits in the EXTI_IMR register.
- For configurable event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
- Enable the associated interrupt source in the CPU NVIC or use the SEVONPEND, so that an interrupt coming from the CPU interrupt signal is detectable by the CPU after a WFI/WFE instruction.
  - For configurable event inputs the associated EXTI pending bit needs to be cleared.

20.5.2 EXTI CPU event procedure

- Unmask the event input by setting the corresponding mask bits of the EXTI_EMR register.
- For configurable event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
- The CPU event signal is detected by the CPU after a WFE instruction.
  - For configurable event inputs there is no EXTI pending bit to clear.

20.5.3 EXTI CPU wakeup procedure

- Unmask the event input by setting at least one of the corresponding mask bits in the EXTI_IMR and/or EXTI_EMR registers. The CPU wakeup is generated at the same time as the unmasked CPU interrupt and/or CPU event.
- For configurable event inputs, enable the event input by setting either one or both of the corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
- Direct events automatically generate a CPU wakeup.

20.5.4 EXTI software interrupt/event trigger procedure

Any of the configurable event inputs can be triggered from the software interrupt/event register (the associated CPU interrupt and/or CPU event must be enabled by their respective procedure).

- Enable the event input by setting at least one of the corresponding edge trigger bits in the EXTI_RTSR and/or EXTI_FTSR registers.
- Unmask the software interrupt/event trigger by setting at least one of the corresponding mask bits in the EXTI_IMR and/or EXTI_EMR registers.
- Trigger the software interrupt/event by writing “1” to the corresponding bit in the EXTI_SWIER register.
- The event input may be disabled by clearing the EXTI_RTSR and EXTI_FTSR register bits.

Note: An edge on the configurable event input also triggers an interrupt/event.
20.6 EXTI registers

The registers can only be accessed with a 32-bit (word). A byte or half-word cannot be read or written.

20.6.1 EXTI rising trigger selection register (EXTI_RTSR1)

Address offset: 0x00
Reset value: 0x0000 0000

Refer to Section 2.3 on page 149 for the register boundary addresses.
21 Cyclic redundancy check calculation unit (CRC)

21.1 Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

21.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  $x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-, 16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of CRC_DR register that can be accessed by words, right-aligned half-words and right-aligned bytes
21.3 CRC functional description

21.3.1 CRC block diagram

<td>Digital input</td>
<td>AHB clock</td>
</tr>
</tbody>
</table>

21.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit accesses are allowed.

The duration of the computation depends on data width:
- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait-states due to the previous CRC calculation.
The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register.

For example, 0x1A2B3C4D input data are used for CRC calculation as:
- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register.

The operation is done at bit level. For example, 0x11223344 output data are converted to 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

**Polynomial programmability**

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

*Note: The type of an even polynomial is \( X + X^2 + \ldots + X^n \), while the type of an odd polynomial is \( 1 + X + X^2 + \ldots + X^n \).*

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.
### 21.4 CRC registers

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes. For the other registers only 32-bit accesses are allowed.

#### 21.4.1 CRC data register (CRC_DR)

**Address offset:** 0x00

Bits 31:8  Reserved, must be kept at reset value.

Bit 7  **REV_OUT**: Reverse output data  
This bit controls the reversal of the bit order of the output data.  
0: Bit order not affected  
1: Bit-reversed output format

Bits 6:5  **REV_IN[1:0]**: Reverse input data  
This bitfield controls the reversal of the bit order of the input data  
00: Bit order not affected  
01: Bit reversal done by byte  
10: Bit reversal done by half-word  
11: Bit reversal done by word

Bits 4:3  **POLYSIZE[1:0]**: Polynomial size  
These bits control the size of the polynomial.  
00: 32 bit polynomial  
01: 16 bit polynomial  
10: 8 bit polynomial  
11: 7 bit polynomial

Bits 2:1  Reserved, must be kept at reset value.

Bit 0  **RESET**: RESET bit  
This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by hardware.
21.4.4 CRC initial value (CRC_INIT)

Refer to Section 2.3 on page 149 for the register boundary addresses.
22 CORDIC coprocessor (CORDIC)

22.1 CORDIC introduction

The CORDIC coprocessor provides hardware acceleration of mathematical functions (mainly trigonometric ones) commonly used in motor control, metering, signal processing, and many other applications.

It speeds up the calculation of these functions compared to a software implementation, making possible the use of a lower operating frequency, or freeing up processor cycles to perform other tasks.

22.2 CORDIC main features

- 24-bit CORDIC rotation engine
- Circular and Hyperbolic modes
- Rotation and Vectoring modes
- Functions: sine, cosine, sinh, cosh, atan, atan2, atanh, modulus, square root, natural logarithm
- Programmable precision
- Low latency AHB slave interface
- Results can be read as soon as ready, without polling or interrupt
- DMA read and write channels
- Multiple register read/write by DMA

22.3 CORDIC functional description

22.3.1 General description

The CORDIC is a cost-efficient successive approximation algorithm for evaluating trigonometric and hyperbolic functions.

In trigonometric (circular) mode, the sine and cosine of an angle $\theta$ are determined by rotating the unit vector [1, 0] through decreasing angles until the cumulative sum of the rotation angles equals the input angle $\theta$. The x and y cartesian components of the rotated vector then correspond, respectively, to the cosine and sine of $\theta$. Inversely, the angle of a vector [x, y] corresponding to arctangent (y / x), is determined by rotating [x, y] through successively decreasing angles to obtain the unit vector [1, 0]. The cumulative sum of the rotation angles gives the angle of the original vector.

The CORDIC algorithm can also be used for calculating hyperbolic functions (sinh, cosh, atanh), by replacing the successive circular rotations by steps along a hyperbole.

Other functions can be derived from the basic functions described above.

