Bits 31:16 **INEPTXFD[15:0]**: IN endpoint Tx FIFO depth
This value is in terms of 32-bit words.
Minimum value is 16

Bits 15:0 **INEPTXSA[15:0]**: IN endpoint FIFOx transmit RAM start address
This field contains the memory start address for IN endpoint transmit FIFOx. The address must be aligned with a 32-bit memory location.

61.15.23 Host-mode registers

Bit values in the register descriptions are expressed in binary unless otherwise specified.

Host-mode registers affect the operation of the core in the host mode. Host mode registers must not be accessed in device mode, as the results are undefined. Host mode registers can be categorized as follows:
61.15.24 OTG host configuration register (OTG_HCFG)

This register configures the core after power-on. Do not make changes to this register after initializing the host.

Address offset: 0x400
Reset value: 0x0000 0000

<table>
<thead>

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 FSLSS: FS- and LS-only support
The application uses this bit to control the core’s enumeration speed. Using this bit, the application can make the core enumerate as an FS host, even if the connected device supports HS traffic. Do not make changes to this field after initial programming.
1: FS/LS-only, even if the connected device can support HS (read-only).

Bits 1:0 FSLSPCS[1:0]: FS/LS PHY clock select

- **Condition:** FS Host mode
  - 01: PHY clock is running at 48 MHz
  - Others: Reserved

- **Condition:** LS Host mode
  - 00: Reserved
  - 01: Select 48 MHz PHY clock frequency
  - 10: Select 6 MHz PHY clock frequency
  - 11: Reserved

_Note:_ The FSLSPCS must be set on a connection event according to the speed of the connected device (after changing this bit, a software reset must be performed).

61.15.25 OTG host frame interval register (OTG_HFIR)

This register stores the frame interval information for the current speed to which the OTG_FS controller has enumerated.

Address offset: 0x404
Reset value: 0x0000 EA60

</tbody>
</table>

- **Bits 15:0** **FRIVL[15:0]:** Frame interval

  - The value that the application programs to this field, specifies the interval between two consecutive SOFs (FS) or Keep-Alive tokens (LS). This field contains the number of PHY clocks that constitute the required frame interval. The application can write a value to this register only after the port enable bit of the host port control and status register (PENA bit in OTG_HPRT) has been set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS/LS PHY clock select field of the host configuration register (FSLSPCS in OTG_HCFG). Do not change the value of this field after the initial configuration, unless the RLDCTRL bit is set. In such case, the FRIVL is reloaded with each SOF event.

  \[ \text{Frame interval} = 1 \text{ ms} \times (\text{FRIVL} - 1) \]

Bits 31:24 **PTXQTOP[7:0]**: Top of the periodic transmit request queue

This indicates the entry in the periodic Tx request queue that is currently being processed by the MAC.

This register is used for debugging.

Bit 31: Odd/Even frame
0XXXXXXX: send in even frame
1XXXXXXX: send in odd frame

Bits 30:27: Channel/endpoint number

Bits 26:25: Type
XXXXX00X: IN/OUT
XXXXX01X: Zero-length packet
XXXXX11X: Disable channel command

Bit 24: Terminate (last entry for the selected channel/endpoint)

Bits 23:16 **PTXQSAV[7:0]**: Periodic transmit request queue space available

Indicates the number of free locations available to be written in the periodic request queue. This queue holds both IN and OUT requests.

00: Periodic transmit request queue is full
01: 1 location available
10: 2 locations available
n: n locations available (0 ≤ n ≤ 8)

Others: Reserved

Bits 15:0 **PTXFSAVL[15:0]**: Periodic transmit data FIFO space available

Indicates the number of free locations available to be written to in the periodic Tx FIFO.

Values are in terms of 32-bit words

0000: Periodic Tx FIFO is full
0001: 1 word available
0010: 2 words available
n: n words available (where 0 ≤ n ≤ PTXFD)

Others: Reserved
61.15.28 OTG host all channels interrupt register (OTG_HAINT)

When a significant event occurs on a channel, the host all channels interrupt register interrupts the application using the host channels interrupt bit of the core interrupt register (HCINT bit in OTG_GINTSTS). This is shown in Figure 900. There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears the corresponding host channel-x interrupt register.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 HAINM[15:0]: Channel interrupt mask
0: Masked interrupt
1: Unmasked interrupt
One bit per channel: Bit 0 for channel 0, bit 15 for channel 15
This register is available only in host mode. Currently, the OTG host supports only one port.

A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. It is shown in Figure 900. The rc_w1 bits in this register can trigger an interrupt to the application through the host port interrupt bit of the core interrupt register (HPRTINT bit in OTG_GINTSTS). On a port interrupt, the application must read this register and clear the bit that caused the interrupt. For the rc_w1 bits, the application must write a 1 to the bit to clear the interrupt.

- Bit 11: Logic level of OTG_DM

Bit 9 Reserved, must be kept at reset value.
Bit 8 **PRST**: Port reset

When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete.

- 0: Port not in reset
- 1: Port in reset

The application must leave this bit set for a minimum duration of at least 10 ms to start a reset on the port. The application can leave it set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by the USB standard.

- High speed: 50 ms
- Full speed/Low speed: 10 ms

Bit 7 **PSUSP**: Port suspend

The application sets this bit to put this port in suspend mode. The core only stops sending SOFs when this is set. To stop the PHY clock, the application must set the port clock stop bit, which asserts the suspend input pin of the PHY.

The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wakeup signal is detected or the application sets the port reset bit or port resume bit in this register or the resume/remote wakeup detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT in OTG_GINTSTS, respectively).

- 0: Port not in suspend mode
- 1: Port in suspend mode

Bit 6 **PRES**: Port resume

The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit.

If the core detects a USB remote wakeup sequence, as indicated by the port resume/remote wakeup detected interrupt bit of the core interrupt register (WKUPINT bit in OTG_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently driving resume signaling.

- 0: No resume driven
- 1: Resume driven

When LPM is enabled and the core is in L1 state, the behavior of this bit is as follows:

1. The application sets this bit to drive resume signaling on the port.
2. The core continues to drive the resume signal until a predetermined time specified in BESLTHRS[3:0] field of OTG_GLPMCFG register.
3. If the core detects a USB remote wakeup sequence, as indicated by the port L1Resume/Remote L1Wakeup detected interrupt bit of the core interrupt register (WKUPINT in OTG_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit at the end of resume. This bit can be set or cleared by both the core and the application. This bit is cleared by the core even if there is no device connected to the host.

Bit 5 **POCCHNG**: Port overcurrent change

The core sets this bit when the status of the port overcurrent active bit (bit 4) in this register changes.

Bit 4 **POCA**: Port overcurrent active

Indicates the overcurrent condition of the port.

- 0: No overcurrent condition
- 1: Overcurrent condition

Bit 3 **PENCHNG**: Port enable/disable change

The core sets this bit when the status of the port enable bit 2 in this register changes.
Bit 2 **PENA**: Port enable
A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot set this bit by a register write. It can only clear it to disable the port. This bit does not trigger any interrupt to the application.
0: Port disabled
1: Port enabled

Bit 1 **PCDET**: Port connect detected
The core sets this bit when a device connection is detected to trigger an interrupt to the application using the host port interrupt bit in the core interrupt register (HPRTINT bit in OTG_GINTSTS). The application must write a 1 to this bit to clear the interrupt.

Bit 0 **PCSTS**: Port connect status
0: No device is attached to the port
1: A device is attached to the port

### 61.15.31 OTG host channel x characteristics register (OTG_HCCHARx)

**Address offset**: 0x500 + 0x20 * x, (x = 0 to 11)

**Reset value**: 0x0000 0000

**Bit 31: CHENA**: Channel enable
This field is set by the application and cleared by the OTG host.
0: Channel disabled
1: Channel enabled

**Bit 30: CHDIS**: Channel disable
The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the Channel disabled interrupt before treating the channel as disabled.

**Bit 29: ODDFRM**: Odd frame
This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd frame. This field is applicable for only periodic (isochronous and interrupt) transactions.
0: Even frame
1: Odd frame

**Bits 28:22: DAD[6:0]**: Device address
This field selects the specific device serving as the data source or sink.
Bits 21:20  **MCNT[1:0]:** Multicount  
This field indicates to the host the number of transactions that must be executed per frame for this periodic endpoint. For non-periodic transfers, this field is not used  
00: Reserved. This field yields undefined results  
01: 1 transaction  
10: 2 transactions per frame to be issued for this endpoint  
11: 3 transactions per frame to be issued for this endpoint  
*Note: This field must be set to at least 01.*

Bits 19:18  **EPTYP[1:0]:** Endpoint type  
Indicates the transfer type selected.  
00: Control  
01: Isochronous  
10: Bulk  
11: Interrupt  

Bit 17  **LSDEV:** Low-speed device  
This field is set by the application to indicate that this channel is communicating to a low-speed device.  

Bit 16  Reserved, must be kept at reset value.  

Bit 15  **EPDIR:** Endpoint direction  
Indicates whether the transaction is IN or OUT.  
0: OUT  
1: IN  

Bits 14:11  **EPNUM[3:0]:** Endpoint number  
Indicates the endpoint number on the device serving as the data source or sink.  

Bits 10:0  **MPSIZ[10:0]:** Maximum packet size  
Indicates the maximum packet size of the associated endpoint.

### 61.15.32  **OTG host channel x interrupt register (OTG_HCINTx)**

This register indicates the status of a channel with respect to USB- and AHB-related events. It is shown in *Figure 900*. The application must read this register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG_GINTSTS) is set. Before the application can read this register, it must first read the host all channels interrupt (OTG_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_HAINT and OTG_GINTSTS registers.  

Address offset: 0x508 + 0x20 * x, (x = 0 to 11)  
Reset value: 0x0000 0000
Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **DTERR**: Data toggle error.

Bit 9 **FRMOR**: Frame overrun.

Bit 8 **BBERR**: Babble error.

Bit 7 **TXERR**: Transaction error.
   Indicates one of the following errors occurred on the USB.
   CRC check failure
   Timeout
   Bit stuff error
   False EOP

Bit 6 Reserved, must be kept at reset value.

Bit 5 **ACK**: ACK response received/transmitted interrupt.

Bit 4 **NAK**: NAK response received interrupt.

Bit 3 **STALL**: STALL response received interrupt.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CHH**: Channel halted.
   Indicates the transfer completed abnormally either because of any USB transaction error or
   in response to disable request by the application.

Bit 0 **XFRC**: Transfer completed.
   Transfer completed normally without any errors.

### 61.15.33 OTG host channel x interrupt mask register (OTG_HCINTMSKx)

This register reflects the mask for each channel status described in the previous section.

Address offset: 0x50C + 0x20 * x, (x = 0 to 11)

Reset value: 0x0000 0000

</table>
Bit 31 DOPNG: Do Ping
This bit is used only for OUT transfers. Setting this field to 1 directs the host to do PING protocol.
Note: Do not set this bit for IN transfers. If this bit is set for IN transfers, it disables the channel.

Bits 30:29 DPID[1:0]: Data PID
The application programs this field with the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer.
00: DATA0
10: DATA1
11: SETUP (control) / reserved (non-control)

Bits 28:19 PKTCNT[9:0]: Packet count
This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN).
The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion.

Bits 18:0 XFRSIZ[18:0]: Transfer size
For an OUT, this field is the number of data bytes the host sends during the transfer.
For an IN, this field is the buffer size that the application has reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).

61.15.35 Device-mode registers
These registers must be programmed every time the core changes to device mode

61.15.36 OTG device configuration register (OTG_DCFG)
This register configures the core in device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.
Address offset: 0x800
Reset value: 0x0220 0000

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 ERRATIM: Erratic error interrupt mask
1: Mask early suspend interrupt on erratic error
0: Early suspend interrupt is generated on erratic error

Bit 14 Reserved, must be kept at reset value.

Bit 13 Reserved, must be kept at reset value.
Bits 12:11 **PFIVL[1:0]**: Periodic frame interval
Indicates the time within a frame at which the application must be notified using the end of periodic frame interrupt. This can be used to determine if all the isochronous traffic for that frame is complete.
- 00: 80% of the frame interval
- 01: 85% of the frame interval
- 10: 90% of the frame interval
- 11: 95% of the frame interval

Bits 10:4 **DAD[6:0]**: Device address
The application must program this field after every SetAddress control command.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **NZLSOHKS**: Non-zero-length status OUT handshake
The application can use this field to select the handshake the core sends on receiving a nonzero-length data packet during the OUT transaction of a control transfer’s status stage.
- 1: Send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application.
- 0: Send the received OUT packet to the application (zero-length or nonzero-length) and send a handshake based on the NAK and STALL bits for the endpoint in the device endpoint control register.

Bits 1:0 **DSPD[1:0]**: Device speed
Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected.
- 00: Reserved
- 01: Reserved
- 10: Reserved
- 11: Full speed (USB 1.1 transceiver clock is 48 MHz)

</table>
Bits 31:19  Reserved, must be kept at reset value.

Bit 18  **DBESLRJCT**: Deep sleep BESL reject
Core rejects LPM request with BESL value greater than BESL threshold programmed.
NYET response is sent for LPM tokens with BESL value greater than BESL threshold. By default, the deep sleep BESL reject feature is disabled.

Bits 17:12  Reserved, must be kept at reset value.

Bit 11  **POPRGDNE**: Power-on programming done
The application uses this bit to indicate that register programming is completed after a wakeup from power down mode.

Bit 10  **CGONAK**: Clear global OUT NAK
Writing 1 to this field clears the Global OUT NAK.

Bit 9  **SGONAK**: Set global OUT NAK
Writing 1 to this field sets the Global OUT NAK.
The application uses this bit to send a NAK handshake on all OUT endpoints.
The application must set the this bit only after making sure that the Global OUT NAK effective bit in the core interrupt register (GONAKEFF bit in OTG_GINTSTS) is cleared.

Bit 8  **CGINAK**: Clear global IN NAK
Writing 1 to this field clears the Global IN NAK.

Bit 7  **SGINAK**: Set global IN NAK
Writing 1 to this field sets the Global non-periodic IN NAK. The application uses this bit to send a NAK handshake on all non-periodic IN endpoints.
The application must set this bit only after making sure that the Global IN NAK effective bit in the core interrupt register (GINAKEFF bit in OTG_GINTSTS) is cleared.

Bits 6:4  **TCTL[2:0]**: Test control
000: Test mode disabled
001: Test_J mode
010: Test_K mode
011: Test_SE0_NAK mode
100: Test_Packet mode
101: Test_Force_Enable
Others: Reserved

Bit 3  **GONSTS**: Global OUT NAK status
0: A handshake is sent based on the FIFO status and the NAK and STALL bit settings.
1: No data is written to the Rx FIFO, irrespective of space availability. Sends a NAK handshake on all packets, except on SETUP transactions. All isochronous OUT packets are dropped.
Bit 2 **GINSTS**: Global IN NAK status

0: A handshake is sent out based on the data availability in the transmit FIFO.

1: A NAK handshake is sent out on all non-periodic IN endpoints, irrespective of the data availability in the transmit FIFO.

Bit 1 **SDIS**: Soft disconnect

The application uses this bit to signal the USB OTG core to perform a soft disconnect. As long as this bit is set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit.

0: Normal operation. When this bit is cleared after a soft disconnect, the core generates a device connect event to the USB host. When the device is reconnected, the USB host restarts device enumeration.

1: The core generates a device disconnect event to the USB host.

Bit 0 **RWUSIG**: Remote wakeup signaling

When the application sets this bit, the core initiates remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the suspend state. As specified in the USB 2.0 specification, the application must clear this bit 1 ms to 15 ms after setting it.

If LPM is enabled and the core is in the L1 (sleep) state, when the application sets this bit, the core initiates L1 remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the sleep state. As specified in the LPM specification, the hardware automatically clears this bit 50 µs (TL1DevDrvResume) after being set by the application. The application must not set this bit when bRemoteWake from the previous LPM transaction is zero (refer to REMWAKE bit in GLPMCFG register).

*Table 661* contains the minimum duration (according to device state) for which the Soft disconnect (SDIS) bit must be set for the USB host to detect a device disconnect. To accommodate clock jitter, it is recommended that the application add some extra delay to the specified minimum duration.

<table>

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 DEVLNSTS[1:0]: Device line status
Indicates the current logic level USB data lines.
- Bit [23]: Logic level of D+
- Bit [22]: Logic level of D-

Bits 21:8 FNSOF[13:0]: Frame number of the received SOF

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 EERR: Erratic error
The core sets this bit to report any erratic errors.
Due to erratic errors, the OTG_FS controller goes into suspended state and an interrupt is generated to the application with Early suspend bit of the OTG_GINTSTS register (ESUSP bit in OTG_GINTSTS). If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover.

Bits 2:1 ENUMSPD[1:0]: Enumerated speed
Indicates the speed at which the OTG_FS controller has come up after speed detection through a chirp sequence.
- 11: Full speed using embedded FS PHY
- Others: reserved

Bit 0 SUSPSTS: Suspend status
In device mode, this bit is set as long as a suspend condition is detected on the USB. The core enters the suspended state when there is no activity on the USB data lines for a period of 3 ms. The core comes out of the suspend:
- When there is an activity on the USB data lines
- When the application writes to the remote wakeup signaling bit in the OTG_DCTL register (RWUSIG bit in OTG_DCTL).
61.15.39  OTG device IN endpoint common interrupt mask register (OTG_DIEPMSK)

This register works with each of the OTG_DIEPINTx registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the OTG_DIEPINTx register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

Address offset: 0x810

61.15.40 OTG device OUT endpoint common interrupt mask register (OTG_DOEPMSK)

This register works with each of the OTG_DOEPINTx registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the OTG_DOEPINTx register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

### 61.15.41 OTG device all endpoints interrupt register (OTG_DAINT)

When a significant event occurs on an endpoint, a OTG_DAINT register interrupts the application using the device OUT endpoints interrupt bit or device IN endpoints interrupt bit of the OTG_GINTSTS register (OEPINT or IEPINT in OTG_GINTSTS, respectively). There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding device endpoint-x interrupt register (OTG_DIEPINTx/OTG_DOEPINTx).

---
Bit 31 EPENA: Endpoint enable
   The application sets this bit to start transmitting data on the endpoint 0.
   The core clears this bit before setting any of the following interrupts on this endpoint:
   - Endpoint disabled
   - Transfer completed

Bit 30 EPDIS: Endpoint disable
   The application sets this bit to stop transmitting data on an endpoint, even before the
   transfer for that endpoint is complete. The application must wait for the endpoint disabled
   interrupt before treating the endpoint as disabled. The core clears this bit before setting the
   endpoint disabled interrupt. The application must set this bit only if endpoint enable is
   already set for this endpoint.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 SNAK: Set NAK
   A write to this bit sets the NAK bit for the endpoint.
   Using this bit, the application can control the transmission of NAK handshakes on an
   endpoint. The core can also set this bit for an endpoint after a SETUP packet is received on
   that endpoint.

Bit 26 CNAK: Clear NAK
   A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 TXFNUM[3:0]: Tx FIFO number
   This value is set to the FIFO number that is assigned to IN endpoint 0.

Bit 21 STALL: STALL handshake
   The application can only set this bit, and the core clears it when a SETUP token is received
   for this endpoint. If a NAK bit, a Global IN NAK or Global OUT NAK is set along with this bit,
   the STALL bit takes priority.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 EPTYP[1:0]: Endpoint type
   Hardcoded to ‘00’ for control.

Bit 17 NAKSTS: NAK status
   Indicates the following:
   0: The core is transmitting non-NAK handshakes based on the FIFO status
   1: The core is transmitting NAK handshakes on this endpoint.
   When this bit is set, either by the application or core, the core stops transmitting data, even
   if there are data available in the Tx FIFO. Irrespective of this bit’s setting, the core always
   responds to SETUP data packets with an ACK handshake.

Bit 16 Reserved, must be kept at reset value.
Bit 15 **USBAEP**: USB active endpoint
This bit is always set to 1, indicating that control endpoint 0 is always active in all configurations and interfaces.

Bits 14:2 Reserved, must be kept at reset value.

Bits 1:0 **MPSIZ[1:0]**: Maximum packet size
The application must program this field with the maximum packet size for the current logical endpoint.
- 00: 64 bytes
- 01: 32 bytes
- 10: 16 bytes
- 11: 8 bytes

### 61.15.49 OTG device IN endpoint x control register [alternate] (OTG_DIEPCTLx)
Valid for INT/BULK endpoints, see next section for ISO endpoints.
The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

Address offset: 0x900 + 0x20 * x, (x = 1 to 5)
Reset value: 0x0000 0000

<td></td>
<td></td>
</tr>
</tbody>
</table>
Bit 27 **SNAK**: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 **TXFNUM[3:0]**: Tx FIFO number
These bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number.
This field is valid only for IN endpoints.

Bit 21 **STALL**: STALL handshake
Applies to non-control, non-isochronous IN endpoints only (access type is rw).
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority.
Only the application can clear this bit, never the core.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **EPTYP[1:0]**: Endpoint type
This is the transfer type supported by this logical endpoint.
00: Control
01: Isochronous
10: Bulk
11: Interrupt

Bit 17 **NAKSTS**: NAK status
It indicates the following:
0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.
When either the application or the core sets this bit:
For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there are data available in the Tx FIFO.
For isochronous IN endpoints: The core sends out a zero-length data packet, even if there are data available in the Tx FIFO.
Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 **DPID**: Endpoint data PID
Applies to interrupt/bulk IN endpoints only.
Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.
0: DATA0
1: DATA1
Bit 15 **USBAEP**: USB active endpoint
Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11
Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size
The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

61.15.50 **OTG device IN endpoint x control register [alternate]**
(OTG_DIEPCTLx)
Valid for ISO endpoints, see previous section for INT/BULK endpoints.
The application uses this register to control the behavior of each logical endpoint other than endpoint 0.
Address offset: 0x900 + 0x20 * x, (x = 1 to 5)
Reset value: 0x0000 0000

Bit 31 **EPENA**: Endpoint enable
The application sets this bit to start transmitting data on an endpoint.
The core clears this bit before setting any of the following interrupts on this endpoint:
- SETUP phase done
- Endpoint disabled
- Transfer completed

Bit 30 **EPDIS**: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

Bit 29 **SODDFRM**: Set odd frame
Applies to isochronous IN and OUT endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.

Bit 28 **SEVNFRM**: Set even frame
Applies to isochronous IN endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to even frame.
Bit 27 **SNAK:** Set NAK  
A write to this bit sets the NAK bit for the endpoint.  
Using this bit, the application can control the transmission of NAK handshakes on an  
endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt,  
or after a SETUP is received on the endpoint.

Bit 26 **CNAK:** Clear NAK  
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 **TXFNUM[3:0]:** Tx FIFO number  
These bits specify the FIFO number associated with this endpoint. Each active IN endpoint  
must be programmed to a separate FIFO number.  
This field is valid only for IN endpoints.

Bit 21 **STALL:** STALL handshake  
Applies to non-control, non-isochronous IN endpoints only (access type is rw).  
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK  
bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority.  
Only the application can clear this bit, never the core.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **EPTYP[1:0]:** Endpoint type  
This is the transfer type supported by this logical endpoint.  
00: Control  
01: Isochronous  
10: Bulk  
11: Interrupt

Bit 17 **NAKSTS:** NAK status  
It indicates the following:  
0: The core is transmitting non-NAK handshakes based on the FIFO status.  
1: The core is transmitting NAK handshakes on this endpoint.  
When either the application or the core sets this bit:
For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint,  
even if there are data available in the Tx FIFO.  
For isochronous IN endpoints: The core sends out a zero-length data packet, even if there  
are data available in the Tx FIFO.  
Irrespective of this bit’s setting, the core always responds to SETUP data packets with an  
ACK handshake.

Bit 16 **EONUM:** Even/odd frame  
Applies to isochronous IN endpoints only.  
Indicates the frame number in which the core transmits/receives isochronous data for this  
endpoint. The application must program the even/odd frame number in which it intends to  
transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM  
fields in this register.  
0: Even frame  
1: Odd frame
This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in Figure 900. The application must read this register when the IN endpoints interrupt bit of the core interrupt register (IEPINT in OTG_GINTSTS) is set. Before the application can read this register, it must first read the device all endpoints interrupt (OTG_DAINT) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.

Address offset: 0x908 + 0x20 * x, (x = 0 to 5)

Reset value: 0x0000 0080

| Bit 31:14 | Reserved, must be kept at reset value. |
| Bit 13 | NAK: NAK input |
| The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO. |
| Bit 12 | Reserved, must be kept at reset value. |
| Bit 11 | PKTDRPSTS: Packet dropped status |
| This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. |
| Bits 10:8 | Reserved, must be kept at reset value. |
| Bit 7 | TXFE: Transmit FIFO empty |
| This interrupt is asserted when the Tx FIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the Tx FIFO Empty Level bit in the OTG_GAHBCFG register (TXFELVL bit in OTG_GAHBCFG). |
Bit 6 **INEPNE**: IN endpoint NAK effective  
This bit can be cleared when the application clears the IN endpoint NAK by writing to the CNAK bit in OTG_DIEPCTLx.
This interrupt indicates that the core has sampled the NAK bit set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core.
This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.

Bit 5 **INEPNM**: IN token received with EP mismatch  
Indicates that the data in the top of the non-periodic Tx FIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 4 **ITTXFE**: IN token received when Tx FIFO is empty  
Indicates that an IN token was received when the associated Tx FIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 3 **TOC**: Timeout condition  
Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **EPDISD**: Endpoint disabled interrupt  
This bit indicates that the endpoint is disabled per the application’s request.

Bit 0 **XFRC**: Transfer completed interrupt  
This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.

### 61.15.52 OTG device IN endpoint 0 transfer size register (OTG_DIEPTSIZ0)

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the device control endpoint 0 control registers (EPENA in OTG_DIEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–3.

Address offset: 0x910  
Reset value: 0x0000 0000
Bits 31:21  Reserved, must be kept at reset value.

Bits 20:19  **PKTCNT[1:0]:** Packet count  
Indicates the total number of USB packets that constitute the transfer size amount of data for endpoint 0.  
This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:7  Reserved, must be kept at reset value.

Bits 6:0  **XFRSIZ[6:0]:** Transfer size  
Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.  
The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

### 61.15.53  OTG device IN endpoint transmit FIFO status register  
(OTG_DTXFSTSx)

This read-only register contains the free space information for the device IN endpoint Tx FIFO.

Address offset: 0x918 + 0x20 * x, (x = 0 to 5)

Reset value: 0x0000 0200

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **INEPTFSAV[15:0]:** IN endpoint Tx FIFO space available  
Indicates the amount of free space available in the endpoint Tx FIFO.  
Values are in terms of 32-bit words:  
0: Endpoint Tx FIFO is full  
1: 1 word available  
2: 2 words available  
n: n words available  
Others: Reserved
61.15.54 OTG device IN endpoint x transfer size register (OTG_DIEPTSIZx)

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using the endpoint enable bit in the OTG_DIEPCTLx registers (EPENA bit in OTG_DIEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **MCNT[1:0]: Multi count**
For periodic IN endpoints, this field indicates the number of packets that must be transmitted per frame on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints.
- 01: 1 packet
- 10: 2 packets
- 11: 3 packets

Bits 28:19 **PKTCNT[9:0]: Packet count**
Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.
This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:0 **XFRSIZ[18:0]: Transfer size**
This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
The core decrements this field every time a packet from the external memory is written to the Tx FIFO.
61.15.55  **OTG device control OUT endpoint 0 control register**  
(OTG_DOEPCTL0)

This section describes the OTG_DOEPCTL0 register. Nonzero control endpoints use registers for endpoints 1–3.

Address offset: 0xB00

Reset value: 0x0000 8000

| Bit 31 | EPENA: Endpoint enable  
| The application sets this bit to start transmitting data on endpoint 0.  
| The core clears this bit before setting any of the following interrupts on this endpoint:  
| – SETUP phase done  
| – Endpoint disabled  
| – Transfer completed  

| Bit 30 | EPDIS: Endpoint disable  
| The application cannot disable control OUT endpoint 0.  

| Bits 29:28 | Reserved, must be kept at reset value.  

| Bit 27 | SNAK: Set NAK  
| A write to this bit sets the NAK bit for the endpoint.  
| Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit on a transfer completed interrupt, or after a SETUP is received on the endpoint.  

| Bit 26 | CNAK: Clear NAK  
| A write to this bit clears the NAK bit for the endpoint.  

| Bits 25:22 | Reserved, must be kept at reset value.  

| Bit 21 | STALL:STALL handshake  
| The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.  

| Bit 20 | SNPM: Snoop mode  
| This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.  

| Bits 19:18 | EPTYP[1:0]: Endpoint type  
| Hardcoded to 2'b00 for control.  

---

## USB on-the-go full-speed (OTG_FS)  
RM0477
Bit 17 **NAKSTS**: NAK status

Indicates the following:

0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit, the core stops receiving data, even if there is space in the Rx FIFO to accommodate the incoming packet. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **USBAEP**: USB active endpoint

This bit is always set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces.

Bits 14:2 Reserved, must be kept at reset value.

Bits 1:0 **MPSIZ[1:0]**: Maximum packet size

The maximum packet size for control OUT endpoint 0 is the same as what is programmed in control IN endpoint 0.

- 00: 64 bytes
- 01: 32 bytes
- 10: 16 bytes
- 11: 8 bytes

61.15.56 **OTG device OUT endpoint x interrupt register (OTG_DOEPINTx)**

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in Figure 900. The application must read this register when the OUT endpoints interrupt bit of the OTG_GINTSTS register (OEPINT bit in OTG_GINTSTS) is set. Before the application can read this register, it must first read the OTG_DAINT register to get the exact endpoint number for the OTG_DOEPINTx register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NAK**: NAK input

The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 **BERR**: Babble error interrupt

The core generates this interrupt when babble is received for the endpoint.
Bits 11:10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bit 7 Reserved, must be kept at reset value.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **STSPHSRX**: Status phase received for control write

This interrupt is valid only for control OUT endpoints. This interrupt is generated only after OTG_FS has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a control write transfer. The application can use this interrupt to ACK or STALL the status phase, after it has decoded the data phase.

Bit 4 **OTEPDIS**: OUT token received when endpoint disabled

 Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received.

Bit 3 **STUP**: SETUP phase done

 Applies to control OUT endpoint only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **EPDISD**: Endpoint disabled interrupt

This bit indicates that the endpoint is disabled per the application’s request.

Bit 0 **XFRC**: Transfer completed interrupt

This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.

### 61.15.57 OTG device OUT endpoint 0 transfer size register (OTG_DOEPTSIZ0)

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the OTG_DOEPCCTL0 registers (EPENA bit in OTG_DOEPCCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–5.

Address offset: 0xB10

Reset value: 0x0000 0000

2990/3791
Bit 31  Reserved, must be kept at reset value.

Bits 30:29  STUPCNT[1:0]: SETUP packet count
   This field specifies the number of back-to-back SETUP data packets the endpoint can receive.
   01: 1 packet
   10: 2 packets
   11: 3 packets

Bits 28:20  Reserved, must be kept at reset value.

Bit 19  PKTCNT: Packet count
   This field is decremented to zero after a packet is written into the Rx FIFO.

Bits 18:7  Reserved, must be kept at reset value.

Bits 6:0  XFRSIZ[6:0]: Transfer size
   Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
   The core decrements this field every time a packet is read from the Rx FIFO and written to the external memory.

### 61.15.58  OTG device OUT endpoint x control register [alternate]
(OTG_DOEPCTLx)

Valid for INT/BULK endpoints, see next section for ISO endpoints.

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

Address offset: 0xB00 + 0x20 * x, (x = 1 to 5)

Reset value: 0x0000 0000
Bit 31  **EPENA**: Endpoint enable
Applies to IN and OUT endpoints.
The application sets this bit to start transmitting data on an endpoint.
The core clears this bit before setting any of the following interrupts on this endpoint:
– SETUP phase done
– Endpoint disabled
– Transfer completed

Bit 30  **EPDIS**: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before
the transfer for that endpoint is complete. The application must wait for the endpoint
disabled interrupt before treating the endpoint as disabled. The core clears this bit before
setting the endpoint disabled interrupt. The application must set this bit only if endpoint
enable is already set for this endpoint.

Bit 29  **SD1PID**: Set DATA1 PID
Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the endpoint
data PID (DPID) field in this register to DATA1.

Bit 28  **SD0PID**: Set DATA0 PID
Applies to interrupt/bulk OUT endpoints only.
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.

Bit 27  **SNAK**: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an
endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt,
or after a SETUP is received on the endpoint.

Bit 26  **CNAK**: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22  Reserved, must be kept at reset value.

Bit 21  **STALL**: STALL handshake
Applies to non-control, non-isochronous OUT endpoints only (access type is rw).
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK
bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes
priority. Only the application can clear this bit, never the core.
Applies to control endpoints only (access type is rs).
The application can only set this bit, and the core clears it, when a SETUP token is received
for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit,
the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to
SETUP data packets with an ACK handshake.

Bit 20  **SNPM**: Snoop mode
This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check
the correctness of OUT packets before transferring them to application memory.

Bits 19:18  **EPTYP[1:0]**: Endpoint type
This is the transfer type supported by this logical endpoint.
00: Control
01: Isochronous
10: Bulk
11: Interrupt
Bit 17 **NAKSTS**: NAK status
Indicates the following:
0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.
When either the application or the core sets this bit:
The core stops receiving any data on an OUT endpoint, even if there is space in the Rx FIFO to accommodate the incoming packet.
Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 **DPID**: Endpoint data PID
Applies to interrupt/bulk OUT endpoints only.
Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.
0: DATA0
1: DATA1

Bit 15 **USBAEP**: USB active endpoint
Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size
The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

61.15.59 **OTG device OUT endpoint x control register [alternate]**
(OTG_DOEPCTLx)
Valid for ISO endpoints, see previous section for INT/BULK endpoints.
The application uses this register to control the behavior of each logical endpoint other than endpoint 0.
Address offset: 0xB00 + 0x20 * x, (x = 1 to 5)
Reset value: 0x0000 0000

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 |

Bit 31 **EPENA**: Endpoint enable

Applies to IN and OUT endpoints.
The application sets this bit to start transmitting data on an endpoint.
The core clears this bit before setting any of the following interrupts on this endpoint:
- SETUP phase done
- Endpoint disabled
- Transfer completed

Bit 30 **EPDIS**: Endpoint disable

The application sets this bit to stop transmitting/receiving data on an endpoint, even before
the transfer for that endpoint is complete. The application must wait for the endpoint
disabled interrupt before treating the endpoint as disabled. The core clears this bit before
setting the endpoint disabled interrupt. The application must set this bit only if endpoint
enable is already set for this endpoint.

Bit 29 **SODDFRM**: Set odd frame

Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd
frame (EONUM) field to odd frame.

Bit 28 **SEVNFRM**: Set even frame

Applies to isochronous OUT endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to even frame.

Bit 27 **SNAK**: Set NAK

A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an
endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt,
or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK

A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **STALL**: STALL handshake

Applies to non-control, non-isochronous OUT endpoints only (access type is rw).
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK
bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes
priority. Only the application can clear this bit, never the core.
Applies to control endpoints only (access type is rs).
The application can only set this bit, and the core clears it, when a SETUP token is received
for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit,
the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to
SETUP data packets with an ACK handshake.

Bit 20 **SNPM**: Snoop mode

This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check
the correctness of OUT packets before transferring them to application memory.

Bits 19:18 **EPTYP[1:0]**: Endpoint type

This is the transfer type supported by this logical endpoint.
00: Control
01: Isochronous
10: Bulk
11: Interrupt
Bit 17 NAKSTS: NAK status
Indicates the following:
0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.
When either the application or the core sets this bit:
The core stops receiving any data on an OUT endpoint, even if there is space in the Rx FIFO to accommodate the incoming packet.
Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 EONUM: Even/odd frame
Applies to isochronous IN and OUT endpoints only.
Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.
0: Even frame
1: Odd frame

Bit 15 USBAEP: USB active endpoint
Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 MPSIZ[10:0]: Maximum packet size
The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

61.15.60 OTG device OUT endpoint x transfer size register (OTG_DOEPTSIZx)
The application must modify this register before enabling the endpoint. Once the endpoint is enabled using endpoint enable bit of the OTG_DOEPCTLx registers (EPENA bit in OTG_DOEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.
Address offset: 0xB10 + 0x20 * x, (x = 1 to 5)
Reset value: 0x0000 0000

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

XFRSIZ[15:0]
Bit 31  Reserved, must be kept at reset value.

Bits 30:29  RXDPID[1:0]:
  Condition: isochronous OUT endpoints
  Received data PID
  This is the data PID received in the last packet for this endpoint.
  00: DATA0
  01: DATA2
  10: DATA1
  11: MDATA
  Condition: control OUT endpoints
  STUPCNT[1:0]: SETUP packet count
  This field specifies the number of back-to-back SETUP data packets the endpoint can receive.
  01: 1 packet
  10: 2 packets
  11: 3 packets

Bits 28:19  PKTCNT[9:0]: Packet count
  Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.
  This field is decremented every time a packet (maximum size or short packet) is written to the Rx FIFO.

Bits 18:0  XFRSIZ[18:0]: Transfer size
  This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
  The core decrements this field every time a packet is read from the Rx FIFO and written to the external memory.

61.15.61  OTG power and clock gating control register (OTG_PCGCCTL)

This register is available in host and device modes.

Bits 31:8  Reserved, must be kept at reset value.

Bit 7  SUSP: Deep Sleep
  This bit indicates that the PHY is in Deep Sleep when in L1 state.

Bit 6  PHYSLEEP: PHY in Sleep
  This bit indicates that the PHY is in the Sleep state.
Bit 5 **EN1GTG**: Enable sleep clock gating
   When this bit is set, core internal clock gating is enabled in Sleep state if the core cannot assert utmi_l1_suspend_n. When this bit is not set, the PHY clock is not gated in Sleep state.

Bit 4 **PHYSUSP**: PHY suspended
   Indicates that the PHY has been suspended. This bit is updated once the PHY is suspended after the application has set the STPPCLK bit.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **GATEHCLK**: Gate HCLK
   The application sets this bit to gate HCLK to modules other than the AHB Slave and Master and wakeup logic when the USB is suspended or the session is not valid. The application clears this bit when the USB is resumed or a new session starts.

Bit 0 **STPPCLK**: Stop PHY clock
   The application sets this bit to stop the PHY clock when the USB is suspended, the session is not valid, or the device is disconnected. The application clears this bit when the USB is resumed or a new session starts.

**Table 662. OTG_FS register map and reset values**

**Offset**: Address offset from the base address of the USB OTG controller.

**Reset value**: The reset value of the register.

**Register name**: The name of the register.

**Register map**: The map of the register, showing the control bits and their reset values.

Refer to **Section 2.3 on page 149** for the register boundary addresses.
61.16 **OTG_FS programming model**

61.16.1 **Core initialization**

The application must perform the core initialization sequence. If the cable is connected during power-up, the current mode of operation bit in the OTG_GINTSTS (CMOD bit in OTG_GINTSTS) reflects the mode. The OTG_FS controller enters host mode when an “A” plug is connected or device mode when a “B” plug is connected.

This section explains the initialization of the OTG_FS controller after power-on. The application must follow the initialization sequence irrespective of host or device mode operation. All core global registers are initialized according to the core’s configuration:

1. Program the following fields in the OTG_GAHBCFG register:
   - Global interrupt mask bit GINTMSK = 1
   - Rx FIFO non-empty (RXFLVL bit in OTG_GINTSTS)
   - Periodic Tx FIFO empty level

2. Program the following fields in the OTG_GUSBCFG register:
   - OTG_FS timeout calibration field
   - USB turnaround time field

3. The software must unmask the following bits in the OTG_GINTMSK register:
   - OTG interrupt mask
   - Mode mismatch interrupt mask

4. The software can read the CMOD bit in OTG_GINTSTS to determine whether the OTG_FS controller is operating in host or device mode.
61.16.2 Host initialization

To initialize the core as host, the application must perform the following steps:

1. Program the HPRTINT in the OTG_GINTMSK register to unmask
2. Program the OTG_HCFG register to select full-speed host
3. Program the PPWR bit in OTG_HPRT to 1. This drives $V_{BUS}$ on the USB.
4. Wait for the PCDET interrupt in OTG_HPRT0. This indicates that a device is connecting to the port.
5. Program the PRST bit in OTG_HPRT to 1. This starts the reset process.
6. Wait at least 10 ms for the reset process to complete.
7. Program the PRST bit in OTG_HPRT to 0.
8. Wait for the PENCHNG interrupt in OTG_HPRT.
9. Read the PSPD bit in OTG_HPRT to get the enumerated speed.
10. Program the HFIR register with a value corresponding to the selected PHY clock 1
11. Program the FSLSPCS field in the OTG_HCFG register following the speed of the device detected in step 9. If FSLSPCS has been changed a port reset must be performed.
12. Program the OTG_GRXFSIZ register to select the size of the receive FIFO.
13. Program the OTG_HNPTXFSIZ register to select the size and the start address of the Non-periodic transmit FIFO for non-periodic transactions.
14. Program the OTG_HPTXFSIZ register to select the size and start address of the periodic transmit FIFO for periodic transactions.

To communicate with devices, the system software must initialize and enable at least one channel.

61.16.3 Device initialization

The application must perform the following steps to initialize the core as a device on power-up or after a mode change from host to device.

1. Program the following fields in the OTG_DCFG register:
   - Device speed
   - Non-zero-length status OUT handshake
   - Periodic Frame Interval
2. Clear the DCTL.SDIS bit. The core issues a connect after this bit is cleared.
3. Program the OTG_GINTMSK register to unmask the following interrupts:
   - USB reset
   - Enumeration done
   - Early suspend
   - USB suspend
   - SOF
4. Wait for the USBRST interrupt in OTG_GINTSTS. It indicates that a reset has been detected on the USB that lasts for about 10 ms on receiving this interrupt.
5. Wait for the ENUMDNE interrupt in OTG_GINTSTS. This interrupt indicates the end of reset on the USB. On receiving this interrupt, the application must read the OTG_DSTS
register to determine the enumeration speed and perform the steps listed in *Endpoint initialization on enumeration completion on page 3030*.

At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0.

### 61.16.4 Host programming model

#### Channel initialization

The application must initialize one or more channels before it can communicate with connected devices. To initialize and enable a channel, the application must perform the following steps:

1. Program the OTG_GINTMSK register to unmask the following:
2. Channel interrupt
   - Non-periodic transmit FIFO empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
   - Non-periodic transmit FIFO half-empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
3. Program the OTG_HAINTMSK register to unmask the selected channels' interrupts.
4. Program the OTG_HCINTMSK register to unmask the transaction-related interrupts of interest given in the host channel interrupt register.
5. Program the selected channel's OTG_HCTSIZx register with the total transfer size, in bytes, and the expected number of packets, including short packets. The application must program the PID field with the initial data PID (to be used on the first OUT transaction or to be expected from the first IN transaction).
6. Program the OTG_HCCHARx register of the selected channel with the device's endpoint characteristics, such as type, speed, direction, and so forth. (The channel can be enabled by setting the channel enable bit to 1 only when the application is ready to transmit or receive any packet).

#### Halting a channel

The application can disable any channel by programming the OTG_HCCHARx register with the CHDIS and CHENA bits set to 1. This enables the OTG_FS host to flush the posted requests (if any) and generates a channel halted interrupt. The application must wait for the CHH interrupt in OTG_HCINTx before reallocating the channel for other transactions. The OTG_FS host does not interrupt the transaction that has already been started on the USB.

Before disabling a channel, the application must ensure that there is at least one free space available in the non-periodic request queue (when disabling a non-periodic channel) or the periodic request queue (when disabling a periodic channel). The application can simply flush the posted requests when the request queue is full (before disabling the channel), by programming the OTG_HCCHARx register with the CHDIS bit set to 1 which automatically clears the CHENA bit to 0.

The application is expected to disable a channel on any of the following conditions:
1. When an STALL, TXERR, BBERR or DTERR interrupt in OTG_HCINTx is received for an IN or OUT channel. The application must be able to receive other interrupts (DTERR, Nak, data, TXERR) for the same channel before receiving the halt.
2. When a DISCINT (disconnect device) interrupt in OTG_GINTSTS is received. (The application is expected to disable all enabled channels).
3. When the application aborts a transfer before normal completion.

Operational model

The application must initialize a channel before communicating to the connected device. This section explains the sequence of operation to be performed for different types of USB transactions.

- **Writing the transmit FIFO**
  The OTG_FS host automatically writes an entry (OUT request) to the periodic/non-periodic request queue, along with the last 32-bit word write of a packet. The application must ensure that at least one free space is available in the periodic/non-periodic request queue before starting to write to the transmit FIFO. The application must always write to the transmit FIFO in 32-bit words. If the packet size is non-32-bit word aligned, the application must use padding. The OTG_FS host determines the actual packet size based on the programmed maximum packet size and transfer size.

![Figure 901. Transmit FIFO write task](image)

- **Reading the receive FIFO**
  The application must ignore all packet statuses other than IN data packet (bx0010).
- **Bulk and control OUT/SETUP transactions**
  
  A typical bulk or control OUT/SETUP pipelined transaction-level operation is shown in Figure 903. See channel 1 (ch_1). Two bulk OUT packets are transmitted. A control SETUP transaction operates in the same way but has only one packet. The assumptions are:
  
  - The application is attempting to send two maximum-packet-size packets (transfer size = 1,024 bytes).
  - The non-periodic transmit FIFO can hold two packets (128 bytes for FS).
  - The non-periodic request queue depth = 4.

- **Normal bulk and control OUT/SETUP operations**
  
  The sequence of operations in (channel 1) is as follows:
  
  1. Initialize channel 1
  2. Write the first packet for channel 1
  3. Along with the last word write, the core writes an entry to the non-periodic request queue
  4. As soon as the non-periodic queue becomes non-empty, the core attempts to send an OUT token in the current frame
  5. Write the second (last) packet for channel 1
  6. The core generates the XFRC interrupt as soon as the last transaction is completed successfully
  7. In response to the XFRC interrupt, de-allocate the channel for other transfers
  8. Handling non-ACK responses
**Figure 903. Normal bulk/control OUT/SETUP**

1. The grayed elements are not relevant in the context of this figure.
The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions is shown in the following code samples.

- **Interrupt service routine for bulk/control OUT/SETUP and bulk/control IN transactions**
  - a) Bulk/control OUT/SETUP

Unmask (NAK/TXERR/STALL/XFRC)

```c
if (XFRC)
{
  Reset Error Count
  Mask ACK
  De-allocate Channel
}
else if (STALL)
{
  Transfer Done = 1
  Unmask CHH
  Disable Channel
}
else if (NAK or TXERR )
{
  Rewind Buffer Pointers
  Unmask CHH
  Disable Channel
  if (TXERR)
  {
    Increment Error Count
    Unmask ACK
  }
  else
  {
    Reset Error Count
  }
}
else if (CHH)
{
  Mask CHH
  if (Transfer Done or (Error_count == 3))
  {
    De-allocate Channel
  }
  else
  {
    Re-initialize Channel
  }
}
```
else if (ACK)
{
  Reset Error Count
  Mask ACK
}

The application is expected to write the data packets into the transmit FIFO when the space is available in the transmit FIFO and the request queue. The application can make use of the NPTXFE interrupt in OTG_GINTSTS to find the transmit FIFO space.

b) Bulk/control IN

Unmask (TXERR/XFRC/BBERR/STALL/DTE_RR)

if (XFRC)
{
  Reset Error Count
  Unmask CHH
  Disable Channel
  Reset Error Count
  Mask ACK
}

else if (TXERR or BBERR or STALL)
{
  Unmask CHH
  Disable Channel
  if (TXERR)
    {
      Increment Error Count
      Unmask ACK
    }
}

else if (CHH)
{
  Mask CHH
  if (Transfer Done or (Error_count == 3))
    {
      De-allocate Channel
    }
  else
    {
      Re-initialize Channel
    }
}

else if (ACK)
{
  Reset Error Count
  Mask ACK
}
else if (DTERR)
{
    Reset Error Count
}

The application is expected to write the requests as and when the request queue space is available and until the XFRC interrupt is received.

- **Bulk and control IN transactions**

  A typical bulk or control IN pipelined transaction-level operation is shown in *Figure 904*. See channel 2 (ch_2). The assumptions are:
  - The application is attempting to receive two maximum-packet-size packets (transfer size = 1024 bytes).
  - The receive FIFO can contain at least one maximum-packet-size packet and two status words per packet (72 bytes for FS).
  - The non-periodic request queue depth = 4.
Figure 904. Bulk/control IN transactions

1. The grayed elements are not relevant in the context of this figure.
The sequence of operations is as follows:

1. Initialize channel 2.
2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the non-periodic request queue.
3. The core attempts to send an IN token after completing the current OUT transaction.
4. The core generates an RXFLVL interrupt as soon as the received packet is written to the receive FIFO.
5. In response to the RXFLVL interrupt, mask the RXFLVL interrupt and read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. Following this, unmask the RXFLVL interrupt.
6. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO.
7. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in OTG_GRXSTSR ≠ 0b0010).
8. The core generates the XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, disable the channel and stop writing the OTG_HCCHAR2 register for further requests. The core writes a channel disable request to the non-periodic request queue as soon as the OTG_HCCHAR2 register is written.
10. The core generates the RXFLVL interrupt as soon as the halt status is written to the receive FIFO.
11. Read and ignore the receive packet status.
12. The core generates a CHH interrupt as soon as the halt status is popped from the receive FIFO.
13. In response to the CHH interrupt, de-allocate the channel for other transfers.
14. Handling non-ACK responses

- **Control transactions**

  Setup, data, and status stages of a control transfer must be performed as three separate transfers. Setup-, data- or status-stage OUT transactions are performed similarly to the bulk OUT transactions explained previously. Data- or status-stage IN transactions are performed similarly to the bulk IN transactions explained previously. For all three stages, the application is expected to set the EPTYP field in
OTG_HCCHAR1 to control. During the setup stage, the application is expected to set
the PID field in OTG_HCTSIZ1 to SETUP.

- **Interrupt OUT transactions**
  A typical interrupt OUT operation is shown in Figure 905. The assumptions are:
  - The application is attempting to send one packet in every frame (up to 1 maximum
    packet size), starting with the odd frame (transfer size = 1 024 bytes)
  - The periodic transmit FIFO can hold one packet (1 Kbyte)
  - Periodic request queue depth = 4

  The sequence of operations is as follows:
  1. Initialize and enable channel 1. The application must set the ODDFRM bit in
     OTG_HCCHAR1.
  2. Write the first packet for channel 1.
  3. Along with the last word write of each packet, the OTG_FS host writes an entry to the
     periodic request queue.
  4. The OTG_FS host attempts to send an OUT token in the next (odd) frame.
  5. The OTG_FS host generates an XFRC interrupt as soon as the last packet is
     transmitted successfully.
  6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
**Figure 905. Normal interrupt OUT**

1. The grayed elements are not relevant in the context of this figure.

- **Interrupt service routine for interrupt OUT/IN transactions**
  
  a) Interrupt OUT

  **Unmask** (NAK/TXERR/STALL/XFRC/FRMOR)

---

MSv36020V1
if (XFRC)
{
  Reset Error Count
  Mask ACK
  De-allocate Channel
}
else
if (STALL or FRMOR)
{
  Mask ACK
  Unmask CHH
  Disable Channel
  if (STALL)
  {
    Transfer Done = 1
  }
}
else
if (NAK or TXERR)
{
  Rewind Buffer Pointers
  Reset Error Count
  Mask ACK
  Unmask CHH
  Disable Channel
}
else
if (CHH)
{
  Mask CHH
  if (Transfer Done or (Error_count == 3))
  {
    De-allocate Channel
  }
  else
  {
    Re-initialize Channel (in next b_interval - 1 Frame)
  }
}
else
if (ACK)
{
  Reset Error Count
  Mask ACK
}
The application uses the NPTXFE interrupt in O TG_GINTSTS to find the transmit FIFO space.

• **Interrupt IN transactions**
The assumptions are:
  – The application is attempting to receive one packet (up to 1 maximum packet size) in every frame, starting with odd (transfer size = 1024 bytes).
  – The receive FIFO can hold at least one maximum-packet-size packet and two status words per packet (1031 bytes).
  – Periodic request queue depth = 4.

• **Normal interrupt IN operation**
The sequence of operations is as follows:
1. Initialize channel 2. The application must set the ODDFRM bit in OTG_HCCHAR2.
2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the periodic request queue.
3. The OTG_FS host writes an IN request to the periodic request queue for each OTG_HCCHAR2 register write with the CHENA bit set.
4. The OTG_FS host attempts to send an IN token in the next (odd) frame.
5. As soon as the IN packet is received and written to the receive FIFO, the OTG_FS host generates an RXFLVL interrupt.
6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask after reading the entire packet.
7. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in GRXSTSR ≠ 0b0010).
8. The core generates an XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, read the PKTCNT field in OTG_HCTSIZ2. If the PKTCNT bit in OTG_HCTSIZ2 is not equal to 0, disable the channel before re-
initializing the channel for the next transfer, if any). If PKTCNT bit in OTG_HCTSIZ2 = 0, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG_HCCHAR2.
1. The grayed elements are not relevant in the context of this figure.

- **Isochronous OUT transactions**

  A typical isochronous OUT operation is shown in Figure 907. The assumptions are:
  - The application is attempting to send one packet every frame (up to 1 maximum
packet size), starting with an odd frame. (transfer size = 1 024 bytes).
– The periodic transmit FIFO can hold one packet (1 Kbyte).
– Periodic request queue depth = 4.

The sequence of operations is as follows:
1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG_HCCHAR1.
2. Write the first packet for channel 1.
3. Along with the last word write of each packet, the OTG_FS host writes an entry to the periodic request queue.
4. The OTG_FS host attempts to send the OUT token in the next frame (odd).
5. The OTG_FS host generates the XFRC interrupt as soon as the last packet is transmitted successfully.
6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
7. Handling non-ACK responses
1. The grayed elements are not relevant in the context of this figure.

      {
        De-allocate Channel
      }
else
{
    Re-initialize Channel
}

- **Isochronous IN transactions**
  
The assumptions are:
  - The application is attempting to receive one packet (up to 1 maximum packet size) in every frame starting with the next odd frame (transfer size = 1 024 bytes).
  - The receive FIFO can hold at least one maximum-packet-size packet and two status word per packet (1 031 bytes).
  - Periodic request queue depth = 4.

  The sequence of operations is as follows:
  1. Initialize channel 2. The application must set the ODDFRM bit in OTG_HCCHAR2.
  2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the periodic request queue.
  3. The OTG_FS host writes an IN request to the periodic request queue for each OTG_HCCHAR2 register write with the CHENA bit set.
  4. The OTG_FS host attempts to send an IN token in the next odd frame.
  5. As soon as the IN packet is received and written to the receive FIFO, the OTG_FS host generates an RXFLVL interrupt.
  6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask it after reading the entire packet.
  7. The core generates an RXFLVL interrupt for the transfer completion status entry in the receive FIFO. This time, the application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS bit in OTG_GRXSTSR ≠ 0b0010).
  8. The core generates an XFRC interrupt as soon as the receive packet status is read.
  9. In response to the XFRC interrupt, read the PKTCNT field in OTG_HCTSIZ2. If PKTCNT ≠ 0 in OTG_HCTSIZ2, disable the channel before re-initializing the channel for the next transfer, if any. If PKTCNT = 0 in OTG_HCTSIZ2, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG_HCCHAR2.
Figure 908. Isochronous IN transactions

1. The grayed elements are not relevant in the context of this figure.

- **Selecting the queue depth**
  Choose the periodic and non-periodic request queue depths carefully to match the number of periodic/non-periodic endpoints accessed.

  The non-periodic request queue depth affects the performance of non-periodic...
transfers. The deeper the queue (along with sufficient FIFO size), the more often the core is able to pipeline non-periodic transfers. If the queue size is small, the core is able to put in new requests only when the queue space is freed up.

The core’s periodic request queue depth is critical to perform periodic transfers as scheduled. Select the periodic queue depth, based on the number of periodic transfers scheduled in a microframe. If the periodic request queue depth is smaller than the periodic transfers scheduled in a microframe, a frame overrun condition occurs.

- **Handling babble conditions**
  OTG_FS controller handles two cases of babble: packet babble and port babble. Packet babble occurs if the device sends more data than the maximum packet size for the channel. Port babble occurs if the core continues to receive data from the device at EOF2 (the end of frame 2, which is very close to SOF).

When OTG_FS controller detects a packet babble, it stops writing data into the Rx buffer and waits for the end of packet (EOP). When it detects an EOP, it flushes already written data in the Rx buffer and generates a Babble interrupt to the application.

When OTG_FS controller detects a port babble, it flushes the Rx FIFO and disables the port. The core then generates a port disabled interrupt (HPRTINT in OTG_GINTSTS, PENCHNG in OTG_HPRT). On receiving this interrupt, the application must determine that this is not due to an overcurrent condition (another cause of the port disabled interrupt) by checking POCA in OTG_HPRT, then perform a soft reset. The core does not send any more tokens after it has detected a port babble condition.

### 61.16.5 Device programming model

#### Endpoint initialization on USB reset

1. Set the NAK bit for all OUT endpoints
   - SNAK = 1 in OTG_DOEPCTLx (for all OUT endpoints)
2. Unmask the following interrupt bits
   - INEP0 = 1 in OTG_DAINTMSK (control 0 IN endpoint)
   - OUTEP0 = 1 in OTG_DAINTMSK (control 0 OUT endpoint)
   - STUPM = 1 in OTG_DOEPMSK
   - XFRCM = 1 in OTG_DOEPMSK
   - XFRCM = 1 in OTG_DIEPMSK
   - TOM = 1 in OTG_DIEPMSK
3. Set up the data FIFO RAM for each of the FIFOs
   - Program the OTG_GRXFSIZ register, to be able to receive control OUT data and setup data. If thresholding is not enabled, at a minimum, this must be equal to 1 max packet size of control endpoint 0 + 2 words (for the status of the control OUT data packet) + 10 words (for setup packets).
   - Program the OTG_DIEPTXF0 register (depending on the FIFO number chosen) to be able to transmit control IN data. At a minimum, this must be equal to 1 max packet size of control endpoint 0.
4. Program the following fields in the endpoint-specific registers for control OUT endpoint 0 to receive a SETUP packet
   - STUPCNT = 3 in OTG_DOEPTSIZ0 (to receive up to 3 back-to-back SETUP packets)
At this point, all initialization required to receive SETUP packets is done.

**Endpoint initialization on enumeration completion**

1. On the Enumeration Done interrupt (ENUMDNE in OTG_GINTSTS), read the OTG_DSTS register to determine the enumeration speed.
2. Program the MPSIZ field in OTG_DIEPCTL0 to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for a control endpoint depends on the enumeration speed.

At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

**Endpoint initialization on SetAddress command**

This section describes what the application must do when it receives a SetAddress command in a SETUP packet.

1. Program the OTG_DCFG register with the device address received in the SetAddress command
2. Program the core to send out a status IN packet

**Endpoint initialization on SetConfiguration/SetInterface command**

This section describes what the application must do when it receives a SetConfiguration or SetInterface command in a SETUP packet.

1. When a SetConfiguration command is received, the application must program the endpoint registers to configure them with the characteristics of the valid endpoints in the new configuration.
2. When a SetInterface command is received, the application must program the endpoint registers of the endpoints affected by this command.
3. Some endpoints that were active in the prior configuration or alternate setting are not valid in the new configuration or alternate setting. These invalid endpoints must be deactivated.
4. Unmask the interrupt for each active endpoint and mask the interrupts for all inactive endpoints in the OTG_DAINTMSK register.
5. Set up the data FIFO RAM for each FIFO.
6. After all required endpoints are configured; the application must program the core to send a status IN packet.

At this point, the device core is configured to receive and transmit any type of data packet.

**Endpoint activation**

This section describes the steps required to activate a device endpoint or to configure an existing device endpoint to a new type.
1. Program the characteristics of the required endpoint into the following fields of the
   OTG_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG_DOEPCTLx
   register (for OUT or bidirectional endpoints).
   - Maximum packet size
   - USB active endpoint = 1
   - Endpoint start data toggle (for interrupt and bulk endpoints)
   - Endpoint type
   - Tx FIFO number

2. Once the endpoint is activated, the core starts decoding the tokens addressed to that
   endpoint and sends out a valid handshake for each valid token received for the
   endpoint.

Endpoint deactivation

This section describes the steps required to deactivate an existing endpoint.

1. In the endpoint to be deactivated, clear the USB active endpoint bit in the
   OTG_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG_DOEPCTLx
   register (for OUT or bidirectional endpoints).

2. Once the endpoint is deactivated, the core ignores tokens addressed to that endpoint,
   which results in a timeout on the USB.

Note: The application must meet the following conditions to set up the device core to handle
traffic:
NPTXFEM and RXFLVLM in the OTG_GINTMSK register must be cleared.

Operational model

SETUP and OUT data transfers:

This section describes the internal data flow and application-level operations during data
OUT transfers and SETUP transactions.

- Packet read

This section describes how to read packets (OUT data and SETUP packets) from the
receive FIFO.

1. On catching an RXFLVL interrupt (OTG_GINTSTS register), the application must read
   the receive status pop register (OTG_GRXSTSP).

2. The application can mask the RXFLVL interrupt (in OTG_GINTSTS) by writing to
   RXFLVLM = 0 (in OTG_GINTMSK), until it has read the packet from the receive FIFO.

3. If the received packet’s byte count is not 0, the byte count amount of data is popped
   from the receive data FIFO and stored in memory. If the received packet byte count is
   0, no data is popped from the receive data FIFO.

4. The receive status readout of the packet of FIFO indicates one of the following:
   a) Global OUT NAK pattern:
      PKTSTS = Global OUT NAK, BCNT = 0x000, EPNUM = (0x0),
      DPID = (0b00).
      These data indicate that the global OUT NAK bit has taken effect.
   b) SETUP packet pattern:
      PKTSTS = SETUP, BCNT = 0x008, EPNUM = Control EP Num,
DPID = DATA0. These data indicate that a SETUP packet for the specified endpoint is now available for reading from the receive FIFO.

c) Setup stage done pattern:
PKTSTS = Setup Stage Done, BCNT = 0x0, EPNUM = Control EP Num, DPID = (0b00).
These data indicate that the setup stage for the specified endpoint has completed and the data stage has started. After this entry is popped from the receive FIFO, the core asserts a setup interrupt on the specified control OUT endpoint.

d) Data OUT packet pattern:
PKTSTS = DataOUT, BCNT = size of the received data OUT packet (0 ≤ BCNT ≤ 1 024), EPNUM = EPNUM on which the packet was received, DPID = Actual Data PID.

e) Data transfer completed pattern:
PKTSTS = Data OUT transfer done, BCNT = 0x0, EPNUM = OUT EP Num on which the data transfer is complete, DPID = (0b00).
These data indicate that an OUT data transfer for the specified OUT endpoint has completed. After this entry is popped from the receive FIFO, the core asserts a transfer completed interrupt on the specified OUT endpoint.

5. After the data payload is popped from the receive FIFO, the RXFLVL interrupt (OTG_GINTSTS) must be unmasked.

6. Steps 1–5 are repeated every time the application detects assertion of the interrupt line due to RXFLVL in OTG_GINTSTS. Reading an empty receive FIFO can result in undefined core behavior.

Figure 909 provides a flowchart of the above procedure.

Figure 909. Receive FIFO packet read

SETUP transactions
This section describes how the core handles SETUP packets and the application's sequence for handling SETUP transactions.

**Application requirements**

1. To receive a SETUP packet, the STUPCNT field (OTG_DOEPTSIZx) in a control OUT endpoint must be programmed to a non-zero value. When the application programs the STUPCNT field to a non-zero value, the core receives SETUP packets and writes them to the receive FIFO, irrespective of the NAK status and EPENA bit setting in OTG_DOEPCTLx. The STUPCNT field is decremented every time the control endpoint receives a SETUP packet. If the STUPCNT field is not programmed to a proper value before receiving a SETUP packet, the core still receives the SETUP packet and decrements the STUPCNT field, but the application may not be able to determine the correct number of SETUP packets received in the setup stage of a control transfer.  
   - STUPCNT = 3 in OTG_DOEPTSIZx

2. The application must always allocate some extra space in the receive data FIFO, to be able to receive up to three SETUP packets on a control endpoint.
   - The space to be reserved is 10 words. Three words are required for the first SETUP packet, 1 word is required for the setup stage done word and 6 words are required to store two extra SETUP packets among all control endpoints.
   - 3 words per SETUP packet are required to store 8 bytes of SETUP data and 4 bytes of SETUP status (setup packet pattern). The core reserves this space in the receive data FIFO to write SETUP data only, and never uses this space for data packets.

3. The application must read the 2 words of the SETUP packet from the receive FIFO.

4. The application must read and discard the setup stage done word from the receive FIFO.

**Internal data flow**

1. When a SETUP packet is received, the core writes the received data to the receive FIFO, without checking for available space in the receive FIFO and irrespective of the endpoint's NAK and STALL bit settings.
   - The core internally sets the IN NAK and OUT NAK bits for the control IN/OUT endpoints on which the SETUP packet was received.

2. For every SETUP packet received on the USB, 3 words of data are written to the receive FIFO, and the STUPCNT field is decremented by 1.
   - The first word contains control information used internally by the core
   - The second word contains the first 4 bytes of the SETUP command
   - The third word contains the last 4 bytes of the SETUP command

3. When the setup stage changes to a data IN/OUT stage, the core writes an entry (setup stage done word) to the receive FIFO, indicating the completion of the setup stage.

4. On the AHB side, SETUP packets are emptied by the application.

5. When the application pops the setup stage done word from the receive FIFO, the core interrupts the application with an STUP interrupt (OTG_DOEPINTx), indicating it can process the received SETUP packet.

6. The core clears the endpoint enable bit for control OUT endpoints.

**Application programming sequence**
1. Program the OTG_DOEPTSIZx register.
   - STUPCNT = 3

2. Wait for the RXFLVL interrupt (OTG_GINTSTS) and empty the data packets from the receive FIFO.

3. Assertion of the STUP interrupt (OTG_DOEPINTx) marks a successful completion of the SETUP data transfer.
   - On this interrupt, the application must read the OTG_DOEPTSIZx register to determine the number of SETUP packets received and process the last received SETUP packet.

Figure 910. Processing a SETUP packet

- Handling more than three back-to-back SETUP packets

Per the USB 2.0 specification, normally, during a SETUP packet error, a host does not send more than three back-to-back SETUP packets to the same endpoint. However, the USB 2.0 specification does not limit the number of back-to-back SETUP packets a host can send to the same endpoint. When this condition occurs, the OTG_FS controller generates an interrupt (B2BSTUP in OTG_DOEPINTx).

- Setting the global OUT NAK

Internal data flow:
1. When the application sets the Global OUT NAK (SGONAK bit in OTG_DCTL), the core stops writing data, except SETUP packets, to the receive FIFO. Irrespective of the
space availability in the receive FIFO, non-isochronous OUT tokens receive a NAK handshake response, and the core ignores isochronous OUT data packets.

2. The core writes the Global OUT NAK pattern to the receive FIFO. The application must reserve enough receive FIFO space to write this data pattern.

3. When the application pops the Global OUT NAK pattern word from the receive FIFO, the core sets the GONAKEFF interrupt (OTG_GINTSTS).

4. Once the application detects this interrupt, it can assume that the core is in Global OUT NAK mode. The application can clear this interrupt by clearing the SGONAK bit in OTG_DCTL.

Application programming sequence:

1. To stop receiving any kind of data in the receive FIFO, the application must set the Global OUT NAK bit by programming the following field:
   – SGONAK = 1 in OTG_DCTL

2. Wait for the assertion of the GONAKEFF interrupt in OTG_GINTSTS. When asserted, this interrupt indicates that the core has stopped receiving any type of data except SETUP packets.

3. The application can receive valid OUT packets after it has set SGONAK in OTG_DCTL and before the core asserts the GONAKEFF interrupt (OTG_GINTSTS).

4. The application can temporarily mask this interrupt by writing to the GONAKEFFM bit in the OTG_GINTMSK register.
   – GONAKEFFM = 0 in the OTG_GINTMSK register

5. Whenever the application is ready to exit the Global OUT NAK mode, it must clear the SGONAK bit in OTG_DCTL. This also clears the GONAKEFF interrupt (OTG_GINTSTS).
   – CGONAK = 1 in OTG_DCTL

6. If the application has masked this interrupt earlier, it must be unmasked as follows:
   – GONAKEFFM = 1 in OTG_GINTMSK

- **Disabling an OUT endpoint**

The application must use this sequence to disable an OUT endpoint that it has enabled.

Application programming sequence:
1. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core.
   - SGONAK = 1 in OTG_DCTL
2. Wait for the GONAKEFF interrupt (OTG_GINTSTS)
3. Disable the required OUT endpoint by programming the following fields:
   - EPDIS = 1 in OTG_DOEPCTLx
   - SNAK = 1 in OTG_DOEPCTLx
4. Wait for the EPDISD interrupt (OTG_DOEPINTx), which indicates that the OUT endpoint is completely disabled. When the EPDISD interrupt is asserted, the core also clears the following bits:
   - EPDIS = 0 in OTG_DOEPCTLx
   - EPENA = 0 in OTG_DOEPCTLx
5. The application must clear the Global OUT NAK bit to start receiving data from other non-disabled OUT endpoints.
   - SGONAK = 0 in OTG_DCTL

• **Transfer Stop Programming for OUT endpoints**

   The application must use the following programming sequence to stop any transfers (because of an interrupt from the host, typically a reset).

   **Sequence of operations:**
   1. Enable all OUT endpoints by setting
      - EPENA = 1 in all OTG_DOEPCTLx registers.
   2. Flush the RxFIFO as follows
      - Poll OTG_GRSTCTL.AHBIDL until it is 1. This indicates that AHB master is idle.
      - Perform read modify write operation on OTG_GRSTCTL.RXFFLSH = 1
      - Poll OTG_GRSTCTL.RXFFLSH until it is 0, but also using a timeout of less than 10 milli-seconds (corresponds to minimum reset signaling duration). If 0 is seen before the timeout, then the RxFIFO flush is successful. If at the moment the timeout occurs, there is still a 1, (this may be due to a packet on EP0 coming from the host) then go back (once only) to the previous step (“Perform read modify write operation”).
   3. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core, according to the instructions in “Setting the global OUT NAK on page 3034”. This ensures that data in the RxFIFO is sent to the application successfully. Set SGONAK = 1 in OTG_DCTL
   4. Wait for the GONAKEFF interrupt (OTG_GINTSTS)
   5. Disable all active OUT endpoints by programming the following register bits:
      - EPDIS = 1 in registers OTG_DOEPCTLx
      - SNAK = 1 in registers OTG_DOEPCTLx
   6. Wait for the EPDIS interrupt in OTG_DOEPINTx for each OUT endpoint programmed in the previous step. The EPDIS interrupt in OTG_DOEPINTx indicates that the
corresponding OUT endpoint is completely disabled. When the EPDIS interrupt is asserted, the following bits are cleared:
- EPENA = 0 in registers OTG_DOEPCTLx
- EPDIS = 0 in registers OTG_DOEPCTLx
- SNAK = 0 in registers OTG_DOEPCTLx

• **Generic non-isochronous OUT data transfers**

This section describes a regular non-isochronous OUT data transfer (control, bulk, or interrupt).

Application requirements:
1. Before setting up an OUT transfer, the application must allocate a buffer in the memory to accommodate all data to be received as part of the OUT transfer.
2. For OUT transfers, the transfer size field in the endpoint's transfer size register must be a multiple of the maximum packet size of the endpoint, adjusted to the word boundary.
   - transfer size[EPNUM] = \( n \times (MPSIZ[EPNUM] + 4 - (MPSIZ[EPNUM] \mod 4)) \)
   - packet count[EPNUM] = \( n \)
   - \( n > 0 \)
3. On any OUT endpoint interrupt, the application must read the endpoint's transfer size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
   - Payload size in memory = application programmed initial transfer size – core updated final transfer size
   - Number of USB packets in which this payload was received = application programmed initial packet count – core updated final packet count

Internal data flow:
1. The application must set the transfer size and packet count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
2. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the packet count field for that endpoint by 1.
   - OUT data packets received with bad data CRC are flushed from the receive FIFO automatically.
   - After sending an ACK for the packet on the USB, the core discards non-isochronous OUT data packets that the host, which cannot detect the ACK, re-sends. The application does not detect multiple back-to-back data OUT packets on the same endpoint with the same data PID. In this case the packet count is not decremented.
   - If there is no space in the receive FIFO, isochronous or non-isochronous data packets are ignored and not written to the receive FIFO. Additionally, non-isochronous OUT tokens receive a NAK handshake reply.
   - In all the above three cases, the packet count is not decremented because no data are written to the receive FIFO.
3. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or non-isochronous data packets are ignored and not written to the receive FIFO, and non-isochronous OUT tokens receive a NAK handshake reply.

4. After the data are written to the receive FIFO, the application reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.

5. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.

6. The OUT data transfer completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions:
   - The transfer size is 0 and the packet count is 0
   - The last OUT data packet written to the receive FIFO is a short packet (0 ≤ packet size < maximum packet size)

7. When either the application pops this entry (OUT data transfer completed), a transfer completed interrupt is generated for the endpoint and the endpoint enable is cleared.

Application programming sequence:
1. Program the OTG_DOEPTSIZx register for the transfer size and the corresponding packet count.
2. Program the OTG_DOEPCTLx register with the endpoint characteristics, and set the EPENA and CNAK bits.
   - EPENA = 1 in OTG_DOEPCTLx
   - CNAK = 1 in OTG_DOEPCTLx
3. Wait for the RXFLVL interrupt (in OTG_GINTSTS) and empty the data packets from the receive FIFO.
   - This step can be repeated many times, depending on the transfer size.
4. Asserting the XFRC interrupt (OTG_DOEPI TX ) marks a successful completion of the non-isochronous OUT data transfer.
5. Read the OTG_DOEPTSIZx register to determine the size of the received data payload.

- **Generic isochronous OUT data transfer**

This section describes a regular isochronous OUT data transfer.

Application requirements:
1. All the application requirements for non-isochronous OUT data transfers also apply to isochronous OUT data transfers.
2. For isochronous OUT data transfers, the transfer size and packet count fields must always be set to the number of maximum-packet-size packets that can be received in a single frame and no more. Isochronous OUT data transfers cannot span more than 1 frame.
3. The application must read all isochronous OUT data packets from the receive FIFO (data and status) before the end of the periodic frame (EOPF interrupt in OTG_GINTSTS).
4. To receive data in the following frame, an isochronous OUT endpoint must be enabled after the EOPF (OTG_GINTSTS) and before the SOF (OTG_GINTSTS).

Internal data flow:
1. The internal data flow for isochronous OUT endpoints is the same as that for non-
   isochronous OUT endpoints, but for a few differences.
2. When an isochronous OUT endpoint is enabled by setting the endpoint enable and
   clearing the NAK bits, the Even/Odd frame bit must also be set appropriately. The core
   receives data on an isochronous OUT endpoint in a particular frame only if the
   following condition is met:
   – $\text{EONUM (in OTG\_DOEPCTLx) = FNSOF}[0] \text{ (in OTG\_DSTS)}$
3. When the application completely reads an isochronous OUT data packet (data and
   status) from the receive FIFO, the core updates the RXDPID field in OTG\_DOEPTSIZx
   with the data PID of the last isochronous OUT data packet read from the receive FIFO.

Application programming sequence:
1. Program the OTG\_DOEPTSIZx register for the transfer size and the corresponding
   packet count
2. Program the OTG\_DOEPCTLx register with the endpoint characteristics and set the
   endpoint enable, ClearNAK, and Even/Odd frame bits.
   – $\text{EPENA = 1}$
   – $\text{CNAK = 1}$
   – $\text{EONUM = (0: Even/1: Odd)}$
3. Wait for the RXFLVL interrupt (in OTG\_GINTSTS) and empty the data packets from the
   receive FIFO
   – This step can be repeated many times, depending on the transfer size.
4. The assertion of the XFRC interrupt (in OTG\_DOEPINTx) marks the completion of the
   isochronous OUT data transfer. This interrupt does not necessarily mean that the data
   in memory are good.
5. This interrupt cannot always be detected for isochronous OUT transfers. Instead, the
   application can detect the INCOMPISOOUT interrupt in OTG\_GINTSTS.
6. Read the OTG\_DOEPTSIZx register to determine the size of the received transfer and
   to determine the validity of the data received in the frame. The application must treat
   the data received in memory as valid only if one of the following conditions is met:
   – $\text{RXDPID = DATA0 (in OTG\_DOEPTSIZx) and the number of USB packets in}
     \text{which this payload was received = 1}$
   – $\text{RXDPID = DATA1 (in OTG\_DOEPTSIZx) and the number of USB packets in}
     \text{which this payload was received = 2}$
   \text{The number of USB packets in which this payload was received =}
   \text{Application programmed initial packet count – core updated final packet count}
   \text{The application can discard invalid data packets.}

- **Incomplete isochronous OUT data transfers**

This section describes the application programming sequence when isochronous OUT data
packets are dropped inside the core.

Internal data flow:
1. For isochronous OUT endpoints, the XFRC interrupt (in OTG\_DOEPINTx) may not
   always be asserted. If the core drops isochronous OUT data packets, the application
could fail to detect the XFRC interrupt (OTG_DOEPINTx) under the following circumstances:
– When the receive FIFO cannot accommodate the complete ISO OUT data packet, the core drops the received ISO OUT data
– When the isochronous OUT data packet is received with CRC errors
– When the isochronous OUT token received by the core is corrupted
– When the application is very slow in reading the data from the receive FIFO

2. When the core detects an end of periodic frame before transfer completion to all isochronous OUT endpoints, it asserts the incomplete isochronous OUT data interrupt (INCOMPISOOUT in OTG_GINTSTS), indicating that an XFRC interrupt (in OTG_DOEPINTx) is not asserted on at least one of the isochronous OUT endpoints. At this point, the endpoint with the incomplete transfer remains enabled, but no active transfers remain in progress on this endpoint on the USB.

Application programming sequence:
1. Asserting the INCOMPISOOUT interrupt (OTG_GINTSTS) indicates that in the current frame, at least one isochronous OUT endpoint has an incomplete transfer.

2. If this occurs because isochronous OUT data is not completely emptied from the endpoint, the application must ensure that the application empties all isochronous OUT data (data and status) from the receive FIFO before proceeding.
   – When all data are emptied from the receive FIFO, the application can detect the XFRC interrupt (OTG_DOEPINTx). In this case, the application must re-enable the endpoint to receive isochronous OUT data in the next frame.

3. When it receives an INCOMPISOOUT interrupt (in OTG_GINTSTS), the application must read the control registers of all isochronous OUT endpoints (OTG_DOEPCTLx) to determine which endpoints had an incomplete transfer in the current microframe. An endpoint transfer is incomplete if both the following conditions are met:
   – EONUM bit (in OTG_DOEPCTLx) = FNSOF[0] (in OTG_DSTS)
   – EPENA = 1 (in OTG_DOEPCTLx)

4. The previous step must be performed before the SOF interrupt (in OTG_GINTSTS) is detected, to ensure that the current frame number is not changed.

5. For isochronous OUT endpoints with incomplete transfers, the application must discard the data in the memory and disable the endpoint by setting the EPDIS bit in OTG_DOEPCTLx.

6. Wait for the EPDISD interrupt (in OTG_DOEPINTx) and enable the endpoint to receive new data in the next frame.
   – Because the core can take some time to disable the endpoint, the application may not be able to receive the data in the next frame after receiving bad isochronous data.

- **Stalling a non-isochronous OUT endpoint**

This section describes how the application can stall a non-isochronous endpoint.
1. Put the core in the Global OUT NAK mode.
2. Disable the required endpoint
   - When disabling the endpoint, instead of setting the SNAK bit in OTG_DOEPCTL, set STALL = 1 (in OTG_DOEPCTL).
     The STALL bit always takes precedence over the NAK bit.
3. When the application is ready to end the STALL handshake for the endpoint, the
   STALL bit (in OTG_DOEPCTLx) must be cleared.
4. If the application is setting or clearing a STALL for an endpoint due to a
   SetFeature.Endpoint Halt or ClearFeature.Endpoint Halt command, the STALL bit must
   be set or cleared before the application sets up the status stage transfer on the control
   endpoint.

Examples
This section describes and depicts some fundamental transfer types and scenarios.
- Bulk OUT transaction

*Figure 911* depicts the reception of a single Bulk OUT data packet from the USB to the AHB
and describes the events involved in the process.

*Figure 911. Bulk OUT transaction*

After a SetConfiguration/SetInterface command, the application initializes all OUT endpoints
by setting CNAK = 1 and EPENA = 1 (in OTG_DOEPCTLx), and setting a suitable
XFRSIZ and PKTCNT in the OTG_DOEPTSIZx register.
1. host attempts to send data (OUT token) to an endpoint.
2. When the core receives the OUT token on the USB, it stores the packet in the Rx FIFO because space is available there.
3. After writing the complete packet in the Rx FIFO, the core then asserts the RXFLVL interrupt (in OTG_GINTSTS).
4. On receiving the PKTCNT number of USB packets, the core internally sets the NAK bit for this endpoint to prevent it from receiving any more packets.
5. The application processes the interrupt and reads the data from the Rx FIFO.
6. When the application has read all the data (equivalent to XFRSIZ), the core generates an XFRC interrupt (in OTG_DOEPINTx).
7. The application processes the interrupt and uses the setting of the XFRC interrupt bit (in OTG_DOEPINTx) to determine that the intended transfer is complete.

**IN data transfers**

- **Packet write**
  This section describes how the application writes data packets to the endpoint FIFO when dedicated transmit FIFOs are enabled.
  1. The application can either choose the polling or the interrupt mode.
     - In polling mode, the application monitors the status of the endpoint transmit data FIFO by reading the OTG_DTXFSTSx register, to determine if there is enough space in the data FIFO.
     - In interrupt mode, the application waits for the TXFE interrupt (in OTG_DIEPINTx) and then reads the OTG_DTXFSTSx register, to determine if there is enough space in the data FIFO.
     - To write a single non-zero length data packet, there must be space to write the entire packet in the data FIFO.
     - To write zero length packet, the application must not look at the FIFO space.
  2. Using one of the above mentioned methods, when the application determines that there is enough space to write a transmit packet, the application must first write into the endpoint control register, before writing the data into the data FIFO. Typically, the application, must do a read modify write on the OTG_DIEPCTLx register to avoid modifying the contents of the register, except for setting the endpoint enable bit.

The application can write multiple packets for the same endpoint into the transmit FIFO, if space is available. For periodic IN endpoints, the application must write packets only for one microframe. It can write packets for the next periodic transaction only after getting transfer complete for the previous transaction.

- **Setting IN endpoint NAK**

  Internal data flow:
1. When the application sets the IN NAK for a particular endpoint, the core stops transmitting data on the endpoint, irrespective of data availability in the endpoint’s transmit FIFO.

2. Non-isochronous IN tokens receive a NAK handshake reply
   - Isochronous IN tokens receive a zero-data-length packet reply

3. The core asserts the INEPNE (IN endpoint NAK effective) interrupt in OTG_DIEPINTx in response to the SNAK bit in OTG_DIEPCTLx.

4. Once this interrupt is seen by the application, the application can assume that the endpoint is in IN NAK mode. This interrupt can be cleared by the application by setting the CNAK bit in OTG_DIEPCTLx.

**Application programming sequence:**

1. To stop transmitting any data on a particular IN endpoint, the application must set the IN NAK bit. To set this bit, the following field must be programmed.
   - SNAK = 1 in OTG_DIEPCTLx

2. Wait for assertion of the INEPNE interrupt in OTG_DIEPINTx. This interrupt indicates that the core has stopped transmitting data on the endpoint.

3. The core can transmit valid IN data on the endpoint after the application has set the NAK bit, but before the assertion of the NAK Effective interrupt.

4. The application can mask this interrupt temporarily by writing to the INEPNEM bit in OTG_DIEPMSK.
   - INEPNEM = 0 in OTG_DIEPMSK

5. To exit endpoint NAK mode, the application must clear the NAK status bit (NAKSTS) in OTG_DIEPCTLx. This also clears the INEPNE interrupt (in OTG_DIEPINTx).
   - CNAK = 1 in OTG_DIEPCTLx

6. If the application masked this interrupt earlier, it must be unmasked as follows:
   - INEPNEM = 1 in OTG_DIEPMSK

---

**IN endpoint disable**

Use the following sequence to disable a specific IN endpoint that has been previously enabled.

**Application programming sequence:**
1. The application must stop writing data on the AHB for the IN endpoint to be disabled.
2. The application must set the endpoint in NAK mode.
   - SNAK = 1 in OTG_DIEPCTLx
3. Wait for the INEPNE interrupt in OTG_DIEPINTx.
4. Set the following bits in the OTG_DIEPCTLx register for the endpoint that must be disabled.
   - EPDIS = 1 in OTG_DIEPCTLx
   - SNAK = 1 in OTG_DIEPCTLx
5. Assertion of the EPDISD interrupt in OTG_DIEPINTx indicates that the core has completely disabled the specified endpoint. Along with the assertion of the interrupt, the core also clears the following bits:
   - EPENA = 0 in OTG_DIEPCTLx
   - EPDIS = 0 in OTG_DIEPCTLx
6. The application must read the OTG_DIEPTSIZx register for the periodic IN EP, to calculate how much data on the endpoint were transmitted on the USB.
7. The application must flush the data in the endpoint transmit FIFO, by setting the following fields in the OTG_GRSTCTL register:
   - TXFNUM (in OTG_GRSTCTL) = Endpoint transmit FIFO number
   - TXFFLSH in (OTG_GRSTCTL) = 1
   The application must poll the OTG_GRSTCTL register, until the TXFFLSH bit is cleared by the core, which indicates the end of flush operation. To transmit new data on this endpoint, the application can re-enable the endpoint at a later point.

   **Transfer Stop Programming for IN endpoints**

   The application must use the following programming sequence to stop any transfers (because of an interrupt from the host, typically a reset).

   **Sequence of operations:**
   1. Disable the IN endpoint by setting:
      - EPDIS = 1 in all OTG_DIEPCTLx registers
   2. Wait for the EPDIS interrupt in OTG_DIEPINTx, which indicates that the IN endpoint is completely disabled. When the EPDIS interrupt is asserted the following bits are cleared:
      - EPDIS = 0 in OTG_DIEPCTLx
      - EPENA = 0 in OTG_DIEPCTLx
   3. Flush the TxFIFO by programming the following bits:
      - TXFFLSH = 1 in OTG_GRSTCTL
      - TXFNUM = “FIFO number specific to endpoint” in OTG_GRSTCTL
   4. The application can start polling till TXFFLSH in OTG_GRSTCTL is cleared. When this bit is cleared, it ensures that there is no data left in the Tx FIFO.

   **Generic non-periodic IN data transfers**

   Application requirements:
1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer are part of a single buffer.

2. For IN transfers, the transfer size field in the endpoint transfer size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
   - To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
     \[
     \text{Transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}
     \]
     If (sp > 0), then \(\text{packet count}[\text{EPNUM}] = x + 1\).
     Otherwise, \(\text{packet count}[\text{EPNUM}] = x\).
   - To transmit a single zero-length data packet:
     \(\text{Transfer size}[\text{EPNUM}] = 0\)
     \(\text{Packet count}[\text{EPNUM}] = 1\)
   - To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer into two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.
     \(\text{First transfer: transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}];\) \(\text{packet count} = n;\)
     \(\text{Second transfer: transfer size}[\text{EPNUM}] = 0;\) \(\text{packet count} = 1;\)

3. Once an endpoint is enabled for data transfers, the core updates the transfer size register. At the end of the IN transfer, the application must read the transfer size register to determine how much data posted in the transmit FIFO have already been sent on the USB.

4. Data fetched into transmit FIFO = Application-programmed initial transfer size – core-updated final transfer size
   - Data transmitted on USB = (application-programmed initial packet count – core updated final packet count) \(\times \text{MPSIZ}[\text{EPNUM}]\)
   - Data yet to be transmitted on USB = (Application-programmed initial transfer size – data transmitted on USB)

Internal data flow:
1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the transmit FIFO for the endpoint.
3. Every time a packet is written into the transmit FIFO by the application, the transfer size for that endpoint is decremented by the packet size. The data is fetched from the memory by the application, until the transfer size for the endpoint becomes 0. After writing the data into the FIFO, the “number of packets in FIFO” count is incremented (this is a 3-bit count, internally maintained by the core for each IN endpoint transmit FIFO. The maximum number of packets maintained by the core at any time in an IN endpoint FIFO is eight). For zero-length packets, a separate flag is set for each FIFO, without any data in the FIFO.
4. Once the data are written to the transmit FIFO, the core reads them out upon receiving an IN token. For every non-isochronous IN data packet transmitted with an ACK
handshake, the packet count for the endpoint is decremented by one, until the packet count is zero. The packet count is not decremented on a timeout.

5. For zero length packets (indicated by an internal zero length flag), the core sends out a zero-length packet for the IN token and decrements the packet count field.

6. If there are no data in the FIFO for a received IN token and the packet count field for that endpoint is zero, the core generates an “IN token received when Tx FIFO is empty” (ITTXFE) interrupt for the endpoint, provided that the endpoint NAK bit is not set. The core responds with a NAK handshake for non-isochronous endpoints on the USB.

7. The core internally rewinds the FIFO pointers and no timeout interrupt is generated.

8. When the transfer size is 0 and the packet count is 0, the transfer complete (XFRC) interrupt for the endpoint is generated and the endpoint enable is cleared.

Application programming sequence:

1. Program the OTG_DIEPTSIZx register with the transfer size and corresponding packet count.

2. Program the OTG_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA (endpoint enable) bits.

3. When transmitting non-zero length data packet, the application must poll the OTG_DTXFSTx register (where x is the FIFO number associated with that endpoint) to determine whether there is enough space in the data FIFO. The application can optionally use TXFE (in OTG_DIEPINTx) before writing the data.

App. 1

Generic periodic IN data transfers

This section describes a typical periodic IN data transfer.

Application requirements:

1. Application requirements 1, 2, 3, and 4 of Generic non-periodic IN data transfers on page 3044 also apply to periodic IN data transfers, except for a slight modification of requirement 2.
   - The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To
transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met:

\[
\text{transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + sp
\]

(where \( x \) is an integer \( \geq 0 \), and \( 0 \leq sp < \text{MPSIZ}[\text{EPNUM}] \))

If \( sp > 0 \), packet count[EPNUM] = \( x + 1 \)
Otherwise, packet count[EPNUM] = \( x \);

\[
\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]
\]

– The application cannot transmit a zero-length data packet at the end of a transfer. It can transmit a single zero-length data packet by itself. To transmit a single zero-length data packet:

– transfer size[EPNUM] = 0

packet count[EPNUM] = 1

\[
\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]
\]

2. The application can only schedule data transfers one frame at a time.

– \((\text{MCNT} – 1) \times \text{MPSIZ} \leq \text{XFERSIZ} \leq \text{MCNT} \times \text{MPSIZ}\)

– \(\text{PKTCNT} = \text{MCNT} \) (in OTG\_DIEPTSZx)

– If \( \text{XFERSIZ} < \text{MCNT} \times \text{MPSIZ} \), the last data packet of the transfer is a short packet.

– Note that: \( \text{MCNT} \) is in OTG\_DIEPTSZx, \( \text{MPSIZ} \) is in OTG\_DIEPCTLx, \( \text{PKTCNT} \) is in OTG\_DIEPTSZx and \( \text{XFERSIZ} \) is in OTG\_DIEPTSZx

3. The complete data to be transmitted in the frame must be written into the transmit FIFO by the application, before the IN token is received. Even when 1 word of the data to be transmitted per frame is missing in the transmit FIFO when the IN token is received, the core behaves as when the FIFO is empty. When the transmit FIFO is empty:

– A zero data length packet would be transmitted on the USB for isochronous IN endpoints

– A NAK handshake would be transmitted on the USB for interrupt IN endpoints

Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.

2. The application must also write the required data to the associated transmit FIFO for the endpoint.

3. Every time the application writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data are fetched from application memory until the transfer size for the endpoint becomes 0.

4. When an IN token is received for a periodic endpoint, the core transmits the data in the FIFO, if available. If the complete data payload (complete packet, in dedicated FIFO
mode) for the frame is not present in the FIFO, then the core generates an IN token received when Tx FIFO empty interrupt for the endpoint.

- A zero-length data packet is transmitted on the USB for isochronous IN endpoints
- A NAK handshake is transmitted on the USB for interrupt IN endpoints

5. The packet count for the endpoint is decremented by 1 under the following conditions:
- For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
- For interrupt endpoints, when an ACK handshake is transmitted
- When the transfer size and packet count are both 0, the transfer completed interrupt for the endpoint is generated and the endpoint enable is cleared.

6. At the “Periodic frame Interval” (controlled by PFIVL in OTG_DCFG), when the core finds non-empty any of the isochronous IN endpoint FIFOs scheduled for the current frame non-empty, the core generates an IISOIXFR interrupt in OTG_GINTSTS.

Application programming sequence:
1. Program the OTG_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA bits.
2. Write the data to be transmitted in the next frame to the transmit FIFO.
3. Asserting the ITTXFE interrupt (in OTG_DIEPINTx) indicates that the application has not yet written all data to be transmitted to the transmit FIFO.
4. If the interrupt endpoint is already enabled when this interrupt is detected, ignore the interrupt. If it is not enabled, enable the endpoint so that the data can be transmitted on the next IN token attempt.
5. Asserting the XFRC interrupt (in OTG_DIEPINTx) with no ITTXFE interrupt in OTG_DIEPINTx indicates the successful completion of an isochronous IN transfer. A read to the OTG_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
6. Asserting the XFRC interrupt (in OTG_DIEPINTx), with or without the ITTXFE interrupt (in OTG_DIEPINTx), indicates the successful completion of an interrupt IN transfer. A read to the OTG_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
7. Asserting the incomplete isochronous IN transfer (IISOIXFR) interrupt in OTG_GINTSTS with none of the aforementioned interrupts indicates the core did not receive at least 1 periodic IN token in the current frame.

- Incomplete isochronous IN data transfers

This section describes what the application must do on an incomplete isochronous IN data transfer.

Internal data flow:
1. An isochronous IN transfer is treated as incomplete in one of the following conditions:
   a) The core receives a corrupted isochronous IN token on at least one isochronous IN endpoint. In this case, the application detects an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG_GINTSTS).
   b) The application is slow to write the complete data payload to the transmit FIFO and an IN token is received before the complete data payload is written to the FIFO. In this case, the application detects an IN token received when Tx FIFO empty interrupt in OTG_DIEPINTx. The application can ignore this interrupt, as it
eventually results in an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG_GINTSTS) at the end of periodic frame.

The core transmits a zero-length data packet on the USB in response to the received IN token.

2. The application must stop writing the data payload to the transmit FIFO as soon as possible.

3. The application must set the NAK bit and the disable bit for the endpoint.

4. The core disables the endpoint, clears the disable bit, and asserts the endpoint disable interrupt for the endpoint.

Application programming sequence:

1. The application can ignore the IN token received when Tx FIFO empty interrupt in OTG_DIEPINTx on any isochronous IN endpoint, as it eventually results in an incomplete isochronous IN transfer interrupt (in OTG_GINTSTS).

2. Assertion of the incomplete isochronous IN transfer interrupt (in OTG_GINTSTS) indicates an incomplete isochronous IN transfer on at least one of the isochronous IN endpoints.

3. The application must read the endpoint control register for all isochronous IN endpoints to detect endpoints with incomplete IN data transfers.

4. The application must stop writing data to the Periodic Transmit FIFOs associated with these endpoints on the AHB.

5. Program the following fields in the OTG_DIEPCTLx register to disable the endpoint:
   - SNAK = 1 in OTG_DIEPCTLx
   - EPDIS = 1 in OTG_DIEPCTLx

6. The assertion of the endpoint disabled interrupt in OTG_DIEPINTx indicates that the core has disabled the endpoint.
   - At this point, the application must flush the data in the associated transmit FIFO or overwrite the existing data in the FIFO by enabling the endpoint for a new transfer in the next microframe. To flush the data, the application must use the OTG_GRSTCTL register.

- **Stalling non-isochronous IN endpoints**

This section describes how the application can stall a non-isochronous endpoint.

Application programming sequence:
1. Disable the IN endpoint to be stalled. Set the STALL bit as well.
2. EPDIS = 1 in OTG_DIEPCTLx, when the endpoint is already enabled
   – STALL = 1 in OTG_DIEPCTLx
   – The STALL bit always takes precedence over the NAK bit
3. Assertion of the endpoint disabled interrupt (in OTG_DIEPINTx) indicates to the
   application that the core has disabled the specified endpoint.
4. The application must flush the non-periodic or periodic transmit FIFO, depending on
   the endpoint type. In case of a non-periodic endpoint, the application must re-enable
   the other non-periodic endpoints that do not need to be stalled, to transmit data.
5. Whenever the application is ready to end the STALL handshake for the endpoint, the
   STALL bit must be cleared in OTG_DIEPCTLx.
6. If the application sets or clears a STALL bit for an endpoint due to a
   SetFeature.Endpoint Halt command or ClearFeature.Endpoint Halt command, the
   STALL bit must be set or cleared before the application sets up the status stage
   transfer on the control endpoint.

Special case: stalling the control OUT endpoint

The core must stall IN/OUT tokens if, during the data stage of a control transfer, the host
sends more IN/OUT tokens than are specified in the SETUP packet. In this case, the
application must enable the ITTXFE interrupt in OTG_DIEPINTx and the OTEPDIS interrupt
in OTG_DOEPINTx during the data stage of the control transfer, after the core has
transferred the amount of data specified in the SETUP packet. Then, when the application
receives this interrupt, it must set the STALL bit in the corresponding endpoint control
register, and clear this interrupt.

61.16.6 Worst case response time

When the OTG_FS controller acts as a device, there is a worst case response time for any
tokens that follow an isochronous OUT. This worst case response time depends on the AHB
clock frequency.

The core registers are in the AHB domain, and the core does not accept another token
before updating these register values. The worst case is for any token following an
isochronous OUT, because for an isochronous transaction, there is no handshake and the
next token could come sooner. This worst case value is 7 PHY clocks when the AHB clock
is the same as the PHY clock. When the AHB clock is faster, this value is smaller.

If this worst case condition occurs, the core responds to bulk/interrupt tokens with a NAK
and drops isochronous and SETUP tokens. The host interprets this as a timeout condition
for SETUP and retries the SETUP packet. For isochronous transfers, the Incomplete
isochronous IN transfer interrupt (IISOIXFR) and Incomplete isochronous OUT transfer
interrupt (IISOOXFR) inform the application that isochronous IN/OUT packets were
dropped.

Choosing the value of TRDT in OTG_GUSBCFG

The value in TRDT (OTG_GUSBCFG) is the time it takes for the MAC, in terms of PHY
clocks after it has received an IN token, to get the FIFO status, and thus the first data from
the PFC block. This time involves the synchronization delay between the PHY and AHB
clocks. The worst case delay for this is when the AHB clock is the same as the PHY clock.
In this case, the delay is 5 clocks.
Once the MAC receives an IN token, this information (token received) is synchronized to the AHB clock by the PFC (the PFC runs on the AHB clock). The PFC then reads the data from the SPRAM and writes them into the dual clock source buffer. The MAC then reads the data out of the source buffer (4 deep).

If the AHB is running at a higher frequency than the PHY, the application can use a smaller value for TRDT (in OTG_GUSBCFG).

*Figure 912* has the following signals:
- `tkn_rcvd`: Token received information from MAC to PFC
- `dynced_tkn_rcvd`: Doubled sync `tkn_rcvd`, from PCLK to HCLK domain
- `spr_read`: Read to SPRAM
- `spr_addr`: Address to SPRAM
- `spr_rdata`: Read data from SPRAM
- `srcbuf_push`: Push to the source buffer
- `srcbuf_rdata`: Read data from the source buffer. Data seen by MAC

To calculate the value of TRDT, refer to *Table 660: TRDT values*.

*Figure 912. TRDT max timing case*
61.16.7 OTG programming model

The OTG_FS controller is an OTG device. When the core is connected to an “A” plug, it is referred to as an A-device. When the core is connected to a “B” plug it is referred to as a B-device.
62 USB on-the-go high-speed (OTG_HS)

62.1 Introduction

Portions Copyright (c) Synopsys, Inc. All rights reserved. Used with permission.

This section presents the architecture and the programming model of the OTG_HS controller.

The following acronyms are used throughout the section:

- FS Full-speed
- LS Low-speed
- HS High-speed
- MAC Media access controller
- OTG On-the-go
- PFC Packet FIFO controller
- PHY Physical layer
- USB Universal serial bus
- UTMU USB 2.0 Transceiver Macrocell interface (UTMI)
- LPM Link power management
- BCD Battery charging detector
- HNP Host negotiation protocol
- SRP Session request protocol

References are made to the following documents:

- USB On-The-Go Supplement, Revision 2.0
- Universal Serial Bus Revision 2.0 Specification
- USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007
- Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007
- Battery Charging Specification, Revision 1.2

The USB OTG is a dual-role device (DRD) controller that supports both device and host functions and is fully compliant with the On-The-Go Supplement to the USB 2.0 Specification. It can also be configured as a host-only or device-only controller, fully compliant with the USB 2.0 Specification. OTG_HS supports the speeds defined in the Table 663: OTG_HS speeds supported below. The only external device required is a charge pump for VBUS in OTG mode.

62.2 OTG_HS main features

The main features can be divided into three categories: general, host-mode, and device-mode features.

62.2.1 General features

The OTG_HS interface general features are the following:

- It is USB-IF certified to the Universal Serial Bus Specification Rev 2.0.
- OTG_HS supports the following PHY interfaces:
  - A UTMI interface for internal HS PHY
- It includes support (PHY) for the optional On-The-Go (OTG) protocol detailed in the On-The-Go Supplement Rev 2.0 specification
  - Integrated support for A-B device identification (ID line)
  - It allows host to turn VBUS off to conserve battery power in OTG applications.
  - It supports OTG monitoring of VBUS levels with internal comparators.
- It is software-configurable to operate as:
  - USB On-The-Go Full-Speed Dual Role device
- It supports HS SOF and LS Keep-alives with
  - SOF pulse PAD connectivity
  - SOF pulse internal connection to timer (TIMx)
  - Configurable framing period
  - Configurable end of frame interrupt
- OTG_HS embeds an internal DMA with thresholding support and software selectable AHB burst type in DMA mode.
- It includes power saving features such as system stop during USB suspend, switch-off of clock domains internal to the digital core, PHY and DFIFO power management.
- It features a dedicated RAM of 4 Kbytes with advanced FIFO control:
  - Configurable partitioning of RAM space into different FIFOs for flexible and efficient use of RAM
  - Each FIFO can hold multiple packets.
  - Dynamic memory allocation
  - Configurable FIFO sizes that are not powers of 2 to allow the use of contiguous memory locations
- It guarantees max USB bandwidth for up to one frame (1 ms) without system intervention.
- It supports charging port detection as described in Battery Charging Specification Revision 1.2.
62.2.2 Host-mode features

The OTG_HS interface main features and requirements in host-mode are the following:

- External charge pump for VBUS voltage generation
- Up to 16 host channels (pipes): each channel is dynamically reconfigurable to allocate any type of USB transfer.
- Built-in hardware scheduler holding:
  - Up to 16 interrupt plus isochronous transfer requests in the periodic hardware queue
  - Up to 16 control plus bulk transfer requests in the non-periodic hardware queue
- Management of a shared Rx FIFO, a periodic Tx FIFO and a nonperiodic Tx FIFO for efficient usage of the USB data RAM.

62.2.3 Peripheral-mode features

The OTG_HS interface main features in peripheral-mode are the following:

- 1 bidirectional control endpoint0
- 8 IN endpoints (EPs) configurable to support bulk, interrupt or isochronous transfers
- 8 OUT endpoints configurable to support bulk, interrupt or isochronous transfers
- Management of a shared Rx FIFO and a Tx-OUT FIFO for efficient usage of the USB data RAM
- Management of up to 9 dedicated Tx-IN FIFOs (one for each active IN EP) to put less load on the application
- Support for the soft disconnect feature.

62.4.3 OTG_HS core

The OTG_HS receives the 60 MHz clock from the reset and clock controller (RCC). This is typically generated in the PLL associated with the HS PHY and enabled in the RCC. This clock is used for driving the 60 MHz domain at high-speed (480 Mbit/s) and must be enabled prior to configuring the OTG core.

The CPU reads and writes from/to the OTG core registers through the AHB peripheral bus. It is informed of USB events through the single USB OTG interrupt line described in Section 62.12: OTG_HS interrupts.

The CPU submits data over the USB by writing 32-bit words to dedicated OTG locations (push registers). The data are then automatically stored into Tx-data FIFOs configured within the USB data RAM. There is one Tx FIFO push register for each in-endpoint (peripheral mode) or out-channel (host mode).

The CPU receives the data from the USB by reading 32-bit words from dedicated OTG addresses (pop registers). The data are then automatically retrieved from a shared Rx FIFO configured within the 4-Kbyte USB data RAM. There is one Rx FIFO pop register for each out-endpoint or in-channel.

The USB protocol layer is driven by the serial interface engine (SIE) and serialized over the USB by the transceiver module within the on-chip physical layer (PHY).

Caution: To guarantee a correct operation for the USB OTG_HS peripheral, the AHB frequency must be higher than 30 MHz.

62.4.4 OTG detections

Additionally the OTG_HS uses the following functions:

- Integrated ID pull-up resistor used to sample the ID line for A/B device identification.
- $V_{BUS}$ sensing comparators with hysteresis used to detect $V_{BUS}$ valid, A-B session valid and session-end voltage thresholds. They are used to detect valid startup and end-of-session conditions, and constantly monitor the $V_{BUS}$ supply during USB operations.

62.4.5 High-speed OTG PHY connected to OTG_HS

Note: Refer to implementation table to determine if an HS PHY is embedded.

The USB OTG core includes an internal UTMI interface which is connected to the embedded HS PHY (see Section 62.4.1: OTG_HS block diagram).

62.5 OTG_HS dual role device (DRD)

![Diagram](MSv36917V2)

1. External voltage regulator only needed when building a VBUS powered device.
2. STMPS2141STR needed only if the application has to support a VBUS powered device. A basic power switch can be used if 5 V are available on the application board.

62.5.1 ID line detection

The host or peripheral (the default) role is assumed depending on the ID input pin. The ID line status is determined on plugging in the USB cable, depending on whether a MicroA or MicroB plug is connected to the micro-AB receptacle.

- If the B-side of the USB cable is connected with a floating ID wire, the integrated pull-up resistor detects a high ID level and the default peripheral role is confirmed. In this configuration the OTG_HS complies with the standard FSM described in section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.
- If the A-side of the USB cable is connected with a grounded ID, the OTG_HS issues an ID line status change interrupt (CIDSCHG bit in OTG_GINTSTS) for host software initialization, and automatically switches to the host role. In this configuration the OTG_HS complies with the standard FSM described by section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.

62.6 OTG_HS as a USB peripheral

This section gives the functional description of the OTG_HS in the USB peripheral mode. The OTG_HS works as an USB peripheral in the following circumstances:

- OTG B-Peripheral
  - OTG B-device default state if B-side of USB cable is plugged in
- B-device
  - If the ID line is present, functional and connected to the B-side of the USB cable.
- Peripheral only
  - The force device mode bit (FDMOD) in the Section 62.14.4: OTG USB configuration register (OTG_GUSBCFG) is set to 1, forcing the OTG_HS core to
work as an USB peripheral-only. In this case, the ID line is ignored even if it is present on the USB connector.

Note: To build a bus-powered device implementation in case of the B-device or peripheral-only configuration, an external regulator has to be added, that generates the necessary power-supply from \( V_{BUS} \).

**Figure 915. OTG_HS peripheral-only connection**

1. Use a regulator to build a bus-powered device.

### 62.6.1 Peripheral states

#### Powered state

The \( V_{BUS} \) input detects the B-session valid voltage by which the USB peripheral is allowed to enter the powered state (see USB2.0 section 9.1). The OTG_HS then automatically connects the DP pull-up resistor to signal full-speed device connection to the host and generates the session request interrupt (SRQINT bit in OTG_GINTSTS) to notify the powered state.

The \( V_{BUS} \) input also ensures that valid \( V_{BUS} \) levels are supplied by the host during USB operations. If a drop in \( V_{BUS} \) below B-session valid happens to be detected (for instance because of a power disturbance or if the host port has been switched off), the OTG_HS automatically disconnects and the session end detected (SEDET bit in OTG_GOTGINT) interrupt is generated to notify that the OTG_HS has exited the powered state.

In the powered state, the OTG_HS expects to receive some reset signaling from the host. No other USB operation is possible. When a reset signaling is received the reset detected interrupt (USBRST in OTG_GINTSTS) is generated. When the reset signaling is complete, the enumeration done interrupt (ENUMDNE bit in OTG_GINTSTS) is generated and the OTG_HS enters the Default state.

#### Soft disconnect

The powered state can be exited by software with the soft disconnect feature. The DP pull-up resistor is removed by setting the soft disconnect bit in the device control register (SDIS
bit in OTG_DCTL), causing a device disconnect detection interrupt on the host side even though the USB cable was not really removed from the host port.

**Default state**

In the Default state the OTG_HS expects to receive a SET_ADDRESS command from the host. No other USB operation is possible. When a valid SET_ADDRESS command is decoded on the USB, the application writes the corresponding number into the device address field in the device configuration register (DAD bit in OTG_DCFG). The OTG_HS then enters the address state and is ready to answer host transactions at the configured USB address.

**Suspended state**

The OTG_HS peripheral constantly monitors the USB activity. After counting 3 ms of USB idleness, the early suspend interrupt (ESUSP bit in OTG_GINTSTS) is issued, and confirmed 3 ms later, if appropriate, by the suspend interrupt (USBSUSP bit in OTG_GINTSTS). The device suspend bit is then automatically set in the device status register (SUSPSTS bit in OTG_DSTS) and the OTG_HS enters the suspended state.

The suspended state may optionally be exited by the device itself. In this case the application sets the remote wake-up signaling bit in the device control register (RWUSIG bit in OTG_DCTL) and clears it after 1 to 15 ms.

When a resume signaling is detected from the host, the resume interrupt (WKUPINT bit in OTG_GINTSTS) is generated and the device suspend bit is automatically cleared.

### 62.6.2 Peripheral endpoints

The OTG_HS core instantiates the following USB endpoints:

- **Control endpoint 0:**
  - Bidirectional and handles control messages only
  - Separate set of registers to handle in and out transactions
  - Dedicated control (OTG_DIEPCTL0/OTG_DOEPCTL0), transfer configuration (OTG_DIEPTSIZ0/OTG_DOEPTSIZ0), and status-interrupt (OTG_DIEPINT0/OTG_DOEPINT0) registers. The available set of bits inside the control and transfer size registers slightly differs from that of other endpoints

- **eight IN endpoints**
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has dedicated control (OTG_DIEPCTLx), transfer configuration (OTG_DIEPTSIZx), and status-interrupt (OTG_DIEPINTx) registers
  - The device IN endpoints common interrupt mask register (OTG_DIEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the IN endpoints (EP0 included)
  - Support for incomplete isochronous IN transfer interrupt (IISOIXFR bit in OTG_GINTSTS), asserted when there is at least one isochronous IN endpoint on
which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG_GINTSTS/EOPF).

- eight OUT endpoints
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has a dedicated control (OTG_DOEPCTLx), transfer configuration (OTG_DOEPTSIZx) and status-interrupt (OTG_DOEPINTx) register
  - Device OUT endpoints common interrupt mask register (OTG_DOEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the OUT endpoints (EP0 included)
  - Support for incomplete isochronous OUT transfer interrupt (INCOMPISOOUT bit in OTG_GINTSTS), asserted when there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG_GINTSTS/EOPF).

**Endpoint control**

- The following endpoint controls are available to the application through the device endpoint-x IN/OUT control register (OTG_DIEPCTLx/OTG_DOEPCTLx):
  - endpoint enable/disable
  - endpoint activate in current configuration
  - program USB transfer type (isochronous, bulk, interrupt)
  - program supported packet size
  - program Tx FIFO number associated with the IN endpoint
  - program the expected or transmitted data0/data1 PID (bulk/interrupt only)
  - program the even/odd frame during which the transaction is received or transmitted (isochronous only)
  - optionally program the NAK bit to always negative-acknowledge the host regardless of the FIFO status
  - optionally program the STALL bit to always stall host tokens to that endpoint
  - optionally program the SNOOP mode for OUT endpoint not to check the CRC field of received data

**Endpoint transfer**

The device endpoint-x transfer size registers (OTG_DIEPTSIZx/OTG_DOEPTSIZx) allow the application to program the transfer size parameters and read the transfer status. Programming must be done before setting the endpoint enable bit in the endpoint control register. Once the endpoint is enabled, these fields are read-only as the OTG_HS core updates them with the current transfer status.

The following transfer parameters can be programmed:

- transfer size in bytes
- number of packets that constitute the overall transfer size

**Endpoint status/interrupt**

The device endpoint-x interrupt registers (OTG_DIEPINTx/OTG_DOPEPINTx) indicate the status of an endpoint with respect to USB- and AHB-related events. The application must read these registers when the OUT endpoint interrupt bit or the IN endpoint interrupt bit in
the core interrupt register (OEPINT bit in OTG_GINTSTS or IEPINT bit in OTG_GINTSTS, respectively) is set. Before the application can read these registers, it must first read the device all endpoints interrupt (OTG_DAINTE) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINTE and OTG_GINTSTS registers.

The peripheral core provides the following status checks and interrupt generation:

- transfer completed interrupt, indicating that data transfer was completed on both the application (AHB) and USB sides
- setup stage has been done (control-out only)
- associated transmit FIFO is half or completely empty (in endpoints)
- NAK acknowledge has been transmitted to the host (isochronous-in only)
- IN token received when Tx FIFO was empty (bulk-in/interrupt-in only)
- Out token received when endpoint was not yet enabled
- babble error condition has been detected
- endpoint disable by application is effective
- endpoint NAK by application is effective (isochronous-in only)
- more than 3 back-to-back setup packets were received (control-out only)
- timeout condition detected (control-in only)
- isochronous out packet has been dropped, without generating an interrupt

### 62.7 OTG_HS as a USB host

This section gives the functional description of the OTG_HS in the USB host mode. The OTG_HS works as a USB host in the following circumstances:

- OTG A-host
  - OTG A-device default state when the A-side of the USB cable is plugged in
- A-device
  - If the ID line is present, functional and connected to the A-side of the USB cable. Integrated pull-down resistors are automatically set on the DP/DM lines.
- Host only
  - The force host mode bit (FHMOD) in the *OTG USB configuration register (OTG_GUSBCFG)* forces the OTG_HS core to work as a USB host-only. Integrated pull-down resistors are automatically set on the DP/DM lines.

**Note:** *On-chip 5 V VBUS generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch must be added externally to drive the 5 V VBUS line. The external charge pump can be driven by any GPIO output. This is required for the OTG A-host, A-device and host-only configurations.*
1. $V_{DD}$ range is between 2 V and 3.6 V.

### 62.7.1 USB host states

**Host port power**

On-chip 5 V $V_{BUS}$ generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch, must be added externally to drive the 5 V $V_{BUS}$ line. The external charge pump can be driven by any GPIO output or via an I2C interface connected to an external PMIC (power management IC). When the application decides to power on $V_{BUS}$, it must also set the port power bit in the host port control and status register (PPWR bit in OTG_HPRT).

**$V_{BUS}$ valid**

In Host mode, the $V_{BUS}$ sensing pin does not need to be connected to $V_{BUS}$.

The charge pump overcurrent flag can also be used to prevent electrical damage. Connect the overcurrent flag output from the charge pump to any GPIO input and configure it to generate a port interrupt on the active level. The overcurrent ISR must promptly disable the $V_{BUS}$ generation and clear the port power bit.

**Host detection of a peripheral connection**

USB peripherals or B-device are detected as soon as they are connected. The OTG_HS core issues a host port interrupt triggered by the device connected bit in the host port control and status (PCDET bit in OTG_HPRT).

**Host detection of peripheral a disconnection**

The peripheral disconnection event triggers the disconnect detected interrupt (DISCINT bit in OTG_GINTSTS).

**Host enumeration**

After detecting a peripheral connection the host must start the enumeration process by sending USB reset and configuration commands to the new peripheral.

The application drives a USB reset signaling (single-ended zero) over the USB by keeping the port reset bit set in the host port control and status register (PRST bit in OTG_HPRT) for
a minimum of 10 ms and a maximum of 20 ms. The application takes care of the timing count and then of clearing the port reset bit.

Once the USB reset sequence has completed, the host port interrupt is triggered by the port enable/disable change bit (PENCHNG bit in OTG_HPRT). This informs the application that the speed of the enumerated peripheral can be read from the port speed field in the host port control and status register (PSPD bit in OTG_HPRT) and that the host is starting to drive SOFs (FS) or Keep alives (LS). The host is now ready to complete the peripheral enumeration by sending peripheral configuration commands.

**Host suspend**

The application decides to suspend the USB activity by setting the port suspend bit in the host port control and status register (PSUSP bit in OTG_HPRT). The OTG_HS core stops sending SOFs and enters the suspended state.

The suspended state can be optionally exited on the remote device’s initiative (remote wake-up). In this case the remote wake-up interrupt (WKUPINT bit in OTG_GINTSTS) is generated upon detection of a remote wake-up signaling, the port resume bit in the host port control and status register (PRES bit in OTG_HPRT) self-sets, and resume signaling is automatically driven over the USB. The application must time the resume window and then clear the port resume bit to exit the suspended state and restart the SOF.

If the suspended state is exited on the host initiative, the application must set the port resume bit to start resume signaling on the host port, time the resume window and finally clear the port resume bit.

### 62.7.2 Host channels

The OTG_HS core instantiates 16 host channels. Each host channel supports an USB host transfer (USB pipe). The host is not able to support more than 16 transfer requests at the same time. If more than 16 transfer requests are pending from the application, the host controller driver (HCD) must re-allocate channels when they become available from previous duty, that is, after receiving the transfer completed and channel halted interrupts.

Each host channel can be configured to support in/out and any type of periodic/nonperiodic transaction. Each host channel makes us of dedicated control (OTG_HCCHARx), transfer configuration (OTG_HCTSIZEx) and status/interrupt (OTG_HCINTx) registers with associated mask (OTG_HCINTMSKx) registers.

**Host channel control**

- The following host channel controls are available to the application through the host channel-x characteristics register (OTG_HCCHARx):
  - Channel enable/disable
  - Program the HS/FS/LS speed of target USB peripheral
  - Program the address of target USB peripheral
  - Program the endpoint number of target USB peripheral
  - Program the transfer IN/OUT direction
  - Program the USB transfer type (control, bulk, interrupt, isochronous)
  - Program the maximum packet size (MPS)
  - Program the periodic transfer to be executed during odd/even frames
Host channel transfer

The host channel transfer size registers (OTG_HCTSIZx) allow the application to program the transfer size parameters, and read the transfer status. Programming must be done before setting the channel enable bit in the host channel characteristics register. Once the endpoint is enabled the packet count field is read-only as the OTG_HS core updates it according to the current transfer status.

- The following transfer parameters can be programmed:
  - transfer size in bytes
  - number of packets making up the overall transfer size
  - initial data PID

Host channel status/interrupt

The host channel-x interrupt register (OTG_HCINTx) indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read these register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG_GINTSTS) is set. Before the application can read these registers, it must first read the host all channels interrupt (OTG_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_HAINT and OTG_GINTSTS registers. The mask bits for each interrupt source of each channel are also available in the OTG_HCINTMSKx register.

- The host core provides the following status checks and interrupt generation:
  - Transfer completed interrupt, indicating that the data transfer is complete on both the application (AHB) and USB sides
  - Channel has stopped due to transfer completed, USB transaction error or disable command from the application
  - Associated transmit FIFO is half or completely empty (IN endpoints)
  - ACK response received
  - NAK response received
  - STALL response received
  - USB transaction error due to CRC failure, timeout, bit stuff error, false EOP
  - Babble error
  - frame overrun
  - data toggle error

62.7.3 Host scheduler

The host core features a built-in hardware scheduler which is able to autonomously re-order and manage the USB transaction requests posted by the application. At the beginning of each frame the host executes the periodic (isochronous and interrupt) transactions first, followed by the nonperiodic (control and bulk) transactions to achieve the higher level of priority granted to the isochronous and interrupt transfer types by the USB specification.

The host processes the USB transactions through request queues (one for periodic and one for nonperiodic). Each request queue can hold up to 8 entries. Each entry represents a pending transaction request from the application, and holds the IN or OUT channel number along with other information to perform a transaction on the USB. The order in which the
requests are written to the queue determines the sequence of the transactions on the USB interface.

At the beginning of each frame, the host processes the periodic request queue first, followed by the nonperiodic request queue. The host issues an incomplete periodic transfer interrupt (IPXFR bit in OTG_GINTSTS) if an isochronous or interrupt transaction scheduled for the current frame is still pending at the end of the current frame. The OTG_HS core is fully responsible for the management of the periodic and nonperiodic request queues. The periodic transmit FIFO and queue status register (OTG_HPTXSTS) and nonperiodic transmit FIFO and queue status register (OTG_HNPTXSTS) are read-only registers which can be used by the application to read the status of each request queue. They contain:

- The number of free entries currently available in the periodic (nonperiodic) request queue (8 max)
- Free space currently available in the periodic (nonperiodic) Tx FIFO (out-transactions)
- IN/OUT token, host channel number and other status information.

As request queues can hold a maximum of eight entries each, the application can push to schedule host transactions in advance with respect to the moment they physically reach the SB for a maximum of eight pending periodic transactions plus 8 pending non-periodic transactions.

To post a transaction request to the host scheduler (queue) the application must check that there is at least 1 entry available in the periodic (nonperiodic) request queue by reading the PTXQSAV bits in the OTG_HNPTXSTS register or NPTQXSAV bits in the OTG_HNPTXSTS register.

### 62.8 OTG_HS SOF trigger

**Figure 917. SOF connectivity (SOF trigger output to TIM and ITR1 connection)**

The OTG_HS core provides means to monitor, track and configure SOF framing in the host and peripheral, as well as an SOF pulse output connectivity feature.

Such utilities are especially useful for adaptive audio clock generation techniques, where the audio peripheral needs to synchronize to the isochronous stream provided by the PC, or the host needs to trim its framing rate according to the requirements of the audio peripheral.
62.8.1 Host SOFs

In host mode the number of PHY clocks occurring between the generation of two consecutive SOF (HS/FS) or Keep-alive (LS) tokens is programmable in the host frame interval register (HFIR), thus providing application control over the SOF framing period. An interrupt is generated at any start of frame (SOF bit in OTG_GINTSTS). The current frame number and the time remaining until the next SOF are tracked in the host frame number register (HFNUM).

A SOF pulse signal, is generated at any SOF starting token and with a width of 20 HCLK cycles. The SOF pulse is also internally connected to the input trigger of the timer, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.

62.8.2 Peripheral SOFs

In device mode, the start of frame interrupt is generated each time an SOF token is received on the USB (SOF bit in OTG_GINTSTS). The corresponding frame number can be read from the device status register (FNSOF bit in OTG_DSTS). A SOF pulse signal with a width of 20 HCLK cycles is also generated. The SOF pulse signal is also internally connected to the TIM input trigger, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.

The end of periodic frame interrupt (OTG_GINTSTS/EOPF) is used to notify the application when 80%, 85%, 90% or 95% of the time frame interval elapsed depending on the periodic frame interval field in the device configuration register (PFIVL bit in OTG_DCFG). This feature can be used to determine if all of the isochronous traffic for that frame is complete.

62.9 OTG_HS low-power modes

Table 667 below defines the STM32 low power modes and their compatibility with the OTG.

<table>

</tbody>
</table>

1. Within Stop mode there are different possible settings. Some restrictions may also exist, refer to Section 6: Power control (PWR) to understand which (if any) restrictions apply when using OTG.

The following bits and procedures reduce power consumption.
The power consumption of the OTG PHY is controlled by the following bit in the general core configuration register:

- **VBUS detection enable (OTG_GCCFG/VBDEN)**
  It switches on/off the VBUS sensing comparators associated with OTG operations.

Power reduction techniques are available while in the USB suspended state, when the USB session is not yet valid or the device is disconnected.

- **Stop PHY clock (STPPCLK bit in OTG_PCGCCTL)**
  When setting the stop PHY clock bit in the clock gating control register, most of the transceiver is disabled, and only the part in charge of detecting the asynchronous resume or remote wake-up event is kept alive.

- **Gate HCLK (GATEHCLK bit in OTG_PCGCCTL)**
  When setting the Gate HCLK bit in the clock gating control register, most of the system clock domain internal to the OTG_HS core is switched off by clock gating. Only the register read and write interface is kept alive. The dynamic power consumption due to the USB clock switching activity is cut even if the system clock is kept running by the application for other purposes.

- **USB system stop**
  When the OTG_HS is in the USB suspended state, the application may decide to drastically reduce the overall power consumption by a complete shut down of all the clock sources in the system. USB System Stop is activated by first setting the Stop PHY clock bit and then configuring the system deep sleep mode in the power control system module (PWR).
  The OTG_HS core automatically reactivates both system and USB clocks by asynchronous detection of remote wake-up (as an host) or resume (as a device) signaling on the USB.

To save dynamic power, the USB data FIFO is clocked only when accessed by the OTG_HS core.

### 62.10 OTG_HS Dynamic update of the OTG_HFIR register

The USB core embeds a dynamic trimming capability of micro-SOF framing period in host mode allowing to synchronize an external device with the micro-SOF frames.

When the OTG_HFIR register is changed within a current micro-SOF frame, the SOF period correction is applied in the next frame as described in Figure 918.

For a dynamic update, it is required to set RLDCTRL=1.
62.11 OTG_HS data FIFOs

The USB system features 4 Kbytes of dedicated RAM with a sophisticated FIFO control mechanism. The packet FIFO controller module in the OTG_HS core organizes RAM space into Tx FIFOs into which the application pushes the data to be temporarily stored before the USB transmission, and into a single Rx FIFO where the data received from the USB are temporarily stored before retrieval (popped) by the application. The number of instructed FIFOs and how these are organized inside the RAM depends on the device’s role. In peripheral mode an additional Tx FIFO is instructed for each active IN endpoint. Any FIFO size is software configured to better meet the application requirements.
62.11.1 Peripheral FIFO architecture

Peripheral Rx FIFO

The OTG peripheral uses a single receive FIFO that receives the data directed to all OUT endpoints. Received packets are stacked back-to-back until free space is available in the Rx FIFO. The status of the received packet (which contains the OUT endpoint destination number, the byte count, the data PID and the validity of the received data) is also stored by the core on top of the data payload. When no more space is available, host transactions are NACKed and an interrupt is received on the addressed endpoint. The size of the receive FIFO is configured in the receive FIFO size register (OTG_GRXFSIZ).

The single receive FIFO architecture makes it more efficient for the USB peripheral to fill in the receive RAM buffer:

- All OUT endpoints share the same RAM buffer (shared FIFO)
- The OTG_HS core can fill in the receive FIFO up to the limit for any host sequence of OUT tokens

The application keeps receiving the Rx FIFO non-empty interrupt (RXFLVL bit in OTG_GINTSTS) as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register (OTG_GRXSTSP) and finally pops data off the receive FIFO by reading from the endpoint-related pop address.
Peripheral Tx FIFOs

The core has a dedicated FIFO for each IN endpoint. The application configures FIFO sizes by writing the endpoint 0 transmit FIFO size register (OTG_DIEPTXF0) for IN endpoint 0 and the device IN endpoint transmit FIFOx registers (OTG_DIEPTXFx) for IN endpoint-x.

62.11.2 Host FIFO architecture

Host Rx FIFO

The host uses one receiver FIFO for all periodic and nonperiodic transactions. The FIFO is used as a receive buffer to hold the received data (payload of the received packet) from the USB until it is transferred to the system memory. Packets received from any remote IN endpoint are stacked back-to-back until free space is available. The status of each received packet with the host channel destination, byte count, data PID and validity of the received data are also stored into the FIFO. The size of the receive FIFO is configured in the receive FIFO size register (OTG_GRXFSIZ).

The single receive FIFO architecture makes it highly efficient for the USB host to fill in the receive data buffer:

- All IN configured host channels share the same RAM buffer (shared FIFO)
- The OTG_HS core can fill in the receive FIFO up to the limit for any sequence of IN tokens driven by the host software

The application receives the Rx FIFO not-empty interrupt as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register and finally pops the data off the receive FIFO.
Host Tx FIFOs

The host uses one transmit FIFO for all non-periodic (control and bulk) OUT transactions and one transmit FIFO for all periodic (isochronous and interrupt) OUT transactions. FIFOs are used as transmit buffers to hold the data (payload of the transmit packet) to be transmitted over the USB. The size of the periodic (nonperiodic) Tx FIFO is configured in the host periodic (nonperiodic) transmit FIFO size OTG_HPTXFSIZ / OTG_HNPTXFSIZ) register.

The two Tx FIFO implementation derives from the higher priority granted to the periodic type of traffic over the USB frame. At the beginning of each frame, the built-in host scheduler processes the periodic request queue first, followed by the nonperiodic request queue.

The two transmit FIFO architecture provides the USB host with separate optimization for periodic and nonperiodic transmit data buffer management:

- All host channels configured to support periodic (nonperiodic) transactions in the OUT direction share the same RAM buffer (shared FIFOs)
- The OTG_HS core can fill in the periodic (nonperiodic) transmit FIFO up to the limit for any sequence of OUT tokens driven by the host software

The OTG_HS core issues the periodic Tx FIFO empty interrupt (PTXFE bit in OTG_GINTSTS) as long as the periodic Tx FIFO is half or completely empty, depending on the value of the periodic Tx FIFO empty level bit in the AHB configuration register (PTXSELVL bit in OTG_GAHBCFG). The application can push the transmission data in advance as long as free space is available in both the periodic Tx FIFO and the periodic request queue. The host periodic transmit FIFO and queue status register (OTG_HPTXSTS) can be read to know how much space is available in both.

OTG_HS core issues the non periodic Tx FIFO empty interrupt (NPTXFE bit in OTG_GINTSTS) as long as the nonperiodic Tx FIFO is half or completely empty depending on the non periodic Tx FIFO empty level bit in the AHB configuration register (TXFELVL bit in OTG_GAHBCFG). The application can push the transmission data as long as free space is available in both the nonperiodic Tx FIFO and nonperiodic request queue. The host nonperiodic transmit FIFO and queue status register (OTG_HNPTXSTS) can be read to know how much space is available in both.

62.11.3 FIFO RAM allocation

Device mode

Receive FIFO RAM allocation: the application must allocate RAM for SETUP packets:

- 10 locations must be reserved in the receive FIFO to receive SETUP packets on control endpoint. The core does not use these locations, which are reserved for SETUP packets, to write any other data.
- One location is to be allocated for Global OUT NAK.
- Status information is written to the FIFO along with each received packet. Therefore, a minimum space of \((\text{largest packet size} / 4) \times 1\) must be allocated to receive packets. If multiple isochronous endpoints are enabled, then at least two \((\text{largest packet size} / 4) + 1\) spaces must be allocated to receive back-to-back packets. Typically, two \((\text{largest packet size} / 4) + 1\) spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.
- Along with the last packet for each endpoint, transfer complete status information is also pushed to the FIFO. One location for each OUT endpoint is recommended.
Device RxFIFO =
(5 * number of control endpoints + 8) + ((largest USB packet used / 4) + 1 for status information) + (2 * number of OUT endpoints) + 1 for Global NAK

Example: The MPS is 1,024 bytes for a periodic USB packet and 512 bytes for a non-periodic USB packet. There are three OUT endpoints, three IN endpoints, one control endpoint, and three host channels.

Device RxFIFO = (5 * 1 + 8) + ((1,024 / 4) +1) + (2 * 4) + 1 = 279

Transmit FIFO RAM allocation: the minimum RAM space required for each IN endpoint Transmit FIFO is the maximum packet size for that particular IN endpoint.

Note: More space allocated in the transmit IN endpoint FIFO results in better performance on the USB.

Host mode

Receive FIFO RAM allocation:
Status information is written to the FIFO along with each received packet. Therefore, a minimum space of (largest packet size / 4) + 1 must be allocated to receive packets. If multiple isochronous channels are enabled, then at least two (largest packet size / 4) + 1 spaces must be allocated to receive back-to-back packets. Typically, two (largest packet size / 4) + 1 spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.

Along with the last packet in the host channel, transfer complete status information is also pushed to the FIFO. So one location must be allocated for this.

Host RxFIFO = (largest USB packet used / 4) + 1 for status information + 1 transfer complete

Example: Host RxFIFO = ((1,024 / 4) + 1) + 1 = 258

Transmit FIFO RAM allocation:
The minimum amount of RAM required for the host Non-periodic Transmit FIFO is the largest maximum packet size among all supported non-periodic OUT channels.

Typically, two largest packet sizes worth of space is recommended, so that when the current packet is under transfer to the USB, the CPU can get the next packet.

Non-Periodic TxFIFO = largest non-periodic USB packet used / 4

Example: Non-Periodic TxFIFO = (512 / 4) = 128

The minimum amount of RAM required for host periodic Transmit FIFO is the largest maximum packet size out of all the supported periodic OUT channels. If there is at least one isochronous OUT endpoint, then the space must be at least two times the maximum packet size of that channel.

Host Periodic TxFIFO = largest periodic USB packet used / 4

Example: Host Periodic TxFIFO = (1,024 / 4) = 256

Note: More space allocated in the Transmit Non-periodic FIFO results in better performance on the USB.
62.12 OTG_HS interrupts

When the OTG_HS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

*Figure 921* shows the interrupt hierarchy.
1. OTG_HS_WKUP becomes active (high state) when resume condition occurs during L1 SLEEP or L2 SUSPEND states.
62.13 OTG_HS control and status registers

By reading from and writing to the control and status registers (CSRs) through the AHB slave interface, the application controls the OTG_HS controller. These registers are 32 bits wide, and the addresses are 32-bit block aligned. The OTG_HS registers must be accessed by words (32 bits).

CSRs are classified as follows:

- Core global registers
- Host-mode registers
- Host global registers
- Host port CSRs
- Host channel-specific registers
- Device-mode registers
- Device global registers
- Device endpoint-specific registers
- Power and clock-gating registers
- Data FIFO (DFIFO) access registers

Only the core global, power and clock-gating, data FIFO access, and host port control and status registers can be accessed in both host and device modes. When the OTG_HS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

62.13.1 CSR memory map

The host and device mode registers occupy different addresses. All registers are implemented in the AHB clock domain.

Global CSR map

These registers are available in both host and device modes.

Data FIFO (DFIFO) access register map

These registers, available in both host and device modes, are used to read or write the FIFO space for a specific endpoint or a channel, in a given direction. If a host channel is of type IN, the FIFO can only be read on the channel. Similarly, if a host channel is of type OUT, the FIFO can only be written on the channel.

Power and clock gating CSR map

There is a single register for power and clock gating. It is available in both host and device modes.
62.14 OTG_HS registers

These registers are available in both host and device modes, and do not need to be reprogrammed when switching between these modes.

Bit values in the register descriptions are expressed in binary unless otherwise specified.

62.14.1 OTG control and status register (OTG_GOTGCTL)

The OTG_GOTGCTL register controls the behavior and reflects the status of the OTG function of the core.

Address offset: 0x000

Reset value: 0x0001 0000

</tr>
</tbody>
</table>

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 CURMOD: Current mode of operation
Indicates the current mode (host or device).
0: Device mode
1: Host mode

Bit 20 OTGVER: OTG version
Selects the OTG revision.
0: OTG Version 1.3. OTG1.3 is obsolete for new product development.
1: OTG Version 2.0. In this version the core supports only data line pulsing for SRP.

Bit 19 BSVLD: B-session valid
Indicates the device mode transceiver status.
0: B-session is not valid.
1: B-session is valid.
In OTG mode, the user can use this bit to determine if the device is connected or disconnected.

Note: Only accessible in device mode.
Bit 18 **ASVLD**: A-session valid
   Indicates the host mode transceiver status.
   0: A-session is not valid
   1: A-session is valid
   *Note*: **Only accessible in host mode.**

Bit 17 **DBCT**: Long/short debounce time
   Indicates the debounce time of a detected connection.
   0: Long debounce time, used for physical connections (100 ms + 2.5 µs)
   1: Short debounce time, used for soft connections (2.5 µs)
   *Note*: **Only accessible in host mode.**

Bit 16 **CIDSTS**: Connector ID status
   Indicates the connector ID status on a connect event.
   0: The OTG_HS controller is in A-device mode
   1: The OTG_HS controller is in B-device mode
   *Note*: Accessible in both device and host modes.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **EHEN**: Embedded host enable
   It is used to select between OTG A device state machine and embedded host state machine.
   0: OTG A device state machine is selected
   1: Embedded host state machine is selected

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **BVALOVAL**: B-peripheral session valid override value
   This bit is used to set override value for Bvalid signal when BVALOEN bit is set.
   0: Bvalid value is ‘0’ when BVALOEN = 1
   1: Bvalid value is ‘1’ when BVALOEN = 1
   *Note*: **Only accessible in device mode.**

Bit 6 **BVALOEN**: B-peripheral session valid override enable
   This bit is used to enable/disable the software to override the Bvalid signal using the BVALOVAL bit.
   0: Override is disabled and Bvalid signal from the respective PHY selected is used internally by the core
   1: Internally Bvalid received from the PHY is overridden with BVALOVAL bit value
   *Note*: **Only accessible in device mode.**

Bit 5 **AVALOVAL**: A-peripheral session valid override value
   This bit is used to set override value for Avalid signal when AVALOEN bit is set.
   0: Avalid value is ‘0’ when AVALOEN = 1
   1: Avalid value is ‘1’ when AVALOEN = 1
   *Note*: **Only accessible in host mode.**

Bit 4 **AVALOEN**: A-peripheral session valid override enable
   This bit is used to enable/disable the software to override the Avalid signal using the AVALOVAL bit.
   0: Override is disabled and Avalid signal from the respective PHY selected is used internally by the core
   1: Internally Avalid received from the PHY is overridden with AVALOVAL bit value
   *Note*: **Only accessible in host mode.**
Bit 3 **VBVALOVAL**: $V_{BUS}$ valid override value
This bit is used to set override value for vbusvalid signal when VBVALOEN bit is set.
0: vbusvalid value is '0' when VBVALOEN = 1
1: vbusvalid value is '1' when VBVALOEN = 1
**Note**: Only accessible in host mode.

Bit 2 **VBVALOEN**: $V_{BUS}$ valid override enable
This bit is used to enable/disable the software to override the vbusvalid signal using the VBVALOVAL bit.
0: Override is disabled and vbusvalid signal from the respective PHY selected is used internally by the core.
1: Internally vbusvalid received from the PHY is overridden with VBVALOVAL bit value
**Note**: Only accessible in host mode.

Bits 1:0 Reserved, must be kept at reset value.

### 62.14.2 OTG interrupt register (OTG_GOTGINT)

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

Address offset: 0x004
Reset value: 0x0000 0000

```

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **ADTOCHG**: A-device timeout change
The core sets this bit to indicate that the A-device has timed out while waiting for the B-device to connect.

**Note**: Accessible in both device and host modes.

Bits 17:3 Reserved, must be kept at reset value.

Bit 2 **SEDET**: Session end detected
The core sets this bit to indicate that the level of the voltage on $V_{BUS}$ is no longer valid for a B-Peripheral session when $V_{BUS} < 0.8$ V.

**Note**: Accessible in both device and host modes.

Bits 1:0 Reserved, must be kept at reset value.
62.14.3 OTG AHB configuration register (OTG_GAHBCFG)

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **PTXFE LVL**: Periodic Tx FIFO empty level
Indicates when the periodic Tx FIFO empty interrupt bit in the OTG_GINTSTS register (PTXFE bit in OTG_GINTSTS) is triggered:
0: PTXFE (in OTG_GINTSTS) interrupt indicates that the Periodic Tx FIFO is half empty
1: PTXFE (in OTG_GINTSTS) interrupt indicates that the Periodic Tx FIFO is completely empty

*Note: Only accessible in host mode.*

Bit 7 **TXFE LVL**: Tx FIFO empty level

**Condition: device mode**
This bit indicates when IN endpoint Transmit FIFO empty interrupt (TXFE in OTG_DIEPINTx) is triggered:
0: The TXFE (in OTG_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is half empty
1: The TXFE (in OTG_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is completely empty

**Condition: host mode**
This bit indicates when the nonperiodic Tx FIFO empty interrupt (NPTXFE bit in OTG_GINTSTS) is triggered:
0: The NPTXFE (in OTG_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is half empty
1: The NPTXFE (in OTG_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is completely empty

Bit 6 Reserved, must be kept at reset value.
Bit 5 **DMAEN**: DMA enabled
   0: The core operates in slave mode
   1: The core operates in DMA mode

Bits 4:1 **HBSTLEN[3:0]**: Burst length/type
   0000 Single: Bus transactions use single 32 bit accesses (not recommended)
   0001 INCR: Bus transactions use unspecified length accesses (not recommended, uses the
               INCR AHB bus command)
   0011 INCR4: Bus transactions target 4x 32 bit accesses
   0101 INCR8: Bus transactions target 8x 32 bit accesses
   0111 INCR16: Bus transactions based on 16x 32 bit accesses
   Others: Reserved

Bit 0 **GINTMSK**: Global interrupt mask
   The application uses this bit to mask or unmask the interrupt line assertion to itself.
   Irrespective of this bit setting, the interrupt status registers are updated by the core.
   0: Mask the interrupt assertion to the application.
   1: Unmask the interrupt assertion to the application.

*Note: Accessible in both device and host modes.*

### 62.14.4 OTG USB configuration register (OTG_GUSBCFG)

This register can be used to configure the core after power-on or a changing to host mode
or device mode. It contains USB and USB-PHY related configuration parameters. The
application must program this register before starting any transactions on either the AHB or
the USB. Do not make changes to this register after the initial programming.

</tr>
</tbody>
</table>
Bit 31  Reserved, must be kept at reset value.

Bit 30  **FDMOD**: Force device mode
        Writing a 1 to this bit, forces the core to device mode irrespective of the OTG_ID input pin.
        0: Normal mode
        1: Force device mode
        After setting the force bit, the application must wait at least 25 ms before the change takes effect.
        
        *Note:* Accessible in both device and host modes.

Bit 29  **FHMOD**: Force host mode
        Writing a 1 to this bit, forces the core to host mode irrespective of the OTG_ID input pin.
        0: Normal mode
        1: Force host mode
        After setting the force bit, the application must wait at least 25 ms before the change takes effect.
        
        *Note:* Accessible in both device and host modes.

Bits 28:26  Reserved, must be kept at reset value.

Bits 25:23  Reserved, must be kept at reset value.

Bit 22  **TSDPS**: TermSel DLine pulsing selection
        This bit selects utmi_termselect to drive the data line pulse during SRP (session request protocol).
        0: Data line pulsing using utmi_txvalid (default)
        1: Data line pulsing using utmi_termselect

Bits 21:16  Reserved, must be kept at reset value.

Bit 15  **PHYLPC**: PHY Low-power clock select
        This bit selects either 480 MHz or 48 MHz (low-power) PHY mode. In FS and LS modes, the PHY can usually operate on a 48 MHz clock to save power.
        0: 480 MHz internal PLL clock
        1: 48 MHz external clock
        In 480 MHz mode, the UTMI interface operates at either 60 or 30 MHz, depending on whether the 8- or 16-bit data width is selected. In 48 MHz mode, the UTMI interface operates at 48 MHz in FS and LS modes.

Bit 14  Reserved, must be kept at reset value.

Bits 13:10  **TRDT[3:0]**: USB turnaround time
        These bits allow to set the turnaround time in PHY clocks. They must be configured according to Table 673: **TRDT values**, depending on the application AHB frequency. Higher TRDT values allow stretching the USB response time to IN tokens in order to compensate for longer AHB read access latency to the data FIFO.
        
        *Note:* Only accessible in device mode.

Bits 9:8  Reserved, must be kept at reset value.

Bit 7  Reserved, must be kept at reset value.

Bit 6  Reserved, must be kept at reset value.

Bit 5  Reserved, must be kept at reset value.
Bit 4  Reserved, must be kept at reset value.
Bit 3  Reserved, must be kept at reset value.

Bits 2:0  **TOCAL[2:0]:** FS timeout calibration

The number of PHY clocks that the application programs in this field is added to the full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the line state condition can vary from one PHY to another.

The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock is 0.25 bit times.

Bit 31  **AHBIDL:** AHB master idle

Indicates that the AHB master state machine is in the Idle condition.

*Note:* Accessible in both device and host modes.

Bit 30  **DMAREQ:** DMA request signal enabled

This bit indicates that the DMA request is in progress. Used for debug.

Bits 29:11  Reserved, must be kept at reset value.
Bits 10:6 **TXFNUM[4:0]**: Tx FIFO number

This is the FIFO number that must be flushed using the Tx FIFO Flush bit. This field must not be changed until the core clears the Tx FIFO Flush bit.

Condition: host mode

- 00000: Non-periodic Tx FIFO flush
- 00001: Periodic Tx FIFO flush
- 10000: Flush all the transmit FIFOs

Condition: device mode

- 00000: Tx FIFO 0 flush
- 00001: Tx FIFO 1 flush
- 00010: Tx FIFO 2 flush
- ...
- 01111: Tx FIFO 15 flush
- 10000: Flush all the transmit FIFOs

*Note:* Accessible in both device and host modes.

Bit 5 **TXFFLSH**: Tx FIFO flush

This bit selectively flushes a single or all transmit FIFOs, but cannot do so if the core is in the midst of a transaction.

The application must write this bit only after checking that the core is neither writing to the Tx FIFO nor reading from the Tx FIFO. Verify using these registers:

- Read—NAK Effective interrupt ensures the core is not reading from the FIFO
- Write—AHBIDL bit in OTG_GRSTCTL ensures the core is not writing anything to the FIFO.

Flushing is normally recommended when FIFOs are reconfigured. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower clock of phy_clk or hclk.

*Note:* Accessible in both device and host modes.

Bit 4 **RXFFLSH**: Rx FIFO flush

The application can flush the entire Rx FIFO using this bit, but must first ensure that the core is not in the middle of a transaction.

The application must only write to this bit after checking that the core is neither reading from the Rx FIFO nor writing to the Rx FIFO.

The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear.

*Note:* Accessible in both device and host modes.

Bit 3 **Reserved, must be kept at reset value.**
Bit 2  **FCRST**: Host frame counter reset
The application writes this bit to reset the (micro-)frame number counter inside the core. 
When the (micro-)frame counter is reset, the subsequent SOF sent out by the core has a 
frame number of 0. 
When application writes "1" to the bit, it might not be able to read back the value as it gets 
cleared by the core in a few clock cycles.
*Note:*  *Only accessible in host mode.*

Bit 1  **PSRST**: Partial soft reset
Resets the internal state machines but keeps the enumeration info. Can be used to recover 
some specific PHY errors.
*Note:*  *Accessible in both device and host modes.*

Bit 0  **CSRST**: Core soft reset
Resets the HCLK and PHY clock domains as follows:
Clears the interrupts and all the CSR register bits except for the following bits:
– GATEHCLK bit in OTG_PCGCCTL
– STPPCLK bit in OTG_PCGCCTL
– FSLSPCS bits in OTG_HCFG
– DSPD bit in OTG_DCFG
– SDIS bit in OTG_DCTL
– OTG_GCCFG register
– FDMOD bit in OTG_GUSBCFG
– FHMOD bit in OTG_GUSBCFG
– PHYLPC bit in OTG_GUSBCFG
– TSDPS bit in OTG_GUSBCFG
All module state machines (except for the AHB slave unit) are reset to the Idle state, and all 
the transmit FIFOs and the receive FIFO are flushed.
Any transactions on the AHB Master are terminated as soon as possible, after completing the 
last data phase of an AHB transfer. Any transactions on the USB are terminated immediately. 
The application can write to this bit any time it wants to reset the core. This is a self-clearing 
bit and the core clears this bit after all the necessary logic is reset in the core, which can take 
several clocks, depending on the current state of the core. Once this bit has been cleared, 
the software must wait at least 3 PHY clocks before accessing the PHY domain 
(synchronization delay). The software must also check that bit 31 in this register is set to 1 
(AHB Master is Idle) before starting any operation.
Typically, the software reset is used during software development and also when the user 
dynamically changes the PHY selection bits in the above listed USB configuration registers. 
When the user changes the PHY, the corresponding clock for the PHY is selected and used 
in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper 
operation.
*Note:*  *Accessible in both device and host modes.*
62.14.6  OTG core interrupt register [alternate] (OTG_GINTSTS)

Valid for Host mode, see next section for Device mode.

This register also indicates the current mode. To clear the interrupt status bits of the rc_w1 type, the application must write 1 into the bit.

This register interrupts the application for system-level events in the current mode (device mode or host mode).

The FIFO status interrupts are read-only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the OTG_GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

Address offset: 0x014

Reset value: 0x0400 0020

Bit 27  **LPMINT:** LPM interrupt

In device mode, this interrupt is asserted when the device receives an LPM transaction and responds with a non-ERRORed response.

In host mode, this interrupt is asserted when the device responds to an LPM transaction with a non-ERRORed response or when the host core has completed LPM transactions for the programmed number of times (RETRYCNT bit in OTG_GLCFG).

This field is valid only if the LPMEN bit in OTG_GLCFG is set to 1.

Bit 26  **PTXFE:** Periodic Tx FIFO empty

Asserted when the periodic transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the periodic request queue. The half or completely empty status is determined by the periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (PTXFELVL bit in OTG_GAHBCFG).

*Note:* Only accessible in host mode.

Bit 25  **HCINT:** Host channels interrupt

The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in host mode). The application must read the OTG_HAIN register to determine the exact number of the channel on which the interrupt occurred, and then read the corresponding OTG_HCINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the OTG_HCINTx register to clear this bit.

*Note:* Only accessible in host mode.

Bit 24  **HPRTINT:** Host port interrupt

The core sets this bit to indicate a change in port status of one of the OTG_HS controller ports in host mode. The application must read the OTG_HPRT register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_HPRT register to clear this bit.

*Note:* Only accessible in host mode.

Bit 23  **RSTDET:** Reset detected interrupt

In device mode, this interrupt is asserted when a reset is detected on the USB in partial power-down mode when the device is in suspend.

*Note:* Only accessible in device mode.

Bit 22  **DATAFSUSP:** Data fetch suspended

This interrupt is valid only in DMA mode. This interrupt indicates that the core has stopped fetching data for IN endpoints due to the unavailability of TxFIFO space or request queue space. This interrupt is used by the application for an endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application:

- Sets a global nonperiodic IN NAK handshake
- Disables IN endpoints
- Flushes the FIFO
- Determines the token sequence from the IN token sequence learning queue
- Re-enables the endpoints

Clears the global nonperiodic IN NAK handshake if the global nonperiodic IN NAK is cleared, the core has not yet fetched data for the IN endpoint, and the IN token is received: the core generates an “IN token received when FIFO empty” interrupt. The OTG then sends a NAK response to the host. To avoid this scenario, the application can check the FetSusp interrupt in OTG_GINTSTS, which ensures that the FIFO is full before clearing a global NAK handshake. Alternatively, the application can mask the “IN token received when FIFO empty” interrupt when clearing a global IN handshake.

Bit 21  **IPXFR:** Incomplete periodic transfer

In host mode, the core sets this interrupt bit when there are incomplete periodic transactions still pending, which are scheduled for the current frame.
Bit 20  **ISOIXFR**: Incomplete isochronous IN transfer

The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

*Note: Only accessible in device mode.*

Bit 19  **OEPINT**: OUT endpoint interrupt

The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in device mode). The application must read the OTG_DAINT register to determine the exact number of the OUT endpoint on which the interrupt occurred, and then read the corresponding OTG_DOEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG_DOEPINTx register to clear this bit.

*Note: Only accessible in device mode.*

Bit 18  **IEPINT**: IN endpoint interrupt

The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in device mode). The application must read the OTG_DAINT register to determine the exact number of the IN endpoint on which the interrupt occurred, and then read the corresponding OTG_DIEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG_DIEPINTx register to clear this bit.

*Note: Only accessible in device mode.*

Bits 17:16  Reserved, must be kept at reset value.

Bit 15  **EOPF**: End of periodic frame interrupt

Indicates that the period specified in the periodic frame interval field of the OTG_DCFG register (PFIVL bit in OTG_DCFG) has been reached in the current frame.

*Note: Only accessible in device mode.*

Bit 14  **ISOODRP**: Isochronous OUT packet dropped interrupt

The core sets this bit when it fails to write an isochronous OUT packet into the Rx FIFO because the Rx FIFO does not have enough space to accommodate a maximum size packet for the isochronous OUT endpoint.

*Note: Only accessible in device mode.*

Bit 13  **ENUMDNE**: Enumeration done

The core sets this bit to indicate that speed enumeration is complete. The application must read the OTG_DSTS register to obtain the enumerated speed.

*Note: Only accessible in device mode.*

Bit 12  **USBRST**: USB reset

The core sets this bit to indicate that a reset is detected on the USB.

*Note: Only accessible in device mode.*

Bit 11  **USBSUSP**: USB suspend

The core sets this bit to indicate that a suspend was detected on the USB. The core enters the suspended state when there is no activity on the data lines for an extended period of time.

*Note: Only accessible in device mode.*

Bit 10  **ESusp**: Early suspend

The core sets this bit to indicate that an Idle state has been detected on the USB for 3 ms.

*Note: Only accessible in device mode.*

Bits 9:8  Reserved, must be kept at reset value.
Bit 7  **GONAKEFF**: Global OUT NAK effective  
Indicates that the Set global OUT NAK bit in the OTG_DCTL register (SGONAK bit in OTG_DCTL), set by the application, has taken effect in the core. This bit can be cleared by writing the Clear global OUT NAK bit in the OTG_DCTL register (CGONAK bit in OTG_DCTL).

*Note: Only accessible in device mode.*

Bit 6  **GINAKEFF**: Global IN non-periodic NAK effective  
Indicates that the Set global non-periodic IN NAK bit in the OTG_DCTL register (SGINAK bit in OTG_DCTL), set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. This bit can be cleared by clearing the Clear global non-periodic IN NAK bit in the OTG_DCTL register (CGINAK bit in OTG_DCTL). This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit.

*Note: Only accessible in device mode.*

Bit 5  **NPTXFE**: Non-periodic Tx FIFO empty  
This interrupt is asserted when the non-periodic Tx FIFO is either half or completely empty, and there is space for at least one entry to be written to the non-periodic transmit request queue. The half or completely empty status is determined by the non-periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (TXFELVL bit in OTG_GAHBCFG).

*Note: Accessible in host mode only.*

Bit 4  **RXFLVL**: Rx FIFO non-empty  
Indicates that there is at least one packet pending to be read from the Rx FIFO.

*Note: Accessible in both host and device modes.*

Bit 3  **SOF**: Start of frame  
In host mode, the core sets this bit to indicate that an SOF (FS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt. In device mode, in the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the OTG_DSTS register to get the current frame number. This interrupt is seen only when the core is operating in FS.

*Note: This register may return ‘1’ if read immediately after power on reset. If the register bit reads ‘1’ immediately after power on reset it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit.*

*Note: Accessible in both host and device modes.*
Bit 2  **OTGINT**: OTG interrupt

The core sets this bit to indicate an OTG protocol event. The application must read the OTG interrupt status (OTG_GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_GOTGINT register to clear this bit.

*Note: Accessible in both host and device modes.*

Bit 1  **MMIS**: Mode mismatch interrupt

The core sets this bit when the application is trying to access:

- A host mode register, when the core is operating in device mode
- A device mode register, when the core is operating in host mode

The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core.

*Note: Accessible in both host and device modes.*

Bit 0  **CMOD**: Current mode of operation

Indicates the current mode.

0: Device mode
1: Host mode

*Note: Accessible in both host and device modes.*

### 62.14.7  OTG core interrupt register [alternate] (OTG_GINTSTS)

Valid for Device mode, see previous section for Host mode.

This register also indicates the current mode. To clear the interrupt status bits of the rc_w1 type, the application must write 1 into the bit.

This register interrupts the application for system-level events in the current mode (device mode or host mode).

The FIFO status interrupts are read-only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the OTG_GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

```
Bit 31 **WKUPINT**: Resume/remote wake-up detected interrupt
Wake-up interrupt during suspend(L2) or LPM(L1) state.
– During suspend(L2):
  In device mode, this interrupt is asserted when a resume is detected on the USB. In host mode, this interrupt is asserted when a remote wake-up is detected on the USB.
– During LPM(L1):
  This interrupt is asserted for either host initiated resume or device initiated remote wake-up on USB.
*Note:* Accessible in both device and host modes.

Bit 30 **SRQINT**: Session request/new session detected interrupt
In host mode, this interrupt is asserted when a session request is detected from the device. In device mode, this interrupt is asserted when $V_{BUS}$ is in the valid range for a B-peripheral device. Accessible in both device and host modes.

Bit 29 **DISCINT**: Disconnect detected interrupt
Asserted when a device disconnect is detected.
*Note:* Only accessible in host mode.

Bit 28 **CIDSCHG**: Connector ID status change
The core sets this bit when there is a change in connector ID status.
*Note:* Accessible in both device and host modes.

Bit 27 **LPMINT**: LPM interrupt
In device mode, this interrupt is asserted when the device receives an LPM transaction and responds with a non-ERRORed response.
In host mode, this interrupt is asserted when the device responds to an LPM transaction with a non-ERRORed response or when the host core has completed LPM transactions for the programmed number of times (RETRYCNT bit in OTG_GLPMCFG). This field is valid only if the LPMEN bit in OTG_GLPMCFG is set to 1.

Bit 26 **PTXFE**: Periodic Tx FIFO empty
Asserted when the periodic transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the periodic request queue. The half or completely empty status is determined by the periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (PTXFELVL bit in OTG_GAHBCFG).
*Note:* Only accessible in host mode.

Bit 25 **HCINT**: Host channels interrupt
The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in host mode). The application must read the OTG_HAINT register to determine the exact number of the channel on which the interrupt occurred, and then read the corresponding OTG_HCINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the OTG_HCINTx register to clear this bit.
*Note:* Only accessible in host mode.

Bit 24 **HPRTINT**: Host port interrupt
The core sets this bit to indicate a change in port status of one of the OTG_HS controller ports in host mode. The application must read the OTG_HPRT register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_HPRT register to clear this bit.
*Note:* Only accessible in host mode.
Bit 23  **RSTDET**: Reset detected interrupt

In device mode, this interrupt is asserted when a reset is detected on the USB in partial power-down mode when the device is in suspend.

*Note: Only accessible in device mode.*

Bit 22  **DATAFSUSP**: Data fetch suspended

This interrupt is valid only in DMA mode. This interrupt indicates that the core has stopped fetching data for IN endpoints due to the unavailability of TxFIFO space or request queue space. This interrupt is used by the application for an endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application:

- Sets a global nonperiodic IN NAK handshake
- Disables IN endpoints
- Flushes the FIFO
- Determines the token sequence from the IN token sequence learning queue
- Re-enables the endpoints

Clears the global nonperiodic IN NAK handshake if the global nonperiodic IN NAK is cleared, the core has not yet fetched data for the IN endpoint, and the IN token is received: the core generates an “IN token received when FIFO empty” interrupt. The OTG then sends a NAK response to the host. To avoid this scenario, the application can check the FetSusp interrupt in OTG_GINTSTS, which ensures that the FIFO is full before clearing a global NAK handshake. Alternatively, the application can mask the “IN token received when FIFO empty” interrupt when clearing a global IN NAK handshake.

Bit 21  **INCOMISOOUT**: Incomplete isochronous OUT transfer

In device mode, the core sets this interrupt to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

Bit 20  **IISOIXFR**: Incomplete isochronous IN transfer

The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

*Note: Only accessible in device mode.*

Bit 19  **OEPINT**: OUT endpoint interrupt

The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in device mode). The application must read the OTG_DAINT register to determine the exact number of the OUT endpoint on which the interrupt occurred, and then read the corresponding OTG_DOEPIINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG_DOEPIINTx register to clear this bit.

*Note: Only accessible in device mode.*

Bit 18  **IEPINT**: IN endpoint interrupt

The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in device mode). The application must read the OTG_DAINT register to determine the exact number of the IN endpoint on which the interrupt occurred, and then read the corresponding OTG_DIEPIINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG_DIEPIINTx register to clear this bit.

*Note: Only accessible in device mode.*

Bits 17:16  Reserved, must be kept at reset value.
Bit 15 **EOPF:** End of periodic frame interrupt
Indicates that the period specified in the periodic frame interval field of the OTG_DCFG register (PFIVL bit in OTG_DCFG) has been reached in the current frame.
*Note: Only accessible in device mode.*

Bit 14 **ISOODRP:** Isochronous OUT packet dropped interrupt
The core sets this bit when it fails to write an isochronous OUT packet into the Rx FIFO because the Rx FIFO does not have enough space to accommodate a maximum size packet for the isochronous OUT endpoint.
*Note: Only accessible in device mode.*

Bit 13 **ENUMDNE:** Enumeration done
The core sets this bit to indicate that speed enumeration is complete. The application must read the OTG_DSTS register to obtain the enumerated speed.
*Note: Only accessible in device mode.*

Bit 12 **USBRS:** USB reset
The core sets this bit to indicate that a reset is detected on the USB.
*Note: Only accessible in device mode.*

Bit 11 **USBSSP:** USB suspend
The core sets this bit to indicate that a suspend was detected on the USB. The core enters the suspended state when there is no activity on the data lines for an extended period of time.
*Note: Only accessible in device mode.*

Bit 10 **ESUSP:** Early suspend
The core sets this bit to indicate that an Idle state has been detected on the USB for 3 ms.
*Note: Only accessible in device mode.*

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **GONAKEFF:** Global OUT NAK effective
Indicates that the Set global OUT NAK bit in the OTG_DCTL register (SGONAK bit in OTG_DCTL), set by the application, has taken effect in the core. This bit can be cleared by writing the Clear global OUT NAK bit in the OTG_DCTL register (CGONAK bit in OTG_DCTL).
*Note: Only accessible in device mode.*

Bit 6 **GINAKEFF:** Global IN non-periodic NAK effective
Indicates that the Set global non-periodic IN NAK bit in the OTG_DCTL register (SGINAK bit in OTG_DCTL), set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. This bit can be cleared by clearing the Clear global non-periodic IN NAK bit in the OTG_DCTL register (CGINAK bit in OTG_DCTL). This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit.
*Note: Only accessible in device mode.*

Bit 5 **NPTXFE:** Non-periodic Tx FIFO empty
This interrupt is asserted when the non-periodic Tx FIFO is either half or completely empty, and there is space for at least one entry to be written to the non-periodic transmit request queue. The half or completely empty status is determined by the non-periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (TXFELVL bit in OTG_GAHBCFG).
*Note: Accessible in host mode only.*
Bit 4  **RXFLVL**: Rx FIFO non-empty
Indicates that there is at least one packet pending to be read from the Rx FIFO.
*Note: Accessible in both host and device modes.*

Bit 3  **SOF**: Start of frame
In host mode, the core sets this bit to indicate that an SOF (FS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt.
In device mode, in the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the OTG_DSTS register to get the current frame number. This interrupt is seen only when the core is operating in FS.
*Note: This register may return ‘1’ if read immediately after power on reset. If the register bit reads ‘1’ immediately after power on reset it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit.*
*Note: Accessible in both host and device modes.*

Bit 2  **OTGINT**: OTG interrupt
The core sets this bit to indicate an OTG protocol event. The application must read the OTG interrupt status (OTG_GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_GOTGINT register to clear this bit.
*Note: Accessible in both host and device modes.*

Bit 1  **MMIS**: Mode mismatch interrupt
The core sets this bit when the application is trying to access:
– A host mode register, when the core is operating in device mode
– A device mode register, when the core is operating in host mode
The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core.
*Note: Accessible in both host and device modes.*

Bit 0  **CMOD**: Current mode of operation
Indicates the current mode.
0: Device mode
1: Host mode
*Note: Accessible in both host and device modes.*
### 62.14.8 OTG interrupt mask register [alternate] (OTG_GINTMSK)

Valid for Host mode, see next section for Device mode.

This register works with the core interrupt register to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the core interrupt (OTG_GINTSTS) register bit corresponding to that interrupt is still set.

Address offset: 0x018

Reset value: 0x0000 0000

1: Unmasked interrupt

Bits 9:8 Reserved, must be kept at reset value.
Bit 7 **GONAKEFFM**: Global OUT NAK effective mask
0: Masked interrupt
1: Unmasked interrupt

Bit 6 **GINAKEFFM**: Global non-periodic IN NAK effective mask
0: Masked interrupt
1: Unmasked interrupt

Bit 5 Reserved, must be kept at reset value.

Bit 4 **RXFLVLM**: Receive FIFO non-empty mask
0: Masked interrupt
1: Unmasked interrupt

Bit 3 **SOFM**: Start of frame mask
0: Masked interrupt
1: Unmasked interrupt

Bit 2 **OTGINT**: OTG interrupt mask
0: Masked interrupt
1: Unmasked interrupt

Bit 1 **MMISM**: Mode mismatch interrupt mask
0: Masked interrupt
1: Unmasked interrupt

Bit 0 Reserved, must be kept at reset value.

### 62.14.10 OTG receive status debug read register [alternate]
(OTG_GRXSTSR)

This description is for register OTG_GRXSTSR in Device mode.

A read to the receive status debug read register returns the contents of the top of the receive FIFO.

The core ignores the receive status read when the receive FIFO is empty and returns a value of 0x0000 0000.

Address offset: 0x01C

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31-28 Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 27 <strong>STSPHST</strong>: Status phase start</td>

<tr>
<td>Indicates the start of the status phase for a control write transfer. This bit is set along with the OUT transfer completed PKTSTS pattern.</td>
</tr>
<tr>
<td>Bits 26-25 Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
Bits 24:21 **FRMNUM[3:0]:** Frame number  
This is the least significant 4 bits of the frame number in which the packet is received on the USB. This field is supported only when isochronous OUT endpoints are supported.

Bits 20:17 **PKTSTS[3:0]:** Packet status  
Indicates the status of the received packet  
0001: Global OUT NAK (triggers an interrupt)  
0010: OUT data packet received  
0011: OUT transfer completed (triggers an interrupt)  
0100: SETUP transaction completed (triggers an interrupt)  
0110: SETUP data packet received  
Others: Reserved

Bits 16:15 **DPID[1:0]:** Data PID  
Indicates the data PID of the received OUT data packet  
00: DATA0  
10: DATA1  
01: DATA2  
11: MDATA

Bits 14:4 **BCNT[10:0]:** Byte count  
Indicates the byte count of the received data packet.

Bits 3:0 **EPNUM[3:0]:** Endpoint number  
Indicates the endpoint number to which the current received packet belongs.

62.14.11 **OTG receive status debug read register [alternate]**  
(OTG_GRXSTSR)

This description is for register OTG_GRXSTSR in Host mode.

A read to the receive status debug read register returns the contents of the top of the receive FIFO.

The core ignores the receive status read when the receive FIFO is empty and returns a value of 0x0000 0000.

Address offset: 0x01C

Reset value: 0x0000 0000
USB on-the-go high-speed (OTG_HS) RM0477

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:17 **PKTSTS[3:0]:** Packet status
Indicates the status of the received packet
- 0010: IN data packet received
- 0011: IN transfer completed (triggers an interrupt)
- 0101: Data toggle error (triggers an interrupt)
- 0111: Channel halted (triggers an interrupt)
Others: Reserved

Bits 16:15 **DPID[1:0]:** Data PID
Indicates the data PID of the received packet
- 00: DATA0
- 10: DATA1
- 01: DATA2
- 11: MDATA

Bits 14:4 **BCNT[10:0]:** Byte count
Indicates the byte count of the received IN data packet.

Bits 3:0 **CHNUM[3:0]:** Channel number
Indicates the channel number to which the current received packet belongs.

### 62.14.12 OTG status read and pop registers (OTG_GRXSTSP)

This description is for register OTG_GRXSTSP in Device mode.

Similarly to OTG_GRXSTSR (receive status debug read register) where a read returns the contents of the top of the receive FIFO, a read to OTG_GRXSTSP (receive status read and pop register) additionally pops the top data entry out of the Rx FIFO.

The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x0000 0000. The application must only pop the receive status FIFO when the receive FIFO non-empty bit of the core interrupt register (RXFLVL bit in OTG_GINTSTS) is asserted.

Address offset: 0x020

Reset value: 0x0000 0000

| Bit 27   | Reserved, must be kept at reset value. |
| Bit 26   | Reserved, must be kept at reset value. |
| Bit 25   | **FORCEHOSTPD**: Force host mode pull-downs  
            If the ID pin functions are enabled, the host mode pull-downs on DP and DM activate automatically. However, whenever that is not the case, yet host mode is required, this bit must be used to force the pull-downs active.  
            0: Do not force host mode pull-downs  
            1: Force host mode pull-downs |
| Bit 24   | **VBVALOVEN**: Enables a software override of the VBUS B-session detection.  
            0: Use hardware  
            1: Use VBVALOVAL to indicate B-session active |
| Bit 23   | **VBVALOVAL**: Software override value of the VBUS B-session detection  
            0: B-session inactive  
            1: B-session active |
| Bit 22   | **SDEN**: Secondary detection enable  
            0: Secondary detection disabled  
            1: Secondary detection enabled |
| Bit 21   | **VBDEN**: VBUS detection enable  
            Enables VBUS Sensing Comparators in order to detect VBUS presence and/or perform OTG operation.  
            0: VBUS detection disabled  
            1: VBUS detection enabled |
| Bit 20   | **PDEN**: Primary detection enable  
            0: Primary detection disabled  
            1: Primary detection enabled |
| Bit 19   | **DCDEN**: Data Contact Detection enable  
            0: Data Contact Detection disabled  
            1: Data Contact Detection enabled |
Bit 18 **HVDMSRCEN**: Host CDP port Voltage source enable on DM
0: DM voltage source disabled
1: DM Voltage source enabled

Bit 17 **HCDPDETEN**: Host CDP port voltage detector enable on DP
0: DP voltage detection disabled
1: DP voltage detection enabled

Bit 16 **HCDPEN**: Host CDP behavior enable
0: Disable CDP behavior
1: Enable CDP behavior

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **SESSVLD**: VBUS session indicator
Indicates if VBUS is above VBUS session threshold.
0: VBUS is below VBUS session threshold
1: VBUS is above VBUS session threshold

Bit 2 **FSVMINUS**: Single-Ended DM indicator
This bit gives the voltage level on DM (also result of the comparison with $V_{LGC}$ threshold as defined in BC v1.2 standard).
0: DM voltage at low level
1: DM voltage at high level

Bit 1 **FSVPLUS**: Single-Ended DP indicator
This bit gives the voltage level on DP (also result of the comparison with $V_{LGC}$ threshold as defined in BC v1.2 standard).
0: DM voltage at low level
1: DM voltage at high level

Bit 0 **CHGDET**: Charger detection, result of the current mode (primary or secondary).
0: Low value on pin
1: High value on pin

62.14.19 **OTG core ID register (OTG_CID)**

This is a register containing the Product ID as reset value.

Address offset: 0x03C
Reset value: 0x0000 5000

</tbody>
</table>

**Bits 31:29** Reserved, must be kept at reset value.

**Bit 28** **ENBESL**: Enable best effort service latency

This bit enables the BESL feature as defined in the LPM errata:

0: The core works as described in the following document:

USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007

1: The core works as described in the LPM Errata:

Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007

Note: Only the updated behavior (described in LPM Errata) is considered in this document and so the ENBESL bit must be set to ‘1’ by application SW.

**Bits 27:25** **LPMRCNTSTS[2:0]**: LPM retry count status

Number of LPM host retries still remaining to be transmitted for the current LPM sequence.

Note: Accessible only in host mode.

**Bit 24** **SNDLPM**: Send LPM transaction

When the application software sets this bit, an LPM transaction containing two tokens, EXT and LPM is sent. The hardware clears this bit once a valid response (STALL, NYET, or ACK) is received from the device or the core has finished transmitting the programmed number of LPM retries.

Note: This bit must be set only when the host is connected to a local port.

Note: Accessible only in host mode.

**Bits 23:21** **LPMRCNT[2:0]**: LPM retry count

When the device gives an ERROR response, this is the number of additional LPM retries that the host performs until a valid device response (STALL, NYET, or ACK) is received.

Note: Accessible only in host mode.

**Bits 20:17** **LPMCHIDX[3:0]**: LPM Channel Index

The channel number on which the LPM transaction has to be applied while sending an LPM transaction to the local device. Based on the LPM channel index, the core automatically inserts the device address and endpoint number programmed in the corresponding channel into the LPM transaction.

Note: Accessible only in host mode.
Bit 16  **L1RSMOK**: Sleep state resume OK
Indicates that the device or host can start resume from Sleep state. This bit is valid in LPM sleep (L1) state. It is set in sleep mode after a delay of 50 μs ($T_{L1\text{Residency}}$).
This bit is reset when SLPSTS is 0.
0: The application or host cannot start resume from Sleep state
1: The application or host can start resume from Sleep state

Bit 15  **SLPSTS**: Port sleep status
Device mode:
This bit is set as long as a Sleep condition is present on the USB bus. The core enters the Sleep state when an ACK response is sent to an LPM transaction and the $T_{L1\text{TokenRetry}}$ timer has expired. To stop the PHY clock, the application must set the STPPCLK bit in OTG_PCGCCTL, which asserts the PHY suspend input signal.
The application must rely on SLPSTS and not ACK in LPMRSP to confirm transition into sleep.
The core comes out of sleep:
– When there is any activity on the USB linestate
– When the application writes to the RWUSIG bit in OTG_DCTL or when the application resets or soft-disconnects the device.
Host mode:
The host transitions to Sleep (L1) state as a side-effect of a successful LPM transaction by the core to the local port with ACK response from the device. The read value of this bit reflects the current Sleep status of the port.
The core clears this bit after:
– The core detects a remote L1 wake-up signal,
– The application sets the PRST bit or the PRES bit in the OTG_HPRT register, or
– The application sets the L1Resume/ remote wake-up detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT bit in OTG_GINTSTS, respectively).
0: Core not in L1
1: Core in L1

Bits 14:13  **LPMRSP[1:0]**: LPM response
Device mode:
The response of the core to LPM transaction received is reflected in these two bits.
Host mode:
Handshake response received from local device for LPM transaction
11: ACK
10: NYET
01: STALL
00: ERROR (No handshake response)

Bit 12  **L1DSEN**: L1 deep sleep enable
Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit must be set to ‘1’ by application SW in all the cases.
Bits 11:8 **BESLTHRS[3:0]**: BESL threshold

**Device mode:**
The core puts the PHY into deep low power mode in L1 when BESL value is greater than or equal to the value defined in this field BESL_Thres[3:0].

**Host mode:**
The core puts the PHY into deep low power mode in L1. BESLTHRS[3:0] specifies the time for which resume signaling is to be reflected by host (T_{L1HubDrvResume2}) on the USB bus when it detects device initiated resume.

BESLTHRS must not be programmed with a value greater than 1100b in host mode, because this exceeds maximum T_{L1HubDrvResume2}.

**Thres[3:0]** host mode resume signaling time (μs):
- 0000: 75
- 0001: 100
- 0010: 150
- 0011: 250
- 0100: 350
- 0101: 450
- 0110: 950
- All other values: reserved

Bit 7 **L1SSEN**: L1 Shallow Sleep enable
Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit must be set to ‘1’ by application SW in all the cases.

Bit 6 **REMWAKE**: bRemoteWake value

**Host mode:**
The value of remote wake up to be sent in the wIndex field of LPM transaction.

**Device mode (read-only):**
This field is updated with the received LPM token bRemoteWake bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.
Bits 5:2 **BESL[3:0]**: Best effort service latency

**Host mode:**
The value of BESL to be sent in an LPM transaction. This value is also used to initiate resume for a duration $T_{LHubDrvResume}$ for host initiated resume.

**Device mode (read-only):**
This field is updated with the received LPM token BESL bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.

$BESL[3:0]T_{BESL}$ (μs)

</tbody>
</table>

Bit 1 **LPMACK**: LPM token acknowledge enable
Handshake response to LPM token preprogrammed by device application software.

1: ACK
Even though ACK is preprogrammed, the core device responds with ACK only on successful LPM transaction. The LPM transaction is successful if:
- No PID/CRC5 errors in either EXT token or LPM token (else ERROR)
- Valid bLinkState = 0001B (L1) received in LPM transaction (else STALL)
- No data pending in transmit queue (else NYET).

0: NYET
The preprogrammed software bit is over-ridden for response to LPM token when:
- The received bLinkState is not L1 (STALL response), or
- An error is detected in either of the LPM token packets because of corruption (ERROR response).

**Note:** Accessible only in device mode.

Bit 0 **LPMEN**: LPM support enable
The application uses this bit to control the OTG_HS core LPM capabilities.
If the core operates as a non-LPM-capable host, it cannot request the connected device or hub to activate LPM mode.
If the core operates as a non-LPM-capable device, it cannot respond to any LPM transactions.

0: LPM capability is not enabled
1: LPM capability is enabled

62.14.23 Host-mode registers

Bit values in the register descriptions are expressed in binary unless otherwise specified. Host-mode registers affect the operation of the core in the host mode. Host mode registers must not be accessed in device mode, as the results are undefined. Host mode registers can be categorized as follows:
62.14.24 OTG host configuration register (OTG_HCFG)

This register configures the core after power-on. Do not make changes to this register after initializing the host.

Address offset: 0x400
Reset value: 0x0000 0000

<table>

FSLSS    FSLSPCS[1:0]

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 FSLSS: FS- and LS-only support

The application uses this bit to control the core enumeration speed. Using this bit, the application can make the core enumerate as an FS host, even if the connected device supports HS traffic. Do not make changes to this field after initial programming.

Bits 1:0 FSLSPCS[1:0]: FS/LS PHY clock select

<table>

15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0

FRIVL[15:0]

rw    rw    rw    rw    rw    rw    rw    rw    rw    rw    rw    rw    rw    rw    rw    rw

Note: The FSLSPCS must be set on a connection event according to the speed of the connected device (after changing this bit, a software reset must be performed).
Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **RLDCTRL**: Reload control
This bit allows dynamic reloading of the HFIR register during run time.
- 0: The HFIR cannot be reloaded dynamically
- 1: The HFIR can be dynamically reloaded during run time.
This bit needs to be programmed during initial configuration and its value must not be changed during run time.

**Caution**: RLDCTRL = 0 is not recommended.

Bits 15:0 **FRIVL[15:0]**: Frame interval
The value that the application programs to this field, specifies the interval between two consecutive micro-SOFs (HS) or Keep-Alive tokens (LS). This field contains the number of PHY clocks that constitute the required frame interval. The application can write a value to this register only after the port enable bit of the host port control and status register (PENA bit in OTG_HPRT) has been set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS/LS PHY clock select field of the host configuration register (FSLSPCS in OTG_HCFG). Do not change the value of this field after the initial configuration, unless the RLDCTRL bit is set. In such case, the FRIVL is reloaded with each SOF event.

- Frame interval = 125 μs × (FRIVL - 1) in high speed operation
- Frame interval = 1 ms × (FRIVL - 1) in low/full speed operation

### 62.14.26 OTG host frame number/frame time remaining register (OTG_HFNUM)
This register indicates the current frame number. It also indicates the time remaining (in terms of the number of PHY clocks) in the current frame.

Address offset: 0x408
Reset value: 0x0000 3FFF

Bits 31:16 **FTREM[15:0]**: Frame time remaining
Indicates the amount of time remaining in the current frame, in terms of PHY clocks. This field decrements on each PHY clock. When it reaches zero, this field is reloaded with the value in the Frame interval register and a new SOF is transmitted on the USB.

Bits 15:0 **FRNUM[15:0]**: Frame number
This field increments when a new SOF is transmitted on the USB, and is cleared to 0 when it reaches 0x3FFF.
62.14.27  OTG_Host periodic transmit FIFO/queue status register (OTG_HPTXSTS)

This read-only register contains the free space information for the periodic Tx FIFO and the periodic transmit request queue.

Address offset: 0x410

Bits 31:24  PTXQTOP[7:0]: Top of the periodic transmit request queue
This indicates the entry in the periodic Tx request queue that is currently being processed by the MAC.
This register is used for debugging.
Bit 31: Odd/Even frame
0XXXXXXX: send in even frame
1XXXXXXX: send in odd frame
Bits 30:27: Channel/endpoint number
Bits 26:25: Type
XXXXX00X: IN/OUT
XXXXX01X: Zero-length packet
XXXXX11X: Disable channel command
Bit 24: Terminate (last entry for the selected channel/endpoint)

Bits 23:16  PTXQSAV[7:0]: Periodic transmit request queue space available
Indicates the number of free locations available to be written in the periodic transmit request queue. This queue holds both IN and OUT requests.
0: Periodic transmit request queue is full
1: 1 location available
2: 2 locations available
n: n locations available (0 ≤ n ≤ 8)
Others: Reserved

Bits 15:0  PTXFSAVL[15:0]: Periodic transmit data FIFO space available
Indicates the number of free locations available to be written to in the periodic Tx FIFO.
Values are in terms of 32-bit words
0: Periodic Tx FIFO is full
1: 1 word available
2: 2 words available
n: n words available (where 0 ≤ n ≤ PTXFD)
Others: Reserved
When a significant event occurs on a channel, the host all channels interrupt register interrupts the application using the host channels interrupt bit of the core interrupt register (HCINT bit in OTG_GINTSTS). This is shown in Figure 921. There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding host channel-x interrupt register.

Address offset: 0x414
Reset value: 0x0000 0000

Bits 31:16  Reserved, must be kept at reset value.
Bits 15:0  HAIN[T[15:0]: Channel interrupts
  One bit per channel: Bit 0 for Channel 0, bit 15 for Channel 15

The host all channel interrupt mask register works with the host all channel interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

Address offset: 0x418
Reset value: 0x0000 0000

Bits 31:16  Reserved, must be kept at reset value.
Bits 15:0  HAIN[TM[15:0]: Channel interrupt mask
  0: Masked interrupt
  1: Unmasked interrupt
  One bit per channel: Bit 0 for channel 0, bit 15 for channel 15
62.14.30 OTG host port control and status register (OTG_HPRT)

This register is available only in host mode. Currently, the OTG host supports only one port. A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. It is shown in Figure 921. The rc_w1 bits in this register can trigger an interrupt to the application through the host port interrupt bit of the core interrupt register (HPRTINT bit in OTG_GINTSTS). On a port interrupt, the application must read this register and clear the bit that caused the interrupt. For the rc_w1 bits, the application must write a 1 to the bit to clear the interrupt.

Address offset: 0x440
Reset value: 0x0000 0000

| 3   |              |                                            |
| 2   |              |                                            |
| 1   |              |                                            |
| 0   |              |                                            |
Bit 9  Reserved, must be kept at reset value.

Bit 8  **PRST**: Port reset
When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete.
0: Port not in reset
1: Port in reset
The application must leave this bit set for a minimum duration of at least 10 ms to start a reset on the port. The application can leave it set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by the USB standard.
High speed: 50 ms
Full speed/Low speed: 10 ms

Bit 7  **PSUSP**: Port suspend
The application sets this bit to put this port in suspend mode. The core only stops sending SOFs when this is set. To stop the PHY clock, the application must set the port clock stop bit, which asserts the suspend input pin of the PHY.
The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wake-up signal is detected or the application sets the port reset bit or port resume bit in this register or the resume/remote wake-up detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT in OTG_GINTSTS, respectively).
0: Port not in suspend mode
1: Port in suspend mode

Bit 6  **PRES**: Port resume
The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit.
If the core detects a USB remote wake-up sequence, as indicated by the port resume/remote wake-up detected interrupt bit of the core interrupt register (WKUPINT bit in OTG_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently driving resume signaling.
0: No resume driven
1: Resume driven
When LPM is enabled and the core is in L1 state, the behavior of this bit is as follow:
1. The application sets this bit to drive resume signaling on the port.
2. The core continues to drive the resume signal until a predetermined time specified in BESLTHRS[3:0] field of OTG_GLPMCFG register.
3. If the core detects a USB remote wake-up sequence, as indicated by the port L1Resume/Remote L1wake-up detected interrupt bit of the core interrupt register (WKUPINT in OTG_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit at the end of resume. This bit can be set or cleared by both the core and the application. This bit is cleared by the core even if there is no device connected to the host.

Bit 5  **POCCHNG**: Port overcurrent change
The core sets this bit when the status of the port overcurrent active bit (bit 4) in this register changes.

Bit 4  **POCA**: Port overcurrent active
Indicates the overcurrent condition of the port.
0: No overcurrent condition
1: Overcurrent condition
Bit 3 **PENCHNG:** Port enable/disable change
The core sets this bit when the status of the port enable bit 2 in this register changes.

Bit 2 **PENA:** Port enable
A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot set this bit by a register write. It can only clear it to disable the port. This bit does not trigger any interrupt to the application.
0: Port disabled
1: Port enabled

Bit 1 **PCDET:** Port connect detected
The core sets this bit when a device connection is detected to trigger an interrupt to the application using the host port interrupt bit in the core interrupt register (HPRTINT bit in OTG_GINTSTS). The application must write a 1 to this bit to clear the interrupt.

Bit 0 **PCSTS:** Port connect status
0: No device is attached to the port
1: A device is attached to the port

62.14.31 **OTG host channel x characteristics register (OTG_HCCHARx)**
Address offset: 0x500 + 0x20 * x, (x = 0 to 15)
Reset value: 0x0000 0000

**Bit 31 CHENA:** Channel enable
This field is set by the application and cleared by the OTG host.
0: Channel disabled
1: Channel enabled

**Bit 30 CHDIS:** Channel disable
The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the Channel disabled interrupt before treating the channel as disabled.

**Bit 29 ODDFRM:** Odd frame
This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd frame. This field is applicable for only periodic (isochronous and interrupt) transactions.
0: Even frame
1: Odd frame

**Bits 28:22 DAD[6:0]:** Device address
This field selects the specific device serving as the data source or sink.
Bits 21:20 **MCNT[1:0]: Multicount**
This field indicates to the host the number of transactions that must be executed per frame for this periodic endpoint. For non-periodic transfers, this field is not used.
- 00: Reserved. This field yields undefined results
- 01: 1 transaction
- 10: 2 transactions per frame to be issued for this endpoint
- 11: 3 transactions per frame to be issued for this endpoint

*Note: This field must be set to at least 01.*

Bits 19:18 **EPTYP[1:0]: Endpoint type**
Indicates the transfer type selected.
- 00: Control
- 01: Isochronous
- 10: Bulk
- 11: Interrupt

Bit 17 **LSDEV: Low-speed device**
This field is set by the application to indicate that this channel is communicating to a low-speed device.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **EPDIR: Endpoint direction**
Indicates whether the transaction is IN or OUT.
- 0: OUT
- 1: IN

Bits 14:11 **EPNUM[3:0]: Endpoint number**
Indicates the endpoint number on the device serving as the data source or sink.

Bits 10:0 **MPSIZ[10:0]: Maximum packet size**
Indicates the maximum packet size of the associated endpoint.

### 62.14.32 OTG host channel x split control register (OTG_HCSPLTx)

Bit 31 **SPLITEN**: Split enable
The application sets this bit to indicate that this channel is enabled to perform split transactions.

Bits 30:17 Reserved, must be kept at reset value.

Bit 16 **COMPLSPLT**: Do complete split
The application sets this bit to request the OTG host to perform a complete split transaction.
Bits 15:14  **XACTPOS[1:0]**: Transaction position
This field is used to determine whether to send all, first, middle, or last payloads with each OUT transaction.
11: All. This is the entire data payload of this transaction (which is less than or equal to 188 bytes)
10: Begin. This is the first data payload of this transaction (which is larger than 188 bytes)
00: Mid. This is the middle payload of this transaction (which is larger than 188 bytes)
01: End. This is the last payload of this transaction (which is larger than 188 bytes)

Bits 13:7  **HUBADDR[6:0]**: Hub address
This field holds the device address of the transaction translator hub.