22.3.2 CORDIC functions

The first step when using the coprocessor is to select the required function, by programming the FUNC field of the CORDIC_CR register accordingly.
Table 149 lists the functions supported by the CORDIC coprocessor.

### Table 149. CORDIC functions

</tbody>
</table>

Several functions take two input arguments (ARG1 and ARG2) and some generate two results (RES1 and RES2) simultaneously. This is a side-effect of the algorithm and means that only one operation is needed to obtain two values. This is the case, for example, when performing polar-to-rectangular conversion: \( \sin \theta \) also generates \( \cos \theta \), \( \cos \theta \) also generates \( \sin \theta \). Similarly, for rectangular-to-polar conversion (\( \text{phase}(x,y) \), \( \text{modulus}(x,y) \) and for hyperbolic functions (\( \cosh \theta \), \( \sinh \theta \)).

**Note:** The exponential function, \( \exp x \), can be obtained as the sum of \( \sinh x \) and \( \cosh x \). Furthermore, base \( N \) logarithms, \( \log_N x \), can be derived by multiplying \( \ln x \) by a constant \( K \), where \( K = 1/\ln N \).

For certain functions (atan, log, sqrt) a scaling factor (see Section 22.3.4) can be applied to extend the range of the function beyond the maximum [-1, 1] supported by the q1.31 fixed point format. The scaling factor must be set to 0 for all other circular functions, and to 1 for hyperbolic functions.

### Cosine

#### Table 150. Cosine parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARG1</td>
<td>Angle ( \theta ) in radians, divided by ( \pi )</td>
<td>[-1, 1]</td>
</tr>
<tr>
<td>ARG2</td>
<td>Modulus ( m )</td>
<td>[0, 1]</td>
</tr>
<tr>
<td>RES1</td>
<td>( m \cdot \cos \theta )</td>
<td>[-1, 1]</td>
</tr>
</tbody>
</table>
This function calculates the cosine of an angle in the range \(-\pi\) to \(\pi\). It can also be used to perform polar to rectangular conversion.

The primary argument is the angle \(\theta\) in radians. It must be divided by \(\pi\) before programming ARG1.

The secondary argument is the modulus \(m\). If \(m\) is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the cosine of the angle, multiplied by the modulus.

The secondary result, RES2, is the sine of the angle, multiplied by the modulus.

### Sine

This function calculates the sine of an angle in the range \(-\pi\) to \(\pi\). It can also be used to perform polar to rectangular conversion.

The primary argument is the angle \(\theta\) in radians. It must be divided by \(\pi\) before programming ARG1.

The secondary argument is the modulus \(m\). If \(m\) is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the sine of the angle, multiplied by the modulus.

The secondary result, RES2, is the cosine of the angle, multiplied by the modulus.

### Phase

This function calculates the phase angle \(\theta\) in radians, divided by \(\pi\). It can also be used to perform polar to rectangular conversion.

The primary argument is the angle \(\theta\) in radians. It must be divided by \(\pi\) before programming ARG1.

The secondary argument is the modulus \(m\). If \(m\) is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the cosine of the angle, multiplied by the modulus.

The secondary result, RES2, is the cosine of the angle, multiplied by the modulus.
This function calculates the phase angle in the range \(-\pi\) to \(\pi\) of a vector \(v = [x, y]\) (also known as \(\text{atan2}(y, x)\)). It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If \(|x| > 1\), a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If \(|y| > 1\), a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the phase angle \(\theta\) of the vector \(v\). RES1 must be multiplied by \(\pi\) to obtain the angle in radians. Note that values close to \(\pi\) may sometimes wrap to \(-\pi\) due to the circular nature of the phase angle.

The secondary result, RES2, is the modulus, given by: \(|v| = \sqrt{x^2 + y^2}\). If \(|v| > 1\) the result in RES2 is saturated to 1.

**Modulus**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARG1</td>
<td>x coordinate</td>
<td>[-1, 1]</td>
</tr>
<tr>
<td>ARG2</td>
<td>y coordinate</td>
<td>[-1, 1]</td>
</tr>
<tr>
<td>RES1</td>
<td>Modulus m</td>
<td>[0, 1]</td>
</tr>
<tr>
<td>RES2</td>
<td>Phase angle (\theta)</td>
<td>[-1, 1]</td>
</tr>
<tr>
<td>SCALE</td>
<td>Not applicable</td>
<td>0</td>
</tr>
</tbody>
</table>

This function calculates the magnitude, or modulus, of a vector \(v = [x, y]\). It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If \(|x| > 1\), a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If \(|y| > 1\), a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the modulus, given by: \(|v| = \sqrt{x^2 + y^2}\). If \(|v| > 1\) the result in RES1 is saturated to 1.

The secondary result, RES2, is the phase angle \(\theta\) of the vector \(v\). RES2 must be multiplied by \(\pi\) to obtain the angle in radians. Note that values close to \(\pi\) may sometimes wrap to \(-\pi\) due to the circular nature of the phase angle.
Arctangent

Table 154. Arctangent parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARG1</td>
<td>( x \cdot 2^{-n} )</td>
<td>[-1, 1]</td>
</tr>
<tr>
<td>ARG2</td>
<td>Not applicable</td>
<td>-</td>
</tr>
<tr>
<td>RES1</td>
<td>( 2^{-n} \cdot \tan^{-1} x ), in radians, divided by ( \pi )</td>
<td>[-1, 1]</td>
</tr>
<tr>
<td>RES2</td>
<td>Not applicable</td>
<td>-</td>
</tr>
<tr>
<td>SCALE</td>
<td>( n )</td>
<td>[0, 7]</td>
</tr>
</tbody>
</table>

This function calculates the arctangent, or inverse tangent, of the input argument \( x \).