Bits 6:0  **PRTADDR[6:0]**: Port address
This field is the port number of the recipient transaction translator.

### 62.14.33 OTG host channel x interrupt register (OTG_HCINTx)
This register indicates the status of a channel with respect to USB- and AHB-related events. It is shown in Figure 921. The application must read this register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG_GINTSTS) is set. Before the application can read this register, it must first read the host all channels interrupt (OTG_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_HAINT and OTG_GINTSTS registers.

Address offset: 0x508 + 0x20 * x, (x = 0 to 15)

Bits 31:11 Reserved, must be kept at reset value.

- **Bit 10  DTErr**: Data toggle error.
- **Bit 9  FRMOR**: Frame overrun.
- **Bit 8  BBErr**: Babble error.
- **Bit 7  TXErr**: Transaction error.
  Indicates one of the following errors occurred on the USB.
  - CRC check failure
  - Timeout
  - Bit stuff error
  - False EOP

- **Bit 6  NYET**: Not yet ready response received interrupt.
- **Bit 5  ACK**: ACK response received/transmitted interrupt.
- **Bit 4  NAK**: NAK response received interrupt.
Bit 3  **STALL**: STALL response received interrupt.

Bit 2  **AHBERR**: AHB error
This error is generated only in Internal DMA mode when an AHB error occurs during an AHB read/write operation. The application can read the corresponding DMA channel address register to get the error address.

Bit 1  **CHH**: Channel halted
This indicates that the transfer completed:
- because of any USB transaction error
- in response to disable request by the application
- normally

Bit 0  **XFRC**: Transfer completed.
Transfer completed normally without any errors.

### 62.14.34 OTG host channel x interrupt mask register (OTG_HCINTMSKx)

This register reflects the mask for each channel status described in the previous section.

Address offset: 0x50C + 0x20 * x, (x = 0 to 15)
Reset value: 0x0000 0000

**XFRSIZ[15:0]**

| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bit 31 **DOPNG**: Do Ping

This bit is used only for OUT transfers. Setting this field to 1 directs the host to do PING protocol.

*Note*: Do not set this bit for IN transfers. If this bit is set for IN transfers, it disables the channel.

Bits 30:29 **DPID[1:0]**: Data PID

The application programs this field with the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer.

00: DATA0
01: DATA2
10: DATA1
11: SETUP (control) / MDATA (non-control)
Bits 28:19  **PKTCNT[9:0]:** Packet count
This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN).
The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion.

Bits 18:0  **XFRSIZ[18:0]:** Transfer size
For an OUT, this field is the number of data bytes the host sends during the transfer.
For an IN, this field is the buffer size that the application has reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).

### 62.14.36  OTG host channel x DMA address register (OTG_HCDMAx)

Bits 31:0  **DMAADDR[31:0]:** DMA address
This field holds the start address in the external memory from which the data for the endpoint must be fetched or to which it must be stored. This register is incremented on every AHB transaction.

### 62.14.37  Device-mode registers

These registers must be programmed every time the core changes to device mode

### 62.14.38  OTG device configuration register (OTG_DCFG)

This register configures the core in device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

Address offset: $0x800$
Reset value: $0x0220\ 0000$

Bits 31:26  Reserved, must be kept at reset value.
Bits 25:24 **PERSCHIVL[1:0]:** Periodic schedule interval

This field specifies the amount of time the Internal DMA engine must allocate for fetching periodic IN endpoint data. Based on the number of periodic endpoints, this value must be specified as 25, 50 or 75% of the (micro) frame.

- When any periodic endpoints are active, the internal DMA engine allocates the specified amount of time in fetching periodic IN endpoint data
- When no periodic endpoint is active, then the internal DMA engine services nonperiodic endpoints, ignoring this field
- After the specified time within a (micro) frame, the DMA switches to fetching nonperiodic endpoints

00: 25% of (micro)frame  
01: 50% of (micro)frame  
10: 75% of (micro)frame  
11: Reserved

Bits 23:16 Reserved, must be kept at reset value.

Bit 15 **ERRATIM:** Erratic error interrupt mask

1: Mask early suspend interrupt on erratic error  
0: Early suspend interrupt is generated on erratic error

Bit 14 Reserved, must be kept at reset value.

Bit 13 Reserved, must be kept at reset value.

Bits 12:11 **PFIVL[1:0]:** Periodic frame interval

Indicates the time within a frame at which the application must be notified using the end of periodic frame interrupt. This can be used to determine if all the isochronous traffic for that frame is complete.

00: 80% of the frame interval  
01: 85% of the frame interval  
10: 90% of the frame interval  
11: 95% of the frame interval

Bits 10:4 **DAD[6:0]:** Device address

The application must program this field after every SetAddress control command.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **NZLSOHSK:** Non-zero-length status OUT handshake

The application can use this field to select the handshake the core sends on receiving a nonzero-length data packet during the OUT transaction of a control transfer’s status stage.

1: Send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application.  
0: Send the received OUT packet to the application (zero-length or nonzero-length) and send a handshake based on the NAK and STALL bits for the endpoint in the device endpoint control register.
Bits 1:0 **DSPD[1:0]: Device speed**

Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected.

- 00: High speed
- 01: Full speed
- 10: Reserved
- 11: Reserved

Bits 31:19 Reserved, must be kept at reset value.

- **Bit 18 DSBESLRJCT:** Deep sleep BESL reject
  Core rejects LPM request with BESL value greater than BESL threshold programmed. NYET response is sent for LPM tokens with BESL value greater than BESL threshold. By default, the deep sleep BESL reject feature is disabled.

Bits 17:12 Reserved, must be kept at reset value.

- **Bit 11 POPRGDNE:** Power-on programming done
  The application uses this bit to indicate that register programming is completed after a wake-up from power down mode.

- **Bit 10 CGONAK:** Clear global OUT NAK
  Writing 1 to this field clears the Global OUT NAK.

- **Bit 9 SGNOK:** Set global OUT NAK
  Writing 1 to this field sets the Global OUT NAK.
The application uses this bit to send a NAK handshake on all OUT endpoints. The application must set this bit only after making sure that the Global OUT NAK effective bit in the core interrupt register (GONAKEFF bit in OTG_GINTSTS) is cleared.

- **Bit 8 CGINAK:** Clear global IN NAK
  Writing 1 to this field clears the Global IN NAK.

- **Bit 7 SGINAK:** Set global IN NAK
  Writing 1 to this field sets the Global non-periodic IN NAK. The application uses this bit to send a NAK handshake on all non-periodic IN endpoints. The application must set this bit only after making sure that the Global IN NAK effective bit in the core interrupt register (GINAKEFF bit in OTG_GINTSTS) is cleared.
Table 674 contains the minimum duration (according to device state) for which the Soft disconnect (SDIS) bit must be set for the USB host to detect a device disconnect. To accommodate clock jitter, it is recommended that the application add some extra delay to the specified minimum duration.

- **Bits 31:24** Reserved, must be kept at reset value.
- **Bits 23:22** **DEVLNSTS[1:0]:** Device line status
  - Indicating the current logic level USB data lines.
  - Bit [23]: Logic level of D+
  - Bit [22]: Logic level of D-
- **Bits 21:8** **FNSOF[13:0]:** Frame number of the received SOF
  - Bits 7:4 Reserved, must be kept at reset value.
- **Bit 3** **EERR:** Erratic error
  - The core sets this bit to report any erratic errors.
  - Due to erratic errors, the OTG_HS controller goes into suspended state and an interrupt is generated to the application with Early suspend bit of the OTG_GINTSTS register (ESUSP bit in OTG_GINTSTS). If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover.
- **Bits 2:1** **ENUMSPD[1:0]:** Enumerated speed
  - Indicates the speed at which the OTG_HS controller has come up after speed detection through a chirp sequence.
  - **00:** High Speed
  - **01:** Full Speed
  - **11:** Reserved
  - Others: reserved
- **Bit 0** **SUSPSTS:** Suspend status
  - In device mode, this bit is set as long as a suspend condition is detected on the USB. The core enters the suspended state when there is no activity on the USB data lines for a period of 3 ms. The core comes out of the suspend:
    - When there is an activity on the USB data lines
    - When the application writes to the remote wake-up signaling bit in the OTG_DCTL register (RWUSIG bit in OTG_DCTL).
62.14.41 OTG device IN endpoint common interrupt mask register (OTG_DIEPMSK)

This register works with each of the OTG_DIEPINTx registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the OTG_DIEPINTx register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

Address offset: 0x810

Reset value: 0x0000 0000

| Bit 31:14 | Reserved, must be kept at reset value. |
| Bit 13 | NAKM: NAK interrupt mask |
| 0 | Masked interrupt |
| 1 | Unmasked interrupt |

   Applies to control OUT endpoints only.
   0: Masked interrupt
   1: Unmasked interrupt
Bit 5 **STSPHRSRM**: Status phase received for control write mask
0: Masked interrupt
1: Unmasked interrupt

Bit 4 **OTEPDM**: OUT token received when endpoint disabled mask. Applies to control OUT endpoints only.
0: Masked interrupt
1: Unmasked interrupt

Bit 3 **STUPM**: SETUP phase done mask. Applies to control endpoints only.
0: Masked interrupt
1: Unmasked interrupt

Bit 2 **AHBERRM**: AHB error mask
0: Masked interrupt
1: Unmasked interrupt

Bit 1 **EPDM**: Endpoint disabled interrupt mask
0: Masked interrupt
1: Unmasked interrupt

Bit 0 **XFRCM**: Transfer completed interrupt mask
0: Masked interrupt
1: Unmasked interrupt

**62.14.43 OTG device all endpoints interrupt register (OTG_DAINT)**

When a significant event occurs on an endpoint, a OTG_DAINT register interrupts the application using the device OUT endpoints interrupt bit or device IN endpoints interrupt bit of the OTG_GINTSTS register (OEPINT or IEPINT in OTG_GINTSTS, respectively). There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding device endpoint-x interrupt register (OTG_DIEPINTx/OTG_DOEPINTx).

Address offset: 0x818
Reset value: 0x0000 0000

<tbody>
<tr>
<td>Bit 27</td>
<td>ARPEN: Arbiter parking enable</td>
</tr>
<tr>
<td>This bit controls internal DMA arbiter parking for IN endpoints. When thresholding is enabled and this bit is set to one, then the arbiter parks on the IN endpoint for which there is a token received on the USB. This is done to avoid getting into underrun conditions. By default parking is enabled.</td>
<td></td>
</tr>
<tr>
<td>Bit 26</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
Bits 25:17 **RXTHRLEN[8:0]:** Receive threshold length  
This field specifies the receive thresholding size in 32-bit words. This field also specifies the amount of data received on the USB before the core can start transmitting on the AHB. The threshold length has to be at least eight 32-bit words. The recommended value for RXTHRLEN is to be the same as the programmed AHB burst length (HBSTLEN bit in OTG_GAHBCFG).

Bit 16 **RXTHREN:** Receive threshold enable  
When this bit is set, the core enables thresholding in the receive direction.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:2 **TXTHRLEN[8:0]:** Transmit threshold length  
This field specifies the transmit thresholding size in 32-bit words. This field specifies the amount of data in bytes to be in the corresponding endpoint transmit FIFO before the core can start transmitting on the USB. The threshold length has to be at least eight 32-bit words. This field controls both isochronous and nonisochronous IN endpoint thresholds. The recommended value for TXTHRLEN is to be the same as the programmed AHB burst length (HBSTLEN bit in OTG_GAHBCFG).

Bit 1 **ISOTHREN:** ISO IN endpoint threshold enable  
When this bit is set, the core enables thresholding for isochronous IN endpoints.

Bit 0 **NONISOTHREN:** Nonisochronous IN endpoints threshold enable  
When this bit is set, the core enables thresholding for nonisochronous IN endpoints.

### 62.14.46 OTG device IN endpoint FIFO empty interrupt mask register  
(OTG_DIEPEMMPMSK)

This register is used to control the IN endpoint FIFO empty interrupt generation (TXFE_OTG_DIEPINTx).

#### Bit 31 EPENA: Endpoint enable
The application sets this bit to start transmitting data on an endpoint.
The core clears this bit before setting any of the following interrupts on this endpoint:
- SETUP phase done
- Endpoint disabled
- Transfer completed

#### Bit 30 EPDIS: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

#### Bit 29 SD1PID: Set DATA1 PID
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA1.

#### Bit 28 SD0PID: Set DATA0 PID
Applies to interrupt/bulk IN endpoints only.
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.

#### Bit 27 SNAK: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.

#### Bit 26 CNAK: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

#### Bits 25:22 TXFNUM[3:0]: Tx FIFO number
These bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number.
This field is valid only for IN endpoints.
Bit 21  **STALL**: STALL handshake  
Applies to non-control, non-isochronous IN endpoints only (access type is rw).  
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK  
bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority.  
Only the application can clear this bit, never the core.  

Bit 20  Reserved, must be kept at reset value.  

Bits 19:18  **EPTYP[1:0]**: Endpoint type  
This is the transfer type supported by this logical endpoint.  
00: Control  
01: Isochronous  
10: Bulk  
11: Interrupt  

Bit 17  **NAKSTS**: NAK status  
It indicates the following:  
0: The core is transmitting non-NAK handshakes based on the FIFO status.  
1: The core is transmitting NAK handshakes on this endpoint.  
When either the application or the core sets this bit:  
For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint,  
even if there are data available in the Tx FIFO.  
For isochronous IN endpoints: The core sends out a zero-length data packet, even if there  
are data available in the Tx FIFO.  
Irrespective of this bit’s setting, the core always responds to SETUP data packets with an  
ACK handshake.  

Bit 16  **DPID**: Endpoint data PID  
Applies to interrupt/bulk IN endpoints only.  
Contains the PID of the packet to be received or transmitted on this endpoint. The  
application must program the PID of the first packet to be received or transmitted on this  
endpoint, after the endpoint is activated. The application uses the SD0PID and SD1PID  
register fields to program either DATA0 or DATA1 PID.  
0: DATA0  
1: DATA1  

Bit 15  **USBAEP**: USB active endpoint  
Indicates whether this endpoint is active in the current configuration and interface. The core  
clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving  
the SetConfiguration and SetInterface commands, the application must program endpoint  
registers accordingly and set this bit.  

Bits 14:11  Reserved, must be kept at reset value.  

Bits 10:0  **MPSIZ[10:0]**: Maximum packet size  
The application must program this field with the maximum packet size for the current logical  
endpoint. This value is in bytes.
62.14.48 OTG device IN endpoint x control register [alternate] (OTG_DIEPCTLx)

Valid for ISO endpoints, see previous section for INT/BULK endpoints.

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

Address offset: 0x900 + 0x20 * x, (x = 0 to 8)
Reset value: 0x0000 0000

Bit 31 EPENA: Endpoint enable
The application sets this bit to start transmitting data on an endpoint.
The core clears this bit before setting any of the following interrupts on this endpoint:
– SETUP phase done
– Endpoint disabled
– Transfer completed

Bit 30 EPDIS: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before
the transfer for that endpoint is complete. The application must wait for the endpoint
disabled interrupt before treating the endpoint as disabled. The core clears this bit before
setting the endpoint disabled interrupt. The application must set this bit only if endpoint
enable is already set for this endpoint.

Bit 29 SODDFRM: Set odd frame
Applies to isochronous IN and OUT endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.

Bit 28 SEVNFRM: Set even frame
Applies to isochronous IN endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to even frame.

Bit 27 SNAK: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an
endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt,
or after a SETUP is received on the endpoint.

Bit 26 CNAK: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 TXFNUM[3:0]: Tx FIFO number
These bits specify the FIFO number associated with this endpoint. Each active IN endpoint
must be programmed to a separate FIFO number.
This field is valid only for IN endpoints.
Bit 21 **STALL**: STALL handshake

Applies to non-control, non-isochronous IN endpoints only (access type is rw).

The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **EPTYP[1:0]**: Endpoint type

This is the transfer type supported by this logical endpoint.

00: Control
01: Isochronous
10: Bulk
11: Interrupt

Bit 17 **NAKSTS**: NAK status

It indicates the following:

0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit:

For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there are data available in the Tx FIFO.

For isochronous IN endpoints: The core sends out a zero-length data packet, even if there are data available in the Tx FIFO.

Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 **EONUM**: Even/odd frame

Applies to isochronous IN endpoints only.

Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.

0: Even frame
1: Odd frame

Bit 15 **USBAEP**: USB active endpoint

Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size

The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.
62.14.49  OTG device IN endpoint x interrupt register (OTG_DIEPINTx)

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in Figure 921. The application must read this register when the IN endpoints interrupt bit of the core interrupt register (IEPINT in OTG_GINTSTS) is set. Before the application can read this register, it must first read the device all endpoints interrupt (OTG_DAINT) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.

Address offset: 0x908 + 0x20 * x, (x = 0 to 8)

Reset value: 0x0000 0080

<td>INEPNE: IN endpoint NAK effective</td>
</tr>
<tr>
<td>15</td>
<td>This bit can be cleared when the application clears the IN endpoint NAK by writing to the CNAK bit in OTG_DIEPCTLx. This interrupt indicates that the core has sampled the NAK bit set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.</td>
</tr>
</tbody>
</table>
Bit 5 **INEPNM**: IN token received with EP mismatch
 Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 4 **ITTXFE**: IN token received when Tx FIFO is empty
 Indicates that an IN token was received when the associated Tx FIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 3 **TOC**: Timeout condition
 Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint.

Bit 2 **AHBERR**: AHB error
 This is generated only in internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address.

Bit 1 **EPDISD**: Endpoint disabled interrupt
 This bit indicates that the endpoint is disabled per the application’s request.

Bit 0 **XFRC**: Transfer completed interrupt
 This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.

**62.14.50 OTG device IN endpoint 0 transfer size register (OTG_DIEPTSIZ0)**

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the device control endpoint 0 control registers (EPENA in OTG_DIEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–3.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 INEPTFSAV[15:0]: IN endpoint Tx FIFO space available
Indicates the amount of free space available in the endpoint Tx FIFO.
Values are in terms of 32-bit words:
0x0: Endpoint Tx FIFO is full
0x1: 1 word available
0x2: 2 words available
0xn: n words available
Others: Reserved
62.14.53 OTG device IN endpoint x transfer size register (OTG_DIEPTSIZx)

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using the endpoint enable bit in the OTG_DIEPCTLx registers (EPENA bit in OTG_DIEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

</tbody>
</table>

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 MCNT[1:0]: Multi count
For periodic IN endpoints, this field indicates the number of packets that must be transmitted per frame on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints.
01: 1 packet
10: 2 packets
11: 3 packets

Bits 28:19 PKTCNT[9:0]: Packet count
Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.
This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:0 XFRSIZ[18:0]: Transfer size
This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

62.14.54 OTG device control OUT endpoint 0 control register (OTG_DOEPCTL0)

This section describes the OTG_DOEPCTL0 register. Nonzero control endpoints use registers for endpoints 1–8.

Address offset: 0xB00
Reset value: 0x0000 8000
Bit 31 EPENA: Endpoint enable
The application sets this bit to start transmitting data on endpoint 0. The core clears this bit before setting any of the following interrupts on this endpoint:
- SETUP phase done
- Endpoint disabled
- Transfer completed

Bit 30 EPDIS: Endpoint disable
The application cannot disable control OUT endpoint 0.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 SNAK: Set NAK
A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 CNAK: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 STALL: STALL handshake
The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 20 SNPM: Snoop mode
This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.

Bits 19:18 EPTYP[1:0]: Endpoint type
Hardcoded to 00 for control.

Bit 17 NAKSTS: NAK status
Indicates the following:
0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.
When either the application or the core sets this bit, the core stops receiving data, even if there is space in the Rx FIFO to accommodate the incoming packet. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 Reserved, must be kept at reset value.

Bit 15 USBAEP: USB active endpoint
This bit is always set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces.
62.14.55 OTG device OUT endpoint x interrupt register (OTG_DOEPINTx)

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in Figure 921. The application must read this register when the OUT endpoints interrupt bit of the OTG_GINTSTS register (OEPINT bit in OTG_GINTSTS) is set. Before the application can read this register, it must first read the OTG_DAINT register to get the exact endpoint number for the OTG_DOEPINTx register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.

</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **STPKTRX:** Setup packet received
Applicable for control OUT endpoints in only in the Buffer DMA Mode. Set by the OTG_HS, this bit indicates that this buffer holds 8 bytes of setup data. There is only one setup packet per buffer. On receiving a setup packet, the OTG_HS closes the buffer and disables the corresponding endpoint after SETUP_COMPLETE status is seen in the Rx FIFO. OTG_HS puts a SETUP_COMPLETE status into the Rx FIFO when it sees the first IN or OUT token after the SETUP packet for that particular endpoint. The application must then re-enable the endpoint to receive any OUT data for the control transfer and reprogram the buffer start address. Because of the above behavior, OTG_HS can receive any number of back to back setup packets and one buffer for every setup packet is used.

Bit 14 **NYET:** NYET interrupt
This interrupt is generated when a NYET response is transmitted for a non isochronous OUT endpoint.

Bit 13 **NAK:** NAK input
The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.
Bit 12 **BERR**: Babble error interrupt
The core generates this interrupt when babble is received for the endpoint.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 **OUTPKTERR**: OUT packet error
This interrupt is asserted when the core detects an overflow or a CRC error for an OUT packet. This interrupt is valid only when thresholding is enabled.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **B2BSTUP**: Back-to-back SETUP packets received
Applies to control OUT endpoint only.
This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint.

Bit 5 **STSPHSRX**: Status phase received for control write
This interrupt is valid only for control OUT endpoints. This interrupt is generated only after OTG_HS has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a control write transfer. The application can use this interrupt to ACK or STALL the status phase, after it has decoded the data phase.

Bit 4 **OTEPDIS**: OUT token received when endpoint disabled
Applies only to control OUT endpoints.
Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received.

Bit 3 **STUP**: SETUP phase done
Applies to control OUT endpoint only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet.

Bit 2 **_AHBERR**: AHB error
This is generated only in internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address.

Bit 1 **EPDISD**: Endpoint disabled interrupt
This bit indicates that the endpoint is disabled per the application’s request.

Bit 0 **XFRC**: Transfer completed interrupt
This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.
62.14.56  **OTG device OUT endpoint 0 transfer size register (OTG_DOEPTSIZ0)**

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the OTG_DOEPCTL0 registers (EPENA bit in OTG_DOEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–8.

Bit 31 *EPENA*: Endpoint enable
Applies to IN and OUT endpoints.
The application sets this bit to start transmitting data on an endpoint.
The core clears this bit before setting any of the following interrupts on this endpoint:
– SETUP phase done
– Endpoint disabled
– Transfer completed

Bit 30 *EPDIS*: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.
Bit 29 **SD1PID**: Set DATA1 PID
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA1.

Bit 28 **SD0PID**: Set DATA0 PID
Applies to interrupt/bulk OUT endpoints only.
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.

Bit 27 **SNAK**: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **STALL**: STALL handshake
Applies to non-control, non-isochronous OUT endpoints only (access type is rw).
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.
Applies to control endpoints only (access type is rs).
The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 20 **SNPM**: Snoop mode
This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.

Bits 19:18 **EPTYP[1:0]**: Endpoint type
This is the transfer type supported by this logical endpoint.
00: Control
01: Isochronous
10: Bulk
11: Interrupt

Bit 17 **NAKSTS**: NAK status
Indicates the following:
0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.
When either the application or the core sets this bit:
The core stops receiving any data on an OUT endpoint, even if there is space in the Rx FIFO to accommodate the incoming packet.
Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.
Bit 16 **DPID**: Endpoint data PID  
Applies to interrupt/bulk OUT endpoints only.  
Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID and SD1PID register fields to program either DATA0 or DATA1 PID.  
0: DATA0  
1: DATA1

Bit 15 **USBAEP**: USB active endpoint  
Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size  
The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

### 62.14.59 OTG device OUT endpoint x control register [alternate]  
(OTG_DOEPCTLx)

Valid for ISO endpoints, see previous section for INT/BULK endpoints.

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

Address offset: 0xB00 + 0x20 * x, (x = 1 to 8)

Reset value: 0x0000 0000

| Bit 31 | EPENA: Endpoint enable | Applies to IN and OUT endpoints.  
The application sets this bit to start transmitting data on an endpoint.  
The core clears this bit before setting any of the following interrupts on this endpoint:  
– SETUP phase done  
– Endpoint disabled  
– Transfer completed |
Bit 30 **EPDIS**: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

Bit 29 **SODDFRM**: Set odd frame
Applies to isochronous IN and OUT endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.

Bit 28 **SEVNF RM**: Set even frame
Applies to isochronous OUT endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to even frame.

Bit 27 **SNAK**: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **STALL**: STALL handshake
Applies to non-control, non-isochronous OUT endpoints only (access type is rw).
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.
Applies to control endpoints only (access type is rs).
The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 20 **SNPM**: Snoop mode
This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.

Bits 19:18 **EPTYP[1:0]**: Endpoint type
This is the transfer type supported by this logical endpoint.
00: Control
01: Isochronous
10: Bulk
11: Interrupt

Bit 17 **NAKSTS**: NAK status
Indicates the following:
0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.
When either the application or the core sets this bit:
The core stops receiving any data on an OUT endpoint, even if there is space in the Rx FIFO to accommodate the incoming packet.
Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.
Bit 16 **EONUM**: Even/odd frame
Applies to isochronous OUT endpoints only.
Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.
0: Even frame
1: Odd frame

Bit 15 **USBAEP**: USB active endpoint
Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size
The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

### 62.14.60 OTG device OUT endpoint x transfer size register (OTG_DOEPTSIZx)

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using endpoint enable bit of the OTG_DOEPCTLx registers (EPENA bit in OTG_DOEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Address offset: 0xB10 + 0x20 * x, (x = 1 to 8)
Reset value: 0x0000 0000

**XFRSIZ[15:0]**

Bit 31: Reserved, must be kept at reset value.
USB on-the-go high-speed (OTG_HS)  

62.14.61 OTG power and clock gating control register (OTG_PCGCCTL)

This register is available in host and device modes.

Address offset: 0xE00

Reset value: 0x200B 8000

Bits 30:29 **RXDPID[1:0]:**
- **Condition:** isochronous OUT endpoints
- Received data PID
- This is the data PID received in the last packet for this endpoint.
- 00: DATA0
- 01: DATA2
- 10: DATA1
- 11: MDATA

**Condition:** control OUT endpoints

STUPCNT[1:0]: SETUP packet count
- This field specifies the number of back-to-back SETUP data packets the endpoint can receive.
- 01: 1 packet
- 10: 2 packets
- 11: 3 packets

Bits 28:19 **PKTCNT[9:0]:** Packet count
- Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.
- This field is decremented every time a packet (maximum size or short packet) is written to the Rx FIFO.

Bits 18:0 **XFRSIZ[18:0]:** Transfer size
- This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
- The core decrements this field every time a packet is read from the Rx FIFO and written to the external memory.

This register is available in host and device modes.

Address offset: 0xE00

Reset value: 0x200B 8000

### Bit 5 **ENL1GTG**: Enable sleep clock gating
When this bit is set, core internal clock gating is enabled in Sleep state if the core cannot assert utmi_i1_suspend_n. When this bit is not set, the PHY clock is not gated in Sleep state.

### Bit 4 **PHYSUSP**: PHY suspended
Indicates that the PHY has been suspended. This bit is updated once the PHY is suspended after the application has set the STPPCLK bit.

### Bits 3:2 Reserved, must be kept at reset value.

### Bit 1 **GATEHCLK**: Gate HCLK
The application sets this bit to gate HCLK to modules other than the AHB Slave and Master and wake-up logic when the USB is suspended or the session is not valid. The application clears this bit when the USB is resumed or a new session starts.

### Bit 0 **STPPCLK**: Stop PHY clock
The application sets this bit to stop the PHY clock when the USB is suspended, the session is not valid, or the device is disconnected. The application clears this bit when the USB is resumed or a new session starts.

### 62.14.62 OTG power and clock gating control register 1 (OTG_PCGCCTL1)

This register is available in host and device modes.

Refer to Section 2.3 on page 149 for the register boundary addresses.
62.15 OTG_HS programming model

62.15.1 Core initialization

The application must perform the core initialization sequence. If the cable is connected during power-up, the current mode of operation bit in the OTG_GINTSTS (CMOD bit in OTG_GINTSTS) reflects the mode. The OTG_HS controller enters host mode when an “A” plug is connected or device mode when a “B” plug is connected.

This section explains the initialization of the OTG_HS controller after power-on. The application must follow the initialization sequence irrespective of host or device mode operation. All core global registers are initialized according to the core’s configuration:

1. Program the following fields in the OTG_GAHBCFG register:
   - Global interrupt mask bit GINTMSK = 1
   - Rx FIFO non-empty (RXFLVL bit in OTG_GINTSTS)
   - Periodic Tx FIFO empty level

2. Program the following fields in the OTG_GUSBCFG register:
   - OTG_HS timeout calibration field
   - USB turnaround time field

3. The software must unmask the following bits in the OTG_GINTMSK register:
   - OTG interrupt mask
   - Mode mismatch interrupt mask

4. The software can read the CMOD bit in OTG_GINTSTS to determine whether the OTG_HS controller is operating in host or device mode.
62.15.2 Host initialization

To initialize the core as host, the application must perform the following steps:

1. Program the HPRTINT in the OTG_GINTMSK register to unmask
2. Program the OTG_HCFG register to select full-speed host
3. Program the PPWR bit in OTG_HPRT to 1. The port is now considered powered however this does not actually drive VBUS on the USB, so a further action must be taken to control the external circuitry in the system so as to enable VBUS generation.
4. Wait for the PCDET interrupt in OTG_HPRT0. This indicates that a device is connecting to the port.
5. Program the PRST bit in OTG_HPRT to 1. This starts the reset process.
6. Wait at least 10 ms for the reset process to complete.
7. Program the PRST bit in OTG_HPRT to 0.
8. Wait for the PENCHNG interrupt in OTG_HPRT.
9. Read the PSPD bit in OTG_HPRT to get the enumerated speed.
10. Program the HFIR register with a value corresponding to the selected PHY clock 1
11. Program the FSLSPCS field in the OTG_HCFG register following the speed of the device detected in step 9. If FSLSPCS has been changed a port reset must be performed.
12. Program the OTG_GRXFSIZ register to select the size of the receive FIFO.
13. Program the OTG_HNPTXFSIZ register to select the size and the start address of the Non-periodic transmit FIFO for non-periodic transactions.
14. Program the OTG_HPTXFSIZ register to select the size and start address of the periodic transmit FIFO for periodic transactions.

To communicate with devices, the system software must initialize and enable at least one channel.
62.15.3 Device initialization

The application must perform the following steps to initialize the core as a device on power-up or after a mode change from host to device.

1. Program the following fields in the OTG_DCFG register:
   - Device speed
   - Non-zero-length status OUT handshake
   - Periodic Frame Interval

2. Program the Device threshold control register. This is required only if you are using DMA mode and you are planning to enable thresholding.

3. Clear the DCTL.SDIS bit. The core issues a connect after this bit is cleared.

4. Program the OTG_GINTMSK register to unmask the following interrupts:
   - USB reset
   - Enumeration done
   - Early suspend
   - USB suspend
   - SOF

5. Wait for the USBRST interrupt in OTG_GINTSTS. It indicates that a reset has been detected on the USB that lasts for about 10 ms on receiving this interrupt.

6. Wait for the ENUMDNE interrupt in OTG_GINTSTS. This interrupt indicates the end of reset on the USB. On receiving this interrupt, the application must read the OTG_DSTS register to determine the enumeration speed and perform the steps listed in Endpoint initialization on enumeration completion on page 3199.

At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0.

62.15.4 DMA mode

The OTG host uses the AHB master interface to fetch the transmit packet data (AHB to USB) and receive the data update (USB to AHB). The AHB master uses the programmed DMA address (OTG_HCDMAx register in host mode and OTG_DIEPDMAx/OTG_DOEPDMAx register in peripheral mode) to access the data buffers.

62.15.5 Host programming model

Channel initialization

The application must initialize one or more channels before it can communicate with connected devices. To initialize and enable a channel, the application must perform the following steps:
1. Program the OTG_GINTMSK register to unmask the following:

2. Channel interrupt
   - Non-periodic transmit FIFO empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
   - Non-periodic transmit FIFO half-empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).

3. Program the OTG_HAINTMSK register to unmask the selected channels' interrupts.

4. Program the OTG_HCINTMSK register to unmask the transaction-related interrupts of interest given in the host channel interrupt register.

5. Program the selected channel’s OTG_HCTSiZx register with the total transfer size, in bytes, and the expected number of packets, including short packets. The application must program the PID field with the initial data PID (to be used on the first OUT transaction or to be expected from the first IN transaction).

6. Program the OTG_HCCHARx register of the selected channel with the device’s endpoint characteristics, such as type, speed, direction, and so forth. (The channel can be enabled by setting the channel enable bit to 1 only when the application is ready to transmit or receive any packet).

7. Program the selected channels in the OTG_HCSPLTx register(s) with the hub and port addresses (split transactions only).

8. Program the selected channels in the OTG_HCDMAx register(s) with the buffer start address (DMA transactions only).

### Halting a channel

The application can disable any channel by programming the OTG_HCCHARx register with the CHDIS and CHENA bits set to 1. This enables the OTG_HS host to flush the posted requests (if any) and generates a channel halted interrupt. The application must wait for the CHH interrupt in OTG_HCINTx before reallocating the channel for other transactions. The OTG_HS host does not interrupt the transaction that has already been started on the USB.

To disable a channel in DMA mode operation, the application does not need to check for space in the request queue. The OTG_HS host checks for space to write the disable request on the disabled channel’s turn during arbitration. Meanwhile, all posted requests are dropped from the request queue when the CHDIS bit in OTG_HCCHARx is set to 1.

Before disabling a channel, the application must ensure that there is at least one free space available in the non-periodic request queue (when disabling a non-periodic channel) or the periodic request queue (when disabling a periodic channel). The application can simply flush the posted requests when the request queue is full (before disabling the channel), by programming the OTG_HCCHARx register with the CHDIS bit set to 1 which automatically clears the CHENA bit to 0.

The application is expected to disable a channel on any of the following conditions:
1. When an STALL, TXERR, BBERR or DTERR interrupt in OTG_HCINTx is received for an IN or OUT channel. The application must be able to receive other interrupts (DTERR, Nak, data, TXERR) for the same channel before receiving the halt.

2. When an XFRC interrupt in OTG_HCINTx is received during a non periodic IN transfer or high-bandwidth interrupt IN transfer.

3. When a DISCINT (disconnect device) interrupt in OTG_GINTSTS is received. (The application is expected to disable all enabled channels).

4. When the application aborts a transfer before normal completion.

**Ping protocol**

When the OTG_HS host operates in high speed, the application must initiate the ping protocol when communicating with high-speed bulk or control (data and status stage) OUT endpoints. The application must initiate the ping protocol when it receives a NAK/NYET/TXERR interrupt. When the OTG_HS host receives one of the above responses, it does not continue any transaction for a specific endpoint, drops all posted or fetched OUT requests (from the request queue), and flushes the corresponding data (from the transmit FIFO). This is valid in slave mode only. In Slave mode, the application can send a ping token either by setting the DOPING bit in OTG_HCTSIZx before enabling the channel or by just writing the OTG_HCTSIZx register with the DOPING bit set when the channel is already enabled. This enables the OTG_HS host to write a ping request entry to the request queue. The application must wait for the response to the ping token (a NAK, ACK, or TXERR interrupt) before continuing the transaction or sending another ping token. The application can continue the data transaction only after receiving an ACK from the OUT endpoint for the requested ping. In DMA mode operation, the application does not need to set the DOPING bit in OTG_HCTSIZx for a NAK/NYET response in case of bulk/control OUT. The OTG_HS host automatically sets the DOPING bit in OTG_HCTSIZx, and issues the ping tokens for bulk/control OUT. The OTG_HS host continues sending ping tokens until it receives an ACK, and then switches automatically to the data transaction.

**Operational model**

The application must initialize a channel before communicating to the connected device. This section explains the sequence of operation to be performed for different types of USB transactions.

- **Writing the transmit FIFO**
  The OTG_HS host automatically writes an entry (OUT request) to the periodic/non-periodic request queue, along with the last 32-bit word write of a packet. The application must ensure that at least one free space is available in the periodic/non-periodic request queue before starting to write to the transmit FIFO. The application must always write to the transmit FIFO in 32-bit words. If the packet size is non-32-bit word aligned, the application must use padding. The OTG_HS host determines the actual packet size based on the programmed maximum packet size and transfer size.
• **Reading the receive FIFO**

  The application must ignore all packet statuses other than IN data packet (0x0010).
• **Bulk and control OUT/SETUP transactions**

A typical bulk or control OUT/SETUP pipelined transaction-level operation is shown in Figure 924. See channel 1 (ch_1). Two bulk OUT packets are transmitted. A control SETUP transaction operates in the same way but has only one packet. The assumptions are:

- The application is attempting to send two maximum-packet-size packets (transfer size = 1, 024 bytes).
- The non-periodic transmit FIFO can hold two packets (1 Kbyte for HS).
- The non-periodic request queue depth = 4.

• **Normal bulk and control OUT/SETUP operations**

The sequence of operations in (channel 1) is as follows:

1. Initialize channel 1
2. Write the first packet for channel 1
3. Along with the last word write, the core writes an entry to the non-periodic request queue
4. As soon as the non-periodic queue becomes non-empty, the core attempts to send an OUT token in the current frame
5. Write the second (last) packet for channel 1
6. The core generates the XFRC interrupt as soon as the last transaction is completed successfully
7. In response to the XFRC interrupt, de-allocate the channel for other transfers
8. Handling non-ACK responses
Figure 924. Normal bulk/control OUT/SETUP

1. The grayed elements are not relevant in the context of this figure.
The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions is shown in the following code samples.

- **Interrupt service routine for bulk/control OUT/SETUP and bulk/control IN transactions**
  a) Bulk/control OUT/SETUP

```c
Unmask (NAK/TXERR/STALL/XFRC)
if (XFRC)
{
    Reset Error Count
    Mask ACK
    De-allocate Channel
}
else if (STALL)
{
    Transfer Done = 1
    Unmask CHH
    Disable Channel
}
else if (NAK or TXERR )
{
    Rewind Buffer Pointers
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
    else
    {
        Reset Error Count
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}
```
else if (ACK)
{
    Reset Error Count
    Mask ACK
}

The application is expected to write the data packets into the transmit FIFO when the space is available in the transmit FIFO and the request queue. The application can make use of the NPTXFE interrupt in OTG_GINTSTS to find the transmit FIFO space.

b) Bulk/control IN

Unmask (TXERR/XFRC/BBERR/STALL/DERR)
if (XFRC)
{
    Reset Error Count
    Unmask CHH
    Disable Channel
    Reset Error Count
    Mask ACK
}
else if (TXERR or BBERR or STALL)
{
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}
else if (ACK)
{
    Reset Error Count
    Mask ACK
}
else if (DTERR)
{
    Reset Error Count
}

The application is expected to write the requests as and when the request queue space is available and until the XFRC interrupt is received.

- **Bulk and control IN transactions**

  A typical bulk or control IN pipelined transaction-level operation is shown in Figure 925. See channel 2 (ch_2). The assumptions are:
  
  - The application is attempting to receive two maximum-packet-size packets (transfer size = 1024 bytes).
  - The receive FIFO can contain at least one maximum-packet-size packet and two status words per packet (520 bytes for HS).
  - The non-periodic request queue depth = 4.
Figure 925. Bulk/control IN transactions

1. The grayed elements are not relevant in the context of this figure.
The sequence of operations is as follows:

1. Initialize channel 2.
2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the non-periodic request queue.
3. The core attempts to send an IN token after completing the current OUT transaction.
4. The core generates an RXFLVL interrupt as soon as the received packet is written to the receive FIFO.
5. In response to the RXFLVL interrupt, mask the RXFLVL interrupt and read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. Following this, unmask the RXFLVL interrupt.
6. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO.
7. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in OTG_GRXSTSR ≠ 0b0010).
8. The core generates the XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, disable the channel and stop writing the OTG_HCCHAR2 register for further requests. The core writes a channel disable request to the non-periodic request queue as soon as the OTG_HCCHAR2 register is written.
10. The core generates the RXFLVL interrupt as soon as the halt status is written to the receive FIFO.
11. Read and ignore the receive packet status.
12. The core generates a CHH interrupt as soon as the halt status is popped from the receive FIFO.
13. In response to the CHH interrupt, de-allocate the channel for other transfers.
14. Handling non-ACK responses

• Control transactions

Setup, data, and status stages of a control transfer must be performed as three separate transfers. Setup-, data- or status-stage OUT transactions are performed similarly to the bulk OUT transactions explained previously. Data- or status-stage IN transactions are performed similarly to the bulk IN transactions explained previously. For all three stages, the application is expected to set the EPTYP field in
OTG_HCCHAR1 to control. During the setup stage, the application is expected to set the PID field in OTG_HCTSIZ1 to SETUP.

- **Interrupt OUT transactions**

  A typical interrupt OUT operation is shown in *Figure 926*. The assumptions are:
  - The application is attempting to send one packet in every frame (up to 1 maximum packet size), starting with the odd frame (transfer size = 1 024 bytes)
  - The periodic transmit FIFO can hold one packet (1 Kbyte)
  - Periodic request queue depth = 4

  The sequence of operations is as follows:

1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG_HCCHAR1.
2. Write the first packet for channel 1.
3. Along with the last word write of each packet, the OTG_HS host writes an entry to the periodic request queue.
4. The OTG_HS host attempts to send an OUT token in the next (odd) frame.
5. The OTG_HS host generates an XFRC interrupt as soon as the last packet is transmitted successfully.
6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
1. The grayed elements are not relevant in the context of this figure.

• Interrupt IN transactions
  The assumptions are:
  – The application is attempting to receive one packet (up to 1 maximum packet size) in every frame, starting with odd (transfer size = 1 024 bytes).
  – The receive FIFO can hold at least one maximum-packet-size packet and two status words per packet (1 031 bytes).
  – Periodic request queue depth = 4.

• Normal interrupt IN operation
  The sequence of operations is as follows:
  1. Initialize channel 2. The application must set the ODDFRM bit in OTG_HCCHAR2.
  2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the periodic request queue.
  3. The OTG_HS host writes an IN request to the periodic request queue for each OTG_HCCHAR2 register write with the CHENA bit set.
  4. The OTG_HS host attempts to send an IN token in the next (odd) frame.
  5. As soon as the IN packet is received and written to the receive FIFO, the OTG_HS host generates an RXFLVL interrupt.
  6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask after reading the entire packet.
  7. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in GRXSTSR ≠ 0b0010).
  8. The core generates an XFRC interrupt as soon as the receive packet status is read.
  9. In response to the XFRC interrupt, read the PKTCNT field in OTG_HCTSIZ2. If the PKTCNT bit in OTG_HCTSIZ2 is not equal to 0, disable the channel before re-
initializing the channel for the next transfer, if any). If PKTCNT bit in OTG_HCTSIZ2 = 0, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG_HCCHAR2.
1. The grayed elements are not relevant in the context of this figure.

- **Isochronous OUT transactions**

  A typical isochronous OUT operation is shown in Figure 928. The assumptions are:
  
  - The application is attempting to send one packet every frame (up to 1 maximum
packet size), starting with an odd frame. (transfer size = 1 024 bytes).

– The periodic transmit FIFO can hold one packet (1 Kbyte).
– Periodic request queue depth = 4.

The sequence of operations is as follows:

1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG_HCCHAR1.
2. Write the first packet for channel 1.
3. Along with the last word write of each packet, the OTG_HS host writes an entry to the periodic request queue.
4. The OTG_HS host attempts to send the OUT token in the next frame (odd).
5. The OTG_HS host generates the XFRC interrupt as soon as the last packet is transmitted successfully.
6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
7. Handling non-ACK responses

- **Isochronous IN transactions**
  The assumptions are:
  - The application is attempting to receive one packet (up to 1 maximum packet size) in every frame starting with the next odd frame (transfer size = 1 024 bytes).
  - The receive FIFO can hold at least one maximum-packet-size packet and two status word per packet (1 031 bytes).
  - Periodic request queue depth = 4.

  The sequence of operations is as follows:
  1. Initialize channel 2. The application must set the ODDFRM bit in OTG_HCCHAR2.
  2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the periodic request queue.
  3. The OTG_HS host writes an IN request to the periodic request queue for each OTG_HCCHAR2 register write with the CHENA bit set.
  4. The OTG_HS host attempts to send an IN token in the next odd frame.
  5. As soon as the IN packet is received and written to the receive FIFO, the OTG_HS host generates an RXFLVL interrupt.
  6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask it after reading the entire packet.
  7. The core generates an RXFLVL interrupt for the transfer completion status entry in the receive FIFO. This time, the application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS bit in OTG_GRXSTSR ≠ 0b0010).
  8. The core generates an XFRC interrupt as soon as the receive packet status is read.
  9. In response to the XFRC interrupt, read the PKTCNT field in OTG_HCTSIZ2. If PKTCNT ≠ 0 in OTG_HCTSIZ2, disable the channel before re-initializing the channel for the next transfer, if any. If PKTCNT = 0 in OTG_HCTSIZ2, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG_HCCHAR2.
Figure 929. Isochronous IN transactions

1. The grayed elements are not relevant in the context of this figure.

**Selecting the queue depth**

Choose the periodic and non-periodic request queue depths carefully to match the number of periodic/non-periodic endpoints accessed.

The non-periodic request queue depth affects the performance of non-periodic
transfers. The deeper the queue (along with sufficient FIFO size), the more often the core is able to pipeline non-periodic transfers. If the queue size is small, the core is able to put in new requests only when the queue space is freed up.

The core’s periodic request queue depth is critical to perform periodic transfers as scheduled. Select the periodic queue depth, based on the number of periodic transfers scheduled in a microframe. If the periodic request queue depth is smaller than the periodic transfers scheduled in a microframe, a frame overrun condition occurs.

- **Handling babble conditions**
  
  OTG_HS controller handles two cases of babble: packet babble and port babble. Packet babble occurs if the device sends more data than the maximum packet size for the channel. Port babble occurs if the core continues to receive data from the device at EOF2 (the end of frame 2, which is very close to SOF).

  When OTG_HS controller detects a packet babble, it stops writing data into the Rx buffer and waits for the end of packet (EOP). When it detects an EOP, it flushes already written data in the Rx buffer and generates a Babble interrupt to the application.

  When OTG_HS controller detects a port babble, it flushes the Rx FIFO and disables the port. The core then generates a port disabled interrupt (HPRTINT in OTG_GINTSTS, PENCHNG in OTG_HPRT). On receiving this interrupt, the application must determine that this is not due to an overcurrent condition (another cause of the port disabled interrupt) by checking POCA in OTG_HPRT, then perform a soft reset. The core does not send any more tokens after it has detected a port babble condition.

- **Bulk and control OUT/SETUP transactions in DMA mode**
  
  The sequence of operations is as follows:

  1. Initialize and enable channel 1 as explained in Section: Channel initialization.
  2. The OTG_HS host starts fetching the first packet as soon as the channel is enabled. For internal DMA mode, the OTG_HS host uses the programmed DMA address to fetch the packet.
  3. After fetching the last 32-bit word of the second (last) packet, the OTG_HS host masks channel 1 internally for further arbitration.
  4. The OTG_HS host generates a CHH interrupt as soon as the last packet is sent.
  5. In response to the CHH interrupt, de-allocate the channel for other transfers.
**NAK and NYET handling with internal DMA:**

1. The OTG_HS host sends a bulk OUT transaction.
2. The device responds with NAK or NYET.
3. If the application has unmasked NAK or NYET, the core generates the corresponding interrupt(s) to the application. The application is not required to service these interrupts, since the core takes care of rewinding the buffer pointers and re-initializing the Channel without application intervention.
4. The core automatically issues a ping token.
5. When the device returns an ACK, the core continues with the transfer. Optionally, the application can utilize these interrupts, in which case the NAK or NYET interrupt is masked by the application.
The core does not generate a separate interrupt when NAK or NYET is received by the host functionality.

- **Bulk and control IN transactions in DMA mode**
  The sequence of operations is as follows:
  1. Initialize and enable the used channel (channel x) as explained in Section: Channel initialization.
  2. The OTG_HS host writes an IN request to the request queue as soon as the channel receives the grant from the arbiter (arbitration is performed in a round-robin fashion).
  3. The OTG_HS host starts writing the received data to the system memory as soon as the last byte is received with no errors.
  4. When the last packet is received, the OTG_HS host sets an internal flag to remove any extra IN requests from the request queue.
  5. The OTG_HS host flushes the extra requests.
  6. The final request to disable channel x is written to the request queue. At this point, channel 2 is internally masked for further arbitration.
  7. The OTG_HS host generates the CHH interrupt as soon as the disable request comes to the top of the queue.
  8. In response to the CHH interrupt, de-allocate the channel for other transfers.
Interrupt OUT transactions in DMA mode

1. Initialize and enable channel x as explained in Section : Channel initialization.
2. The OTG_HS host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last 32-bit word fetch. In high-bandwidth transfers, the OTG_HS host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.
3. The OTG_HS host attempts to send the OUT token at the beginning of the next odd HS frame/micro-frame.
4. After successfully transmitting the packet, the OTG_HS host generates a CHH interrupt.
5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 932. Normal interrupt OUT transactions - DMA mode**

- **Interrupt IN transactions in DMA mode**
  The sequence of operations (channelx) is as follows:
  1. Initialize and enable channel x as explained in *Section: Channel initialization*.
  2. The OTG_HS host writes an IN request to the request queue as soon as the channel x gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the OTG_HS host writes consecutive writes up to MC times.
3. The OTG_HS host attempts to send an IN token at the beginning of the next (odd) frame/micro-frame.
4. As soon the packet is received and written to the receive FIFO, the OTG_HS host generates a CHH interrupt.
5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 93. Normal interrupt IN transactions - DMA mode**

- **Isochronous OUT transactions in DMA mode**
  1. Initialize and enable channel x as explained in Section: Channel initialization.
  2. The OTG_HS host starts fetching the first packet as soon as the channel is enabled, and writes the OUT request along with the last 32-bit word fetch. In high-bandwidth
transfers, the OTG_HS host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.

3. The OTG_HS host attempts to send an OUT token at the beginning of the next (odd) frame/micro-frame.

4. After successfully transmitting the packet, the OTG_HS host generates a CHH interrupt.

5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 934. Normal isochronous OUT transaction - DMA mode**

- **Isochronous IN transactions in DMA mode**
  
  The sequence of operations ((channel x) is as follows:
  
  1. Initialize and enable channel x as explained in *Section: Channel initialization*.
  2. The OTG_HS host writes an IN request to the request queue as soon as the channel x gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the OTG_HS host performs consecutive write operations up to MC times.
3. The OTG_HS host attempts to send an IN token at the beginning of the next (odd) frame/micro-frame.
4. As soon the packet is received and written to the receive FIFO, the OTG_HS host generates a CHH interrupt.
5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

![Figure 935. Normal isochronous IN transactions - DMA mode](image)

- **Bulk and control OUT/SETUP split transactions in DMA mode**
  The sequence of operations in (channel x) is as follows:
  1. Initialize and enable channel x for start split as explained in *Section : Channel initialization*.
  2. The OTG_HS host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last 32-bit word fetch.
  3. After successfully transmitting start split, the OTG_HS host generates the CHH interrupt.
  4. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT1 to send the complete split.
5. After successfully transmitting complete split, the OTG_HS host generates the CHH interrupt.
6. In response to the CHH interrupt, de-allocate the channel.

**Bulk/control IN split transactions in DMA mode**

The sequence of operations (channel x) is as follows:

1. Initialize and enable channel x as explained in [Section: Channel initialization].
2. The OTG_HS host writes the start split request to the nonperiodic request after getting the grant from the arbiter. The OTG_HS host masks the channel x internally for the arbitration after writing the request.
3. As soon as the IN token is transmitted, the OTG_HS host generates the CHH interrupt.
4. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT2 and re-enable the channel to send the complete split token. This unmask channel x for arbitration.
5. The OTG_HS host writes the complete split request to the nonperiodic request after receiving the grant from the arbiter.
6. The OTG_HS host starts writing the packet to the system memory after receiving the packet successfully.
7. As soon as the received packet is written to the system memory, the OTG_HS host generates a CHH interrupt.
8. In response to the CHH interrupt, de-allocate the channel.

**Interrupt OUT split transactions in DMA mode**

The sequence of operations in (channel x) is as follows:

1. Initialize and enable channel 1 for start split as explained in [Section: Channel initialization]. The application must set the ODDFRM bit in OTG_HCCHAR1.
2. The OTG_HS host starts reading the packet.
3. The OTG_HS host attempts to send the start split transaction.
4. After successfully transmitting the start split, the OTG_HS host generates the CHH interrupt.
5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT1 to send the complete split.
6. After successfully completing the complete split transaction, the OTG_HS host generates the CHH interrupt.
7. In response to CHH interrupt, de-allocate the channel.

**Interrupt IN split transactions in DMA mode**

The sequence of operations in (channel x) is as follows:

1. Initialize and enable channel x for start split as explained in [Section: Channel initialization].
2. The OTG_HS host writes an IN request to the request queue as soon as channel x receives the grant from the arbiter.
3. The OTG_HS host attempts to send the start split IN token at the beginning of the next odd micro-frame.
4. The OTG_HS host generates the CHH interrupt after successfully transmitting the start split IN token.
5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT2 to send the complete split.
6. As soon as the packet is received successfully, the OTG_HS host starts writing the data to the system memory.

7. The OTG_HS host generates the CHH interrupt after transferring the received data to the system memory.

8. In response to the CHH interrupt, de-allocate or reinitialize the channel for the next start split.

- **Isochronous OUT split transactions in DMA mode**
  The sequence of operations (channel x) is as follows:
  1. Initialize and enable channel x for start split (begin) as explained in *Section : Channel initialization*. The application must set the ODDFRM bit in OTG_HCCHAR1. Program the MPS field.
  2. The OTG_HS host starts reading the packet.
  3. After successfully transmitting the start split (begin), the OTG_HS host generates the CHH interrupt.
  4. In response to the CHH interrupt, reinitialize the registers to send the start split (end).
  5. After successfully transmitting the start split (end), the OTG_HS host generates a CHH interrupt.
  6. In response to the CHH interrupt, de-allocate the channel.

- **Isochronous IN split transactions in DMA mode**
  The sequence of operations (channel x) is as follows:
  1. Initialize and enable channel x for start split as explained in *Section : Channel initialization*.
  2. The OTG_HS host writes an IN request to the request queue as soon as channel x receives the grant from the arbiter.
  3. The OTG_HS host attempts to send the start split IN token at the beginning of the next odd micro-frame.
  4. The OTG_HS host generates the CHH interrupt after successfully transmitting the start split IN token.
  5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT2 to send the complete split.
  6. As soon as the packet is received successfully, the OTG_HS host starts writing the data to the system memory. The OTG_HS host generates the CHH interrupt after transferring the received data to the system memory. In response to the CHH interrupt, de-allocate the channel or reinitialize the channel for the next start split.
62.15.6 Device programming model

Endpoint initialization on USB reset

1. Set the NAK bit for all OUT endpoints
   – SNAK = 1 in OTG_DOEPCTLx (for all OUT endpoints)
2. Unmask the following interrupt bits
   – INEP0 = 1 in OTG_DAINTMSK (control 0 IN endpoint)
   – OUTEP0 = 1 in OTG_DAINTMSK (control 0 OUT endpoint)
   – STUPM = 1 in OTG_DOEPMSK
   – XFRCM = 1 in OTG_DOEPMSK
   – XFRCM = 1 in OTG_DIEPMSK
   – TOM = 1 in OTG_DIEPMSK
3. Set up the data FIFO RAM for each of the FIFOs
   – Program the OTG_GRXFSIZ register, to be able to receive control OUT data and setup data. If thresholding is not enabled, at a minimum, this must be equal to 1 max packet size of control endpoint 0 + 2 words (for the status of the control OUT data packet) + 10 words (for setup packets).
   – Program the OTG_DIEPTXF0 register (depending on the FIFO number chosen) to be able to transmit control IN data. At a minimum, this must be equal to 1 max packet size of control endpoint 0.
4. Program the following fields in the endpoint-specific registers for control OUT endpoint 0 to receive a SETUP packet
   – STUPCNT = 3 in OTG_DOEPTSIZ0 (to receive up to 3 back-to-back SETUP packets)
5. For USB OTG_HS in DMA mode, the OTG_DOEPDMA0 register must have a valid memory address to store any SETUP packets received.

At this point, all initialization required to receive SETUP packets is done.

Endpoint initialization on enumeration completion

1. On the Enumeration Done interrupt (ENUMDNE in OTG_GINTSTS), read the OTG_DSTS register to determine the enumeration speed.
2. Program the MPSIZ field in OTG_DIEPCTL0 to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for a control endpoint depends on the enumeration speed.
3. For USB OTG_HS in DMA mode, program the OTG_DOEPCTL0 register to enable control OUT endpoint 0, to receive a SETUP packet.

At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

Endpoint initialization on SetAddress command

This section describes what the application must do when it receives a SetAddress command in a SETUP packet.

1. Program the OTG_DCFG register with the device address received in the SetAddress command
2. Program the core to send out a status IN packet
Endpoint initialization on SetConfiguration/SetInterface command

This section describes what the application must do when it receives a SetConfiguration or SetInterface command in a SETUP packet.

1. When a SetConfiguration command is received, the application must program the endpoint registers to configure them with the characteristics of the valid endpoints in the new configuration.

2. When a SetInterface command is received, the application must program the endpoint registers of the endpoints affected by this command.

3. Some endpoints that were active in the prior configuration or alternate setting are not valid in the new configuration or alternate setting. These invalid endpoints must be deactivated.

4. Unmask the interrupt for each active endpoint and mask the interrupts for all inactive endpoints in the OTG_DAINTMSK register.

5. Set up the data FIFO RAM for each FIFO.

6. After all required endpoints are configured; the application must program the core to send a status IN packet.

At this point, the device core is configured to receive and transmit any type of data packet.

Endpoint activation

This section describes the steps required to activate a device endpoint or to configure an existing device endpoint to a new type.

1. Program the characteristics of the required endpoint into the following fields of the OTG_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG_DOEPCTLx register (for OUT or bidirectional endpoints).
   - Maximum packet size
   - USB active endpoint = 1
   - Endpoint start data toggle (for interrupt and bulk endpoints)
   - Endpoint type
   - Tx FIFO number

2. Once the endpoint is activated, the core starts decoding the tokens addressed to that endpoint and sends out a valid handshake for each valid token received for the endpoint.

Endpoint deactivation

This section describes the steps required to deactivate an existing endpoint.

1. In the endpoint to be deactivated, clear the USB active endpoint bit in the OTG_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG_DOEPCTLx register (for OUT or bidirectional endpoints).

2. Once the endpoint is deactivated, the core ignores tokens addressed to that endpoint, which results in a timeout on the USB.

Note: The application must meet the following conditions to set up the device core to handle traffic:

NPTXFEM and RXFLVLM in the OTG_GINTMSK register must be cleared.
Operational model

SETUP and OUT data transfers:

This section describes the internal data flow and application-level operations during data OUT transfers and SETUP transactions.

- Packet read

This section describes how to read packets (OUT data and SETUP packets) from the receive FIFO.

1. On catching an RXFLVL interrupt (OTG_GINTSTS register), the application must read the receive status pop register (OTG_GRXSTSP).

2. The application can mask the RXFLVL interrupt (in OTG_GINTSTS) by writing to RXFLVLM = 0 (in OTG_GINTMSK), until it has read the packet from the receive FIFO.

3. If the received packet’s byte count is not 0, the byte count amount of data is popped from the receive data FIFO and stored in memory. If the received packet byte count is 0, no data is popped from the receive data FIFO.

4. The receive status readout of the packet of FIFO indicates one of the following:
   a) Global OUT NAK pattern:
      PKTSTS = Global OUT NAK, BCNT = 0x000, EPNUM = (0x0), DPID = (0b00).
      These data indicate that the global OUT NAK bit has taken effect.
   b) SETUP packet pattern:
      PKTSTS = SETUP, BCNT = 0x008, EPNUM = Control EP Num, DPID = DATA0. These data indicate that a SETUP packet for the specified endpoint is now available for reading from the receive FIFO.
   c) Setup stage done pattern:
      PKTSTS = Setup Stage Done, BCNT = 0x0, EPNUM = Control EP Num, DPID = (0b00).
      These data indicate that the setup stage for the specified endpoint has completed and the data stage has started. After this entry is popped from the receive FIFO, the core asserts a setup interrupt on the specified control OUT endpoint.
   d) Data OUT packet pattern:
      PKTSTS = DataOUT, BCNT = size of the received data OUT packet (0 ≤ BCNT ≤ 1 024), EPNUM = EPNUM on which the packet was received, DPID = Actual Data PID.
   e) Data transfer completed pattern:
      PKTSTS = Data OUT transfer done, BCNT = 0x0, EPNUM = OUT EP Num on which the data transfer is complete, DPID = (0b00).
      These data indicate that an OUT data transfer for the specified OUT endpoint has completed. After this entry is popped from the receive FIFO, the core asserts a transfer completed interrupt on the specified OUT endpoint.

5. After the data payload is popped from the receive FIFO, the RXFLVL interrupt (OTG_GINTSTS) must be unmasked.

6. Steps 1–5 are repeated every time the application detects assertion of the interrupt line due to RXFLVL in OTG_GINTSTS. Reading an empty receive FIFO can result in undefined core behavior.

*Figure 936* provides a flowchart of the above procedure.
SETUP transactions

This section describes how the core handles SETUP packets and the application's sequence for handling SETUP transactions.

- **Application requirements**
  1. To receive a SETUP packet, the STUPCNT field (OTG_DOEPTSIZx) in a control OUT endpoint must be programmed to a non-zero value. When the application programs the STUPCNT field to a non-zero value, the core receives SETUP packets and writes them to the receive FIFO, irrespective of the NAK status and EPENA bit setting in OTG_DOEPCTLx. The STUPCNT field is decremented every time the control endpoint receives a SETUP packet. If the STUPCNT field is not programmed to a proper value before receiving a SETUP packet, the core still receives the SETUP packet and decrements the STUPCNT field, but the application may not be able to determine the correct number of SETUP packets received in the setup stage of a control transfer.
    - STUPCNT = 3 in OTG_DOEPTSIZx
  2. The application must always allocate some extra space in the receive data FIFO, to be able to receive up to three SETUP packets on a control endpoint.
    - The space to be reserved is 10 words. Three words are required for the first SETUP packet, 1 word is required for the setup stage done word and 6 words are required to store two extra SETUP packets among all control endpoints.
    - 3 words per SETUP packet are required to store 8 bytes of SETUP data and 4 bytes of SETUP status (setup packet pattern). The core reserves this space in the
receive data FIFO to write SETUP data only, and never uses this space for data packets.

3. The application must read the 2 words of the SETUP packet from the receive FIFO.
4. The application must read and discard the setup stage done word from the receive FIFO.

- **Internal data flow**
  1. When a SETUP packet is received, the core writes the received data to the receive FIFO, without checking for available space in the receive FIFO and irrespective of the endpoint's NAK and STALL bit settings.
     - The core internally sets the IN NAK and OUT NAK bits for the control IN/OUT endpoints on which the SETUP packet was received.
  2. For every SETUP packet received on the USB, 3 words of data are written to the receive FIFO, and the STUPCNT field is decremented by 1.
     - The first word contains control information used internally by the core
     - The second word contains the first 4 bytes of the SETUP command
     - The third word contains the last 4 bytes of the SETUP command
  3. When the setup stage changes to a data IN/OUT stage, the core writes an entry (setup stage done word) to the receive FIFO, indicating the completion of the setup stage.
  4. On the AHB side, SETUP packets are emptied by the application.
  5. When the application pops the setup stage done word from the receive FIFO, the core interrupts the application with an STUP interrupt (OTG_DOEPINTx), indicating it can process the received SETUP packet.
  6. The core clears the endpoint enable bit for control OUT endpoints.

- **Application programming sequence**
  1. Program the OTG_DOEPTSIZx register.
     - STUPCNT = 3
  2. Wait for the RXFLVL interrupt (OTG_GINTSTS) and empty the data packets from the receive FIFO.
  3. Assertion of the STUP interrupt (OTG_DOEPINTx) marks a successful completion of the SETUP data transfer.
     - On this interrupt, the application must read the OTG_DOEPTSIZx register to determine the number of SETUP packets received and process the last received SETUP packet.
Handling more than three back-to-back SETUP packets

Per the USB 2.0 specification, normally, during a SETUP packet error, a host does not send more than three back-to-back SETUP packets to the same endpoint. However, the USB 2.0 specification does not limit the number of back-to-back SETUP packets a host can send to the same endpoint. When this condition occurs, the OTG_HS controller generates an interrupt (B2BSTUP in OTG_DOEPINTx).

Setting the global OUT NAK

Internal data flow:
1. When the application sets the Global OUT NAK (SGONAK bit in OTG_DCTL), the core stops writing data, except SETUP packets, to the receive FIFO. Irrespective of the space availability in the receive FIFO, non-isochronous OUT tokens receive a NAK handshake response, and the core ignores isochronous OUT data packets.
2. The core writes the Global OUT NAK pattern to the receive FIFO. The application must reserve enough receive FIFO space to write this data pattern.
3. When the application pops the Global OUT NAK pattern word from the receive FIFO, the core sets the GONAKEFF interrupt (OTG_GINTSTS).
4. Once the application detects this interrupt, it can assume that the core is in Global OUT NAK mode. The application can clear this interrupt by clearing the SGONAK bit in OTG_DCTL.

Application programming sequence:
1. To stop receiving any kind of data in the receive FIFO, the application must set the Global OUT NAK bit by programming the following field:
   - SGONAK = 1 in OTG_DCTL
2. Wait for the assertion of the GONAKEFF interrupt in OTG_GINTSTS. When asserted, this interrupt indicates that the core has stopped receiving any type of data except SETUP packets.
3. The application can receive valid OUT packets after it has set SGONAK in OTG_DCTL and before the core asserts the GONAKEFF interrupt (OTG_GINTSTS).
4. The application can temporarily mask this interrupt by writing to the GONAKEFFM bit in the OTG_GINTMSK register.
   - GONAKEFFM = 0 in the OTG_GINTMSK register
5. Whenever the application is ready to exit the Global OUT NAK mode, it must clear the SGONAK bit in OTG_DCTL. This also clears the GONAKEFF interrupt (OTG_GINTSTS).
   - CGONAK = 1 in OTG_DCTL
6. If the application has masked this interrupt earlier, it must be unmasked as follows:
   - GONAKEFFM = 1 in OTG_GINTMSK

**Disabling an OUT endpoint**
The application must use this sequence to disable an OUT endpoint that it has enabled.

Application programming sequence:
1. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core.
   - SGONAK = 1 in OTG_DCTL
2. Wait for the GONAKEFF interrupt (OTG_GINTSTS)
3. Disable the required OUT endpoint by programming the following fields:
   - EPDIS = 1 in OTG_DOEPCTLx
   - SNAK = 1 in OTG_DOEPCTLx
4. Wait for the EPDISD interrupt (OTG_DOEPINTx), which indicates that the OUT endpoint is completely disabled. When the EPDISD interrupt is asserted, the core also clears the following bits:
   - EPDIS = 0 in OTG_DOEPCTLx
   - EPENA = 0 in OTG_DOEPCTLx
5. The application must clear the Global OUT NAK bit to start receiving data from other non-disabled OUT endpoints.
   - SGONAK = 0 in OTG_DCTL

**Transfer Stop Programming for OUT endpoints**
The application must use the following programming sequence to stop any transfers (because of an interrupt from the host, typically a reset).

**Sequence of operations:**
1. Enable all OUT endpoints by setting
   – EPENA = 1 in all OTG_DOEPCTLx registers.

2. Flush the RxFIFO as follows
   – Poll OTG_GRSTCTL.AHBIDL until it is 1. This indicates that AHB master is idle.
   – Perform read modify write operation on OTG_GRSTCTL.RXFFLSH = 1
   – Poll OTG_GRSTCTL.RXFFLSH until it is 0, but also using a timeout of less than
     10 milli-seconds (corresponds to minimum reset signaling duration). If 0 is seen
     before the timeout, then the RxFIFO flush is successful. If at the moment the
     timeout occurs, there is still a 1, (this may be due to a packet on EP0 coming from
     the host) then go back (once only) to the previous step ("Perform read modify write
     operation").

3. Before disabling any OUT endpoint, the application must enable Global OUT NAK
   mode in the core, according to the instructions in “Setting the global OUT NAK on
   page 3204”. This ensures that data in the RxFIFO is sent to the application
   successfully. Set SGONAK = 1 in OTG_DCTL

4. Wait for the GONAKEFF interrupt (OTG_GINTSTS)

5. Disable all active OUT endpoints by programming the following register bits:
   – EPDIS = 1 in registers OTG_DOEPCTLx
   – SNAK = 1 in registers OTG_DOEPCTLx

6. Wait for the EPDIS interrupt in OTG_DOEPINTx for each OUT endpoint programmed
   in the previous step. The EPDIS interrupt in OTG_DOEPINTx indicates that the
   corresponding OUT endpoint is completely disabled. When the EPDIS interrupt is
   asserted, the following bits are cleared:
   – EPENA = 0 in registers OTG_DOEPCTLx
   – EPDIS = 0 in registers OTG_DOEPCTLx
   – SNAK = 0 in registers OTG_DOEPCTLx

- **Generic non-isochronous OUT data transfers**

This section describes a regular non-isochronous OUT data transfer (control, bulk, or
interrupt).

Application requirements:

1. Before setting up an OUT transfer, the application must allocate a buffer in the memory
   to accommodate all data to be received as part of the OUT transfer.

2. For OUT transfers, the transfer size field in the endpoint’s transfer size register must be
   a multiple of the maximum packet size of the endpoint, adjusted to the word boundary.
   – packet count[EPNUM] = n
   – n > 0

3. On any OUT endpoint interrupt, the application must read the endpoint's transfer size
   register to calculate the size of the payload in the memory. The received payload size
   can be less than the programmed transfer size.
   – Payload size in memory = application programmed initial transfer size – core
     updated final transfer size
   – Number of USB packets in which this payload was received = application
     programmed initial packet count – core updated final packet count
Internal data flow:
1. The application must set the transfer size and packet count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
2. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the packet count field for that endpoint by 1.
   - OUT data packets received with bad data CRC are flushed from the receive FIFO automatically.
   - After sending an ACK for the packet on the USB, the core discards non-isochronous OUT data packets that the host, which cannot detect the ACK, resends. The application does not detect multiple back-to-back data OUT packets on the same endpoint with the same data PID. In this case the packet count is not decremented.
   - If there is no space in the receive FIFO, isochronous or non-isochronous data packets are ignored and not written to the receive FIFO. Additionally, non-isochronous OUT tokens receive a NAK handshake reply.
   - In all the above three cases, the packet count is not decremented because no data are written to the receive FIFO.
3. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or non-isochronous data packets are ignored and not written to the receive FIFO, and non-isochronous OUT tokens receive a NAK handshake reply.
4. After the data are written to the receive FIFO, the application reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.
5. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.
6. The OUT data transfer completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions:
   - The transfer size is 0 and the packet count is 0
   - The last OUT data packet written to the receive FIFO is a short packet (0 ≤ packet size < maximum packet size)
7. When either the application pops this entry (OUT data transfer completed), a transfer completed interrupt is generated for the endpoint and the endpoint enable is cleared.

Application programming sequence:
1. Program the OTG_DOEPTSIZx register for the transfer size and the corresponding packet count.
2. Program the OTG_DOEPCTLx register with the endpoint characteristics, and set the EPENA and CNAK bits.
   - EPENA = 1 in OTG_DOEPCTLx
   - CNAK = 1 in OTG_DOEPCTLx
3. Wait for the RXFLVL interrupt (in OTG_GINTSTS) and empty the data packets from the receive FIFO.
   - This step can be repeated many times, depending on the transfer size.
4. Asserting the XFRC interrupt (OTG_DOEPINTx) marks a successful completion of the non-isochronous OUT data transfer.
5. Read the OTG_DOEPTSIZx register to determine the size of the received data payload.

- **Generic isochronous OUT data transfer**

  This section describes a regular isochronous OUT data transfer.

  **Application requirements:**
  1. All the application requirements for non-isochronous OUT data transfers also apply to isochronous OUT data transfers.
  2. For isochronous OUT data transfers, the transfer size and packet count fields must always be set to the number of maximum-packet-size packets that can be received in a single frame and no more. Isochronous OUT data transfers cannot span more than 1 frame.
  3. The application must read all isochronous OUT data packets from the receive FIFO (data and status) before the end of the periodic frame (EOPF interrupt in OTG_GINTSTS).
  4. To receive data in the following frame, an isochronous OUT endpoint must be enabled after the EOPF (OTG_GINTSTS) and before the SOF (OTG_GINTSTS).

  **Internal data flow:**
  1. The internal data flow for isochronous OUT endpoints is the same as that for non-isochronous OUT endpoints, but for a few differences.
  2. When an isochronous OUT endpoint is enabled by setting the endpoint enable and clearing the NAK bits, the Even/Odd frame bit must also be set appropriately. The core receives data on an isochronous OUT endpoint in a particular frame only if the following condition is met:
     - EONUM (in OTG_DOEPCTLx) = FNSOF[0] (in OTG_DSTS)
  3. When the application completely reads an isochronous OUT data packet (data and status) from the receive FIFO, the core updates the RXDPID field in OTG_DOEPTSIZx with the data PID of the last isochronous OUT data packet read from the receive FIFO.

  **Application programming sequence:**
1. Program the OTG_DOEPTSIZx register for the transfer size and the corresponding packet count
2. Program the OTG_DOEPCTLx register with the endpoint characteristics and set the endpoint enable, ClearNAK, and Even/Odd frame bits.
   - EPENA = 1
   - CNAK = 1
   - EONUM = (0: Even/1: Odd)
3. Wait for the RXFLVL interrupt (in OTG_GINTSTS) and empty the data packets from the receive FIFO
   - This step can be repeated many times, depending on the transfer size.
4. The assertion of the XFRC interrupt (in OTG_DOEPINTx) marks the completion of the isochronous OUT data transfer. This interrupt does not necessarily mean that the data in memory are good.
5. This interrupt cannot always be detected for isochronous OUT transfers. Instead, the application can detect the INCOMPSISOOUT interrupt in OTG_GINTSTS.
6. Read the OTG_DOEPTSIZx register to determine the size of the received transfer and to determine the validity of the data received in the frame. The application must treat the data received in memory as valid only if one of the following conditions is met:
   - RXDPID = DATA0 (in OTG_DOEPTSIZx) and the number of USB packets in which this payload was received = 1
   - RXDPID = DATA1 (in OTG_DOEPTSIZx) and the number of USB packets in which this payload was received = 2
   - RXDPID = D2 (in OTG_DOEPTSIZx) and the number of USB packets in which this payload was received = 3
   The number of USB packets in which this payload was received = Application programmed initial packet count – core updated final packet count
   The application can discard invalid data packets.

- Incomplete isochronous OUT data transfers

This section describes the application programming sequence when isochronous OUT data packets are dropped inside the core.

Internal data flow:
1. For isochronous OUT endpoints, the XFRC interrupt (in OTG_DOEPINTx) may not always be asserted. If the core drops isochronous OUT data packets, the application may fail to detect the XFRC interrupt (OTG_DOEPINTx) under the following circumstances:
   - When the receive FIFO cannot accommodate the complete ISO OUT data packet, the core drops the received ISO OUT data
   - When the isochronous OUT data packet is received with CRC errors
   - When the isochronous OUT token received by the core is corrupted
   - When the application is very slow in reading the data from the receive FIFO
2. When the core detects an end of periodic frame before transfer completion to all isochronous OUT endpoints, it asserts the incomplete isochronous OUT data interrupt (INCOMPSISOOUT in OTG_GINTSTS), indicating that an XFRC interrupt (in OTG_DOEPINTx) is not asserted on at least one of the isochronous OUT endpoints. At
this point, the endpoint with the incomplete transfer remains enabled, but no active transfers remain in progress on this endpoint on the USB.

Application programming sequence:

1. Asserting the INCOMPSIOOUT interrupt (OTG_GINTSTS) indicates that in the current frame, at least one isochronous OUT endpoint has an incomplete transfer.

2. If this occurs because isochronous OUT data is not completely emptied from the endpoint, the application must ensure that the application empties all isochronous OUT data (data and status) from the receive FIFO before proceeding.
   - When all data are emptied from the receive FIFO, the application can detect the XFRC interrupt (OTG_DOEPINTx). In this case, the application must re-enable the endpoint to receive isochronous OUT data in the next frame.

3. When it receives an INCOMPSIOOUT interrupt (in OTG_GINTSTS), the application must read the control registers of all isochronous OUT endpoints (OTG_DOEPCTLx) to determine which endpoints had an incomplete transfer in the current microframe. An endpoint transfer is incomplete if both the following conditions are met:
   - EONUM bit (in OTG_DOEPCTLx) = FNSOF[0] (in OTG_DSTS)
   - EPENA = 1 (in OTG_DOEPCTLx)

4. The previous step must be performed before the SOF interrupt (in OTG_GINTSTS) is detected, to ensure that the current frame number is not changed.

5. For isochronous OUT endpoints with incomplete transfers, the application must discard the data in the memory and disable the endpoint by setting the EPDIS bit in OTG_DOEPCTLx.

6. Wait for the EPDISD interrupt (in OTG_DOEPINTx) and enable the endpoint to receive new data in the next frame.
   - Because the core can take some time to disable the endpoint, the application may not be able to receive the data in the next frame after receiving bad isochronous data.

• **Stalling a non-isochronous OUT endpoint**

This section describes how the application can stall a non-isochronous endpoint.

1. Put the core in the Global OUT NAK mode.

2. Disable the required endpoint
   - When disabling the endpoint, instead of setting the SNAK bit in OTG_DOEPCTL, set STALL = 1 (in OTG_DOEPCTL).
     The STALL bit always takes precedence over the NAK bit.

3. When the application is ready to end the STALL handshake for the endpoint, the STALL bit (in OTG_DOEPCTLx) must be cleared.

4. If the application is setting or clearing a STALL for an endpoint due to a SetFeature.Endpoint Halt or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the status stage transfer on the control endpoint.

**Examples**

This section describes and depicts some fundamental transfer types and scenarios.

• Bulk OUT transaction
Figure 938 depicts the reception of a single Bulk OUT data packet from the USB to the AHB and describes the events involved in the process.

**Figure 938. Bulk OUT transaction**

After a SetConfiguration/SetInterface command, the application initializes all OUT endpoints by setting CNAK = 1 and EPENA = 1 (in OTG_DOEPCTLx), and setting a suitable XFRSIZ and PKTCNT in the OTG_DOEPTSIZx register.

1. host attempts to send data (OUT token) to an endpoint.
2. When the core receives the OUT token on the USB, it stores the packet in the Rx FIFO because space is available there.
3. After writing the complete packet in the Rx FIFO, the core then asserts the RXFLVL interrupt (in OTG_GINTSTS).
4. On receiving the PKTCNT number of USB packets, the core internally sets the NAK bit for this endpoint to prevent it from receiving any more packets.
5. The application processes the interrupt and reads the data from the Rx FIFO.
6. When the application has read all the data (equivalent to XFRSIZ), the core generates an XFRC interrupt (in OTG_DOEPINTx).
7. The application processes the interrupt and uses the setting of the XFRC interrupt bit (in OTG_DOEPINTx) to determine that the intended transfer is complete.

**IN data transfers**

- **Packet write**

This section describes how the application writes data packets to the endpoint FIFO when dedicated transmit FIFOs are enabled.
1. The application can either choose the polling or the interrupt mode.
   – In polling mode, the application monitors the status of the endpoint transmit data FIFO by reading the OTG_DTXFSTx register, to determine if there is enough space in the data FIFO.
   – In interrupt mode, the application waits for the TXFE interrupt (in OTG_DIEPINTx) and then reads the OTG_DTXFSTx register, to determine if there is enough space in the data FIFO.
   – To write a single non-zero length data packet, there must be space to write the entire packet in the data FIFO.
   – To write zero length packet, the application must not look at the FIFO space.

2. Using one of the above mentioned methods, when the application determines that there is enough space to write a transmit packet, the application must first write into the endpoint control register, before writing the data into the data FIFO. Typically, the application must do a read modify write on the OTG_DIEPCTLx register to avoid modifying the contents of the register, except for setting the endpoint enable bit.

The application can write multiple packets for the same endpoint into the transmit FIFO, if space is available. For periodic IN endpoints, the application must write packets only for one microframe. It can write packets for the next periodic transaction only after getting transfer complete for the previous transaction.

- **Setting IN endpoint NAK**

Internal data flow:
1. When the application sets the IN NAK for a particular endpoint, the core stops transmitting data on the endpoint, irrespective of data availability in the endpoint’s transmit FIFO.
2. Non-isochronous IN tokens receive a NAK handshake reply
   – Isochronous IN tokens receive a zero-data-length packet reply
3. The core asserts the INEPNE (IN endpoint NAK effective) interrupt in OTG_DIEPINTx in response to the SNAK bit in OTG_DIEPCTLx.
4. Once this interrupt is seen by the application, the application can assume that the endpoint is in IN NAK mode. This interrupt can be cleared by the application by setting the CNAK bit in OTG_DIEPCTLx.

Application programming sequence:
1. To stop transmitting any data on a particular IN endpoint, the application must set the IN NAK bit. To set this bit, the following field must be programmed.
   – SNAK = 1 in OTG_DIEPCTLx
2. Wait for assertion of the INEPNE interrupt in OTG_DIEPINTx. This interrupt indicates that the core has stopped transmitting data on the endpoint.
3. The core can transmit valid IN data on the endpoint after the application has set the NAK bit, but before the assertion of the NAK Effective interrupt.
4. The application can mask this interrupt temporarily by writing to the INEPNEM bit in OTG_DIEPMSK.
   – INEPNEM = 0 in OTG_DIEPMSK
5. To exit endpoint NAK mode, the application must clear the NAK status bit (NAKSTS) in OTG_DIEPCTLx. This also clears the INEPNNE interrupt (in OTG_DIEPINTx).
6. If the application masked this interrupt earlier, it must be unmasked as follows:
   - INEPNEM = 1 in OTG_DIEPMSK

**IN endpoint disable**

Use the following sequence to disable a specific IN endpoint that has been previously enabled.

Application programming sequence:
1. The application must stop writing data on the AHB for the IN endpoint to be disabled.
2. The application must set the endpoint in NAK mode.
   - SNAK = 1 in OTG_DIEPCTLx
3. Wait for the INEPNE interrupt in OTG_DIEPINTx.
4. Set the following bits in the OTG_DIEPCTLx register for the endpoint that must be disabled.
   - EPDIS = 1 in OTG_DIEPCTLx
   - SNAK = 1 in OTG_DIEPCTLx
5. Assertion of the EPDISD interrupt in OTG_DIEPINTx indicates that the core has completely disabled the specified endpoint. Along with the assertion of the interrupt, the core also clears the following bits:
   - EPENA = 0 in OTG_DIEPCTLx
   - EPDIS = 0 in OTG_DIEPCTLx
6. The application must read the OTG_DIEPTSIZx register for the periodic IN EP, to calculate how much data on the endpoint were transmitted on the USB.
7. The application must flush the data in the endpoint transmit FIFO, by setting the following fields in the OTG_GRSTCTL register:
   - TXFNUM (in OTG_GRSTCTL) = Endpoint transmit FIFO number
   - TXFFLSH in (OTG_GRSTCTL) = 1

The application must poll the OTG_GRSTCTL register, until the TXFFLSH bit is cleared by the core, which indicates the end of flush operation. To transmit new data on this endpoint, the application can re-enable the endpoint at a later point.

**Transfer Stop Programming for IN endpoints**

The application must use the following programing sequence to stop any transfers (because of an interrupt from the host, typically a reset).
Sequence of operations:

1. Disable the IN endpoint by setting:
   - EPDIS = 1 in all OTG_DIEPCTLx registers
2. Wait for the EPDIS interrupt in OTG_DIEPINTx, which indicates that the IN endpoint is completely disabled. When the EPDIS interrupt is asserted the following bits are cleared:
   - EPDIS = 0 in OTG_DIEPCTLx
   - EPENA = 0 in OTG_DIEPCTLx
3. Flush the TxFIFO by programming the following bits:
   - TXFFLSH = 1 in OTG_GRSTCTL
   - TXFNUM = “FIFO number specific to endpoint” in OTG_GRSTCTL
4. The application can start polling till TXFFLSH in OTG_GRSTCTL is cleared. When this bit is cleared, it ensures that there is no data left in the Tx FIFO.

Generic non-periodic IN data transfers

Application requirements:

1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer are part of a single buffer.
2. For IN transfers, the transfer size field in the endpoint transfer size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
   - To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
     Transfer size[EPNUM] = x × MPSIZ[EPNUM] + sp
     If (sp > 0), then packet count[EPNUM] = x + 1.
     Otherwise, packet count[EPNUM] = x
   - To transmit a single zero-length data packet:
     Transfer size[EPNUM] = 0
     Packet count[EPNUM] = 1
   - To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer into two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.
     First transfer: transfer size[EPNUM] = x × MPSIZ[epnum]; packet count = n;
     Second transfer: transfer size[EPNUM] = 0; packet count = 1;
3. Once an endpoint is enabled for data transfers, the core updates the transfer size register. At the end of the IN transfer, the application must read the transfer size register to determine how much data posted in the transmit FIFO have already been sent on the USB.
4. Data fetched into transmit FIFO = Application-programmed initial transfer size – core-updated final transfer size
   - Data transmitted on USB = (application-programmed initial packet count – core updated final packet count) × MPSIZ[EPNUM]
   - Data yet to be transmitted on USB = (Application-programmed initial transfer size – data transmitted on USB)
Internal data flow:
1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the transmit FIFO for the endpoint.
3. Every time a packet is written into the transmit FIFO by the application, the transfer size for that endpoint is decremented by the packet size. The data is fetched from the memory by the application, until the transfer size for the endpoint becomes 0. After writing the data into the FIFO, the “number of packets in FIFO” count is incremented (this is a 3-bit count, internally maintained by the core for each IN endpoint transmit FIFO. The maximum number of packets maintained by the core at any time in an IN endpoint FIFO is eight). For zero-length packets, a separate flag is set for each FIFO, without any data in the FIFO.
4. Once the data are written to the transmit FIFO, the core reads them out upon receiving an IN token. For every non-isochronous IN data packet transmitted with an ACK handshake, the packet count for the endpoint is decremented by one, until the packet count is zero. The packet count is not decremented on a timeout.
5. For zero length packets (indicated by an internal zero length flag), the core sends out a zero-length packet for the IN token and decrements the packet count field.
6. If there are no data in the FIFO for a received IN token and the packet count field for that endpoint is zero, the core generates an “IN token received when Tx FIFO is empty” (ITTXFE) interrupt for the endpoint, provided that the endpoint NAK bit is not set. The core responds with a NAK handshake for non-isochronous endpoints on the USB.
7. The core internally rewinds the FIFO pointers and no timeout interrupt is generated.
8. When the transfer size is 0 and the packet count is 0, the transfer complete (XFRC) interrupt for the endpoint is generated and the endpoint enable is cleared.

Application programming sequence:
1. Program the OTG_DIEPTSIZx register with the transfer size and corresponding packet count.
2. Program the OTG_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA (endpoint enable) bits.
3. When transmitting non-zero length data packet, the application must poll the OTG_DTXFSTSx register (where x is the FIFO number associated with that endpoint) to determine whether there is enough space in the data FIFO. The application can optionally use TXFE (in OTG_DIEPINTx) before writing the data.

• Generic periodic IN data transfers

This section describes a typical periodic IN data transfer.

Application requirements:
1. Application requirements 1, 2, 3, and 4 of Generic non-periodic IN data transfers on page 3214 also apply to periodic IN data transfers, except for a slight modification of requirement 2.
   – The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To
transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met:

\[
\text{transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}
\]

(where \(x\) is an integer \(\geq 0\), and \(0 \leq \text{sp} < \text{MPSIZ}[\text{EPNUM}]\))

If (\(\text{sp} > 0\)), packet count[EPNUM] = \(x + 1\)

Otherwise, packet count[EPNUM] = \(x\);

\[
\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]
\]

– The application cannot transmit a zero-length data packet at the end of a transfer. It can transmit a single zero-length data packet by itself. To transmit a single zero-length data packet:

\[
\text{transfer size}[\text{EPNUM}] = 0
\]

\[
\text{packet count}[\text{EPNUM}] = 1
\]

\[
\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]
\]

2. The application can only schedule data transfers one frame at a time.

\[
(\text{MCNT} – 1) \times \text{MPSIZ} \leq \text{XFERSIZ} \leq \text{MCNT} \times \text{MPSIZ}
\]

– PKTCNT = MCNT (in OTG_DIEPTSIZx)

– If \(\text{XFERSIZ} < \text{MCNT} \times \text{MPSIZ}\), the last data packet of the transfer is a short packet.

– Note that: \(\text{MCNT}\) is in OTG_DIEPTSIZx, \(\text{MPSIZ}\) is in OTG_DIEPCTLx, PKTCNT is in OTG_DIEPTSIZx and Xfersiz is in OTG_DIEPTSIZx

3. The complete data to be transmitted in the frame must be written into the transmit FIFO by the application, before the IN token is received. Even when 1 word of the data to be transmitted per frame is missing in the transmit FIFO when the IN token is received, the core behaves as when the FIFO is empty. When the transmit FIFO is empty:

– A zero data length packet would be transmitted on the USB for isochronous IN endpoints

– A NAK handshake would be transmitted on the USB for interrupt IN endpoints

Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.

2. The application must also write the required data to the associated transmit FIFO for the endpoint.

3. Every time the application writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data are fetched from application memory until the transfer size for the endpoint becomes 0.

4. When an IN token is received for a periodic endpoint, the core transmits the data in the FIFO, if available. If the complete data payload (complete packet, in dedicated FIFO
mode) for the frame is not present in the FIFO, then the core generates an IN token received when Tx FIFO empty interrupt for the endpoint.

− A zero-length data packet is transmitted on the USB for isochronous IN endpoints
− A NAK handshake is transmitted on the USB for interrupt IN endpoints

5. The packet count for the endpoint is decremented by 1 under the following conditions:

− For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
− For interrupt endpoints, when an ACK handshake is transmitted
− When the transfer size and packet count are both 0, the transfer completed interrupt for the endpoint is generated and the endpoint enable is cleared.

6. At the “Periodic frame Interval” (controlled by PFiVL in OTG_DCFG), when the core finds non-empty any of the isochronous IN endpoint FIFOs scheduled for the current frame non-empty, the core generates an IISOIXFR interrupt in OTG_GINTSTS.

Application programming sequence:

1. Program the OTG_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA bits.
2. Write the data to be transmitted in the next frame to the transmit FIFO.
3. Asserting the ITTXFE interrupt (in OTG_DIEPINTx) indicates that the application has not yet written all data to be transmitted to the transmit FIFO.
4. If the interrupt endpoint is already enabled when this interrupt is detected, ignore the interrupt. If it is not enabled, enable the endpoint so that the data can be transmitted on the next IN token attempt.
5. Asserting the XFRC interrupt (in OTG_DIEPINTx) with no ITTXFE interrupt in OTG_DIEPINTx indicates the successful completion of an isochronous IN transfer. A read to the OTG_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
6. Asserting the XFRC interrupt (in OTG_DIEPINTx), with or without the ITTXFE interrupt (in OTG_DIEPINTx), indicates the successful completion of an interrupt IN transfer. A read to the OTG_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
7. Asserting the incomplete isochronous IN transfer (IISOIXFR) interrupt in OTG_GINTSTS with none of the aforementioned interrupts indicates the core did not receive at least 1 periodic IN token in the current frame.

• Incomplete isochronous IN data transfers

This section describes what the application must do on an incomplete isochronous IN data transfer.

Internal data flow:

1. An isochronous IN transfer is treated as incomplete in one of the following conditions:
   a) The core receives a corrupted isochronous IN token on at least one isochronous IN endpoint. In this case, the application detects an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG_GINTSTS).
   b) The application is slow to write the complete data payload to the transmit FIFO and an IN token is received before the complete data payload is written to the FIFO. In this case, the application detects an IN token received when Tx FIFO empty interrupt in OTG_DIEPINTx. The application can ignore this interrupt, as it
eventually results in an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG_GINTSTS) at the end of periodic frame.

The core transmits a zero-length data packet on the USB in response to the received IN token.

2. The application must stop writing the data payload to the transmit FIFO as soon as possible.

3. The application must set the NAK bit and the disable bit for the endpoint.

4. The core disables the endpoint, clears the disable bit, and asserts the endpoint disable interrupt for the endpoint.

Application programming sequence:

1. The application can ignore the IN token received when Tx FIFO empty interrupt in OTG_DIEPINTx on any isochronous IN endpoint, as it eventually results in an incomplete isochronous IN transfer interrupt (in OTG_GINTSTS).

2. Assertion of the incomplete isochronous IN transfer interrupt (in OTG_GINTSTS) indicates an incomplete isochronous IN transfer on at least one of the isochronous IN endpoints.

3. The application must read the endpoint control register for all isochronous IN endpoints to detect endpoints with incomplete IN data transfers.

4. The application must stop writing data to the Periodic Transmit FIFOs associated with these endpoints on the AHB.

5. Program the following fields in the OTG_DIEPCTLx register to disable the endpoint:
   - SNAK = 1 in OTG_DIEPCTLx
   - EPDIS = 1 in OTG_DIEPCTLx

6. The assertion of the endpoint disabled interrupt in OTG_DIEPINTx indicates that the core has disabled the endpoint.
   - At this point, the application must flush the data in the associated transmit FIFO or overwrite the existing data in the FIFO by enabling the endpoint for a new transfer in the next microframe. To flush the data, the application must use the OTG_GRSTCTL register.

- **Stalling non-isochronous IN endpoints**

  This section describes how the application can stall a non-isochronous endpoint.

  Application programming sequence:
1. Disable the IN endpoint to be stalled. Set the STALL bit as well.
2. EPDIS = 1 in OTG_DIEPCTLx, when the endpoint is already enabled
   - STALL = 1 in OTG_DIEPCTLx
   - The STALL bit always takes precedence over the NAK bit
3. Assertion of the endpoint disabled interrupt (in OTG_DIEPINTx) indicates to the
   application that the core has disabled the specified endpoint.
4. The application must flush the non-periodic or periodic transmit FIFO, depending on
   the endpoint type. In case of a non-periodic endpoint, the application must re-enable
   the other non-periodic endpoints that do not need to be stalled, to transmit data.
5. Whenever the application is ready to end the STALL handshake for the endpoint, the
   STALL bit must be cleared in OTG_DIEPCTLx.
6. If the application sets or clears a STALL bit for an endpoint due to a
   SetFeature.Endpoint Halt command or ClearFeature.Endpoint Halt command, the
   STALL bit must be set or cleared before the application sets up the status stage
   transfer on the control endpoint.

Special case: stalling the control OUT endpoint

The core must stall IN/OUT tokens if, during the data stage of a control transfer, the host
sends more IN/OUT tokens than are specified in the SETUP packet. In this case, the
application must enable the ITTXFE interrupt in OTG_DIEPINTx and the OTEPDIS interrupt
in OTG_DOEPINTx during the data stage of the control transfer, after the core has
transferred the amount of data specified in the SETUP packet. Then, when the application
receives this interrupt, it must set the STALL bit in the corresponding endpoint control
register, and clear this interrupt.

62.15.7 Worst case response time

When the OTG_HS controller acts as a device, there is a worst case response time for any
tokens that follow an isochronous OUT. This worst case response time depends on the AHB
clock frequency.

The core registers are in the AHB domain, and the core does not accept another token
before updating these register values. The worst case is for any token following an
isochronous OUT, because for an isochronous transaction, there is no handshake and the
next token may come sooner. This worst case value is 7 PHY clocks when the AHB clock is
the same as the PHY clock. When the AHB clock is faster, this value is smaller.

If this worst case condition occurs, the core responds to bulk/interrupt tokens with a NAK
and drops isochronous and SETUP tokens. The host interprets this as a timeout condition
for SETUP and retries the SETUP packet. For isochronous transfers, the Incomplete
isochronous IN transfer interrupt (IISOIXFR) and Incomplete isochronous OUT transfer
interrupt (IISOOXFR) inform the application that isochronous IN/OUT packets were
dropped.

Choosing the value of TRDT in OTG_GUSBCFG

The value in TRDT (OTG_GUSBCFG) is the time it takes for the MAC, in terms of PHY
clocks after it has received an IN token, to get the FIFO status, and thus the first data from
the PFC block. This time involves the synchronization delay between the PHY and AHB
clocks. The worst case delay for this is when the AHB clock is the same as the PHY clock.
In this case, the delay is 5 clocks.
Once the MAC receives an IN token, this information (token received) is synchronized to the AHB clock by the PFC (the PFC runs on the AHB clock). The PFC then reads the data from the SPRAM and writes them into the dual clock source buffer. The MAC then reads the data out of the source buffer (4 deep).

If the AHB is running at a higher frequency than the PHY, the application can use a smaller value for TRDT (in OTG_GUSBCFG).

Figure 939 has the following signals:
- tkn_rcvd: Token received information from MAC to PFC
- dynced_tkn_rcvd: Doubled sync tkn_rcvd, from PCLK to HCLK domain
- spr_read: Read to SPRAM
- spr_addr: Address to SPRAM
- spr_rdata: Read data from SPRAM
- srcbuf_push: Push to the source buffer
- srcbuf_rdata: Read data from the source buffer. Data seen by MAC

To calculate the value of TRDT, refer to Table 673: TRDT values.

**Figure 939. TRDT max timing case**

![TRDT max timing case diagram](image-url)
62.15.8 **OTG programming model**

The OTG_HS controller is an OTG device. When the core is connected to an “A” plug, it is referred to as an A-device. When the core is connected to a “B” plug it is referred to as a B-device.
63 USB Type-C®/USB Power Delivery interface (UCPD)

63.1 Introduction

The USB Type-C/USB Power Delivery interface complies with:
- Universal Serial Bus Type-C Cable and Connector Specification: release 2.3, Oct 2023
- Universal Serial Bus Power Delivery specifications:
  - revision 2.0, version 1.3, January 12, 2017
  - revision 3.2, version 1.0, October 2023

It integrates the physical layer of the Power Delivery (PD) specification, with CC signaling method (no VBUS), for operation with Type-C cables.

63.2 UCPD main features

- Compliance with USB Type-C specification release 2.3
- Compliance with USB Power Delivery specifications revision 2.0 and 3.2
  - Enabling advanced applications such as PPS (programmable power supply)
- Stop mode low-power operation support
- Built-in analog PHY
  - USB Type-C pull-up (Rp, all values) and pull-down (Rd) resistors
  - “Dead battery” Rd support
  - USB Power Delivery message transmission and reception
  - FRS (fast role swap) Rx support
- Digital controller
  - BMC (bi-phase mark coding) encode and decode
  - 4b5b encode and decode
  - USB Type-C level detection with de-bounce, generating interrupts
  - FRS signaling
  - FRS detection, generating an interrupt
  - DMA-compatible byte-level interface for USB Power Delivery payload, generating interrupts
  - USB Power Delivery clock pre-scaler / dividers
  - CRC generation/checking
  - Support of ordered sets, with a programmable ordered set mask at receive
  - Clock recovery from incoming Rx stream

63.3 UCPD implementation

The devices have one UCPD controller to support one USB Type-C port.
63.4 UCPD functional description

The UCPD peripheral provides hardware support for the USB Power Delivery control interface specification, using I/Os specifically designed for that purpose.

The built-in PHY directly detects Type-C voltage levels, supports Power Delivery BIST carrier mode 2 (Tx only), BIST test data (Tx and Rx), and Power Delivery Rx FRS signaling.

For Power Delivery FRS Tx signaling, the device can be configured to control, through UCPD_FRSTX1/2 pins (alternate functions), external NMOS transistors that ensure low-resistance pull-down on CC lines.

The UCPD transmitter BMC (bi-phase mark) encodes and transmits data: preamble, SOP, payload data from protocol layer (after 4b5b-encoding), CRC, and EOP on the Type-C connector CC lines. It automatically inserts inter-frame gap and executes “Hard Reset”.

The UCPD receiver detects SOP, BMC-decodes the incoming stream, recovers the preamble, 4b5b-decodes payload data, detects EOP, and checks CRC. It automatically detects five K-code SOP and two Reset ordered sets, plus two software-defined patterns (allows for only three out of four K-codes being correctly received, as defined by the standard).
In Stop mode, the peripheral maintains the ability to detect incoming USB Power Delivery messages and FRS signaling, which allows low-power operation.

### 63.4.2 UCPD reset and clocks

The peripheral has a single reset signal (APB bus reset).

The register section is clocked with the APB clock (ucpd_pclk).

The main functional part of the transmitter is clocked with ucpd_clk clock, pre-scaled from the ucpd_ker_ck clock according to the PSC_UCPDCLK[2:0] bitfield of the UCPD_CFGR1 register. The main functional part of the receiver is clocked with the ucpd_rx_clk recovered from the incoming bitstream.

The receiver is designed to work in the clock frequency range from 6 to 18 MHz. However, the optimum performance is ensured in the range from 6 to 12 MHz.

The following diagram shows the clocking and timing elements of the UCPD peripheral.

![Figure 941. Clock division and timing elements](image)

Refer to the USB PD specification in order to set appropriate delays. For $t_{TransitionWindow}$ and especially for $t_{InterFrameGap}$, the clock frequency uncertainty must be taken into account so as to respect specified timings in all cases.
63.4.3 Physical layer protocol

The physical layer covers the signaling underlying the USB Power Delivery specification. On the transmitter side its main function is to form packets according to the defined packet format including generally:

- preamble
- start of packet (SOP, ordered set)
- payload header
- payload data
- cyclic redundancy check (CRC) information
- end of packet (EOP)

Before going on the CC line, the data stream is BMC-encoded, respecting specified timing restrictions.

On the receive side, the principle task is to:

- extract start of packet (SOP, ordered set) information
- extract payload header
- extract payload data
- receive and check CRC
- receive end of packet (EOP)

The receive is basically a reverse of the transmit process, thus starting with BMC data stream decoding.

Symbol encoding

Apart from the preamble all symbols are encoded with a 4b5b scheme according to the specification shown in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>4b</th>
<th>5b</th>

Ordered sets

An ordered set consists of four K-codes as shown in the following figure.

Figure 942. K-code transmission

The following table lists the defined ordered sets, including all possible SOP* sequences. At the physical layer, the Hard Reset has higher priority than the other ordered sets so it can interrupt an ongoing Tx message.

Table 681. Ordered sets

- Provided by the protocol layer, 4b5b-encoded

Hard Reset

The physical layer handles the Hard Reset signaling differently than the other types of message as it has higher priority to be able to interrupt an ongoing transfer.

The physical layer specification implies the following sequence in the case of an ongoing Tx message:

1. Terminate the message by sending an EOP K-code and discard the rest of the message.
2. Wait for InterFrameGap time.
3. If the CC line is not idle, wait until it goes idle.
4. Send the preamble followed by the four K-codes of Hard Reset signaling.
5. Disable the CC channel (stop sending and receiving), reset the physical layer and inform the protocol layer that the physical layer is reset.
6. Re-enable the channel when requested by the protocol layer.

![Line format of Hard Reset](image)

**Figure 945. Line format of Hard Reset**

</tbody>
</table>

Collision avoidance

The physical layer respects the tInterFrameGap delay between end of last-transmitted bit of a Tx message, and the first bit of a following message.

It also checks the idle state of the CC line before starting transmission. The CC line is considered idle if it shows less than three (nTransitionCount) transitions within tTransitionWindow (12 to 20 μs). The Power Delivery specification revision 3.1 also requires to manage the Rp value (source) and monitor Type-C voltage level for these Rp modifications (at the sink).

Physical layer signaling schemes

The bit are signaled with bi-phase mark coding (BMC).

BIST

Depending on the BIST action required by the protocol layer, either of the following can be run:

- a Tx BIST pattern test, achieved by writing TXMODE and TXSEND
- an Rx BIST pattern test, achieved by writing RXMODE to the correct value for RXBIST.

The two possible patterns supported in UCPD (corresponding to “BMC” mode) are:

- BIST Test Data (192 bit pattern), applies to Tx and Rx. In the case of Rx, the message is received (but discarded rather than passing to the protocol layer, which must nevertheless still generate a GoodCRC Tx message in acknowledgment).
- BIST Carrier Mode 2 (single pattern, infinite length message), applies to Tx only. As opposed to Tx, the receiver in this mode simply ignores the CC line during this state.

BIST test data pattern

The test data pattern is not viewed as a special case in UCPD.
The BIST test data packet frame format is shown in the following figure.

**Figure 947. BIST test data frame**

This is a fixed length test data pattern. In reality the only aspect that marks its difference from the general packet format already shown in *Figure 944: Packet format* is the contents of the Header. As UCPD receives the Tx Header contents via programming (it is simply viewed as part of the payload), it is only this programming (and not the block’s behavior) that differentiates the general packet from the BIST Test Data packet.

**BIST Carrier Mode 2**

When required, this BIST test mode sends an alternating pattern of 1010 that is continually repeated. As this mode is intended for signal analysis it is stable condition with (in V1.0 of the USB PD specification) no defined length. Starting from V1.1 of the USB PD specification, the protocol layer defines a counter that indicates when to exit this mode.

The way to quit the infinite 1010 sequence (according to requirements of the USB PD specification) is to disable the UCPD peripheral via the UCPDEN bit.

**Figure 948. BIST Carrier Mode 2 frame**

**63.4.4 UCPD BMC transmitter**

The BMC transmitter comprises 4b5b encoding, CRC generation, and BMC encode, as shown in the following figure. Its output goes to the analog PHY through a channel switch.

The half-bit clock hbit_clk is derived from ucpd_clk through a simple divider controlled by the HBITCLKDIV[5:0] bitfield of the UCPD_CFGR1 register. This ensures the same duration of high and low half-bit periods (if neglecting a small difference due to different rising and falling edge duration and due to jitter), and the same bit duration (if neglecting jitter).

Transmitter timing and collision avoidance

Hardware support of collision avoidance is made as a function of the half bit time for the transmitter. Two counters are implemented:

- \( t_{\text{InterFrameGap}} \): via IFRGAP (pre-defined value, can be altered)
- \( t_{\text{TransitionWindow}} \): via TRANSWIN (pre-defined value, can be altered)

These two counters once set correctly generates the interframe gap.

Hard Reset in transmitter

In order to facilitate generation of a Hard Reset, a special code of TXMODE field is used. No other fields need to be written.

On writing the correct code, the hardware forces Hard Reset Tx under the correct (optimal) timings with respect to an ongoing Tx message, which (if still in progress) is cleanly terminated by truncating the current sequence and directly appending an EOP K-code sequence. No specific interrupt is generated relating to this truncation event.

Transmitter behavior in the case of errors

The under-run condition (TXUND interrupt) may happen by accident and in this case, the UCPD is starved of (the correct) Tx payload and is not able to complete the Tx message correctly. This is a serious error (for this to happen the software fails to respond in time). As a result the hardware ensures the CRC is incorrect at the end of the message, thus guaranteeing the message to be discarded at the receiver.
63.4.5 UCPD BMC receiver

The UCPD BMC receiver performs:
- Clock recovery
- Preamble detection / timing derivation
- BMC decoding
- 4b5b decoding
- K-code ordered set recognition
- CRC checking
- SOP detection
- EOP detection

The receiver is activated as soon as the UCPD peripheral is enabled (via UCPDEN), but it waits for an idle CC line state before attempting to receive a message.

The following figure shows the UCPD BMC receiver high-level architecture.

**Figure 950. UCPD BMC receiver architecture**

CRC checker

The received bits are fed into a CRC checker which evolves a 32-bit state during the received the payload bitstream. At the end the 32 bits of the CRC also fed into the logic

The EOP detection (5 bits) halts the process and a check is performed for the fixed residual state which confirms correct reception of the payload (in fact the residual is 0xC704DD78).

At this point the UCPD raises interrupt RXMSGEND. If the CRC was not correct then RXERR is set true and the receive data must be discarded.

Under normal operation, this interrupt would previously have been acknowledged and thus cleared. If this is not the case, a different interrupt RXOVR is generated in place of RXMSGEND.
Ordered set detection

This function detects the different ordered sets each consisting of four 5-bit K-codes.

Once we are in the preamble we open a sliding window detection of the ordered set (4 words of 5 bits).

The ordered sets detected include all SOP* codes (SOP, SOP’, and SOP’’), but also Hard Reset, Cable Reset, SOP’_Debug, SOP’’_Debug, and two extensions defined by registers UCPD_RX_ORDEXT1 and UCPD_RX_ORDEXT2.

EOP detection and Hard Reset exception handling

EOP is a fixed 5-bit K-code marking the end of a message.

The way in which a transmitter is required to send a Hard Reset (if a previous message transmit is still in progress) is that this previous message is truncated early with an EOP.

If Hard Reset were ignored, then the EOP detection can be done only at the expected time. However, due to the Hard Reset issue, the EOP detector must be active while an Rx message is arriving. When an “early EOP” is detected, the truncated Rx message is immediately discarded.

Truncated or corrupted message exception

Once the ordered set has been detected, depending on the message, there may be data bytes to be received which is completed with a CRC and EOP. If at any point during these phases an error condition happens:

- the line becomes static for a time significantly longer than one “UI” period (the exact threshold for this condition is not critical but the exception must occur before three UIs), or
- the message goes to the end but it is not recognized (for example EOP is corrupted).

In both cases, the receiver quits the current message, raising RXMSGEND and RXERR flags.

Short preamble or incomplete ordered set exception

In the exceptional case of the receiver seeing less than half of the expected preamble, the frequency estimation allowing correct BMC-decode becomes impossible. Even if the full preamble is seen, allowing frequency estimation, but the ordered set is not fully received before the line becomes static, the receiver state machine does not start.

In both of these cases, the clock-recovery/BMC decoder re-starts, checking initially for an IDLE condition, followed by a preamble, and then estimating frequency.

63.4.6 UCPD Type-C pull-ups (Rp) and pull-downs (Rd)

UCPD offers simple control of these resistors via ANAMODE and ANASUBMODE[1:0]. In case only one of the CC lines is to be used, it is possible to optimize power consumption by disabling control on the other line, through the CCENABLE[1:0] bitfield.

When the MCU is unpowered, it still presents the “dead battery” Rd, provided that UCPDx_DBCC1 and UCPDx_DBCC2 pins are each connected to UCPDx_CC1 and UCPDx_CC2 pins, respectively.

If dead battery behavior is not required (for example for source only products), then UCPDx_DBCC1 and UCPDx_DBCC2 pins must both be tied to ground.
After power arrives and the MCU boots, the desired behavior (for example source) must be programmed into ANAMODE and ANASUBMODE[1:0] before setting the UCPD_DBDIS bit of the PWR_UCPDR register to remove dead battery pull-down resistor and allow the values just programmed to take effect.

Use of Standby low-power mode is possible for sinks in the unattached state.

63.4.7 UCPD Type-C voltage monitoring and de-bouncing

For correct operation of the Type-C state machine and for detecting the cable orientation, the CC1/2 lines must be monitored for voltage level, while ignoring fast events such as peaks.

Thresholds between voltage levels on the CC1/2 lines are determined through PHY threshold detector settings.

The TYPEC_VSTATE_CC1/2[1:0] bitfields reflect the CC1/2 line levels processed with a hardware de-bouncing filter that suppresses high-speed line events such as peaks. The PHYCCSEL bit selects the line, CC1 or CC2, to be used for Power Delivery signaling.

For minimizing the power consumption, it is recommended to use the polling method, with the Type-C detectors only turned on for the instant of polling, rather than keeping the Type-C detectors permanently on and wake the device up from Stop mode upon CC1/2 line events.

63.4.8 UCPD fast role swap (FRS)

FRS signaling

The FRS condition (a pulse of a specific length), is generated upon setting the FRSTX bit.

For the duration of FRS condition, the currently active I/O configured as UCPD_FRSTX1 (or 2) (alternate function) controls, with high level, the gate of an external NMOS transistor that pulls the active CC line down.

FRS detection

FRS monitoring is enabled by setting the bit FRSRXEN, after writing PHYCCSEL that selects the active CC line depending on the cable orientation detected.

63.4.9 UCPD DMA Interface

DMA is implemented in the UCPD and when it is enabled the byte-level interrupts to handle UCPD1_TXDR and UCPD1_RXDR registers (Tx and Rx data register, each one byte) are no longer needed.

By enabling bits TXDMAEN and/or RXDMAEN, DMA can be activated independently for Tx and/or Rx functionality.

63.4.10 Wake-up from Stop mode

For power consumption optimization, it is useful to use Stop mode and wait for events on CC lines to wake the MCU up.

In order for this to work, it must be first enabled by writing a 1 to WUPEN.
The events causing the wake-up can be:

- Events on the BMC receiver (RXORDDET, RXHRSTDET), hardware enable PHYRXEN
- Event on the FRS detector (FRSEVT), hardware enable FRSRXEN
- Events on the Type-C detectors (TYPECEVT1, TYPECEVT2), hardware enables CC1TCDIS, CC2TCDIS

### 63.5 UCPD programming sequences

The normal sequence of use of the UCPD unit is:

1. Configure UCPD.
2. Enable UCPD.
3. Concurrently:
   - On demand from protocol layer, send Tx message
   - Intercept (poll or wait for interrupt) relevant Rx messages and recover detail to hand off to protocol layer

Repeat the last point infinitely.

#### 63.5.1 Initialization phase

Use the following sequence for a clean startup:

1. Prepare all initial clock divider values, by writing the UCPD_CFG register.
2. Enable the unit, by setting the UCPDEN bit.
3. Enable the analog Rx filter of either CC line, via the RXAFILTEN bit of the UCPD_CFGR2 register.

#### 63.5.2 Type-C state machine handling

For the general application cases of source, sink, or dual-role port (the last alternating the source and the sink), the software must implement a corresponding USB Type-C state machine. The basic coding is in the following table.

<table>
<thead>
<tr>
<th>ANAMODE</th>
<th>ANASUBMODE[1:0]</th>
<th>Notes</th>
<th>TYPEC_VSTATE_CCx[1:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>00</td>
</tr>
<tr>
<td>0: Source</td>
<td>00: Disabled</td>
<td>Disabled</td>
<td>N/A</td>
</tr>
<tr>
<td></td>
<td>01: Default USB Rp</td>
<td>-</td>
<td>vRa[Def]</td>
</tr>
<tr>
<td></td>
<td>10: 1.5A Rp</td>
<td>-</td>
<td>vRa[1.5]</td>
</tr>
<tr>
<td>1: Sink</td>
<td>xx</td>
<td>-</td>
<td>vRa</td>
</tr>
</tbody>
</table>

The CCENABLE[1:0] bitfield can disable pull-up/pull-downs on one of the CC lines.

**Note:** The Type-C state machine depends not only on CC line levels, but also on VBUS presence detection (sink mode) and, when in source mode, determines VCONN generation and
VBUS state (ON/OFF/+voltage level); discharge. UCPD does not directly control VBUS generation circuitry nor VCONN load switch (enabling VCONN supply generator to be connected to the CC line), but the application needs these inputs and controls, to function correctly.

General programming sequence (with UCPD configured then enabled)

1. Set ANAMODE and ANASUBMODE[1:0] based on the current position in USB Type-C state machine (and also the current advertisement in the case of a source). This turns on the appropriate pull-ups/pull-downs on the CC lines, and defines the voltage levels that the TYPEC_VSTATE fields represent. Note that before programming, the PHY is effectively off.

2. Read TYPEC_VSTATE_CC1/2 to determine the initial Type-C state (for example whether the local source is connected to a remote sink).

3. In the case of no connection, wait for a connection event.

4. Assuming a connection is detected and assuming a local Power Delivery functionality is implemented, start sending/receiving Power Delivery messages.

5. When a new interrupt/event occurs on PHY_EVT1/2 indicating a change in stable voltage, re-evaluate the implications and give this input to the Type-C state machine.

Case of a source that needs to change between one of the three possible Rp values (Default-USB / 1.5A / 3.0A) and the sink connected to it:

- [Source] Simply reprogram ANASUBMODE[1:0]
- [Sink behavior from that time] PHY_EVT1/2 occurs and the TYPEC_VSTATE1/2 changes accordingly

Programming for a dual-role port (DRP) toggling from source to sink:

- Simply re-program ANAMODE and ANASUBMODE[1:0] to start the new behavior

Detailed programming sequence (example):

- Set ANAMODE and ANASUBMODE[1:0] based on the current position in USB Type-C state machine (and also the current advertisement in the case of a source). This turns on the appropriate pull-ups/pull-downs on the CC lines, and defines the voltage levels that the TYPEC_VSTATE fields represent. Note that before programming, the PHY is effectively off.

- Read TYPEC_VSTATE_CC1/2 to determine the initial Type-C state (for example whether the local source is connected to a remote sink).

- In the case of no connection, wait for a connection event.

- Assuming a connection is detected and assuming a local Power Delivery functionality is implemented, start sending/receiving Power Delivery messages.

- When a new interrupt/event occurs on PHY_EVT1/2 indicating a change in stable voltage, re-evaluate the implications and give this input to the Type-C state machine.

Case of a source that needs to change between one of the three possible Rp values (Default-USB / 1.5A / 3.0A) and the sink connected to it:

- [Source] Simply reprogram ANASUBMODE[1:0]
- [Sink behavior from that time] PHY_EVT1/2 occurs and the TYPEC_VSTATE1/2 changes accordingly

Programming for a dual-role port (DRP) toggling from source to sink:

- Simply re-program ANAMODE and ANASUBMODE[1:0] to start the new behavior

Detailed programming sequence (example):

1. Two GPIOs to enable VCONN through external load switch components

#### 63.5.3 USB PD transmit

On reception of a message from the protocol layer (that is, to be sent), prepare Tx message contents by writing the UCPD_TX_ORDSET and UCPD_TX_PAYSZ registers.

The message transmission is triggered by setting the TXSEND bit, with an appropriate value of the TXMODE bitfield.

When the data byte is transmitted, the TXIS flag is raised to request a new data write to the UCPD_TXDR register.

This re-iterates until the entire payload of data is transmitted.
 Upon sending the CRC packet, the TXMSGSENT flag is set to indicate the completion of the message transmission.

**Hard Reset transmission**

As soon as it is known that a Hard Reset needs to be transmitted, setting the TXHRST bit of the UCPD_CR register forces the internal state machine to generate the correct sequence. The value of UCPD_TX_ORDSET does not require update in this precise case (the correct code for Hard Reset is sent by UCPD).

The USB Power Delivery specification requires that in the case of an ongoing message transmission, the Hard Reset takes precedence. In this case, for example, UCPD truncates the payload of the current message, appending EOP to the end. No notification is available via the registers (for example through the TXMSGSEND flag). This is justified by the fact that the Hard Reset takes precedence over any previous activity (for which it is therefore no longer important to know if it is completed).

**Use of DMA for transmission**

DMA (Direct Memory Access) can be enabled for transmission by setting the TXDMAEN bit in the UCPD_CR register.

For each message:
- Prepare the whole message in memory (starting with two header bytes)
- Program the DMA operation with a length corresponding to the two header bytes plus a number of data bytes corresponding to the number of data words multiplied by four
- Write TXSEND to initiate the message transfer
- If TXMSGDISC then go back to previous line (TXSEND)
- Wait for DMA transfer complete interrupt (that is, when last Tx byte written to UCPD)
- Double-check subsequent TXMSGSENT interrupt appears

**63.5.4 USB PD receive**

Notification of start of the receive message sequence is triggered by an interrupt on UCPD_SR (bit RXORDDET).

The information is recovered by reading:
- UCPD_RX_SOP (on interrupt RXORDDET)
- UCPD_RXDR (on interrupt RXNE, repeats for each byte)
- UCPD_RXPAYSZ (on interrupt RXMSGEND)

The data previously read from UCPD_RXDR above must be discarded at this point if the RXERR flag is set.

If the CRC is valid, the received data is transferred to the protocol layer.

For debug purposes, it may be desirable to track statistics of the number of incorrect K-codes received (this is done only when 3/4 K-codes were valid as defined in the specification). This is facilitated through:
- RXSOP3OF4 bit indicating the presence of at least one invalid K-code
- RXSOPKINVALID bitfield identifying the order of invalid K-code in the ordered set
**Use of DMA for reception**

DMA (Direct Memory Access) can be enabled for reception by setting the RXDMAEN bit in the UCPD_CR register.

Whenever a Rx message is expected:
- Program a DMA receive operation (and spare buffer) a little longer than the maximum possible message (length depends on extended message support).
- After receiving RXORDDET, DMA operation starts working in the background.
- On reception of RXMSGEND interrupt, read RXPAYSZ.
- Double-check RXPAYSZ vs. the number of DMA Rx bytes (must correspond but DMA read of RXDR is slightly after RXDR gets last byte).
- Process the DMA Rx buffer.
- Prepare next Rx DMA buffer as soon as possible in order to be ready.

**63.5.5 UCPD software trimming**

The CC pull-up (Rp) and pull-down (Rd) devices must be trimmed on each part, to meet the required accuracy. The trimming values are saved in the non-volatile memory.

To trim the CC pull-up and pull-down devices by software, apply the following procedure:
1. Retrieve the trim values from the non-volatile memory (refer to Table 677: UCPD software trim data)
2. At initialization, write the trim values to the UCPD_CFG3 register bitfields as follows:
   - 3A0_CC1[3:0] to TRIM_CC1_RP[3:0]
   - 3A0_CC2[3:0] to TRIM_CC2_RP[3:0]
   - Rd_CC1[3:0] to TRIM_CC1_RD[3:0]
   - Rd_CC2[3:0] to TRIM_CC2_RD[3:0]
3. At each setting of ANASUBMODE to 1A5 or 3A0, respectively, write the trimming values to the UCPD_CFG3 register bitfields as follows:
   - 1A5_CC1[3:0] or 3A0_CC1[3:0], respectively, to TRIM_CC1_RP[3:0]
   - 1A5_CC2[3:0] or 3A0_CC2[3:0], respectively, to TRIM_CC2_RP[3:0]

**63.6 UCPD low-power modes**

A summary of low-power modes is shown below in Table 686: Effect of low power modes on the UCPD.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect</td>
</tr>
<tr>
<td>Stop</td>
<td>Detection of events (Type-C, BMC Rx, FRS detection) remains operational and can wake up the MCU.</td>
</tr>
<tr>
<td>Standby</td>
<td>UCPD is not operating, and cannot wake up the MCU. Pull-downs remain active if configured.</td>
</tr>
<tr>
<td>Unpowered</td>
<td>Dead battery pull-downs remain active.</td>
</tr>
</tbody>
</table>
The UCPD is able to wake up the MCU from Stop mode when it recognizes a relevant event, either:

- Type-C event relating to a change in the voltage range seen on either of the CC lines, visible in TYPEC_VSTATE_CCx
- Power delivery receive message with an ordered set matching those filtered according to RXORDSETEN[8:0], visible by reading RXORDSET

Wake-up from Stop mode is enabled by setting the WUPEN bit in the UCPD_CFG2 register.

At UCPD level three types of event requiring kernel clock activity may occur during Stop mode:

- Activity on the analog PHY voltage threshold detectors which can later be confirmed to be a stable change between voltage ranges defined in the Type-C specification
- Activity on Power Delivery BMC receiver (coming from the selected CC line) which can potentially generate an Rx message event (that is, RXORDSET) later
- Activity on Power Delivery FRS detector which can potentially generate an FRS signaling detection event (that is, FRSEVT) later

It order to function correctly with the RCC, the clock request signal is activated (conditional on WUPEN) when there is asynchronous activity on:

- Type-C voltage threshold detectors (coming from either CC line)
- Power Delivery receiver signal (from the selected CC line)
- FRS detection signal (from the selected CC line)

### 63.7 UCPD interrupts

The table below lists the UCPD event flags, with the associated flag clear bits and interrupt enable bits.

<table>
<thead>

<td>TXMSGABTIE</td>
</tr>
</tbody>
</table>
When an interrupt from the UCPD is received, then the software has to check what is the source of the interrupt by reading the UCPD_SR register. Depending on which bit is at 1, the ISR must handle that condition and clear the bit by a write to the appropriate bit of the UCPD_ICR register.

### 63.8 UCPD registers

#### 63.8.1 UCPD configuration register 1 (UCPD_CFGR1)

Address offset: 0x000  
Reset value: 0x0000 0000  
General configuration of the peripheral. Writing to this register is only effective when UCPD is disabled (UCPDEN = 0).

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>UCPDEN</td>
</tr>
<tr>
<td>30</td>
<td>RXDMAEN</td>
</tr>
<tr>
<td>29</td>
<td>TXDMAEN</td>
</tr>
<tr>
<td>28</td>
<td>RXORDSETEN[8:0]</td>
</tr>
<tr>
<td>27</td>
<td>PSC_UCPDCLK[2:0]</td>
</tr>
</tbody>
</table>

Bit 31 **UCPDEN**: UCPD peripheral enable  
General enable of the UCPD peripheral.  
0: Disable  
1: Enable  
Upon disabling, the peripheral instantly quits any ongoing activity and all control bits and bitfields default to their reset values. They must be set to their desired values each time the peripheral transits from disabled to enabled state.

Bit 30 **RXDMAEN**: Reception DMA mode enable  
When set, the bit enables DMA mode for reception.  
0: Disable  
1: Enable
Bit 29 **TXDMAEN**: Transmission DMA mode enable
When set, the bit enables DMA mode for transmission.
0: Disable
1: Enable

Bits 28:20 **RXORDSETEN[8:0]**: Receiver ordered set enable
The bitfield determines the types of ordered sets that the receiver must detect. When set/cleared, each bit enables/disables a specific function:

- 0bXXXXXXXX1: SOP detect enabled
- 0bXXXXXXXX1X: SOP' detect enabled
- 0bXXXXXXXX1XX: SOP'' detect enabled
- 0bXXXXXXX1XXX: Hard Reset detect enabled
- 0bXXXXXXX1XXXX: Cable Detect reset enabled
- 0bXXXXXXX1XXXXX: SOP_DEBUG enabled
- 0bXXXXXXX1XXXXXX: SOP''_Debug enabled
- 0bXXXXXXX1XXXXXXX: SOP extension#1 enabled
- 0bXXXXXXX1XXXXXXXX: SOP extension#2 enabled

Bits 19:17 **PSC_UCPDCLK[2:0]**: Pre-scaler division ratio for generating ucpd_clk
The bitfield determines the division ratio of a kernel clock pre-scaler producing UCPD peripheral clock (ucpd_clk).

- 0x0: 1 (bypass)
- 0x1: 2
- 0x2: 4
- 0x3: 8
- 0x4: 16

It is recommended to use the pre-scaler so as to set the ucpd_clk frequency in the range from 6 to 9 MHz.

Bit 16 Reserved, must be kept at reset value.

Bits 15:11 **TRANSWIN[4:0]**: Transition window duration
The bitfield determines the division ratio (the bitfield value minus one) of a hbit_clk divider producing $t_{TransitionWindow}$ interval.

- 0x00: Not supported
- 0x01: 2
- 0x09: 10 (recommended)
- 0x1F: 32

Set a value that produces an interval of 12 to 20 us, taking into account the ucpd_clk frequency and the HBITCLKDIV[5:0] bitfield setting.

Bits 10:6 **IFRGAP[4:0]**: Division ratio for producing inter-frame gap timer clock
The bitfield determines the division ratio (the bitfield value minus one) of a ucpd_clk divider producing inter-frame gap timer clock ($t_{InterFrameGap}$).

- 0x00: Not supported
- 0x01: 2
- 0x0D: 14
- 0x0E: 15
- 0x0F: 16
- 0x1F: 32

The division ratio 15 is to apply for Tx clock at the USB PD 2.0 specification nominal value. The division ratios below 15 are to apply for Tx clock below nominal, and the division ratios above 15 for Tx clock above nominal.
Bits 5:0  **HBITCLKDIV[5:0]**: Division ratio for producing half-bit clock
   The bitfield determines the division ratio (the bitfield value plus one) of a ucpd_clk divider producing half-bit clock (hbit_clk).
   0x00: 1 (bypass)
   0x1A: 27
   0x3F: 64

### 63.8.2 UCPD configuration register 2 (UCPD_CFGR2)

**Address offset**: 0x004

**Reset value**: 0x0000 0000

Configuration of the UCPD Rx signal filtering. Writing to this register is only effective when UCPD is disabled (UCPDEN = 0).

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>

</tr>
</tbody>
</table>

**Bits 31:9**  Reserved, must be kept at reset value.

**Bit 8**  **RXAFILTEN**: Rx analog filter enable
   Setting the bit enables the Rx analog filter required for optimum Power Delivery reception.
   0: Disable
   1: Enable

**Bits 7:4**  Reserved, must be kept at reset value.

**Bit 3**  **WUPEN**: Wake-up from Stop mode enable
   Setting the bit enables the UCPD_ASYNC_INT signal.
   0: Disable
   1: Enable

**Bit 2**  **FORCECLK**: Force CkReq clock request
   0: Do not force clock request
   1: Force clock request

**Bit 1**  **RXFILT2N3**: BMC decoder Rx pre-filter sampling method
   Number of consistent consecutive samples before confirming a new value.
   0: 3 samples
   1: 2 samples

**Bit 0**  **RXFILTDIS**: BMC decoder Rx pre-filter enable
   0: Enable
   1: Disable
   The sampling clock is that of the receiver (that is, after pre-scaler).
### 63.8.3 UCPD configuration register 3 (UCPD_CCFGR3)

- **Address offset:** 0x008
- **Reset value:** 0x0000 0000

Configuration of UCPD trimming of the CC pull-up and pull-down devices. The trimming is managed by hardware until the first software write into this register.

The register is reserved (must not be written) for devices that support the fully automatic trimming. Refer to Table 676: UCPD implementation.

</table>
Bits 31:22  Reserved, must be kept at reset value.

Bit 21  **CC2TCDIS**: CC2 Type-C detector disable
The bit disables the Type-C detector on the CC2 line.
0: Enable
1: Disable
When enabled, the Type-C detector for CC2 is configured through ANAMODE and ANASUBMODE[1:0].

Bit 20  **CC1TCDIS**: CC1 Type-C detector disable
The bit disables the Type-C detector on the CC1 line.
0: Enable
1: Disable
When enabled, the Type-C detector for CC1 is configured through ANAMODE and ANASUBMODE[1:0].

Bit 19  Reserved, must be kept at reset value.

Bit 18  **RDCH**: Rdch condition drive
The bit drives Rdch condition on the CC line selected through the PHYCCSEL bit (thus associated with VCONN), by remaining set during the source-only UnattachedWait.SRC state, to respect the Type-C state. Refer to "USB Type-C ECN for Source VCONN Discharge". The CCENABLE[1:0] bitfield must be set accordingly, too.
0: No effect
1: Rdch condition drive

Bit 17  **FRSTX**: FRS Tx signaling enable.
Setting the bit enables FRS Tx signaling.
0: No effect
1: Enable
The bit is cleared by hardware after a delay respecting the USB Power Delivery specification Revision 3.1.

Bit 16  **FRSRXEN**: FRS event detection enable
Setting the bit enables FRS Rx event (FRSEVT) detection on the CC line selected through the PHYCCSEL bit. 0: Disable
1: Enable
Clear the bit when the device is attached to an FRS-incapable source/sink.

Bit 15  Reserved, must be kept at reset value.

Bit 14  Reserved, must be kept at reset value.

Bit 13  Reserved, must be kept at reset value.

Bit 12  Reserved, must be kept at reset value.

Bits 11:10  **CCENABLE[1:0]**: CC line enable
This bitfield enables CC1 and CC2 line analog PHYs (pull-ups and pull-downs) according to ANAMODE and ANASUBMODE[1:0] setting.
0x0: Disable both PHYs
0x1: Enable CC1 PHY
0x2: Enable CC2 PHY
0x3: Enable CC1 and CC2 PHY
A single line PHY can be enabled when, for example, the other line is driven by VCONN via an external VCONN switch. Enabling both PHYs is the normal usage for sink/source.
Bit 9 **ANAMODE**: Analog PHY operating mode
- 0: Source
- 1: Sink
The use of CC1 and CC2 depends on CCENABLE. Refer to Table 684: Coding for ANAMODE, ANASUBMODE and link with TYPEC_VSTATE_CCx for the effect of this bitfield in conjunction with ANASUBMODE[1:0].

Bits 8:7 **ANASUBMODE[1:0]**: Analog PHY sub-mode
Refer to Table 684: Coding for ANAMODE, ANASUBMODE and link with TYPEC_VSTATE_CCx for the effect of this bitfield.

Bit 6 **PHYCCSEL**: CC1/CC2 line selector for USB Power Delivery signaling
- 0: Use CC1 IO for Power Delivery communication
- 1: Use CC2 IO for Power Delivery communication
The selection depends on the cable orientation as discovered at attach.

Bit 5 **PHYRXEN**: USB Power Delivery receiver enable
- 0: Disable
- 1: Enable
Both CC1 and CC2 receivers are disabled when the bit is cleared. Only the CC receiver selected via the PHYCCSEL bit is enabled when the bit is set.

Bit 4 **RXMODE**: Receiver mode
Determines the mode of the receiver.
- 0: Normal receive mode
- 1: BIST receive mode (BIST test data mode)
When the bit is set, RXORDSET behaves normally, RXDR no longer receives bytes yet the CRC checking still proceeds as for a normal message. As this mode prevents reception of the header (containing MessageID), software has to auto-increment a received MessageID counter for inclusion in the GoodCRC acknowledge that must still be transmitted during this test.

Bit 3 **TXHRST**: Command to send a Tx Hard Reset
- 0: No effect
- 1: Start Tx Hard Reset message
The bit is cleared by hardware as soon as the message transmission begins or is discarded.

Bit 2 **TXSEND**: Command to send a Tx packet
- 0: No effect
- 1: Start Tx packet transmission
The bit is cleared by hardware as soon as the packet transmission begins or is discarded.

Bits 1:0 **TXMODE[1:0]**: Type of Tx packet
Writing the bitfield triggers the action as follows, depending on the value:
- 0x0: Transmission of Tx packet previously defined in other registers
- 0x1: Cable Reset sequence
- 0x2: BIST test sequence (BIST Carrier Mode 2)
- Others: invalid
From V1.1 of the USB PD specification, there is a counter defined for the duration of the BIST Carrier Mode 2. To quit this mode correctly (after the "tBISTContMode" delay), disable the peripheral (UCPDEN = 0).
### 63.8.5 UCPD interrupt mask register (UCPD_IMR)

Address offset: 0x010  
Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

- **Bit 7**: Reserved, must be kept at reset value.
63.8.6 UCPD status register (UCPD_SR)

Address offset: 0x014
Reset value: 0x0000 0000

The flags (single-bit status bitfields) are associated with interrupt request. Interrupt is generated if enabled by the corresponding bit of the UCPD_IMR register.

Bits 31:21 Reserved, must be kept at reset value.
Bit 20  **FRSEVT**: FRS detection event
The flag is cleared by setting the FRSEVT CF bit.
0: No new event
1: New FRS receive event occurred

Bits 19:18  **TYPEC_VSTATE_CC2[1:0]**: CC2 line voltage level
The status bitfield indicates the voltage level on the CC2 line in its steady state.
0x0: Lowest
0x1: Low
0x2: High
0x3: Highest
The voltage variation on the CC2 line during USB PD messages due to the BMC PHY modulation does not impact the bitfield value.

Bits 17:16  **TYPEC_VSTATE_CC1[1:0]**:
The status bitfield indicates the voltage level on the CC1 line in its steady state.
0x0: Lowest
0x1: Low
0x2: High
0x3: Highest
The voltage variation on the CC1 line during USB PD messages due to the BMC PHY modulation does not impact the bitfield value.

Bit 15  **TYPECEVT2**: Type-C voltage level event on CC2 line
The flag indicates a change of the TYPEC_VSTATE_CC2[1:0] bitfield value, which corresponds to a new Type-C event. It is cleared by setting the TYPECEVT2 CF bit.
0: No new event
1: A new Type-C event

Bit 14  **TYPECEVT1**: Type-C voltage level event on CC1 line
The flag indicates a change of the TYPEC_VSTATE_CC1[1:0] bitfield value, which corresponds to a new Type-C event. It is cleared by setting the TYPECEVT2 CF bit.
0: No new event
1: A new Type-C event

Bit 13  **RXERR**: Receive message error
The flag indicates errors of the last Rx message declared (via RXMSGEND), such as incorrect CRC or truncated message (a line becoming static before EOP is met). It is asserted whenever the RXMSGEND flag is set.
0: No error detected
1: Error(s) detected

Bit 12  **RXMSGEND**: Rx message received
The flag indicates whether a message (except Hard Reset message) has been received, regardless the CRC value. The flag is cleared by setting the RXMSGENDCF bit.
0: No new Rx message received
1: A new Rx message received
The RXERR flag set when the RXMSGEND flag goes high indicates errors in the last-received message.

Bit 11  **RXOVR**: Rx data overflow detection
The flag indicates Rx data buffer overflow. It is cleared by setting the RXOVR CF bit.
0: No overflow
1: Overflow
The buffer overflow can occur if the received data are not read fast enough.
Bit 10 **RXHRSTDET**: Rx Hard Reset receipt detection
The flag indicates the receipt of valid Hard Reset message. It is cleared by setting the RXHRSTDET bit.
0: Hard Reset not received
1: Hard Reset received

Bit 9 **RXORDDET**: Rx ordered set (4 K-codes) detection
The flag indicates the detection of an ordered set. The relevant information is stored in the RXORDSET[2:0] bitfield of the UCPD_RX_ORDSET register. It is cleared by setting the RXORDDETCF bit.
0: No ordered set detected
1: A new ordered set detected

Bit 8 **RXNE**: Receive data register not empty detection
The flag indicates that the UCPD_RXDR register is not empty. It is automatically cleared upon reading UCPD_RXDR.
0: Rx data register empty
1: Rx data register not empty

Bit 7 Reserved, must be kept at reset value.

Bit 6 **TXUND**: Tx data underrun detection
The flag indicates that the Tx data register (UCPD_TXDR) was not written in time for a transmit message to execute normally. It is cleared by setting the TXUNDCF bit.
0: No Tx data underrun detected
1: Tx data underrun detected

Bit 5 **HRSTSENT**: Hard Reset message sent
The flag indicates that the Hard Reset message is sent. The flag is cleared by setting the HRSTSENT bit.
0: No Hard Reset message sent
1: Hard Reset message sent

Bit 4 **HRSTDISC**: Hard Reset discarded
The flag indicates that the Hard Reset message is discarded. The flag is cleared by setting the HRSTDISCCF bit.
0: No Hard Reset discarded
1: Hard Reset discarded

Bit 3 **TXMSGABT**: Transmit message abort
The flag indicates that a Tx message is aborted due to a subsequent Hard Reset message send request taking priority during transmit. It is cleared by setting the TXMSGABTCF bit.
0: No transmit message abort
1: Transmit message abort

Bit 2 **TXMSGSSENT**: Message transmission completed
The flag indicates the completion of packet transmission. It is cleared by setting the TXMSGSSENT bit.
0: No Tx message completed
1: Tx message completed
In the event of a message transmission interrupted by a Hard Reset, the flag is not raised.
Bit 1 **TXMSGDISC**: Message transmission discarded
The flag indicates that a message transmission was dropped. The flag is cleared by setting the TXMSGDISCCF bit.
- 0: No Tx message discarded
- 1: Tx message discarded
Transmission of a message can be dropped if there is a concurrent receive in progress or at excessive noise on the line. After a Tx message is discarded, the flag is only raised when the CC line becomes idle.

Bit 0 **TXIS**: Transmit interrupt status
The flag indicates that the UCPD_TXDR register is empty and new data write is required (as the amount of data sent has not reached the payload size defined in the TXPAYSZ bitfield).
- 0: New Tx data write not required
- 1: New Tx data write required

### 63.8.7 UCPD interrupt clear register (UCPD_ICR)

Address offset: 0x018
Reset value: 0x0000 0000
Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

Bits 31:21 Reserved, must be kept at reset value.

- Bit 20 **FRSEVTCF**: FRS event flag (FRSEVT) clear
  Setting the bit clears the FRSEVT flag in the UCPD_SR register.

Bits 19:16 Reserved, must be kept at reset value.

- Bit 15 **TYPECEVT2CF**: Type-C CC2 line event flag (TYPECEVT2) clear
  Setting the bit clears the TYPECEVT2 flag in the UCPD_SR register

- Bit 14 **TYPECEVT1CF**: Type-C CC1 event flag (TYPECEVT1) clear
  Setting the bit clears the TYPECEVT1 flag in the UCPD_SR register

- Bit 13 Reserved, must be kept at reset value.

- Bit 12 **RXMSGENDCF**: Rx message received flag (RXMSGEND) clear
  Setting the bit clears the RXMSGEND flag in the UCPD_SR register.
Bit 11 **RXOVRCF**: Rx overflow flag (RXOVR) clear
   Setting the bit clears the RXOVR flag in the UCPD_SR register.

Bit 10 **RXHRSTDETCF**: Rx Hard Reset detect flag (RXHRSTDET) clear
   Setting the bit clears the RXHRSTDET flag in the UCPD_SR register.

Bit 9 **RXORDDETCF**: Rx ordered set detect flag (RXORDDET) clear
   Setting the bit clears the RXORDDET flag in the UCPD_SR register.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TXUNDCF**: Tx underflow flag (TXUND) clear
   Setting the bit clears the TXUND flag in the UCPD_SR register.

Bit 5 **HRSTSENTCF**: Hard reset send flag (HRSTSENT) clear
   Setting the bit clears the HRSTSENT flag in the UCPD_SR register.

Bit 4 **HRSTDISCCF**: Hard reset discard flag (HRSTDISC) clear
   Setting the bit clears the HRSTDISC flag in the UCPD_SR register.

Bit 3 **TXMSGABTCF**: Tx message abort flag (TXMSGABT) clear
   Setting the bit clears the TXMSGABT flag in the UCPD_SR register.

Bit 2 **TXMSGSENCF**: Tx message send flag (TXMSGSEN) clear
   Setting the bit clears the TXMSGSEN flag in the UCPD_SR register.

Bit 1 **TXMSGDISCF**: Tx message discard flag (TXMSGDISC) clear
   Setting the bit clears the TXMSGDISC flag in the UCPD_SR register.

Bit 0 Reserved, must be kept at reset value.

### 63.8.8 UCPD Tx ordered set type register (UCPD_TX_ORDSETR)

**Address offset**: 0x01C
**Reset value**: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1) and no packet transmission is in progress (TXSEND and TXHRST bits are both low).

</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **TXORDSET[19:0]**: Ordered set to transmit
   The bitfield determines a full 20-bit sequence to transmit, consisting of four K-codes, each of five bits, defining the packet to transmit. The bit 0 (bit 0 of K-code1) is the first, the bit 19 (bit 4 of K-code4) the last.
63.8.9 UCPD Tx payload size register (UCPD_TX_PAYSZR)

Address offset: 0x020
Reset value: 0x0000 0000
Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

| Bits 31:10 | Reserved, must be kept at reset value. |
| Bits 9:0   | TXPAYSZ[9:0]: Payload size yet to transmit |
|           | The bitfield is modified by software and by hardware. It contains the number of bytes of a payload (including header but excluding CRC) yet to transmit: each time a data byte is written into the UCPD_TXDR register, the bitfield value decrements and the TXIS bit is set, except when the bitfield value reaches zero. The enumerated values are standard payload sizes before the start of transmission. |
|           | 0x2: 2 bytes - the size of Control message from the protocol layer |
|           | 0x6: 6 bytes - the shortest Data message allowed from the protocol layer |
|           | 0x1E: 30 bytes - the longest non-extended Data message allowed from the protocol layer |
|           | 0x106: 262 bytes - the longest possible extended message |
|           | 0x3FF: 1024 bytes - the longest possible payload (for future expansion) |

63.8.10 UCPD Tx data register (UCPD_TXDR)

Address offset: 0x024
Reset value: 0x0000 0000
Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

| Bits 31:8  | Reserved, must be kept at reset value. |
| Bits 7:0   | TXDATA[7:0]: Data byte to transmit |

<td>0</td>
</tr>
</tbody>
</table>

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **RXPAYSZ[9:0]**: Rx payload size received

This bitfield contains the number of bytes of a payload (including header but excluding CRC) received: each time a new data byte is received in the UCPD_RXDR register, the bitfield value increments and the RXMSGEND flag is set (and an interrupt generated if enabled).

- 0x2: 2 bytes - the size of Control message from the protocol layer
- 0x6: 6 bytes - the shortest Data message allowed from the protocol layer
- 0x1E: 30 bytes - the longest non-extended Data message allowed from the protocol layer
- 0x106: 262 bytes - the longest possible extended message
- 0x3FF: 1024 bytes - the longest possible payload (for future expansion)

The bitfield may return a spurious value when a byte reception is ongoing (the RXMSGEND flag is low).

63.8.13 UCPD receive data register (UCPD_RXDR)

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **RXDATA[7:0]**: Data byte received
63.8.14 UCPD Rx ordered set extension register 1
(UCPD_RX_ORDEXT1)

Address offset: 0x034
Reset value: 0x0000 0000
Writing to this register is only effective when the peripheral is disabled (UCPDEN = 0).

Bits 31:20 Reserved, must be kept at reset value.
Bits 19:0 RXSOPX1[19:0]: Ordered set 1 received
The bitfield contains a full 20-bit sequence received, consisting of four K-codes, each of five bits. The bit 0 (bit 0 of K-code1) is receive first, the bit 19 (bit 4 of K-code4) last.

63.8.15 UCPD Rx ordered set extension register 2
(UCPD_RX_ORDEXT2)

Address offset: 0x038
Reset value: 0x0000 0000
Writing to this register is only effective when the peripheral is disabled (UCPDEN = 0).

Bits 31:20 Reserved, must be kept at reset value.
Bits 19:0 RXSOPX2[19:0]: Ordered set 2 received
The bitfield contains a full 20-bit sequence received, consisting of four K-codes, each of five bits. The bit 0 (bit 0 of K-code1) is receive first, the bit 19 (bit 4 of K-code4) last.
## 63.8.16 UCPD register map

### Table 688. UCPD register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

64 Ethernet (ETH): media access control (MAC) with DMA controller

64.1 Ethernet introduction

Portions Copyright (c) Synopsys, Inc. All rights reserved. Used with permission.

The Ethernet peripheral enables to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2008 standard.

The peripheral is configurable to meet the needs of a large variety of consumer and industrial applications.

64.2 Ethernet main features

The Ethernet peripheral embeds a dedicated DMA for direct memory interface, a media access controller (MAC) and a PHY interface block supporting several formats.

64.2.1 Standard compliance

The Ethernet peripheral is compliant with the following standards:

- IEEE 802.3-2008 for Ethernet MAC and media independent interface (MII)
- IEEE 1588-2008 for precision networked clock synchronization (PTP)
- IEEE 802.3az-2010 for Energy Efficient Ethernet (EEE)
- AMBA 2.0 for AHB master and AHB slave ports
- RMII specification version 1.2 from RMII consortium

64.2.2 MAC features

MAC Tx and Rx common features

- Separate transmission, reception, and control interfaces to the application
- 10, 100 Mbps data transfer rates with the following PHY interfaces:
  - IEEE 802.3-compliant MII interface to communicate with an external Fast Ethernet PHY
  - RMII interface to communicate with an external Fast Ethernet PHY
- Half-duplex operation:
  - CSMA/CD protocol support
  - Flow control using backpressure (based on implementation-specific white papers and UNH Ethernet Clause 4 MAC Test Suite - Annex D)
- Standard IEEE 802.3az-2010 for Energy Efficient Ethernet in MII PHYs
• 32-bit data transfer interface on the application side
• Full-duplex flow control operations (IEEE 802.3x Pause packets and Priority flow control)
• Network statistics with RMON or MIB counters (partial support of RFC2819/RFC2665)
• Ethernet packet timestamping as described in IEEE 1588-2002 and IEEE 1588-2008 (64-bit timestamps given in the Tx or Rx status of PTP packet). Both one-step and two-step timestamping are supported in Tx direction.
• Flexibility to control pulse-per-second (PPS) output signal (eth_ptp_pps_out and ETH_PPS_OUT)
• MDIO (Clause 22 and Clause 45) master interface for PHY device configuration and management

MAC Tx features
• Preamble and start-of-frame data (SFD) insertion
• Separate 32-bit status for each packet transmitted from the application
• Automatic CRC and pad generation controllable on a per-frame basis
• Programmable packet length to support Standard or Jumbo Ethernet packets of up to 16 Kbytes
• Programmable Inter Packet Gap (40–96 bit times in steps of 8)
• IEEE 802.3x Flow Control automatic transmission of zero-quanta Pause packet when flow control input transitions from assertion to de-assertion (in Full-duplex mode)
• Source address field insertion or replacement, and VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control
• Insertion, replacement, or deletion of up to two VLAN tags
• Option to transmit packets with reduced preamble size in Full-duplex mode
• Insert, replace, or delete queue/channel-based VLAN tags

MAC Rx features
• Automatic Pad and CRC stripping options
• Option to disable automatic CRC checking
• Preamble and SFD deletion
• Separate 112-bit or 128-bit status
• Programmable watchdog timeout limit
• Flexible address filtering modes:
  – Four 48-bit perfect (DA) address filters with masks for each byte
  – Four 48-bit SA address comparison check with masks for each byte
  – 64 bit Hash filter for multicast and unicast (DA) addresses
• Option to pass all multicast addressed packets
• Promiscuous mode to pass all packets without any filtering for network monitoring
• Pass all incoming packets (as per filter) with a status report
- Additional packet filtering:
  - VLAN tag-based: Perfect match and Hash-based filtering based either on the outer or inner VLAN tag
  - Layer 3 and Layer 4-based: TCP or UDP over IPv4 or IPv6
- IEEE 802.1Q VLAN tag detection and option to delete the VLAN tags in received packets
- Detection of remote wake-up packets and AMD magic packets
- Optional forwarding of received Pause packets to the application (in Full-duplex mode)
- Layer 3/Layer 4 checksum offload for received packets
- Stripping of up to two VLAN tags and providing the tags in the status

64.2.3 Transaction layer (MTL) features

MTL Tx and Rx Common Features
- 32-bit Transaction Layer block (bridges the application and the MAC)
- Optimization for packet-oriented transfers with packets delimiters
- Programmable burst length, up to half the size of the MTL Rx queue or Tx queue size, to support burst data transfer in the EQOS-MTL configuration
- Programmable threshold capability for each queue (default of 64 bytes)

MTL Tx features
- 2048-byte Transmit FIFO with programmable threshold capability
- Store-and-forward mechanism or threshold mode (cut-through) for transmission to the MAC
- Automatic retransmission of collision packets in Half-duplex mode
- Discard packets on late collision, excessive collisions, excessive deferral, and under-run conditions with appropriate status
- Module to calculate and insert IPv4 header checksum and TCP, UDP, or ICMP checksum on frames transmitted in Store-and-forward mode
- Statistics by generating pulses for packets dropped (because of underflow) in the Tx FIFO
- Packet-level control for
  - VLAN tag insertion or replacement
  - Ethernet source address insertion
  - Layer 3/Layer 4 checksum insertion control
  - One-step timestamp
  - Timestamp control
  - CRC and pad control
MTL Rx features

- 2048-byte Receive FIFO with configurable threshold
- Programmable Rx queue threshold (default fixed at 64 bytes) in Threshold (or cut-through) mode
- Option to filter all error packets on reception and not forward them to the application in the store-and-forward mode
- Option to forward the undersized good packets
- Statistics by generating pulses for packets dropped (because of overflow) in the Rx FIFO
- Automatic generation of Pause packet control or backpressure signal to the MAC based on the Rx Queue fill level

64.2.4 DMA block features

The DMA block exchanges data between the peripheral and the system memory. DMA transfers are driven by software descriptors structure. The application can use a set of registers (see Section 64.11.2: Ethernet DMA registers) to control the DMA operations. The DMA block supports the following features:

- 32-bit data transfers
- Separate DMA in Transmit path and receive paths
- Optimization for packet-oriented DMA transfers with packet delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) descriptor support
- Descriptor architecture allowing large blocks of data transfer with minimum CPU intervention (each descriptor can transfer up to 32 Kbytes of data)
- Comprehensive status reporting normal operation and transfer errors
- Individual programmable burst length for Tx DMA and Rx DMA engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions
- Per-packet Transmit or Receive Complete Interrupt control
- Round-robin or fixed-priority arbitration between the Receive and Transmit engines
- Start and Stop modes
- Separate ports for host control (AHB) access and host data interface
- Tx DMA channel with TCP segmentation offload (TSO) feature enabled
- Programmable control for Transmit Descriptor posted writes to improve the throughput

64.2.5 Bus interface features

AHB master interface

The AHB master interface features are the following:

- Interfaces with the application through AHB
- 32-bit data on the AHB master port
- Split, Retry, and Error AHB responses
- AHB 1-Kbyte boundary burst splitting
- Software-selected type of AHB burst (fixed burst, indefinite burst, or mix of both)
The AHB master interface does not generate the following:
- Wrap burst
- Locked or protected transfers

**AHB slave interface**

The AHB slave interface supports the following features:
- Interfaces with the application through AHB
- AHB slave interface (32-bit) for CSR access
- All AHB burst types

The AHB slave interface does not generate the following responses:
- Split
- Retry
- Error

### 64.3 Ethernet pins and internal signals

*Table 689* lists the Ethernet inputs and output signals connected to package pins or balls. Active pins depend on the PHY type selected (MII or RMII) and on the device configuration. *Table 690* shows the internal Ethernet signals.

</table>
The Ethernet peripheral is composed of 4 main functional modules:

- **The control and status register module (CSR)** that controls the registers access through AHB 32-bit slave interface
- The direct memory access interface (DMA)
  This is the logical DMA module with one physical channel for reception and one for transmission. It controls the data transfers between MAC and system memory through the AMBA AHB 32-bit master interface.
- **The media access control module (MAC)** in charge of implementing the Ethernet protocol
- **The MAC transaction layer (MTL)** in charge of controlling the data flow between application and MAC.

A protocol adaption module is added to support the RMII PHY Media Independent Interfaces.
64.4.1 DMA controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines. The Tx engine transfers data from the system memory to the MAC Transaction Layer (MTL), whereas the Rx engine transfers data from the device port (PHY) to the system memory.

The controller uses descriptors to efficiently move data from source to destination with minimal application CPU intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The controller can be programmed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

DMA data structures

The DMA and the application communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA transfers the data packets received by the MAC to the Rx buffer in system memory and Tx data packets from the Tx buffer in the system memory. The descriptors that reside in the system memory contain the pointers to these buffers.
The base address of each list is written to the respective Tx and Rx registers: Channel Tx descriptor list address register (ETH_DMACTXDLAR) and Channel Rx descriptor list address register (ETH_DMACRXDLAR).

The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. The number of descriptors in the list is programmed in the respective Tx/Rx, Channel Tx descriptor ring length register (ETH_DMACTXRLR) and Channel Rx descriptor ring length register (ETH_DMACRXRLR).

Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List address register to create a descriptor ring. The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used and physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet, but cannot exceed a single packet. Buffers contain only data. The buffer status is saved in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP is detected.

Descriptors are specified in Section 64.10: Descriptors.

**DMA arbitration**

The DMA module incorporates an arbiter that performs the arbitration between the Tx and Rx channels accesses from the AHB master interface. The following two types of arbitrations are supported and can be selected through DMA mode register (ETH_DMAMR):

- **Round-robin arbitration**: the arbiter allocates the data bus between Rx and Tx in ratio set by Bits [14:12] of ETH_DMAMR.
- **Fixed-priority arbitration**: by default Rx DMA always gets priority over Tx DMA for data access. Setting bit 11 of ETH_DMAMR register gives priority to the Tx DMA.
DMA transmission in default mode

The Tx DMA engine in default mode proceeds as follows:

1. The application sets up the Transmit descriptor (TDES0–TDES3) and sets the Own bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet Packet data.
2. The application shifts the descriptor tail pointer offset value of the Transmit channel.
3. The DMA fetches the descriptor from the application memory.
4. If the DMA detects one of the following conditions, the transmission from that channel is suspended, bit 2 and 16 of the corresponding DMA channel Status register are set, and the Tx engine proceeds to step 11:
   - The descriptor is flagged as owned by the application (TDES3[31] = 0).
   - The descriptor tail pointer is equal to the current descriptor pointer in Ring Descriptor list mode.
   - An error condition occurs.
5. If the acquired descriptor is flagged as owned by the DMA (TDES3[31] = 1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.
6. The DMA fetches the Transmit data from the system memory and transfers the data to the MTL for transmission.
7. If an Ethernet packet is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3 through 7 are repeated until the end-of-Ethernet-packet data is transferred to the MTL.
8. When packet transmission is complete, if IEEE 1588 timestamp feature was enabled for the packet (as indicated in the Tx status), the timestamp value obtained from MTL is written to the Tx descriptor (TDES0 and TDES1) that contains the EOP buffer. The status information is written to this Tx descriptor (TDES3). The application now owns this descriptor because the Own bit is cleared during this step. If the timestamp feature is disabled for this packet, the DMA does not alter TDES0 and TDES1 contents.
9. Bit 0 of Channel status register (ETH_DMACSR) is set after completing transmission of a packet that has Interrupt on Completion (TDES2[31]) set in its Last Descriptor. The DMA engine returns to step 3.
10. In the Suspend state, the DMA tries to acquire the descriptor again (and thereby return to step 3). A poll demand command is triggered by writing any value to the Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. If the application stopped the DMA by clearing Bit 0 of Transmit control register of corresponding DMA channel, the DMA enters the Stop state.
DMA transmission in OSP (Operate on Second Packet) mode

In Run state, if bit 4 is set in the Channel transmit control register (ETH_DMACTXCR), the Transmit process can simultaneously acquire two packets without closing the Status descriptor of the first packet. While the Transmit process completes the first packet transfer, it immediately polls the Transmit descriptor list for the second packet. If the second packet is valid, the Transmit process transfers this packet before writing the status information of the first packet.
In OSP mode, DMA transmission in the Run state operates as described in the following sequence:

1. The DMA executes steps 1 to 7 of the DMA transmission sequence in default mode (see Section: DMA transmission in default mode).
2. The DMA fetches the next descriptor without closing previous packet last descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and jumps to step 7.
4. The DMA fetches the Transmit packet from the system memory and transfers the packet to the MTL until the EOP data is transferred, closing the intermediate descriptors if this packet is split across multiple descriptors.
5. The DMA waits for the packet transmission status and timestamp of previous packet. When the status is available, the DMA writes the timestamp to TDES0 and TDES1 if such timestamp was captured (as indicated by a status bit). The DMA writes the status, with a cleared Own bit, to the corresponding TDES3, thus closing the descriptor. If Timestamp feature is not enabled for the previous packet, the DMA does not alter the contents of TDES2 and TDES3.
6. The Transmit interrupt is set (if enabled). The DMA fetches the next descriptor and proceeds to step 3 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (step 7).
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA performs the following operations:
   a) The DMA writes the timestamp (if enabled for the current packet) to TDES2 and TDES3.
   a) The DMA writes the status to the corresponding TDES3.
   a) The DMA sets the relevant interrupts and returns to Suspend mode.
   If no status is pending and the application stopped the DMA by clearing bit 0 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state.
8. The DMA can exit Suspend mode and enter the Run state (it goes either to step 1 or to step 2 depending on pending status) only after receiving a Transmit Poll demand in Transmit Descriptor Tail Pointer register of corresponding channel.

A description of the basic DMA transmission flow in OSP mode in given in Figure 954: Receive DMA flow.
Figure 953. DMA transmission flow (OSP mode)

1. Start Tx DMA
2. (Re-)fetch next descriptor from Tx Queue
3. Own bit set?

   - No: DMA Tx stopped?
10. DMA Tx stopped?
    - Yes: Stop DMA
    - No: Yes

MS40863V1
DMA reception

In the Receive path, the DMA reads a packet from the MTL receive queue and writes it to the packet data buffers of the corresponding DMA channel.

The DMA Rx descriptor ring structure is described in **Section 64.10: Descriptors**.

The reception sequence for Rx DMA engine is as follows (see also **Figure 954: Receive DMA flow**):

1. The application sets up the Rx descriptors (RDES0-RDES3) and the Own bit (RDES3[31]). The application should set the correct value in the Receive descriptor tail pointer register of corresponding DMA channel to indicate the location of the last valid descriptor for the DMA. If the tail pointer points to descriptor N, the last valid descriptor for the DMA is descriptor N - 1.

2. When bit 0 of **Channel receive control register (ETH_DMACRXCR)** is set, the DMA enters the Run state. The DMA looks for free descriptors based on the Rx Current Descriptor and Descriptor tail pointer register values. The descriptors referenced between the current descriptor and the tail pointer registers are available for the DMA. If there are no free descriptors, the DMA channel enters the Suspend state and goes to step 11.

3. The DMA fetches the next available descriptor in the ring and decodes the receive data buffer address from acquired descriptors.

4. If IEEE 1588 timestamping is enabled and the timestamp is available for the previous packet, the DMA writes the timestamp (if available) to the RDES0 and RDES1 of current descriptor and sets the CTXT field (RDES3[30]).

5. The DMA processes the incoming packets and stores them in the data buffers of acquired descriptor.

6. If the current packet transfer is not complete, the DMA closes the current descriptor as intermediate and goes to step 10.

7. The DMA retrieves the status of the Receive frame from the MTL and writes the status word to current descriptor with the Own bit cleared and the Last descriptor bit set.

8. The DMA writes the Frame Length to RDES3 and the VLAN tag to RDES0. The DMA also writes the MAC control frame opcode, OAM control frame code, and extended status information (if available) to RDES1 of the last descriptor.

9. The DMA stores the timestamp (if available). The DMA writes the context descriptor after the last descriptor for the current packet (in the next available descriptor).

10. If more descriptors are available in the Rx DMA descriptor ring, go to step 3, otherwise go to the Suspend state (step 11).

11. The Receive DMA exits the Suspend state when a Receive Poll demand is given, and the application updates the channel Receive descriptor tail pointer register to indicate the location of the last valid descriptor for DMA. Then, the engine proceeds to step 2 and fetches again the next descriptor.

**Note:** Refer to **Section : Descriptor tail pointer handling examples** for updating the correct value in receive descriptor tail pointer register.

- **Timestamp pending?**
  - Yes: **Write timestamp to RDES0 and RDES1**
  - No: **Clear pending timestamp**
- **Receive Poll demand**
  - Yes: **Start Rx DMA**
  - No: **Supsend Rx DMA**
Priority scheme for Tx DMA and Rx DMA

The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channel 0 to access descriptors and data buffers. The DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin. The DA bit of the DMA mode register (ETH_DMAMR) specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a given channel.

If the Tx DMA and Rx DMA of a given channel are enabled, the DMA which gets the bus when the channel gets control of the bus must be specified. The priority between the corresponding Tx DMA and Rx DMA can be configured through the TXPR field of the DMA mode register (ETH_DMAMR). For round-robin arbitration, the weighted priority between the Tx DMA and Rx DMA is configured through the PR field of the DMA mode register (ETH_DMAMR). Table 691 provides information about the priority scheme between Tx DMA and Rx DMA.

64.4.2 MTL

The MAC Transaction Layer (MTL) provides the FIFO memory interface to buffer and regulate the packets between the application system memory and the MAC. It also enables the data to be transferred between the application clock and MAC clock domains. The MTL layer features two 32-bit wide data paths: the Transmit path and the Receive Path.

- **Transmit path**
  The application or internal DMA pushes the Ethernet packets read from the application or system memory into the Tx FIFO. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the application or internal DMA. The Tx queue size is 2048 bytes.

- **Receive path**
  The MTL Rx module receives the packets from the MAC and pushes them into the Rx queue. The status (fill level) of the queue is indicated to the application or to DMA when it crosses the configured Receive threshold (RTC bits[1:0] defined in *Rx queue operating mode register (ETH_MTLRXQOMR)*), or when the complete packet was received. The MTL also indicates the queue fill level so that the DMA can initiate preconfigured burst transfers towards the master interface. The Rx queue size is 2048 bytes.

64.4.3 MAC

The MAC is responsible of the Ethernet protocol processing. In Transmission mode, it receives data from MTL before transferring it to the PHY interface. In Reception mode, the MAC receives data from the PHY interface before transferring them to the Rx FIFO of the MTL module.

This section briefly describes transmission and reception sequences.

**MAC transmission**

The transmission sequence is as follows:

1. Transmission is initiated when the MTL application pushes in data with the SOP (Start of packet) signal asserted.
2. When the SOP signal is detected, the MAC accepts the data and begins the transmission to the MII.
3. When the EOP (End of packet) is transferred to the MAC, the MAC does one of the following:
   - The MAC completes the normal transmission and provides the transmission status to the MTL.
   - If a normal collision (in Half-duplex mode) occurs during transmission, the MAC provides the Transmit status to the MTL, with the Retry bit set. The MAC provides the Retry request till one of the following is true:
     - the packet was successfully transmitted;
     - the maximum number of Retry requests expires. In this case, the MAC aborts the packet transmission with Excessive Collision Transmit status. The MAC accepts and drops all further data until the next SOP is received. The MTL block should retransmit the same packet from SOP when a Retry request (in the Status) is observed from the MAC.
- If any one of the following event happens, the MAC aborts the packet transmission:
  - no carrier (Half-duplex mode)
  - loss of carrier (Half-duplex mode)
  - excessive deferral (Half-duplex mode)
  - late collisions (Half-duplex mode)
  - jabber
  the MAC accepts and drops all further data until the next SOP is received.

4. The MAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. The MAC accepts and drops all further data until the next SOP is received.

5. During the normal transfer of a packet from MTL, if the MAC receives a SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as continuation of the previous packet.

*Figure 955: Overview of MAC transmission flow* illustrates the MAC transmission process flow.
Figure 955. Overview of MAC transmission flow

Start

Wait for data & SOP From MTL

Condition A

Drop all the data received from MTL and abort transmission

NO

A. EOP asserted by MTL?
B. Underflow asserted by MAC?

Condition B

Normal transmission completed and Transmission status conveyed to MTL
MAC reception

A receive operation is initiated when the MAC detects an SFD on MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

The reception sequence is as follows:

1. When the receive data valid signal (RxDV) of MII becomes active, the Receive State Machine (RSM) starts looking for the SFD field (0xD nibble).
   
   The state machine drops received packets until it detects SFD.

2. When SFD is detected, the state machine starts sending the data of Ethernet packet to the RPC module, beginning with the first byte following the SFD (destination address).

3. If IEEE 1588 timestamp feature is enabled, the MAC takes a snapshot of the system time at which SFD of any packet is detected on MII. If this packet is not dropped during MAC filtering, the timestamp is passed to the application. The MAC converts the received nibble data into bytes and forwards the valid packet data to the RFC module.

4. The receive state machine decodes the Length/Type field of the Ethernet packet being received.

   If the Length/Type field is less than 1,536 and if the MAC is programmed for the Auto CRC/Pad Stripping (bit 20 of the Operating mode configuration register (ETH_MACCR)), the state machine sends the packet data up to the count specified in the Length/Type field and starts dropping bytes (including the FCS field). The state machine decodes the Length/Type field and checks for the Length interpretation.

5. If the Length/Type field is greater than or equal to 1,536, the RPE module sends all received Ethernet packet data to the RFC module if you have not enabled the CRC stripping for Type packet in Bit 21 of the Operating mode configuration register (ETH_MACCR). However, if the CRC stripping has been enabled for Type packets and not enabled the Receive Checksum Offload Engine, the MAC strips and drops the last 4 bytes of all packets of ether type before forwarding the packets to the application.

6. By default, the MAC is programmed for watchdog timer to be enabled, that is, packets above 2,048 (10,240 if Jumbo Packet is enabled) bytes (DA + SA + LT + DATA + PAD + FCS) are cut off at the RPE module. In addition, you can use a programmable watchdog timer (bit 16 of Watchdog timeout register (ETH_MACWTR)) to override the fixed timeout of 2,048 or 10,240 bytes. You can disable the watchdog timer by programming bit 19 of Operating mode configuration register (ETH_MACCR). However, even if the watchdog timer is disabled, a packet greater than 32 Kbytes is cut off and a watchdog timeout status is given.
Figure 956. MAC reception flow

1. Start
2. Wait for phy_rxdv_i from GMII/MII
3. Wait until SFD is detected
4. Start sending the received Ethernet packet to the application layer, starting from DA field
5. IEEE 1588 timestamp feature enabled?
   - Yes: Store the snapshot of the system time when SFD detected
   - No: Length/Type field ≤1536
     - Length/Type field ≥1536
       - CRC stripping for Type packets enabled?
         - Yes: Receive checksum Offload engine enabled?
           - Yes: Send all received Ethernet packet data to RFC
           - No: Drop the last 4 bytes of all Ether type packets and send the remaining bytes to RFC
         - No: CRC error? OR Packet to be filtered?
           - No: Send the packet, timestamp and Status to the Application layer
           - Yes: Drop the packet and send the Status to the Application layer
       - NO: Send only the number of bytes (specified in the Length field) of the received Ethernet packet to RFC. Drop extra padding and FCS field
64.5 Ethernet functional description: MAC

64.5.1 Double VLAN processing

The Ethernet peripheral supports the double VLAN (Virtual LAN) tagging feature in which the MAC can process up to two VLAN tags (inner and outer).

The MAC supports the following:
- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status

Transmit path

*Table 692: Double VLAN processing features in Tx path* describes the features supported by the MAC on the Transmit side.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
</table>
| Support for C-VLAN and S-VLAN Tag types | The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of *VLAN inclusion register (ETH_MACVIR)* and *Inner VLAN inclusion register (ETH_MACIVIR)*, respectively. The Ethernet peripheral supports processing of any sequence of outer and inner VLAN tags. However, it does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following:
  - The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled.
  - The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled.
  - The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN.
  - The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN. |
| VLAN Tag deletion | VLAN tag deletion can be enabled for outer or inner tag through VLC field in the *VLAN inclusion register (ETH_MACVIR)* or *Inner VLAN inclusion register (ETH_MACIVIR)*, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the tag. |
| VLAN Tag Insertion or Replacement | VLAN tag insertion or replacement can be enabled for outer or inner tag through VLC field in the *VLAN inclusion register (ETH_MACVIR)* or *Inner VLAN inclusion register (ETH_MACIVIR)*, respectively. When VLAN tag insertion or replacement is enabled, the VLTI bit in the previous register is used to determine whether the VLAN tag should be taken from the register or the control word. |
Table 693: Double VLAN processing in Rx path describes the features supported by the MAC on the Receive side and the corresponding bits in the VLAN tag register (ETH_MACVTR).

### 64.5.2 Source address and VLAN insertion, replacement, or deletion

#### Source address insertion or replacement

The software can use the SA (source address) insertion or replacement feature to instruct the MAC to do the following for Tx packets:

- Insert the content of the MAC Address registers in the SA field
- Replace the content of the SA field with the content of the MAC Address registers

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC. The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

SA insertion or replacement feature can be enabled for all Transmit packets or selective packets:

- Enabling SA insertion or replacement for all packets
  
  To enable this feature for all packets, program the SARC field of the Operating mode configuration register (ETH_MACCR).

- Enabling SA insertion or replacement for selective packets
  
  To enable this feature for selective packets, use the following program the SA Insertion Control field (bits[25:23] of Transmit Descriptor Word 3/TDES3, refer to Section 64.10.3: Transmit descriptor) in the first Transmit descriptor of the packet. When Bit 25 of TDES3 is set, the SA Insertion Control field indicates insertion or
replacement by MAC Address1 registers. When bit 25 of TDES3 is reset, it indicates insertion or replacement by MAC Address 0 registers.

If MAC Address1 registers are not enabled, the MAC Address0 registers are used for insertion or replacement whatever of the value of the most-significant bit of the SA Insertion Control field.

**VLAN insertion, replacement, or deletion**

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields
- Insert or replace the VLAN Type and VLAN Tag fields

Insertion or replacement is performed based on the setting of VLTI bit in the VLAN inclusion register (ETH_MACVIR) as described in **Table 694: VLAN insertion or replacement based on VLTI bit**.

**Table 694. VLAN insertion or replacement based on VLTI bit**

<table>
<thead>
<tr>
<th>Condition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLTI bit is set</td>
<td>The MAC inserts or replaces the following:</td>
</tr>
<tr>
<td></td>
<td>VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of VLAN inclusion register (ETH_MACVIR))</td>
</tr>
<tr>
<td></td>
<td>VLAN Tag field with VT field of Transmit context descriptor of the packet</td>
</tr>
<tr>
<td>VLTI bit is reset</td>
<td>The MAC inserts or replaces the following:</td>
</tr>
<tr>
<td></td>
<td>VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of VLAN inclusion register (ETH_MACVIR))</td>
</tr>
<tr>
<td></td>
<td>VLAN Tag field with the VLT field of VLAN inclusion register (ETH_MACVIR)</td>
</tr>
</tbody>
</table>

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88A8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

You can enable the VLAN insertion, replacement, or deletion feature for all Tx packets or selective packets:

- To enable this feature for all packets, program the VLC and VLP fields of VLAN inclusion register (ETH_MACVIR).
- To enable this feature for selective packets, program the VTIR field of TDES2 Normal Descriptor (see **Table 727: TDES2 normal descriptor (read format)**).

In addition, the VLP (VLAN Priority control) bit must be reset in VLAN inclusion register (ETH_MACVIR) (for outer VLAN) and Inner VLAN inclusion register (ETH_MACIVIR) (in inner VLAN) for the MAC to take the control inputs from the host, depending on the configuration.
64.5.3 Packet filtering

The MAC supports the following types of filtering for Rx packets:

- **MAC source or destination address filtering**: the Address Filtering Module (AFM) checks the source address and destination address fields of each incoming packet.
- **VLAN filtering**: the MAC supports the VLAN tag-based and VLAN Hash filtering.
- **Layer 3 and Layer 4 filtering**: Layer 3 filtering refers to IP source address and destination address filtering. Layer 4 filtering refers to source port and destination port filtering.

The three filter types can be cascaded. *Figure 957* shows the filtering sequence for Rx packets.

*Figure 957. Packet filtering sequence*

The sequence shown in *Figure 957* is valid when all the filters (L2, VLAN, L3, L4) are active. If any of the Layer filters are not enabled, that filter is bypassed and the subsequent filter is applied. A packet that fails any of the filters is discarded. However, the discarded packet can be forwarded to the host based on the register control.

For example, when RA bit of *Packet filtering control register (ETH_MACPFR)* is set to 1, all the discarded packets are forwarded to the host but with their packet status indicating the
specific filter failure. If RA bit is cleared to 0, VTFE and IPFE bits of Packet filtering control register (ETH_MACPFR) control if the packets that fail the VLAN filter and Layer 3-4 filter should be discarded or forwarded to the host.

**MAC source or destination address filtering**

The MAC address filtering module checks the source address (SA) and destination address (DA) fields of each incoming packet.

**Unicast destination address filtering**

The MAC supports 4 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of Packet filtering control register (ETH_MACPFR) is reset), the MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. The default MacAddr0 is always enabled.

The MacAddr1 to MacAddr3 addresses are selected with an individual enable bit. You can mask each byte during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in MAC Address x high register (ETH_MACAxHR). This enables group address filtering for the DA.

In Hash filtering mode (when HUC bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For Hash filtering, the MAC uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 00000 selects bit 0 of selected register, and a value of 11111 selects bit 63 of Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.

**Multicast destination address filtering**

To program the MAC to pass all multicast packets, set the PM bit in Packet filtering control register (ETH_MACPFR). If the PM bit is reset, the MAC performs the filtering for multicast addresses based on the HMC bit of the Packet filtering control register (ETH_MACPFR).

In Perfect filtering mode, the multicast address is compared with the programmed MAC destination address registers. Group address filtering is also supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. The MAC uses the upper 6-bits CRC of received multicast address to index the content of the Hash table. A value of 000000 selects bit 0 of selected register and a value of 111111 selects bit 63 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

**Hash or Perfect address filtering**

To configure the DA filter to pass a packet when its DA matches either the Hash filter or the Perfect filter, set the HPF bit and the corresponding HUC or HMC bits in Packet filtering control register (ETH_MACPFR). This is applicable to both unicast and multicast packets. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to receive packet.

**Broadcast address filtering**

The MAC does not filter any broadcast packets by default. To program the MAC to reject all broadcast packets, set the DBF bit in Packet filtering control register (ETH_MACPFR).

**Unicast source address filtering**
The MAC can perform perfect filtering based on the source address field of received packets. By default, the MAC compares the SA field with the values programmed in the SA registers. You can configure the MAC Address registers to use SA instead of DA for comparison by setting bit 30 of MAC Address x high register (ETH_MACAxHR).

The MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in Packet filtering control register (ETH_MACPFR). Otherwise, the result of the SA filter is given as a status bit in the Receive Status word (see Table 696). When the SAF bit is set, the SA filter and DA filter result is ANDed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

**Inverse filtering**

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of Packet filtering control register (ETH_MACPFR). The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Table 695 and Table 696 summarize the DA and SA filtering based on the type of packets received.

**Note:** When the RA bit of Packet filtering control register (ETH_MACPFR) is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx status.

</table>
The MAC supports Perfect and Hash VLAN filtering. Refer to Section 64.9.14: Programming guidelines to perform VLAN filtering on the receiver for detailed programming steps.

**VLAN tag Perfect filtering**

In VLAN tag Perfect filtering, the MAC compares the VLAN tag of received packet and provides the VLAN packet status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of received VLAN tag to determine the perfect match.

If VLAN tag Perfect filtering is enabled, the MAC forwards the VLAN-tagged packets along with VLAN tag match status and drops the VLAN packets that do not match. You can also enable the inverse matching for VLAN packets by setting the VTIM bit of VLAN tag register \( \text{ETH\_MACVTR} \). In addition, you can enable matching of S-VLAN tagged packets along with the default C-VLAN tagged packets by setting the ESVL bit of VLAN tag register \( \text{ETH\_MACVTR} \). The VLAN packet status bit (bit 10 of RDES0) indicates the VLAN tag match status for the matched packets.

**Note:** The source or destination address (if enabled) has precedence over the VLAN tag filters. This means that a packet that fails the source or destination address filter is dropped irrespective of the VLAN tag filter results.

**VLAN tag Hash filtering**

The 16-bit VLAN Hash Table is used for group address filtering based on the VLAN tag. The VLAN tag Hash filtering feature can be enabled using the VTHM (VLAN tag Hash Table match enable) bit of the VLAN tag register \( \text{ETH\_MACVTR} \). If the VTHM bit is set, the most significant four bits of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.
Note: The 16 or 12 bits of VLAN Tag are considered for CRC-32 computation based on ETV bit in ETH_MACVTR register.

When ETV bit is reset, most significant four bits of CRC-32 of VLAN Tag are inverted and used to index the content of VLAN Hash table register (ETH_MACVHTR).

When ETV bit is set, most significant four bits of CRC-32 of VLAN Tag are directly used to index the content of VLAN tag register (ETH_MACVTR).

The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the Perfect or Hash filter, the packet should be dropped. If the VLAN perfect and VLAN Hash match are enabled, a packet is considered as matched if either the VLAN Hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and Hash filters indicate mismatch.

Table 697 shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of Packet filtering control register (ETH_MACPFR) is set, all packets are received and the VLAN match status is indicated in the VF bit of RDES2 normal descriptor (write-back format). When the RA bit is not set and the VTFE bit is set in Packet filtering control register (ETH_MACPFR), the packet is dropped if the final VLAN match status is Fail. In Table 697, value X means that this column can have any value.

When VLAN VID is programmed to 0 in the VL field of VLAN tag register (ETH_MACVTR), all VLAN-tagged packets are considered as perfect matched but the status of the VLAN Hash match depends on the VTHM and VTIM bits in VLAN tag register (ETH_MACVTR).

Layer 3 and Layer 4 filtering

The MAC supports Layer 3 and Layer 4 based packet filtering. The Layer 3 filtering refers to the IP Source or Destination Address filtering in the IPv4 or IPv6 packets whereas Layer 4 filtering refers to the Source or Destination Port number filtering in TCP or UDP.

The Layer 3 and Layer 4 packet filtering feature automatically enables the IPC Full Checksum Offload Engine on the Receive side. For Layer 3 or Layer 4 filtering operation, you must set the IPC bit of the Operating mode configuration register (ETH_MACCR) to enable the Rx Checksum Offload engine.

When Layer 3 and Layer 4 filtering is enabled, the packets are filtered in the following way:

- Matched packets
  The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of Operating mode configuration register (ETH_MACCR) is set and one of the following conditions is true:
    - All enabled Layer 3 and Layer 4 fields match.
    - At least one of the enabled field matches and other fields are bypassed or disabled
      When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides the status of the lowest filter where Filter 0 is the lowest filter and Filter 3 is the highest filter. For example, if Filter 0 and Filter 1 match, the MAC gives the status corresponding to filter 0.

  Note: The source or destination address and VLAN tag filters (if enabled) have precedence over Layer 3 and Layer 4 filter. This means that a packet which fails the source or destination address or VLAN tag filter is dropped irrespective of the Layer 3 and Layer 4 filter results.

- Unmatched packets
  The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets. The aborted or partial packets are dropped in the MTL Rx FIFO. If the Rx FIFO operates in the Threshold (cut-through) mode and the threshold is programmed to a small value, such packet transfer to the application starts before the failed Layer 3 and Layer 4 filter results are available, the application may receive a partial packet with appropriate abort status.

- Non-TCP or UDP IP Packets
  By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP packets.

Layer 3 filtering

The MAC supports perfect matching or inverse matching for IP Source Address and Destination Address. In addition, you can match the complete IP address or mask the lower bits matching, that is, compare all bits of the address except the specified lower mask bits.

For IPv6 packets filtering, you can enable the last four data registers of a register set to contain the 128-bit IP Source Address or IP Destination Address. The IP Source Address or Destination Address should be programmed in the order defined in the IPv6 specification, that is, the first byte of the IP Source Address or Destination Address in the received packet is in the higher byte of the register and the subsequent registers follow the same order.
For IPv4 packet filtering, you can enable the second and third data registers of a register set to contain the 32-bit IP Source Address and IP Destination Address. The remaining two data registers are reserved. The IP Source Address or Destination Address should be programmed in the order defined in the IPv4 specification, that is, the first byte of IP Source Address and Destination Address in the received packet in the higher byte of the respective register.

Layer 4 filtering

The MAC supports perfect matching or inverse matching for TCP or UDP Source and Destination Port numbers. However, you can program only one type (TCP or UDP) at a time. The first data register contains the 16-bit Source and Destination Port numbers of TCP or UDP, that is, the lower 16 bits for Source Port number and higher 16 bits for Destination Port number.

The TCP or UDP Source and Destination Port numbers should be programmed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP Source and Destination Port number in the received packet is in the higher byte of the register.

Layer 3 and Layer 4 filters register set

The MAC implements two sets of registers for Layer 3 and Layer 4 based packet filtering. In a register set, there is a control register, such as L3 and L4 control 0 register (ETH_MACL3L4C0R), to control the packet filtering. In addition, there are five address registers to program the Layer 3 and Layer 4 fields to be matched, such as:

- Layer4 Address filter 0 register (ETH_MACL4A0R)
- Layer3 Address 0 filter 0 register (ETH_MACL3A00R)
- Layer3 Address 1 filter 0 register (ETH_MACL3A10R)
- Layer3 Address 2 filter 0 register (ETH_MACL3A20R)
- Layer3 Address 3 filter 0 register (ETH_MACL3A30R)

The second, and independent set of registers are: L3 and L4 control 1 register (ETH_MACL3L4C1R), Layer 4 address filter 1 register (ETH_MACL4A1R), Layer3 address 0 filter 1 Register (ETH_MACL3A01R), Layer3 address 1 filter 1 register (ETH_MACL3A11R), Layer3 address 2 filter 1 Register (ETH_MACL3A21R) and Layer3 address 3 filter 1 register (ETH_MACL3A31R).

64.5.4 IEEE 1588 timestamp support

The IEEE 1588 standard defines a precision time protocol (PTP) which allows precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the submicrosecond range with minimal network and local clock computing resources.

This chapter contains the following sections:

- IEEE 1588 timestamp support
- IEEE 1588 system time source
- IEEE 1588 auxiliary snapshots
- Flexible pulse-per-second output
IEEE 1588 timestamp support

The Ethernet peripheral supports the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2). The IEEE 1588-2002 supports PTP transported over UDP/IP. The IEEE 1588-2008 supports PTP transported over Ethernet. The peripheral provides programmable support for both standards. It supports the following features:

- Support of both timestamp formats
- Optional snapshot of all packets or only PTP type packets
- Optional snapshot of only event messages
- Optional snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent
- Optional selection of the node to act as master or slave for ordinary and boundary clock
- Identification of the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Optional measurement subsecond time in digital or binary format

Clock types

The MAC supports the following clock types defined in the IEEE 1588-2008 specifications:

- Ordinary clock
  
The ordinary clock of a domain supports a single copy of the protocol. It has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device.
  
The ordinary clock can be a grandmaster or a slave clock. It supports the following features:
  
  - Transmission and reception of PTP messages. The timestamp snapshot can be controlled as described in Timestamp control Register (ETH_MACTSCR).
  - Maintenance of the data sets such as timestamp values.

  The table below shows the messages for which you can take the timestamp snapshot on the receive side for master and slave nodes.

  **Table 698. Ordinary clock: PTP messages for snapshot**

<table>
<thead>
<tr>
<th>Master</th>
<th>Slave</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delay_Req</td>
<td>SYNC</td>
</tr>
</tbody>
</table>

For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the TSVER2ENA bit and selecting the snapshot mode in Timestamp control Register (ETH_MACTSCR).

- Boundary clock
The boundary clock typically has several physical ports which communicate with the network. The messages related to synchronization, master-slave hierarchy, and signaling end in the protocol engine of the boundary clock. Such messages are not forwarded. The PTP message type status given by the MAC helps to identify the type of message and take appropriate action.

The boundary clock is similar to the ordinary clock except for the following features:
- The clock data sets are common to all ports of the boundary clock.
- The local clock is common to all ports of the boundary clock.

- **End-to-end transparent clock**
  The end-to-end transparent clock supports the end-to-end delay measurement mechanism between the slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the Ingress port to the Egress port.

  The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both Ingress and Egress ports only for the messages mentioned in Table 699. You can take the snapshot by setting the SNAPTYPESEL bits to 10 in the Timestamp control Register (ETH_MACTSCCR).

<table>
<thead>
<tr>
<th>PTP messages</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>SYNC</td>
<td></td>
</tr>
<tr>
<td>Delay_Req</td>
<td></td>
</tr>
</tbody>
</table>

- **Peer-to-peer transparent clock**
  In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer.

  The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.

  The residence time of the Pdelay_Req and the associated Pdelay_Resp packets is added and inserted into the correction field of the associated Pdelay_Resp_Followup packet. Therefore, support for taking snapshot for the event messages related to Pdelay is added as shown in Table 707.
You can take the snapshot by setting the SNAPTYPESEL bit to 11 in Timestamp control Register (ETH_MACTSCR).

**Delay request-response mechanism**

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Figure 958 shows the process that PTP uses for synchronizing a slave node with a master node by exchanging PTP messages.