The primary argument, ARG1, is the input value, \( x = \tan \theta \). If \(|x| > 1\), a scaling factor of \( 2^{-n} \) must be applied in software such that \(-1 < x \cdot 2^{-n} < 1\). The scaled value \( x \cdot 2^{-n} \) is programmed in ARG1 and the scale factor \( n \) must be programmed in the SCALE parameter.

Note that the maximum input value allowed is \( \tan \theta = 128 \), which corresponds to an angle \( \theta = 89.55 \) degrees. For \(|x| > 128\), a software method must be used to find \( \tan^{-1} x \).

The secondary argument, ARG2, is unused.

The primary result, RES1, is the angle \( \theta = \tan^{-1} x \). RES1 must be multiplied by \( 2^n \cdot \pi \) to obtain the angle in radians.

The secondary result, RES2, is unused.

Hyperbolic cosine

Table 155. Hyperbolic cosine parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARG1</td>
<td>( x \cdot 2^{-n} )</td>
<td>[-0.559, 0.559]</td>
</tr>
<tr>
<td>ARG2</td>
<td>Not applicable</td>
<td>-</td>
</tr>
<tr>
<td>RES1</td>
<td>( 2^{-n} \cdot \cosh x )</td>
<td>[0.5, 0.846]</td>
</tr>
<tr>
<td>RES2</td>
<td>( 2^{-n} \cdot \sinh x )</td>
<td>[-0.683, 0.683]</td>
</tr>
<tr>
<td>SCALE</td>
<td>( n )</td>
<td>1</td>
</tr>
</tbody>
</table>

This function calculates the hyperbolic cosine of a hyperbolic angle \( x \). It can also be used to calculate the exponential functions \( e^x = \cosh x + \sinh x \), and \( e^{-x} = \cosh x - \sinh x \).

The primary argument is the hyperbolic angle \( x \). Only values of \( x \) in the range \([-1.118, 1.118]\) are supported. Since the minimum value of \( \cosh x \) is 1, which is beyond the range of the q1.31 format, a scaling factor of \( 2^{-n} \) must be applied in software. The factor \( n = 1 \) must be programmed in the SCALE parameter.

The secondary argument is not used.
The primary result, RES1, is the hyperbolic cosine, cosh x. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic sine, sinh x. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic sine

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARG1</td>
<td>$x \cdot 2^{-n}$</td>
<td>[-0.559, 0.559]</td>

<tr>
<td>RES2</td>
<td>$2^{-n} \cdot \cosh x$</td>
<td>[0.5, 0.846]</td>
</tr>
<tr>
<td>SCALE</td>
<td>$n$</td>
<td>1</td>
</tr>
</tbody>
</table>

This function calculates the hyperbolic sine of a hyperbolic angle $x$. It can also be used to calculate the exponential functions $e^x = \cosh x + \sinh x$, and $e^{-x} = \cosh x - \sinh x$.

The primary argument is the hyperbolic angle $x$. Only values of $x$ in the range $-1.118$ to $+1.118$ are supported. For all input values, a scaling factor of $2^{-n}$ must be applied in software, where $n = 1$. The scaled value $x \cdot 0.5$ is programmed in ARG1 and the factor $n = 1$ must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic sine, sinh $x$. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic cosine, cosh $x$. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic arctangent

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>

</tr>
<tr>
<td>RES2</td>
<td>Not applicable</td>
<td>-</td>
</tr>
<tr>
<td>SCALE</td>
<td>$n$</td>
<td>1</td>
</tr>
</tbody>
</table>

This function calculates the hyperbolic arctangent of the input argument $x$.

The primary argument is the input value $x$. Only values of $x$ in the range $-0.806$ to $+0.806$ are supported. The value $x$ must be scaled by a factor $2^{-n}$, where $n = 1$. The scaled value
x \cdot 0.5 is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result is the hyperbolic arctangent, \( \text{atanh} \ x \). RES1 must be multiplied by 2 to obtain the correct value.

The secondary result is not used.

**Natural logarithm**

**Table 158. Natural logarithm parameters**

<table>

This function calculates the natural logarithm of the input argument \( x \).

The primary argument is the input value \( x \). Only values of \( x \) in the range 0.107 to 9.35 are supported. The value \( x \) must be scaled by a factor \( 2^{-n} \), such that \( x \cdot 2^{-n} < 1-2^{-n} \). The scaled value \( x \cdot 2^{-n} \) is programmed in ARG1 and the factor \( n \) must be programmed in the SCALE parameter.

**Table 159** lists the valid scaling factors, \( n \), and the corresponding ranges of \( x \) and ARG1.

**Table 159. Natural log scaling factors and corresponding ranges**

<table>

</tbody>
</table>

The secondary argument is not used.

The primary result is the natural logarithm, \( \ln x \). RES1 must be multiplied by \( 2^{(n+1)} \) to obtain the correct value.

The secondary result is not used.
Square root

This function calculates the square root of the input argument \( x \).

The primary argument is the input value \( x \). Only values of \( x \) in the range 0.027 to 2.34 are supported. The value \( x \) must be scaled by a factor \( 2^{-n} \), such that \( x \cdot 2^{-n} < (1 - 2^{(n-2)}) \).

The scaled value \( x \cdot 2^{-n} \) is programmed in ARG1 and the factor \( n \) must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result is the square root of \( x \). RES1 must be multiplied by \( 2^n \) to obtain the correct value.

The secondary result is not used.

22.3.3 Fixed point representation

The CORDIC operates in fixed point signed integer format. Input and output values can be either q1.31 or q1.15.

In q1.31 format, numbers are represented by one sign bit and 31 fractional bits (binary decimal places). The numeric range is therefore -1 (0x80000000) to 1 - \( 2^{-31} \) (0x7FFFFFFF).

In q1.15 format, the numeric range is 1 (0x8000) to 1 - \( 2^{-15} \) (0x7FFF). This format has the advantage that two input arguments can be packed into a single 32-bit write, and two results can be fetched in one 32-bit read.