**Figure 958. Networked time synchronization**

As shown in Figure 958, the PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at $t_1$. This time must be captured for Ethernet ports at MII.
2. The slave receives the SYNC message and also captures the exact time, $t_2$, using its timing reference.
3. The master sends a Follow_up message to the slave, which contains $t_1$ information for later use.
4. The slave sends a Delay_Req message to the master and notes the exact time, $t_3$, at which this packet leaves the MII interface.
5. The master receives the message, capturing the exact time \( t_4 \), at which the message enters its system.

6. The master sends the \( t_4 \) information to the slave in the Delay_Resp message.

7. The slave uses the four values of \( t_1, t_2, t_3, \) and \( t_4 \) to synchronize its local timing reference with the timing reference of the master.

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

**Peer-to-peer PTP transparent clock (P2P TC) message support**

The IEEE 1588-2008 standard supports peer-to-peer PTP (Pdelay) message in addition to the Sync, Delay Request, Follow_up, and Delay Response messages. *Figure 959* shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

**Figure 959. Propagation delay calculation in clocks supporting peer-to-peer path correction**

As shown in *Figure 959*, the propagation delay is calculated as follows:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (\( t_1 \)) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp (\( t_2 \)) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t₃) for this message.
   To minimize errors caused by frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:
   – Difference between the timestamps t₂ and t₃ in the Pdelay_Resp message
   – Difference between the timestamps t₂ and t₃ in the Pdelay_Resp_Follow_Up message
   – Timestamps t₂ and t₃ in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively

4. Port 1 generates a timestamp (t₄) on receiving the Pdelay_Resp message.
5. Port 1 uses all four timestamps to compute the mean link delay.

**Timestamp correction**

According to the IEEE 1588 specifications, a timestamp must be captured when the message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network.

As the MAC takes the timestamp at an internal point far from the actual boundary of the node and network, this captured timestamp is corrected/updated for the ingress/egress path latency (including the delay in the PHY layers). Further correction is done for the inaccuracies/errors introduced due to the clock (MII Tx, Rx clock) being different at the capture point as compared to the PTP clock (clk_ptp_ref_i) that is used to generate the time. The resultant CDC (clock domain crossing) circuits add an error the depends on the clock period of the MII and PTP clocks.

**Ingress correction**

In the Receive side, the timestamp captured at the internal snapshot point is delayed (later in time) as compared to the time at which that packet SFD bit is received at the port boundary. Therefore, the captured timestamp must be reduced by the ingress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the Timestamp Ingress correction nanosecond register (ETH_MACTSICNR).

The correction value consists of the following three components:

1. External latency in the PHY layer between boundary point and the input of the core
   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has registers indicating the maximum and minimum ingress latency. The software can read these registers and determine the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), the ingress latency must be determined from the PHY datasheet or timing characteristics.

2. Internal latency from the input of the core to the internal capture point
   The latency differs based on the active PHY interface (such as MII or RMII) and the operating speed, as shown in Table 701.

3. CDC synchronization
   The CDC synchronization error is almost equal to twice the clock-period of the PTP clock (clk_ptp_ref_i).
The values determined from these three components should be added by the software and must be written into the TSIC field of the *Timestamp Ingress correction nanosecond register (ETH_MACTSICNR)*.

**Note:** The value written to the register must be negative (two’s complement), because it has to be subtracted from the captured timestamp. The MAC receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When TSCTRLSSR bit in *Timestamp control Register (ETH_MACTSCR)* is set, the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1 ns. So bit 31 of TSIC must be set to 1 (for negative value) and bits 30 to 0 must be programmed with "10^9 – total ingress_correction_value[nanosecond part]" represented in binary. For example, if the required correction value is −5 ns, then the value is 0xBB9A C9FB.

When TSCTRLSSR bit in *Timestamp control Register (ETH_MACTSCR)* is reset, the nanoseconds field of the captured timestamp is in binary format with a granularity of −0.466 ns. Therefore, bits[30:0] must be written with "2^{31} – total ingress_correction_value" represented in binary with bit[31] = 1.

**Egress correction**

In the Transmit side, the timestamp captured at the internal snapshot point is earlier (advanced in time) as compared to the time at which that packet SFD bit is output at the port boundary. Therefore, the captured timestamp must be compensated by the egress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the *Timestamp Egress correction nanosecond register (ETH_MACTSECNR)*.

The correction value consists of the following three components:

1. **External latency in the PHY layer between the output of the core and the boundary of the port and the network**
   
   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has registers indicating the maximum and minimum egress latency. The software can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), the egress latency must be determined from the PHY datasheet or timing characteristics.

2. **Internal latency from the internal capture point and the output of the core**
   
   The latency differs based on the active PHY interface (RMII, MII, etc.) and the operating speed as shown in *Table 701*.

3. **CDC synchronization error**
   
   The timestamp correction because of synchronization is compensated by adding
   
   \[
   \text{EGRESS}_\text{SYNC}_\text{CORR} = (1 \times \text{PTP}_\text{CLK}_\text{PER} + 4 \times \text{TX}_\text{CLK}_\text{PER})
   \]
   
   *Table 701* lists the Egress and Ingress latency values for various PHY interfaces:

</table>
Frequency range of reference timing clock

The timestamp information are transferred across asynchronous clock domains, from the MAC clock domain to the application clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is four clock cycles of MII and three clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second packet.

The PTP clock frequency limitations are the following:

- **Maximum PTP clock frequency**
  
  The maximum PTP clock frequency is limited by the maximum resolution of the reference time (10 ns at 100 MHz). In addition, the resolution or granularity of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance.

- **Minimum PTP clock frequency**
  
  The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes and the time taken for synchronizing the time with the MII clock domain. This relationship is given by the following equation:

  \[
  3 \times \text{PTP clock period} + 4 \times \text{MII clock period} \leq \text{Minimum gap between two SFDs}
  \]

  The MII clock frequency is fixed by IEEE specifications. Therefore, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC as shown in Table 702.

### Table 702. Minimum PTP clock frequency example

1. The controlField is used in version 1. In version 2, the messageType field is used for detecting different message types.

Some fields of the Ethernet payload can be used to detect the PTP packet type and control the snapshot to be taken. These fields are different for the following PTP packets:

- PTP packets over IPv4
- PTP frames over IPv6
- PTP packets over Ethernet

#### PTP packets over IPv4

Table 704 provides information about the fields that are matched to control the snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format defined in Table 703.

Transmit path functions

The MAC captures a timestamp when the start packet delimiter (SFD) of a packet is sent on the MII interface. The packets, for which a timestamp has to be captured, can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for it.

The MAC does not process the transmitted packets to identify the PTP packets. The packets for which a timestamp has to be captured must be specified. The packets can be defined by using the control bits in the Transmit Descriptor (see Section 64.10.3: Transmit descriptor). The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus automatically connecting the timestamp to the specific PTP packet.

The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

Receive path functions

The MAC can be programmed to capture the timestamp of all packets received on the MII interface or to process packets to identify the valid PTP messages. The snapshot of the time to be sent to the application can be controlled by using the following options of the Timestamp control Register (ETH_MACTSCR):

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp

1. The unicast address match of destination addresses (DA), programmed in MAC address 0 to 31, is used if the **TSENMACADDR** bit of Timestamp control Register (ETH_MACTSCR) is set.
2. IEEE 1588-2008, Annex F
3. The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.
Ethernet (ETH): media access control (MAC) with DMA controller

- Enable snapshot for PTP packets transmitted directly over Ethernet or UDP-IP-Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type
  This feature controls the type of messages for which snapshots are taken.

**Note:** The peripheral also supports the PTP messages over VLAN packets.

*Table 707* indicates the PTP messages for which a snapshot is taken depending on the SNAPTYPESEL field in *Timestamp control Register (ETH_MACTSCR)*.

The DMA returns the timestamp to the software application inside the corresponding Receive descriptor. The extended status, containing the timestamp message status and the IPC status, is written in the RDES1 normal descriptor and the snapshot of the timestamp is written in RDES0 and RDES1 fields of the context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

**Programming guidelines for IEEE 1588 timestamping (system time correction)**

See *Section : System time correction* in *Section 64.9.9: Programming guidelines for IEEE 1588 timestamping on page 3366*.

**IEEE 1588 system time source**

To get a snapshot of the time, the MAC requires a reference time in 64-bit format as defined in the IEEE 1588-2002 (80-bit format as defined in the IEEE 1588-2008).

**Description of IEEE 1588 system time source**

The peripheral uses the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps.

The timestamp has the following fields:
- Ulinteger48 seconds field
The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bit wide. For example, 2.000000001 seconds are represented as secondsField = 0x0000 0000 0002.

- **UInteger32 nanosecondsField**
  
The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds. For example, 2.000000001 seconds are represented as nanoSeconds = 0x0000 0001.

  The nanoseconds field supports the following two modes:
  - **Digital rollover mode**: In this mode, the maximum value in the nanoseconds field is 0x3B9A C9FF, that is, (10e9-1) nanoseconds.
  - **Binary rollover mode**: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF FFFF. Accuracy is \(~0.466\) ns per bit.

  These modes can be set through TSCTRLSSR bit in *Timestamp control Register (ETH_MACTSCR)*.

**System time register module**

The 64-bit PTP time is updated using the PTP input reference clock, clk_ptp_ref_i. This PTP time is used as a source to take snapshots (timestamps) of the Ethernet frames being transmitted or received at the MII.

The system time counter can be initialized or corrected using either the coarse or the fine correction method.

In the coarse correction method, the initial value or the offset value is written to the timestamp update register. For initialization, the system time counter is programmed with the value in the timestamp update registers, whereas for system time correction the offset value (timestamp update register) is added to or subtracted from the system time.

In the fine correction method, the slave clock (reference clock) frequency drift with respect to the master clock (as defined in IEEE 1588-2002 specifications) is corrected over a period of time, unlike in the coarse correction method where it is corrected in a single clock cycle. The longer correction time helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register as shown in *Figure 960*. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. The accumulator acts as a high-precision frequency multiplier or divider.

This system time update algorithm is shown in *Figure 960*.
The system time update logic requires a 50 MHz clock frequency to achieve 20 ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. For example, if the reference clock (clk_ptp_ref_i) is 66 MHz, this ratio is calculated as 66 MHz/50 MHz = 1.32. Therefore, the default addend value to be set in the register is $2^{32} / 1.32$, 0xC1F07C1F.

If the reference clock drifts lower, for example, to 65 MHz, the ratio is 65 / 50, that is 1.3 and the value to set in the addend register is $2^{32} / 1.30$, or 0xC4EC 4EC4.

If the clock drifts higher, for example to 67 MHz, the addend register must be set to 0xBF0B 7672. When there is not clock drift, the default addend value of 0xC1F0 7C1F ($2^{32} / 1.32$) must be programmed.

In Figure 960, the constant value used to accumulate the subsecond register is decimal 43, which achieves a system time accuracy of 20 ns (in other words, it is incremented in 20 ns steps).

The software must calculate the drift in frequency based on the SYNC messages and accordingly update the Addend register.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$$\text{FreqCompensationValue}_0 = 2^{32} / \text{FreqDivisionRatio}$$
If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm given in this section must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and resynchronize with the master using the new value.

The algorithm is as follows:

1. At time MasterSyncTimeₙ the master sends the slave clock a SYNC message. The slave receives this message when its local clock is SlaveClockTimeₙ and computes MasterClockTimeₙ as follows:
   \[ \text{MasterClockTime}_n = \text{MasterSyncTime}_n + \text{MasterToSlaveDelay}_n \]

2. The master clock counts for current Sync cycle, MasterClockCountₙ is
   \[ \text{MasterClockCount}_n = \text{MasterClockTime}_n - \text{MasterClockTime}_{n-1} \]
   (assuming that MasterToSlaveDelay is the same for Sync cycles n and n – 1)

3. The slave clock count for current Sync cycle, SlaveClockCountₙ is
   \[ \text{SlaveClockCount}_n = \text{SlaveClockTime}_n - \text{SlaveClockTime}_{n-1} \]

4. The difference between master and slave clock counts for current Sync cycle, ClockDiffCountₙ is
   \[ \text{ClockDiffCount}_n = \text{MasterClockTime}_n - \text{SlaveClockTime}_n \]

5. The frequency-scaling factor for slave clock, FreqScaleFactorₙ is
   \[ \text{FreqScaleFactor}_n = (\text{MasterClockCount}_n + \text{ClockDiffCount}_n) / \text{SlaveClockCount}_n \]

6. The frequency compensation value for Addend register, FreqCompensationValueₙ is
   \[ \text{FreqCompensationValue}_n = \text{FreqScaleFactor}_n \times \text{FreqCompensationValue}_{n-1} \]

In theory, this algorithm achieves the lock in one Sync cycle. However, it may take several cycles, because of changing network propagation delays and operating conditions. This algorithm is self-correcting. If the slave clock is initially set to an incorrect value by the master, the algorithm corrects it at the cost of additional Sync cycles.

Refer to Section 64.9.9: Programming guidelines for IEEE 1588 timestamping for detailed programming steps.

**IEEE 1588 auxiliary snapshots**

The auxiliary snapshot feature enables to store a snapshot of the system time based on an external event. The event is considered to be the rising edge of the eth_ptp_trgx (where \( x = 1 \) to 4) sideband signal.

Up to four auxiliary snapshot inputs can be configured and up to four snapshots can be stored. A FIFO is accessible through registers: \text{Auxiliary timestamp seconds register (ETH_MACATSSR)} and \text{Auxiliary timestamp nanoseconds register (ETH_MACATSNR)}.

The snapshots taken for any input are stored in a common FIFO; only 64 bits are kept. The application can read the \text{Timestamp status register (ETH_MACTSSR)} to know the timestamp of which input is available for reading at the top of this FIFO.
When a snapshot is stored, the MAC indicates this to the application with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, a snapshot trigger-missed status (ATSSTM) is set in the Timestamp status register (ETH_MACTSSR). This indicates that the latest auxiliary snapshot of the timestamp is not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full.

When an application reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting the ATSFC bit in Auxiliary control register (ETH_MACACR). When multiple snapshots are present in the FIFO, the count is indicated in bits[27:25] of Timestamp status register (ETH_MACTSSR).

**Flexible pulse-per-second output**

The MAC supports either a fixed pulse-per-second output mode (also called fixed mode) or a flexible pulse-per-second output mode for the ETH_PPS_OUT and eth_ptp_pps_out outputs:

- **Fixed pulse-per-second output**
  
  In this mode, only the frequency of the PPS output can be changed by setting the PPSCTRL0 field in the PPS control register (ETH_MACPPSCR).

- **Flexible pulse-per-second output**
  
  In this mode, the software has the flexibility to program the start or stop time, width, and interval of the pulse generated on the eth_ptp_pps_out output:
  
  The start and stop times are programmed through **PPS target time seconds register (ETH_MACPPSTTSR)** and **PPS target time nanoseconds register (ETH_MACPPSTTNR)**.
  
  The PPS width and interval are programmed in terms of granularity of system time (number of the units of subsecond increment value) through **PPS width register (ETH_MACPPSWR)** and **PPS interval register (ETH_MACPPSIR)**, respectively.

**Note:** By default, the peripheral is in Fixed mode and indicates one second interval. When Fixed mode is selected by clearing PPSEN0 to 0 in the PPS control register (ETH_MACPPSCR):

- the output on all PPS outputs is controlled by the value programmed in the PPSCTRL_PPSCMD field. Independent control of individual PPS output is not supported in Fixed mode.
- **PPS target time seconds register (ETH_MACPPSTTSR)** and **PPS target time nanoseconds register (ETH_MACPPSTTNR)** are used only for generating target time reached interrupt; they are not used for PPS output generation.
- TRGTMODSEL0/1/2/3 must be programmed to 0.
- the frequency of the PPS output can be changed by setting the PPSCTRL0 field in the PPS control register (ETH_MACPPSCR).
Description of flexible pulse-per-second (PPS) output

The peripheral supports the following features with the flexible PPS outputs:

- Programming the start or stop time in terms of system time.
- Programming the start point of the single pulse and start and stop points of the pulse train in terms of 64-bit system time. The Target Time registers are used to program the start and stop time.
- Programming the stop time in advance, that is, the stop time can be programmed before the actual start time has elapsed.
- Programming the width between the rising edge and corresponding falling edge of PPS signal output in terms of number of units of subsecond increment value programmed in the Subsecond increment register (ETH_MACSSIR). The pulse width can be programmed from 1 to 232−1 units of subsecond increment value.
- Programming the interval, between the rising edges of PPS signal, in terms of number of units of subsecond increment value. You can program the interval between pulses from 1 to 232−1 units of subsecond increment value.
- Option to cancel the programmed PPS start or stop request.
- Error if the start or stop time being programmed has already elapsed.

**Note:** The PTP reference clock mentioned in the following sections is the clock at which the system time is updated. When the TSCFUPDT bit of Timestamp control Register (ETH_MACTSCR) is set to 0, this clock is similar to the clk_ptp_ref_i clock. In Fine correction mode, this is the clock tick at which the system time is updated (using Subsecond increment register (ETH_MACSSIR) (as shown in Figure 960).

Refer to Section 64.9.12: Programming guidelines for flexible pulse-per-second (PPS) output for further details on how configuring flexible pulse output.

**PPS start and stop times**

The initial start time can be programmed in the Target Time registers.

If required, the start or stop time can be programmed again. However, this can be done only after the earlier programmed value is synchronized with the PTP clock domain. Bit 31 of PPS target time nanoseconds register (ETH_MACPPSTTNR) indicates that the synchronization is complete. This enables to program the start or stop time in advance even before the earlier stop or start time has elapsed.

To ensure proper PPS signal output, it is recommended to program advanced system time for the start or stop time. If the application programs a start or stop time that has already elapsed, the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

**PPS width and interval**

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of subsecond increment value. For example, to obtain a PPS pulse width of 40 ns and an interval of 100 ns with a PTP reference clock of 50 MHz, program the width and interval to values 2 and 5, respectively. Smaller granularity can be achieved by using a faster PTP reference clock.

Before giving the command to trigger a pulse or pulse train on the PPS output, program or update the interval and width of the PPS signal output.
PTP timestamp offload function

This feature enables the automatic generation of specific PTP packets to be performed, when the MAC operates as a specific node in the PTP network.

These packets can be generated periodically or triggered by the host software. In other modes, this feature can parse the incoming PTP packets on the receiver, and automatically generate and respond to the required PTP packets. It helps to offload certain PTP node functions with better accuracy and lower response latency.

The PTP offload feature is selected through **PTP Offload control register (ETH_MACPOCR)**. 80-bit PTP node identity is configured through the following three registers: **PTP Source Port Identity 0 Register (ETH_MACSPI0R)**, **PTP Source port identity 1 register (ETH_MACSPI1R)** and **PTP Source port identity 2 register (ETH_MACSPI2R)**.

Description of PTP offload function

Depending on the programmed mode, the MAC generates PTP Ethernet messages periodically or from the application, or based on reception of a particular PTP message. 

**Table 708** indicates the PTP message generation criteria.

All other programming combinations are invalid for PTP Offload feature.

Note: Clocks supporting peer delay mechanism must not generate delay request/delay response messages, according to IEEE 1588-2008 specifications. However, the peripheral controller supports this for flexibility, with a programmable control bit (DRRDIS) in the PTP Offload control register (ETH_MACPOCR).

The DRRDIS bit can be used to control the response generation for delay request/delay response message. For example, in transparent slave mode, delay request is generated in response to received SYNC only when the bit is reset.

When the MAC is set as an Ordinary or Boundary Slave clock in the PTP network, it can respond to the reception of SYNC messages with an automatic generation and transmission of the corresponding Delay_Req message. Similarly, various other modes of operation are explained in Table 708.

The MAC supports the multicast communication model for the generation of SYNC and Pdelay_Req PTP messages. For instance, the Destination Address field of the generated PTP over Ethernet packet is the defined special multicast addresses (0x011B 1900 0000 for all except peer delay mechanism messages and 0x0180 C200 000E for peer delay mechanism messages).

When the MAC responds to received SYNC, Delay_Req and Pdelay_Req PTP messages with special multicast destination address, it also uses the corresponding special multicast address in the DA field of the automatically generated Delay_Req, Delay_Resp, and Pdelay_Resp PTP messages, respectively.

When the MAC responds to received SYNC, Delay_Req and Pdelay_Req PTP messages with unicast destination address, it takes the SA field of the received packets and makes
them as the DA field of the automatically generated Delay_Req, Delay_Resp, and Pdelay_Resp PTP messages, respectively.

At the same time, all the received PTP messages are forwarded to the application along with Rx status, indicating whether the response was generated by the MAC, if it satisfies the packet filtering logic of the MAC receiver.

When the MAC automatically generates a PdelayReq or responds with a Delay_Req, the egress timestamp of these two PTP messages are provided in the Tx TS status (Tx Timestamp Status register and interrupt generated).

In addition to messageType and versionPTP fields match for basic PTP over Ethernet message detection, the following additional fields are matched to qualify the received PTP message type:

1. The domainNumber field is checked for a match against the value programmed in the CSR.
2. The twoStepFlag in flagField field is checked for one-step indication (0b0).
3. The transportSpecific field is checked for Default PTP over Ethernet (0b0000) or 802.1AS mode (0b1111) when enabled.

**PTP packet generation**

This section explains the format and content of the automatically generated PTP packets by the MAC when this mode is enabled. It provides the template of the common PTP message header, as well as the detailed description of the fields of the specific PTP packets generated.

PTP message header fields

- **messageType**
  The following encoded values are used for PTP message types:
  - SYNC: 0000
  - Delay_Req: 0001
  - Pdelay_Req: 0010
  - Pdelay_Resp: 0011
  - Delay_Resp: 1001

- **transportSpecific**
  The following transport protocol encoding is used:
  - Default PTP over Ethernet: 0000
  - 802.1AS mode: 0001

- **versionPTP**
  It is always set to 2 because PTP version 2 is supported.

- **domainNumber**
  This field contains the value from the PTP Offload control register (ETH_MACPOCR).

- **flagField**
  The following values are used:
  - alternateMasterFlag (Octet 0 bit 0): 0 for SYNC and Delay_Resp
  - twoStepFlag (Octet 0 bit 1): 0 for SYNC and Pdelay_Resp
  - unicastFlag (Octet 0 bit 2): 0 for Multicast Address, 1 for Unicast Address

- **correctionField**
  For more information, see Table 710.

- **sourcePortIdentity**
  This field takes the value programmed in the PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R).

- **sequenceId**
  Pdelay_Resp and Delay_Resp use the same sequenceId field from received Pdelay_Req and Delay_Req PTP messages. For SYNC/Delay_Req, Pdelay_Req, a separate sequenceId counter is maintained. These sequenceId counters get incremented by 1 every time the corresponding message is generated and transmitted.

- **controlField**
  The following encoded values are used for controlField:
  - SYNC: 0000 0000
  - Delay_Req: 0000 0001
  - Pdelay_Req: 0000 0010
  - Pdelay_Resp: 0000 0101
  - Delay_Resp: 0000 0011

- **logMessageInterval**
  - SYNC:
    This field contains logSyncInterval from the corresponding MAC_Log_Message_Interval register.
Delay_Resp:
This field contains the sum of DRSYNCR and logSyncInterval value taken from the Log message interval register (ETH_MACLMIR) for a multicast PTP message and 0111 1111 for unicast PTP message.

Delay_Req, Pdelay_Req and Pdelay_Resp: 0111 1111
where logSyncInterval = \log_2 (\text{Mean Value of Interval in seconds})

The MAC supports values of –15 to 15 for logSyncInterval fields, which translates to a range from 32.768 micro second (2–15) to 215 second. For a given value of log sync interval (N), the time interval between two SYNC packets is given by the following:

- $2^{(30+N)}$ ns, when N is negative (–1 to –15)
- $2^N$ seconds, when N is positive (0 to 15)

For example:
- When logSyncInterval is programmed to 1, the interval is $2^1$; therefore, the SYNC message is sent once every 2 seconds.
- When logSyncInterval is programmed to -1, the interval is $2^{-1} = 0.536$ seconds; therefore, the SYNC message is sent once every 536 milliseconds. The value is 0.536 seconds, because $2^{-30} = 1$ ns.
- When logSyncInterval is programmed to –5, the interval is $2^{-5} = 33.55$ ms; therefore, the SYNC message is sent once every 33.55 ms.

Note: The MAC uses the PTP system time to generate the intervals for periodic packet transmission. For negative values of log message interval programmed, the generated period may deviate from the value given by the equation $2^{(30+N)}$, because of the non-binary nature of the nanoseconds field of the system time.

PTP message-specific fields

The message-specific fields are the following:

- **messageLength**
  There is no suffix supported, so this field contains the length of the PTP message that includes 34-byte PTP common header and the body specific to the message type. For SYNC and Delay_Req packets, this field contains 44, whereas for Delay_Resp, Pdelay_Req and Pdelay_Resp, it contains 54.

- **originTimestamp**
  This field is the captured egress timestamp for SYNC, Delay_Req, and Pdelay_Req PTP messages.

- **receiveTimestamp**
  For Delay_Resp PTP message, this is the ingress timestamp of the corresponding received Delay_Req PTP message.

- **requestingPortIdentity**
  For Delay_Resp and Pdelay_Resp PTP messages, this is the sourcePortIdentity field taken from the corresponding received Delay_Req and Pdelay_Req PTP messages.

- **requestReceiptTimestamp**
  For the Pdelay_Resp PTP message, this field is set to 0.
One-step timestamp

The MAC supports the one-step timestamp feature that enables to identify the offset in the packet and inserts the timestamp received from the application at that offset.

MAC Transmit PTP mode for one-step timestamp

Depending upon the type of message and its mode, the MAC updates the following fields of Transmit PTP packets:

- correctionField in the PTP header of messages
- originTimestamp in SYNC, Delay_Req, and Pdelay_Req messages

Table 710 shows how the PTP mode is selected based on the settings of SNAPTYPSEL, TSMSTRENA, and TSEVNTENA bits of the Timestamp control Register (ETH_MACTSCR) and the fields that are updated for the incoming PTP packets based on the message type in that mode, during the one-step timestamping operation.

Note: Residence time/ turnaround time is calculated as the difference between the captured timestamp (egress timestamp) and the ingress timestamp. Clocks supporting peer delay mechanism do not use delay request or response, but it is included in OST for flexibility.

Enabling one-step timestamp

The one-step timestamp feature can be enabled for a given packet by setting bit 20 (OSTC) in TDES3 context descriptor. To update the correction field in certain PTP packets, the ingress timestamp must be given in the TSSL and TSSH fields.

The one-step timestamp feature is supported only for the PTP over Ethernet packets. It is not supported for PTP over IPv4/IPv6 packets.

64.5.5 Checksum offload engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, as well as error detection in the Receive path.

Transmit checksum offload engine

In the transmit path, the MAC calculates the checksum and inserts it in the Tx packet. This feature helps reducing the load on the software and can improve the overall system throughput.

The COE module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 bits[17:16]).
Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, the Tx FIFO automatically operates in the Store-and-forward mode even if the MAC is configured in Threshold (cut-through) mode.

Make sure that the Tx FIFO is deep enough to store a complete packet before that packet is transferred to the MAC transmitter, the reason being that when space is not available to accept the programmed burst length of data, then the MTL Tx FIFO starts reading to avoid deadlock. In such a case, the COE fails as the start of the packet header is read out before the payload checksum can be calculated and inserted. Therefore, the checksum insertion must be enabled only in the packets that are less than the number of bytes, given by the following equation:

\[
\text{Packet size} < \text{TxQSize} - (\text{PBL} + 7) \times 4
\]

where
- TxQSize corresponds to the TQS bitfield of Tx queue operating mode register (ETH_MTLTXQOMR)
- PBL corresponds to the TxPBL bitfield of Channel transmit control register (ETH_DMACTXCR)

Refer to IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460, and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6, and ICMPv6 packet header specifications, respectively.

**IP header checksum engine**

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

Note: IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status it in the Transmit status (bit 0 in Table 732: TDES3 normal descriptor (write-back format)).

This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as
indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86DD but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

TCP/UDP/ICMP checksum engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

Note: For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 0x0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 0x0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (bit 12 in Table 732: TDES3 normal descriptor (write-back format)). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Table 711 describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as “No” in the table.

Note: Do not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Section: Transmit checksum offload engine because it might result in incorrect checksum insertion or unexpected behavior.

</table>
**Receive checksum offload engine**

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

The Receive Checksum Offload Engine (Rx COE) can be enabled by setting the IPC bit of **Operating mode configuration register (ETH_MACCCR)**. When this bit is set, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the EDVLP bit of the **VLAN tag register (ETH_MACVTR)** is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

Packets with TCP/IP errors (header or payload) are dropped in MTL when DIS_TCP_EF bit of the **Rx queue operating mode register (ETH_MTLRXQOMR)** is reset and FEP bit is set.

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

**Table 712: Receive checksum offload engine functions for different packet types** describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

**Note:** The MAC does not append any payload checksum bytes to the received Ethernet packets.

</table>
64.5.6 TCP segmentation offload

The MAC supports the TCP segmentation offload (TSO) feature in which the DMA splits a large TCP packet into multiple small packets and passes these packets to the MTL as shown in Figure 961.

This feature is enabled by programming the TSE bit of corresponding ETH_DMACCR register (see Channel transmit control register (ETH_DMACTXCR)). It is only supported when the MAC operates in Full-duplex mode.

For detailed programming steps, refer to Section 64.9.13: Programming guidelines for TSO.

**Figure 961. TCP segmentation offload overview**
DMA operation with TSO feature

*Figure 962* shows the TSO flow.

**Figure 962. TCP segmentation offload flow**

For the TSO feature, the Tx DMA operation is as follows:

1. The application sets up the Transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES3[31]) after setting up the corresponding data buffer(s) with Ethernet packet data.
2. The application increases the offset value of the descriptor tail pointer of the DMA Tx channel.
3. While in the Run state, the DMA fetches the next available descriptor and performs one of the following actions:
   - If the descriptor is a context descriptor and the context is not between the first and last descriptors of a packet, the DMA stores the context values.
- If the descriptor is a context descriptor and the context is between the first and last descriptors of a packet, the DMA closes the context descriptor indicating a Context Descriptor Error (TDES3[23]) and fetches the next descriptor.
- If the descriptor is a normal descriptor, the DMA checks the TSE bit. If the TSE bit is not set, the DMA continues with the default mode of operation or OSF operation (if enabled).

4. The DMA calculates the number of segments from the TCP payload length (TDES3[17:0]) and the MSS value.

5. The DMA goes through channel arbitration to fetch the data buffers. The DMA fetches the header and payload separately.

6. For the first segment, the DMA fetches the header from the system memory and stores it in the TSO memory (if present and when the length of header is not greater than the TSO memory size). If the current segmented packet is not the first segment, it fetches again the header buffer in system memory, as done for the first segment. In such cases, the DMA does not close the first descriptor containing the header buffer until the header for last segment is fetched.

7. The required fields in the header bytes are modified/updated as per the segmentation requirements and written into the corresponding MTL Tx queue.

8. The DMA then takes the payload buffer pointer, fetches the MSS number of payload bytes from the system memory, and directly pushes it into the MTL Tx queue. If the buffer(s) in the descriptor do(es) not have enough data for the MSS payload (except for the last segment), the DMA closes this descriptor.

9. The DMA jumps to Step 3 and repeats the process until the last segment is written into the Tx queue.

10. The DMA closes the last descriptor and the first descriptor (containing the header buffer when it is not stored in TSO memory), and then moves on to the next packet transfer.

The DMA repeats all these steps if more descriptors are available. When no more descriptor are available, the DMA enters the suspend state.

Note: The TSO engine determines whether to perform TSO or USO operation based on the THL field (TCP Header Length) in TDES3 of first Normal Tx descriptor for the packet. The value of 2 indicates USO and any value greater than or equal to 5 indicates TSO.
TCP/IP header fields

While segmenting a TCP packet, the DMA automatically updates the TCP/IP header fields. *Table 713* describes how the TCP and IP headers are updated.

<table>
<thead>
<tr>
<th>Packet sequence</th>
<th>TCP header</th>
<th>IP header</th>
</tr>
</thead>
</table>
| **First packet** | 1. The sequence number is not updated. The value provided in the header is used.

Payload Length + TCP Header Length + IP Extension Header Length |
Header and payload fields of segmented packets

After segmentation, the split packets use the same header as the parent TCP packet for header fields other than the ones described in Table 713: TSO: TCP and IP header fields. Figure 963: Header and payload fields of segmented packets shows how same header is used for the header fields of segmented packets.

The application must create the header in Buffer 1 of the first descriptor of the packet to be segmented and provide the header length in TDES2 of the first descriptor (FD = 1). When the FD bit is set, the DMA reads the header from the header buffer to which the TDES0 is pointing. Buffer 2 of the first descriptor can be used for payload and TDES0 and TDES1 of subsequent descriptors. For subsequent descriptors (FD = 0), the address to which the TDES0 and TDES1 are pointing is treated as payload buffer address of the same packet.

Figure 963. Header and payload fields of segmented packets

Context descriptor sequence

The context descriptor can provide the maximum segment size (MSS) value for segmentation. The application must provide the context descriptor before the normal descriptor to be used for the corresponding TCP packet. If the application needs to provide a new MSS, it must create the context descriptor in the descriptor list before the first normal descriptor of the packet to be segmented with the new MSS value. The MSS value in the context descriptor is valid only if the TCMSSV bit of TDES3 in context descriptor is set and the OSTC bit is reset (refer to Section 64.10.3: Transmit descriptor).

When the application provides a context descriptor with a valid MSS value, the DMA internally stores the MSS value and uses this value for all subsequent packets for which the TSO is enabled through the TSE bit of TDES3 normal descriptor.
If the application places a context descriptor in the middle of a packet (between the first and last descriptors of a packet), the DMA does the following:

1. The DMA ignores the context and closes the descriptor.
2. The DMA indicates the error in descriptor status.
3. The DMA generates an interrupt if the CDEE bit is set in the Interrupt enable register corresponding to a DMA channel (see **Channel interrupt enable register (ETH_DMAMEN)**).

The application can read the interrupt status through CDE bit of Status register corresponding to a DMA channel (see **Channel status register (ETH_DMACSR)**).

**Building the Descriptor and the packet for the TSO feature**

To enable segmentation for a packet, the application must set the TSE bit of TDES3 of first normal descriptor (see **Section 64.10.3: Transmit descriptor**). If the TSE bit is set in TDES3 for a non TCP/IP packet, the DMA behavior is unpredictable.

The application must program the length of the TCP packet payload in TDES3[17:0] and the TCP header in TDES3[22:19]. The maximum length of TCP packet payload that can be segmented is 256 Kbytes.

The header of the packet including Ethernet header, L3 header and L4 header should be provided in Buffer1 of the first normal descriptor of the TSO packet. Only buffer 1 of the first normal descriptor of a packet enabled for TSO is taken as the buffer containing the header.

The TCP payload can begin from buffer 2 of the first normal descriptor and continue to buffer 1 and buffer 2 of second normal descriptor and subsequent descriptors.

The TCP payload may span across multiple buffers and multiple descriptors. The size of buffers containing the TCP payload should add up to be equal to the TCP payload length provided in TDES3[17:0] of the first normal descriptor.

The MAC always calculates and appends CRC and inserts Padding (if required) for all packets segmented by the DMA. If the TSE bit of TDES3 is enabled, the CRC PAD Control (CPC) field of TDES3 is reserved. To determine the size of a TCP packet after segmentation, the DMA uses the Maximum Segment Size (MSS) provided by the application through context descriptor. The DMA segments only those packets which have payload size greater than MSS. The application must provide the MSS by either programming the MSS value in ETH_DMAMCR (see **Channel control register (ETH_DMAMCR)**) or by providing a context descriptor. The DMA uses the last programmed value of MSS or the last MSS value provided through context (whichever is provided later).

The header length plus the MSS size (which is equal to the size of each TCP segment) should not exceed 16383 bytes otherwise the MAC transmitter truncates the packet after 16383 bytes causing a CRC error.

The header length plus MSS size plus programmed PBL value in ETH_DMACTXCR register (see **Channel transmit control register (ETH_DMACTXCR)**) should be lesser than the Tx queue size programmed in TQS field of ETH_MTLTXQOMR register (see **Tx queue operating mode register (ETH_MTLTXQOMR)**). A MSS plus header equal to half the programmed Tx queue size is recommended.

The DMA also supports segmentation of VLAN-tagged TCP/IP frames. If the TCP packet has a VLAN tag, then the same tag is used for all the segments irrespective of the VLAN tag type provided (C-VLAN or S-VLAN). The VLAN tag insert/replace control bits are used for all segments.
If the Double VLAN feature is selected, then the DMA passes both tags for all segments irrespective of the VLAN tag types provided (C-VLAN or S-VLAN). The VLAN tag Insert/Replace control bits for both tags is applicable to all segments. If the Double VLAN feature is not selected, then the application must not set the TSE bit in TDES3 for a TCP/IP packet with two tags. The DMA behavior in this scenario is unpredictable.

If the TSE bit is set in TDES3 for the packet and TCP header length provided is less than 5 (meaning this is an invalid TCP header because it is less than 20 bytes), the DMA does not perform segmentation, instead it transmits the entire packet as a single packet. In this scenario, the CRC pad control bits are forced by DMA to 00 (MAC does CRC and padding) and checksum insertion control bits are forced to 11 (hardware does the checksum calculation for both header and payload).

64.5.7 IPv4 ARP offload

The MAC supports the Address Recognition Protocol (ARP) Offload for IPv4 packets. This feature allows to process the IPv4 ARP request packet in the receive path and to generate the corresponding ARP response packet in the transmit path.

The MAC generates the ARP reply packets for appropriate ARP request packets. ARP packets for IPv4 are L2 layer packets with Length/Type of 0x0806.

The ARP offloading sequence is as follows:
1. The MAC receiver gets an ARP request if the request Target Protocol Address matches the IPv4 address programmed in the MAC L3 register.
2. The MAC generates an ARP reply packet.
3. The MAC copies the Sender Hardware Address field in the ARP request to the following fields:
   - DA field of the Ethernet packet header
   - Target Hardware Address field of the ARP reply packet
4. The MAC copies the Sender Protocol Address field in the ARP request to the Target Protocol Address field in the ARP reply packet.
5. The MAC places its MAC address in the following fields:
   - SA field of the Ethernet packet header
   - Sender Hardware Address field of the ARP reply packet
6. The MAC copies the Target Protocol Address field in the ARP request to the Sender Protocol Address field in the ARP reply packet.
7. The MAC sets the opcode field in ARP reply packet to 2 indicating ARP reply.
8. The MAC recalculates the CRC and performs padding for the generated ARP reply packet.
9. The MAC transmitter sends the ARP reply.

The MAC processes only one ARP request at a time. It does not store the fields of multiple ARP requests. If the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC does not generate the ARP reply for new ARP request. The MAC forwards the new ARP request packet to the application with ARP Reply Not Generated status bit set (bit 34). However, in power-down mode, if the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC drops the new ARP request. If the Disable CRC check (DCRCC) bit of the Extended operating mode configuration register (ETH_MACECR) is set, then the MAC does not check for valid CRC of a ARP
request packet. It can generate an ARP response packet if the other conditions are valid. The ARP request packet must always have a valid CRC.

Note: When the received ARP request is less than the 64-byte packet length, the MAC does not send an ARP response. It is treated as a normal packet and forwarded to the application based on the MAC filter settings.

64.5.8 Loopback

The MAC supports loopback of transmitted packets to its receiver.

Guidelines for using loopback mode

Below some guidelines for using the loopback mode:

- Enable loopback only with the Full-duplex mode. In Half-duplex mode, the carrier sense signal or collision signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip, externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets since they may get corrupted in the loopback FIFO.

The Transmit and Receive clocks can have an asynchronous timing relationship. Therefore, an asynchronous FIFO is used to make the loopback path of the transmitted data to the Receive path. The FIFO is free-running to write on the write clock (eth_tx_clk) and read on every read clock (eth_rx_clk). At the start of each packet read from the FIFO, the write and read pointers are reinitialized to have an offset of four (in 10/100 Mbps mode). This avoids overflow or underflow during a packet transfer, and ensures that the overflow or underflow occurs only during the IPG period between the packets. The FIFO depth of five or nine is sufficient to prevent data corruption for packet sizes up to 9,022 bytes with a difference of 200 ppm between MII Transmit and Receive clock frequencies.

Therefore, bigger packets should not be looped back because they may get corrupted in this loopback FIFO.

At the end of every received packet, the Receive Protocol Engine module generates received packet status and sends it to the Receive Packet Controller module. The control, missed packet, and filter fail status are added to the Receive status in the Receive Packet Controller module. The MAC does not process ARP or PMT packets that are looped back.

Enabling loopback mode

To enable this feature, program the LM bit of the Operating mode configuration register (ETH_MACCR). Loopback can be enabled for all PHY interfaces. The data is always looped back through internal asynchronous FIFO on to the internal Receive MII interface, irrespective of which PHY interface is selected.

The loopback data is also passed through the corresponding transmit PHY interface block, onto the Ethernet line.

Note: During loopback, the data/packet is reflected on mii_txd signal.

Preemption is not supported in loopback mode.
64.5.9 Flow control

The transmit flow control involves transmitting Pause packets in Full-duplex mode and back-pressure in Half-duplex mode to control the flow of packets from the remote end. This section describes the flow control for transmit and receive paths.

**Flow control in Full-duplex mode**

In Full-duplex mode, the MAC uses IEEE 802.3x Pause packets for flow control. Table 714 describes the fields of a Pause packet.

### Table 714. Pause packet fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DA</td>
<td>Contains the special multicast address</td>
</tr>
<tr>
<td>SA</td>
<td>Contains the MAC address 0</td>
</tr>
<tr>
<td>Type</td>
<td>Contains 8808</td>
</tr>
<tr>
<td>MAC Control opcode</td>
<td>Contains 0001 for IEEE 802.3x Pause Control packets</td>
</tr>
<tr>
<td>PT</td>
<td>Contains Pause time specified in the PT field of the Tx Queue flow control register (ETH_MACQTXFCR)</td>
</tr>
</tbody>
</table>

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

**Flow control in Half-duplex mode**

In Half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

*Table 715* describes the flow control in the Tx path based on the setting of the following bits:

- TFE bit of *Tx Queue flow control register (ETH_MACQTXFCR)*
- DM bit of *Operating mode configuration register (ETH_MACCR)*

Flow control is similar for all queues.
Transmit flow control

The transmit flow control is enabled when TFE bit is set in Transmission queue flow control register (ETH_MACQTXFCR).

Flow control trigger

The application can request the MAC to send a Pause packet or initiate back-pressure by setting the FCB bit in the corresponding Transmit queue flow control register (ETH_MACQTXFCR).

Receive flow control

In the Receive path, the flow control is functional only in Full-duplex mode. If any Pause packet is received in Half-duplex mode, the packet is considered as a normal control packet.

Description of receive flow control

Table 716 describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of Receive flow control register (ETH_MACRXFCR)
- DM bit of Operating mode configuration register (ETH_MACCR)

<table>
<thead>
<tr>
<th>TFE</th>
<th>DM</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>x</td>
<td>The MAC transmitter does not perform the flow control or backpressure operation.</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>The MAC transmitter performs backpressure when Bit 0 of Transmit queue flow control register (ETH_MACQTXFCR) is set.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>The MAC transmitter sends the Pause packet when Bit 0 of Transmit queue flow control register (ETH_MACQTXFCR) is set.</td>
</tr>
</tbody>
</table>

Table 715. Tx MAC flow control

Table 716. Rx MAC flow control

The following sequence describes the Rx flow control:

1. The MAC checks the destination address (DA) of the received Pause packet for either of the following:
   - Multicast destination address: the DA matches the unique multicast address specified for the control packet (0x0180 C200 0001).
   - Unicast destination address: the DA matches the content of the MAC Address 0 registers (MAC Address 0 high register (ETH_MACA0HR) and MAC Address X...
low register (ETH_MACAxLR)) and the UP bit of Rx flow control register (ETH_MACRXFCR) is set.

If the UP bit is set, the MAC processes Pause packets with unicast destination address in addition to the unique multicast address.

2. The MAC decodes the following fields of the received packet:
   - Type field: this field is checked for 0x8808.
   - Opcode field: this field is checked for 0x0001 (Pause packet).
   - Pause time: the Pause time (for Pause packet) is captured to determine the time for which the transmitter needs to be blocked.

3. If the byte count of the status indicates 64 bytes and there is no CRC error, the MAC transmitter pauses the transmission of any data packet for the duration of the decoded Pause Time value multiplied by the slot time (64 byte times).

If subsequent Pause packets are received before the earlier Pause Time expires, the MAC updates the Pause Timer with new value.

**Enabling receive flow control**

Set the RFE bit in the Rx flow control register (ETH_MACRXFCR) to enable the Pause flow control.
64.5.10 MAC management counters

The peripheral supports storing the statistics about the received and transmitted packets in registers that are accessible through the application.

The counters in the MAC management counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The register set includes a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the AHB slave interface in the same way the CSR registers are accessed. The organization of these registers is shown in Section 64.11.4: Ethernet MAC and MMC registers.

The MMC counters are free running. There is no separate enable for the counters to start. A particular MMC counter starts counting when corresponding packet is received or transmitted.

The Receive MMC counters are updated for packets that are passed by the Address Filter (AFM) block. The statistics of packets dropped by the AFM module, are not updated unless they are runt packets of less than 6 bytes (DA bytes are not received fully). To get statistics of all packets, set bit 0 in the Packet filtering control register (ETH_MACPFR). The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet packets.

In addition to control registers, two sets of registers are implemented:

- Six registers used for collision, error, and good packet counters:
  - Tx single collision good packets register (ETH_TX_SINGLE_COLLISION_GOOD_PACKETS)
  - Tx multiple collision good packets register (ETH_TX_MULTIPLE_COLLISION_GOOD_PACKETS)
  - Tx packet count good register (ETH_TX_PACKET_COUNT_GOOD)
  - Rx CRC error packets register (ETH_RX_CRC_ERROR_PACKETS)
  - Rx alignment error packets register (ETH_RX_ALIGNMENT_ERROR_PACKETS)
  - Rx unicast packets good register (ETH_RX_UNICAST_PACKETS_GOOD)

- Four registers to record LPI mode transition:
  - Tx LPI microsecond timer register (ETH_TX_LPI_USEC_CNTR)
  - Tx LPI transition counter register (ETH_TX_LPI_TRAN_CNTR)
  - Rx LPI microsecond counter register (ETH_RX_LPI_USEC_CNTR)
  - Rx LPI transition counter register (ETH_RX_LPI_TRAN_CNTR)
Definitions

The following terminology is used in MMC register descriptions:

- Transmitted packets are considered “good” if transmitted successfully. In other words, a transmitted packet is good if the packets transmission is not aborted because of any of the following errors:
  - Jabber timeout
  - No carrier or loss of carrier
  - Late collision
  - Packet underflow
  - Excessive deferral
  - Excessive collision

- Received packets are considered “good” if none of the following errors exists:
  - CRC error
  - Runt packet (shorter than 64 bytes)
  - Alignment error (in 10/100 Mbps only)
  - Length error (non-Type packet only)
  - Out of range (non-Type packet only, longer than 1518 bytes)

- The maximum transmit frame size depends on the frame type, as follows:
  - Untagged frame maxsize = 1,518
  - VLAN frame maxsize = 1,522
  - Jumbo frame maxsize = 9,018
  - JumboVLAN frame maxsize = 9,022

- The maximum receive packet size depends on the packet type and control bits (JE, S2KP, GPSLCE and EDVLP), as shown in the Table 717.

### Table 717. Size of the maximum receive packet

64.5.11 Interrupts generated by the MAC

Interrupts can be generated from the MAC as a result of various events. These interrupt events are combined with the events in the DMA on the eth_sbd_intr_it signal. The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The interrupt status register (ETH_MACISR) describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt on the eth_sbd_intr_it signals by setting the corresponding mask bits in the interrupt enable register (ETH_MACIER).

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt.

64.5.12 MAC and MMC register descriptions

Refer to Section 64.11.4: Ethernet MAC and MMC registers.
64.6 Ethernet functional description: PHY interfaces

The Ethernet peripheral support several PHY interfaces. The root interface is the MII one. All other interfaces are derived from it as shown in Figure 964.

Figure 964. Supported PHY interfaces

This section describes the SMA module used for PHY control and different PHY interfaces. It contains the following sections:

- Station management agent (SMA)
- Media independent interface (MII)
- Reduced media independent interface (RMII)

64.6.1 Station management agent (SMA)

The application can access the PHY registers through the station management agent (SMA) module. The SMA includes a two-wire station management interface (MIM).

The SMA module supports accessing up to 32 PHYs. The application can address one of the 32 registers from any 32 PHYs. Only one register in one PHY can be addressed at a time. The application sends the control data to the PHY and receives status information from the PHY through the SMA module, as shown in Figure 965.

Figure 965. SMA Interface block
SMA functional overview

The MAC initiates the management write or read operation with respect to the MDC clock. The MDC clock is derived from the CSR clock (eth_hclk). The maximum operating frequency of the ETH_MDC pin is 2.5 MHz, as specified in IEEE 802.3 specifications. However, a different divider can be selected if the system supports higher clock frequencies. The division factor depends on the clock range setting through CR[3:0] in the MDIO address register (ETH_MACMDIOAR) register. The MDC clock is selected as follows:

<table>
<thead>
<tr>
<th>Selection</th>

</tbody>
</table>

The data exchange between the MAC and the PHY is performed through a three-state buffer and brought out as ETH_MDIO line connected to the PHY.

*Figure 966* shows the structure of a Clause 45 MDIO packet, while *Table 719* provides a detailed description of the packet fields.

**Figure 966. MDIO packet structure (Clause 45)**
The frame structure for Clause 22 frames is also supported. The C45E bit in MDIO address register (ETH_MACMDIOAR) can be programmed to enable Clause 22 or Clause 45 mode of operation. Figure 967 shows the structure of a Clause 22 MDIO packet, while Table 720 provides a detailed description of the packet fields.

**Table 719. MDIO Clause 45 frame structure**

</tbody>
</table>

The frame structure for Clause 22 frames is also supported. The C45E bit in MDIO address register (ETH_MACMDIOAR) can be programmed to enable Clause 22 or Clause 45 mode of operation. Figure 967 shows the structure of a Clause 22 MDIO packet, while Table 720 provides a detailed description of the packet fields.

**Figure 967. MDIO packet structure (Clause 22)**

```
In addition to normal read and write operations, the SMA also supports post-read increment address while operating in Clause 45 mode.

**MII management write operations**

After the station management agent receives the PHY address and the write data from the MAC CSR module, the SMA starts a write operation to the PHY registers.

*Figure 968* illustrates the flow for a write operation from the SMA module to the PHY registers.

<table>

<tr>
<td>DATA</td>
<td>Any 16-bit value. In a Write operation, the MAC drives ETH_MDIO. In a Read operation, the PHY drives it.</td>
</tr>
</tbody>
</table>
When bits[3:2] are set to 01 and bit 0 to 1 in the MDIO address register (ETH_MACMDIOAR), the MAC CSR module transfers the PHY address, the register address in PHY, and the write data (MDIO data register (ETH_MACMDIODR)) to the SMA to initiate a Write operation into the PHY registers. At this point, the SMA module starts a Write operation on the MII management interface using the management packet format specified in the MII specifications (as per IEEE 802.3-2002 specifications, Section 22.2.4.5).

When the SMA module starts a Write operation, the write data packet is transmitted on the MDIO line. The MAC drives the MDIO for complete duration of the packet. The Busy bit is set high until the write operation is complete. The CSR ignores the Write operations performed to the MDIO address register (ETH_MACMDIOAR) or the MDIO data register.
(ETH_MACMDIODR) during this period (the Busy bit is high). When the Write operation is complete, the SMA module indicates this to the CSR, and the CSR resets the Busy bit. The packet format for the Write operation is as follows:

**Figure 969. Write data packet**

<table>
<thead>
<tr>
<th>IDLE</th>
<th>PREAMBLE</th>
<th>START</th>
<th>OPCODE</th>
<th>PHY ADDR</th>
<th>REG ADDR</th>

<td>01</td>
<td>01</td>
<td>AAAA</td>
<td>RRRRR</td>
<td>10</td>
<td>DDD...DDD</td>
<td>Z</td>
</tr>
</tbody>
</table>

**MII management read operation**

When bits[3:2] are set to 11 and bit 0 to 1 in the MDIO address register (ETH_MACMDIOAR), the MAC CSR module transfers the PHY address and the register address in PHY to the SMA to initiate a Read operation in the PHY registers. At this point, the SMA module starts a Read operation on the MII management interface using the management packet format specified in the MII specifications (as per IEEE 802.3-2002 specifications, Section 22.2.4.5).

When the SMA module starts a Read operation on the MDIO, the CSR ignores the Write operations to the MDIO address register (ETH_MACMDIOAR) or MDIO data register (ETH_MACMDIODR) during this period (the Busy bit is high) and the transaction is completed without any error on the MCI interface. When the Read operation is complete, the SMA indicates this to the CSR. The CSR resets the Busy bit and updates the MDIO data register (ETH_MACMDIODR) with the data read from the PHY. The MAC drives the MDIO line for the complete duration of the frame except during the Data fields when the PHY is driving the MDIO line. For more information about the communication from the application to the PHYs, see the Reconciliation Sublayer and Media Independent Interface Specifications sections of the IEEE 802.3z, 1000BASE Ethernet.

The packet format for the Read operation is as follows:

**Figure 970. Read data packet**

Preamble suppression

The IEEE standard specifies 32-bit preamble (all-ones) for the MDIO frames. The peripheral provides controls to support preamble suppression. It transmits MDIO frames with only 1 preamble bit. The preamble suppression can be enabled by setting the PSE bit in MDIO address register (ETH_MACMDIOAR).

Trailing clocks and back-to-back transactions

The peripheral drives the ETH_MDC clock for the duration of the MDIO frame. There is no clock driven during the idle period. The trailing clock feature can be used if the PHY needs the ETH_MDC clock to be active for some cycles after the MDIO frame. The NTC[2:0] bitfield in MDIO address register (ETH_MACMDIOAR) allows the programming of trailing clocks from 0 to 7.

The peripheral supports back-to-back transactions which allow starting the next MDIO frame even before the trailing clocks are complete for previous MDIO frame. This feature can be enabled by setting BTB bit in MDIO address register (ETH_MACMDIOAR) when the trailing clock feature is also enabled. When back-to-back transactions are enabled, the GMII busy bit (GB) is cleared immediately after MDIO frame completion. This allows the software to issue the next command, which is executed by the peripheral while trailing clocks are still on for the previous MDIO frame. When (GB) transactions are not enabled, the GMII busy bit is cleared after the trailing clocks are complete for the MDIO frame.

Interrupt for MDIO transaction completion

The peripheral can generate an interrupt on completion of MDIO read or write transactions. Therefore, the application need not poll the GMII busy bit of the MDIO address register (ETH_MACMDIOAR) to know the completion of MDIO commands.
64.6.2 Media independent interface (MII)

The media-independent interface (MII) defines the interconnection between the MAC sublayer and the PHY for data transfer at 10 Mbit/s and 100 Mbit/s.

MII signals are given in Figure 971: Media independent interface (MII) signals.

- **TX_CLK**: continuous clock that provides the timing reference for Tx data transfers. The nominal frequency is 2.5 MHz at 10 Mbit/s and 25 MHz at 100 Mbit/s.
- **TXD[3:0]**: transmit data.
  TXD is a bundle of 4 data signals driven synchronously by the MAC sublayer and qualified (valid data) on the assertion of the TX_EN signal. TXD[0] is the least significant bit, TXD[3] is the most significant bit. While TX_EN is deasserted, the transmit data must have no effect upon the PHY.
- **TX_EN**: transmission enable signal indicating that the MAC is presenting nibbles on the MII for transmission. It must be asserted synchronously (TX_CLK) with the first nibble of the preamble and must remain asserted while all nibbles to be transmitted are presented to the MII.
- **TX_ER (optional)**: required only for Energy Efficient Ethernet (EEE). The transmit error is indicated by inverting the CRC. The remote station can detect the Transmit error through incorrect CRC.
- **RX_CLK**: continuous clock that provides the timing reference for Rx data transfers. The nominal frequency is 2.5 MHz at 10 Mbit/s, 25 MHz at 100 Mbit/s.
- **RXD[3:0]**: receive data
  RXD is a bundle of 4 data signals driven synchronously by the PHY and qualified (valid data) on the assertion of the RX_DV signal. RXD[0] is the least significant bit, RXD[3] is
the most significant bit. While RX_EN is deasserted and RX_ER is asserted, a specific
RXD[3:0] value is used to transfer specific information from the PHY.

- **RX_DV**: receive data valid
  This signal indicates that the PHY is presenting recovered and decoded nibbles on the
  MII for reception. It must be asserted synchronously (RX_CLK) with the first recovered
  nibble of the frame and must remain asserted through the final recovered nibble. It
  must be deasserted prior to the first clock cycle that follows the final nibble. In order
to receive the frame correctly, the RX_DV signal must encompass the frame, starting no
later than the SFD field.

- **RX_ER**: receive error
  This signal must be asserted for one or more clock periods (RX_CLK) to indicate to the
  MAC sublayer that an error was detected somewhere in the frame. This error condition
  must be qualified by RX_DV assertion.

- **CRS**: carrier sense.
  This signal is asserted by the PHY when either the transmit or receive medium is non
  idle. It is deasserted by the PHY when both transmit and receive media are idle. The
  PHY must ensure that the CS signal remains asserted throughout the duration of a
  collision condition. This signal is not required to transition synchronously with respect
to the Tx and Rx clocks. In Full-duplex mode the state of this signal is don’t care for the
  MAC sublayer.

- **COL**: collision detection signal
  This signal must be asserted by the PHY upon detection of a collision on the medium
  and must remain asserted while the collision condition persists. This signal is not
  required to transition synchronously with respect to the Tx and Rx clocks. In Full-duplex
  mode, the state of this signal is don’t care for the MAC sublayer.

### Reduced media independent interface (RMII)

The reduced media independent interface (RMII) specification reduces the pin count
between Ethernet PHYs and STM32 MCU. According to the IEEE 802.3u, an MII contains
16 pins for data and control. RMII specification reduces the pin count to 7.

Part of the Ethernet peripheral, the RMII module is instantiated at the MAC output. This
helps in translating the MII of the MAC into the RMII. The RMII block has the following
characteristics:

- **Supports 10 Mbps and 100 Mbps operating rates. It does not support the 1000 Mbps
  operation.**
- **Provides independent 2-bits wide Transmit and Receive paths by sourcing two clock
  references externally.**
RMII block diagram

*Figure 972: RMII block diagram* shows the position of the RMII block relative to the MAC and RMII PHY. The RMII block is placed in front of the MAC to translate the MII signals to RMII signals.

**Figure 972. RMII block diagram**

- **RMII_REF_CLK**: continuous 50 MHz reference clock input
- **TXD[1:0]**: transmit data
- **TX_EN**: transmit data enable. When high, this bit indicates that valid data are being transmitted on TXD[1:0].
- **RXD[1:0]**: receive data
- **CRS_DV**: carrier Sense (CRS) and RX_Data Valid (RX_DV) multiplexed on alternate clock cycles. In 10 Mbit/s mode, it alternates every 10 clock cycles.
Transmit bit order

Each nibble from the MII interface must be transmitted on the RMII interface di-bit at a time with the order of di-bit transmission shown in Figure 973: Transmission bit order. The lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

Figure 973. Transmission bit order
Receive bit order

Each nibble is transmitted to the MII interface from the di-bit received from the RMII interface in the nibble transmission order shown in Figure 974: Receive bit order. The lower order bits (D0 and D1) are received first, followed by the higher order bits (D2 and D3).

Figure 974. Receive bit order
64.7 Ethernet low-power modes

64.7.1 Low-power management

The Ethernet peripheral supports the following techniques to save power:

- Magic packet
- Remote wake-up

The magic packet and remove wake-up techniques are used to save power in the host system when it is in low-power mode, and has to be woken up only at the reception of specific packets from the Ethernet network. In low-power mode, the clocks on most of the host logic, along with the majority of the peripherals (except the MAC receiver logic), can be disabled. On receiving the specific packets from the network, the MAC generates the trigger to wake up the host system and come back to normal state. Refer to the power control (PWR) section of the reference manual for the list of the system operating modes that support Ethernet low-power modes.

The Energy Efficient Ethernet (EEE) mode is compliant with the IEEE 802.3az-2010 standard. It is primarily targeted to save power in the Ethernet port when there is no traffic on the line. In this mode, the host indicates to the far-end that it does not have any packets to transmit in the near future and puts the transmitter port (MAC controller, PCS and PHY layers) in low-power mode. Similarly, the receiver port can also be put in low-power mode when the far-end host indicates that it does not have any traffic to transfer. This allows significant saving of power in the Ethernet port (mainly in the PHY) with intermittent and burst traffic profile. The triggering of entry and exit out of the EEE mode is controlled by the MAC and is supported within the peripheral.

Simultaneous operation of the EEE mode along with any or both the other power saving modes is also supported.

Description of magic packet mode

This section describes how to save power through magic packet detection.

Note: The magic packet feature is based on the magic packet technology white paper from Advanced Micro Device (AMD).

The watchdog timeout limit for a magic packet is 2,048 bytes irrespective of the value programmed in WD bit in Operating mode configuration register (ETH_MACCR) and PWE bit in Watchdog timeout register (ETH_MACWTR).

In the magic-packet-based power saving mode, the reception of a valid magic packet by the MAC receiver triggers an exit from low-power mode. The MAC enters power saving mode when PWRDWN bit of PMT control status register (ETH_MACPCSR) is programmed to 1. Exit from the magic-packet-based power saving mode is enabled by setting the MGPKTEN bit of PMT control status register (ETH_MACPCSR) to 1.

The magic packet contains a unique pattern at any offset after the Destination address, Source address, and Length/Type fields. In addition to the unique pattern matching, the MAC receiver also checks for the following, to detect the received packet as a valid magic packet:

- The packet must be addressed to it (Destination Address of the received packet should perfect match the MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register (ETH_MACA0LR)) or with multicast/broadcast address.
The packet must not have any length error, FCS error, dribble bit error, GMII error, and collision.

The packet must not be runt (length including Ethernet header and FCS is at least 64 bytes).

**Magic packet data format**

The content of the unique pattern in magic packets is described as follows:

- Six bytes of all-ones (0xFF FF FF FF FF FF) called synchronization stream. There can be more than six bytes of 0xFF, but only the last six are considered.
- The synchronization stream is immediately followed by 16 repetitions of the Destination address field of the packet (MAC Address 0 high register (ETH_MACA0HR) and the MAC Address 0 low register (ETH_MACA0LR)) or multicast/broadcast address.
- No break or interruption between synchronization stream and first repetition of Destination address field or within its 16 repetitions.

If the MAC address of a node is 0x00 11 22 33 44 55, the MAC scans for the following data sequence:

```
Destination Address Source Address Length/Type............... FF FF FF FF FF FF
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 ...CRC
```

**Description of remote wake-up packet mode**

This section describes the power saving mode based on remote wake-up packet.

*Note:* The remote wake-up packet feature implementation is based on the Device Class Power Management Reference Specification and various implementation-specific white papers.

The watchdog timeout limit for a magic packet is 2,048 bytes irrespective of the value programmed in WD bit in Operating mode configuration register (ETH_MACCR) and PWE bit in Watchdog timeout register (ETH_MACWTR).

In the remote-wake-up-magic-packet-based power saving mode, the reception of expected remote wake-up packet by the MAC receiver triggers the exit from low-power mode. The MAC enters power saving mode when PWRDWN bit in PMT control status register (ETH_MACPCSR) is programmed to 1. Exit from the remote-wake-up-magic-packet-based power saving mode is enabled by programming RWKPKTEN bit of PMT control status register (ETH_MACPCSR) to 1.

The MAC implements a filter lookup table (programmed through Remote wake-up packet filter register (ETH_MACRWKPFR) in which CRC, offset, and byte mask of the pattern embedded in remote wake-up packet and the filter operation commands are programmed.

The pattern embedded in the remote wake-up packet is located at any offset after the Destination address and Source address fields. In addition to the CRC match for the pattern, the MAC receiver also checks the following, to detect the received packet as a valid remote wake-up packet:

- The packet must be addressed to it (Destination Address of the received packet should perfect match the MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register (ETH_MACA0LR)) or with multicast/broadcast address.
• The packet must not have any length error, FCS error, dribble bit error, GMII error, and collision.
• The packet must not be runt (length including Ethernet header and FCS is at least 64 bytes).

When a valid remote wake-up packet is received, the MAC receiver sets the RWKPRCVD bit in **PMT control status register (ETH_MACPCSR)** and triggers the interrupt on pmt_intr_o output port. The PMTIS bit in **Interrupt status register (ETH_MACISR)** is set when power-gating is not enabled in low-power mode. An interrupt is triggered to the application on the sbd_intr_o output port when interrupt is enabled (PMTIE bit in **Interrupt enable register (ETH_MACIER)** is set) and CSR clock is not gated off in low-power mode.

**Remote wake-up packet filters**

When the remote-wake-up-based power saving mode is enabled, four remote wake-up filters can be selected. The structure of the remote wake-up filters is shown in **Table 721: Remote wake-up packet filter register**.

**Table 721. Remote wake-up packet filter register**

<table>
<thead>
<tr>
<th>Register</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filter i Byte mask</td>
<td>The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2 or 3) to determine whether or not a packet is a wake-up packet.</td>
</tr>
<tr>
<td></td>
<td>– The MSB (31st bit) must be zero.</td>
</tr>
<tr>
<td></td>
<td>– Bit j[30:0] is the byte mask.</td>
</tr>
<tr>
<td></td>
<td>– If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.</td>
</tr>
<tr>
<td>Filter i Command</td>
<td>The 4-bit filter i command controls the filter i operation.</td>
</tr>
<tr>
<td></td>
<td>– Bit 3 specifies the address type, defining the destination address type of the pattern.</td>
</tr>
<tr>
<td></td>
<td>When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.</td>
</tr>
<tr>
<td></td>
<td>– Bit 2 (Inverse mode), when set, reverses the logic of the CRC16 Hash function signal, to reject a packet with matching CRC_16 value.</td>
</tr>
<tr>
<td></td>
<td>Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as &quot;Pattern 1 AND NOT Pattern 2&quot;.</td>
</tr>
<tr>
<td></td>
<td>– Bit 1 (And_Previous) implements the Boolean logic(1).</td>
</tr>
<tr>
<td></td>
<td>When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set.</td>
</tr>
<tr>
<td></td>
<td>– Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled.</td>
</tr>
<tr>
<td>Filter i Offset</td>
<td>This filter i offset register defines the offset (within the packet) from which the filter i examines the packets.</td>
</tr>
<tr>
<td></td>
<td>– This 8-bit pattern-offset is the offset for the filter i first byte to be examined.</td>
</tr>
<tr>
<td></td>
<td>– The minimum allowed offset is 12, which refers to the 13th byte of the packet.</td>
</tr>
<tr>
<td></td>
<td>– The offset value 0 refers to the first byte of the packet.</td>
</tr>
<tr>
<td>Filter i CRC-16</td>
<td>This filter i CRC-16 register contains the CRC_16 value calculated from the pattern and also the byte mask programmed to the wake-up filter register block.</td>
</tr>
<tr>
<td></td>
<td>– The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1</td>
</tr>
<tr>
<td></td>
<td>Each mask, used in the Hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:</td>
</tr>
<tr>
<td></td>
<td>– 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC16 calculation.</td>
</tr>
<tr>
<td></td>
<td>– 8-bit Offset Pointer: Specifies the byte to start the CRC16 computation.</td>
</tr>
<tr>
<td></td>
<td>The pointer and the mask are used together to locate the bytes to be used in the CRC16 calculations.</td>
</tr>
</tbody>
</table>

1. The And_Previous bit setting is applicable within a set of four filters. Setting And_Previous bit of a filter that is not enabled has no effect, that is setting And_Previous bit of lowest number filter in the set of four filters has no effect. For example, setting And_Previous bit of Filter 0 has no effect. If And_Previous bit is set for a given filter to form an AND chained filter, the AND chain breaks when it finds a disabled filter. For example: If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set) but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 2 is not enabled (bit 0 in Filter 2 command is reset), then since setting Filter 2 And_Previous bit has no effect, only Filter 1 result ORed with Filter 3 result is considered. If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 in Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 in Filter 2 command is reset) indicating unicast detection or vice versa, then a remote wake-up frame does not pass the AND chained filter as a remote wake-up frame cannot be of both unicast and multicast address types.
The remote wake-up filter registers are implemented as eight indirect access registers (wkuppktfilter_reg#i) for four remote wake-up filters, and accessed by the application through Remote wake-up packet filter register (ETH_MACRWKPFR). The entire set of wkuppktfilter_reg registers must be written to program the remote wake-up filters. The wkuppktfilter_reg register is programmed by sequentially writing the eight register values in Remote wake-up packet filter register (ETH_MACRWKPFR) for wkuppktfilter_reg0 to wkuppktfilter_reg3, respectively. The wkuppktfilter_reg register is read in a similar way. The MAC updates the wkuppktfilter_reg register current pointer value in RWKPTR field of PMT control status register (ETH_MACPCSR).

Note: If the Remote wake-up packet filter register (ETH_MACRWKPFR) is accessed in byte or half-word mode, the internal counter to access the appropriate wkuppktfilter_reg is incremented when the CPU accesses Lane 3.

When Remote wake-up packet filter register (ETH_MACRWKPFR) is written, the content is transferred from CSR clock domain to PHY receive clock domain after the write operation. There should not be any further write to the Remote wake-up packet filter register (ETH_MACRWKPFR) until the first write is updated in PHY receive clock domain. Otherwise, the second write operation does not get updated to the PHY receive clock domain. Therefore, the delay between two write operations to the Remote wake-up packet filter register (ETH_MACRWKPFR) should be at least 4 cycles of the PHY receive clock.

PMT interrupt

The PMT interrupt signal is asserted when a valid remote wake-up packet is received. Table 723 lists the remote wake-up scenarios in which PMT interrupt is generated.

1. In all other combinations, the Remote Wake-up packet is not detected and PMT interrupt is not generated.

In addition to sbd_intr_o signal, the pmt_intr_o (synchronous to Rx clock) signal is asserted. The pmt_intr_o signal, synchronous to the Rx clock domain, is provided so that the application clock can be stopped by software when the MAC is in the power-down mode. It is ORed with lpi_intr_o signal (see Section : LPI interrupt) and tied to the EXTI peripheral.

As the pmt_intr_o signal is generated in the PHY Rx clock domain, it is not cleared immediately when the PMT control status register (ETH_MACPCSR) is read. This is
because the resultant clear signal has to cross to the PHY Rx clock domain, and then clear the interrupt source. This delay is at least 4 clock cycles of Rx clock and can be significant when the peripheral is operating in the 10 Mbps mode. When the application clears the PWRDWN bit in Remote wake-up packet filter register (ETH_MACRWKPFR), the MAC comes out of the power-down mode, but this event does not generate the PMT interrupt.

Power-down sequence

The software must perform the following tasks to initiate the power-down sequence:

- Disable the Transmit DMA (if applicable) by clearing the ST bit of the Channel transmit control register (ETH_DMACTXCR).
- Wait for any previous frame transmissions to complete. You can check this by reading TFCSTS[1:0] and TPESTS bits in Debug register (ETH_MACDR) and TXQSTS bit in Tx queue debug register (ETH_MTLTXQDR) of all MTL Tx Queues.
- Disable the MAC transmitter and MAC receiver by clearing TE and RE bits in Operating mode configuration register (ETH_MACCR).
- Wait till the Receive DMA empties all frames from the Rx FIFO. You can check this by reading PRXQ[13:0] in Rx queue debug register (ETH_MTLRXQDR) of all Rx Queues. If these bits are zero, it indicates that the Rx FIFO is empty.
- Configure the magic packet (MGKPKTEN) and/or remote wake-up (RWKPKTEN) detection in the PMT control status register (ETH_MACPCSR).
- Set bit 31 (ARPEN) in the Operating mode configuration register (ETH_MACCR).
- Enable the MAC Receiver by setting RE bit and then set PWRDWN bit in the PMT control status register (ETH_MACPCSR) to initiate the power-down sequence in MAC.

Note: If the feature is enabled and the MAC Transmitter is in the LPI mode when it is put into the power-down mode, then the MII interface gets clamped to assert the LPI pattern. If the MAC Transmitter is not in the LPI mode when it is put into the power-down mode, the GMII or MII interface gets clamped to all-zero.

Power-up sequence

The MAC wakes up on receiving the magic packet or remote wake-up frame. The power-up sequence is as follows:

- The MAC asserts pmt_intr_o. When only clock-gating is employed in low-power mode, the pmt_intr_o signal can be used to start the clocks that were gated-off after entering low-power mode.
- The software performs the following tasks:
  - De-assert the pmt_intr_o by reading the PMT control status register (ETH_MACPCSR).
  - Perform a write operation (with reset values) to the PMT control status register (ETH_MACPCSR) and the Remote wake-up packet filter register (ETH_MACRWKPFR) so that the corresponding values in the always-on block gets synchronized. Otherwise, the values of these registers are different.
  - Perform write operations to the Operating mode configuration register (ETH_MACCR), MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register (ETH_MACA0LR) to synchronize the values in the CSR module and the respective bits in the always-on block. Otherwise, the MAC receiver is on even though the Receive Enable bit is set to 0.
After completing these steps, the software must initialize all registers, enable the transmitter, and program the DMA (in DMA configurations) to resume the normal operation.

64.7.2 Energy Efficient Ethernet (EEE)

EEE is an operational mode that enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps. The peripheral supports the IEEE 802.3az-2010 for EEE.

The LPI mode allows saving power by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functionalities to save power during the periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

Transmit path functions

The transmit path functions include tasks that the MAC must perform to make the PHY enter the LPI state.

In the transmit path, the software must set the LPIEN bit of the LPI control and status register (ETH_MACLCSR) to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER LST[9:0] bitfield of LPI timers control register (ETH_MACLTCR). The PHY Link Status PLS bit of the LPI control and status register (ETH_MACLCSR) indicates the link status of the PHY.

Note: The EEE feature is not supported when the MAC is configured to use the RMII.

According to the standard (IEEE 802.3az-2010), the PHY must not stop the TxCLK clock during the LPI state in the MII (10 or 100) mode.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts TX_EN.
2. Asserts TX_ER.
3. Sets TXD[3:0] to 0x1 (for 100 Mbps)
4. Updates the status (TLPIEN bit of LPI control and status register (ETH_MACLCSR)) and generates an interrupt.

Note: The MAC maintains the same state of the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.
To bring the PHY out of the LPI state, that is when the software resets the LPIEN bit, the MAC performs the following tasks:

1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern.
2. Starts the LPI TW TIMER:
   The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field of the LPI timers control register (ETH_MACLT) and generates an interrupt.
3. Updates the LPI exit status (TLPIEX bit of the LPI control and status register (ETH_MACCSR)) and generates an interrupt.

Figure 975 shows the behavior of TX_EN, TX_ER, and TXD[3:0] signals during the LPI mode transitions.

**Note:** The MAC does not stop the TX_CLK clock. The application can stop this clock (as shown in Figure 975) if the PHY supports it and when the MAC sets the sbd_tx_clk_gating_ctrl_o signal to 1. The sbd_tx_clk_gating_ctrl_o signal is asserted after nine Tx Clock Cycles, one Pulse Synchronizer delay, and one CSR clock cycle. The assertion of the sbd_tx_clk_gating_ctrl_o signal depends on the LPITCSE bit of the LPI control and status register (ETH_MACCSR) and can be done automatically as shown on Figure 976.

If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern and so the Tx Clock cannot be gated.

If the MAC is in the Tx LPI mode and the Tx clock is stopped, the application should not write to CSR registers that are synchronized to Tx clock domain.

If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC transmitter comes out of the LPI mode.

**Figure 975. LPI transitions (Transmit, 100 Mbds)**
Automated entry/exit from LPI mode in transmit path

The MAC transmitter can be programmed to enter and exit LPI Idle mode automatically based on whether it is Idle for a specific period of time or has a packet to transfer. These modes are enabled and controlled by the LPI control and status register (ETH_MACLCSR).

When LPITXA and LPIEN of LPI control and status register (ETH_MACLCSR) are set, the MAC transmitter enters LPI Idle state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter exits the LPI Idle state and clears the LPITXEN bit as soon as any of functions in the TX path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition, when LPITE is also set, the MAC transmitter enters LPI Idle state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in LPI entry timer register (ETH_MACLETR). In this mode also, the MAC transmitter exits the LPI Idle state as soon as any of the functions becomes non-idle. However, the LPIEN bit is not cleared but remains active so that reentry to LPI Idle state is possible without any software intervention when the MAC becomes idle again.

When both LPITE and LPITXA bits are cleared, the application can directly control the entry and exit of LPI Idle state by programming the LPIEN bit.

Receive path Functions

The receive path functions include the tasks that the PHY and MAC must perform when the PHY receives signals from the link partner to exit the LPI state.

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER.
2. The PHY sets RXD[3:0] to 0x1 (for 100 Mbps).
3. The PHY de-asserts RX_DV.
4. The MAC updates the RLPIEN bit of the LPI control and status register (ETH_MACLCSR) and immediately generates an interrupt.
Note: The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.

If the LPI pattern is detected for a very short duration (that is, less than two cycles of Rx clock), the MAC does not enter the Rx LPI mode.

If the duration between the end of the current Rx LPI pattern and the start of the next Rx LPI pattern is very short (that is, less than two Rx clock cycles), then the MAC exits and enters again the Rx LPI mode. The MAC does not trigger the Rx LPI Exit and Entry interrupts.

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the LPI control and status register (ETH_MACLCSR) and generates an interrupt immediately. The sideband signal lpi_intr_o (synchronous to Rx clock) is also asserted.

Figure 977 shows the behavior of RX_ER, RX_DV, and RXD[3:0] signals during the LPI mode transitions.

Figure 977. LPI transitions (receive, 100 Mbps)

Note: If the RX_CLK_stoppable bit (in the PHY register written through MDIO) is asserted when the PHY is indicating LPI to the MAC, the PHY may halt the RX_CLK at any time more than nine clock cycles after the start of the LPI state as shown in Figure 977.

If the MAC is in LPI mode and the application issues a soft reset or hard reset, the MAC receiver exits from LPI mode during reset. If the LPI pattern is still received after the reset is de-asserted, the MAC receiver enters again the LPI state.

If the RX clock is stopped in the RX LPI mode, the application should not write to the CSR registers that are being synchronized to the RX clock domain.

When the PHY sends the LPI pattern, if EEE feature is enabled, the MAC automatically enters the LPI state. There is no software control to prevent the MAC from entering the LPI state.
LPI timers

The transmitter maintains the LPI LS TIMER, LPI TW TIMER, and LPI AUTO ENTRY TIMER timers.

The following LPI timers are loaded with the respective values from the LPI timers control register (ETH_MACLTCR) and LPI entry timer register (ETH_MACLETR):

- **LPI LS TIMER**
  The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in the LST[9:0] bitfield in the LPI timers control register (ETH_MACLTCR). The LPI LS TIMER is 10-bit wide. The software can program up to 1023 milliseconds.

- **LPI TW TIMER**
  The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programmed in Bit[15:0] of LPI timers control register (ETH_MACLTCR). The terminal count of the timer is the value of resolved Transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count. The MAC supports the LPI TW TIMER in units of microsecond. The LPI TW TIMER is 16-bit wide. Therefore, the software can program up to 65535 micro seconds.

- **LPI AUTO ENTRY TIMER**
  This timer counts in steps of eight microseconds, the time for which the MAC transmit path has to remain in idle state (no activity), before the MAC Transmitter enters the LPI IDLE state and starts transmitting the LPI pattern. This timer is enabled when LPITE bit in LPI control and status register (ETH_MACLCSR) is set.

LPI interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The interrupt sbd_intr_o is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the LPI control and status register (ETH_MACLCSR).

When the MAC exits the Rx LPI state, then in addition to the sbd_intr_o, the sideband signal lpi_intr_o (synchronous to Rx clock) is asserted. The lpi_intr_o signal can be used to trigger the external clock-gating circuitry to restore the application clock to the MAC. The lpi_intr_o signal, synchronous to the Rx clock domain, is provided so that the application clock can be stopped by software when the MAC is in the LPI state. It is ORed with pmt_intr_o signal (see Section : PMT interrupt) and tied to the EXTI peripheral.

The lpi_intr_o signal is generated in the Rx clock domain. It may not be cleared immediately after the LPI control and status register (ETH_MACLCSR) is read. This is because the clear signal, generated in CSR clock domain, has to cross the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the peripheral is operating in the 10 Mbps mode.

Programming guidelines for Energy Efficient Ethernet

For detailed guidelines on the programming guidelines, see Section 64.9.11: Programming guidelines for Energy Efficient Ethernet (EEE) on page 3371.
64.8 Ethernet interrupts

The Ethernet peripheral generates a single interrupt signal (eth_sbd_intr_it). This signal can be raised as a result of various events. These events are captured in status registers and interrupt enables are provided for each source of interrupt such that the interrupt signal is asserted for an event only when the corresponding interrupt enable is set.

The interrupt status and corresponding enable registers are organized in a hierarchical manner so that it is easier for software to traverse and identify the source of interrupt event quickly. When interrupt is asserted, the Interrupt status register (ETH_DMAISR) register is first level that indicates the major blocks for the interrupt event source. This register is read-only, and it contains bits corresponding to each DMA channel (TX & RX pair), the MTL, and the MAC. The software application must then read one (or more) of the following registers corresponding to the bits that are set:

- ETH_DMACSR: Channel Status (see Channel status register (ETH_DMACSR))
- ETH_MTLISR: Interrupt Status (see Interrupt status register (ETH_MTLISR))
- ETH_MACISR: Interrupt Status (see Interrupt status register (ETH_MACISR))

64.8.1 DMA interrupts

Interrupt registers description

The ETH_DMACSR: Channel Status register (see Channel status register (ETH_DMACSR)) captures all the interrupt events of that TxDMA and RxDMA channel. The ETH_DMACIER: Channel Interrupt Enable register (see Channel interrupt enable register (ETH_DMACIER)) contains the corresponding enable bits for each of the interrupt event.

There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by Bits[15:14] of ETH_DMACSR register respectively. The normal group is for events that happen during the normal transfer of packets (TI: transmit interrupt, RI: receive interrupt, TBU: Transmit buffer unavailable) while the abnormal interrupt events are for error events.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated. An interrupt is generated only once for multiple events. The driver must scan the Interrupt status register (ETH_DMAISR) for the cause of the interrupt and clear the source in the respective Status register. The interrupt is cleared only when all the bits of Interrupt status register (ETH_DMAISR) are cleared.

Periodic scheduling of Transmit and Receive Interrupt

It is not preferable to generate interrupts for every packet transferred by DMA (RI and TI) for system throughput performance reasons. The Ethernet peripheral gives the flexibility to schedule the interrupt at regular intervals using two methods:

1. Set Interrupt on Completion bit in Transmit descriptor (TDES2[31] in Table 727: TDES2 normal descriptor (read format)) once for every “required” number of packets to be transmitted.

2. Similarly, set the IOC (RDES3[30] in Table 740: RDES3 normal descriptor (read format)) bit only at some specific intervals of Receive descriptors. This way, whenever a received packet transfer to system memory is complete and any of the descriptors used for that packet transfer has the IOC bit set, only then the RI event is generated.
In addition to above, an interrupt timer (ETH_DMACRXIWTR: Channel Rx Interrupt
Watchdog Timer) is given for flexible control and periodic scheduling of Receive Interrupt. When this interrupt timer is programmed with a nonzero value, it gets activated as soon as the Rx DMA completes a transfer of a received packet to system memory without asserting the Receive Interrupt because the corresponding interrupt of completion IOC bit (RDES3[30] in Table 740: RDES3 normal descriptor (read format)) is not set. When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding RIE is enabled in ETH_DMACIER register (see Channel interrupt enable register (ETH_DMACIER)). The timer is stopped and cleared before it expires, if the RI is set for a packet transfer whose descriptor’s IOC was set. The timer is reactivated automatically after the next packet transfer is complete without the RI event being generated.

Channel transfer complete interrupt

The Transmit Transfer complete interrupt (TI) and Receive Transfer complete interrupt (RI) is reflected in the Channel Status register (Channel status register (ETH_DMACSR)). The TI bit is set whenever the Tx DMA channel closes the descriptor in which the IOC bit is set (Interrupt On Completion - TDES2[31]). Similarly, the RI bit is set whenever the Rx DMA channel closes a descriptor with the LD bit set and, in any of the descriptors used for transferring that packet, IOC bit is set (Interrupt Enable on completion - RDES3[30]).

The interrupt signal is asserted for the Transfer complete interrupts only when the corresponding interrupts are enabled in the channel interrupt enable register (Channel interrupt enable register (ETH_DMACIER)).

The behavior of the RI/TI interrupts changes depending on the settings of INTM field (bits[17:16]) in the ETH_DMAMR register (DMA mode register (ETH_DMAMR)). Table 724 explains the behavior of the Transfer Complete interrupt.

<table>
<thead>
<tr>
<th>Interrupt Mode</th>
<th>Behavior of TI/RI and interrupt signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTM=0</td>
<td>The TI/RI status signals are set whenever the Transfer complete event is detected. These bits are cleared whenever the software driver writes 1 to these bits. The interrupt signal is asserted whenever the corresponding interrupts are also enabled in ETH_DMACIER register.</td>
</tr>
<tr>
<td>INTM=1</td>
<td>The TI/RI is set as explained above. However, the interrupt is not asserted for any RI/TI event.</td>
</tr>
<tr>
<td>INTM=2</td>
<td>The RI/TI status bits are set whenever the Transfer Complete event is detected and are reset whenever software driver clears them by writing 1. However, if another Transfer complete event is detected before it is cleared (serviced) by the software, then these status bits are automatically set again. However, the interrupt is not generated based on TI/RI.</td>
</tr>
</tbody>
</table>
64.8.2 MTL interrupts

MTL interrupt events are combined with the events in the DMA to generate the interrupt signal.

The register *Interrupt status register (ETH_MTLISR)* report the queue number responsible for the event. *ETH_MTLQICSR: Queue Interrupt Control Status* must be read for event description.

The MTL interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the *Interrupt status register (ETH_MTLISR)* register.

MTL interrupt signal is driven by one of these events:
- Receive Queue Overflow Interrupt
- Transmit Queue Underflow

64.8.3 MAC Interrupts

MAC interrupt events are combined with the events in the DMA to generate the interrupt signal.

The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The *Interrupt status register (ETH_MACISR)* describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the *Interrupt status register (ETH_MACISR)*.

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt.

MAC interrupt signal is driven by one of these events:
- Receive Status Interrupt
- Transmit Status Interrupt
- Timestamp Interrupt Status
- MMC Interrupt Status
  - MMC Receive Checksum Offload Interrupt Status
  - MMC Transmit Interrupt Status
  - MMC Receive Interrupt Status
- LPI Interrupt Status
- PMT Interrupt Status
- PHY Interrupt

*Note:* Two sidebands signals are generated together with LPI and PMT interrupts: lpi_intr_o and pmt_intr_o. They are used for wake-up event detection at EXTI level.
64.9 Ethernet programming model

This chapter provides the instructions for initializing the DMA or MAC registers in the proper sequence. It contains the following sections:

- DMA initialization (see Section 64.9.1)
- MTL initialization (see Section 64.9.2)
- MAC initialization (see Section 64.9.3)
- Performing normal receive and transmit operation (see Section 64.9.4)
- Stopping and starting transmission (see Section 64.9.5)
- Programming guidelines for MII link state transitions (see Section 64.9.6)
- Programming guidelines for Energy Efficient Ethernet (see Section 64.9.7)
- Programming guidelines for IEEE 1588 timestamping (see Section 64.9.8)
- Programming guidelines for flexible pulse-per-second (PPS) output (see Section 64.9.9)
- Programming guidelines for MII link state transitions (see Section 64.9.10)
- Programming guidelines for VLAN filtering on the receiver (see Section 64.9.11)
- Programming guidelines for TSO (see Section 64.9.12)
- Programming guidelines for VLAN filtering on the receiver (see Section 64.9.13)
- Programming guidelines for TSO (see Section 64.9.14)

64.9.1 DMA initialization

Complete the following steps to initialize the DMA:

1. Provide a software reset to reset all MAC internal registers and logic (bit 0 of DMA mode register (ETH_DMAMR)).
2. Wait for the completion of the reset process (poll bit 0 of the DMA mode register (ETH_DMAMR), which is cleared when the reset operation is completed).
3. Program the following fields to initialize the System bus mode register (ETH_DMASBMR):
   a) AAL
   b) Fixed burst or undefined burst
   c) Burst mode values in case of AHB bus interface.
4. Create a transmit and a receive descriptor list. In addition, ensure that the receive descriptors are owned by the DMA (set bit 31 of TDES3/RDES3 descriptor). For more information on descriptors, refer to Section 64.10: Descriptors.

Note: Descriptor address from start to end of the ring should not cross the 4GB boundary.

5. Program ETH_DMACTXRLR and ETH_DMCRXLRLR registers (see Channel Tx descriptor ring length register (ETH_DMACTXRLR) and Channel Rx descriptor ring length register (ETH_DMCRXLRLR)). The programmed ring length must be at least 4.
6. Initialize receive and transmit descriptor list address with the base address of transmit and receive descriptor (Channel Tx descriptor list address register (ETH_DMACTXDLAR), Channel Rx descriptor list address register (ETH_DMCRXLAR)). In addition, program the transmit and receive tail pointer registers that inform the DMA about the available descriptors (see Channel Tx descriptor tail pointer register (ETH_DMACTXTPR) and Channel Rx descriptor tail pointer register (ETH_DMCRXTTPR)).
7. Program ETH_DMACC, ETH_DMACTXCR and ETH_DMCRXCR registers (see Channel control register (ETH_DMACC), Channel transmit control register (ETH_DMACTXCR) and Channel receive control register (ETH_DMCRXCR)) to
configure the parameters such as the maximum burst-length (PBL) initiated by the DMA, descriptor skip lengths, OSP for TxDMA, RBSZ[13:0] for RxDMA, and so on.

8. Enable the interrupts by programming the ETH_DMACIER register (see Channel interrupt enable register (ETH_DMACIER)).

9. Start the Receive and Transmit DMAs by setting SR (bit 0) of Channel receive control register (ETH_DMACRXCR) and ST (bit 0) of the ETH_DMACTXCR (see Channel transmit control register (ETH_DMACTXCR)).

64.9.2 MTL initialization

Complete the following steps to initialize the MTL registers:

1. Program the following fields to initialize the operating mode in Tx queue operating mode register (ETH_MTLTXQOMR).
   a) Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) if the Threshold mode is used.
   b) Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue 0.
   c) Transmit Queue Size (TQS).

2. Program the following fields to initialize the operating mode in the ETH_MTLRXQOMR register (see Rx queue operating mode register (ETH_MTLRXQOMR)):
   a) Receive Store and Forward (RSF) or RTC if Threshold mode is used.
   b) Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD).
   c) Error Packet and undersized good Packet forwarding enable (FEP and FUP).
   d) Receive Queue Size (RQS).

64.9.3 MAC initialization

The MAC configuration registers establish the operating mode of the MAC. If possible, these registers must be initialized before initializing the DMA. The following MAC Initialization operations can also be performed after DMA initialization. If the MAC initialization is complete before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC Address x low register (ETH_MACAxLR), MAC Address 0 high register (ETH_MACA0HR) and MAC Address x high register (ETH_MACAxHR).

2. Program the following fields to set the appropriate filters for the incoming frames in the Packet filtering control register (ETH_MACPFR):
   a) Receive All.
   b) Promiscuous mode.
   c) Hash or Perfect Filter.
   d) Unicast, multicast, broadcast, and control frames filter settings.

3. Program the following fields for proper flow control in the Tx Queue flow control register (ETH_MACQTXFCR):
   a) Pause time and other Pause frame control bits.
   b) Transmit Flow control bits.
   c) Flow Control Busy.
4. Program the Interrupt enable register (ETH_MACIER) as required, if it is applicable for your configuration.

5. Program the appropriate fields in the Operating mode configuration register (ETH_MACCR) register. For example, Inter-packet gap while transmission and jabber disable.

6. Set bit 0 and 1 in Operating mode configuration register (ETH_MACCR) register to start the MAC transmitter and receiver.

To support Jumbo Transmit/Receive packets, follow these steps:
- In the Operating mode configuration register (ETH_MACCR)
  a) Set JE bit to 1.
  b) Set JD and WD bits to 0 to avoid giant packet error reporting.
  c) Set GPSLCE bit to 1
  d) Set GPSL bitfield of the Extended operating mode configuration register (ETH_MACECR) to a value > 9026

To support Transmit/Receive packets, up to 16K, follow these steps:
- In the Operating mode configuration register (ETH_MACCR)
  a) Set JD and WD bits to 1 to avoid giant packet error reporting.
  b) Set GPSLCE bit to 1.
  c) Set GPSL bitfield of the Extended operating mode configuration register (ETH_MACECR) to 16383.

64.9.4 Performing normal receive and transmit operation

For normal operation, complete the following steps:
1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptor by reading the status of the descriptor owned by the Host (either transmit or receive).

2. Set the descriptors to appropriate values. Make sure that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.

3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into Suspend state. The transmission or reception can be resumed by freeing the descriptors and writing the ETH_DMACTXDTPR (see Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR)) and ETH_DMACRXDTPR (see Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR)).

4. In debug mode, the values of the current host transmitter or receiver descriptor address pointer can be read in ETH_DMACCATXDR and ETH_DMACCARXDR registers (see Channel current application transmit descriptor register (ETH_DMACCATXDR) and Channel current application receive descriptor register (ETH_DMACCARXDR)).

5. In debug mode, the values of the current host transmit buffer address pointer and receive buffer address pointer can be read in ETH_DMACCATXDR and ETH_DMACCARXDR registers (see Channel current application transmit descriptor register (ETH_DMACCATXDR) and Channel current application receive descriptor register (ETH_DMACCARXDR)).
64.9.5 Stopping and starting transmission

Complete the following steps to pause the transmission for some time:

1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of ETH_DMACTXCR register (see Channel transmit control register (ETH_DMACTXCR)).
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Tx queue debug register (ETH_MTLTXQDR) (TRCSTS[1:0] is not 01 and TXQSTS = 0).
3. Disable the MAC transmitter and MAC receiver by clearing RE and TE bits of the Operating mode configuration register (ETH_MACCR) Register.
4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of Tx queue debug register (ETH_MTLTXQDR), PRXQ=0 and RXQSTS[1:0] = 00).
5. Make sure that both Tx queue and Rx queue are empty (TXQSTS is 0 in Tx queue debug register (ETH_MTLTXQDR) and RXQSTS[1:0] is set to 00.
6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

Note: Do not change the configuration (such as duplex mode, speed, port, or loopback) when the MAC is actively transmitting or receiving. These parameters are changed by software only when the MAC transmitter and receiver are not active. Similarly, do not change the DMA-related configuration when Transmit and Receive DMA are active.

64.9.6 Programming guidelines for switching to new descriptor list in RxDMA

Switching to a new descriptor list is different in the Rx DMA compared to the Tx DMA. Switching to a new descriptor list is permitted when the RxDMA is in Suspend state, as explained below:

- Generally, RxDMA prepares the descriptors in advance.
- If the RxDMA goes to Suspend state due to descriptors not being available, a major failure occurs (software is not able to free the filled-up descriptors/buffers). If this issue is not rectified immediately, frames are lost because of an RxFIFO overflow. Therefore, the software is allowed to create a new descriptor list and program the RxDMA to start using it immediately, without going into Stop state.

64.9.7 Programming guidelines for switching the AHB clock frequency

To dynamically change the AHB clock frequency (without applying soft reset or hard reset), follow these steps:

1. Disable the Transmit DMA (if applicable) and wait for any previous frame transmissions to complete. When the frame transmissions is complete, the Tx FIFO becomes empty and the Tx DMA enters Stop state. The Tx FIFO status is given in the Tx queue debug
register (ETH_MTLTXQDR) and the status of DMA is given in Debug status register (ETH_DMADSR).

2. Disable the MAC transmitter and the MAC receiver by clearing the appropriate bits in Operating mode configuration register (ETH_MACCR).

3. Disable the Receive DMA (if applicable) after making sure that the data in the Rx FIFO is transferred to the system memory. The Rx FIFO empty status is given in Rx queue debug register (ETH_MTLRXQDR).

4. Ensure that the application does not perform any register read or write operation.

5. Change the frequency of the AHB clock.

6. Enable the MAC Transmitter or the MAC Receiver and the Transmit or Receive DMA. These steps ensure that no valid data is present in the Tx FIFO or Rx FIFO at the time of clock frequency switching and prevent any data corruption.

64.9.8 Programming guidelines for MII link state transitions

Transmit and Receive clocks are running when the link is down

Complete the following steps when the link is down while the Transmit and Receive clocks are running:

1. Disable the Transmit DMA (if applicable) by clearing bit 0 (ST) of Channel control register (ETH_DMACCR).

2. Disable the MAC receiver by clearing RE bit of Operating mode configuration register (ETH_MACCR).

3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Tx queue debug register (ETH_MTLTXQDR) (TRCSTS[1:0] is not 01).
   or
   Flush the Tx FIFO for faster empty operation.

4. Disable the MAC transmitter by clearing TE bit of the Operating mode configuration register (ETH_MACCR) Register.

5. Make sure that both Tx and Rx queues are empty (TXQSTS is set to 0 in Tx queue debug register (ETH_MTLTXQDR) and RXQSTS[1:0] to 00 in Rx queue debug register (ETH_MTLRXQDR)).

6. After the link is up, read the PHY registers to identify the latest configuration and program the MAC registers accordingly.

7. Restart the operation by starting the Tx DMA. Then enable the MAC Transmitter and Receiver.
   The Rx DMA does not need to be enabled: since the Receiver is disabled, there are no data in the Rx FIFO.
Transmit and Receive clocks are stopped when the link is down

Complete the following steps when the link is down and the Transmit and Receive clocks are stopped:

1. Disable the MAC Transmitter and Receiver by clearing RE and TE bits in the *Operating mode configuration register* (*ETH_MACCR*). This does not take immediate effect as the clocks are absent.
2. Wait till the link is up and the clocks are restored.
3. Wait until the transfer of any partial frame is complete if any was ongoing when the Transmit/Receive clock is stopped. This can be checked by reading the *Debug register* (*ETH_MACDR*) (all bits should be set to 0). Some old packets may still remain in the TXFIFO as the MAC Transmitter is stopped.
4. Read the PHY registers to identify the latest operating mode and program the MAC registers accordingly.
5. Restart the MAC Transmitter and Receiver by setting RE and TE bits.

### 64.9.9 Programming guidelines for IEEE 1588 timestamping

#### Initializing the System time generation

The timestamp feature can be enabled by setting bit 0 of the *Timestamp control Register* (*ETH_MACTSCR*). However, it is essential that the timestamp counter is initialized after this bit is set. Complete the following steps to perform the peripheral initialization:

1. Mask the Timestamp Trigger interrupt by clearing bit 12 of *Interrupt enable register* (*ETH_MACIER*).
2. Set bit 0 of *Timestamp control Register* (*ETH_MACTSCR*) to enable timestamping.
3. Program *Subsecond increment register* (*ETH_MACSSIR*) based on the PTP clock frequency.
4. If you use the Fine Correction method, program *Timestamp addend register* (*ETH_MACTSAR*) and set bit 5 of *Timestamp control Register* (*ETH_MACTSCR*).
5. Poll the *Timestamp control Register* (*ETH_MACTSCR*) until bit 5 is cleared.
6. Program bit 1 of *Timestamp control Register* (*ETH_MACTSCR*) to select the Fine Update method (if required).
7. Program *System time seconds update register* (*ETH_MACSTSUR*) and *System time nanoseconds update register* (*ETH_MACSTNUR*) with the appropriate time value.
8. Set bit 2 in *Timestamp control Register* (*ETH_MACTSCR*).

The timestamp counter starts as soon as it is initialized with the value written in the timestamp update registers. If one-step timestamping is required:

a) Enable one-step timestamping by programming bit 27 of the TDES3 Context Descriptor.

b) Program *Timestamp Ingress asymmetric correction register* (*ETH_MACTSIACR*) to update the correction field in PDelay_Req PTP messages.

9. Enable the MAC receiver and transmitter for proper timestamping.

*Note:* If timestamp operation is disabled by clearing bit 0 of *Timestamp control Register* (*ETH_MACTSCR*), repeat all these steps to restart the timestamp operation.
System time correction

To synchronize or update the system time in one shot (coarse correction method), complete the following steps:

1. Set the offset (positive or negative) in the timestamp update registers (System time seconds update register (ETH_MACSTSUR) and System time nanoseconds update register (ETH_MACSTNUR)).
2. Set bit 3 (TSUPDT) of the Timestamp control Register (ETH_MACTSCR).
   The value in the timestamp update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

To synchronize or update the system time to reduce system-time jitter (fine correction method), complete the following steps:

1. With the help of the algorithm described in Section : System time register module, calculate at which rate you intend to increment or decrement the system time.
2. Update the Timestamp addend register (ETH_MACTSAR) with the new value and set bit 5 of the Timestamp control Register (ETH_MACTSCR) Register.
3. Wait for the time during which you want the new value of the Addend register to be active. This can be done by enabling the Timestamp Trigger interrupt after the system time reaches the target value.
4. Program the required target time in PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR).
5. Enable the Timestamp interrupt in bit 12 of Interrupt enable register (ETH_MACIER).
6. Set bit 4 in Register Timestamp control Register (ETH_MACTSCR).
7. When this trigger generates an interrupt, read Interrupt status register (ETH_MACISR).
8. Reprogram Timestamp addend register (ETH_MACTSAR) with the old value and set bit 5 again.

64.9.10 Programming guidelines for PTP offload feature

Programming guidelines to enable automatic periodic generation of PTP sync messages

Follow these steps to enable automatic periodic generation of PTP sync messages:

1. Program SNAPTYPSEL, TSMSTRENA, and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 0, 1, and 1 respectively, to configure the node as Ordinary or Boundary Master (1, 1, and 1 for Transparent Master).
2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to send in egress PTP Sync message.
3. Program the ASYNCECN bit of PTP Offload control register (ETH_MACPOCR) to enable periodic generation of PTP Sync messages.
4. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP
5. Program the LSI field of Log message interval register (ETH_MACLMIR) to program the periodicity of the PTP Sync messages.

For example, a value of 1 corresponds to 2^1 which translates to PTP Sync message every 2 seconds, and a value of 0xFF (two's complement of -1) corresponds to 2^-1 which translates to PTP Sync message every 0.536 seconds.

6. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

7. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR).

Programming guidelines to enable periodic generation of PTP Pdelay_Req messages

Follow these steps to enable automatic periodic generation of PTP Pdelay_Req messages

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 1, 0, and 1 respectively to configure the node as Transparent Slave (1, 1, and 1 for Transparent Master OR 3, X, and X for Peer-to-Peer Transparent).

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to send in egress PTP Pdelay_Req message.

3. Program the APDREQEN bit of PTP Offload control register (ETH_MACPOCR) to enable periodic generation of PTP Pdelay_Req messages.

4. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to send in egress PTP Pdelay_Req message.

5. Program the LMPDRI field of Log message interval register (ETH_MACLMIR) to program the periodicity of the PTP Pdelay_Req messages.

For example, a value of 1 corresponds to 2^1 which translates to PTP Pdelay_Req message every 2 seconds, and a value of 0xFF (two's complement of -1) corresponds to 2^-1 which translates to PTP Pdelay_Req message every 0.536 seconds.

6. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

7. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR).

Programming guidelines to enable the generation of PTP response messages for Ordinary or Boundary Master mode

Follow these steps to enable the generation of PTP response messages for Ordinary or Boundary Master mode (Periodic PTP Sync messages generated and PTP Delay_Resp message generated in response to PTP Delay_Req message):
1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 0, 1, and 1 respectively.

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to match with ingress PTP Delay_Req message and send in egress PTP Delay_Resp message.

3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Delay_Req message and send in egress PTP Delay_Resp message.

4. Program the DRSYNCR and LSI fields in Log message interval register (ETH_MACLMRI). The sum of both fields is updated in logMinDelayReqInterval field of PTP Delay_Resp message.

Programming guidelines to enable the generation of PTP response messages for Ordinary or Boundary Slave mode

Follow these steps to enable generation of PTP response messages for Ordinary or Boundary Slave mode (PTP Delay_Req message generated in response to PTP Sync message):

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 0, 0, and 1 respectively.

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to match with ingress PTP Sync message and send in egress PTP Delay_Req message.

3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Sync message and send in egress PTP Delay_Req message.

4. Program the DRSYNCR field in Log message interval register (ETH_MACLMRI) to 1 to indicate one PTP Delay_Req message is generated in response to how many received PTP Sync messages.

Programming guidelines to enable the generation of PTP response messages for Transparent Slave mode

Follow these steps to enable generation of PTP response messages for Transparent Slave mode (PTP Delay_Req message generated in response to PTP Sync message, PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req messages generated):

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 1, 0, and 1 respectively.

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to match with ingress PTP Sync or Pdelay_Req message and send in egress PTP Delay_Req or Pdelay_Resp or Pdelay_Req message.

3. Program the DRSYNCR field in Log message interval register (ETH_MACLMRI) to indicate one PTP Delay_Req message is generated in response to how many received PTP Sync or Pdelay_Req messages.
Pdelay_Req message and send in egress PTP Delay_Req or Pdelay_Resp or Pdelay_Req message.

4. Program the DRSYNCR and LMPDRI fields in Log message interval register (ETH_MACLMIR) to indicate one PTP Delay_Req message is generated in response to how many received PTP Sync messages and periodicity of the PTP Pdelay_Req messages.

5. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

6. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) for egress PTP Pdelay_Req and Pdelay_Resp messages.

**Programming guidelines to enable the generation of PTP response messages for Transparent Master mode**

Follow these steps to enable generation of PTP response messages for Transparent Master mode (PTP Delay_Resp message generated in response to PTP Delay_Req message, PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req or Sync messages generated):

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 1, 1, and 1 respectively.

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to match with ingress PTP Delay_Req or Pdelay_Req message and send in egress PTP Delay_Resp or Pdelay_Resp or Pdelay_Req or Sync messages.

3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Delay_Req or Pdelay_Req message and send in egress PTP Delay_Resp or Pdelay_Resp or Pdelay_Req or Sync message.

4. Program the DRSYNCR, LSI and LMPDRI fields in Log message interval register (ETH_MACLMIR), the sum of DRSYNCR and LSI is updated in logMinDelayReqInterval field of PTP Delay_Resp message and periodicity of the PTP Sync or Pdelay_Req messages.

5. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

6. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) for egress PTP Sync, Pdelay_Req and Pdelay_Resp messages.

**Programming guidelines to enable the generation of PTP response messages for Peer-to-Peer Transparent mode**

Follow these steps to enable generation of PTP response messages for Peer-to-Peer Transparent mode (PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req messages generated):
1. Program the SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 3, X, and X respectively.

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain Number to match with ingress PTP Pdelay_Req message and send in egress PTP Pdelay_Resp message.

3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Pdelay_Req message and send in egress PTP Pdelay_Resp message.

4. Program the LMPDRI field in Log message interval register (ETH_MACLMIR) to indicate periodicity of the PTP Pdelay_Req messages.

5. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

6. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) for egress PTP Pdelay_Req and Pdelay_Resp messages.

64.9.11 Programming guidelines for Energy Efficient Ethernet (EEE)

Entering and exiting Tx LPI mode

EEE enables the IEEE 802.3 Media Access Control (MAC) sublayer along with a family of physical layers to operate in the Low-power idle (LPI) mode. In the Transmit path, the software must set the LPIEN bit of the LPI control and status register (ETH_MACLCSR) to indicate to the MAC to stop transmission and initiate the LPI protocol.

Complete the following steps during MAC initialization:

1. Read the PHY register through the MDIO interface and check if the remote end has the EEE capability. Then negotiate the timer values.

2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop Rx clock in LPI mode or not).

3. Program bits 25 to 16 and bits 15 to 0 in LPI timers control register (ETH_MACLTCR).

4. Read the PHY link status by using the MDIO interface and update bit 17 of LPI control and status register (ETH_MACLCSR).

   Update LPI control and status register (ETH_MACLCSR) accordingly. This update should be done whenever the link status in the PHY chip changes.

5. Program One-microsecond-tick counter register (ETH_MAC1USTCR) as per the frequency of the clock used for accessing the CSR slave port.

6. Program the LPIET bit in the LPI entry timer register (ETH_MACLETR) with the IDLE time for which the MAC should wait before entering the LPI state on its own.
7. Set LPITE and LPITXA (bits 20 to 19) of **LPI control and status register (ETH_MACLCSR)** to enable LPI auto-entry and MAC auto-exit from LPI state.

8. Set bit 16 of **LPI control and status register (ETH_MACLCSR)** to put the MAC transmitter in LPI state.

   The MAC enters the LPI state when all scheduled packets are completed. It remains IDLE for the time indicated by LPIET bits. It sets the TLPIEN (bit 0) after entering LPI state.

9. When a packet transmission is scheduled (when the TxDMA exits IDLE state or when a packet is presented at ATI or MTI interface), the MAC Transmitter automatically exits LPI state. It waits for TWT time before setting the TLPIEX interrupt status bit and then resume the packet transmission.

10. The MAC Transmitter enters again LPI state if it remains IDLE for LPIET time. It then sets the TLPIEN bit and the entry-exit cycle continues.

11. Reset LPIEN bit if the application needs to override the auto-entry/exit modes and directly exit the MAC Transmitter from LPI state.

**Note:** To make sure the MAC enters the LPI state only after the transmission of all the queued frames in the Tx FIFO is complete, set LPITXA bit in **LPI control and status register (ETH_MACLCSR)**.

   To switch off the CSR clock or power to the rest of the system during the LPI state, wait for the TLPIEN interrupt of **LPI control and status register (ETH_MACLCSR)** to be generated. Restore the clocks before performing step 6 when you want to come out of the LPI state.

**Gating Off the CSR Clock in the LPI mode**

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode.

**Gating off the CSR clock in the Rx LPI mode**

The following operations are performed when the MAC receives the LPI pattern from the PHY:

1. The MAC RX enters the LPI mode and the Rx LPI entry interrupt status (RLPIEN interrupt of **LPI control and status register (ETH_MACLCSR)**) is set.

2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the **LPI control and status register (ETH_MACLCSR)**.

After the sbd_intr_o interrupt is asserted and the MAC Tx is also in the LPI mode, the CSR clock can be gated off. If the MAC TX is not in LPI mode when the CSR clock is gated off, the events on the MAC transmitter do not get reported or updated in the CSR. To restore the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on lpi_intr_o (synchronous to clk_rx_i). The lpi_intr_o interrupt is cleared when **LPI control and status register (ETH_MACLCSR)** is read.

**Gating off the CSR clock in the Tx LPI mode**

The following operations are performed when bit 16 (LPIEN) of **LPI control and status register (ETH_MACLCSR)** is set:

1. The Transmit LPI Entry interrupt (TLPIEN bit of **LPI control and status register (ETH_MACLCSR)**) is set.

2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the **LPI control and status register (ETH_MACLCSR)**.
After the sbd_intr_o interrupt is asserted and the MAC RX is also in the LPI mode, the CSR clock can be gated off. If the MAC RX is not in LPI mode when the CSR clock is gated off, the events on the MAC receiver do not get reported or updated in the CSR. To restore the CSR clock, switch on the CSR clock when the MAC has exited TX LPI mode. After the CSR clock is resumed, reset bit 16 (LPIEN) of the LPI control and status register (ETH_MACLCSR) to exit the MAC from LPI mode.

64.9.12 Programming guidelines for flexible pulse-per-second (PPS) output

Generating a single pulse on PPS

To generate a single pulse on PPS:

1. Program TRGTMODSEL[1:0] bit to 11 or 10 (for interrupt) in PPS control register (ETH_MACPPSCR). This instructs the MAC to use the Target Time registers (PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)) as start time of PPS signal output.

2. Program the start time value in the Target Time registers (register PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)).

3. Program the width of the PPS signal output in PPS width register (ETH_MACPPSWR) Register.

4. Program PPSCMD[3:0] of PPS control register (ETH_MACPPSCR) to 0001. This instructs the MAC to generate a single pulse on the PPS signal output at the time programmed in the Target Time registers.

Generating next pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time has elapsed. You can also program the behavior of the next pulse in advance. To program the next pulse:

1. Program the start time for the next pulse in the Target Time registers. This time should be higher than the time at which the falling edge occurs for the previous pulse.

2. Program the width of the next PPS signal output in PPS width register (ETH_MACPPSWR).

3. Program PPSCMD[3:0] bits of PPS control register (ETH_MACPPSCR) to generate a single pulse after the previous pulse is deasserted. This instructs the MAC to generate a single pulse on the PPS signal output at the time programmed in Target Time registers.

If this command is given before the previous pulse becomes low, then the new command overwrites the previous command and the peripheral may generate only 1 extended pulse.

Generating a pulse train on PPS

To generate a pulse train on PPS:

1. Program TRGTMODSEL[1:0] bits to 11 or 10 (for interrupt) in PPS control register (ETH_MACPPSCR). This instructs the MAC to use the Target Time registers (PPS
target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR) for start time of the PPS signal output.

2. Program the start time value in the Target Time registers (register PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)).

3. Program the interval value between the train of pulses on the PPS signal output in PPS interval register (ETH_MACPPSIR).

4. Program the width of the PPS signal output in PPS width register (ETH_MACPPSWR).

5. Program PPSCMD[3:0] bits in PPS control register (ETH_MACPPSCR) to 0010. This instructs the MAC to generate a train of pulses on the PPS signal output at the start time programmed in Target Time registers.

   By default, the PPS pulse train is free-running unless it is stopped by issuing a ‘STOP Pulse train at time’ or ‘STOP Pulse Train immediately’ commands.

6. Program the stop value in the Target Time registers. Ensure that TSTRBUSY bit in PPS target time nanoseconds register (ETH_MACPPSTTNR) is reset before programming the Target Time registers again.

7. Program the PPSCMD[3:0] bits in PPS control register (ETH_MACPPSCR) to 0100 to stop the train of pulses on PPS signal output after the programmed stop time specified at step 6 has elapsed.

   The pulse train can be stopped at any time by programming 0101 in the PPSCMD[3:0] field.

   Similarly, the Stop Pulse train command (given in Step 7) can be canceled by programming PPSCMD[3:0] bits to 0110 before the time (programmed at step 6) has elapsed.

   The pulse train generation can be stopped by programming PPSCMD[3:0] to 0011 before the start time programmed at step 2) has elapsed.

Generating an interrupt without affecting the PPS

TRGTMODSEL[1:0] bits in PPS control register (ETH_MACPPSCR) enable you to program the Target Time registers (PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)) to do any one of the following:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

To program the Target Time registers to generate only interrupt event:

1. Program TRGTMODSEL[1:0] bits of PPS control register (ETH_MACPPSCR) to 00 (for interrupt). This instructs the MAC to use the Target Time registers for target time interrupt.

2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.

   If TRGTMODSEL[1:0] bits are changed (for example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

Note: The TSTRGTERR0 bit in Timestamp status register (ETH_MACTSSR) is set when the programmed target time is smaller (that is corresponds to a time in the past) compared to
the system time in the System time seconds register (ETH_MACSTSR) and System time nanoseconds register (ETH_MACSTNR).

An interrupt is generated (sbd_intr_o) if the TSIE bit in the Interrupt enable register (ETH_MACIER) is set.

Therefore, to avoid unwanted interrupt, the correct writing order is as follow:

1. PPS target time nanoseconds register (ETH_MACPPSTTNR).
2. PPS target time seconds register (ETH_MACPPSTTSR).
3. PPS interval register (ETH_MACPPSIR).
4. PPS width register (ETH_MACPPPSWR).
5. PPSCTRL[3:0] and PPSCTRL[3:0] and PPSEN0 bitfields of PPS control register (ETH_MACPPSCR).

64.9.13 Programming guidelines for TSO

The TCP Segmentation Offload (TSO) engine is used to offload the TCP segmentation functions to the hardware. To program the TSO, set the TSE bit to enable TCP packet segmentation, and program descriptor fields to enable TSO for the current packet.

Follow the steps below to program TSO:

1. Program TSE bit of the corresponding Channel transmit control register (ETH_DMACTXCR) to enable TCP packet segmentation in that DMA.
2. In addition to the normal transfer descriptor setting, the following descriptor fields must be programmed to enable TSO for the current packet:
   a) Enable TSE of TDES3 (bit 18).
   b) Program the length of the unsegmented TCP/IP packet payload in bits 17 to 0 of TDES3, and the TCP header in bits 22 to 19 of TDES3.
   c) Program the maximum size of the segment in:
      – MSS[13:0] of Channel control register (ETH_DMACCR)
      – or MSS in the context descriptor
        If MSS[13:0] field is programmed in both Channel control register (ETH_DMACCR) and in the context descriptor, the latest software programmed sequence is considered.
3. The unsegmented TCP/IP packet header should be stored in Buffer 1 of the first descriptor. This buffer must not hold any payload bytes. The payload is allocated to Buffer 2 and the buffers of the subsequent descriptors.

Caution: If TSE is enabled in TDES3 for a non-TCP-IP packet, the result is unpredictable.
### 64.9.14 Programming guidelines to perform VLAN filtering on the receiver

Follow the sequence below to perform VLAN filtering on the receiver:

1. Program **VLAN tag register (ETH_MACVTR)** for the following bit to select the filtering method:
   - **ETV**: Enable 12-bit VLAN Tag Comparison or 16-bit VLAN Tag comparison.
   - **VTHM**: VLAN Tag Hash Table Match Enable.
   - **ERIVLT**: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should be enabled by setting EDVLP)
   - **ERSVLM**: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL)
   - **DOVLTC**: Ignores VLAN Type for Tag Match
   - **VTIM**: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching

2. Program **VL** bit in **VLAN tag register (ETH_MACVTR)** for the 12-bit or 16-bit VLAN tag.

3. If VLAN tag Hash filtering is enabled, program **VLAN Hash table register (ETH_MACVHTR)**:
   - When the ETV bit is reset, the upper 4 bits of the calculated CRC-32 of VLAN tag are inverted and used to index the content of the **VLAN Hash table register (ETH_MACVHTR)**.
   - When ETV bit is set, the upper 4 bits of the calculated CRC-32 of VLAN tag are used to index the content of **VLAN Hash table register (ETH_MACVHTR)**.

For example, when ETV bit is set, a hash value of 0b1000 selects bit 8 of the VLAN Hash table. When ETV bit is reset, a hash value of 0b1000 selects bit 7 of the VLAN Hash table.

### 64.10 Descriptors

#### 64.10.1 Descriptor overview

In the Ethernet peripheral, the DMA transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory (SRAM). The following two types of descriptors are supported:

- **Normal descriptors**
  The normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.

- **Context descriptors**
  The context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

There is no limit to the number of descriptors that can be used for a single packet.
64.10.2 Descriptor structure

The Ethernet peripheral supports the ring structure for DMA descriptors.

Figure 978. Descriptor ring structure

In a ring structure, descriptors are separated by the 32-bit word number programmed in the DSL field of the Channel control register (ETH_DMACCR). The application needs to program the total ring length, that is the total number of descriptors in ring span, in the following registers of a DMA channel:

- Channel Tx descriptor ring length register (ETH_DMACTXRLR)
- Channel Rx descriptor ring length register (ETH_DMACRXRLR)

The Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) or Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR) contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer;

The DMA enters the Suspend state when this condition occurs. The application must perform a write operation to the descriptor tail pointer register and update the tail pointer so that the following condition is met:

Descriptor Tail Pointer > Current Descriptor Pointer;
The DMA automatically wraps around the base address when the end of ring is reached, as shown in *Figure 979: DMA descriptor ring*.

For descriptors owned by the application, the OWN bit of DES3 is reset to 0.

For descriptors owned by the DMA, the OWN bit is set to 1.

At the beginning, if the application has only one descriptor, it sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA then processes the first descriptor and waits for the application to increment the tail pointer.
Descriptor tail pointer handling examples

Figure 980. Descriptor tail pointer example 1

When the current descriptor pointer points to descriptor 4 (D4) and the descriptor tail pointer points to descriptor 7 (D7), the last descriptor owned by the DMA is descriptor 6 (D6) and there are three descriptors (D4, D5, D6) available for the DMA, as shown in Figure 980: Descriptor tail pointer example 1.

Figure 981. Descriptor tail pointer example 2

As shown in Figure 981: Descriptor tail pointer example 2, the application frees four descriptors (D7, D8, D9 and D0) and updates the descriptor tail pointer to point to descriptor 1 (D1).
The last descriptor owned by the DMA is descriptor 0 (D0). The descriptors referenced between the current descriptor pointer (D4) and the descriptor tail pointer (D1) are available to the DMA.

64.10.3 Transmit descriptor

The Ethernet peripheral DMA requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor features control fields which can be used to manage the MAC operation on per-transmit packet basis. The Transmit normal descriptor has the following two formats: Read format and Write-back format.

Transmit normal descriptor (read format)

Figure 982 shows the Read format for Transmit normal descriptor. Table 725 to Table 728 provide a detailed description of all Transmit normal descriptors (read format).

Figure 982. Transmit descriptor (read format)

| 15:14  | VTIR   | **VLAN Tag Insertion or Replacement:** These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN tag insertion, replacement, or deletion is enabled for the packet. The values of these bits are as follows:
00: Do not add a VLAN tag.
01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets.
10: Insert a VLAN tag with the tag value programmed in the VLAN inclusion register (ETH_MACVIR) or context descriptor.
11: Replace the VLAN tag in packets with the tag value programmed in the VLAN inclusion register (ETH_MACVIR) or context descriptor. This option should be used only with the VLAN packets. |

<th>Description</th>
</tr>
</thead>
</table>
| 13:0 | HL or B1L | Header length or buffer 1 length  
For Header length, only bits [9:0] are taken into account. Bits 13 to 0 are applicable only to buffer 1 length.  
If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length (expressed in bytes) from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes.  
If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length. |

| 29   | FD   | First Descriptor  
When this bit is set, it indicates that the buffer contains the first segment of a packet. |
| 28   | LD   | Last Descriptor  
When this bit is set, it indicates that the buffer contains the last segment of the packet. B1L or B2L field should have a non-zero value. |
This field controls the CRC and Pad Insertion for Tx packet. It is valid only when the first descriptor bit (TDES3[29]) is set. The values of bits[27:26] are the following:

**00**: CRC and Pad Insertion

The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packets whose length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes.

**01**: CRC Insertion (Disable Pad Insertion)

The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes.

**10**: Disable CRC Insertion

The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.

**11**: CRC Replacement

The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.

When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.

These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must appropriately set the CRC Pad Control bits when SA Insertion Control is enabled for the packet.

Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement.

The following list describes the values of Bits[24:23]:

**00**: Do not include the source address

**01**: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses.

**10**: Replace the source address. For reliable transmission, the application must provide frames with source addresses.

**11**: Reserved

These bits are valid when the First Segment control bit (TDES3[29]) is set.

If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. THL value must be equal to 2 for UDP header. This field is valid only for the first descriptor.

When this bit is set, the DMA performs the TCP/UDP segmentation for a packet. This bit is valid only if the FD bit is set.
Transmit normal descriptor (write-back format)

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

*Figure 983* shows the write-back format for Transmit normal descriptors. *Table 729 to Table 732* provide a detailed description of all Transmit Normal descriptors (Write-Back Format).

| 31  | OWN  | **Own bit**
When this bit is set, it indicates that the DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is set to 0. |
| 30  | CTXT | **Context Type**
This bit should be set to 0 for normal descriptors. |
| 29  | FD   | **First Descriptor**
This bit indicates that the buffer contains the first segment of a packet. |
| 28  | LD   | **Last Descriptor**
This bit is set 1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet. |
| 27:18 | | **Reserved** |
| 17  | TTSS | **Tx Timestamp Status**
This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES0 and TDES1 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is set. |
| 16  | | **Reserved** |
### Error Summary
This bit indicates the logical OR of the following bits:
- TDES3[0]: IP Header Error
- TDES3[14]: Jabber Timeout
- TDES3[13]: Packet Flush
- TDES3[12]: Payload Checksum Error
- TDES3[11]: Loss of Carrier
- TDES3[10]: No Carrier
- TDES3[9]: Late Collision
- TDES3[8]: Excessive Collision
- TDES3[3]: Excessive Deferral
- TDES3[2]: Underflow Error

### Jabber Timeout
This bit indicates that the MAC transmitter has experienced a jabber timeout. This bit is set only when the JD bit of the Operating mode configuration register (ETH_MACCR) is not set.

### Packet Flushed
This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.

### Payload Checksum Error
This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either caused by insufficient bytes, as indicated by the Payload Length field of the IP Header, or by the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when a Bus error is detected during packet transfer.

### Loss of Carrier
This bit indicates that Loss of Carrier occurred during packet transmission (that is, the ETH_CRS signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the Half-duplex mode.

### No Carrier
This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.

### Late Collision
This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode). This bit is not valid if Underflow Error is set.

Transmit context descriptor

The Transmit context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction, and VLAN Tag ID for VLAN insertion feature. Write-back is only done on a context descriptor to reset the OWN bit.

Note: The VLAN tag IDs and MSS values, which are provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA.

When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag.

Table 732. TDES3 normal descriptor (write-back format)(1) (continued)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 8   | EC   | Excessive Collision  
This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the Operating mode configuration register (ETH_MACCR), this bit is set after first collision and the transmission of the packet is aborted. |
| 7:4 | CC   | Collision Count  
This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set. |
| 3   | ED   | Excessive Deferral  
This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times if DC bit is set in the Operating mode configuration register (ETH_MACCR). |
| 2   | UF   | Underflow Error  
This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions:  
The DMA encountered an empty Transmit Buffer while transmitting the packet  
The application filled the MTL Tx FIFO slower than the MAC transmit rate  
The transmission process enters the Suspend state and sets the underflow bit corresponding to a queue in the ETH_MTLISR register. |
| 1   | DB   | Deferred Bit  
This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the Half-duplex mode. |
| 0   | IHE  | IP Header Error  
When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. |

1. This format is only applicable to the last descriptor of a packet.
stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The Inner VLAN Tag Control input is used only for the packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

Figure 984 shows the format for Transmit context descriptors. Table 733 to Table 736 provide a detailed description of all Transmit context descriptors.

**Figure 984. Transmit context descriptor format**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31 | OWN | Own bit  
1: the DMA owns the descriptor.  
0: the application owns the descriptor.  
The DMA clears this bit immediately after a read operation. |
| 30 | CTXT | Context Type  
This bit should be set to 1 for context descriptor. |
| 29:28 | Reserved |
| 27 | OSTC | One-Step Timestamp Correction Enable  
When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1. |
One-Step Timestamp Correction Input or MSS Valid
When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid. When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.

Context Descriptor Error
When this bit is set, it indicates that the context descriptor is incorrect. The DMA sets this bit during write-back while closing the context descriptor.

Context Descriptor errors can be:
- Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet.
- All 1s.

Note: When a Context Descriptor error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA sets the TI bit in the Channel status register (ETH_DMACSR).

Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent. This error is categorized as an abnormal event; recovery is only by issuing a software reset (DMA stopping-reconfiguring-restarting recovery mechanism is not supported).

Inner VLAN Tag Insert or Replace
When these bits are set, they request the MAC to perform Inner VLAN tagging or untagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes.

This bitfield has the following values:
00: Do not add the inner VLAN tag.
01: Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames.
10: Insert an inner VLAN tag with the tag value programmed in the Inner VLAN inclusion register (ETH_MACIVIR) or context descriptor.
11: Replace the inner VLAN tag in packets with the tag value programmed in the Inner VLAN inclusion register (ETH_MACIVIR) or context descriptor. This option should be used only with the VLAN frames.

Inner VLAN Tag Valid
When this bit is set, it indicates that the IVT field of TDES2 is valid.

| 16   | VLTV | VLAN Tag Valid  
When this bit is set, it indicates that the VT field of TDES3 is valid. |
| 15:0 | VT   | VLAN Tag  
This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the VLAN inclusion register (ETH_MACVIR) is reset. |
64.10.4 Receive descriptor

The DMA in the Ethernet peripheral attempts to read a descriptor only if the Tail pointer is different from the Base pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC; otherwise, the performance of the DMA is greatly impacted because of the unavailability of the descriptors. In such a situation, the MTL RxFIFO becomes full and starts dropping packets.

The following Receive descriptors are present:
- Normal descriptors with read and write-back formats
- Context descriptors

All received descriptors are prepared by the software and given to the DMA as “normal” descriptors (see Figure 985: Receive normal descriptor (read format) for a description of their content). The DMA reads this descriptor and, after transferring a received packet (or part of it) to the buffers indicated by the descriptor, the Rx DMA closes the descriptor with the corresponding packet status. The status format is given in Figure 986: Receive normal descriptor (write-back format).

For some packets, the normal descriptor bits are not sufficient to write the complete status. For such packets, the Rx DMA writes the extended status to the next descriptor (without processing or using the Buffers pointers embedded in that descriptor). The format and content of this write-back descriptor is described in Figure 987: Receive context descriptor.

Receive normal descriptor (read format)

Figure 985 shows the read format for Receive normal descriptors. Table 737 to Table 740 provide a detailed description of all Receive normal descriptors (read format).

![Figure 985. Receive normal descriptor (read format)](image)

**Note:** In the Receive descriptor (read format), if the Buffer Address field contains only 0s, the MAC does not transfer data to this buffer and skips to the next buffer or next descriptor.

However, while transferring the start of packet, the DMA performs a write operation with RDES2[1:0]=0 (in case of 64-/128-bit configuration) as zero. However, the packet data is shifted by the actual offset as given in the buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.</td>

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31:29 | L3L4FM | Layer 3 and Layer 4 Filter Number Matched  
These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet:  
- 000: Filter 0  
- 001: Filter 1  
- 010: Filter 2  
- 011: Filter 3  
- 100: Filter 4  
- 101: Filter 5  
- 110: Filter 6  
- 111: Filter 7  
This field is valid only when bit 28 or bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter. |

| 28 | L4FM | Layer 4 Filter Match  
When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true:  
- Layer 3 fields are not enabled and all enabled Layer 4 fields match  
- All enabled Layer 3 and Layer 4 filter fields match  
When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by bits[31:29]. |
**Table 743. RDES2 normal descriptor (write-back format) (continued)**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 27  | L3FM | Layer 3 Filter Match  
When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true:  
– All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed  
– All enabled filter fields match  
When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by bits[31:29]. |
| 26:19 | MADRM | MAC Address Match or Hash Value  
When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset.  
When the HF bit is set, this field contains the Hash value computed by the MAC. A packet passes the Hash filter when the bit corresponding to the Hash value is set in the Hash filter register. |
| 18  | HF   | Hash Filter Status  
When this bit is set, it indicates that the packet passed the MAC address Hash filter. Its[26:19] indicate the Hash value. |
| 17  | DAF  | Destination Address Filter Fail  
When this bit is set, it indicates that the packet failed the DA Filter in the MAC. |
| 16  | SAF  | SA Address Filter Fail  
When this bit is set, it indicates that the packet failed the SA Filter in the MAC. |
| 15  | VF   | VLAN Filter Status  
When this bit is set, it indicates that the VLAN Tag of received packet passed the VLAN filter. |
| 14:11 | Reserved |  |
| 10  | ARPNR | ARP Reply Not Generated  
When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). |
| 9:0 | Reserved |  |

### Error Summary

When this bit is set, it indicates the logical OR of the following bits:
- RDES3[19]: Dribble Error
- RDES3[20]: Receive Error
- RDES3[21]: Overflow Error
- RDES3[22]: Watchdog Timeout
- RDES3[23]: Giant Packet
- RDES3[24]: CRC Error

This field is valid only when the LD bit of RDES3 is set.

### Packet Length

These bits indicate the byte length of the received packet that was transferred to system memory (including CRC).

This field is valid when both the LD bit of RDES3 is set and the Overflow Error bit is reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet.

When LD bit of RDES3 is reset, this field contains the accumulated number of bytes (partial) that have been transferred for the current packet.

<table>

| 14:0| PL   | Packet Length  
These bits indicate the byte length of the received packet that was transferred to system memory (including CRC).  
This field is valid when both the LD bit of RDES3 is set and the Overflow Error bit is reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet.  
When LD bit of RDES3 is reset, this field contains the accumulated number of bytes (partial) that have been transferred for the current packet. |
Receive context descriptor

This descriptor is read-only for the application. This descriptor can be written only by the DMA.

The context descriptor provides information about the extended status related to the last received packet. Bit 30 of RDES3 indicates the context type descriptor.

Figure 987 shows the format for Receive context descriptors. Table 745 to Table 748 provide a detailed description of all Receive context descriptors.

</table>

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **RB**: Rebuild INCRx Burst

When this bit is set high and the AHB master gets SPLIT, RETRY, or Early Burst Termination (EBT) response, the AHB master interface rebuilds the pending beats of any initiated burst transfer with INCRx and SINGLE transfers. By default, the AHB master interface rebuilds pending beats of an EBT with an unspecified (INCR) burst.

Bit 14 **MB**: Mixed Burst

When this bit is set high and the FB bit is low, the AHB master performs undefined bursts transfers (INCR) for burst length of 16 or more. For burst length of 16 or less, the AHB master performs fixed burst transfers (INCRx and SINGLE).
Bit 12 **AAL**: Address-Aligned Beats  
When this bit is set to 1, the master performs address-aligned burst transfers on Read and Write channels.

Bits 11:1 Reserved, must be kept at reset value.

Bit 0 **FB**: Fixed Burst Length  
When this bit is set to 1, the AHB master initiates burst transfers of specified length (INCRx or SINGLE).  
When this bit is set to 0, the AHB master initiates transfers of unspecified length (INCR) or SINGLE transfers.
Interrupt status register (ETH_DMAISR)

Address offset: 0x1008
Reset value: 0x0000 0000

The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **MACIS**: MAC Interrupt Status
This bit indicates an interrupt event in the MAC. To reset this bit to 1'b0, the software must read the corresponding register in the MAC to get the exact cause of the interrupt and clear its source.

Bit 16 **MTLIS**: MTL Interrupt Status
This bit indicates an interrupt event in the MTL. To reset this bit to 1'b0, the software must read the corresponding register in the MTL to get the exact cause of the interrupt and clear its source.

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **DC0IS**: DMA Channel Interrupt Status
This bit indicates an interrupt event in DMA Channel. To reset this bit to 0, the software must read the corresponding register in DMA Channel to get the exact cause of the interrupt and clear its source.

Debug status register (ETH_DMADSR)

Address offset: 0x100C
Reset value: 0x0000 0000

The Debug status register gives the Receive and Transmit process status for DMA Channel for debugging purpose.

RM0477 Ethernet (ETH): media access control (MAC) with DMA controller

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:12 **TPSO[3:0]**: DMA Channel Transmit Process State
This field indicates the Tx DMA FSM state for Channel:
- 000: Stopped (Reset or Stop Transmit Command issued)
- 001: Running (Fetching Tx Transfer Descriptor)
- 010: Running (Waiting for status)
- 011: Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO))
- 100: Timestamp write state
- 101: Reserved for future use
- 110: Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow)
- 111: Running (Closing Tx Descriptor)
The MSB of this field always returns 0. This field does not generate an interrupt.

Bits 11:8 **RPSO[3:0]**: DMA Channel Receive Process State
This field indicates the Rx DMA FSM state for Channel:
- 000: Stopped (Reset or Stop Receive Command issued)
- 001: Running (Fetching Rx Transfer Descriptor)
- 010: Reserved for future use
- 011: Running (Waiting for Rx packet)
- 100: Suspended (Rx Descriptor Unavailable)
- 101: Running (Closing the Rx Descriptor)
- 110: Timestamp write state
- 111: Running (Transferring the received packet data from the Rx buffer to the system memory)
The MSB of this field always returns 0. This field does not generate an interrupt.

Bits 7:1  Reserved, must be kept at reset value.

Bit 0 **AXWHSTS**: AHB Master Write Channel
When high, this bit indicates that the write channel of the AHB master FMSs are in non-idle state.

**Channel control register (ETH_DMACCR)**

Address offset: 0x1100

Reset value: 0x0000 0000

The DMA Channel control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.
Bits 31:21  Reserved, must be kept at reset value.

Bits 20:18  **DSL[2:0]:** Descriptor Skip Length  
This bit specifies the 32-bit word number to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor.  
When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.

Bit 17  Reserved, must be kept at reset value.

Bit 16  **PBLX8:** 8xPBL mode  
When this bit is set, the PBL value programmed in Bits[21:16] in *Channel transmit control register (ETH_DMACTXCR)* and in Bits[21:16] in *Channel receive control register (ETH_DMACRXCR)* is multiplied eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value.

Bits 15:14  Reserved, must be kept at reset value.

Bits 13:0  **MSS[13:0]:** Maximum Segment Size  
This field specifies the maximum segment size that should be used while segmenting the packet. This field is valid only if the TSE bit of *Channel transmit control register (ETH_DMACTXCR)* is set.  
The value programmed in this field must be more than the configured Data width in bytes. It is recommended to use a MSS value of 64 bytes or more.

---

**Channel transmit control register (ETH_DMACTXCR)**

Address offset: 0x1104  
Reset value: 0x0000 0000  
The DMA Channel Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

| Bit 31 | Bit 30 | Bit 29 | Bit 28 | Bit 27 | Bit 26 | Bit 25 | Bit 24 | Bit 23 | Bit 22 | Bit 21 | Bit 20 | Bit 19 | Bit 18 | Bit 17 | Bit 16 | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9  | Bit 8  | Bit 7  | Bit 6  | Bit 5  | Bit 4  | Bit 3  | Bit 2  | Bit 1  | Bit 0  |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     |
Bits 31:22 Reserved, must be kept at reset value.

Bits 21:16 **TXPBL[5:0]: Transmit Programmable Burst Length**
These bits indicate the maximum number of beats to be transferred in one DMA data transfer. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior.

To transfer more than 32 beats, perform the following steps:

- a) Set the PBLx8 mode in ETH_DMACCR.
- b) Set the TXPBL[5:0].

Note: The maximum value of TXPBL must be less than or equal to half the Tx Queue size (TQS field of *Tx queue operating mode register (ETH_MTLTXQOMR)*) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. The total locations in Tx Queue of size 2048 bytes is 512. TXPBL and 8xPBL needs to be programmed to less than or equal to 512/2.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **TSE: TCP Segmentation Enabled**
When this bit is set, the DMA performs the TCP segmentation for packets in Channel x. The TCP segmentation is done only for those packets for which the TSE bit (TDES0[19]) is set in the Tx Normal descriptor. When this bit is set, the TxPBL value must be greater than or equal to 4.

Bits 11:5 Reserved, must be kept at reset value.

Bit 4 **OSF: Operate on Second Packet**
When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **ST: Start or Stop Transmission Command**
When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions:

- The current position in the list: this is the base address of the Transmit list set by the ETH_DMACTXDCLR register.
- The position at which the transmission was previously stopped

If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the ETH_DMACSR is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the ETH_DMACTXDCLR register, the DMA behavior is unpredictable.

When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program ETH_DMACTXDCLR register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state.

**Channel receive control register (ETH_DMACRXCR)**

Address offset: 0x1108
Reset value: 0x0000 0000
The DMA Channel Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

| Bits 30:22 | Reserved, must be kept at reset value. |

| Bits 21:16 | RXPBL[5:0]: Receive Programmable Burst Length |
|           | These bits indicate the maximum number of beats to be transferred in one DMA data transfer. |
|           | This is the maximum value that is used in a single block Read or Write. The DMA always |
|           | attempts to burst as specified in PBL each time it starts a burst transfer on the application |
|           | bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other |
|           | value results in undefined behavior. |
|           | To transfer more than 32 beats, perform the following steps: |
|           | a) Set the PBLx8 mode in the ETH_DMACCR. |
|           | b) Set the RXPBL[5:0]. |
|           | Note: The maximum value of RXPBL must be less than or equal to half the Rx Queue size |
|           | (RQS field of Rx queue operating mode register (ETH_MTLRXQOMR)) in terms of beats. This is |
|           | required so that the Rx Queue has space to store at least another Rx PBL worth of data while |
|           | the MTL Rx Queue Controller is transferring data to MAC. The total locations in Rx Queue |
|           | of size 2048 bytes is 512, RXPBL and 8xPBL needs to be programmed to less than or equal to |
|           | 512/2. |
Bit 15  Reserved, must be kept at reset value.

Bits 14:1  **RBSZ[13:0]**: Receive Buffer size

This field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16 Kbytes.

**Note:** The buffer size must be a multiple of 4. This is required even if the value of buffer address pointer is not aligned to bus width. If the buffer size is not a multiple of 4, it may result into an undefined behavior.

The LSB bits (1:0) are ignored and the DMA internally takes the LSB bits as all-zero. Therefore, these LSB bits are read-only (RO).

Bit 0  **SR**: Start or Stop Receive

When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets.

The DMA tries to acquire descriptor from either of the following positions:

- The current position in the list: this is the address set by the Channel Rx descriptor list address register (ETH_DMACRXDLAR).
- The position at which the Rx process was previously stopped

If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the ETH_DMACS is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the Channel Rx descriptor list address register (ETH_DMACRXDLAR), the DMA behavior is unpredictable.

When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state.

**Channel Tx descriptor list address register (ETH_DMACTXDLAR)**

Address offset: 0x1114

Reset value: 0x0000 0000

Channel Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be word-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

Writing to this register is permitted only when the Tx DMA has stopped, that is, the ST bit is cleared in ETH_DMACTXCR register. When stopped, this register can be written with a new descriptor list address. When the ST bit is set, the DMA takes the newly-programmed descriptor base address. If this register is not changed when ST bit is cleared, the DMA takes the descriptor address where it was stopped earlier.
Bits 31:0  **TDESLA[31:0]**: Start of Transmit List
This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0) for 32-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).

Channel Rx descriptor list address register (ETH_DMACRXDLAR)

Address offset: 0x111C
Reset value: 0x0000 0000
The Channel Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be word-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in ETH_DMACRXCR register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Bits 31:0  **RDESLA[31:0]**: Start of Receive List
This field contains the base address of the first descriptor in the Rx Descriptor list. The DMA ignores the LSB bits (1:0) for 32-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).
Channel Tx descriptor tail pointer register (ETH_DM ACTXDTPR)

Address offset: 0x1120
Reset value: 0x0000 0000

The Channel Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Bits 31:0 **TDT[31:0]**: Transmit Descriptor Tail Pointer
This field contains the tail pointer for the Tx descriptor ring. The software writes the tail pointer to add more descriptors to the Tx channel. The hardware tries to transmit all packets referenced by the descriptors between the head and the tail pointer registers.

Channel Rx descriptor tail pointer register (ETH_DMA CRXDTPR)

Address offset: 0x1128
Reset value: 0x0000 0000

The Channel Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Bits 31:0 **RDT[31:0]**: Receive Descriptor Tail Pointer
This field contains the tail pointer for the Rx descriptor ring. The software writes the tail pointer to add more descriptors to the Rx channel. The hardware tries to write all received packets to the descriptors referenced between the head and the tail pointer registers.

Channel Tx descriptor ring length register (ETH_DMACTXRLR)

Address offset: 0x112C
Reset value: 0x0000 0000

The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.
**Channel Rx descriptor ring length register (ETH_DMACRXRLR)**

Address offset: 0x1130

Reset value: 0x0000 0000

The Channel Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.

Bits 31:10  Reserved, must be kept at reset value.

Bits 9:0  **TDRL[9:0]:** Transmit Descriptor Ring Length

This field sets the maximum number of Tx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. It is recommended to put a minimum ring descriptor length of 4.

For example, you can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **ARBS[7:0]:** Alternate Receive Buffer Size

Indicates size in bytes for Buffer 1 when ARBS[7:0] is programmed to a non-zero value.

When ARBS[7:0] = 0, Rx Buffer1 and Rx Buffer2 sizes are based on RBSZ[13:0] field of Channel receive control register (ETH_DMACRXCR).

Bits 15:10  Reserved, must be kept at reset value.

Bits 9:0  **RDRL[9:0]:** Receive Descriptor Ring Length

This register sets the maximum number of Rx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors.

For example, you can program any value up to 0x3FF in this field. This field is 10-bit wide. If you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

**Channel interrupt enable register (ETH_DMACIER)**

Address offset: 0x1134

Reset value: 0x0000 0000

The Channel Interrupt Enable register enables the interrupts reported by the Status register.
RM0477 Ethernet (ETH): media access control (MAC) with DMA controller

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 NIE: Normal Interrupt Summary Enable
When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the Channel status register (ETH_DMACSR):
- Bit 0: Transmit Interrupt
- Bit 2: Transmit Buffer Unavailable
- Bit 6: Receive Interrupt
- Bit 11: Early Receive Interrupt
When this bit is reset, the normal interrupt summary is disabled.

Bit 14 AIE: Abnormal Interrupt Summary Enable
When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the Channel status register (ETH_DMACSR):
- Bit 1: Transmit Process Stopped
- Bit 7: Rx Buffer Unavailable
- Bit 8: Receive Process Stopped
- Bit 9: Receive Watchdog Timeout
- Bit 10: Early Transmit Interrupt
- Bit 12: Fatal Bus Error
When this bit is reset, the abnormal interrupt summary is disabled.

Bit 13 CDEE: Context Descriptor Error Enable
When this bit is set along with the AIE bit, the Context Descriptor error interrupt is enabled. When this bit is reset, the Context Descriptor error interrupt is disabled.

Bit 12 FBEE: Fatal Bus Error Enable
When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled.

Bit 11 ERIE: Early Receive Interrupt Enable
When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled.

Bit 10 ETIE: Early Transmit Interrupt Enable
When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. When this bit is reset, the Early Transmit interrupt is disabled.

Bit 9 RWTE: Receive Watchdog Timeout Enable
When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. When this bit is reset, the Receive Watchdog Timeout interrupt is disabled.

Bit 8 RSE: Receive Stopped Enable
When this bit is set along with the AIE bit, the Receive Stopped interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled.

Bit 7 RBUE: Receive Buffer Unavailable Enable
When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled. When this bit is reset, the Receive Buffer Unavailable interrupt is disabled.
Bit 6 **RIE**: Receive Interrupt Enable
When this bit is set along with the NIE bit, the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled.

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **TBUE**: Transmit Buffer Unavailable Enable
When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable interrupt is disabled.

Bit 1 **TXSE**: Transmit Stopped Enable
When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled. When this bit is reset, the Transmission Stopped interrupt is disabled.

Bit 0 **TIE**: Transmit Interrupt Enable
When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled.
Figure 988. Generation of ETH_DMAISR flags
Channel Rx interrupt watchdog timer register (ETH_DMACRXIWTR)

Address offset: 0x1138
Reset value: 0x0000 0000

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the Channel status register (ETH_DMACSR).

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 **RWTU[1:0]**: Receive Interrupt Watchdog Timer Count Units

This field indicates the number of system clock cycles corresponding to one unit in RWT[7:0] field.

- 00: 256
- 01: 512
- 10: 1024
- 11: 2048

For example, when RWT[7:0] = 2 and RWTU[1:0] = 1, the watchdog timer is set for 2 × 512 = 1024 system clock cycles.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **RWT[7:0]**: Receive Interrupt Watchdog Timer Count

This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set.

The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the ETH_DMACSR, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30].

When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.
Channel current application transmit descriptor register
(ETH_DMACCATXDR)

Address offset: 0x1144
Reset value: 0x0000 0000

The Channel Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Channel current application receive descriptor register
(ETH_DMACCARXDR)

Address offset: 0x114C
Reset value: 0x0000 0000

The Channel Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.

Bits 31:0 CURTDESAPTR[31:0]: Application Transmit Descriptor Address Pointer
The DMA updates this pointer during Tx operation. This pointer is cleared on reset.

Bits 31:0 CURRDESAPTR[31:0]: Application Receive Descriptor Address Pointer
The DMA updates this pointer during Rx operation. This pointer is cleared on reset.
**Channel current application transmit buffer register (ETH_DMACCATXBR)**

Address offset: 0x1154  
Reset value: 0x0000 0000  
The Channel Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA.

Bits 31:0 CURTBUFAPTR[31:0]: Application Transmit Buffer Address Pointer  
The DMA updates this pointer during Tx operation. This pointer is cleared on reset.

**Channel current application receive buffer register (ETH_DMACCARXBR)**

Address offset: 0x115C  
Reset value: 0x0000 0000  
The Channel Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA.

Bits 31:0 CURRBUFAPTR[31:0]: Application Receive Buffer Address Pointer  
The DMA updates this pointer during Rx operation. This pointer is cleared on reset.

**Channel status register (ETH_DMACSR)**

Address offset: 0x1160  
Reset value: 0x0000 0000  
The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA.

3422/3791  
RM0477 Rev 6
Bits 31:22  Reserved, must be kept at reset value.

Bits 21:19  **REB[2:0]: Rx DMA Error Bits**
This field indicates the type of error that caused a bus error. For example, error response on the AHB interface.
Bit [2]: Error during data transfer by Rx DMA when 1, no error during data transfer by Rx DMA when 0.
Bit[1]: Error during descriptor access when 1, error during data buffer access when 0
Bit[0]: Error during read transfer when 1, error during write transfer when 0
This field is valid only when the FBE bit is set. This field does not generate an interrupt.

Bits 18:16  **TEB[2:0]: Tx DMA Error Bits**
This field indicates the type of error that caused a bus error. For example, error response on the AHB interface.
Bit[2]: Error during data transfer by Tx DMA when 1, no error during data transfer by Tx DMA when 0
Bit[1]: Error during descriptor access when 1, error during data buffer access when 0
Bit[0]: Error during read transfer when 1, Error during write transfer when 0
This field is valid only when the FBE bit is set. This field does not generate an interrupt.

Bit 15  **NIS**: Normal Interrupt Summary
Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the ETH_DMACIER register:
Bit 0: Transmit Interrupt
Bit 2: Transmit Buffer Unavailable
Bit 6: Receive Interrupt
Bit 11: Early Receive Interrupt
Only unmasked bits (interrupts for which interrupt enable is set in ETH_DMACIER register) affect the Normal Interrupt Summary bit.
This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared.

Bit 14  **AIS**: Abnormal Interrupt Summary
Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the ETH_DMACIER register:
Bit 1: Transmit Process Stopped
Bit 7: Receive Buffer Unavailable
Bit 8: Receive Process Stopped
Bit 10: Early Transmit Interrupt
Bit 12: Fatal Bus Error
Bit 13: Context Descriptor Error
Only unmasked bits affect the Abnormal Interrupt Summary bit.
This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared.

Bit 13  **CDE**: Context Descriptor Error
This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid.

Bit 12  **FBE**: Fatal Bus Error
This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses.
Bit 11 **ERI**: Early Receive Interrupt
   This bit indicates that the DMA filled the first data buffer of the packet. The RI bit of this register automatically clears this bit.

Bit 10 **ETI**: Early Transmit Interrupt
   This bit indicates that the packet to be transmitted is fully transferred to the MTL Tx FIFO.

Bit 9 **RWT**: Receive Watchdog Timeout
   This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received.

Bit 8 **RPS**: Receive Process Stopped
   This bit is asserted when the Rx process enters the Stopped state.

Bit 7 **RBU**: Receive Buffer Unavailable
   This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor.

Bit 6 **RI**: Receive Interrupt
   This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES1 is reset in the last descriptor, and the specific packet status information is updated in the descriptor.
   The reception remains in the Running state.

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **TBU**: Transmit Buffer Unavailable
   This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPSi field of the Debug status register (ETH_DMADSR) register explains the Transmit Process state transitions.
   To resume processing the Transmit descriptors, the application should do the following:
   1. Change the ownership of the descriptor by setting Bit 31 of TDES3.
   2. Issue a Transmit Poll Demand command.
   For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel.

Bit 1 **TPS**: Transmit Process Stopped
   This bit is set when the transmission is stopped.

Bit 0 **TI**: Transmit Interrupt
   This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor.
Channel missed frame count register (ETH_DMACMFCR)

Address offset: 0x116C
Reset value: 0x000 0000

This register has the number of packet counter that got dropped by the DMA either due to bus error or due to programing RPF field in Channel receive control register (ETH_DMACRXCR) register.

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **MFCO**: Overflow status of the MFC Counter
When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MFC[10:0]**: Dropped Packet Counters
This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programing RPF field in Channel receive control register (ETH_DMACRXCR). The counter gets cleared when this register is read.

Refer to Section 2.3 on page 149 for the register boundary addresses.
64.11.3 Ethernet MTL registers

Operating mode register (ETH_MTLOMR)

Address offset: 0x0C00
Reset value: 0x0000 0000

The Operating Mode register establishes the Transmit and Receive operating modes and commands.

Bits 31:10  Reserved, must be kept at reset value.

- **Bit 9 CNTCLR**: Counters Reset
  - When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle.
  - If this bit is set along with CNTPRST bit, CNTPRST has precedence.

- **Bit 8 CNTPRST**: Counters Preset
  - When this bit is set:
    - **Tx queue underflow register (ETH_MTLTXQUR)** is initialized/preset to 0x7F0.
    - Missed Packet and Overflow Packet counters in **Rx queue missed packet and overflow counter register (ETH_MTLRXQMPQOCR)** is initialized/preset to 0x7F0
  - This bit is cleared automatically.

- **Bit 7 Reserved, must be kept at reset value.**

Bits 6:2  Reserved, must be kept at reset value.

- **Bit 1 DTXSTS**: Drop Transmit Status
  - When this bit is set, the Tx packet status received from the MAC is dropped in the MTL.
  - When this bit is reset, the Tx packet status received from the MAC is forwarded to the application.

- **Bit 0 Reserved, must be kept at reset value.**
Interrupt status register (ETH_MTLISR)

Address offset: 0x0C20
Reset value: 0x0000 0000

The software driver (application) reads this register during interrupt service routine or polling to determine the interrupt status of MTL queues and the MAC.

<table>
<thead>
<tr>
<th>Bits 31:1</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>
Bits 6:4 TTC[2:0]: Transmit Threshold Control
These bits control the threshold level of the MTL Tx queue. The transmission starts when
the packet size within the MTL Tx queue is larger than the threshold. In addition, full
packets with length less than the threshold are also transmitted. These bits are used only
when the TSF bit is reset.
000: 32
001: 64
010: 96
011: 128
100: 192
101: 256
110: 384
111: 512

Bits 3:2 TXQEN[1:0]: Transmit Queue Enable
This field is used to enable/disable the transmit queue.
00: Not enabled
10: Enabled
Others: Reserved, must not be used.
Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the
Tx queue by programming this field.

Bit 1 TSF: Transmit Store and Forward
When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue.
When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This
bit should be changed only when the transmission is stopped.

Bit 0 FTQ: Flush Transmit Queue
When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all
the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing
operation is complete. Until this bit is reset, you should not write to the ETH_MTLTXQOMR
register. The data which is already accepted by the MAC transmitter is not flushed. It is
scheduled for transmission and results in underflow and runt packet transmission.
Note: The flush operation is complete only when the Tx queue is empty and the application
has accepted the pending Tx Status of all transmitted packets. To complete this flush
operation, the PHY Tx clock (eth_tx_clk) should be active.

Tx queue underflow register (ETH_MTLTXQUR)
Address offset: 0x0D04
Reset value: 0x0000 0000
The Queue Underflow Counter register contains the counter for packets aborted because of
Transmit queue underflow and packets missed because of Receive queue packet flush

<table>
<thead>

</tr>
</tbody>
</table>
The Queue Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

**Bits 31:12** Reserved, must be kept at reset value.

**Bit 11** **UFCNTOVF**: Overflow Bit for Underflow Packet Counter

This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened.

**Bits 10:0** **UFFRMCNT[10:0]**: Underflow Packet Counter

This field indicates the number of packets aborted by the controller because of Tx queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read.

**Tx queue debug register (ETH_MTLTXQDR)**

Address offset: 0x0D08

Reset value: 0x0000 0000

The Queue Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

**Bits 31:23** Reserved, must be kept at reset value.

**Bits 22:20** **STXSTSF[2:0]**: Number of Status Words in Tx Status FIFO of Queue

This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of ETH_MTLOMR register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.

**Bit 19** Reserved, must be kept at reset value.

**Bits 18:16** **PTXQ[2:0]**: Number of Packets in the Transmit Queue

This field indicates the current number of packets in the Tx queue. When the DTXSTS bit of Operating mode register (ETH_MTLOMR) register is set to 1, this field does not reflect the number of packets in the Transmit queue.

**Bits 15:6** Reserved, must be kept at reset value.

**Bit 5** **TXSTSFSTS**: MTL Tx Status FIFO Full Status

When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.

**Bit 4** **TXQSTS**: MTL Tx Queue Not Empty Status

When this bit is high, it indicates that the MTL Tx queue is not empty and some data is left for transmission.
Bit 3 **TWCSTS**: MTL Tx Queue Write Controller Status
When high, this bit indicates that the MTL Tx queue Write Controller is active, and it is transferring the data to the Tx queue.

Bits 2:1 **TRCSTS[1:0]**: MTL Tx Queue Read Controller Status
This field indicates the state of the Tx Queue Read Controller:
00: Idle state
01: Read state (transferring data to the MAC transmitter)
10: Waiting for pending Tx Status from the MAC transmitter
11: Flushing the Tx queue because of the Packet Abort request from the MAC

Bit 0 **TXQPAUSED**: Transmit Queue in Pause
When this bit is high and the Rx flow control is enabled, it indicates that the Tx queue is in the Pause condition (in the Full-duplex only mode) because of the following:
- Reception of the PFC packet for the priorities assigned to the Tx queue when PFC is enabled
- Reception of 802.3x Pause packet when PFC is disabled

**Queue interrupt control status register (ETH_MTLQICSR)**
Address offset: 0x0D2C
Reset value: 0x0000 0000

This register contains the interrupt enable and status bits for the queue interrupts.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **RXOIE**: Receive Queue Overflow Interrupt Enable
When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled.

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **RXOVFIS**: Receive Queue Overflow Interrupt Status
This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit.

Bits 15:9 Reserved, must be kept at reset value.
### Bit 8  **TXUIE**: Transmit Queue Underflow Interrupt Enable

- When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled.

### Bits 7:1  Reserved, must be kept at reset value.

### Bit 0  **TXUNFIS**: Transmit Queue Underflow Interrupt Status

- This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit.
**Rx queue operating mode register (ETH_MTLRXQOMR)**

Address offset: 0x0D30  
Reset value: 0x0070 0000

The Queue Receive operating Mode register establishes the Receive queue operating modes and command.

| Bits 31:23 | Reserved, must be kept at reset value. |
| Bits 22:20 | **RQS[2:0]**: Receive Queue Size  
This field is read-only and the configured Rx FIFO size in blocks of 256 bytes is reflected in the reset value. The size of the Queue is (RQS + 1) × 256 bytes. |
| Bits 19:7 | Reserved, must be kept at reset value. |
| Bit 6 | **DIS_TCP_EF**: Disable Dropping of TCP/IP Checksum Error Packets  
When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC.  
When this bit is reset, all error packets are dropped if the FEP bit is reset. |
| Bit 5 | **RSF**: Receive Queue Store and Forward  
When this bit is set, the Ethernet peripheral reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. |
| Bit 4 | **FEP**: Forward Error Packets  
When this bit is reset, the Rx queue drops packets with error status (CRC error, receive error, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped.  
When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. |
Bit 3 **FUP**: Forward Undersized Good Packets

When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **RTC[1:0]**: Receive Queue Threshold Control

These bits control the threshold level of the MTL Rx queue (in bytes):

- 00: 64
- 01: 32
- 10: 96
- 11: 128

The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred.

This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.
Rx queue missed packet and overflow counter register
(ETH_MTLRXQMPOCR)

Address offset: 0x0D34

Reset value: 0x0000 0000

The Queue missed packet and overflow counter registers contain the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

<table>

</tbody>
</table>

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **MISCNTTOVF**: Missed Packet Counter Overflow Bit
When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit.

Bits 26:16 **MISPKTCNT[10:0]**: Missed Packet Counter
This field indicates the number of packets missed by the Ethernet peripheral because the application requested to flush the packets for this queue. This counter is reset when this register is read.
This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability.

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **OVFCNTTOVF**: Overflow Counter Overflow Bit
When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit.

Bits 10:0 **OVFPKTCNT[10:0]**: Overflow Packet Counter
This field indicates the number of packets discarded by the Ethernet peripheral because of Receive queue overflow. This counter is incremented each time the Ethernet peripheral discards an incoming packet because of overflow. This counter is reset when this register is read.
**Rx queue debug register (ETH_MTLRXQDR)**

Address offset: 0x0D38  
Reset value: 0x0000 0000  
The Queue Receive Debug register gives the debug status of various blocks related to the Receive queue.

**Bits 31:30**  Reserved, must be kept at reset value.

**Bits 29:16**  **PRXQ[13:0]: Number of Packets in Receive Queue**  
This field indicates the current number of packets in the Rx queue. The theoretical maximum value for this field is 256 Kbyte/16 bytes = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.

**Bits 15:6**  Reserved, must be kept at reset value.

**Bits 5:4**  **RXQSTS[1:0]: MTL Rx Queue Fill-Level Status**  
This field gives the status of the fill-level of the Rx queue:  
00: Rx queue empty  
01: Rx queue fill-level below flow-control deactivate threshold  
10: Rx queue fill-level above flow-control activate threshold  
11: Rx queue full

**Bit 3**  Reserved, must be kept at reset value.

**Bits 2:1**  **RRCSTS[1:0]: MTL Rx Queue Read Controller State**  
This field gives the state of the Rx queue Read controller:  
00: Idle state  
01: Reading packet data  
10: Reading packet status (or timestamp)  
11: Flushing the packet data and status

**Bit 0**  **RWCSTS: MTL Rx Queue Write Controller Active Status**  
When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx queue.

</tbody>
</table>

**Note:** Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
Bit 27 **IPC**: Checksum Offload
When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled.
The Layer 3 and Layer 4 Packet Filter feature automatically selects the IPC Full Checksum Offload Engine on the Receive side. When this feature is enabled, you must set the IPC bit.

Bits 26:24 **IPG[2:0]**: Inter-Packet Gap
These bits control the minimum IPG between packets during transmission.
000: 96 bit times
001: 88 bit times
010: 80 bit times
... 111: 40 bit times
This range of minimum IPG is valid in Full-duplex mode.
In the Half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered.
When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG.
The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in ETH_MACECR register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in ETH_MACECR register.

Bit 23 **GPSLCE**: Giant Packet Size Limit Control Enable
When this bit is set, the MAC considers the value in GPSL field in ETH_MACECR register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit.
When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet).
The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status.

Bit 22 **S2KP**: IEEE 802.3as Support for 2K Packets
When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets.
When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, see Table 752: Giant Packet Status based on S2KP and JE Bits.

Note: When the JE bit is set, setting this bit has no effect on the giant packet status.

Bit 21 **CST**: CRC stripping for Type packets
When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver.
This function is valid when Type 2 Checksum Offload Engine is enabled.

Note: For information about how the settings of the ACS bit and this bit impact the packet length, see Table 753: Packet Length based on the CST and ACS bits.
Bit 20 **ACS**: Automatic Pad or CRC Stripping  
When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field.  
When this bit is reset, the MAC passes all incoming packets to the application, without any modification.  
*Note:* For information about how the settings of CST bit and this bit impact the packet length, see Table 753: Packet Length based on the CST and ACS bits.  

Bit 19 **WD**: Watchdog Disable  
When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes.  
When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes.  

Bit 18 Reserved, must be kept at reset value.  

Bit 17 **JD**: Jabber Disable  
When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes.  
When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet.  

Bit 16 **JE**: Jumbo Packet Enable  
When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status.  
For more information about how the setting of this bit and the JE bit impact the Giant packet status, see Table 752: Giant Packet Status based on S2KP and JE Bits.  

Bit 15 Reserved, must be kept at reset value.  

Bit 14 **FES**: MAC Speed  
This bit selects the speed in the 10/100 Mbps mode:  
0: 10 Mbps  
1: 100 Mbps  

Bit 13 **DM**: Duplex Mode  
When this bit is set, the MAC operates in the Full-duplex mode in which it can transmit and receive simultaneously.  

Bit 12 **LM**: Loopback Mode  
When this bit is set, the MAC operates in the loopback mode at MII. The MII Rx clock input (eth_rx_clk) is required for the loopback to work properly. This is because the Tx clock is not internally looped back.  

Bit 11 **ECRSFD**: Enable Carrier Sense Before Transmission in Full-duplex mode  
When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the Full-duplex mode. The MAC starts the transmission only when the CRS signal is low.  
When this bit is reset, the MAC transmitter ignores the status of the CRS signal.  

Bit 10 **DO**: Disable Receive Own  
When this bit is set, the MAC disabled the reception of packets when the ETH_TX_EN is asserted in the Half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY.  
This bit is not applicable in the Full-duplex mode. This bit is reserved and read-only (RO) with default value in the Full-duplex-only configurations.
Bit 9  **DCRS**: Disable Carrier Sense During Transmission

When this bit is set, the MAC transmitter ignores the MII CRS signal during packet transmission in the Half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission.

When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission.

Bit 8  **DR**: Disable Retry

When this bit is set, the MAC attempts only one transmission. When a collision occurs on the MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status.

When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the Half-duplex mode.

Bit 7  Reserved, must be kept at reset value.

Bits 6:5  **BL[1:0]**: Back-Off Limit

The back-off limit determines the random integer number (r) of slot time delays (512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision:

- **00**: k = min (n, 10)
- **01**: k = min (n, 8)
- **10**: k = min (n, 4)
- **11**: k = min (n, 1)

where n = retransmission attempt

The random integer r takes the value in the range $0 \leq r < 2^k$.

This bit is applicable only in the Half-duplex mode.

Bit 4  **DC**: Deferral Check

When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode.

Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on MII.

The deferral time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted.

When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive.

This bit is applicable only in the Half-duplex mode.

Bits 3:2  **PRELEN[1:0]**: Preamble Length for Transmit packets

These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the Full-duplex mode.

- **00**: 7 bytes of preamble
- **01**: 5 bytes of preamble
- **10**: 3 bytes of preamble
- **11**: Reserved, must not be used
Bit 1 TE: Transmitter Enable
When this bit is set, the Tx state machine of the MAC is enabled for transmission on the MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets.

Bit 0 RE: Receiver Enable
When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the MII interface.

Table 752 shows how the settings of S2KP and JE bits of the ETH_MACCR register impact the giant packet status.

Table 752. Giant Packet Status based on S2KP and JE Bits\(^{(1)}\)

Extended operating mode configuration register (ETH_MACECR)

Address offset: 0x0004
Reset value: 0x0000 0000

The MAC Extended Configuration register establishes the operating mode of the MAC.

Bits 31:30  Reserved, must be kept at reset value.

Bits 29:25  **EIPG[4:0]**: Extended Inter-Packet Gap

The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits) along with IPG field in Operating mode configuration register (ETH_MACCR), gives the minimum IPG greater than 96 bit times in steps of 8 bit times. For example:
- EIPG = 0 and IPG = 0 give 104 bit times
- EIPG = 0 and IPG = 1 give 112 bit times
- EIPG = 0 and IPG = 2 give 120 bit times
- ..
- EIPG = 7 and IPG = 31 give 2144 bit times

Bit 24  **EIPGEN**: Extended Inter-Packet Gap Enable

When this bit is set, the MAC interprets EIPG field and IPG field in Operating mode configuration register (ETH_MACCR) together as minimum IPG greater than 96 bit times in steps of 8 bit times.

When this bit is reset, the MAC ignores EIPG field and interprets IPG field in Operating mode configuration register (ETH_MACCR) as minimum IPG less than or equal to 96 bit times in steps of 8 bit times.

**Note**: The extended Inter-Packet Gap feature must be enabled when operating in Full-duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-duplex mode.

Bits 23:19  Reserved, must be kept at reset value.

Bit 18  **USP**: Unicast Slow Protocol Packet Detect

When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register MAC Address x low register (ETH_MACAxLR). The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02).

When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2008, Section 5.
Bit 17 **SPEN**: Slow Protocol Detection Enable
When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid subtypes. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets.

Bit 16 **DCRCC**: Disable CRC Checking for Received Packets
When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **GPSL[13:0]**: Giant Packet Size Limit
If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes.
For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. For double VLAN tagged packets, the MAC adds 8 bytes to the programmed value. The value in this field is applicable when the GPSLCE bit is set in ETH_MACCR register.

### Packet filtering control register (ETH_MACPFR)

Address offset: 0x0008
Reset value: 0x0000 0000

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td><strong>RA</strong>: Receive All</td>
</tr>
<tr>
<td>30</td>
<td>receives all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter.</td>
</tr>
<tr>
<td>30:22</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>21</td>
<td><strong>DNTU</strong>: Drop Non-TCP/UDP over IP Packets</td>
</tr>
<tr>
<td>20</td>
<td>When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forwards only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets.</td>
</tr>
</tbody>
</table>
Bit 20  **IPFE**: Layer 3 and Layer 4 Filter Enable
- When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect.
- When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields.

Bits 19:17  Reserved, must be kept at reset value.

Bit 16  **VTFE**: VLAN Tag Filter Enable
- When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag.

Bits 15:11  Reserved, must be kept at reset value.

Bit 10  **HPF**: Hash or Perfect Filter
- When this bit is set, the address filter passes a packet if it matches either the perfect filtering or Hash filtering as set by the HMC or HUC bit.
- When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter.

Bit 9  **SAF**: Source Address Filter Enable
- When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet.
- When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison.

*Note:* According to the IEEE specification, Bit 47 of the SA is reserved. However, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA.

Bit 8  **SAIF**: SA Inverse Filtering
- When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter.
- When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter.

Bits 7:6  **PCF[1:0]**: Pass Control Packets
- These bits control the forwarding of all control packets (including unicast and multicast Pause packets).
- 00: The MAC filters all control packets from reaching the application.
- 01: The MAC forwards all control packets except Pause packets to the application even if they fail the Address filter.
- 10: The MAC forwards all control packets to the application even if they fail the Address filter.
- 11: The MAC forwards the control packets that pass the Address filter.

Bit 5  **DBF**: Disable Broadcast Packets
- When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings.
- When this bit is reset, the AFM module passes all received broadcast packets.

Bit 4  **PM**: Pass All Multicast
- When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is ‘1’) are passed. When this bit is reset, filtering of multicast packet depends on HMC bit.
Bit 3 **DAIF**: DA Inverse Filtering
When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed.

Bit 2 **HMC**: Hash Multicast
When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the Hash table.
When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers.

Bit 1 **HUC**: Hash Unicast
When this bit is set, the MAC performs the destination address filtering of unicast packets according to the Hash table.
When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers.

Bit 0 **PR**: Promiscuous Mode
When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set.

**Watchdog timeout register (ETH_MACWTR)**
Address offset: 0x000C
Reset value: 0x0000 0000
The Watchdog Timeout register controls the watchdog timeout for received packets.
Bits 31:9  Reserved, must be kept at reset value.

Bit 8  PWE: Programmable Watchdog Enable
When this bit is set and the WD bit of the Operating mode configuration register (ETH_MACCR) register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in Operating mode configuration register (ETH_MACCR) register.

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:0  WTO[3:0]: Watchdog Timeout
When the PWE bit is set and the WD bit of the Operating mode configuration register (ETH_MACCR) register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet.
Encoding is as follows:
- 0x0: 2 Kbytes
- 0x1: 3 Kbytes
- 0x2: 4 Kbytes
- 0x3: 5 Kbytes
- ...
- 0xC: 14 Kbytes
- 0xD: 15 Kbytes
- 0xE: 16383 Bytes
- 0xF: Reserved, must not be used

Note: When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped.

Hash Table 0 register (ETH_MACHT0R)
Address offset: 0x0010
Reset value: 0x0000 0000
The Hash Table Register 0 contains the first lower 32 bits of the Hash table (64 bits).
The Hash table is used for group address filtering.
For Hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register 0 or 1) and the least significant five bits determine the bit within the register. For example, a hash value of 0b10000 selects Bit 0 of the Hash Table Register 1.
The Hash value of the destination address is calculated in the following way:
1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper 7 or 8 bits from the value obtained in Step 2.
If the corresponding bit value of the register is 1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in ETH_MACPFR, all multicast packets are accepted regardless of the multicast Hash values.
Ethernet (ETH): media access control (MAC) with DMA controller

Hash Table 1 register (ETH_MACHT1R)

Address offset: 0x0014
Reset value: 0x0000 0000

The Hash Table 1 register contains the upper 32 bits of the Hash table (64 bits).

For Hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of the CRC register are used to index the content of the Hash table. The most significant bits determine the register to be used (Hash Table Register 0 or 1) and the least significant five bits determine the bit within the register. For example, a hash value of 6'b10000 selects Bit 0 of the Hash Table Register 1.

The Hash value of the destination address is calculated in the following way:
1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper 7 or 8 bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in ETH_MACPFR, all multicast packets are accepted regardless of the multicast Hash values.

Bits 31:0  **HT31T0[31:0]**: MAC Hash Table First 32 Bits
This field contains the first 32 Bits [31:0] of the Hash table.

Hash Table 2 register (ETH_MACHT2R)

Bits 31:0  **HT63T32[31:0]**: MAC Hash Table Second 32 Bits
This field contains the second 32 Bits [63:32] of the Hash table.
VLAN tag register (ETH_MACVTR)

Address offset: 0x0050
Reset value: 0x0000 0000

The VLAN Tag register identifies the IEEE 802.1Q VLAN type packets.

</table>
Bits 22:21  **EVLS[1:0]**: Enable VLAN Tag Stripping on Receive

This field indicates the stripping operation on the outer VLAN Tag in received packet:
- 00: Do not strip
- 01: Strip if VLAN filter passes
- 10: Strip if VLAN filter fails
- 11: Always strip

Bit 20  **DOVLT**: Disable VLAN Type Check

When this bit is set, the MAC does not check whether the VLAN Tag specified by the ERIVLT bit is of type S-VLAN or C-VLAN.
When this bit is reset, the MAC filters or matches the VLAN Tag specified by the ERIVLT bit only when VLAN Tag type is similar to the one specified by the ERSVLM bit.

Bit 19  **ERSVLM**: Enable Receive S-VLAN Match

When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets.
The ERIVLT bit determines the VLAN tag position considered for filtering or matching.

Bit 18  **ESVL**: Enable S-VLAN

When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets.

Bit 17  **VTIM**: VLAN Tag Inverse Match Enable

When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched.

Bit 16  **ETV**: Enable 12-Bit VLAN Tag Comparison

When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits[11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. Similarly, when enabled, only 12 bits of the VLAN tag in the received packet are used for Hash-based VLAN filtering.
When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for comparison and VLAN Hash filtering.

Bits 15:0  **VL[15:0]**: VLAN Tag Identifier for Receive Packets

This field contains the 802.1Q VLAN tag to identify the VLAN packets. This VLAN tag identifier is compared to the 15th and 16th bytes of the packets being received for VLAN packets. The following list describes the bits of this field:
- Bits[15:13]: User Priority
- Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)
- Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

When the ETV bit is set, only the VID is used for comparison.
If this field ([11:0] if ETV is set) is all zeros, the MAC does not check the 15th and 16th bytes for VLAN tag comparison and declares all packets with Type field value of 0x8100 or 0x88a8 as VLAN packets.
VLAN Hash table register (ETH_MACVHTR)

Address offset: 0x0058
Reset value: 0x0000 0000

When the VTHM bit of VLAN tag register (ETH_MACVTR) register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For Hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of VLAN tag register (ETH_MACVTR) register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a Hash value of 1000 selects Bit 8 of the VLAN Hash table.

The Hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3).
2. Perform bitwise reversal for the value obtained in step 1.
3. Take the upper four bits from the value obtained in step 2.

</table>

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **VLI**: VLAN Tag Input
When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor.

Bit 19 **CSV**: C-VLAN or S-VLAN
When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.

0: C-LAN
1: S-LAN

Bit 18 **VLP**: VLAN Priority Control
When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, bits[17:16] are ignored.

Bits 17:16 **VLC[1:0]**: VLAN Tag Control in Transmit Packets
00: No VLAN tag deletion, insertion, or replacement
01: VLAN tag deletion. The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags.
10: VLAN tag insertion. The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag.
11: VLAN tag replacement. The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8).

*Note*: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.

Bits 15:0 **VLT[15:0]**: VLAN Tag for Transmit Packets
This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase.
The following list describes the bits of this field:

Bits[15:13]: User Priority
Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)
Bits[11:0]: VLAN Identifier (VID) field of VLAN tag
**Inner VLAN inclusion register (ETH_MACIVIR)**

Address offset: 0x0064

Reset value: 0x0000 0000

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls.

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **VLTI**: VLAN Tag Input

When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor

Bit 19 **CSVL**: C-VLAN or S-VLAN

When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.

0: C-LAN

1: S-LAN

Bit 18 **VLP**: VLAN Priority Control

When this bit is set, the VLC field is used for VLAN deletion, insertion, or replacement. When this bit is reset, the VLC field is ignored.

Bits 17:16 **VLC[1:0]**: VLAN Tag Control in Transmit Packets

00: No VLAN tag deletion, insertion, or replacement

01: VLAN tag deletion

The MAC removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all transmitted packets with VLAN tags.

10: VLAN tag insertion

The MAC inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 17 and 18. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag.

11: VLAN tag replacement

The MAC replaces VLT in bytes 19 and 20 of all VLAN-type transmitted packets (Bytes 17 and 18 are 0x8100 or 0x88a8).

**Note:** Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
Bits 15:0 **VLT[15:0]**: VLAN Tag for Transmit Packets
This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase.
The following list describes the bits of this field:
- Bits[15:13]: User Priority
- Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)
- Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

**Tx Queue flow control register (ETH_MACQTXFCR)**
Address offset: 0x0070
Reset value: 0x0000 0000
The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

**PT[15:0]**: Pause Time
This field holds the value to be used in the Pause Time field in the Tx control packet.

Bits 15:8 Reserved, must be kept at reset value.

**Bit 7 DZPQ: Disable Zero-Quanta Pause**
When this bit is set, it disables the automatic generation of the zero-quanta Pause packets. When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled.
Bits 6:4 \textbf{PLT}[2:0]: Pause Low Threshold

This field configures the threshold of the Pause timer at which the input flow is checked for automatic retransmission of the Pause packet.

The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted at 228 (256-28) slot times after the first Pause packet is transmitted.

The following list provides the threshold values for different values:

000: Pause Time minus 4 Slot Times (PT -4 slot times)
001: Pause Time minus 28 Slot Times (PT -28 slot times)
010: Pause Time minus 36 Slot Times (PT -36 slot times)
011: Pause Time minus 144 Slot Times (PT -144 slot times)
100: Pause Time minus 256 Slot Times (PT -256 slot times)
101: Pause Time minus 512 Slot Times (PT -512 slot times)
110 to 111: Reserved, must not be used

The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 \textbf{TFE}: Transmit Flow Control Enable

\textbf{Full-duplex mode:} when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets.

\textbf{Half-duplex mode:} when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled.

Bit 0 \textbf{FCB\_BPA}: Flow Control Busy or Backpressure Activate

This bit initiates a Pause packet in the Full-duplex mode and activates the backpressure function in the Half-duplex mode if the TFE bit is set.

\textbf{Full-Duplex mode:} this bit should be read as 0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 0. You should not write to this register until this bit is cleared.

\textbf{Half-duplex mode:} When this bit is set (and TFE bit is set) in the Half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. When the MAC is configured for the Full-duplex mode, the BPA is automatically disabled.
**Rx flow control register (ETH_MACRXFCR)**

Address offset: 0x0090  
Reset value: 0x0000 0000

The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.

</tbody>
</table>

Bits 31:2  Reserved, must be kept at reset value.

**Bit 1  UP: Unicast Pause Packet Detect**

A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in *MAC Address 0 high register (ETH_MACA0HR)* and *MAC Address 0 low register (ETH_MACA0LR)* and *MAC Address x low register (ETH_MACAxLR)*.

When this bit is reset, the MAC only detects Pause packets with unique multicast address.

**Note:** The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01 80 C2 00 00 01) is as specified in IEEE 802.1 Qbb-2011.

**Bit 0  RFE: Receive Flow Control Enable**

When this bit is set and the MAC is operating in Full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in Half-duplex mode, the decode function of the Pause packet is disabled.

When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time.
Interrupt status register (ETH_MACISR)

Address offset: 0x00B0
Reset value: 0x0000 0000

The Interrupt Status register contains the status of interrupts.

Bits 31:15  Reserved, must be kept at reset value.

Bit 14  **RXSTSIS:** Receive Status Interrupt

This bit indicates the status of received packets. This bit is set when the RWT bit is set in the *Rx Tx status register (ETH_MACRXTXSR)*. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of *CSR software control register (ETH_MACCSRSWCR)* is set) in the ETH_MACISR register.

Bit 13  **TXSTSIS:** Transmit Status Interrupt

This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the *Rx Tx status register (ETH_MACRXTXSR)*:

- Excessive Collision (EXCOL)
- Late Collision (LCOL)
- Excessive Deferral (EXDEF)
- Loss of Carrier (LCARR)
- No Carrier (NCARR)
- Jabber Timeout (TJT)

This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of *CSR software control register (ETH_MACCSRSWCR)* is set) in the ETH_MACISR register.
Bit 12 **TSIS**: Timestamp Interrupt Status  
If the Timestamp feature is enabled, this bit is set when any of the following conditions is true:

- The system time value is equal to or exceeds the value specified in the Target Time High and Low registers.
- There is an overflow in the Seconds register.
- The Target Time Error occurred, that is, programmed target time already elapsed.

If the Auxiliary Snapshot feature is enabled, this bit is set when the auxiliary snapshot trigger is asserted.

When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the **Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)** and **Tx timestamp status seconds register (ETH_MACTXTSSSR)** registers.

When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the **Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)** and **Tx timestamp status seconds register (ETH_MACTXTSSSR)** registers, for PTO generated Delay Request and Pdelay request packets.

This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of **CSR software control register (ETH_MACCSRSWCR)** is set) in the **Timestamp status register (ETH_MACTSSR)**.

Bit 11 **Reserved**, must be kept at reset value.

Bit 10 **MMCTXIS**: MMC Transmit Interrupt Status  
This bit is set high when an interrupt is generated in the **MMC Tx interrupt register (ETH_MMC_TX_INTERRUPT)**. This bit is cleared when all bits in this interrupt register are cleared.

Bit 9 **MMCRXIS**: MMC Receive Interrupt Status  
This bit is set high when an interrupt is generated in the **MMC Rx interrupt register (ETH_MMC_RX_INTERRUPT)**. This bit is cleared when all bits in this interrupt register are cleared.

Bit 8 **MMS**: MMC Interrupt Status  
This bit is set high when MMCTXIS or MMCRXIS is set high. This bit is cleared only when all these bits are low.

Bits 7:6 **Reserved**, must be kept at reset value.

Bit 5 **LPIIS**: LPI Interrupt Status  
This bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the TLPIEN bit of **LPI control and status register (ETH_MACLCSR)** is read.

Bit 4 **PMTIS**: PMT Interrupt Status  
This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in ETH_MACPCSR register). This bit is cleared when Bits[6:5] are cleared because of a Read operation to the **PMT control status register (ETH_MACPCSR)**.

Bit 3 **PHYIS**: PHY Interrupt  
This bit is set when rising edge is detected on the ETH_PHY_INTN input. This bit is cleared when this register is read.

Bits 2:0 **Reserved**, must be kept at reset value.
Interrupt enable register (ETH_MACIER)

Address offset: 0x00B4
Reset value: 0x0000 0000

The Interrupt Enable register contains the masks for generating the interrupts.

Bits 31:15  Reserved, must be kept at reset value.

Bit 14  RXSTSIE: Receive Status Interrupt Enable

When this bit is set, it enables the assertion of the interrupt signal because of the setting of RXSTSIS bit in the Interrupt status register (ETH_MACISR).

Bit 13  TXSTSIE: Transmit Status Interrupt Enable

When this bit is set, it enables the assertion of the interrupt signal because of the setting of TXSTSIS bit in the Interrupt status register (ETH_MACISR).

Bit 12  TSIE: Timestamp Interrupt Enable

When this bit is set, it enables the assertion of the interrupt signal because of the setting of TSIS bit in Interrupt status register (ETH_MACISR).

Bits 11:6  Reserved, must be kept at reset value.

Bit 5  LPIIE: LPI Interrupt Enable

When this bit is set, it enables the assertion of the interrupt signal because of the setting of LPIIS bit in Interrupt status register (ETH_MACISR).

Bit 4  PMTIE: PMT Interrupt Enable

When this bit is set, it enables the assertion of the interrupt signal because of the setting of PMTIS bit in Interrupt status register (ETH_MACISR).

Bit 3  PHYIE: PHY Interrupt Enable

When this bit is set, it enables the assertion of the interrupt signal because of the setting of PHYIS bit in Interrupt status register (ETH_MACISR).

Bits 2:0  Reserved, must be kept at reset value.
Rx Tx status register (ETH_MACRXTXSR)

Address offset: 0x00B8
Reset value: 0x0000 0000

The Receive Transmit Status register contains the Receive and Transmit Error status.

</tr>
</tbody>
</table>

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 RWT: Receive Watchdog Timeout

This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the Operating mode configuration register (ETH_MACCR). This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the Operating mode configuration register (ETH_MACCR).

Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 EXCOL: Excessive Collisions

When the DTXSTS bit is set in the Operating mode register (ETH_MTLOMR), this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the Operating mode configuration register (ETH_MACCR), this bit is set after the first collision and the packet transmission is aborted.

Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bit 4 LCOL: Late Collision

When the DTXSTS bit is set in the Operating mode register (ETH_MTLOMR), this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode.

This bit is not valid if the Underflow error occurs.

Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bit 3 EXDEF: Excessive Deferral

When the DTXSTS bit is set in the Operating mode register (ETH_MTLOMR) and the DC bit is set in the Operating mode configuration register (ETH_MACCR), this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 when Jumbo packet is enabled).

Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).
Bit 2  **LCARR**: Loss of Carrier
When the DTXSTS bit is set in the *Operating mode register (ETH_MTLOMR)*, this bit indicates that the loss of carrier occurred during packet transmission, that is, the ETH_CRS signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision.
 Cleared on read (or write of 1 when RCWE bit in *CSR software control register (ETH_MACCSRSWCR)* is set).

Bit 1  **NCARR**: No Carrier
When the DTXSTS bit is set in the *Operating mode register (ETH_MTLOMR)*, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission.
 Cleared on read (or write of 1 when RCWE bit in *CSR software control register (ETH_MACCSRSWCR)* is set).

Bit 0  **TJT**: Transmit Jabber Timeout
This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the *Operating mode configuration register (ETH_MACCR)*. This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the *Operating mode configuration register (ETH_MACCR)*.
 Cleared on read (or write of 1 when RCWE bit in *CSR software control register (ETH_MACCSRSWCR)* is set).

**PMT control status register (ETH_MACPCSR)**
Address offset: 0x00C0
Reset value: 0x0000 0000

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 |
|---------------|---------------|---------------|
| RWKFILTRST    | RWKPTR[4:0]   |               |
| rw            | r             | r             |
| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0            |

Bit 31  **RWKFILTRST**: Remote Wake-up Packet Filter Register Pointer Reset
When this bit is set, the remote wake-up packet filter register pointer is reset to 0. It is automatically cleared after 1 clock cycle.

Bits 30:29 Reserved, must be kept at reset value.

Bits 28:24  **RWKPTR[4:0]**: Remote wake-up FIFO Pointer
This field gives the current value (0 to 7) of the Remote wake-up Packet Filter register pointer. When the value of this pointer is equal to 7, the contents of the Remote wake-up Packet Filter Register are transferred to the eth_rx_clk domain when a Write occurs to that register.

Bits 23:11 Reserved, must be kept at reset value.
Bit 10  **RWKPFE**: Remote wake-up Packet Forwarding Enable
When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet.

The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low.

The setting of this bit has no effect when PWRDWN is set high.

*Note: If Magic Packet Enable and wake-up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application.*

Bit 9  **GLBLUCAST**: Global Unicast
When this bit is set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet.

Bits 8:7  Reserved, must be kept at reset value.

Bit 6  **RWKPRCDV**: Remote wake-up Packet Received
When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read.

Bit 5  **MGKPRCDV**: Magic Packet Received
When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read (or written to 1 when RCWE bit in **CSR software control register (ETH_MACCSRWSWC)** is set).

Bits 4:3  Reserved, must be kept at reset value.

Bit 2  **RWKPKTEN**: Remote wake-up Packet Enable
When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet.

Bit 1  **MGKPKTEN**: Magic Packet Enable
When this bit is set, a power management event is generated when the MAC receives a magic packet.

Bit 0  **PWRDWN**: Power Down
When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote wake-up Packet Enable bit is set high.

*Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit.*
Remote wake-up packet filter register (ETH_MACRWKPFR)

Address offset: 0x00C4

Reset value: 0x0000 0000

Bits 31:0 MACRWKPFR[31:0]: Remote wake-up packet filter

Refer to Table 721, Table 722 and Table 723 for details on register content and programming sequence.

The ETH_MACRWKPFR register at address 0x00C4 loads the wake-up Packet Filter register.

To load values in a wake-up Packet Filter register, the entire register (ETH_MACRWKPFR) must be written. The ETH_MACRWKPFR register is loaded by sequentially loading the eight, sixteen or thirty two register values in address (0x00C4) for ETH_MACRWKPFR value 0 to 7, respectively. The ETH_MACRWKPFR register is read in a similar way. The Ethernet peripheral updates the ETH_MACRWKPFR register current pointer value in Bits[26:24] of ETH_MACPCSR register.

LPI control and status register (ETH_MACLCSR)

Address offset: 0x00D0

Reset value: 0x0000 0000

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.
Bits 31:22  Reserved, must be kept at reset value.

Bit 21  **LPITCSE**: LPI Tx Clock Stop Enable
When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not assert sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode.
If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern. The Tx Clock cannot be gated and so the LPITCSE bit cannot be programmed.

Bit 20  **LPITE**: LPI Timer Enable
This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPITE, LPITXA and LPIEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the ETH_MACLETR register.
After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPIEN bit. This enables the re-entry into LPI state when it is IDLE again.
When LPITE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPIEN bit descriptions.

Bit 19  **LPITXA**: LPI Tx Automate
This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side.
If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of ETH_MTLTxQOMR, when the MAC is in the LPI mode, it exits the LPI mode.
When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode.

Bit 18  Reserved, must be kept at reset value.

Bit 17  **PLS**: PHY Link Status
This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER.
When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down.

Bit 16  **LPIEN**: LPI Enable
When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission.
This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission.

Bits 15:10  Reserved, must be kept at reset value.

Bit 9  **RLPIST**: Receive LPI State
When this bit is set, it indicates that the MAC is receiving the LPI pattern on the MII interface.

Bit 8  **TLPIST**: Transmit LPI State
When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the MII interface.

Bits 7:4  Reserved, must be kept at reset value.
Bit 3  **RLPIEX**: Receive LPI Exit
When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register (or by writing it to 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).

*Note:* This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.

Bit 2  **RLPIEN**: Receive LPI Entry
When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register (or by writing it to 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).

*Note:* This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.

Bit 1  **TLPIEX**: Transmit LPI Exit
When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register (or by writing it to 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).

Bit 0  **TLPIEN**: Transmit LPI Entry
When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register (or by writing it to 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).

**LPI timers control register (ETH_MACLTCR)**
Address offset: 0x00D4
Reset value: 0x03E8 0000

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.
LPI entry timer register (ETH_MACLETR)

Address offset: 0x00D8
Reset value: 0x0000 0000

This register controls the Tx LPI entry timer. This counter is enabled only when LPITE bit of LPI control and status register (ETH_MACLCSR) register is set to 1.

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 LPIET[19:0]: LPI Entry Timer

This field specifies the time in microseconds the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.

One-microsecond-tick counter register (ETH_MAC1USTCR)

Address offset: 0x00DC
Reset value: 0x0000 0063

This register controls the generation of the Reference time (one-microsecond tick) for all the LPI timers. This timer has to be programmed by the software initially.
Version register (ETH_MACVR)
Address offset: 0x0110
Reset value: 0x0000 3242

The version register identifies the version of the Ethernet peripheral.

RPESTS

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  TIC_1US_CNTR[11:0]: 1 µs tick Counter
The application must program this counter so that the number of clock cycles of CSR clock is
1 µs (subtract 1 from the value before programming).
For example if the CSR clock is 100 MHz then this field needs to be programmed to
100 - 1 = 99 (which is 0x63).
This is required to generate the 1 µs events that are used to update some of the EEE related
counters.
Bits 31:19  Reserved, must be kept at reset value.

Bits 18:17  **TFCSTS[1:0]:** MAC Transmit Packet Controller Status
- This field indicates the state of the MAC Transmit Packet Controller module:
  - 00: Idle state
  - 01: Waiting for one of the following:
    - Status of the previous packet
    - IPG or backoff period to be over
  - 10: Generating and transmitting a Pause control packet (in Full-duplex mode)
  - 11: Transferring input packet for transmission

Bit 16  **TPESTS:** MAC MII Transmit Protocol Engine Status
- When this bit is set, it indicates that the MAC MII transmit protocol engine is actively transmitting data, and it is not in the Idle state.

Bits 15:3  Reserved, must be kept at reset value.

Bits 2:1  **RFCFCSTS[1:0]:** MAC Receive Packet Controller FIFO Status
- When this bit is set, this field indicates the active state of the small FIFO Read and Write controllers of the MAC Receive Packet Controller module.

Bit 0  **RPESTS:** MAC MII Receive Protocol Engine Status
- When this bit is set, it indicates that the MAC MII receive protocol engine is actively receiving data, and it is not in the Idle state.

**HW feature 0 register (ETH_MACHWF0R)**

Address offset: 0x011C

Reset value: 0x0A0D 73F5

This register indicates the presence of first set of the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.
Bit 31  Reserved, must be kept at reset value.

Bits 30:28  **ACTPHYSEL[2:0]:** Active PHY Selected
   When you have multiple PHY interfaces in your configuration, this field indicates the sampled value of phy_intf_sel_i during reset de-assertion:
   000: GMII or MII
   001: RGMII
   010: SGMII
   011: TBI
   100: RMII
   101: RTBI
   110: SMII
   Others: Reserved, must not be used

Bit 27  **SAVLAININS:** Source Address or VLAN Insertion Enable
   This bit is set to 1 when the Enable SA and VLAN Insertion on Tx option is selected

Bits 26:25  **TSSTSSEL[1:0]:** Timestamp System Time Source
   This bit indicates the source of the Timestamp system time:
   01: Internal
   10: External
   11: Both
   00: Reserved, must not be used
   This bit is set to 1 when the Enable IEEE 1588 Timestamp Support option is selected

Bit 24  **MACADR64SEL:** MAC Addresses 64-127 Selected
   This bit is set to 1 when the Enable Additional 64 MAC Address Registers (64-127) option is selected

Bit 23  **MACADR32SEL:** MAC Addresses 32-63 Selected
   This bit is set to 1 when the Enable Additional 32 MAC Address Registers (32-63) option is selected

Bits 22:18  **ADDMACADRSEL[4:0]:** MAC Addresses 1-31 Selected
   This bit is set to 1 when the Enable Additional 1-31 MAC Address Registers option is selected

Bit 17  Reserved, must be kept at reset value.

Bit 16  **RXCOESEL:** Receive Checksum Offload Enabled
   This bit is set to 1 when the Enable Receive TCP/IP Checksum Check option is selected

Bit 15  Reserved, must be kept at reset value.

Bit 14  **TXCOESEL:** Transmit Checksum Offload Enabled
   This bit is set to 1 when the Enable Transmit TCP/IP Checksum Insertion option is selected

Bit 13  **EEESEL:** Energy Efficient Ethernet Enabled
   This bit is set to 1 when the Enable Energy Efficient Ethernet (EEE) option is selected

Bit 12  **TSSEL:** IEEE 1588-2008 Timestamp Enabled
   This bit is set to 1 when the Enable IEEE 1588 Timestamp Support option is selected

Bits 11:10  Reserved, must be kept at reset value.

Bit 9  **ARPOFFSEL:** ARP Offload Enabled
   This bit is set to 1 when the Enable IPv4 ARP Offload option is selected

Bit 8  **MMCSEL:** RMON Module Enable
   This bit is set to 1 when the Enable MAC management counters (MMC) option is selected
Bit 7 **MGKSEL**: PMT Magic Packet Enable
This bit is set to 1 when the Enable Magic Packet Detection option is selected

Bit 6 **RWKSEL**: PMT Remote Wake-up Packet Enable
This bit is set to 1 when the Enable Remote Wake-up Packet Detection option is selected

Bit 5 **SMASEL**: SMA (MDIO) Interface
This bit is set to 1 when the Enable Station Management (MDIO Interface) option is selected

Bit 4 **VLHASH**: VLAN Hash Filter Selected
This bit is set to 1 when the Enable VLAN Hash Table Based Filtering option is selected

Bit 3 **PCSSEL**: PCS Registers (TBI, SGMII, or RTBI PHY interface)
This bit is set to 1 when the TBI, SGMII, or RTBI PHY interface option is selected

Bit 2 **HDSEL**: Half-duplex Support
This bit is set to 1 when the Half-duplex mode is selected

Bit 1 **GMIISEL**: 1000 Mbps Support
This bit is set to 1 when 1000 Mbps is selected as operating mode.

Bit 0 **MIISEL**: 10 or 100 Mbps Support
This bit is set to 1 when 10/100 Mbps is selected as operating mode.

**HW feature 1 register (ETH_MACHWF1R)**

Address offset: 0x0120

Reset value: 0x1104 1904

This register indicates the presence of second set of the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.
Bit 31  Reserved, must be kept at reset value.

Bits 30:27  **L3L4FNUM[3:0]**: Total number of L3 or L4 Filters
   This field indicates the total number of L3 or L4 filters:
   0000: No L3 or L4 Filter
   0001: 1 L3 or L4 Filter
   0010: 2 L3 or L4 Filters
   ...
   1000: 8 L3 or L4

Bit 26  Reserved, must be kept at reset value.

Bits 25:24  **HASHTBLSZ[1:0]**: Hash Table Size
   This field indicates the size of the Hash table:
   00: No Hash table
   01: 64
   10: 128
   11: 256

Bit 23  **POUOST**: One Step for PTP over UDP/IP Feature Enable
   This bit is set to 1 when the Enable one step timestamp for PTP over UDP/IP feature is selected.

Bit 22  Reserved, must be kept at reset value.

Bit 21  **RAVSEL**: Rx Side Only AV Feature Enable
   This bit is set to 1 when the Enable Audio video bridging option on Rx Side Only is selected.

Bit 20  **AVSEL**: AV Feature Enable
   This bit is set to 1 when the Enable Audio video bridging option is selected.

Bit 19  **DBGMEMA**: DMA Debug Registers Enable
   This bit is set to 1 when the Debug Mode Enable option is selected.

Bit 18  **TSOEN**: TCP Segmentation Offload Enable
   This bit is set to 1 when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected.

Bit 17  **SPHEN**: Split Header Feature Enable
   This bit is set to 1 when the Enable Split Header Structure option is selected.

Bit 16  **DCBEN**: DCB Feature Enable
   This bit is set to 1 when the Enable Data Center Bridging option is selected.

Bits 15:14  **ADDR64[1:0]**: Address width
   This field indicates the configured address width.
   00: 32 bits
   Others: Reserved, must not be used

Bit 13  **ADVTHWORD**: IEEE 1588 High Word Register Enable
   This bit is set to 1 when the Add IEEE 1588 Higher Word Register option is selected.

Bit 12  **PTOEN**: PTP Offload Enable
   This bit is set to 1 when the Enable PTP Timestamp Offload Feature is selected.

Bit 11  **OSTEN**: One-Step Timestamping Enable
   This bit is set to 1 when the Enable One-Step Timestamp Feature is selected.
Bits 10:6 **TXFIFOSIZE[4:0]**: MTL Transmit FIFO Size

This field contains the configured value of MTL Tx FIFO in bytes expressed as Log to base 2 minus 7, that is, Log2(TXFIFO_SIZE) -7:

- 00000: 128 bytes
- 00001: 256 bytes
- 00010: 512 bytes
- 00011: 1,024 bytes
- 00100: 2,048 bytes
- 00101: 4,096 bytes
- 00110: 8,192 bytes
- 00111: 16,384 bytes
- 01000: 32 Kbytes
- 01001: 64 Kbytes
- 01010: 128 Kbytes
- 01011 to 11111: Reserved, must not be used

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **RXFIFOSIZE[4:0]**: MTL Receive FIFO Size

This field contains the configured value of MTL Rx FIFO in bytes expressed as Log to base 2 minus 7, that is, Log2(RXFIFO_SIZE) -7:

- 00000: 128 bytes
- 00001: 256 bytes
- 00010: 512 bytes
- 00011: 1,024 bytes
- 00100: 2,048 bytes
- 00101: 4,096 bytes
- 00110: 8,192 bytes
- 00111: 16,384 bytes
- 01000: 32 Kbytes
- 01001: 64 Kbytes
- 01010: 128 Kbytes
- 01011: 256 Kbytes
- 01100 to 11111: Reserved, must not be used
HW feature 2 register (ETH_MACHWF2R)

Address offset: 0x0124
Reset value: 0x4100 0000

This register indicates the presence of third set of the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

<table>

Bit 31  Reserved, must be kept at reset value.

Bits 30:28  **AUXSNAPNUM[2:0]**: Number of Auxiliary Snapshot Inputs

This field indicates the number of auxiliary snapshot inputs:
- 000: No auxiliary input
- 001: 1 auxiliary input
- 010: 2 auxiliary inputs
- 011: 3 auxiliary inputs
- 100: 4 auxiliary inputs
- 101 to 111: Reserved, must not be used

Bit 27  Reserved, must be kept at reset value.

Bits 26:24  **PPSOUTNUM[2:0]**: Number of PPS Outputs

This field indicates the number of PPS outputs:
- 000: No PPS output
- 001: 1 PPS output
- 010: 2 PPS outputs
- 011: 3 PPS outputs
- 100: 4 PPS outputs
- 101 to 111: Reserved, must not be used

Bits 23:22  **TDCSZ[1:0]**: Tx DMA Descriptor Cache Size in terms of 16-byte descriptors

- 00: Cache not configured
- 01: Four 16-byte descriptors
- 10: Eight 16-byte descriptors
- 11: Sixteen 16-byte descriptors

Bits 21:18  **TXCHCNT[3:0]**: Number of DMA Transmit Channels

This field indicates the number of DMA Transmit channels:
- 0000: 1 DMA Tx Channel
- 0001: 2 DMA Tx Channels
- ...
- 0111: 8 DMA Tx
Bits 17:16  **RDCSZ[1:0]**: Rx DMA Descriptor Cache Size in terms of 16-byte descriptors
   00: Cache not configured
   01: Four 16-byte descriptors
   10: Eight 16-byte descriptors
   11: Sixteen 16-byte descriptors

Bits 15:12  **RXCHCNT[3:0]**: Number of DMA Receive Channels
   This field indicates the number of DMA Receive channels:
   0000: 1 DMA Rx Channel
   0001: 2 DMA Rx Channels
   ..
   0111: 8 DMA Rx

Bits 11:10  Reserved, must be kept at reset value.

Bits 9:6  **TXQCNT[3:0]**: Number of MTL Transmit Queues
   This field indicates the number of MTL Transmit queues:
   0000: 1 MTL Tx queue
   0001: 2 MTL Tx queues
   ..
   0111: 8 MTL Tx

Bits 5:4  Reserved, must be kept at reset value.

Bits 3:0  **RXQCNT[3:0]**: Number of MTL Receive Queues
   This field indicates the number of MTL Receive queues:
   0000: 1 MTL Rx queue
   0001: 2 MTL Rx queues
   ..
   0111: 8 MTL Rx
HW feature 3 register (ETH_MACHWF3R)

Address offset: 0x0128
Reset value: 0x0000 0020

This register indicates the presence of fourth set the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bit 5 **DVLAN**: Double VLAN processing enable
This bit is set to 1 when Double VLAN processing is enabled.

Bit 4 **CBTISEL**: Queue/Channel based VLAN tag insertion on Tx enable
This bit is set to 1 when the Enable Queue/Channel based VLAN tag insertion on Tx feature is selected.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **NRF[2:0]**: Number of Extended VLAN Tag Filters Enabled
This field indicates the Number of Extended VLAN Tag Filters selected:
- 000: No Extended Rx VLAN Filters
- 001: 4 Extended Rx VLAN Filters
- 010: 8 Extended Rx VLAN Filters
- 011: 16 Extended Rx VLAN Filters

**Bits 31:28** Reserved, must be kept at reset value.

**Bit 27 PSE**: Preamble Suppression Enable

When this bit is set, the SMA suppresses the 32-bit preamble and transmit MDIO frames with only 1 preamble bit.

When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications.

**Bit 26 BTB**: Back to Back transactions

When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which is executed immediately irrespective of the number trailing clocks generated for the previous frame.

When this bit is reset, then the read/write command completion (MII busy is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame.

This bit must not be set when NTC=0.

**Bits 25:21 PA[4:0]**: Physical Layer Address

This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing.

This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.

**Bits 20:16 RDA[4:0]**: Register/Device Address

These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY.

**Bit 15** Reserved, must be kept at reset value.

**Bits 14:12 NTC[2:0]**: Number of Training Clocks

This field controls the number of trailing clock cycles generated on ETH_MDC after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 011 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
Bits 11:8 **CR[3:0]:** CSR Clock Range

The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency (eth_hclk):
- 0000: MDC clock = eth_hclk / 42
- 0001: MDC clock = eth_hclk / 62
- 0010: MDC clock = eth_hclk / 16
- 0011: MDC clock = eth_hclk / 26
- 0100: MDC clock = eth_hclk / 102
- 0101: MDC clock = eth_hclk / 124
- 0110 to 0111: Reserved, must not be used

The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits to 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3.

Program the following values only if the interfacing chips support faster MDC clocks:
- 1000: eth_hclk / 4
- 1001: eth_hclk / 6
- 1010: eth_hclk / 8
- 1011: eth_hclk / 10
- 1100: eth_hclk / 12
- 1101: eth_hclk / 14
- 1110: eth_hclk / 16
- 1111: eth_hclk / 18

Bits 7:5 **Reserved, must be kept at reset value.**

Bit 4 **SKAP:** Skip Address Packet

When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set.

Bits 3:2 **GOC[1:0]:** MII Operation Command

This bit indicates the operation command to the PHY.
- 00: Reserved, must not be used
- 01: Write
- 10: Post Read Increment Address for Clause 45 PHY
- 11: Read

When Clause 22 PHY is enabled, only Write and Read commands are valid.

Bit 1 **C45E:** Clause 45 PHY Enable

When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO.
Bit 0  **MB**: MII Busy

The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIOS. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in **MDIO address register (ETH_MACMDIOAR)** and **MDIO data register (ETH_MACMDIODR)** as long as this bit is set.

For write transfers, the application must first write 16-bit data in the MD field (and also RA field when C45E is set) in **MDIO data register (ETH_MACMDIODR)** register before setting this bit. When C45E is set, it should also write into the RA field of **MDIO data register (ETH_MACMDIODR)** before initiating a read transfer. When a read transfer is completed (MII busy=0), the data read from the PHY register is valid in the MD field of the **MDIO data register (ETH_MACMDIODR)**.

Note: *Even if the addressed PHY is not present, there is no change in the functionality of this bit.*

**MDIO data register (ETH_MACMDIODR)**

Address offset: 0x0204

Reset value: 0x0000 0000

The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in **MDIO address register (ETH_MACMDIOAR)**. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

**Bits 31:16 RA[15:0]: Register Address**

This field is valid only when C45E is set. It contains the Register Address in the PHY to which the MDIO frame is intended for.

**Bits 15:0 MD[15:0]: MII Data**

This field contains the 16-bit data value read from the PHY after a Management Read operation or the 16-bit data value to be written to the PHY before a Management Write operation.
ARP address register (ETH_MACARPAR)

Address offset: 0x0210
Reset value: 0x0000 0000

The ARP Address register contains the IPv4 Destination Address of the MAC.

</tr>
</thead>
</table>

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 SEEN: Slave Error Response Enable
When this bit is set, the MAC responds with a Slave Error for accesses to reserved registers in CSR space.
When this bit is reset, the MAC responds with an Okay response to any register accessed from CSR space.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 RCWE: Register Clear on Write 1 Enable
When this bit is set, the access mode to some register fields changes to rc_w1 (clear on write) meaning that the application needs to set that respective bit to 1 to clear it.
When this bit is reset, the access mode to these register fields remains rc_r (clear on read).
MAC Address 0 high register (ETH_MACA0HR)

Address offset: 0x0300
Reset value: 0x8000 FFFF

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x11 22 33 44 55 66 is received (0x11 in lane 0 of the first column) on the MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x66 55 44 33 22 11.

If the MAC address registers are configured to be double-synchronized to the MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

`ADDRHI[15:0]`

Bit 31  AE: Address Enable
This bit is always set to 1.

Bits 30:16  Reserved, must be kept at reset value.

Bits 15:0  ADDRHI[15:0]: MAC Address0[47:32]
This field contains the upper 16 bits [47:32] of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

MAC Address x low register (ETH_MACAxLR)

Address offset: 0x0304 + 0x8 * x, (x = 0 to 3)
Reset value: 0xFFFF FFFF

The MAC Address x Low register holds the lower 32 bits of the 6-byte first MAC address of the station.

`ADDRLO[31:16]`

`ADDRLO[15:0]`
Bits 31:0  **ADDRLO[31:0]**: MAC Address x [31:0] (x = 0 to 3)
This field contains the lower 32 bits of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

**MAC Address x high register (ETH_MACAxHR)**
Address offset: 0x0308 + 0x8 * (x-1), (x = 1 to 3)
Reset value: 0x0000 FFFF
The MAC Address x High register holds the upper 16 bits of the second 6-byte MAC address of the station.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
AE SA MBC[5:0]

Bit 31  **AE**: Address Enable
When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

Bit 30  **SA**: Source Address
When this bit is set, the MAC Address x[47:0] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC Address x[47:0] is used to compare with the DA fields of the received packet.
0: DA
1: SA

Bits 29:24  **MBC[5:0]**: Mask Byte Control
These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows:
Bit 29: ETH_MACAxHR[15:8]
Bit 28: ETH_MACAxHR[7:0]
Bit 27: ETH_MACAxLR[31:24]
Bit 26: ETH_MACAxLR[23:16]
Bit 25: ETH_MACAxLR[15:8]
Bit 24: ETH_MACAxLR[7:0]
You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.

Bits 23:16  Reserved, must be kept at reset value.

Bits 15:0  **ADDRHI[15:0]**: MAC Address1 [47:32]
This field contains the upper 16 bits[47:32] of the second 6-byte MAC address.
MMC control register (ETH_MMC_CONTROL)

Address offset: 0x0700
Reset value: 0x0000 0000

This register configures the MMC operating mode.

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **UCDBC**: Update MMC Counters for Dropped Broadcast Packets
The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set.
When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of Packet filtering control register (ETH_MACPFR).
When reset, the MMC Counters are not updated for dropped Broadcast packets.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **CNTPRSTLVL**: Full-Half Preset
When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF F800 (Half 2Kbytes) and all packet-counters get preset to 0x7FFF FFF0 (Half 16).
When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF F800 (Full 2Kbytes) and all packet-counters get preset to 0xFFFF FFF0 (Full 16).
For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0.

Bit 4 **CNTPRST**: Counters Preset
When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle.
This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full.

Bit 3 **CNTFREEZ**: MMC Counter Freeze
When this bit is set, it freezes all MMC counters to their current value.
Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.
Ethernet (ETH): media access control (MAC) with DMA controller RM0477

Bit 2 **RSTONRD**: Reset on Read
- When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset).
- The counters are cleared when the least significant byte lane (Bits[7:0]) is read.

Bit 1 **CNTSTOPRO**: Counter Stop Rollover
- When this bit is set, the counter does not roll over to zero after reaching the maximum value.

Bit 0 **CNTRST**: Counters Reset
- When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle.

**MMC Rx interrupt register (ETH_MMC_RX_INTERRUPT)**

Address offset: 0x0704
Reset value: 0x0000 0000

This register maintains the interrupts generated from all Receive statistics counters.

The MMC Receive Interrupt register maintains the interrupts that are generated when the following occur:
- Receive statistic counters reach half of their maximum values (0x8000 0000 for 32-bit counter and 0x8000 for 16-bit counter).
- Receive statistic counters cross their maximum values (0xFFFF FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When the CNTSTOPRO is set in **MMC control register (ETH_MMC_CONTROL)**, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

Bits 31:28  Reserved, must be kept at reset value.

Bit 27 **RXLPITRCIS**: MMC Receive LPI transition counter interrupt status
- This bit is set when the **Rx LPI transition counter register (ETH_RX_LPI_TRAN_CNTR)** counter reaches half of the maximum value or the maximum value.

Bit 26 **RXLPIUSCIS**: MMC Receive LPI microsecond counter interrupt status
- This bit is set when the **Rx LPI microsecond counter register (ETH_RX_LPI_USEC_CNTR)** counter reaches half of the maximum value or the maximum value.

Bits 25:18  Reserved, must be kept at reset value.
Bit 17 **RXUCGPIS**: MMC Receive Unicast Good Packet Counter Interrupt Status
This bit is set when the *Rx unicast packets good register (ETH_RX_UNICAST_PACKETS_GOOD)* counter reaches half of the maximum value or the maximum value.

Bits 16:7 Reserved, must be kept at reset value.

Bit 6 **RXALGNERPIS**: MMC Receive Alignment Error Packet Counter Interrupt Status
This bit is set when the *Rx alignment error packets register (ETH_RX_ALIGNMENT_ERROR_PACKETS)* counter reaches half of the maximum value or the maximum value.

Bit 5 **RXCRCERPIS**: MMC Receive CRC Error Packet Counter Interrupt Status
This bit is set when the *Rx CRC error packets register (ETH_RX_CRC_ERROR_PACKETS)* counter reaches half of the maximum value or the maximum value.

Bits 4:0 Reserved, must be kept at reset value.

**MMC Tx interrupt register (ETH_MMC_TX_INTERRUPT)**

Address offset: 0x0708
Reset value: 0x0000 0000

This register maintains the interrupts generated from all Transmit statistics counters.

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000 0000 for 32-bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF FFFF for 32-bit counter and 0xFFFF FFFF for 16-bit counter).

When **CNTSTOPRO** is set in **MMC control register (ETH_MMC_CONTROL)**, the interrupts are set but the counter remains at all-ones.

The MMC Transmit Interrupt register is a 32-bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

Bits 31:28  Reserved, must be kept at reset value.

- **Bit 27 TXLPITRCS**: MMC Transmit LPI transition counter interrupt status
  - This bit is set when the `Tx LPI transition counter register (ETH_TX_LPI_TRAN_CNTR)` counter reaches half of the maximum value or the maximum value.

- **Bit 26 TXLPIUSCIS**: MMC Transmit LPI microsecond counter interrupt status
  - This bit is set when the `Tx LPI microsecond timer register (ETH_TX_LPI_USEC_CNTR)` counter reaches half of the maximum value or the maximum value.

Bits 25:22  Reserved, must be kept at reset value.

- **Bit 21 TXGPKTIS**: MMC Transmit Good Packet Counter Interrupt Status
  - This bit is set when the `Tx packet count good register (ETH_TX_PACKET_COUNT_GOOD)` counter reaches half of the maximum value or the maximum value.

Bits 20:16  Reserved, must be kept at reset value.

- **Bit 15 TXMCOLGPIS**: MMC Transmit Multiple Collision Good Packet Counter Interrupt Status
  - This bit is set when the `Tx multiple collision good packets register (ETH_TX_MULTIPLE_COLLISION_GOOD_PACKETS)` counter reaches half of the maximum value or the maximum value.

- **Bit 14 TXSCOLGPIS**: MMC Transmit Single Collision Good Packet Counter Interrupt Status
  - This bit is set when the `Tx single collision good packets register (ETH_TX_SINGLE_COLLISION_GOOD_PACKETS)` counter reaches half of the maximum value or the maximum value.

Bits 13:0  Reserved, must be kept at reset value.
MMC Rx interrupt mask register (ETH_MMC_RX_INTERRUPT_MASK)

Address offset: 0x070C
Reset value: 0x0000 0000

The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when receive statistic counters reach half of their maximum value or the maximum values.

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **RXLPITRCIM**: MMC Receive LPI transition counter interrupt Mask
Setting this bit masks the interrupt when the **Rx LPI transition counter register (ETH_RX_LPI_TRAN_CNTR)** counter reaches half of the maximum value or the maximum value.

Bit 26 **RXLPIUSCIM**: MMC Receive LPI microsecond counter interrupt Mask
Setting this bit masks the interrupt when the **Rx LPI microsecond counter register (ETH_RX_LPI_USEC_CNTR)** counter reaches half of the maximum value or the maximum value.

Bits 25:18 Reserved, must be kept at reset value.

Bit 17 **RXUCGPM**: MMC Receive Unicast Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the **Rx unicast packets good register (ETH_RX_UNICAST_PACKETS_GOOD)** counter reaches half of the maximum value or the maximum value.

Bits 16:7 Reserved, must be kept at reset value.

Bit 6 **RXALGNERPM**: MMC Receive Alignment Error Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the **Rx alignment error packets register (ETH_RX_ALIGNMENT_ERROR_PACKETS)** counter reaches half of the maximum value or the maximum value.

Bit 5 **RXCRCERPIM**: MMC Receive CRC Error Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the **Rx CRC error packets register (ETH_RX_CRC_ERROR_PACKETS)** counter reaches half of the maximum value or the maximum value.

Bits 4:0 Reserved, must be kept at reset value.
MMC Tx interrupt mask register (ETH_MMC_TX_INTERRUPT_MASK)

Address offset: 0x0710
Reset value: 0x0000 0000

The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or the maximum values. This register is 32-bit wide.

Bits 31:0  TXLPITRC[31:0]: Tx LPI Transition counter

This field indicates the number of times Tx LPI Entry has occurred. Even if Tx LPI Entry occurs in Automate mode (because of LPITXA bit set in the LPI control and status register (ETH_MACLCSR)), the counter is incremented.

Rx LPI microsecond counter register (ETH_RX_LPI_USEC_CNTR)

Address offset: 0x07F4
Reset value: 0x0000 0000

This register provides the number of microseconds Rx LPI is sampled by Ethernet peripheral.

Bits 31:0  RXLPITRC[31:0]: Rx LPI Transition counter

This field indicates the number of times Rx LPI Entry and Exit, the Timer value can have an error of +/- 1 microsecond.

Rx LPI transition counter register (ETH_RX_LPI_TRAN_CNTR)

Address offset: 0x07F8
Reset value: 0x0000 0000

This register provides the number of times Ethernet peripheral has entered Rx LPI.

Bits 31:22  Reserved, must be kept at reset value.

- **Bit 21**  **L4DPIM0:** Layer 4 Destination Port Inverse Match Enable  
  When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching.  
  This bit is valid and applicable only when the L4DPM0 bit is set high.

- **Bit 20**  **L4DPM0:** Layer 4 Destination Port Match Enable  
  When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching.

- **Bit 19**  **L4SPIM0:** Layer 4 Source Port Inverse Match Enable  
  When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching.  
  This bit is valid and applicable only when the L4SPM0 bit is set high.

- **Bit 18**  **L4SPM0:** Layer 4 Source Port Match Enable  
  When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching.

- **Bit 17**  Reserved, must be kept at reset value.

- **Bit 16**  **L4PEN0:** Layer 4 Protocol Enable  
  When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching.  
  The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set.
Bits 15:11 **L3HDBM0[4:0]**: Layer 3 IP DA higher bits match

Condition: IPv4 packets

This field contains the number of higher bits of IP Destination Address that are masked in the IPv4 packets:

- 0: No bits are masked.
- 1: LSB[0] is masked
- 2: Two LSBs [1:0] are masked
- ...
- 31: All bits except MSb are masked.

Condition: IPv6 packets

Bits[12:11] of this field correspond to Bits[6:5] of L3HDBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. Number of bits masked is given by concatenated values of the L3HDBM0[1:0] and L3HDBM0 bits:

- 0: No bits are masked.
- 1: LSB[0] is masked
- 2: Two LSBs [1:0] are masked
- ...
- 31: All bits except MSb are masked.

This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.

Bits 10:6 **L3HSBM0[4:0]**: Layer 3 IP SA higher bits match

Condition: IPv4 packets

This field contains the number of lower bits of IP source address that are masked for matching in the IPv4 packets. The following list describes the values of this field:

- 0: No bits are masked.
- 1: LSB[0] is masked
- 2: Two LSBs [1:0] are masked
- ...
- 31: All bits except MSb are masked.

Condition: IPv6 packets:

This field contains Bits[4:0] of L3HSBM0. These bits indicate the number of higher bits of IP source or destination address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.

Bit 5 **L3DAIM0**: Layer 3 IP DA Inverse Match Enable

When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching.

This bit is valid and applicable only when the L3DAM0 bit is set high.

Bit 4 **L3DAM0**: Layer 3 IP DA Match Enable

When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching.

*Note: When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering.*

Bit 3 **L3SAIM0**: Layer 3 IP SA Inverse Match Enable

When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Source Address field is enabled for perfect matching.

This bit is valid and applicable only when the L3SAM0 bit is set.
Bit 2 **L3SAM0**: Layer 3 IP SA Match Enable

When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching.

*Note:* When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **L3PEN0**: Layer 3 Protocol Enable

When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets.

The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set.

### Layer4 Address filter 0 register (ETH_MACL4A0R)

**L4SP0[15:0]**

Bits 15:0 **L4SP0[15:0]**: Layer 4 Source Port Number Field

When the L4PEN0 bit is reset and the L4DPM0 bit is set in the **L3 and L4 control 0 register (ETH_MACL3L4C0R)**, this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets.

When the L4PEN0 and L4DPM0 bits are set in **L3 and L4 control 0 register (ETH_MACL3L4C0R)**, this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.
Layer3 Address 0 filter 0 register (ETH_MACL3A00R)

Address offset: 0x0910
Reset value: 0x0000 0000

For IPv4 packets, the Layer 3 Address 0 filter 0 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3 Address 1 filter 0 register (ETH_MACL3A10R)

Address offset: 0x0914
Reset value: 0x0000 0000

For IPv4 packets, the Layer 3 Address 1 filter 0 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.

Bits 31:0 L3A00[31:0]: Layer 3 Address 0 Field

When the L3PEN0 and L3SAM0 bits are set in the L3 and L4 control 0 register (ETH_MACL3L4C0R), this field contains the value to be matched with Bits[31:0] of the IP Source Address field in the IPv6 packets.

When the L3PEN0 and L3DAM0 bits are set in the L3 and L4 control 0 register (ETH_MACL3L4C0R), this field contains the value to be matched with Bits[31:0] of the IP Destination Address field in the IPv6 packets.

When the L3PEN0 bit is reset and the L3SAM0 bit is set in the L3 and L4 control 0 register (ETH_MACL3L4C0R), this field contains the value to be matched with the IP Source Address field in the IPv4 packets.

Layer3 Address 1 filter 0 register (ETH_MACL3A10R)

Address offset: 0x0914
Reset value: 0x0000 0000

For IPv4 packets, the Layer 3 Address 1 filter 0 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.
Bits 31:0  **L3A10[31:0]**: Layer 3 Address 1 Field
When the L3PEN0 and L3SAM0 bits are set in the L3 and L4 control 0 register (ETH_MACL3L4C0R), this field contains the value to be matched with Bits[63:32] of the IP Source Address field in the IPv6 packets.
When the L3PEN0 and L3DAM0 bits are set in the L3 and L4 control 0 register (ETH_MACL3L4C0R), this field contains the value to be matched with Bits[63:32] of the IP Destination Address field in the IPv6 packets.
When the L3PEN0 bit is reset and the L3SAM0 bit is set in the L3 and L4 control 0 register (ETH_MACL3L4C0R), this field contains the value to be matched with the IP Destination Address field in the IPv4 packets.

Layer3 Address 2 filter 0 register (ETH_MACL3A20R)
Address offset: 0x0918
Reset value: 0x0000 0000
The Layer 3 Address 2 filter 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[95:64] of 128-bit IP Source Address or Destination Address field.

Bit 5  **L3DA1M1**: Layer 3 IP DA Inverse Match Enable

When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching.

This bit is valid and applicable only when the L3DA1M1 bit is set high.

Bit 4  **L3DA1M1**: Layer 3 IP DA Match Enable

When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching.

*Note: When the L3PEN1 bit is set, you should set either this bit or the L3SAM1 bit because either IPv6 DA or SA can be checked for filtering.*
Bit 3 L3SAIM1: Layer 3 IP SA Inverse Match Enable
When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching.
When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching.
This bit is valid and applicable only when the L3SAM1 bit is set.

Bit 2 L3SAM1: Layer 3 IP SA Match Enable
When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit
is reset, the MAC ignores the Layer 3 IP Source Address field for matching.

Note: When the L3PEN01 bit is set, you should set either this bit or the L3DAM1 bit because
either IPv6 SA or DA can be checked for filtering.

Bit 1 Reserved, must be kept at reset value.

Bit 0 L3PEN1: Layer 3 Protocol Enable
When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for
IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching
is enabled for IPv4 packets.
The Layer 3 matching is done only when the L3SAM1 or L3DAM1 bit is set.

Layer 4 address filter 1 register (ETH_MACL4A1R)

Bits 31:16 L4DP1[15:0]: Layer 4 Destination Port Number Field
When the L4PEN1 bit is set and the L4DPM1 bit is set in the L3 and L4 control 1 register
(ETH_MACL3L4C1R), this field contains the value to be matched with the TCP Destination
Port Number field in the IPv4 or IPv6 packets.
When the L4PEN1 and L4DPM1 bits are set in L3 and L4 control 1 register
(ETH_MACL3L4C1R), this field contains the value to be matched with the UDP Destination
Port Number field in the IPv4 or IPv6 packets.

Bits 15:0 L4SP1[15:0]: Layer 4 Source Port Number Field
When the L4PEN1 bit is set and the L4DPM1 bit is set in the L3 and L4 control 1 register
(ETH_MACL3L4C1R), this field contains the value to be matched with the TCP Source Port
Number field in the IPv4 or IPv6 packets.
When the L4PEN1 and L4DPM1 bits are set in L3 and L4 control 1 register
(ETH_MACL3L4C1R), this field contains the value to be matched with the UDP Source Port
Number field in the IPv4 or IPv6 packets.
Layer 3 address 0 filter 1 Register (ETH_MACL3A01R)

Address offset: 0x0940
Reset value: 0x0000 0000

For IPv4 packets, the Layer 3 Address 0 filter 1 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Bits 31:0 L3A01[31:0]: Layer 3 Address 0 Field

- When the L3PEN1 and L3SAM1 bits are set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with Bits[31:0] of the IP Source Address field in the IPv6 packets.
- When the L3PEN1 and L3DAM1 bits are set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with Bits[31:0] of the IP Destination Address field in the IPv6 packets.
- When the L3PEN1 bit is reset and the L3SAM1 bit is set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the IP Source Address field in the IPv4 packets.

Layer 3 address 1 filter 1 register (ETH_MACL3A11R)

Address offset: 0x0944
Reset value: 0x0000 0000

For IPv4 packets, the Layer 3 Address 1 filter 1 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.

Bits 31:0 **L3A11[31:0]**: Layer 3 Address 1 Field

When the L3PEN1 and L3SAM1 bits are set in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field contains the value to be matched with Bits[63:32] of the IP Source Address field in the IPv6 packets.

When the L3PEN1 and L3DAM1 bits are set in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field contains the value to be matched with Bits[63:32] of the IP Destination Address field in the IPv6 packets.

When the L3PEN1 bit is reset and the L3SAM1 bit is set in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field contains the value to be matched with the IP Destination Address field in the IPv4 packets.

**Layer 3 address 2 filter 1 Register (ETH_MACL3A21R)**

Address offset: 0x0948

Reset value: 0x0000 0000

The Layer 3 Address 2 filter 1 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[95:64] of 128-bit IP Source Address or Destination Address field.

Bits 31:0  **L3A31[31:0]: Layer 3 Address 3 Field**

When the L3PEN1 and L3SAM1 bits are set in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field contains the value to be matched with Bits[127:96] of the IP Source Address field in the IPv6 packets.

When the L3PEN1 and L3DAM1 bits are set in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field contains the value to be matched with Bits[127:96] of the IP Destination Address field in the IPv6 packets.

When the L3PEN1 bit is reset in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field is not used.

**Timestamp control Register (ETH_MACTSCR)**

Address offset: 0x0B00

Reset value: 0x0000 2000

This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.

Bit 28  **AV8021ASMEM**: AV 802.1AS Mode Enable

When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS operating mode.

When PTP offload feature is enabled, for the purpose of PTP offload, the transport specific field in the PTP header is generated and checked based on the value of this bit.

Bits 27:25  Reserved, must be kept at reset value.

Bit 24  **TXTSSTSM**: Transmit Timestamp Status Mode

When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the **Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)** register.

When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the **Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)**.

Bits 23:19  Reserved, must be kept at reset value.
Bit 18 **TSENMACADDR**: Enable MAC Address for PTP Packet Filtering
When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet.
When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet.
For normal timestamping operation, MAC address registers 0 to 31 is considered for unicast destination address matching.
For PTP offload, only MAC address register 0 is considered for unicast destination address matching.

Bits 17:16 **SNAPTypSEL[1:0]**: Select PTP packets for Taking Snapshots
These bits, along with Bits 15 and 14, define the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Table 707: Timestamp Snapshot Dependency on ETH_MACTSCR bits.

Bit 15 **TSMSTRENA**: Enable Snapshot for Messages Relevant to Master
When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.

Bit 14 **TSEVNTENA**: Enable Timestamp Snapshot for Event Messages
When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, see Table 707: Timestamp Snapshot Dependency on ETH_MACTSCR bits.

Bit 13 **TSIPv4ENA**: Enable Processing of PTP Packets Sent over IPv4-UDP
When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default.

Bit 12 **TSIPv6ENA**: Enable Processing of PTP Packets Sent over IPv6-UDP
When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets.

Bit 11 **TSIPENA**: Enable Processing of PTP over Ethernet Packets
When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets.

Bit 10 **TSVER2ENA**: Enable PTP Packet Processing for Version 2 Format
When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'.

Bit 9 **TSCTRLSSR**: Timestamp Digital or Binary Rollover Control
When this bit is set, the Timestamp Low register rolls over after 0x3B9A C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of subsecond register is 0x7FFF FFFF. The subsecond increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit.

Bit 8 **TSENALL**: Enable Timestamp for All Packets
When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC.

Bits 7:6 Reserved, must be kept at reset value.
Bit 5 **TSADDR**: Update Addend Register
When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set.

Bit 4 **Reserved, must be kept at reset value.**

Bit 3 **TSUPDT**: Update Timestamp
When this bit is set, the system time is updated (added or subtracted) with the value specified in *System time seconds update register (ETH_MACSTSUR)* and *System time nanoseconds update register (ETH_MACSTNUR)*.
This bit should be zero before updating it. This bit is reset when the update is complete in hardware.

Bit 2 **TSINIT**: Initialize Timestamp
When this bit is set, the system time is initialized (overwritten) with the value specified in the *System time seconds update register (ETH_MACSTSUR)* and *System time nanoseconds update register (ETH_MACSTNUR)*.
This bit should be zero before it is updated. This bit is reset when the initialization is complete.

Bit 1 **TSCFUPDT**: Fine or Coarse Timestamp Update
When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp.

Bit 0 **TSENA**: Enable Timestamp
When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode.
On the Receive side, the MAC processes the 1588 packets only if this bit is set.

**Subsecond increment register (ETH_MACSSIR)**
Address offset: 0x0B04
Reset value: 0x0000 0000

In Coarse Update mode (bit TSCFUPDT in *Timestamp control Register (ETH_MACTSCR)*), the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

</table>
Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **SSINC[7:0]**: Subsecond Increment Value

The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the subsecond register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [TSCTRLSSR bit is set in Timestamp control Register *(ETH_MACTSCR)*]. When TSCTRLSSR is cleared, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.

Bits 15:0  Reserved, must be kept at reset value.
System time seconds register (ETH_MACSTSR)

Address offset: 0x0B08
Reset value: 0x0000 0000

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

Bit 31 Reserved, must be kept at reset value.

Bits 30:0 **TSSS[30:0]**: Timestamp subseconds
The value in this field has the subsecond representation of time, with an accuracy of 0.46 ns. When TSCTRLSSR is set in Timestamp control Register (ETH_MACTSCR), each bit represents 1 ns. The maximum value is 0x3B9A C9FF after which it rolls-over to zero.
System time seconds update register (ETH_MACSTSUR)

Address offset: 0x0B10
Reset value: 0x0000 0000

The System Time Seconds Update register, along with the System Time Nanoseconds update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in Timestamp control Register (ETH_MACTSCR).

Bits 31:0 **TSS[31:0]**: Timestamp Seconds

The value in this field is the seconds part of the update.

- When ADDSUB is reset, this field must be programmed with the seconds part of the update value.
- When ADDSUB is set, this field must be programmed with the complement of the seconds part of the update value.

For example, to subtract 2.000000001 seconds from the system time, the TSS field in the ETH_MACSTSUR register must be 0xFFFF FFFE (that is, $2^{32} - 2$).

**Caution:** When the ADDSUB bit is set, TSSS[30:0] field cannot be set to 0 in System time nanoseconds update register (ETH_MACSTNUR). The TSSS bitfield must be programmed to 0x7FFF FFFF (resulting in ~0.46 ns) even if 0 ns must be subtracted.

For example, to subtract 2.000000000 seconds from the system time, the TSS field in the System time seconds update register (ETH_MACSTSUR) must be 0xFFFF FFFE (that is, $2^{32} - 1$) and the System time nanoseconds update register (ETH_MACSTNUR) must be 0xFFFF FFFF (ADDSUB = 1 and TSSS[30:0] field = 0x7FFF FFFF)

System time nanoseconds update register (ETH_MACSTNUR)

Address offset: 0x0B14
Reset value: 0x0000 0000

![System time nanoseconds update register (ETH_MACSTNUR)](image-url)
Bit 31  ADDSUB: Add or Subtract Time

When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register.

Bits 30:0  TSSS[30:0]: Timestamp subseconds

The value in this field is the subseconds part of the update.

- ADDSUB is 1: This field must be programmed with the complement of the subseconds part of the update value as described.
- ADDSUB is 0: This field must be programmed with the subseconds part of the update value, with an accuracy based on the TSCTRLSSR bit of the Timestamp control Register (ETH_MACTSCR).
- TSCTRLSSR field in the Timestamp control Register (ETH_MACTSCR) is 1:
  - The programmed value must be $10^5 - <\text{subsecond value}>$.
  - Each bit represents 1 ns and the programmed value should not exceed 0x3B9A C9FF.
- TSCTRLSSR field in the Timestamp control Register (ETH_MACTSCR) is 0:
  - The programmed value must be $2^{31} - <\text{subsecond value}>$.
  - Each bit represents an accuracy of 0.46 ns.

For example, to subtract 2.000000001 seconds from the system time, then the TSSS field in the ETH_MACSTNUR register must be 0x7FFF FFFF (that is, $2^{31} - 1$), when TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR) is reset and 0x3B9A C9FF (that is, $10^5 - 1$), when TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR) is set.

Caution: When the ADDSUB bit is set, TSSS[30:0] field cannot be set to 0. The TSSS bitfield must be programmed to 0x7FFF FFFF (resulting in –0.46 ns) even if 0 ns must be subtracted.

For example, to subtract 2.000000000 seconds from the system time, System time nanoseconds update register (ETH_MACSTNUR) must be 0xFFFF FFFF (ADDSUB = 1 and TSSS[30:0] = 0) and the TSS field in the System time seconds update register (ETH_MACSTSUR) must be 0xFFFF FFFE (that is, $2^{32} - 1$).

**Timestamp addend register (ETH_MACTSAR)**

Address offset: 0x0B18
Reset value: 0x0000 0000

This register value is used only when the system time is configured for Fine Update mode (TSCFUPD bit in the Timestamp control Register (ETH_MACTSCR)). The content of this register is added to a 32-bit accumulator in every clock cycle of clk_ptp_ref_i and the system time is updated whenever the accumulator overflows.

**TSAR[15:0]**

Bits 31:0  TSAR[31:0]: Timestamp Addend Register

This field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.
**Timestamp status register (ETH_MACTSSR)**

Address offset: 0x0B20

Reset value: 0x0000 0000

All bits except Bits[27:25] gets cleared when the application reads this register.

**Bits 31:30 Reserved, must be kept at reset value.**

**Bits 29:25 ATSSN[4:0]: Number of Auxiliary Timestamp Snapshots**

This field indicates the number of Snapshots available in the FIFO. A value equal to the depth of FIFO (4) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set.

**Bit 24 ATSTM: Auxiliary Timestamp Snapshot Trigger Missed**

This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO.

**Bits 23:20 Reserved, must be kept at reset value.**

**Bits 19:16 ATSTSN[3:0]: Auxiliary Timestamp Snapshot Trigger Identifier**

These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. These bits are applicable only if the number of Auxiliary snapshots is more than one. One bit is assigned for each trigger as shown in the following list:

- Bit 16: Auxiliary trigger 0
- Bit 17: Auxiliary trigger 1
- Bit 18: Auxiliary trigger 2
- Bit 19: Auxiliary trigger 3

The software can read this register to find the triggers that are set when the timestamp is taken.

**Bit 15 TXTSSIS: Tx Timestamp Status Interrupt Status**

When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the *Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)* and *Tx timestamp status seconds register (ETH_MACTXTSSSR)*.

When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the *Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)* and *Tx timestamp status seconds register (ETH_MACTXTSSSR)*, for PTO generated Delay Request and Pdelay request packets.

This bit is cleared when the *Tx timestamp status seconds register (ETH_MACTXTSSSR)* is read (or written to 1 when RCWE bit in *CSR software control register (ETH_MACCSRSWCR)* is set).

**Bits 14:4 Reserved, must be kept at reset value.**
Bit 3 **TSTRGTER0:** Timestamp Target Time Error
This bit is set when the latest target time programmed in the ETH_MACPPSTTSR and ETH_MACPPSTTSNR elapses (see **PPS target time seconds register (ETH_MACPPSTTSR)** and **PPS target time nanoseconds register (ETH_MACPPSTTNR)**). This bit is cleared when the application reads this bit (or writes it to 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).

Bit 2 **AUXSTSTRIG:** Auxiliary Timestamp Trigger Snapshot
This bit is set high when the auxiliary snapshot is written to the FIFO. This bit is cleared when the application reads this bit (or writes it to 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).

Bit 1 **TSTARGTO:** Timestamp Target Time Reached
When set, this bit indicates that the value of system time is greater than or equal to the value specified in the ETH_MACPPSTTSR and ETH_MACPPSTTSNR registers (see **PPS target time seconds register (ETH_MACPPSTTSR)** and **PPS target time nanoseconds register (ETH_MACPPSTTNR)**). This bit is cleared when the application reads this bit (or writes of 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).

Bit 0 **TSSOVF:** Timestamp Seconds Overflow
When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 0xFFFF FFFF. This bit is cleared when the application reads this bit (or writes it to 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).

**Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)**
Address offset: 0x0B30
Reset value: 0x0000 0000
This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled.

Bit 31 **TXTSSMIS:** Transmit Timestamp Status Missed
When this bit is set, it indicates one of the following:
- The timestamp of the current packet is ignored if TXTSSTSM bit of the **Timestamp control Register (ETH_MACTSCR)** is reset
- The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the **Timestamp control Register (ETH_MACTSCR)** is set.

Bits 30:0 **TXTSSLO[30:0]:** Transmit Timestamp Status Low
This field contains the 31 bits of the Nanoseconds field of the Transmit packet’s captured timestamp.
**Tx timestamp status seconds register (ETH_MACTXTSSSR)**

Address offset: 0x0B34  
Reset value: 0x0000 0000  
The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