22.3.4 Scaling factor

Several of the functions listed in Section 22.3.2 specify a scaling factor, SCALE. This allows the function input range to be extended to cover the full range of values supported by the CORDIC, without saturating the input, output, or internal registers. If the scaling factor is
required, it must be calculated by software and programmed into the SCALE field of the CORDIC_CSR register. The input arguments must be scaled accordingly before programming the scaled values in the CORDIC_WDATA register. The scaling must also be undone on the results read from the CORDIC_RDATA register.

Note: The scaling factor entails a loss of precision due to truncation of the scaled value.

22.3.5 Precision

The precision of the result is dependent on the number of CORDIC iterations. The algorithm converges at a constant rate of one binary digit per iteration for trigonometric functions (sine, cosine, phase, modulus), see Figure 159.

For hyperbolic functions (hyperbolic sine, hyperbolic cosine, natural logarithm), the convergence rate is less constant due to the peculiarities of the CORDIC algorithm (see Figure 160). The square root function converges at roughly twice the speed of the hyperbolic functions (see Figure 161).

Figure 159. CORDIC convergence for trigonometric functions
Figure 160. CORDIC convergence for hyperbolic functions

Hyperbolic Sine/Cosine Convergence of q1.23 fixed point Cordic

Max absolute error

q1.15

q1.31

Iterations
Figure 161. CORDIC convergence for square root

Note: The convergence rate decreases as the quantization error starts to become significant.

The CORDIC can perform four iterations per clock cycle. For each function, the maximum error remaining after every four iterations is shown in Table 162, together with the number of clock cycles required to reach that precision. From this table, the desired number of cycles can be determined and programmed in the PRECISION field of the CORDIC_CR register. The coprocessor stops as soon as the programmed number of iterations is completed, and the result can be read immediately.

Table 162. Precision vs. number of iterations

</table>
The fastest way to use the coprocessor is to preprogram the CORDIC_CSR register with the function to be performed (FUNC), the desired number of clock cycles (PRECISION), the size of the input and output values (ARGSIZE, RESSIZE), the number of input arguments (NARGS) and/or results (NRES), and the scaling factor (SCALE), if applicable.

The calculation is triggered by writing the input arguments to the CORDIC_WDATA register. As soon as the correct number of input arguments has been written (and any ongoing calculation has finished), a new calculation is launched using these input arguments and the current CORDIC_CSR settings. There is no need to reprogram the CORDIC_CSR register if there is no change.

If a dual 32-bit input argument is needed (ARGSIZE = 0, NARGS = 1), the primary input argument (ARG1) must be written first, followed by the secondary argument (ARG2). If the secondary argument remains unchanged for a series of calculations, the second write can be avoided, by reprogramming the number of arguments to one (NARGS = 0), once the first calculation has started. The secondary argument retains its programmed value as long as the function is not changed.

Note: ARG2 is set to +1 (0x7FFFFFFF) after a reset.

If two 16-bit arguments are used (ARGSIZE = 1) they must be packed into a 32-bit word, with ARG1 in the least significant half-word and ARG2 in the most significant half-word. The packed 32-bit word is then written to the CORDIC_WDATA register. Only one write is needed in this case (NARGS = 0).

For functions taking only one input argument, ARG1, it is recommended to set NARGS = 0. If NARGS = 1, a second write to CORDIC_WDATA must be performed to trigger the calculation. The ARG2 data in this case is not used.
Once the calculation starts, any attempt to read the CORDIC_RDATA register inserts bus wait-states until the calculation is completed, before returning the result. It is then possible for the software to write the input and immediately read the result without polling to see if it is valid. Alternatively, the processor can wait for the appropriate number of clock cycles before reading the result. This time can be used to program the CORDIC_CSR register for the next calculation, and prepare the next input data, if needed. The CORDIC_CSR register can be reprogrammed while a calculation is in progress, without affecting the result of the ongoing calculation. In the same way, the CORDIC_WDATA register can be updated with the next argument(s) once the previous ones have been taken into account. The next arguments and settings remain pending until the previous calculation has completed.

When a calculation is finished, the result(s) can be read from the CORDIC_RDATA register. If two 32-bit results are expected (NRES = 1, RESSIZE = 0), the primary result (RES1) is read out first, followed by the secondary result (RES2). If only one 32-bit result is expected (NRES = 0, RESSIZE = 0), then RES1 is output on the first read.

If 16-bit results are expected (RESSIZE = 1), a single read to CORDIC_RDATA fetches both results packed into a 32-bit word. RES1 is in the lower half-word, and RES2 in the upper half-word. In this case, it is recommended to program NRES = 0. If NRES = 1, a second read of CORDIC_RDATA must be performed to free up the CORDIC for the next operation. The data from this second read must be discarded.

The next calculation starts when the expected number of results has been read, provided the expected number of arguments has been written. This means that at any time, there can be a calculation in progress, or waiting for the results to be read, and an operation pending. Any further access to CORDIC_WDATA while an operation is pending cancels it and overwrites the data.

The following sequence summarizes the use of the CORDIC_IP in zero-overhead mode:
1. Program the CORDIC_CSR register with the appropriate settings
2. Program the argument(s) for the first calculation in the CORDIC_WDATA register. This launches the first calculation.
3. If needed, update the CORDIC_CSR register settings for the next calculation.
4. Program the argument(s) for the next calculation in the CORDIC_WDATA register.
5. Read the result(s) from the CORDIC_RDATA register. This triggers the next calculation.
6. Go to step 3.

### 22.3.7 Polling mode

When a new result is available in the CORDIC_RDATA register, the RRDY flag is set in the CORDIC_CSR register. The flag can be polled by reading the register. It is reset by reading the CORDIC_RDATA register (once or twice, depending on the NRES field of the CORDIC_CSR register).