```

Bits 31:8 Reserved, must be kept at reset value.

- **Bit 7 ATSEN3**: Auxiliary Snapshot 3 Enable  
  - This bit controls the capturing of Auxiliary Snapshot Trigger 3. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg3 input is enabled. When this bit is reset, the events on this input are ignored.

- **Bit 6 ATSEN2**: Auxiliary Snapshot 2 Enable  
  - This bit controls the capturing of Auxiliary Snapshot Trigger 2. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg2 input is enabled. When this bit is reset, the events on this input are ignored.

- **Bit 5 ATSEN1**: Auxiliary Snapshot 1 Enable  
  - This bit controls the capturing of Auxiliary Snapshot Trigger 1. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg1 input is enabled. When this bit is reset, the events on this input are ignored.
Bit 4 **ATSEN0**: Auxiliary Snapshot 0 Enable
This bit controls the capturing of Auxiliary Snapshot Trigger 0. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg0 input is enabled. When this bit is reset, the events on this input are ignored.

Bits 3:1 Reserved, must be kept at reset value.
Bit 0 **ATSFC**: Auxiliary Snapshot FIFO Clear
When set, this bit resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, the auxiliary snapshots are stored in the FIFO.

**Auxiliary timestamp nanoseconds register (ETH_MACATSNR)**

Address offset: 0x0B48
Reset value: 0x0000 0000

The Auxiliary timestamp nanoseconds register (ETH_MACATSNR), along with Auxiliary timestamp seconds register (ETH_MACATSSR), gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4 words.

You can store multiple snapshots in this FIFO. Bits[29:25] in Timestamp status register (ETH_MACTSSR) indicate the fill-level of the FIFO. The top of the FIFO is removed only when Auxiliary timestamp seconds register (ETH_MACATSSR) is read.

Bits 31:0 **OSTIAC[31:0]**: One-Step Timestamp Ingress Asymmetry Correction
This field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programmed value should be in units of nanoseconds and multiplied by 2^{16}. For example, 2.5 ns is represented as 0x00028000. The value can also be negative, which is represented in 2's complement form with bit 31 representing the sign bit.

**Timestamp Egress asymmetric correction register (ETH_MACTSEACR)**
Address offset: 0x0B54
Reset value: 0x0000 0000
The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.

</tbody>
</table>

Bits 31:0 **OSTEAC[31:0]**: One-Step Timestamp Egress Asymmetry Correction
This field contains the egress path asymmetry value to be subtracted from correctionField of Pdelay_Resp PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^{16}. For example, if the required correction is +2.5 ns, the programmed value must be 0xFFFDF 8000, which is the 2's complement of 0x0002 8000(2.5 × 2^{16}). Similarly, if the required correction is -3.3 ns, the programmed value is 0x0003 4CCC (3.3 × 2^{16}).
**Timestamp Ingress correction nanosecond register (ETH_MACTSICNR)**

Address offset: 0x0B58  
Reset value: 0x0000 0000  
This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path.

Bits 31:0  **TSIC[31:0]: Timestamp Ingress Correction**  
This field contains the ingress path correction value as defined by the Ingress Correction expression.

**Timestamp Egress correction nanosecond register (ETH_MACTSECNR)**

Address offset: 0x0B5C  
Reset value: 0x0000 0000  
This register contains the correction value in nanoseconds to be used with the captured timestamp value in the egress path.

Bits 31:0  **TSEC[31:0]: Timestamp Egress Correction**  
This field contains the nanoseconds part of the egress path correction value as defined by the Egress Correction expression.

**PPS control register (ETH_MACPPSCR)**

Address offset: 0x0B70  
Reset value: 0x0000 0000

---

**Table Examples**

<table>

</tbody>
</table>
Bits 31:7 Reserved, must be kept at reset value.

Bits 6:5 **TRGTMODSEL[1:0]**: Target Time Register Mode for PPS Output
This field indicates the Target Time registers *(PPS target time seconds register (ETH_MACPPSTTSR)) and PPS target time nanoseconds register (ETH_MACPPSTTNR)* mode for PPS output signal:
00: Target Time registers are programmed only for generating the interrupt event.
01: Reserved, must not be used
10: Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS output signal generation.
11: Target Time registers are programmed only for starting or stopping the PPS output signal generation. No interrupt is asserted.

Bit 4 **PPSEN0**: Flexible PPS Output Mode Enable
When this bit is set, PPSCTRL[3:0] function as PPSCMD[3:0]. When this bit is reset, PPSCTRL[3:0] function as PPSCTRL (Fixed PPS mode).

Bits 3:0 **PPSCTRL[3:0]**: PPS Output Frequency Control
This field controls the frequency of the PPS output *(eth_ptp_pps_out)* signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies:
0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz.
0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz.
0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz.
1000: The binary rollover is 16 Hz, and the digital rollover is 8 Hz.

.. 1111: The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz.

**Note:** In the binary rollover mode, the PPS output *(eth_ptp_pps_out)* has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example:

- **When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms.**
- **When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of**
  One clock of 50 percent duty cycle and 537 ms period
  Second clock of 463 ms period (268 ms low and 195 ms high).
- **When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of**
  Three clocks of 50 percent duty cycle and 268 ms period
  Fourth clock of 195 ms period (134 ms low and 61 ms high).

This behavior is because of the non-linear toggling of bits in the digital rollover mode in the ETH_MACSTNR register.
PPS control register [alternate] (ETH_MACPPSCR)

Address offset: 0x0B70
Reset value: 0x0000 0000

Bits 31:7  Reserved, must be kept at reset value.

Bits 6:5  TRGTMODSEL0[1:0]: Target Time Register Mode for PPS Output
This field indicates the Target Time registers (PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)) mode for PPS output signal:
00: Target Time registers are programmed only for generating the interrupt event.
01: Reserved, must not be used
10: Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS output signal generation.
11: Target Time registers are programmed only for starting or stopping the PPS output signal generation. No interrupt is asserted.

Bit 4  PPSEN0: Flexible PPS Output Mode Enable
When this bit is set, Bits[3:0] function as PPSCMD[3:0]. When this bit is reset, Bits[3:0] function as PPSCTRL(Fixed PPS mode).
Bits 3:0 PPSCMD[3:0]: Flexible PPS Output (eth_ptp_pps_out) Control

Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are 'all zero'. The following list describes the values of PPSCMD0:

0000: No Command
0001: START Single Pulse.
This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS Width Register.
0010: START Pulse Train.
This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands.
0011: Cancel START.
This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time.
0100: STOP Pulse Train at time.
This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD[3:0] = 0010) after the time programmed in the Target Time registers elapses.
0101: STOP Pulse Train immediately.
This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD[3:0] = 0010).
0110: Cancel STOP Pulse train.
This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command.
0111 to 1111: Reserved, must not be used

PPS target time seconds register (ETH_MACPPSTTSR)

Address offset: 0x0B80
Reset value: 0x0000 0000

The PPS output Target Time Seconds register, along with PPS target time nanoseconds register (ETH_MACPPSTTNR), is used to schedule an interrupt event (Bit TSSOVF of Timestamp status register (ETH_MACTSSR)) when the system time exceeds the value programmed in these registers.

Bits 31:0 TSTRH0[31:0]: PPS Target Time Seconds Register

This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the PPS control register (ETH_MACPPSCR).
**PPS target time nanoseconds register (ETH_MACPPSTTNR)**

Address offset: 0x0B84
Reset value: 0x0000 0000

The PPS Target Time Nanoseconds register is present only when more than one Flexible PPS output is selected.

### PPS Target Time Nanoseconds register (ETH_MACPPSTTNR)

#### TRGTBUSY

- **Bit 31**: TRGTBUSY0: PPS Target Time Register Busy
  
  The MAC sets this bit when the PPSCMD0 field in the PPS control register (ETH_MACPPSCR) is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers with the PTP clock domain. The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted.

#### TTSL0[30:0]

- **Bits 30:0**: TTSL0[30:0]: Target Time Low for PPS Register
  
  This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in PPS control register (ETH_MACPPSCR).

  When the TSCTRLSSR bit is set in the Timestamp control Register (ETH_MACTSCR), this value should not exceed 0x3B9A C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of subsecond increment value.

**PPS interval register (ETH_MACPPSIR)**

Address offset: 0x0B88
Reset value: 0x0000 0000

The PPS Interval register contains the number of units of subsecond increment value between the rising edges of PPS output.

### PPS Interval register (ETH_MACPPSIR)

#### PPSINT0[31:16]

#### PPSINT0[15:0]
Bits 31:0 **PPSINT0[31:0]**: PPS Output Signal Interval

These bits store the interval between the rising edges of PPS signal output. The interval is stored in terms of number of units of subsecond increment value.

You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS signal output is 100 ns (that is, 5 units of subsecond increment value), you should program value 4 (5-1) in this register.

**PPS width register (ETH_MACPPSWR)**

Address offset: 0x0B8C
Reset value: 0x0000 0000

The PPS Width register contains the number of units of subsecond increment value between the rising and corresponding falling edges of PPS output.

**PPSWIDTH0[31:16]**

Bits 31:0 **PPSWIDTH0[31:0]**: PPS Output Signal Width

These bits store the width between the rising edge and corresponding falling edge of PPS signal output. The width is stored in terms of number of units of subsecond increment value.

You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS signal output is 80 ns (that is, four units of subsecond increment value), you should program value 3 (4-1) in this register.

*Note*: The value programmed in this register must be lesser than the value programmed in **PPS interval register (ETH_MACPPSIR)**.

**PTP Offload control register (ETH_MACPOCR)**

Address offset: 0x0BC0
Reset value: 0x0000 0000

This register controls the PTP Offload Engine operation.

**Note**: The value programmed in this register must be lesser than the value programmed in **PPS interval register (ETH_MACPPSIR)**.
Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DN[7:0]: Domain Number**
This field indicates the domain Number in which the PTP node is operating.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **DRRDIS**: Disable PTO Delay Request/Response response generation
When this bit is set, the Delay Request and Delay response are not generated for received
SYNC and Delay request packet respectively, as required by the programmed mode.

Bit 5 **APDREQTRIG**: Automatic PTP Pdelay_Req message Trigger
When this bit is set, one PTP Pdelay_Req message is transmitted. This bit is automatically
released after the PTP Pdelay_Req message is transmitted. The application should set the
APDREQEN bit for this operation.

Bit 4 **ASYNCTRIG**: Automatic PTP SYNC message Trigger
When this bit is set, one PTP SYNC message is transmitted. This bit is automatically cleared
after the PTP SYNC message is transmitted. The application should set the ASYNCECN bit for
this operation.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **APDREQEN**: Automatic PTP Pdelay_Req message Enable
When this bit is set, PTP Pdelay_Req message is generated periodically based on interval
programmed or trigger from application, when the MAC is programmed to be in Peer-to-Peer
Transparent mode.

Bit 1 **ASYNCECN**: Automatic PTP SYNC message Enable
When this bit is set, PTP SYNC message is generated periodically based on interval
programmed or trigger from application, when the MAC is programmed to be in Clock Master
mode.

Bit 0 **PTOEN**: PTP Offload Enable
When this bit is set, the PTP Offload feature is enabled.

**PTP Source Port Identity 0 Register (ETH_MACSPI0R)**

Address offset: 0x0BC4
Reset value: 0x0000 0000

This register contains Bits[31:0] of the 80-bit Source Port Identity of the PTP node.

**SPI[15:0]**

Bits 31:0 **SPI[31:0]: Source Port Identity 0**
This field indicates bits [31:0] of sourcePortIdentity of PTP node.
PTP Source port identity 1 register (ETH_MACSPI1R)
Address offset: 0x0BC8
Reset value: 0x0000 0000
This register contains Bits[63:32] of the 80-bit Source Port Identity of the PTP node.

PTP Source port identity 2 register (ETH_MACSPI2R)
Address offset: 0x0BCC
Reset value: 0x0000 0000
This register contains Bits[79:64] of the 80-bit Source Port Identity of the PTP node.

Log message interval register (ETH_MACLMIR)
Address offset: 0x0BD0
Reset value: 0x0000 0000
This register contains the periodic intervals for automatic PTP packet generation.
Bits 31:24  **LMPDRI[7:0]**: Log Min Pdelay_Req Interval  
This field indicates logMinPdelayReqInterval of PTP node. This is used to schedule the periodic Pdelay request packet transmission. Allowed values are -15 to 15. Negative value must be represented in 2's-complement form. For example, if the required value is -1, the value programmed must be 0xFF.

Bits 23:11  Reserved, must be kept at reset value.

Bits 10:8  **DRSYNCR[2:0]**:  
Delay_Req to SYNC Ratio  
In Slave mode, it is used for controlling frequency of Delay_Req messages transmitted.  
0: DelayReq generated for every received SYNC  
1: DelayReq generated every alternate reception of SYNC  
2: for every 4 SYNC messages  
3: for every 8 SYNC messages  
4: for every 16 SYNC messages  
5: for every 32 SYNC messages  
Others: Reserved, must not be used  
The master sends this information (logMinDelayReqInterval) in the DelayResp PTP messages to the slave. The reception processes this value from the received DelayResp messages and updates this field accordingly. In the Slave mode, the host must not write/update this register unless it has to override the received value. In Master mode, the sum of this field and logSyncInterval (LSI) field is provided in the logMinDelayReqInterval field of the generated multicast Delay_Resp PTP message.

Bits 7:0  **LSI[7:0]**:  
Log Sync Interval  
This field indicates the periodicity of the automatically generated SYNC message when the PTP node is Master. Allowed values are -15 to 15. Negative value must be represented in 2's-complement form. For example, if the required value is -1, the value programmed must be 0xFF.

Refer to \textit{Section 2.3 on page 149} for the register boundary addresses.
65  **HDMI-CEC controller (CEC)**

65.1  **HDMI-CEC introduction**

Consumer electronics control (CEC) is part of HDMI (high-definition multimedia interface) standard. It contains a protocol that provides high-level control functions between various audiovisual products. CEC operates at low speeds, with minimum processing and memory overhead.

The HDMI-CEC controller provides hardware support for this protocol.

65.2  **HDMI-CEC controller main features**

- Complies with HDMI-CEC v1.4 specification
- Independent 32 kHz CEC kernel (refer to section RCC kernel clock distribution)
- Works in Stop mode for ultra-low-power applications
- Configurable signal-free time before start of transmission
  - Automatic by hardware, according to CEC state and transmission history
  - Fixed by software (7 timing options)
- Configurable peripheral address (OAR)
- Supports Listen mode
  - Enables reception of CEC messages sent to destination address different from OAR without interfering with the CEC line
- Configurable Rx-tolerance margin
  - Standard tolerance
  - Extended tolerance
- Receive-error detection
  - Bit rising error (BRE), with optional stop of reception (BRESTP)
  - Short bit period error (SBPE)
  - Long bit period error (LBPE)
- Configurable error-bit generation
  - on BRE detection (BREGEN)
  - on LBPE detection (LBPEGEN)
  - always generated on SBPE detection
- Transmission error detection (TXERR)
- Arbitration lost detection (ARBLST)
  - with automatic transmission retry
- Transmission underrun detection (TXUDR)
- Reception overrun detection (RXOVR)
65.3 HDMI-CEC functional description

65.3.1 HDMI-CEC pin and internal signals

The CEC bus consists of a single bidirectional line that is used to transfer data in and out of the device. It is connected to a +3.3 V supply voltage via a 27 kΩ pull-up resistor. The output stage of the device must have an open-drain or open-collector to allow a wired-AND connection.

The HDMI-CEC controller manages the CEC bidirectional line as an alternate function of a standard GPIO, assuming that it is configured as alternate function open drain. The 27 kΩ pull-up must be added externally to the microcontroller.

To not interfere with the CEC bus when the application power is removed, it is mandatory to isolate the CEC pin from the bus in such conditions. This can be done by using a MOS transistor, as shown on Figure 989.

Table 756 lists the internal signals that are exchanged between the HDMI-CEC and other functional blocks (such as RCC and EXTI).

65.3.2 **HDMI-CEC block diagram**

Figure 989. HDMI-CEC block diagram

65.3.3 **Message description**

All transactions on the CEC line consist of an initiator and one or more followers. The initiator is responsible for sending the message structure and the data. The follower is the recipient of any data and is responsible for setting any acknowledgment bits.

A message is conveyed in a single frame that consists of a start bit followed by a header block and optionally an opcode and a variable number of operand blocks.

All these blocks are made of a 8-bit payload - most significant bit is transmitted first - followed by an end of message (EOM) bit and an acknowledge (ACK) bit.

The EOM bit is set in the last block of a message and kept reset in all others. In case a message contains additional blocks after an EOM is indicated, those additional blocks must be ignored. The EOM bit may be set in the header block to ‘ping’ other devices, to make sure they are active.

The acknowledge bit is always set to high impedance by the initiator so that it can be driven low either by the follower that has read its own address in the header, or by the follower that needs to reject a broadcast message.

The header consists of the source logical address field, and the destination logical address field. Note that the special address 0xF is used for broadcast messages.

Figure 990. Message structure
65.3.4 Bit timing

The format of the start bit is unique and identifies the start of a message. It must be validated by its low duration and its total duration.

All remaining data bits in the message, after the start bit, have consistent timing. The high-to-low transition at the end of the data bit is the start of the next data bit except for the final bit where the CEC line remains high.

65.4 Arbitration

All devices transmitting - or retransmitting - a message onto the CEC line must ensure that it has been inactive for a number of bit periods. This signal-free time is defined as the time...
starting from the final bit of the previous frame and depends on the initiating device and the current status as shown in the figure below.

**Figure 993. Signal free time**

![Figure 993. Signal free time](MS31007V1)

Since only one initiator is allowed at any one time, an arbitration mechanism is provided to avoid conflict when more than one initiator begins transmitting at the same time.

CEC line arbitration starts with the leading edge of the start bit and continues until the end of the initiator address bits within the header block. During this period, the initiator must monitor the CEC line, if whilst driving the line to high impedance it reads it back to 0. Assuming then it has lost arbitration, it stops transmitting and becomes a follower.

**Figure 994. Arbitration phase**

![Figure 994. Arbitration phase](MS31008V1)

**Figure 995** shows an example for a SFT of three nominal bit periods.

**Figure 995. SFT of three nominal bit periods**

![Figure 995. SFT of three nominal bit periods](MS31009V1)

A configurable time window is counted before starting the transmission.

In the SFT = 0 configuration, HDMI-CEC performs automatic SFT calculation ensuring compliance with the HDMI-CEC standard:

- 2.5 data bit periods if the CEC is the last bus initiator with unsuccessful transmission
- 4 data bit periods if the CEC is the new bus initiator
- 6 data bit periods if the CEC is the last bus initiator with successful transmission
This is done to guarantee the maximum priority to a failed transmission and the lowest one to the last initiator that completed successfully its transmission.

Otherwise there is the possibility to configure the SFT bits to count a fixed timing value. Possible values are 0.5, 1.5, 2.5, 3.5, 4.5, 5.5, 6.5 data bit periods.

65.4.1 SFT option bit

In case of SFTOPT = 0 configuration, SFT starts being counted when the start-of-transmission command is set by software (TXSOM = 1).

In case of SFTOPT = 1, SFT starts automatically being counted by the HDMI-CEC device when a bus-idle or line error condition is detected. If the SFT timer is completed at the time TXSOM command is set then transmission starts immediately without latency. If the SFT timer is still running instead, the system waits until the timer elapses before transmission can start.

In case of SFTOPT = 1 a bus-event condition starting the SFT timer is detected in the following cases:

- In case of a regular end of transmission/reception, when TXEND/RXEND bits are set at the minimum nominal data bit duration of the last bit in the message (ACK bit).
- In case of a transmission error detection, SFT timer starts when the TXERR transmission error is detected (TXERR = 1).
- In case of a missing acknowledge from the CEC follower, the SFT timer starts when the TXACKE bit is set, that is at the nominal sampling time of the ACK bit.
- In case of a transmission underrun error, the SFT timer starts when the TXUDR bit is set at the end of the ACK bit.
- In case of a receive error detection implying reception abort, the SFT timer starts at the same time the error is detected. If an error bit is generated, then SFT starts being counted at the end of the error bit.
- In case of a wrong start bit or of any uncoded low impedance bus state from idle, the SFT timer is restarted as soon as the bus comes back to hi-impedance idleness.

65.5 Error handling

65.5.1 Bit error

If a data bit - excluding the start bit - is considered invalid, the follower is expected to notify such error by generating a low bit period on the CEC line of 1.4 to 1.6 times the nominal data bit period (3.6 ms nominally).

![Figure 996. Error bit timing](MS31010V1)
65.5.2 Message error

A message is considered lost and therefore may be retransmitted under the following conditions:

- a message is not acknowledged in a directly addressed message
- a message is negatively acknowledged in a broadcast message
- a low impedance is detected on the CEC line while it is not expected (line error)

Three kinds of error flag can be detected when the CEC interface is receiving a data bit:

65.5.3 Bit rising error (BRE)

BRE (bit rising error) is set when a bit rising edge is detected outside the windows where it is expected (see Figure 997). BRE flag also generates a CEC interrupt if the BREIE = 1.

In the case of a BRE detection, the message reception can be stopped according to the BRESTP bit value and an error bit can be generated if BREGEN bit is set.

When BRE is detected in a broadcast message with BRESTP = 1 an error bit is generated even if BREGEN = 0 to enforce initiator's retry of the failed transmission. Error bit generation can be disabled by configuring BREGEN = 0, BRDNOGEN = 1.

65.5.4 Short bit period error (SBPE)

SBPE is set when a bit falling edge is detected earlier than expected (see Figure 997). SBPE flag also generates a CEC interrupt if the SBPEIE = 1.

An error bit is always generated on the line in case of a SBPE error detection. An error bit is not generated upon SBPE detection only when Listen mode is set (LSTN = 1) and the following conditions are met:

- A directly addressed message is received containing SBPE
- A broadcast message is received containing SBPE AND BRDNOGEN = 1

65.5.5 Long bit period error (LBPE)

LBPE is set when a bit falling edge is not detected in a valid window (see Figure 997). LBPE flag also generates a CEC interrupt if the LBPEIE = 1.

LBPE always stops the reception, an error bit is generated on the line when LBPEGEN bit is set.

When LBPE is detected in a broadcast message an error bit is generated even if LBPEGEN = 0 to enforce initiator’s retry of the failed transmission. Error bit generation can be disabled by configuring LBPEGEN = 0, BRDNOGEN = 1.

Note: The BREGEN = 1, BRESTP = 0 configuration must be avoided.

</table>
65.5.6 Transmission error detection (TXERR)

The CEC initiator sets the TXERR flag if detecting low impedance on the CEC line when it is transmitting high impedance and is not expecting a follower asserted bit. TXERR flag also generates a CEC interrupt if the TXERRIE = 1.

TXERR assertion stops the message transmission. Application is in charge to retry the failed transmission up to five times.

TXERR checks are performed differently depending on the different states of the CEC line and on the RX tolerance configuration.

HDMI-CEC controller (CEC)

65.6 HDMI-CEC interrupts

An interrupt can be produced:
- during reception if a receive block transfer is finished or if a receive error occurs.
- during transmission if a transmit block transfer is finished or if a transmit error occurs.

<td></td>
<td>rs</td>
<td>rs</td>
<td>rw</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:3  Reserved, must be kept at reset value.

Bit 2  TXEOM: Tx end of message
The TXEOM bit is set by software to command transmission of the last byte of a CEC message. TXEOM is cleared by hardware at the same time and under the same conditions as for TXSOM.

0: TXDR data byte is transmitted with EOM = 0.
1: TXDR data byte is transmitted with EOM = 1.

Note: TXEOM must be set when CECEN = 1.
TXEOM must be set before writing transmission data to TXDR.
If TXEOM is set when TXSOM = 0, transmitted message consists of 1 byte (HEADER) only (PING message).

Bit 1  TXSOM: Tx start of message
TXSOM is set by software to command transmission of the first byte of a CEC message. If the CEC message consists of only one byte, TXEOM must be set before of TXSOM.
Start-bit is effectively started on the CEC line after SFT is counted. If TXSOM is set while a message reception is ongoing, transmission starts after the end of reception.
TXSOM is cleared by hardware after the last byte of the message is sent with a positive acknowledge (TXEND = 1), in case of transmission underrun (TXUDR = 1), negative acknowledge (TXACKE = 1), and transmission error (TXERR = 1). It is also cleared by CECEN = 0. It is not cleared and transmission is automatically retried in case of arbitration lost (ARBLST = 1).
TXSOM can be also used as a status bit informing application whether any transmission request is pending or under execution. The application can abort a transmission request at any time by clearing the CECEN bit.

0: No CEC transmission is on-going.
1: CEC transmission command

Note: TXSOM must be set when CECEN = 1.
TXSOM must be set when transmission data is available into TXDR.
HEADER first four bits containing own peripheral address are taken from TXDR[7:4], not from CEC_CFRGR.OAR that is used only for reception.
Bit 0 **CECEN**: CEC enable

The CECEN bit is set and cleared by software. CECEN = 1 starts message reception and enables the TXSOM control. CECEN = 0 disables the CEC peripheral, clears all bits of CEC_CR register and aborts any on-going reception or transmission.

0: CEC peripheral is off.
1: CEC peripheral is on.

### 65.7.2 CEC configuration register (CEC_CFGR)

This register is used to configure the HDMI-CEC controller.

- **Address offset**: 0x04
- **Reset value**: 0x0000 0000

**Caution**: It is mandatory to write CEC_CFGR only when CECEN = 0.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>

</tr>
<tr>
<td>2</td>
<td>SFT[2:0]</td>
<td></td>
</tr>
</tbody>
</table>

**Bit 31 LSTN**: Listen mode

LSTN bit is set and cleared by software.

0: CEC peripheral receives only message addressed to its own address (OAR). Messages addressed to different destination are ignored. Broadcast messages are always received.

1: CEC peripheral receives messages addressed to its own address (OAR) with positive acknowledge. Messages addressed to different destination are received, but without interfering with the CEC bus: no acknowledge sent.

**Bits 30:16 OAR[14:0]: Own addresses configuration**

The OAR bits are set by software to select which destination logical addresses has to be considered in receive mode. Each bit, when set, enables the CEC logical address identified by the given bit position.

At the end of HEADER reception, the received destination address is compared with the enabled addresses. In case of matching address, the incoming message is acknowledged and received. In case of non-matching address, the incoming message is received only in listen mode (LSTN = 1), but without acknowledge sent. Broadcast messages are always received.

Example:

OAR = 0b0000 0000 0010 0001 means that CEC acknowledges addresses 0x0 and 0x5. Consequently, each message directed to one of these addresses is received.

**Bits 15:9** Reserved, must be kept at reset value.

**Bit 8 SFTOP**: SFT option bit

The SFTOPT bit is set and cleared by software.

0: SFT timer starts when TXSOM is set by software.
1: SFT timer starts automatically at the end of message transmission/reception.
Bit 7  **BRDNOGEN**: Avoid error-bit generation in broadcast
The BRDNOGEN bit is set and cleared by software.
0: BRE detection with BRESTP = 1 and BREGEN = 0 on a broadcast message generates an error-bit on the CEC line. LBPE detection with LBPEGEN = 0 on a broadcast message generates an error-bit on the CEC line.
1: Error-bit is not generated in the same condition as above. An error-bit is not generated even in case of an SBPE detection in a broadcast message if listen mode is set.

Bit 6  **LBPEGEN**: Generate error-bit on long bit period error
The LBPEGEN bit is set and cleared by software.
0: LBPE detection does not generate an error-bit on the CEC line.
1: LBPE detection generates an error-bit on the CEC line.

Note: **If BRDNOGEN = 0, an error-bit is generated upon LBPE detection in broadcast even if LBPEGEN = 0.**

Bit 5  **BREGEN**: Generate error-bit on bit rising error
The BREGEN bit is set and cleared by software.
0: BRE detection does not generate an error-bit on the CEC line.
1: BRE detection generates an error-bit on the CEC line (if BRESTP is set).

Note: **If BRDNOGEN = 0, an error-bit is generated upon BRE detection with BRESTP = 1 in broadcast even if BREGEN = 0.**

Bit 4  **BRESTP**: Rx-stop on bit rising error
The BRESTP bit is set and cleared by software.
0: BRE detection does not stop reception of the CEC message. Data bit is sampled at 1.05 ms.
1: BRE detection stops message reception.

Bit 3  **RXTOL**: Rx-tolerance
The RXTOL bit is set and cleared by software.
0: Standard tolerance margin:
  – Start-bit, +/- 200 µs rise, +/- 200 µs fall
  – Data-bit: +/- 200 µs rise. +/- 350 µs fall
1: Extended tolerance
  – Start-bit: +/- 400 µs rise, +/- 400 µs fall
  – Data-bit: +/- 300 µs rise, +/- 500 µs fall

Bits 2:0  **SFT[2:0]**: Signal free time
SFT bits are set by software. In the SFT = 0x0 configuration, the number of nominal data bit periods waited before transmission is ruled by hardware according to the transmission history. In all the other configurations the SFT number is determined by software.
0x0
  – 2.5 data-bit periods if CEC is the last bus initiator with unsuccessful transmission (ARBLST = 1, TXERR = 1, TXUDR = 1 or TXACKE = 1)
  – 4 data-bit periods if CEC is the new bus initiator
  – 6 data-bit periods if CEC is the last bus initiator with successful transmission (TXEOM = 1)
0x1: 0.5 nominal data bit periods
0x2: 1.5 nominal data bit periods
0x3: 2.5 nominal data bit periods
0x4: 3.5 nominal data bit periods
0x5: 4.5 nominal data bit periods
0x6: 5.5 nominal data bit periods
0x7: 6.5 nominal data bit periods

Bits 31:13 Reserved, must be kept at reset value.
Bit 12 **TXACKE:** Tx-missing acknowledge error
In transmission mode, TXACKE is set by hardware to inform application that no acknowledge was received. In case of broadcast transmission, TXACKE informs application that a negative acknowledge was received. TXACKE aborts message transmission and clears TXSOM and TXEOM controls.
TXACKE is cleared by software write at 1.

Bit 11 **TXERR:** Tx-error
In transmission mode, TXERR is set by hardware if the CEC initiator detects low impedance on the CEC line while it is released. TXERR aborts message transmission and clears TXSOM and TXEOM controls.
TXERR is cleared by software write at 1.

Bit 10 **TXUDR:** Tx-buffer underrun
In transmission mode, TXUDR is set by hardware if application was not in time to load TXDR before of next byte transmission. TXUDR aborts message transmission and clears TXSOM and TXEOM control bits.
TXUDR is cleared by software write at 1

Bit 9 **TXEND:** End of transmission
TXEND is set by hardware to inform application that the last byte of the CEC message has been successfully transmitted. TXEND clears the TXSOM and TXEOM control bits.
TXEND is cleared by software write at 1.

Bit 8 **TXBR:** Tx-byte request
TXBR is set by hardware to inform application that the next transmission data has to be written to TXDR. TXBR is set when the 4th bit of currently transmitted byte is sent. Application must write the next byte to TXDR within six nominal data-bit periods before transmission underrun error occurs (TXUDR).
TXBR is cleared by software write at 1.

Bit 7 **ARBLST:** Arbitration lost
ARBLST is set by hardware to inform application that CEC device is switching to reception due to arbitration lost event following the TXSOM command. ARBLST can be due either to a contending CEC device starting earlier or starting at the same time but with higher HEADER priority. After ARBLST assertion TXSOM bit keeps pending for next transmission attempt.
ARBLST is cleared by software write at 1.

Bit 6 **RXACKE:** Rx-missing acknowledge
In receive mode, RXACKE is set by hardware to inform application that no acknowledgment was seen on the CEC line. RXACKE applies only for broadcast messages and in listen mode also for not directly addressed messages (destination address not enabled in OAR). RXACKE aborts message reception.
RXACKE is cleared by software write at 1.

Bit 5 **LBPE:** Rx-long bit period error
LBPE is set by hardware in case a data-bit waveform is detected with long bit period error. LBPE is set at the end of the maximum bit-extension tolerance allowed by RXTOL, in case falling edge is still longing. LBPE always stops reception of the CEC message. LBPE generates an error-bit on the CEC line if LBPEGEN = 1. In case of broadcast, error-bit is generated even in case of LBPEGEN = 0.
LBPE is cleared by software write at 1.

Bit 4 **SBPE:** Rx-short bit period error
SBPE is set by hardware in case a data-bit waveform is detected with short bit period error. SBPE is set at the time the anticipated falling edge occurs. SBPE generates an error-bit on the CEC line.
SBPE is cleared by software write at 1.
Bit 3 BRE: Rx-bit rising error
BRE is set by hardware in case a data-bit waveform is detected with bit rising error. BRE is set either at the time the misplaced rising edge occurs, or at the end of the maximum BRE tolerance allowed by RXTOL. In case rising edge is still longing, BRE stops message reception if BRESTP = 1. BRE generates an error-bit on the CEC line if BREGEN = 1.
BRE is cleared by software write at 1.

Bit 2 RXOVR: Rx-overrun
RXOVR is set by hardware if RXBR is not yet cleared at the time a new byte is received on the CEC line and stored into RXD. RXOVR assertion stops message reception so that no acknowledge is sent. In case of broadcast, a negative acknowledge is sent.
RXOVR is cleared by software write at 1.

Bit 1 RXEND: End of reception
RXEND is set by hardware to inform application that the last byte of a CEC message is received from the CEC line and stored into the RXD buffer. RXEND is set at the same time of RXBR.
RXEND is cleared by software write at 1.

Bit 0 RXBR: Rx-byte received
The RXBR bit is set by hardware to inform application that a new byte has been received from the CEC line and stored into the RXD buffer.
RXBR is cleared by software write at 1.

65.7.6 CEC interrupt enable register (CEC_IER)
Address offset: 0x14
Reset value: 0x0000 0000

Caution: It is mandatory to write CEC_IER only when CECEN = 0.

<table>
<thead>

</tr>
</thead>
</table>

Bit 12 TXACKIE: Tx-missing acknowledge error interrupt enable
The TXACKIE bit is set and cleared by software.
0: TXACKE interrupt disabled
1: TXACKE interrupt enabled

Bit 11 TXERRIE: Tx-error interrupt enable
The TXERRIE bit is set and cleared by software.
0: TXERR interrupt disabled
1: TXERR interrupt enabled

Bit 10 TXUDRIE: Tx-underrun interrupt enable
The TXUDRIE bit is set and cleared by software.
0: TXUDR interrupt disabled
1: TXUDR interrupt enabled
Bit 9 **TXENDIE**: Tx-end of message interrupt enable
   The TXENDIE bit is set and cleared by software.
   0: TXEND interrupt disabled
   1: TXEND interrupt enabled

Bit 8 **TXBRIE**: Tx-byte request interrupt enable
   The TXBRIE bit is set and cleared by software.
   0: TXBR interrupt disabled
   1: TXBR interrupt enabled

Bit 7 **ARBLSTIE**: Arbitration lost interrupt enable
   The ARBLSTIE bit is set and cleared by software.
   0: ARBLST interrupt disabled
   1: ARBLST interrupt enabled

Bit 6 **RXACKIE**: Rx-missing acknowledge error interrupt enable
   The RXACKIE bit is set and cleared by software.
   0: RXACKE interrupt disabled
   1: RXACKE interrupt enabled

Bit 5 **LBPEIE**: Long bit period error interrupt enable
   The LBPEIE bit is set and cleared by software.
   0: LBPE interrupt disabled
   1: LBPE interrupt enabled

Bit 4 **SBPEIE**: Short bit period error interrupt enable
   The SBPEIE bit is set and cleared by software.
   0: SBPE interrupt disabled
   1: SBPE interrupt enabled

Bit 3 **BREIE**: Bit rising error interrupt enable
   The BREIE bit is set and cleared by software.
   0: BRE interrupt disabled
   1: BRE interrupt enabled

Bit 2 **RXOVRIE**: Rx-buffer overrun interrupt enable
   The RXOVRIE bit is set and cleared by software.
   0: RXOVR interrupt disabled
   1: RXOVR interrupt enabled

Bit 1 **RXENDIE**: End of reception interrupt enable
   The RXENDIE bit is set and cleared by software.
   0: RXEND interrupt disabled
   1: RXEND interrupt enabled

Bit 0 **RXBRIE**: Rx-byte received interrupt enable
   The RXBRIE bit is set and cleared by software.
   0: RXBR interrupt disabled
   1: RXBR interrupt enabled
## 65.7.7 HDMI-CEC register map

Refer to Section 2.3 for the register boundary addresses.
66 Debug infrastructure

66.1 Introduction

The debug infrastructure allows software designers to debug and trace their embedded software.

The debug features can be controlled via a JTAG/Serial-wire debug access port, using industry standard debugging tools. A trace port allows data to be captured for logging and analysis.

The trace and debug system is designed to support a variety of typical use cases:

- **Low cost trace**
  Limited trace capability is available over the single-wire debug output. This supports code instrumentation using “printf”, tracing of data and address watchpoints, interrupt detection and program counter sampling. Single-wire trace can be maintained even when the processor is switched off or clock-stopped.

- **Breakpoint debugging**
  The processor can be debugged using equipment connected to the JTAG/SWD debug port. This allows breakpoint and watchpoint setting, code stepping, memory access and so on.

- **Tracing code execution via the trace port**
  Trace information is combined into a single trace stream and output to a trace port analyzer in real time. An ID embedded in the trace allows the analyzer to identify the source of each information packet.

- **Continuous trace capturing in a circular buffer**
  Instead of streaming it off-chip, the combined trace information can be stored on-chip in a circular buffer. The trace storage can be started and stopped by different means such as a debugger command, a software command, an external trigger signal, an internal event, and so on.

- **Draining the buffer to the trace port**
  The stored trace can be dumped off-chip to the trace port analyzer. The buffer draining can be initiated by the debugger, software, external trigger, internal event and so on.

- **Reading the buffer with the debugger**
  The debugger can read the contents of the trace buffer via the debug port. This is slower than the trace port, but allows basic trace functionality on the debugger without the cost of a trace port analyzer.

- **Analyzing stored trace in software**
  The trace buffer can be read by the processor core, or transferred into system memory by DMA. This powerful feature allows built-in test software to monitor code execution in real time, analyze and identify faults, handle exceptions autonomously, and so on.

- **Uploading stored trace**
  The stored trace can also be uploaded to a host machine using one of the MCU’s many communication interfaces (USB, USART, SPI, I2C, Ethernet, CAN and so on). This is especially useful if the trace port is not accessible, for example remote monitoring and failure analysis of a deployed product.
66.2 Debug infrastructure features

A comprehensive set of trace and debug features is provided to support software development and system integration:

- Breakpoint debugging
- Code execution tracing
- Software instrumentation
- Cross-triggering
- JTAG debug port
- Serial-wire debug port
- Trigger input and output
- Serial-wire trace port
- Trace port
- Arm® CoreSight™ debug and trace components.

The CoreSight components are described at high level in this document. Detailed information is available in the Arm® documents referenced in Section 66.10.

66.3 Debug infrastructure functional description

66.3.1 Debug infrastructure block diagram

The block diagram shows the logical partitioning of the debug infrastructure.

![Block diagram of debug infrastructure](image-url)
66.3.2 Debug infrastructure powering, clocking and reset

Power domains

The debug components are all located in the core power domain. This means that a debug session is disconnected if the core is powered down, for example in standby mode. This can be prevented by enabling low power emulation mode via the DBGMCU_CR.DBG_STANDBY register bit.

Clock domains

The debugger supplies the clock for the debug port, swtclk, via the debug interface pin, JTCK/SWCLK. This clock is used to register the serial input data in both serial wire and JTAG mode, as well as to operate the state machines and internal logic of the debug port. It must therefore continue to toggle for several cycles after the end of an access, to ensure that the debug port returns to the idle state.

The SWJ-DP contains an asynchronous interface to the ck_dbg domain, which covers the rest of the SWJ-DP and the access ports.

ck_dbg clocks the trace components in the core power domain: System ROM table 2, CoreSight trace funnel, ETF, system CTI and TPIU. It is a gated version of the core domain system clock (rcc_hclk3).

traceclkin is the trace port clock. It is derived from the TRACECLKIN input.
The debug clock, ck_dbg, can be enabled and disabled by a register bit in the DBGMCU or by the debugger using the CDBGWRUPREQ bit in the debug port CTRLSTAT register. The clock must be enabled before the debugger can access any of the debug features on the device. It should be disabled at power up and when the debugger is disconnected, to avoid wasting energy.

The debug and trace components included in the processor (ETM ITM, DWG, FPB and so on) are clocked with the corresponding core clock (rcc_c_ck).

**Debug with low-power modes**

The device includes power-saving features allowing individual power domains to be switched off or stopped when not required. If a power domain is switched off or not clocked, all debug components in that domain are inaccessible to the debugger. To avoid this, power saving mode emulation is implemented. If the emulation is enabled for a domain, the domain still enters power saving mode, but its clock and power are maintained. In other words, the domain behaves as if it is in power saving mode, while the debugger does not lose the connection.

The emulation mode is programmed in the MCU Debug (DBGMCU) unit. For more information, refer to Section 66.8

**Reset of debug infrastructure**

The debug components, except for the debug port and access ports, are reset by a system or power on reset. The debug port (SWJ-DP) is reset by a power-on reset or a low level on nJTRST.

**66.3.3 Security**

The trace and debug components allow a high degree of access to the processor and system during product development. In order to protect user code and ensure that the debug features can not be used to alter or compromise the normal operation of the finished product, these features can be disabled or limited in scope.

Debugger access is disabled while the processor is booting from system flash memory.

The following authentication signals are used by the system to determine which debug features are enabled or disabled:

- **dbgen**: global enable for all debug features
  
  0: All debug features are disabled.
  
  1: Debug features are enabled.

- **niden**: enables trace and performance monitoring (non-invasive debug).
  
  0: Trace generation is disabled.
  
  1: Trace generation is enabled.

For detailed information on the behavior of each component according to the state of the authentication signals, refer to the relevant component chapter or to the relevant Arm® technical documentation.
The state of the signals are set according to the debug state as shown in Table 761.