Polling the RRDY flag takes slightly longer than reading the CORDIC_RDATA register directly, since the result is not read as soon as it is available. The processor and bus interface are not stalled while reading the CORDIC_CSR register, so this mode may be of interest if stalling the processor is not acceptable (for example, if low latency interrupts must be serviced).
22.3.8 **Interrupt mode**

By setting the interrupt enable (IE) bit in the CORDIC_CSR register, an interrupt is generated whenever the RRDY flag is set. The interrupt is cleared when the flag is reset.

This mode allows the result of the calculation to be read under interrupt service routine, and hence given a priority relative to other tasks. However, it is slower than directly reading the result, or polling the flag, due to the interrupt handling delays.

22.3.9 **DMA mode**

If the DMA write enable (DMAWEN) bit is set in the CORDIC_CSR register, and no operation is pending, a DMA write channel request is generated. The DMA controller can transfer a primary input argument (ARG1) from memory into the CORDIC_WDATA register. Writing into the register deasserts the DMA request. If NARGS = 1 in the CORDIC_CSR register, a second DMA write channel request is generated to transfer the secondary input argument (ARG2) into the CORDIC_WDATA register. When all input arguments have been written, and any ongoing calculation has been completed (by reading the results), a new calculation is started and another DMA write channel request is generated.

If the DMA read enable (DMAREN) bit is set in the CORDIC_CSR register, the RRDY flag going active generates a DMA read channel request. The DMA controller can then transfer the primary result (RES1) from the CORDIC_RDATA register to memory. Reading the register deasserts the DMA request. If NRES = 1 in the CORDIC_CSR register, a second DMA request is generated to read out the secondary result (RES2). When all results have been read, the RRDY flag is deasserted.

The DMA read and write channels can be enabled separately. If both channels are enabled, the CORDIC can autonomously perform repeated calculations on a buffer of data without processor intervention. This allows the processor to perform other tasks. The DMA controller is operating in memory-to-peripheral mode for the write channel, and peripheral-to-memory mode for the read channel. The sequence is started by the processor setting the DMAWEN flag, the DMA read and write requests are generated as fast as the CORDIC can process the data.

In some cases, the input data may be stored in memory, and the output is transferred at regular intervals to another peripheral, such as a digital-to-analog converter. In this case, the destination peripheral generates a DMA request each time it needs a new data. The DMA controller can directly fetch the next sample from the CORDIC_RDATA register (in this case the DMA controller is operating in memory-to-peripheral mode, even though the source is a peripheral register). The act of reading the result allows the CORDIC to start a new calculation, which in turn generates a DMA write channel request, and the DMA controller transfers the next input value to the CORDIC_WDATA register. The DMA write channel is enabled (DMAWEN = 1), but the read channel must not be enabled.

In a similar way, data coming from another peripheral, such as an ADC, can be transferred directly to the CORDIC_WDATA register (in peripheral-to-memory mode). The DMA write channel must not be enabled. The CORDIC processes the input data and generates a DMA read request when complete, if DMAREN = 1. The DMA controller then transfers the result from CORDIC_RDATA register to memory (peripheral-to-memory mode).

**Note:** No DMA request is generated to program the CORDIC_CSR register. DMA mode is therefore useful only when repeatedly performing the same function with the same settings. The scale factor cannot be changed during a series of DMA transfers.
Note: Each DMA request must be acknowledged, as a result of the DMA performing an access to the CORDIC_WDATA or CORDIC_RDATA register. If an extraneous access to the relevant register occurs before this, the acknowledge is asserted prematurely, and may block the DMA channel. Therefore, when the DMA read channel is enabled, CPU access to the CORDIC_RDATA register must be avoided. Similarly, the processor must avoid accessing the CORDIC_WDATA register when the DMA write channel is enabled.

22.4 CORDIC registers

The CORDIC registers can only be accessed in 32-bit word format.

22.4.1 CORDIC control/status register (CORDIC_CSR)

Address offset: 0x00

Reset value: 0x0000 0050

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

Bit 31 **RRDY**: Result ready flag
- 0: No new data in output register
- 1: CORDIC_RDATA register contains new data.

This bit is set by hardware when a CORDIC operation completes. It is reset by hardware when the CORDIC_RDATA register is read (NRES+1) times.

When this bit is set, if the IEN bit is also set, the CORDIC interrupt is asserted. If the DMAREN bit is set, a DMA read channel request is generated. While this bit is set, no new calculation is started.

Bits 30:23 Reserved, must be kept at reset value.

Bit 22 **ARGSIZE**: Width of input data
- 0: 32-bit
- 1: 16-bit

ARGSIZE selects the number of bits used to represent input data.

If 32-bit data is selected, the CORDIC_WDATA register expects arguments in q1.31 format.

If 16-bit data is selected, the CORDIC_WDATA register expects arguments in q1.15 format.

The primary argument (ARG1) is written to the least significant half-word, and the secondary argument (ARG2) to the most significant half-word.

Bit 21 **RESSIZE**: Width of output data
- 0: 32-bit
- 1: 16-bit

RESSIZE selects the number of bits used to represent output data.

If 32-bit data is selected, the CORDIC_RDATA register contains results in q1.31 format.

If 16-bit data is selected, the least significant half-word of CORDIC_RDATA contains the primary result (RES1) in q1.15 format, and the most significant half-word contains the secondary result (RES2), also in q1.15 format.
Bit 20 **NARGS**: Number of arguments expected by the CORDIC\_WDATA register
0: Only one 32-bit write (or two 16-bit values if ARGSIZE = 1) is needed for the next calculation.
1: Two 32-bit values must be written to the CORDIC\_WDATA register to trigger the next calculation.
Reads return the current state of the bit.

Bit 19 **NRES**: Number of results in the CORDIC\_RDATA register
0: Only one 32-bit value (or two 16-bit values if RESSIZE = 1) is transferred to the CORDIC\_RDATA register on completion of the next calculation. One read from CORDIC\_RDATA resets the RRDY flag.
1: Two 32-bit values are transferred to the CORDIC\_RDATA register on completion of the next calculation. Two reads from CORDIC\_RDATA are necessary to reset the RRDY flag.
Reads return the current state of the bit.

Bit 18 **DMAWEN**: Enable DMA write channel
0: Disabled. No DMA write requests are generated.
1: Enabled. Requests are generated on the DMA write channel whenever no operation is pending.
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 17 **DMAREN**: Enable DMA read channel
0: Disabled. No DMA read requests are generated.
1: Enabled. Requests are generated on the DMA read channel whenever the RRDY flag is set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 16 **IEN**: Enable interrupt
0: Disabled. No interrupt requests are generated.
1: Enabled. An interrupt request is generated whenever the RRDY flag is set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **SCALE[2:0]**: Scaling factor
The value of this field indicates the scaling factor applied to the arguments and/or results. A value n implies that the arguments have been multiplied by a factor $2^{-n}$, and/or the results need to be multiplied by $2^n$. Refer to Section 22.3.2 for the applicability of the scaling factor for each function and the appropriate range.

Bits 7:4 **PRECISION[3:0]**: Precision required (number of iterations)
0: reserved
1 to 15: (Number of iterations)/4
To determine the number of iterations needed for a given accuracy refer to Table 162.
Note that for most functions, the recommended range for this field is 3 to 6.
Bits 3:0 **FUNC[3:0]**: Function

- 0: Cosine
- 1: Sine
- 2: Phase
- 3: Modulus
- 4: Arctangent
- 5: Hyperbolic cosine
- 6: Hyperbolic sine
- 7: Arctanh
- 8: Natural logarithm
- 9: Square root
- 10 to 15: Reserved

### 22.4.2 CORDIC argument register (CORDIC_WDATA)

Address offset: 0x04

Reset value: 0xXXXX XXXX

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ARG[31:16]]</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ARG[15:0]]</td>
</tr>
</tbody>
</table>

Bits 31:0 **ARG[31:0]**: Function input arguments

This register is programmed with the input arguments for the function selected in the CORDIC_CSR register FUNC field.

If 32-bit format is selected (CORDIC_CSR.ARGSIZE = 0) and two input arguments are required (CORDIC_CSR.NARGS = 1), two successive writes are required to this register. The first writes the primary argument (ARG1), the second writes the secondary argument (ARG2).

If 32-bit format is selected and only one input argument is required (NARGS = 0), only one write is required to this register, containing the primary argument (ARG1).

If 16-bit format is selected (CORDIC_CSR.ARGSIZE = 1), one write to this register contains both arguments. The primary argument (ARG1) is in the lower half, ARG[15:0], and the secondary argument (ARG2) is in the upper half, ARG[31:16]. In this case, NARGS must be set to 0.

Refer to Section 22.3.2 for the arguments required by each function, and their permitted range.

When the required number of arguments has been written, the CORDIC evaluates the function designated by CORDIC_CSR.FUNC using the supplied input arguments, provided any previous calculation has completed. If a calculation is ongoing, the ARG1 and ARG2 values are held pending until the calculation is completed and the results read. During this time, a write to the register cancels the pending operation and overwrites the argument data.
22.4.3 CORDIC result register (CORDIC_RDATA)

Address offset: 0x08
Reset value: 0x0000 0000

Bits 31:0 RES[31:0]: Function result

If 32-bit format is selected (CORDIC_CSR.RESSIZE = 0) and two output values are expected (CORDIC_CSR.NRES = 1), this register must be read twice when the RRDY flag is set. The first read fetches the primary result (RES1). The second read fetches the secondary result (RES2) and resets RRDY.

If 32-bit format is selected and only one output value is expected (NRES = 0), only one read of this register is required to fetch the primary result (RES1) and reset the RRDY flag.

If 16-bit format is selected (CORDIC_CSR.RESSIZE = 1), this register contains the primary result (RES1) in the lower half, RES[15:0], and the secondary result (RES2) in the upper half, RES[31:16]. In this case, NRES must be set to 0, and only one read performed. A read from this register resets the RRDY flag in the CORDIC_CSR register.

Refer to Section 2.3 for the register boundary addresses.
23 Flexible memory controller (FMC)

The flexible memory controller (FMC) includes three memory controllers:

- The NOR/PSRAM memory controller
- The NAND memory controller
- The Synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) controller

23.1 FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, SDRAM memories, and NAND flash memory. Its main purposes are:

- to translate AXI transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique Chip Select. The FMC performs only one access at a time to an external device.

The main features of the FMC are the following:

- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR flash memory/OneNAND flash memory
  - PSRAM (4 memory banks)
  - NAND flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) memories
- Burst mode support for faster access to synchronous devices such as NOR flash memory, PSRAM and SDRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-,16- or 32-bit wide data bus
- Independent Chip Select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM and SDRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth
  The Write FIFO is common to all memory controllers and consists of:
  - a Write Data FIFO which stores the data to be written to the memory
  - a Write Address FIFO which stores the address (up to 28 bits) plus the data size (up to 2 bits). When operating in Burst mode, only the start address is stored except when crossing a page boundary (for PSRAM and SDRAM). In this case, the burst is broken into two FIFO entries.
- Cacheable Read FIFO with 6 x64-bit depth (6 x14-bit address tag) for SDRAM controller.

At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.
The FMC registers that define the external device type and associated characteristics are set at boot time and do not change until the next reset or power-up. However, only a few bits can be changed on-the-fly:

- ECCEN and PBKEN bits in the FMC_PCR register
- IFS, IRS and ILS bits in the FMC_SR register
- MODE[2:0], CTB1/CTB2, NRFS and MRD bits in the FMC_SDCMR register
- REIE and CRE bits in the FMC_SDRTR register.

Follow the below sequence to modify parameters while the FMC is enabled:

1. First disable the FMC to prevent further accesses to any memory controller while the register is modified.
2. Update all required configurations.
3. Enable the FMC again.

When the SDRAM controller is used, if the SDCLK Clock ratio or refresh rate has to be modified after initialization phase, the following procedure must be followed.

1. Put the SDRAM device in Self-refresh mode.
2. Disable the FMC by resetting the FMCEN bit in the FMC_BCR1 register.
3. Update the required parameters.
4. Enable the FMC once all parameters have been updated.
5. Then, send the Clock Configuration Enable command to exit Self-fresh mode.

### 23.2 FMC block diagram

The FMC consists of the following main blocks:

- The NOR flash/PSRAM/SRAM controller
- The NAND controller
- The SDRAM controller
- The AXI interface
- The AHB interface (including the FMC configuration registers)

The block diagram is shown in the figure below.
Figure 162. FMC block diagram

- fmc_it to NVIC
- fmc_hclk
- fmc_ker_ck
- 32-bit AHB bus
- 64-bit AXI bus

**NOR/PSRAM memory controller**

<td>FMC interface clock</td>
</tr>
</tbody>
</table>

23.4 **AHB interface**

The AHB slave interface allows internal CPUs to configure the FMC registers. The AHB clock (fmc_hclk) is the reference clock for the FMC register accesses.

23.5 **AXI interface**

The AXI slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AXI transactions are translated into the external device protocol. As the AXI data bus is 64-bit wide, the AXI transactions might be split into several consecutive 32-, 16- or 8-bit accesses according to data size accesses. The FMC Chip Select (FMC_NEx) does not toggle between consecutive accesses except in case of accesses in mode D when the Extended mode is enabled.

The FMC generates an AXI slave error when one of the following conditions is met:

- Reading or writing to an FMC bank (Bank 1 to 4) which is not enabled.
- Writing to a write protected SDRAM bank (WP bit set in the FMC_SDCRx register).
- Violation of the SDRAM address range (access to reserved address range)
- Attempting to read/write access from/to SDRAM bank when it is not yet initialized

The FMC generates an AXI decoder error when ADDR[31:28] address bits are not supported by the FMC bank base address following the BMAP[1:0] bits configuration.

The kernel clock for the FMC is the asynchronous fmc_ker_ck clock (refer to *Section Reset and Clock control (RCC)* for fmc_ker_ck clock source selection).
### 23.5.1 Supported memories and transactions

#### General transaction rules

The requested AXI transaction data size can be 8-, 16-, 32- or 64-bit wide whereas the accessed external device has a fixed data width. The best performance is always achieved with aligned AXI transactions whose size matches the external device data width.

When AXI transaction data size is different from the device data width, the result depends on the following factors:

- **AXI transaction data size is greater than the device data width:**
  - Read/Write transactions: the FMC splits the AXI transaction into smaller consecutive accesses matching the external device data width.

- **AXI transaction data size is smaller than the external device data width and the device supports byte selection (SRAM, PSRAM, SDRAM):**
  - Write transactions, the FMC manages the transaction using the byte lane signals.
  - Read transactions, the FMC returns all bytes according to the external device data width. The useless bytes are discarded by the system.

- **AXI transaction data size is smaller than the external device data width and the device does not support byte selection (NOR and NAND flash memories):**
  - Write transactions: the FMC writes some irrelevant bytes which may corrupt the external device.
  - Read transactions: the FMC returns all bytes according to the external device data width. The useless bytes are discarded by the system.

#### Caution: Address alignment

- Read transactions with unaligned addresses (such as half-word starting at an odd address) are not supported by the FMC.
- Write transactions with unaligned addresses:
  - Their support depends on byte selection availability on the external device:
    - If the device does not support byte selection (NOR and NAND flash memories), narrow write transactions and/or unaligned write transaction are not supported since the FMC would write irrelevant bytes and corrupt the external device.

#### Wrap support for NOR flash/PSRAM and SDRAM

The synchronous memories must be configured in Linear burst mode of undefined length as not all masters can issue wrap transactions.

If a master generates a wrap transaction:

- The read is split into two linear burst transactions.
- The write is split into two linear burst transactions if the write FIFO is enabled and into several linear burst transactions if the write FIFO is disabled.

#### Configuration registers

The FMC can be configured through a set of registers. Refer to Section 23.7.6, for a detailed description of the NOR flash/PSRAM controller registers. Refer to Section 23.8.7, for a detailed description of the NAND flash registers and to Section 23.9.5 for a detailed description of the SDRAM controller registers.
23.6 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see Figure 163):

- Bank 1 is used to address up to 4 NOR flash memory or PSRAM devices. This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated Chip Selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4
- Bank 2 and Bank 4 are not used by the FMC.
- Bank 3 is used to address NAND flash memory devices. The MPU memory attribute for this space must be reconfigured by software to Device.
- Bank 5 and 6 are used to address SDRAM devices (1 device per bank).

For each bank the type of memory to be used can be configured by the user application through the Configuration register.

Figure 163. FMC memory banks (default mapping)
The FMC bank mapping can be modified through the BMAP[1:0] bits in the FMC_BCR1 register. *Table 165* shows the configuration to swap the NOR/PSRAM bank with SDRAM banks.

### Table 165. FMC bank mapping options

<table>
<thead>

<td>NOR/PSRAM bank</td>
</tr>
<tr>
<td>0xD000 0000 - 0xDFFF FFFF</td>
<td>SDRAM bank2</td>
<td>SDRAM bank2</td>
</tr>
</tbody>
</table>

#### 23.6.1 NOR/PSRAM address mapping

ADDR[27:26] bits are used to select one of the four memory banks as shown in *Table 166*.

### Table 166. NOR/PSRAM bank selection

<table>
<thead>
<tr>
<th>ADDR<a href="1">27:26</a></th>
<th>Selected bank</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Bank 1 - NOR/PSRAM 1</td>
</tr>
<tr>
<td>01</td>
<td>Bank 1 - NOR/PSRAM 2</td>
</tr>
<tr>
<td>10</td>
<td>Bank 1 - NOR/PSRAM 3</td>
</tr>
<tr>
<td>11</td>
<td>Bank 1 - NOR/PSRAM 4</td>
</tr>
</tbody>
</table>

1. ADDR are internal address lines that are translated to external memory.

The ADDR[25:0] bits contain the external memory address. Since ADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

### Table 167. NOR/PSRAM External memory address

<table>
<thead>
<tr>
<th>Memory width(1)</th>
<th>Data address issued to the memory</th>
<th>Maximum memory capacity (bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>8-bit</td>
<td>ADDR[25:0]</td>
<td>64 Mbytes x 8 = 512 Mbit</td>
</tr>
<tr>
<td>16-bit</td>
<td>ADDR[25:1] &gt;&gt; 1</td>
<td>64 Mbytes/2 x 16 = 512 Mbit</td>
</tr>
<tr>
<td>32-bit</td>
<td>ADDR[25:2] &gt;&gt; 2</td>
<td>64 Mbytes/4 x 32 = 512 Mbit</td>
</tr>
</tbody>
</table>

1. In case of a 16-bit external memory width, the FMC internally uses ADDR[25:1] to generate the address for external memory FMC_A[24:0]. In case of a 32-bit memory width, the FMC internally uses ADDR[25:2] to generate the external address. Whatever the external memory width, FMC_A[0] should be connected to external memory address A[0].

#### 23.6.2 NAND flash memory address mapping

The NAND bank is divided into memory areas as indicated in *Table 168*. 
For NAND flash memory, the common and attribute memory spaces are subdivided into three sections (see in Table 169 below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common/attribute memory space)
- Address section (next 128 Kbytes in the common/attribute memory space)

The application software uses the 3 sections to access the NAND flash memory:
- To send a command to NAND flash memory, the software must write the command value to any memory location in the command section.
- To specify the NAND flash address that must be read or written, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- To read or write data, the software reads or writes the data from/to any memory location in the data section.

Since the NAND flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

### 23.6.3 SDRAM address mapping

Two SDRAM banks are available as indicated in Table 170.

<table>
<thead>
<tr>
<th>Table 170. SDRAM bank selection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Selected bank</td>
</tr>
<tr>
<td>SDRAM Bank1</td>
</tr>
<tr>
<td>SDRAM Bank2</td>
</tr>
</tbody>
</table>

Table 171 shows SDRAM mapping for a 13-bit row and an 11-bit column configuration.
The ADDR[27:0] bits are translated into an external SDRAM address depending on the SDRAM controller configuration:

- Data size: 8, 16 or 32 bits
- Row size: 11, 12 or 13 bits
- Column size: 8, 9, 10 or 11 bits
- Number of internal banks: two or four internal banks

The following tables show the SDRAM address mapping versus the SDRAM controller configuration.

### Table 171. SDRAM address mapping

<table>
<thead>
<tr>
<th>Memory width(1)</th>
<th>Internal bank</th>
<th>Row address</th>
<th>Column address (2)</th>
<th>Maximum memory capacity (Mbytes)</th>
</tr>
</thead>
</table>

1. When interfacing with a 16-bit memory, the FMC internally uses the ADDR[11:1] internal address lines to generate the external address. When interfacing with a 32-bit memory, the FMC internally uses ADDR[12:2] lines to generate the external address. Whatever the memory width, FMC_A[0] has to be connected to the external memory address A[0].

2. The AutoPrecharge is not supported. FMC_A[10] must be connected to the external memory address A[10] but it is always driven low.

### Table 172. SDRAM address mapping with 8-bit data bus width(1)(2)

<table>
<thead>
<tr>
<th>Row size configuration</th>
<th>ADDR (Internal Address Lines)</th>
<th>27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>

2. Access to Reserved space (Res.) generates an AXI Slave error.
3. BM[1:0]: is the byte mask for 32-bit access.
23.7 NOR flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM and ROM
  - 8 bits
  - 16 bits
  - 32 bits
- PSRAM (Cellular RAM)
  - Asynchronous mode
  - Burst mode for synchronous accesses with configurable option to split burst access when crossing boundary page for CRAM 1.5.
  - Multiplexed or non-multiplexed
- NOR flash memory
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique Chip Select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC_CLK) output.

The FMC output Clock (FMC_CLK) is a sub-multiple of the fmc_ker_ck clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC_BCR1 register:

- If the CCLKEN bit is reset, the FMC generates the clock (FMC_CLK) only during synchronous accesses (Read/write transactions).
- If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC_CLK continuous clock, Bank 1 must be configured in Synchronous mode (see Section 23.7.6: NOR/PSRAM controller registers). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AXI data size has to be the same as the memory data width (MWID) otherwise the FMC_CLK frequency is changed depending on AXI data transaction (refer to Section 23.7.5: Synchronous transactions for FMC_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see Section 23.7.6: NOR/PSRAM controller registers).

The programmable memory parameters include access times (see Table 175) and support for wait management (for PSRAM and NOR flash memory accessed in Burst mode).
23.7.1 External memory interface signals

Table 176, Table 177 and Table 178 list the signals that are typically used to interface with NOR flash memory, SRAM and PSRAM.

Note: The prefix “N” identifies the signals which are active low.