Table 761. Authentication signal states

<table>
<thead>
<tr>
<th>Debug state</th>
<th>Authentication signal state</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPEN</td>
<td>dbgen = 1 niden = 1</td>
<td>Debug and trace is enabled whatever the state of the processor.</td>
</tr>
<tr>
<td>CLOSED</td>
<td>dbgen = 0 niden = 0</td>
<td>Debug and trace is disabled.</td>
</tr>
</tbody>
</table>

The debug state depends on the product life cycle state, and the debug authentication state (see Section 66.3.4: Debug authentication).

</tr>
<tr>
<td>LOCKED</td>
<td>CLOSED</td>
</tr>
</tbody>
</table>

1. The level of debug access is defined by the SBS debug control register (SBS_DBGCR).
66.3.4 Debug authentication

Figure 1001. Product life cycle states and debug authentication states.

If the device is in CLOSED (product life cycle) state, the debug state is CLOSED. The debug authentication procedure allows a trusted debugger to reopen access without compromising sensitive information called the Root Of Trust (ROT).

Re-opening the debug is possible only if sensitive asset security is ensured. This is called Constrained Debug, as constraints ensure the security of the ROT information.

Alternatively, a partial or full regression mechanism can be used when security of sensitive information cannot be guaranteed. This is called regression, as regression ensures removal of the sensitive information before reopening the debug.

- Full regression corresponds to releasing all code and assets. The intermediate state which allows full regression management is called Regression.

Debug authentication control principle

The debug authentication feature is one of the most critical security features of the system considering that with a debugger one can get access to a large part of the system.

In order to control re-opening of the debug, the device imposes a debug authentication protocol.

The protocol implements a challenge response mechanism based on asymmetric cryptography to authenticate the host. It relies on a key pair, with a Public Key stored in the device, and a Private Key from the host library which is used to sign a random value (the challenge) generated by the device.
The protocol implements a bidirectional communication between the host and the device through a mailbox interface located in the DBGMCU.

The host can write to the mailbox via the JTAG/SWD interface. It expects to get responses and messages from the device via the same mailbox. For details on this protocol, refer to the Application.

The Debug Authentication protocol is launched on a Power On Reset of the device, when an “open request” message is posted by the host.

The protocol is based on:
- Initial message => Posted by the host combined with a reset to launch the Debug Authentication process on the device.
- Challenge message => The device generates a random value, to be signed by the host, when sending back the response.
- Response => The host sends a message to the device proving its authenticity. This is done using a tool to generate a token.

The implementation of the feature on the device is ensured by code embedded in the System Flash. This code is called automatically after reset if an initial message has been posted by the host in the mailbox.

After a first sequence of mutual authentication to align on protocol version, type of device, etc. the device generates a random value that should be signed by the host with a Private Key when building the response.

The STMicroelectronics implementation is based on the ARM PSA-ADAC solution for Debug Authentication.

The Debug Authentication can be implemented using a proprietary or open source protocol. As this feature is critical for security, the STM32H7 comes with Debug Authentication provisioned in System Flash. STMicroelectronics provides the host tools integrated with some debug environments (IDEs).

### 66.4 Serial-wire and JTAG debug port (SWJ-DP)

The SWJ-DP is a CoreSight component that implements an external access port for connecting debugging equipment.

The port can be configured as:
- a 5-pin standard JTAG debug port (JTAG-DP)
- a 2-pin (clock + data) “serial-wire” debug port (SW-DP)

The two modes are mutually exclusive, since they share the same IO pins.

By default, the JTAG-DP is selected on system or power-on reset. The five IOs are configured by hardware in debug alternative function mode. The SWJ-DP incorporates pull-up resistors on the JTDI, JTMS/SWDIO, and nJTRST lines, as well as a pull-down resistor on the JTCK/SWCLK line.

A debugger can select the SW-DP by transmitting the following serial data sequence on JTMS/SWDIO: ....(50 or more ones),...,0,1,1,1,0,0,1,1,1,0,0,1,1,1... (50 or more ‘1’s)... JTCK/SWCLK must be cycled for each data bit.
In SW-DP mode, the unused JTAG lines JTDI, JTDO and nJTRST can be used for other
functions.

All SWJ port IOs can be reconfigured to other functions by software, in which case
debugging is no longer possible.

### 66.4.1 Serial wire debug port

The serial wire debug protocol uses two pins:
- **SWCLK**: clock from host to target
- **SWDIO**: bi-directional serial data

Serial data is transferred LSB first, synchronously with the clock. A transfer comprises three
phases:
1. packet request (8 bits) transmitted by the host
2. acknowledge response (3 bits) transmitted by the target
3. data transfer (33 bits) transmitted by the host (in the case of a write) or target (in the
case of a read)

The data transfer only occurs if the acknowledge response is OK.

If the direction of the data is reversed between each phase, a single clock cycle turn-around
time is inserted.

</tbody>
</table>

*Figure 1002 shows successful write and read transfers.*

*Figure 1002. SWD successful data transfer*

For any FAULT or WAIT ACK response from the target, the data transfer phase is canceled, unless overrun detection is enabled, in which case the data is ignored by the target (in the case of a write), or not driven (in the case of a read).

A line reset must be generated by the host when it is first connected, or following a protocol error. The line reset consists of 50 or more SWCLK cycles with SWDIO high, followed by two SWCLK cycles with SWDIO low.

For more details on the Serial Wire debug protocol, refer to the Arm® Debug Interface Architecture Specification [1].

**Note:** The SWJ-DP implements SWD protocol version 2.
66.4.2  JTAG debug port

The JTAG-DP implements a TAP state machine (TAPSM) based on IEEE 1149.1-1990. The state machine is shown in Figure 1003. It controls two scan chains, one associated with an instruction register (IR) and one with a number of data registers (DR).

When the TAPSM goes through the Capture-IR state, 0b0001 is transferred into the instruction register (IR) scan chain. The IR scan chain is connected between JTDI and JTDO.

While the TAPSM is in the Shift-IR state, the IR scan chain shifts one bit for each rising edge of JTCK. This means that on the first tick:
- The LSB of the IR scan chain is output on JTDO
- Bit [n] of the IR scan chain is transferred to bit [n-1]
- The value on JTDI is transferred to the MSB of the IR scan chain.

When the TAPSM goes through the Update-IR state, the value scanned in the IR scan chain is transferred to the instruction register.

When the TAPSM goes through the Capture-DR state, a value is transferred from one of the data registers onto one of the DR scan chains, connected between JTDI and JTDO.
The value held in the instruction register determines which data register, and associated DR scan chain, is selected.

This data is then shifted while the TAPSM is in the Shift-DR state, in the same way as the IR shift in the Shift-IR state.

When the TAPSM goes through the Update-DR state, the value scanned in the DR scan chain is transferred to the selected data register.

When the TAPSM is in the Run-Test/Idle state, no special actions occur. The IDCODE instruction is loaded in IR.

When active, the nJTRST signal resets the state machine asynchronously to the Test-Logic-Reset state.

The data registers corresponding to the 4-bit IR instructions are listed in Table 766.

| 1110                 | IDCODE        | 32                | ID Code  
  0x6BA00477: Arm® JTAG debug port ID code |
| 1111                 | BYPASS        | 1                 | Bypass  
  A single JTCK cycle delay is inserted between JTDI and JTDO |

The DR registers are described in more detail in the Arm® Debug Interface Architecture Specification [1].
### 66.4.3 Debug port registers

The SW-DP and JTAG-DP both access the debug port (DP) registers. These are listed in Table 767.

The debugger can access the DP registers as follows:

1. Program the SELECT register DPBANKSEL field in the DP to select the register bank to be accessed (see Table 767).
2. Program the A[3:2] field in the DPACC register, if using JTAG, with the register address within the bank. Program the R/W bit to select a read or a write. In the case of a write, program the DATA field with the write data. If using SWD, the A[3:2] and R/W fields are part of the Packet Request word sent to the SW-DP with the APnDP bit reset (see Table 763). The write data is sent in the data phase.

#### Table 767. Debug port registers

<table>
<thead>
<tr>
<th>Address</th>
<th>A[3:2] field value</th>
<th>R/W</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0</td>
<td>00</td>
<td>R</td>
<td>DP_DPIDR register(^2). Contains the IDCODE for the debug port.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>W</td>
<td>DP_ABORT register(^1). aborts the current AP transaction. This register is also used to clear the error flags in the DP_CTRL/STAT register.</td>
</tr>
<tr>
<td>0x4</td>
<td>01</td>
<td>R/W</td>
<td>If DPBANKSEL[3:0] = 0x0 (DP_SELECT register): CTRLSTAT register. Controls the DP and provides status information. If DPBANKSEL[3:0] = 0x1 (DP_SELECT register): DP_DLCR register(^2). Controls the operating mode of the SWD Data Link. If DPBANKSEL[3:0] = 0x2 (DP_SELECT register): DP_TARGETID register. Provides target identification information. If DPBANKSEL[3:0] = 0x3 (DP_SELECT register): DLPIDR register(^2). Provides the SWD protocol version.</td>
</tr>
<tr>
<td>0x8</td>
<td>10</td>
<td>R</td>
<td>RESEND register(^2). Returns the value that was returned by the last AP read or DP_RDBUFF read, used in the event of a corrupted read transfer.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>W</td>
<td>DP_SELECT register. Selects the access port, access port register bank, and DP register at address 0x4.</td>
</tr>
<tr>
<td>0xC</td>
<td>11</td>
<td>R</td>
<td>DP_RDBUFF register. Via JTAG-DP, enables the debugger to get the final result after a sequence of operations (without requesting new JTAG-DP operation). Via SW-DP, contains the result of the preceding AP read access, allowing a new AP access to be avoided.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>W</td>
<td>DP_TARGETSEL register(^2). On a write to DP_TARGETSEL immediately following a line reset sequence, the target is selected if the following conditions are both met: – Bits [31:28] match bits [31:28] in the DP_DLPIDR register. – Bits [27:0] match bits [27:0] in the DP_TARGETID register. Writing any other value deselects the target. Debug tools must write 0xFFFFFFFF to deselect all targets. This is an invalid DP_TARGETID value. All other invalid DP_TARGETID values are reserved.</td>
</tr>
</tbody>
</table>

---

1. Access to the AP ABORT register from the JTAG-DP is done using the ABORT instruction.
2. Only accessible via SW-DP. Register is "reserved" via JTAG-DP.

Bits 31:5  Reserved, must be kept at reset value.

Bit 4  **ORUNERRCLR**: Overrun error clear bit
   0: No effect
   1: Clear CTRLSTAT register’s STICKYORUN bit

Bit 3  **WDERRCLR**: Write data error clear bit
   0: No effect
   1: Clear CTRLSTAT register’s WDATAERR bit

Bit 2  **STKERRCLR**: Sticky error clear bit
   0: No effect
   1: Clear CTRLSTAT register’s STICKYERR bit

Bit 1  **STKCMPCLR**: Sticky compare clear bit
   0: No effect
   1: Clear CTRLSTAT register’s STICKYCMP bit

Bit 0  **DAPABORT**: Abort current AP transaction
   The transaction is aborted if an excessive number of WAIT responses are returned, indicating that the transaction has stalled.
   0: No effect
   1: Abort transaction
Debug port control/status register (DP_CTRLSTAT)

Address offset: 0x4
Reset value: 0x0000 0000

</table>

Bit 31 **CSYSWRUPACK**: System domain power-up status bit - not used in this device

Bit 30 **CSYSWRUPREQ**: System domain power-up control bit - not used in this device

Bit 29 **CDBGWRUPACK**: Debug domain power-up status bit
This bit is read-only. It returns the status of the debug domain power-up acknowledge signal from the power controller.
0: domain powered down
1: domain powered up

Bit 28 **CDBGWRUPREQ**: Debug domain power-up/down control bit
This bit controls the debug domain power-up/down request signal to the power controller.
0: power-down requested
1: power-up requested

Bit 27 **CDBGRSSTACK**: Debug domain reset status bit - not used in this device

Bit 26 **CDBGRSRQ**: Debug domain reset control bit - not used in this device

Bits 25:24 Reserved, must be kept at reset value.

Bits 23:12 **TRNCNT[11:0]**: Transaction counter
To program a sequence of transactions to incremental addresses via an AP, TRNCNT bits are loaded with the number of transactions to perform. It is decremented on successful completion of each transaction.

Bits 11:8 **MASKLANE[3:0]**: Pushed-compare and pushed-verify masking bits
The field indicates the bytes to be masked in pushed-compare and pushed-verify operations (DP_CTRLSTAT register’s field TRNMODE = 1 or 2). In the pushed operations, the word supplied in an AP write transaction is compared with the current value at the target AP address.
0b1XXX: include byte lane 3 in comparisons
0bX1XX: include byte lane 2 in comparisons
0bXX1X: include byte lane 1 in comparisons
0bXXXX: include byte lane 0 in comparisons
Bit 7 **WDATAERR**: Write data error in SW-DP
The bit indicates:
- a parity or a framing error on the data phase of a write operation, or
- a write operation that had been accepted by the DP has then been discarded without being submitted to the AP
This bit is read-only. It is reset by writing 1 to the WDERRCLR bit of the DP_ABORT register.
0: No error
1: Error has occurred
This bit is reserved in JTAG-DP.

Bit 6 **READOK**: AP read response in SW-DP
This bit indicates the response to the last AP read access. It is read-only.
0: Read not OK
1: Read OK
This bit is reserved in JTAG-DP.

Bit 5 **STICKYERR**: Transaction error (read-only in SW-DP, R/W in JTAG-DP)
This bit indicates that an error occurred during an AP transaction.
0: No error
1: Error has occurred
In the SW-DP, this bit is reset by writing 1 to the STKERRCLR bit of the DP_ABORT register.
In the JTAG-DP, this bit is reset by programming it to 1.

Bit 4 **STICKYCMP**: Compare match (read-only in SW-DP, R/W in JTAG-DP)
This bit indicates that a match occurred in a pushed operation.
0: Match if TRNMODE = 0x1; no match if TRNMODE = 0x2
1: No match if TRNMODE = 0x1; match if TRNMODE = 0x2
In the SW-DP, this bit is reset by writing 1 to the STKCMPCLR bit in the DP_ABORT register.
In the JTAG-DP, this bit is reset by programming it to 1.

Bits 3:2 **TRNMODE[1:0]**: Transfer mode for AP write operations
For read operations, this field must be set to 0x0.
0x0: Normal operation - AP transactions are passed directly to the AP.
0x1: Pushed-verify operation. The DP stores the write data and performs a read transaction at the target AP address. The result of the read operation is compared with the stored data. If they do not match, the STICKYCMP bit is set.
0x2: Pushed-compare operation. The DP stores the write data and performs a read transaction at the target AP address. The result of the read is compared with the stored data. If they match, the STICKYCMP bit is set.
0x3: Reserved
In pushed operations, only the data bytes indicated by the MASKLANE field are included in the comparison.

Bit 1 **STICKYORUN**: Overrun (read-only in SW-DP, R/W in JTAG-DP)
This bit indicates that an overrun occurred (a new transaction received before previous transaction completed). This bit is only set if the ORUNDETECT bit is set.
0: No overrun
1: Overrun occurred
In the SW-DP, this bit is reset by writing 1 to the ABORT register's ORUNERRCLR bit. In the JTAG-DP, this bit is reset by writing a 1 to it.

Bit 0 **ORUNDETECT**: Overrun detection mode enable
0: Overrun detection disabled
1: Overrun detection enabled. In the event of an overrun, the STICKYORUN bit is set and subsequent transactions are blocked until the STICKYORUN bit is cleared.
Debug port data link control register (DP_DLCR)

Address offset: 0x4
Reset value: 0x0000 0040

**Bits 31:10** Reserved, must be kept at reset value.

**Bits 9:8** \text{TURNROUND}[1:0]: Tristate period for SWDIO
- 0x0: 1 data bit period
- 0x1: 2 data bit periods
- 0x2: 3 data bit periods
- 0x3: 4 data bit periods

**Bits 7:0** Reserved, must be kept at reset value.

Debug port target identification register (DP_TARGETID)

Address offset: 0x4
Reset value: 0x1485 0041

**Bits 31:28** \text{TREVISION}[3:0]: Device revision number
- 0x1

**Bits 27:12** \text{TPARTNO}[15:0]: Target part number
- 0x4850: STM32H7Rx/7Sx

**Bits 11:1** \text{TDESIGNER}[10:0]: Target designer JEDEC code
- 0x020: STMicroelectronics

**Bit 0** Reserved, must be kept at reset value.
Debug port data link protocol identification register (DP_DLPIDR)

- **Bits 31:28 TINSTANCE[3:0]:** Target instance number
  The field defines the instance number for the target device in a multi-drop system. It must be programmed with the same value as TINSTANCE field of DP_DLPIHDR register, in order to select this device.

- **Bits 27:12 TPARTNO[15:0]:** Target part number
  The field defines the part number for the target device. It must be programmed with the same value as TPARTNO field of DP_TARGETID register, in order to select this device.

- **Bits 11:1 TDESIGNER[10:0]:** Target designer JEDEC code
  The field defines the JEDEC code for the target device. It must be programmed with the same value as TDESIGNER field of DP_TARGETID register, in order to select this device.

- **Bit 0 Reserved, must be kept at reset value.**
### 66.4.4 Debug port register map

These registers are not on the CPU memory bus, they are only accessed through SW-DP and JTAG-DP debug interface.

The debug port address offset is 4 bits wide, where the 2 most significant bits are defined in the JTAG-DP register DPACC or SW-DP packet request A[3:2] field. The 2 least significant bits are 00.

**Table 768. Debug port register map and reset values**

| Offset | Register name       | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

Access ports (AP) attached to the DP:

1. **AP1**: Cortex-M7 access port (AHB-AP). Allows access to the debug and trace features integrated in the Cortex-M7 processor core via an AHB-Lite bus connected to the AHB port of the processor.

2. **AP0**: System access port (APB-AP). Allows access to the debug and trace features on the system APB debug bus, that is, all components not included in the processor core.

All access ports are of MEM-AP type, that is, the debug and trace component registers are mapped in the address space of the associated debug bus. The AP is seen by the debugger as a set of 32-bit registers organized in banks of four registers each. Some of these registers are used to configure or monitor the AP itself, while others are used to perform a transfer on the bus. The AP registers are listed in Table 769.
The address of the AP registers is composed of:
- bits [7:4]: content of the DP_SELECT register’s APBANKSEL field
- bits [3:2]: content of the A(3:2) field of the APACC data register in the JTAG-DP (see Table 766) or of the SW-DP Packet Request (see Table 763), depending on the debug interface used
- bits [1:0]: Always set to 0

The content of the SELECT register APSEL field in the DP defines which MEM-AP is being accessed.

The debugger can access the AP registers as follows:
1. Program the DP_SELECT register’s APSEL field to choose one of the APs, and the APBANKSEL field to select the register bank to be accessed.
2. Program the A(3:2) field in the APACC register, if using JTAG, with the register address within the bank. Program the RnW bit to select a read or a write. In the case of a write, program the DATA field with the write data. If using SWD, the A(3:2) and RnW fields are part of the Packet Request word sent to the SW-DP with the APnDP bit set (see Table 763). The write data is sent in the data phase.

The debugger can access the memory mapped debug component registers through the MEM-AP registers (using the AP register access procedure described above) as follows:
1. Program the transaction target address in the TAR register.
2. Program the CSW register, if necessary, with the transfer parameters (AddrInc for example).
3. Write to or read from the DRW register to initiate a bus transaction at the address held in the TAR register. Alternatively, a read or write to banked data register BDn triggers an access to address TAR[31:4] + n (this allows an access to the next four consecutive addresses without changing the address in the TAR register).

For more detailed information on the MEM-AP, refer to the Arm® Debug Interface Architecture Specification [1].

### Access port control/status word register (AP_CSW)

Address offset: 0x0

Reset value: 0x0000 0002 (APB-AP), 0x4000 0002 (AHB-AP)

| Bit 31 | Reserved, must be kept at reset value. |
| Bit 30 | SPROT: Secure transfer request bit |
|        | In the APB-AP, this field is reserved. In the AHB-APs, this field sets the protection attribute HPROT[6] of the bus transfer. |
|        | 0: Reserved. |
|        | 1: Non-secure transfer. |
| Bit 29 | Reserved, must be kept at reset value. |

**Bits 28:24** PROT[4:0]: Bus transfer protection bits

In the APB-AP, this field is reserved. In the AHB-APs, this field sets the protection attributes HPROT[4:0] of the bus transfer.

- 0bXXX00: Instruction fetch
- 0bXXX01: Data access
- 0bXXX0X: User mode
- 0bXXX1X: Privileged mode
- 0bXX0XX: Non-bufferable
- 0bXX1XX: Bufferable
- 0bX00XX: Non-cacheable
- 0bX10XX: Cacheable
- 0b000XX: Non-exclusive
- 0b100XX: Exclusive

**Bit 23** SPISTATUS: Status of SPIDEN authentication signal

This bit determines whether the debugger can access secure memory. This field is reserved in the APB-AP.

- 0: Secure AHB transfers are not supported
- 1: Not used

**Bits 22:12** Reserved, must be kept at reset value.

**Bits 11:8** MODE[3:0]: Barrier support enabled bit

These bits define if the memory barrier operation is supported.

- 0x0: Not supported

**Bit 7** TRINPROG: Transfer in progress

This bit indicates that an AP bus transfer is in progress.

- 0: No transfer in progress.
- 1: Bus transfer in progress.
Bit 6 **DEVICEEN**: Device Enable bit
This bit defines whether the AP can be accessed or not.
1: AP access enabled.

Bits 5:4 **ADDRINC\[1:0\]**: Auto-increment mode bits
These bits define whether the TAR address is automatically incremented after a transaction.
0x0: no auto-increment
0x1: Address is incremented by the size in bytes of the transaction (SIZE field).
0x2: Packed transfers enabled (Only in AHB-APs - reserved in APB-AP). A 32-bit AP access generates a 1 x 32-bit, 2 x 16-bit or 4 x 8-bit bus transaction corresponding to the programmed transaction size. The data is packed or unpacked accordingly.
0x3: Reserved

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **SIZE\[2:0\]**: Size of next memory access transaction (only for AHB-APs)
0x0: Byte (8-bit)
0x1: Half-word (16-bit)
0x2: Word (32-bit)
0x3-0x7: Reserved
For APB-AP, this field is read-only and fixed at 0x2 (32-bit).
**AP transfer address register (AP_TAR)**

Address offset: 0x04  
Reset value: 0x0000 0000

<table>

66.6 Trace and debug subsystem functional description

The trace and debug subsystem features the following CoreSight components:

- System ROM tables
- System cross-trigger interface (CTI)
- Cross-trigger matrix (CTM)
- Trace port interface unit (TPIU)
- Trace bus funnel (CSTF)
- Embedded trace FIFO (ETF)
- Serial wire output (SWO)

These components are accessible by the debugger via the system APB-AP and its associated APB-D debug bus. They are also accessible by the Cortex-M7 processor.

The MCU debug unit (DBGMCU) is also accessed via the APB-D. This component contains registers for configuring the device behavior in Debug mode.

A trace bus replicator branches the trace bus from the CPU’s ITM CoreSight component to ETF and SWO, through trace bus funnels.

66.6.1 System ROM tables

There are two ROM tables on the APB-D bus. The ROM table is a CoreSight component that contains the base addresses of all the CoreSight components on the APB-D bus. These tables allow a debugger to discover the topology of the CoreSight components automatically.

The first table points to the second table, and to the CoreSight components located in D3 power domain: SWO, DBGMCU. The table occupies a 4-Kbyte, 32-bit wide chunk of the APB-D address space, from 0xE00E0000 to 0xE00E0FFC when accessed by the debugger, and from 0x5C000000 to 0x5C000FFC when accessed from the system bus.
The second table occupies a 4-Kbyte, 32-bit wide chunk of APB-D address space, from 0xE00F0000 to 0xE00F0FFC when accessed by the debugger, and from 0x5C010000 to 0x5C010FFC when accessed from the system bus.

The top of each ROM table contains a number of read-only registers, including the standard CoreSight component and peripheral identity registers, see section System ROM registers.

Each debug component occupies one or more 4 Kbyte blocks of address space. This block of address space is referred to as the debug register file for the component.
The component address offset field of a ROM Table entry points to the start of the last 4 Kbyte block of the address space of the component. This block always contains the component and peripheral ID registers for the component, starting at offset 0xFD0 from the start of the block. The 4 Kbyte count field PIDR4 [7:4], specifies the number of 4 Kbyte blocks for the component. Therefore, the process for finding the start of the address space for a component is:

1. Read the ROM-table entry for the component and extract its Address_Offset [18:0] from bits [31:12] of the ROM-table entry.
2. Use the address offset, together with the base address of the ROM table, ROM_Base_Address, to calculate the base address of the component:
   \[
   \text{Component\_Base\_Address} = \text{ROM\_Base\_Address} + \text{Address\_Offset}
   \]
   The Component_Base_Address is the start address of the 4 Kbyte block of the address space for the component.
3. Read the peripheral ID4 register for the component. The address of this register is:
   \[
   \text{Peripheral\_ID4\_address} = \text{Component\_Base\_Address} + 0xFD0
   \]
4. Extract the 4 Kbyte count field [7:4] from the value of the Peripheral ID4 Register.
5. Use the 4 Kbyte count field value to calculate the start address of the address space for the component. If the field value is 0b0000, which corresponds to a count value of 1, the address space for the component starts at Component_Base_Address obtained at stage 2.

The topology for the CoreSight components on the APB-D is shown in Figure 1005.
For more information on the use of the ROM table, refer to the Arm® Debug Interface Architecture Specification [1].
### 66.6.2 System ROM registers

**SYSROM memory type register (SYSROM_MEMTYPE)**

Table 774. System ROM table 2 register map and reset values
**66.6.4 Cross trigger interfaces (CTI) and matrix (CTM)**

The cross trigger interfaces (CTI) and cross trigger matrix (CTM) together form the CoreSight embedded cross trigger feature. There are two CTI components, one at system level and one dedicated to the Cortex-M7. The two CTIs are connected to each other via the CTM. The system-level CTI is accessible to the debugger via the system access port and associated APB-D. The Cortex-M7 CTI is physically integrated in the Cortex-M7 core, and is accessible via the Cortex-M7 access port and associated AHBD.

![Figure 1006. Embedded cross trigger](image)

The CTIs allow events from various sources to trigger debug and/or trace activity. For example, a transition detected on an external trigger input can start code trace.

Each CTI has up to 8 trigger inputs and 8 trigger outputs. Any input can be connected to any output, on the same CTI, or on another CTI via the CTM.

The trigger input and output signals for each CTI are listed in Table 775 to Table 778.

</tbody>
</table>
There are four event channels in the cross trigger matrix, which allows up to four parallel bidirectional connections between trigger inputs and outputs on different CTIs. To connect input number \( m \) on CTI \( x \) to output number \( n \) on CTI \( y \), the input must be connected to an event channel \( p \) using the \( \text{CTIINEN}_m \) register of CTI \( x \). The same channel \( p \) must be connected to the output using the \( \text{CTIOUTEN}_n \) register of CTI \( y \). Note: this applies even if the input and output belong to the same CTI.

An input can be connected to more than one channel (up to four), so an input can be routed to several outputs. Similarly, an output can be connected to several inputs. It is also possible to connect several inputs/outputs to the same channel.

**Figure 1007. Mapping of trigger inputs to outputs**

For more information on the cross-trigger interface CoreSight component, refer to the Arm® CoreSight™ SoC-400 Technical Reference Manual [2].

**w**  w  w  w
CTI application pulse register (CTI_APPPULSE)

Address offset: 0x01C
Reset value: 0x0000 0000

Bits 31:4  Reserved, must be kept at reset value.
Bits 3:0  APPCLEAR[3:0]: Clear channel event
0bXXX0: No effect
0bXXX1: Clear event on Channel 0
0bX0X0: No effect
0bX1X: Clear event on Channel 1
0bX0XX: No effect
0bX1XX: Clear event on Channel 2
0b0XXX: No effect
0b1XXX: Clear event on Channel 3

CTI trigger IN x enable register (CTI_INENx)

Address offset: 0x0A0 + 0x4 * x, (x = 0 to 7)
Reset value: 0x0000 0000

Bits 31:4  Reserved, must be kept at reset value.
Bits 3:0  APPPULSE[3:0]: Pulse channel event
This register clears itself immediately.
0bXXX0: No effect
0bXXX1: Generate pulse on Channel 0
0bX0X0: No effect
0bX1X: Generate pulse on Channel 1
0bX0XX: No effect
0bX1XX: Generate pulse on Channel 2
0b0XXX: No effect
0b1XXX: Generate pulse on Channel 3
Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **TRIGINEN[3:0]**: Cross-trigger event enable

Enables or disables a cross-trigger event on each of the four channels when CTITRIGINx is activated (x = 0 to 7).

- 0bXXX0: Trigger n does not generate events on Channel 0
- 0bXXX1: Trigger n generates events on Channel 0
- 0bXXOX: Trigger n does not generate events on Channel 1
- 0bXX1X: Trigger n generates events on Channel 1
- 0bX0XX: Trigger n does not generate events on Channel 2
- 0bX1XX: Trigger n generates events on Channel 2
- 0b0XXX: Trigger n does not generate events on Channel 3
- 0b1XXX: Trigger n generates events on Channel 3

**CTI trigger OUT x enable register (CTI_OUTENx)**

Address offset: 0x0A0 + 0x4 * x, (x = 0 to 7)

Reset value: 0x0000 0000

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **TRIGOUTEN[3:0]**: Enable trigger upon event

For each channel, the field defines whether an event on that channel generates a trigger on CTITRIGOUTx (x = 0 to 7).

- 0bXXX0: Channel 0 events do not generate triggers on Trigger output n
- 0bXXX1: Channel 0 events generate triggers on Trigger output n
- 0bXX0X: Channel 1 events do not generate triggers on Trigger output n
- 0bXX1X: Channel 1 events generate triggers on Trigger output n
- 0bX0XX: Channel 2 events do not generate triggers on Trigger output n
- 0bX1XX: Channel 2 events generate triggers on Trigger output n
- 0b0XXX: Channel 3 events do not generate triggers on Trigger output n
- 0b1XXX: Channel 3 events generate triggers on Trigger output n

**CTI trigger IN status register (CTI_TRGISTS)**

Address offset: 0x130

Reset value: 0x0000 0000

Links to official STMicroelectronics documentation for further details.
Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **TRIGINSTATUS[7:0]**: Trigger input status
There is one bit of the register for each CTITRIGIN input. When a bit is set to 1 it indicates that the corresponding trigger input is active. When it is set to 0, the corresponding trigger input is inactive.

**CTI trigger OUT status register (CTI_TRGOSTS)**
Address offset: 0x134
Reset value: 0x0000 0000

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **GATEEN[3:0]**: Channel output enable  
For each channel, defines whether an event on that channel can propagate over the CTM to other CTIs.  
0bXXX0: Channel 0 events do not propagate  
0bXXX1: Channel 0 events propagate  
0bXX0X: Channel 1 events do not propagate  
0bXX1X: Channel 1 events propagate  
0bX0XX: Channel 2 events do not propagate  
0bX1XX: Channel 2 events propagate  
0b0XXX: Channel 3 events do not propagate  
0b1XXX: Channel 3 events propagate
CTI claim tag set register (CTI_CLAIMSET)

Address offset: 0xFA0
Reset value: 0x0000 000F

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  CLAIMSET[3:0]: Set claim tag bits
Write:
0000: No effect
0001: Set bit 0
xx1x: Set bit 1
xx1x: Set bit 2
1xxx: Set bit 3
Read:
0xF: Indicates there are four bits in claim tag

CTI claim tag clear register (CTI_CLAIMCLR)

Address offset: 0xFA4
Reset value: 0x0000 0000

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  CLAIMCLR[3:0]: Reset claim tag bits
Write:
0000: No effect
0001: Clear bit 0
xx1x: Clear bit 1
xx1x: Clear bit 2
1xxx: Clear bit 3
Read: Returns current value of claim tag

Bits 31:3  
Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the CTI_LAR register  
0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock  
This bit always returns zero when read by an external debugger.  
0: Write access is permitted  
1: Write access is blocked. Only read access is permitted.

Bit 0 **LOCKEXIST**: Existence of lock control mechanism  
The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.  
0: No lock control mechanism exists  
1: Lock control mechanism is implemented

66.6.7 Trace funnel (CSTF)

The trace funnel is a CoreSight component that combines the ATB buses from two trace sources into one single ATB. The CSTF has two ATB slave ports, and one ATB master port. An arbiter selects the slave ports according to a programmable priority.

The slave ports are connected as follows:
- S0: Cortex-M7 ETM
- S1: Cortex-M7 ITM

The CSTF registers allow the slave ports to be individually enabled, and their priority settings to be configured. The priorities can be modified only when the trace is disabled. The arbitration works as follows:
- The arbiter selects the slave port with the highest assigned priority that has data valid
- Transfers are passed from the selected slave to the master port until *min_hold_time is reached*, where *min_hold_time* is programmable in the CONTROL register.
- A new arbitration is then performed

High priority should be assigned to slave ports connected to sources with a small amount of buffering, or where data loss can not be tolerated. Low priority should be assigned to less critical sources or those with large buffers.

For more information on the ATB Funnel CoreSight component, refer to the Arm® CoreSight™ SoC-400 Technical Reference Manual [2].
### 66.6.8 Trace funnel registers

Bits 31:3  Reserved, must be kept at reset value.
Bit 2 **LOCKTYPE**: Size of the CSTF_LAR register
- 0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock
This bit always returns zero when read by an external debugger.
- 0: Write access is permitted
- 1: Write access is blocked. Only read access is permitted.

Bit 0 **LOCKEXIST**: Existence of lock control mechanism
The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.
- 0: No lock control mechanism exists
- 1: Lock control mechanism is implemented

**CSTF authentication status register (CSTF_AUTHSTAT)**

66.6.10 Embedded trace FIFO (ETF)

The ETF is a 2 Kbyte memory that captures trace data from two trace sources, namely the ETM and ITM of the CPU core. The ETF is a design configuration of the CoreSight™ trace memory controller component.

The ETF can be used in three modes (selected in the mode register):

1. Hardware FIFO mode
   - The trace memory is used as a FIFO that is drained through the ATB master interface. Trace data is captured by the trace RAM and when full, the incoming trace stream is stalled. When the Trace buffer is not empty, trace data is drained out through the ATB master interface to the TPIU.
   - In this mode, the role of the FIFO is to smooth the flow of trace information arriving at the trace port. Since the trace data can be very bursty by nature, the peak data rate can easily exceed the port capability, resulting in an overflow. The ETF allows a steady data rate at the trace port, which can then be sized according to the average rate rather than the peak. The trace is stored off-chip in real time by the trace port analyzer tool, and so the trace log can be very big.

2. Software FIFO mode
   - The trace memory is used as a FIFO that can be read through the RRD Register while the trace is being captured. Trace data is captured by the trace RAM and when full, the incoming trace stream is stalled.
   - This mode allows the trace to be transferred by DMA into the system memory, or to a high speed interface (SPI, USB and so on), or even monitored by software. Note that unlike the hardware FIFO mode, this mode is invasive, since it uses system resources which are shared by the processor.

3. Circular buffer mode
   - The trace memory is used as a circular buffer. Trace data is captured in the trace memory starting from the location pointed to by the write pointer register. When the trace memory is full, incoming trace data continues to be overwritten in the trace memory until a stop condition occurs.
   - In this mode, the ETF stores the trace data on-chip, so the trace log size is limited to that of the ETF SRAM, 2 Kbytes in this case. Being a circular buffer, when the FIFO is full, incoming trace data overwrites the oldest stored data and the oldest stored data is lost. Therefore the content of the trace buffer represents the most recent activity of the processor, up to the point when the buffer was stopped, rather than all the activity since the trace was started.

   There are three possible methods to read the buffer contents once the trace stops:
   - via the Trace port - with the TPIU enabled, the contents of the buffer are output over the Trace port. This can be done by setting the DRAINBUF bit in the ETF_FFCR register.
   - via the Debug port - the debugger can read the buffer via the RRD register that is accessible over the system APB-D.
   - by software - the processor can read the buffer via the RRD register, since the APB-D is accessible from the system bus.
The ETF can be moved to any one of these states:

- **Disabled**
  This state is entered after a reset, or when trace capture is disabled. The ETF must only be programmed in this state.

- **Running**
  Trace capture is performed in this state. It is entered by enabling trace capture while in Disabled state.

- **Stopped**
  Trace capture is stopped in this state, but the contents of the buffer can be read out or drained. This state is entered after a stop event (trigger or flush).

- **Disabling**
  This is a transition state while disabling trace capture.

- **Stopping**
  This is a transition state while stopping trace capture.

- **Draining**
  This state is entered while draining the buffer in Stopped state.

The state transition diagram is shown in Figure 1008.

**Figure 1008. ETF state transition diagram**

For more information on the CoreSight™ trace memory controller component, refer to the Arm® CoreSight™ trace memory controller technical reference manual [3].

Bits 31:5  Reserved, must be kept at reset value.

Bit 4  **EMPTY**: Trace FIFO empty

This bit is valid only when the TCEN bit of the ETF_CTL register is high. This bit reads as zero when TCEN is low.
0: Trace FIFO contains data
1: Trace FIFO is empty.

Note: Empty trace FIFO does not mean that the ETF pipeline is empty. The latter is indicated by the FTEMPY bit.

Bit 3  **FTEMPY**: Formatter empty

This bit is set when a trace capture has stopped, and all internal pipelines and buffers have been drained. Unlike READY, it is not affected by buffer drains. The ACQCOMP output reflects the value of this bit.
Bit 2 **READY**: ETF ready
   This bit is set when a trace capture has stopped and all internal pipelines and buffers have been drained (Stopped or Disabled state)

Bit 1 **TRIGD**: Triggered
   The Triggered bit is set when a trace capture is in progress and the TMC has detected a Trigger Event. This bit is cleared when leaving Disabled state.
   This bit is operational only in the Circular buffer mode. In all other modes, this bit is always low.
   This bit does not indicate that a trigger has been embedded in the formatted output trace data from the TMC. Trigger indication on the output trace stream is determined by the programming of the Formatter and Flush Control Register, ETF_FFCR.

Bit 0 **FULL**: Trace buffer full
   In circular buffer mode, this flag is set when the RAM write pointer wraps around the top of the buffer, and remains set until the TCEN bit of the ETF_CTL register is cleared and set.
   In software and hardware FIFO modes, this flag indicates that the current space in the trace memory is less than or equal to the value programmed in the ETF_BUFWM Register, that is, Fill level >= MEM_SIZE - BUFWM.
   This bit is cleared when leaving Disabled state. The FULL output reflects the value of this register bit.

Bits 31:0 **RRD[31:0]**: RAM Read Data.
   **Circular buffer mode:**
   When in Stopped state and the buffer is not empty, reading this register returns the next word of data from the trace buffer. When the whole trace buffer has been read, the Empty bit in the ETF_STS Register is set, and subsequent reads return 0xFFFFFFF. Reading this register when not in Stopped state returns 0xFFFFFFFF.
   **Software FIFO mode:**
   Reading this register returns data from the FIFO. If this register is read when the FIFO is empty, the data returned is 0xFFFFFFFF.
   **Hardware FIFO mode:**
   Reading this register returns 0xFFFFFFFF.
ETF RAM read pointer register (ETF_RRP)

Bits 31:13  Reserved, must be kept at reset value.

Bits 12:0  **RRP[12:0]: RAM Read Pointer**

The RAM Read Pointer Register contains the value of the read pointer that is used to read entries from the trace memory over the APB interface via the ETF_RRD register. The pointer can be programmed with a byte address, 64-bit aligned (that is, bits 0 to 3 should be zero). The pointer is incremented by 8 each time a full 64-bit FIFO entry has been written. When the pointer reaches its maximum value, it wraps around.

This register can only be written to while in Disabled state. It can be read in Disabled state, in Stopped state in Circular buffer mode and SW FIFO mode, and also in Running and Stopping states in SW FIFO mode.

Bits 31:13  Reserved, must be kept at reset value.

Bits 12:0  **RWP[12:0]: RAM write pointer**

The RAM write pointer register contains the value of the write pointer that is used to write entries into the trace memory over the APB interface via the ETF_RWD register. The pointer can be programmed with a byte address, 64-bit aligned (that is, bits 0 to 3 should be zero). The pointer is incremented by 8 each time a full 64-bit FIFO entry has been read. When the pointer reaches its maximum value, it wraps around.

This register can only be written to while in Disabled state. It can be read in Disabled state, in Stopped state in Circular buffer mode and SW FIFO mode, and also in Running and Stopping states in SW FIFO mode.

</tr>
</tbody>
</table>

Bits 31:11  Reserved, must be kept at reset value.

Bits 10:0  TRG[10:0]: Trigger counter

In Circular buffer mode, specifies the number of 32-bit words to capture in the trace RAM following the detection of either a rising edge on the TRIGIN input or a trigger packet in the incoming trace stream, ATID = 7’h7D. On capturing the specified number of data words, a trigger event occurs. The effect of a trigger event on the ETF behavior is controlled by the FFCR Register.

The number of 32-bit words written into the trace RAM following the trigger is the value stored in this register, plus one. This register is ignored when the ETF is in Software FIFO mode or Hardware FIFO mode. When the trigger counter starts counting, any additional triggers, either on TRIGIN or in the incoming trace stream, are ignored until the counter reaches zero. When the trigger counter has reached zero, it remains at zero until it is re-programmed with a write to this register.

This register is cleared when READY goes high, so that the state of the counter when trace capture has stopped does not affect a subsequent trace capture session. Writing to this register when not in Disabled state results in unpredictable behavior.

A read access to this register is permitted at any time when in Disabled state, or in Circular buffer mode. A read access returns the current value of the trigger counter.

Bits 31:2  **Reserved**, must be kept at reset value.

Bits 1:0  **MODE[1:0]**: Operation mode

00b: Circular buffer mode
In this mode, the trace memory is used as a circular buffer. Trace data is captured in the trace memory starting from the location pointed to by the write pointer register. Even when the trace memory is full, incoming trace data continues to be overwritten into the trace memory until a stop condition has occurred.

01b: Software FIFO mode
In this mode, the trace memory is used as a FIFO that can be read through the RRD Register while a trace is being captured. Trace data is captured in the trace RAM and when full, the incoming trace stream is stalled.

10b: Hardware FIFO mode
In this mode, the trace memory is used as a FIFO that is drained through the ATB master interface. Trace data is captured in the trace RAM and when full, the incoming trace stream is stalled. When the trace buffer is non-empty, trace data is drained out through the ATB master interface to the TPIU.

11b: Reserved
ETF latched buffer fill level register (ETF_LBUFLVL)

</tbody>
</table>

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  LBUFLEVEL[11:0]: Latched buffer fill level

- Reading this register returns the maximum fill level of the trace memory in 32-bit words since this register was last read. Reading this register also results in its contents being updated to the current fill level.
- When entering Disabled state, this register retains its last value. While in Disabled state, reads from this register do not affect its value. When exiting Disabled state, the LBUFLEVEL register is cleared.
- This register is used for performance analysis of the trace system.

ETF current buffer fill level register (ETF_CBUFLVL)

</tr>
</tbody>
</table>

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  CBUFLEVEL[11:0]: Current buffer fill level

- Reading this register returns the current fill level of the trace memory in 32-bit words.
- This register is cleared when TCEN is low.
ETF buffer level watermark register (ETF_BUFWM)

Address offset: 0x034
Reset value: 0x0000 0000

| Bits 31:11 | Reserved, must be kept at reset value. |
| Bits 10:0 | BUFWM[10:0]: Buffer level watermark |

The value programmed into this register indicates the required threshold vacancy level of the trace memory in 32-bit words. When the space in the FIFO is less than or equal to this value, that is, fill level >= MEM_SIZE - BUFWM, the FULL output is pulled high and the FULL bit in the STS Register is set.

This register is used only in Software FIFO and Hardware FIFO modes. In Circular buffer mode, this functionality can be obtained by programming the RWP to the required vacancy trigger level, so that when the pointer wraps around, the FULL bit is set indicating that the vacancy level has fallen below the required level.

The maximum value that can be written into this register is MEM_SIZE - 1. In this case, the FULL bit output is asserted after the first 32-bit word is written to trace memory.

Writing to this register other than when in disabled state results in unpredictable behavior.

ETF formatter and flush status register (ETF_FFSR)

Address offset: 0x300
Reset value: 0x0000 0002

| Bits 31:2 | Reserved, must be kept at reset value. |
| Bit 1 | FTSTOPPED: Formatter stopped |

This bit behaves in the same way as the FEMPTY bit in the ETF_STS register.

| Bit 0 | FLINPROG: Flush in progress |

Indicates whether a flush on the ATB slave port is in progress. This bit reflects the status of the AFVALIDS output. A flush can be initiated by the flush control bits in the ETF_FFCR register, or requested by the ATB master port.

0: No flush in progress
1: Flush in progress

</tr>
</tbody>
</table>

Bits 31:15  Reserved, must be kept at reset value.

Bit 14  DRAINBUF: Drain buffer
This bit is used to enable draining of the trace data through the ATB master interface after the formatter has stopped. This is useful in circular buffer mode to capture trace data into trace memory and then to drain the captured trace through the ATB master interface.
Writing a 1 to this bit when in Stopped state starts the drain of the trace buffer contents through the ATB Master interface. This bit always reads as zero. The READY bit in the ETF_STS register goes low while the drain is in progress.
This bit is only functional when the ETF is in Circular buffer mode and formatting is enabled, that is, the ENFT bit in the ETF_FFCR register is set. Setting this bit when the ETF is in any other mode, or when not in Stopped state, results in Unpredictable behavior.
When trace capture is complete in Circular buffer mode, all of the captured trace must be retrieved from the trace memory through the same mechanism, either read all trace data out through RRD reads, or drain all trace data by setting the DRAINBUF bit. Setting the DRAINBUF bit after some of the captured trace has been read out through RRD results in unpredictable behavior.

Bit 13  STPONTRGEV: Stop on trigger event
0: No effect
1: Stop trace capture when a trigger event occurs
Enabling the ETF in Software FIFO mode or Hardware FIFO mode with this bit set results in unpredictable behavior.

Bit 12  STOPONFL: Stop on flush
0: No effect
1: Stop trace capture when flush is completed
If a flush is initiated by the ATB master interface, its completion does not lead to a formatter stop regardless of the value programmed in this bit.

Bit 11  Reserved, must be kept at reset value.

Bit 10  TRIGONFL: Trigger on flush
0: No effect
1: Indicates a trigger in the trace stream when flush is completed
If ENFT and ENTI are both clear, this bit is ignored and no trigger is inserted into the trace stream.
If a flush is initiated by the ATB master interface, its completion does not lead to a trigger indication regardless of the value programmed in this bit.
Bit 9 **TRGONTRGEV**: Trigger on trigger event
   0: No effect
   1: Indicates a trigger in the trace stream when a trigger event occurs
   If ENFT and ENTI are both clear, this bit is ignored and no trigger is inserted into the trace stream.
   This bit is not supported in Software FIFO mode nor Hardware FIFO mode.

Bit 8 **TRGONTRGIN**: Trigger on trigger in
   0: No effect
   1: Indicate a trigger in the trace stream when a rising edge is detected on the TRIGIN input.
   If ENFT and ENTI are both clear, this bit is ignored and no trigger is inserted into the trace stream.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FLUSHMAN**: Manual flush
   0: No effect
   1: Flush the trace FIFO and pipeline
   This bit is cleared automatically when the flush is complete. If the TCEN bit in the ETF_CTL register is 0, writes to this bit are ignored.

Bit 5 **FONTRGEV**: Flush on trigger event
   0: No effect
   1: Flush the trace FIFO and pipeline if a trigger event occurs
   This bit is not supported in Software FIFO mode or Hardware FIFO mode. If STPONTRGEV is set, this bit is ignored.

Bit 4 **FONFLIN**: Flush on flush in
   0: No effect
   1: Flush the trace FIFO and pipeline if when a rising edge is detected on the FLUSHIN input

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **ENTI**: Enable trigger insertion
   Setting this bit enables the insertion of triggers in the formatted trace stream. A trigger is indicated by inserting one byte of data 8'h00 with ATID 7'h7D in the trace stream. Trigger indication on the trace stream is further controlled by the register bits TRIGONFL, TRGONTRGEV, and TRGONTRGIN in the FFCR Register. This bit can only be changed when READY is high, and TCEN is low. This bit takes effect only when the ENFT register bit in this register is set. If ENTI bit is set to high when ENFT is low, it results in formatting being enabled.

Bit 0 **ENFT**: Enable formatting.
   0: Formatting is disabled. Incoming trace data is assumed to be from a single trace source.
   1: Formatting is enabled.
   If multiple ATIDs are received by the ETF when trace capture is enabled and the formatter is disabled, an interleaving of trace data occurs. Disabling of formatting is supported only in Circular buffer mode. If the ETF is enabled in a mode other than Circular buffer mode with ENFT low, then formatting is enabled. If ENTI bit is set to high when ENFT is low, formatting is enabled.
   This bit is ignored when in Disabled state.
ETF periodic synchronization counter register (ETF_PSCR)

Bits 31:0  ACCESS_W[31:0]: ETF register access enable

Enables write access to some ETF registers by the processor cores (debuggers do not need to unlock the component)
0xC5ACCE55: Enable write access
Other values: Disable write access
ETF lock status register (ETF_LSR)

Address offset: 0xFB4
Reset value: 0x0000 0003

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the ETF_LAR register
0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock
This bit always returns zero when read by an external debugger.
0: Write access is permitted
1: Write access is blocked. Only read access is permitted.

Bit 0 **LOCKEXIST**: Existence of lock control mechanism
The bit indicates whether a lock control mechanism exists. It always returns zero when read
by an external debugger.
0: No lock control mechanism exists
1: Lock control mechanism is implemented

ETF authentication status register (ETF_AUTHSTAT)

Address offset: 0xFB8
Reset value: 0x0000 0000

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 MEMWIDTH[2:0]: Memory interface data bus width
0x3: 64 bits (corresponds to 32-bit ATB data)

Bits 7:6 CONFIGTYPE[1:0]: Configuration type of component (ETB, ETR or ETF)
0x2: ETF

Bit 5 CLKSCHEME: RAM clocking scheme (synchronous or asynchronous)
0: Synchronous

Bits 4:0 ATBINPORTCNT[4:0]: Number/type of ATB input port multiplexing
0x0: None

ETF device type identifier register (ETF_DEVTYPE)

Address offset: 0xFCC
Reset value: 0x0000 0032

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 SUBTYPE[3:0]: Sub-classification
0x3: Captures the ATB slave interface trace data in RAM which can then be drained through the ATB master interface

Bits 3:0 MAJORType[3:0]: Major classification
0x2: The component is a trace link because it has an ATB master interface through which trace data can be drained out in Hardware FIFO mode.
ETF CoreSight peripheral identity register 4 (ETF_PIDR4)

Address offset: 0xFD0
Reset value: 0x0000 0004

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:4  **SIZE[3:0]**: Register file size
- 0x0: Register file occupies a single 4 Kbyte region

Bits 3:0  **JEP106CON[3:0]**: JEP106 continuation code
- 0x4: Arm® JEDEC code

ETF CoreSight peripheral identity register 0 (ETF_PIDR0)

Address offset: 0xFE0
Reset value: 0x0000 0061

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  **PARTNUM[7:0]**: Part number field, bits [7:0]
- 0x61: ETF part number

ETF CoreSight peripheral identity register 1 (ETF_PIDR1)

Address offset: 0xFE4
Reset value: 0x0000 00B9

Bits 31:8  Reserved, must be kept at reset value.

66.6.13 **Trace port interface unit (TPIU)**

The TPIU is a CoreSight™ component that formats the trace stream and outputs it on the external trace port signals. The TPIU has a single ATB slave port for incoming trace data. The trace port is a synchronous parallel port, comprising a clock output, TRACECK, and four data outputs, TRACED(3:0). The trace port width is programmable in the range 1 to 4. Using a smaller port width reduces the number of test points/connector pins needed, and frees up IOs for other purposes. However it restricts the bandwidth of the trace port and hence the quantity of trace information that can be output in real time. The ATB trace bus must be enabled by setting the TRACECLKEN bit in the DBGMCU_CR register before a trace is sent to the TPIU.

Trace data is output on TRACED[3:0] synchronously with the rising and falling edges of TRACECK. TRACECK is synchronous with the TRACECLKIN input, at half the frequency. This means that TRACECK is asynchronous with respect to the ATB clock. The asynchronism is handled by a FIFO in the TPIU, which also regulates the flow of data from the ETF. If the trace port bandwidth is not sufficient to handle the amount of trace data, the ETF can overflow and trace data can be missed. In this case the TRACECLKIN frequency can be increased, or the port size increased, up to a maximum of four pins. Alternatively, the ETM can be programmed to filter unnecessary information.

For more information on the Trace port interface CoreSight™ component, refer to the Arm® CoreSight™ SoC-400 technical reference manual [2].

Bits 31:0 **PORTSIZE[31:0]**: Indicates supported trace port sizes, from 1 to 32 pins. Bit n-1 when set indicates that port size n is supported.  
0x0000 000F: Port sizes 1 to 4 supported

Bits 31:0 **PORTSIZE[31:0]**: Current trace port size  
Setting bit n-1 indicates that the current port size is n-pin wide. The value of n must be within the range of supported port sizes (1-4). Only one bit can be set, or unpredictable behavior may result. This register should only be modified when the formatter is stopped.
Bits 31:18  Reserved, must be kept at reset value.

Bit 17  **TRGRUN**: Trigger running
0: Trigger has not occurred or counter is at 0
1: Trigger has occurred and counter is not at 0

Bit 16  **TRIGD**: Triggered
0: Trigger has not occurred
1: Trigger has occurred and counter has reached 0

Bits 15:9  Reserved, must be kept at reset value.

Bit 8  **TCOUNT8**: 8-bit counter register
1: Implemented

Bits 7:5  Reserved, must be kept at reset value.

Bit 4  **MULT64K**: Multiplying the trigger counter by 65536 support
1: Supported

Bit 3  **MULT256**: Multiplying the trigger counter by 256 support
1: Supported

Bit 2  **MULT16**: Multiplying the trigger counter by 16 support
1: Supported

Bit 1  **MULT4**: Multiplying the trigger counter by 4 support
1: Supported

Bit 0  **MULT2**: Multiplying the trigger counter by 2 support
1: Supported

**TPIU trigger counter value register (TPIU_TRGCNT)**

Address offset: 0x104

Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  **TRIGCOUNT[7:0]**: Enable trigger delay indication

Enables delaying the indication of triggers to any externally connected trace capture or storage devices. This counter is only eight bits wide and is intended to be used only with the counter multipliers in the Trigger multiplier register, 0x108. When a trigger is started, this value, in conjunction with the multiplier, specifies the number of words before the trigger is indicated. When the trigger counter reaches 0, the value written here is reloaded. Writing to this register causes the trigger counter value to reset but does not reset any value on the multiplier. Reading this register returns the preset value, not the current count.
### TPIU Trigger Multiplier Register (TPIU_TRGMULT)

**Address offset:** 0x108

**Reset value:** 0x0000 0000

| Bit 31-5 | Reserved, must be kept at reset value. |

#### Bits 31:18 Reserved, must be kept at reset value.

- **Bit 17** **PCONTEN**: Continuous mode enable
  - 0: Disabled
  - 1: Enabled

- **Bit 16** **PTIMEEN**: Timed mode enable
  - 0: Disabled
  - 1: Enabled

#### Bits 15:4 Reserved, must be kept at reset value.

- **Bit 3** **PATF0**: FF/00 pattern enable
  - Indicates whether the FF/00 pattern is supported as output over the trace port.
  - 0: Disabled
  - 1: Enabled
Bit 2 **PATA5**: AA/55 pattern is enable
- Indicates whether the AA/55 pattern is enabled as output over the trace port
  - 0: Disabled
  - 1: Enabled

Bit 1 **PATW0**: Walking 0’s pattern enable
- Indicates whether the walking 0’s pattern is enabled as output over the trace port
  - 0: Disabled
  - 1: Enabled

Bit 0 **PATW1**: Walking 1’s pattern enable
- Indicates whether the walking 1’s pattern is enabled as output over the trace port
  - 0: Disabled
  - 1: Enabled

**TPIU test pattern repeat counter register (TPIU_TPRCR)**

Address offset: 0x208
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31-8</th>
<th>Bit 7-0</th>

- r: read
- w: write
Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **TCPRESENT**: TRACECTL output pin availability
Indicates whether the optional TRACECTL output pin is available for use.
0: TRACECTL pin is not present in this device.

Bit 1 **FTSTOPPED**: Formatter stopped
The formatter has received a stop request signal and all trace data and post-amble is sent.
Any additional trace data on the ATB interface is ignored.
0: Formatter has not stopped
1: Formatter has stopped

Bit 0 **FLINPROG**: Flush in progress
Indicates whether a flush on the ATB slave port is in progress. This bit reflects the status of the AFVALIDS output. A flush can be initiated by the flush control bits in the TPIU_FFCR register.
0: No flush in progress
1: Flush in progress

**TPIU formatter and flush control register (TPIU_FFCR)**
Address offset: 0x304

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **STOPTRIG**: Stop on trigger event
0: No effect
1: Stop formatter when a trigger event occurs

Bit 12 **STOPFL**: Stop on flush
0: No effect
1: Stop formatter when flush is completed

Bit 11 Reserved, must be kept at reset value.

Bit 10 **TRIGFL**: Trigger on flush
0: No effect
1: Indicate a trigger in the trace stream when flush is completed

Bit 9 **TRIGEVT**: Trigger on trigger event
0: No effect
1: Indicate a trigger in the trace stream when trigger event occurs

Bit 8 **TRIGIN**: Trigger on trigger in
0: No effect
1: Indicate a trigger in the trace stream when the TRIGIN input from the system CTI is asserted.
Bit 7 Reserved, must be kept at reset value.

Bit 6 **FONMAN**: Generate a manual flush
   0: No effect
   1: Flush the trace
   This bit is cleared automatically when the flush completes.

Bit 5 **FONTRIG**: Flush on trigger event
   A trigger event occurs when the trigger counter reaches 0, or, if the trigger counter is 0, when the TRIGIN input from the system CTI is high.
   0: No effect
   1: Flush the trace if a trigger event occurs

Bit 4 **FONFLIN**: Flush on flush in
   0: No effect
   1: Flush the trace if the FLUSHIN input from the system CTI is asserted

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **ENFCONT**: Enable continuous formatting
   0: Continuous formatting is disabled
   1: Continuous formatting is enabled

Bit 0 **ENFTC**: Enable the embedding of triggers in formatted trace
   0: Formatting is disabled
   1: Formatting is enabled

31:12 Reserved, must be kept at reset value.

**Bits 11:0 CYCCOUNT[11:0]**: Enables effective use of TPAs
   Enables effective use of different-sized TPAs without wasting large amounts of storage capacity of the capture device. This counter contains the number of formatter frames since the last synchronization packet of 128 bits. It is a 12-bit counter with a maximum count value of 4096. This equates to a synchronization every 65536 bytes, that is, 4096 packets x 16 bytes per packet. The default is set up for a synchronization packet every 1024 bytes, that is, every 64 formatter frames. If the formatter is configured for continuous mode, full and half-word sync frames are inserted during normal operation. Under these circumstances, the count value is the maximum number of complete frames between full synchronization packets.
### TPIU claim tag set register (TPIU_CLAIMSET)

Bits 31:12  Reserved, must be kept at reset value.

Bit 11  **SWOUARTNRZ**: Support of SWO UART or NRZ  
Indicates whether serial wire output, UART or NRZ, is supported.

0: Not supported

Bit 10  **SWOMAN**: Support of SWO Manchester format  
Indicates whether serial wire output, Manchester encoded format, is supported.

0: Not supported

Bit 9  **TCLKDATA**: Support of trace clock plus data  
0: Not supported
Bits 8:6  **FIFOSIZE[2:0]**: FIFO size in powers of 2
0x2: FIFO size = 4 (16 bytes)

Bit 5  **CLKRELAT**: ATB clock and TRACECLKIN relation
Indicates the relationship between the ATB clock and TRACECLKIN (synchronous or asynchronous)
1: Asynchronous

Bits 4:0  **MAXNUM[4:0]**: Number/type of ATB input port multiplexing
0x0: None

**TPIU device type identifier register (TPIU_DEVTYPE)**
Address offset: 0xFCC
Reset value: 0x0000 0011

66.7 Serial wire output (SWO)

The SWO is a CoreSight component that formats the trace stream from the processor ITM and outputs it on the single wire TRACESWO.

Compared to the TPIU, the SWO contains:
- no formatter
- no pattern generator
- an 8-bit ATB input
- no synchronous trace output, that is, no TRACEDATA or TRACECLK pins
- no support for flush, because this is not required
- no support for triggering

The SWO output supports Manchester encoded and UART NRZ formats.

For more information about the serial wire output CoreSight™ component, refer to the Arm® CoreSight™ Components Technical Reference Manual [4].
### SWO registers

#### SWO current output divisor register (SWO_CODR)

Address offset: 0x010  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:13  Reserved, must be kept at reset value.

Bits 12:0  **PRESCALER[12:0]**: SWO baud rate scaling  
The baud rate is the trace clock frequency divided by (PRESCALER - 1). The baud rate changes instantly, so it is recommended to stop the trace source and wait until the port is idle before writing to this register.

#### SWO selected pin protocol register (SWO_SPPR)

Address offset: 0x0F0  
Reset value: 0x0000 0001

<table>
<thead>
<tr>

<th>TCPRESENT</th>
<th>FTSTOPPED</th>
<th>FLINPROG</th>
</tr>
</thead>
<tbody>
<tr>
<td>r</td>
<td>r</td>
<td>r</td>
<td>r</td>
</tr>
</tbody>
</table>

Bits 31:4 Reserved, must be kept at reset value.

- **Bit 3** FTNONSTOP: Change of settings without stopping formatter
  1: Change of settings is allowed with formatter running

- **Bit 2** TCPRESENT: TRACECTL pin present on SWO
  0: TRACECTL pin not present

- **Bit 1** FTSTOPPED: Formatter stopped
  0: Formatter running
  The bit always returns 0 as the SWO formatter cannot be stopped in this device.

- **Bit 0** FLINPROG: Flush in progress
  0: Flush is not in progress
  The bit always returns 0 as SWO flushing is not supported in this device.

### SWO claim tag set register (SWO_CLAIMSET)

Address offset: 0xFA0

Bits 31:12 Reserved, must be kept at reset value.

- **Bit 11 SWO_UART_NRZ**: SWO UART or NRZ support
  Indicates whether serial wire output, UART or NRZ, is supported.
  1: Supported

- **Bit 10 SWO_MAN**: SWO Manchester format support
  Indicates whether serial wire output, Manchester encoded format, is supported.
  1: Supported

- **Bit 9 TCLK_DATA**: Trace clock plus data support
  Indicates whether trace clock plus data is supported.
  1: Supported

- **Bits 8:6 FIFO_SIZE[2:0]**: FIFO size in powers of 2
  0x2: FIFO size = 4 (16 bytes)

- **Bit 5 CLK_RELAT**: ATB clock to TRACECLKIN relation
  Indicates the relationship between the ATB clock and TRACECLKIN (synchronous or asynchronous)
  1: Asynchronous

- **Bits 4:0 MUXNUM[4:0]**: Number/type of ATB input port multiplexing
  0x0: None

66.8  Microcontroller debug unit (DBGMCU)

The DBGMCU component contains a number of registers that control the power and clock behavior in Debug mode. Specifically it allows the debugger, or debug software, to:

- maintain the clock and power to the processor cores when in low-power modes (sleep, stop or standby)
- maintain the clock and power to the system debug and trace components when in low power modes
- stop the clock to certain peripherals (CAN, SMBUS timeout, Watchdogs, Timers, RTC) when the processor core is stopped in Debug mode. For timers having complementary outputs, these outputs are disabled (as if the MOE bit was reset) for safety purposes when the counter is stopped (TIM1/15/16/17 = 1 in DBGMCU_APB2FZR).

The DBGMCU registers are not reset by a system reset, only by a power on reset. They are accessible to the debugger via the APB-D bus at base address 0xE00E1000. They are also accessible by the processor core at base address 0x5C001000.
66.8.1 DBGMCU registers

DBGMCU identity code register (DBGMCU_IDCODE)

</table>

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 \( \text{TRGOEN} \): External trigger output enable
This bit controls the direction of the bi-directional trigger pin, TRGIO.
0: Input - TRGIO is connected to TRGIN
1: Output - TRGIO is connected to TRGOUT

Bits 27:22 Reserved, must be kept at reset value.

Bit 21 \( \text{DBGCKEN} \): debug clock enable
This bit allows clocks of the debug components (excluding those in the processor core) to be switched off if they are not needed.
0: Disabled - clock debug components are disabled and their clocks gated
1: Enabled - clock debug components are clocked whenever the corresponding domain clock (CK_HCLK) is active
Bit 20  **TRACECLKEN**: Trace port clock enable.
This bit enables the trace port, TRACECLK.
0: Disabled - TRACECLK is disabled
1: Enabled - TRACECLK is active

Bits 19:17  Reserved, must be kept at reset value.

Bit 16  **DCRT**: Debug credentials reset type
This bit selects which type of reset is used to revoke the debug authentication credentials
0: System reset
1: Power reset

Bits 15:3  Reserved, must be kept at reset value.

Bit 2  **DBG_STANDBY**: Debug in Standby mode enable
0: Normal operation - all clocks are disabled and the core powered down automatically in Standby mode.
1: Automatic clock stop/power-down disabled - all active clocks and oscillators continue to run during Standby mode, and the core supply is maintained, allowing full debug capability. On exit from Standby mode, a core reset is performed.

Bit 1  **DBG_STOP**: Debug in Stop mode enable
0: Normal operation - all clocks are disabled automatically in Stop mode
1: Automatic clock stop disabled - all active clocks and oscillators continue to run during Stop mode, allowing full debug capability. On exit from Stop mode, the clock settings are set to the Stop mode exit state.

Bit 0  **DBG_SLEEP**: Debug in Sleep mode enable
0: Normal operation - the processor clock is stopped automatically in Sleep mode
1: Automatic clock stop disabled - processor clock continues to run, allowing full debug capability

**DBGMCU AHB5 peripheral freeze register (DBGMCU_AHB5FZR)**

Address offset: 0x01C
Reset value: 0x0000 0000

Description: This register is accessible to the debugger after successful authentication. Prior to this, debugger accesses are ignored. It is always accessible to software.
Bits 31:16  Reserved, must be kept at reset value.

Bit 15  **HPDMA_15**: HPDMA channel 15 stop in debug
        0: normal operation. HPDMA channel 15 continues to operate while the CPU is in debug mode.
        1: stop in debug. HPDMA channel 15 is frozen while the CPU is in debug mode.

Bit 14  **HPDMA_14**: HPDMA channel 14 stop in debug
        0: normal operation. HPDMA channel 14 continues to operate while the CPU is in debug mode.
        1: stop in debug. HPDMA channel 14 is frozen while the CPU is in debug mode.

Bit 13  **HPDMA_13**: HPDMA channel 13 stop in debug
        0: normal operation. HPDMA channel 13 continues to operate while the CPU is in debug mode.
        1: stop in debug. HPDMA channel 13 is frozen while the CPU is in debug mode.

Bit 12  **HPDMA_12**: HPDMA channel 12 stop in debug
        0: normal operation. HPDMA channel 12 continues to operate while the CPU is in debug mode.
        1: stop in debug. HPDMA channel 12 is frozen while the CPU is in debug mode.

Bit 11  **HPDMA_11**: HPDMA channel 11 stop in debug
        0: normal operation. HPDMA channel 11 continues to operate while the CPU is in debug mode.
        1: stop in debug. HPDMA channel 11 is frozen while the CPU is in debug mode.

Bit 10  **HPDMA_10**: HPDMA channel 10 stop in debug
        0: normal operation. HPDMA channel 10 continues to operate while the CPU is in debug mode.
        1: stop in debug. HPDMA channel 10 is frozen while the CPU is in debug mode.

Bit 9   **HPDMA_9**: HPDMA channel 9 stop in debug
        0: normal operation. HPDMA channel 9 continues to operate while the CPU is in debug mode.
        1: stop in debug. HPDMA channel 9 is frozen while the CPU is in debug mode.

Bit 8   **HPDMA_8**: HPDMA channel 8 stop in debug
        0: normal operation. HPDMA channel 8 continues to operate while the CPU is in debug mode.
        1: stop in debug. HPDMA channel 8 is frozen while the CPU is in debug mode.

Bit 7   **HPDMA_7**: HPDMA channel 7 stop in debug
        0: normal operation. HPDMA channel 7 continues to operate while the CPU is in debug mode.
        1: stop in debug. HPDMA channel 7 is frozen while the CPU is in debug mode.

Bit 6   **HPDMA_6**: HPDMA channel 6 stop in debug
        0: normal operation. HPDMA channel 6 continues to operate while the CPU is in debug mode.
        1: stop in debug. HPDMA channel 6 is frozen while the CPU is in debug mode.

Bit 5   **HPDMA_5**: HPDMA channel 5 stop in debug
        0: normal operation. HPDMA channel 5 continues to operate while the CPU is in debug mode.
        1: stop in debug. HPDMA channel 5 is frozen while the CPU is in debug mode.

Bit 4   **HPDMA_4**: HPDMA channel 4 stop in debug
        0: normal operation. HPDMA channel 4 continues to operate while the CPU is in debug mode.
        1: stop in debug. HPDMA channel 4 is frozen while the CPU is in debug mode.

Bit 3   **HPDMA_3**: HPDMA channel 3 stop in debug
        0: normal operation. HPDMA channel 3 continues to operate while the CPU is in debug mode.
        1: stop in debug. HPDMA channel 3 is frozen while the CPU is in debug mode.
Bit 2  **HPDMA_2**: HPDMA channel 2 stop in debug
   0: normal operation. HPDMA channel 2 continues to operate while the CPU is in debug mode.
   1: stop in debug. HPDMA channel 2 is frozen while the CPU is in debug mode.

Bit 1  **HPDMA_1**: HPDMA channel 1 stop in debug
   0: normal operation. HPDMA channel 1 continues to operate while the CPU is in debug mode.
   1: stop in debug. HPDMA channel 1 is frozen while the CPU is in debug mode.

Bit 0  **HPDMA_0**: HPDMA channel 0 stop in debug
   0: normal operation. HPDMA channel 0 continues to operate while the CPU is in debug mode.
   1: stop in debug. HPDMA channel 0 is frozen while the CPU is in debug mode.

**DBGMCU AHB1 peripheral freeze register (DBGMCU_AHB1FZR)**

Address offset: 0x024

Reset value: 0x0000 0000

Description: This register is accessible to the debugger after successful authentication. Prior to this, debugger accesses are ignored. It is always accessible to software.

Bits 31:16  Reserved, must be kept at reset value.

Bit 15  **GPDMA_15**: GPDMA channel 15 stop in debug
   0: normal operation. GPDMA channel 15 continues to operate while the CPU is in debug mode.
   1: stop in debug. GPDMA channel 15 is frozen while the CPU is in debug mode.

Bit 14  **GPDMA_14**: GPDMA channel 14 stop in debug
   0: normal operation. GPDMA channel 14 continues to operate while the CPU is in debug mode.
   1: stop in debug. GPDMA channel 14 is frozen while the CPU is in debug mode.

Bit 13  **GPDMA_13**: GPDMA channel 13 stop in debug
   0: normal operation. GPDMA channel 13 continues to operate while the CPU is in debug mode.
   1: stop in debug. GPDMA channel 13 is frozen while the CPU is in debug mode.

Bit 12  **GPDMA_12**: GPDMA channel 12 stop in debug
   0: normal operation. GPDMA channel 12 continues to operate while the CPU is in debug mode.
   1: stop in debug. GPDMA channel 12 is frozen while the CPU is in debug mode.

Bit 11  **GPDMA_11**: GPDMA channel 11 stop in debug
   0: normal operation. GPDMA channel 11 continues to operate while the CPU is in debug mode.
   1: stop in debug. GPDMA channel 11 is frozen while the CPU is in debug mode.

Bit 10  **GPDMA_10**: GPDMA channel 10 stop in debug
   0: normal operation. GPDMA channel 10 continues to operate while the CPU is in debug mode.
   1: stop in debug. GPDMA channel 10 is frozen while the CPU is in debug mode.
Bit 9 **GPDMA_9**: GPDMA channel 9 stop in debug
0: normal operation. GPDMA channel 9 continues to operate while the CPU is in debug mode.
1: stop in debug. GPDMA channel 9 is frozen while the CPU is in debug mode.

Bit 8 **GPDMA_8**: GPDMA channel 8 stop in debug
0: normal operation. GPDMA channel 8 continues to operate while the CPU is in debug mode.
1: stop in debug. GPDMA channel 8 is frozen while the CPU is in debug mode.

Bit 7 **GPDMA_7**: GPDMA channel 7 stop in debug
0: normal operation. GPDMA channel 7 continues to operate while the CPU is in debug mode.
1: stop in debug. GPDMA channel 7 is frozen while the CPU is in debug mode.

Bit 6 **GPDMA_6**: GPDMA channel 6 stop in debug
0: normal operation. GPDMA channel 6 continues to operate while the CPU is in debug mode.
1: stop in debug. GPDMA channel 6 is frozen while the CPU is in debug mode.

Bit 5 **GPDMA_5**: GPDMA channel 5 stop in debug
0: normal operation. GPDMA channel 5 continues to operate while the CPU is in debug mode.
1: stop in debug. GPDMA channel 5 is frozen while the CPU is in debug mode.

Bit 4 **GPDMA_4**: GPDMA channel 4 stop in debug
0: normal operation. GPDMA channel 4 continues to operate while the CPU is in debug mode.
1: stop in debug. GPDMA channel 4 is frozen while the CPU is in debug mode.

Bit 3 **GPDMA_3**: GPDMA channel 3 stop in debug
0: normal operation. GPDMA channel 3 continues to operate while the CPU is in debug mode.
1: stop in debug. GPDMA channel 3 is frozen while the CPU is in debug mode.

Bit 2 **GPDMA_2**: GPDMA channel 2 stop in debug
0: normal operation. GPDMA channel 2 continues to operate while the CPU is in debug mode.
1: stop in debug. GPDMA channel 2 is frozen while the CPU is in debug mode.

Bit 1 **GPDMA_1**: GPDMA channel 1 stop in debug
0: normal operation. GPDMA channel 1 continues to operate while the CPU is in debug mode.
1: stop in debug. GPDMA channel 1 is frozen while the CPU is in debug mode.

Bit 0 **GPDMA_0**: GPDMA channel 0 stop in debug
0: normal operation. GPDMA channel 0 continues to operate while the CPU is in debug mode.
1: stop in debug. GPDMA channel 0 is frozen while the CPU is in debug mode.

**DBGMCU APB1 peripheral freeze register (DBGMCU_APB1FZR)**

Address offset: 0x03C
Reset value: 0x0000 0000
Bits 31:24  Reserved, must be kept at reset value.

Bit 23  **I2C3**: I2C3 SMBUS timeout stop in debug
0: Normal operation - I2C3 SMBUS timeout continues operating while the core is in Debug mode
1: Stop in debug - I2C3 SMBUS timeout is frozen while Cortex-M7 is in Debug mode

Bit 22  **I2C2**: I2C2 SMBUS timeout stop in debug
0: Normal operation - I2C2 SMBUS timeout continues operating while the core is in Debug mode
1: Stop in debug - I2C2 SMBUS timeout is frozen while Cortex-M7 is in Debug mode

Bit 21  **I2C1**: I2C1 SMBUS timeout stop in debug
0: Normal operation - I2C1 SMBUS timeout continues operating while the core is in Debug mode
1: Stop in debug - I2C1 SMBUS timeout is frozen while the core is in Debug mode

Bits 20:12  Reserved, must be kept at reset value.

Bit 11  **WWDG**: WWDG stop in debug
0: Normal operation - WWDG continues to operate while the Cortex-M7 is in Debug mode
1: Stop in debug - WWDG is frozen while the Cortex-M7 is in Debug mode

Bit 10  Reserved, must be kept at reset value.

Bit 9  **LPTIM1**: LPTIM1 stop in debug
0: Normal operation - LPTIM1 continues operating while the core is in Debug mode
1: Stop in debug - LPTIM1 is frozen while Cortex-M7 is in Debug mode

Bit 8  **TIM14**: TIM14 stop in debug
0: Normal operation - TIM14 continues operating while the core is in Debug mode
1: Stop in debug - TIM14 is frozen while Cortex-M7 is in Debug mode

Bit 7  **TIM13**: TIM13 stop in debug
0: Normal operation - TIM13 continues operating while the core is in Debug mode
1: Stop in debug - TIM13 is frozen while Cortex-M7 is in Debug mode

Bit 6  **TIM12**: TIM12 stop in debug
0: Normal operation - TIM12 continues operating while the core is in Debug mode
1: Stop in debug - TIM12 is frozen while Cortex-M7 is in Debug mode

Bit 5  **TIM7**: TIM7 stop in debug
0: Normal operation - TIM7 continues operating while the core is in Debug mode
1: Stop in debug - TIM7 is frozen while Cortex-M7 is in Debug mode

Bit 4  **TIM6**: TIM6 stop in debug
0: Normal operation - TIM6 continues operating while the core is in Debug mode
1: Stop in debug - TIM6 is frozen while Cortex-M7 is in Debug mode

Bit 3  **TIM5**: TIM5 stop in debug
0: Normal operation - TIM5 continues operating while the core is in Debug mode
1: Stop in debug - TIM5 is frozen while Cortex-M7 is in Debug mode
Bit 2 **TIM4**: TIM4 stop in debug
0: Normal operation - TIM4 continues operating while the core is in Debug mode
1: Stop in debug - TIM4 is frozen while Cortex-M7 is in Debug mode

Bit 1 **TIM3**: TIM3 stop in debug
0: Normal operation - TIM3 continues operating while the core is in Debug mode
1: Stop in debug - TIM3 is frozen while Cortex-M7 is in Debug mode

Bit 0 **TIM2**: TIM2 stop in debug
0: Normal operation - TIM2 continues operating while the core is in Debug mode
1: Stop in debug - TIM2 is frozen while Cortex-M7 is in Debug mode

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **TIM9**: TIM9 stop in debug
0: Normal operation - TIM9 continues operating while the core is in Debug mode
1: Stop in debug - TIM9 is frozen and TIM9 outputs are disabled while Cortex-M7 is in Debug mode

Bit 18 **TIM17**: TIM17 stop in debug
0: Normal operation - TIM17 continues operating while the core is in Debug mode
1: Stop in debug - TIM17 is frozen and TIM17 outputs are disabled while Cortex-M7 is in Debug mode

Bit 17 **TIM16**: TIM16 stop in debug
0: Normal operation - TIM16 continues operating while the core is in Debug mode
1: Stop in debug - TIM16 is frozen and TIM16 outputs are disabled while Cortex-M7 is in Debug mode

Bit 16 **TIM15**: TIM15 stop in debug
0: Normal operation - TIM15 continues operating while the core is in Debug mode
1: Stop in debug - TIM15 is frozen and TIM15 outputs are disabled while Cortex-M7 is in Debug mode

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **TIM1**: TIM1 stop in debug
0: Normal operation - TIM1 continues operating while the core is in Debug mode
1: Stop in debug - TIM1 is frozen and TIM1 outputs are disabled while Cortex-M7 is in Debug mode.

**DBGMCU APB4 peripheral freeze register (DBGMCU_APB4FZR)**
Address offset: 0x054
### DBGMCU status register (DBGMCU_SR)

**Address offset:** 0x0FC

**Reset value:** 0x0001 0003

**Description:** This register is always accessible.

#### Bits 31:19
Reserved, must be kept at reset value.

#### Bit 18 **IWDG**
- Independent watchdog for stop in debug
- 0: Normal operation - watchdog continues counting while the core is in Debug mode
- 1: Stop in debug - watchdog is frozen while Cortex-M7 is in Debug mode

#### Bit 17 Reserved, must be kept at reset value.

#### Bit 16 **RTC**
- RTC stop in debug
- 0: Normal operation - RTC continues operating while the core is in Debug mode
- 1: Stop in debug - RTC is frozen while Cortex-M7 is in Debug mode

#### Bits 15:13
Reserved, must be kept at reset value.

#### Bit 12 **LPTIM5**
- LPTIM5 stop in debug
- 0: Normal operation - LPTIM5 continues operating while the core is in Debug mode
- 1: Stop in debug - LPTIM5 is frozen while Cortex-M7 is in Debug mode

#### Bit 11 **LPTIM4**
- LPTIM4 stop in debug
- 0: Normal operation - LPTIM4 continues operating while the core is in Debug mode
- 1: Stop in debug - LPTIM4 is frozen while Cortex-M7 is in Debug mode

#### Bit 10 **LPTIM3**
- LPTIM2 stop in debug
- 0: Normal operation - LPTIM2 continues operating while the core is in Debug mode
- 1: Stop in debug - LPTIM2 is frozen while Cortex-M7 is in Debug mode

#### Bit 9 **LPTIM2**
- LPTIM2 stop in debug
- 0: Normal operation - LPTIM2 continues operating while the core is in Debug mode
- 1: Stop in debug - LPTIM2 is frozen while Cortex-M7 is in Debug mode

#### Bits 8:0
Reserved, must be kept at reset value.

66.9  **Cortex-M7 debug functional description**

The Cortex-M7 subsystem features the following CoreSight™ components:

- ROM tables
- System control space (SCS)
- Breakpoint unit (FPB)
- Data watchpoint and trace unit (DWT)
- Instrumentation trace macrocell (ITM)
- Embedded trace macrocell (ETM)
- Cross trigger interface (CTI)

These components are accessible by the debugger via the Cortex-M7 AHB-AP and its associated AHBD bus.

66.9.1  **Cortex-M7 ROM tables**

The ROM table is a CoreSight™ component that contains the base addresses of all the CoreSight debug components accessible via the AHBD. These tables allow a debugger to discover the topology of the CoreSight system automatically.

There are two ROM tables in the Cortex-M7 sub-system:

- Cortex-M7 CPU ROM table
  - This table is pointed to by the BASE register in the Cortex-M7 AHB-AP. It contains the base address pointers for the ETM and CTI, as well as for the Cortex-M7 PPB ROM table.

- Cortex-M7 PPB (private peripheral bus) ROM table
  - This table contains pointers to the Cortex-M7 System Control Space registers allowing the debugger to identify the CPU core, as well as to the remaining CoreSight components in the Cortex-M7 subsystem: FPB, DWT and ITM.

The CPU ROM table occupies a 4-Kbyte, 32-bit wide chunk of AHBD address space, from 0xE00FE000 to 0xE00FEFFC.

1. The TPIU and ETM are included in this table by default, but bit 0 is reset to indicate that they are not present.

The Topology for the CoreSight™ components in the Cortex-M7 subsystem is shown in Figure 1009.

Figure 1009. Cortex-M7 CoreSight Topology
66.9.2 Cortex-M7 CPU ROM registers

CPU ROM memory type register (M7_CPUROM_MEMTYPE)

Address offset: 0xFCC
Reset value: 0x0000 0001

| Bits 31:1 | Reserved, must be kept at reset value. |
| Bits 0  | SYSMEM: System memory presence |
| 1: System memory is present on this bus |

CPU ROM CoreSight peripheral identity register 4 (M7_CPUROM_PIDR4)

Address offset: 0xFD0
Reset value: 0x0000 0000

| Bits 31:8 | Reserved, must be kept at reset value. |
| Bits 7:4 | SIZE[3:0]: Register file size |
| 0x0: Register file occupies a single 4 Kbyte region |
| Bits 3:0 | JEP106CON[3:0]: JEP106 continuation code |
| 0x0: STMicroelectronics JEDEC continuation code |

CPU ROM CoreSight peripheral identity register 0 (M7_CPUROM_PIDR0)

Address offset: 0xFE0
Reset value: 0x0000 0085

| Bits 31:16 | Reserved, must be kept at reset value. |
| Bits 15:8 | PARTNUM[7:0] |
| | STMicroelectronics part number |
| | STMicroelectronics part number |

| Bits 7:4 | SIZE[3:0] |
| 0x0: Register file occupies a single 4 Kbyte region |
| Bits 3:0 | JEP106CON[3:0]: JEP106 continuation code |
| 0x0: STMicroelectronics JEDEC continuation code |
CPU ROM CoreSight peripheral identity register 1 (M7_CPUROM_PIDR1)

Address offset: 0xFE4
Reset value: 0x0000 0004

66.9.6 Cortex-M7 data watchpoint and trace unit (DWT)

The DWT provides four comparators that can be used as:
- watchpoint
- ETM trigger
- PC sampling trigger
- data address sampling trigger
- data comparator (comparator 1 only)
- clock cycle counter comparator (comparator 0 only)

It also contains counters for:
- clock cycles
- folded instructions
- load store unit (LSU) operations
- sleep cycles
- number of cycles per instruction
- interrupt overhead

A DWT comparator compares one of the following with the value held in its DWT_COMP register:
- a data address
- an instruction address
- a data value
- the cycle count value, for comparator 0 only.

For address matching, the comparator can use a mask, so it matches a range of addresses.

On a successful match, the comparator generates one of the following:
- one or more DWT data trace packets, containing one or more of:
  - the address of the instruction that caused a data access
  - an address offset, bits[15:0] of the data access address
  - the matched data value
- a watchpoint debug event, on either the PC value or the accessed data address
- a CMPMATCH[N] event that signals the match outside the DWT unit

A watchpoint debug event either generates a DebugMonitor exception, or causes the processor to halt execution and enter Debug state.

For more details on how to use the DWT, refer to the Arm®v7-M Architecture Reference Manual [5].
66.9.7 Cortex-M7 DWT registers

DWT control register (M7_DWT_CTRL)

Bit 16 **EXCTRKENA**: Enable exception trace generation

0: Disabled
1: Enabled

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **PCSAMPLENA**: POSTCNT counter use enable

Enables the use of POSTCNT counter as a timer for Periodic PC sample packet generation.

0: Disabled
1: Enabled

Bits 11:10 **SYNCTAP[1:0]**: Position of synchronization packet counter tap on CYCCNT counter

This selection determines the synchronization packet rate.

0x0: Disabled - no synchronization packets
0x1: Tap at CYCCNT[24]
0x2: Tap at CYCCNT[26]
0x3: Tap at CYCCNT[28]

Bit 9 **CYCTAP**: Position of the POSTCNT tap on the CYCCNT counter

0: Tap at CYCCNT[6]
1: Tap at CYCCNT[10]

Bits 8:5 **POSTINIT[3:0]**: Initial value of the POSTCNT counter

Writes to this field are ignored if POSTCNT counter is enabled (that is, CYCEVTENA or PCSAMPLENA must be reset prior to writing POSTINIT).

Bits 4:1 **POSTRESET[3:0]**: Reload value of the POSTCNT counter.

Bit 0 **CYCCNTENA**: CYCCNT counter enable

0: Disabled
1: Enabled

Bits 31:8 Reserved, must be kept at reset value.  
Bits 7:0 **SLEEPCNT[7:0]**: Exception overhead cycle counter  
Counts the number of cycles spent in exception processing.
Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  SLEEP_CNT[7:0]: Sleep cycle counter
Counts the number of cycles spent in sleep mode (WFI, WFE, sleep-on-exit).

**DWT LSU count register (M7_DWT_LSUCNT)**

Address offset: 0x014
Reset value: 0x0000 0000

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  LSUCNT[7:0]: Load store counter
Counts additional cycles required to execute load and store instructions.

**DWT fold count register (M7_DWT_FOLDCNT)**

Address offset: 0x018
Reset value: 0x0000 0000

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  FOLDCNT[7:0]: Folded instruction counter
Increments on each instruction that takes 0 cycles.

**DWT program counter sample register (M7_DWT_PCSR)**

Address offset: 0x01C
Reset value: 0x0000 0000

**EIASAMPLE[31:16]**

**EIASAMPLE[15:0]**
Bits 31:0  **EIASAMPLE[31:0]**: Executed instruction address sample value  
Samples the current value of the program counter.

**DWT comparator register x (M7_DWT_COMPx)**

Address offset: 0x020 + x * 0x10 (x = 0 to 3)  
Reset value: 0x0000 0000

Bits 31:5  Reserved, must be kept at reset value.

Bits 4:0  **MASK[4:0]**: Comparator mask size  
Provides the size of the ignore mask applied to the access address for address range matching by comparator n. A debugger can write 0b11111 to this field and then read the register back to determine the maximum mask size supported.

**DWT function register x (M7_DWT_FUNCTx)**

Address offset: 0x028 + x * 0x10 (x = 0 to 3)

3716/3791  RM0477 Rev 6
Bits 31:25  Reserved, must be kept at reset value.

Bit 24  MATCHED: Comparator match (read-only)
Indicates if a comparator match has occurred since the register was last read.

  0: No match
  1: Match occurred

Bits 23:20  Reserved, must be kept at reset value.

Bits 19:16  DATAVADDR1[3:0]: Comparator number of a second comparator
When the DATAVMATCH and LNK1ENA bits are both 1, this field can hold the comparator number of a second comparator to use for linked address comparison.

Bits 15:12  DATAVADDR0[3:0]: Comparator number of a comparator
When the DATAVMATCH and LNK1ENA bits are both 1, this field can hold the comparator number of a comparator to use for linked address comparison.

Bits 11:10  DATAVSIZE[1:0]: Size of required data comparison
For data value matching, specifies the size of the required data comparison.

  0x0: Byte
  0x1: Half word
  0x2: Word
  0x3: Reserved

Bit 9  LINK1ENA: Support of a second linked comparator (read-only)
Indicates whether the use of a second linked comparator is supported (read-only).

  1: Supported

Bit 8  DATAVMATCH: Cycle comparison enable

  0: Perform address comparison
  1: Perform data value comparison

Bit 7  CYCMATCH: Cycle count comparison enable on comparator 0
This field is reserved for other comparators.

  0: No cycle count comparison
  1: Compare DWT_COMP0 with the cycle counter, DWT_CYCCNT

Bit 6  Reserved, must be kept at reset value.

Bit 5  EMITRANGE: Data trace address offset packet enable

  Enables the generation of data trace address offset packets (containing data address bits 0 to 15)

  0: Disabled
  1: Enabled

Bit 4  Reserved, must be kept at reset value.

Bits 3:0  FUNCTION[3:0]: Action on comparator match
The meaning of this bit field depends on the setting of the DATAVMATCH and CYCMATCH fields. See [5].

### 66.9.9 Cortex-M7 instrumentation trace macrocell (ITM)

The ITM generates trace information as packets. There are four sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The four sources in decreasing order of priority are:

1. **Software trace**
   
   Software can write directly to any of 32 x 32-bit ITM stimulus registers to generate packets. The permission level for each port can be programmed. When software writes to an enabled stimulus port, the ITM combines the identity of the port, the size of the write access, and the data written, into a packet that it writes to a FIFO. The ITM
Debug infrastructure

outputs packets from the FIFO onto the trace bus. Reading a stimulus port register returns the status of the stimulus register (empty or pending) in bit 0.

2. Hardware trace
The DWT generates trace packets in response to a data trace event, a PC sample or a performance profiling counter wraparound. The ITM outputs these packets on the trace bus.

3. Local timestamping
The ITM contains a 21-bit counter clocked by the (pre-divided) processor clock. The counter value is output in a timestamp packet on the trace bus. The counter is reset to zero every time a timestamp packet is generated. The timestamps thus indicate the time elapsed since the previous timestamp packet.

4. Global system timestamping
Timesteps can also be generated using the system-wide 64-bit count value coming from the Timestamp Generator component.

66.9.10 Cortex-M7 ITM registers

ITM stimulus register x (M7_ITM_STIMx)
Address offset: 0x000 + x * 0x4 (x = 0 to 31)
Reset value: 0xXXXX XXXX

Bits 31:0 **STIMULUS[31:0]**: Software event packet / FIFOREADY
Write data is output on the trace bus as a software event packet. When reading, bit 0 is a FIFOREADY indicator:
0: Stimulus port buffer is full (or port is disabled)
1: Stimulus port can accept new write data

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **PRIVMASK[3:0]**: Enable unprivileged access to ITM stimulus ports
   Each bit controls eight stimulus ports:
   0bXXX0: Unprivileged access permitted on ports 0 to 7
   0bXXX1: Only privileged access permitted on ports 0 to 7
   0bXX0X: Unprivileged access permitted on ports 8 to 15
   0bXX1X: Only privileged access permitted on ports 8 to 15
   0bX0XX: Unprivileged access permitted on ports 16 to 23
   0bX1XX: Only privileged access permitted on ports 16 to 23
   0b0XXX: Unprivileged access permitted on ports 24 to 31
   0b1XXX: Only privileged access permitted on ports 24 to 31
Bits 31:24  Reserved, must be kept at reset value.

Bit 23  **BUSY**: ITM busy
Indicates whether the ITM is currently processing events (read-only):
0: Not busy
1: Busy

Bits 22:16  **TRACEBUSID[6:0]**: Identifier for multi-source trace stream formatting
If multi-source trace is in use, the debugger must write a non-zero value to this field. Note: different IDs must be used for each trace source in the system.

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:10  **GTSFREQ[1:0]**: Global timestamp frequency
 Defines how often the ITM generates a global timestamp, based on the global timestamp clock frequency, or disables generation of global timestamps. The possible values are:
0x0: Disable generation of global timestamps
0x1: Generate timestamp request whenever the ITM detects a change in global timestamp counter bits [63:7]; this is approximately every 128 cycles
0x2: Generate timestamp request whenever the ITM detects a change in global timestamp counter bits [63:13]; this is approximately every 8192 cycles
0x3: Generate a timestamp after every packet, if the output FIFO is empty

Bits 9:8  **TSPRESCALE[1:0]**: Local timestamp prescale
Prescaler used with the trace packet reference clock The possible values are:
0x0: No prescaling
0x1: Divide by 4
0x2: Divide by 16
0x3: Divide by 64

Bits 7:5  Reserved, must be kept at reset value.

Bit 4  **SWOENA**: Asynchronous clocking enable for the timestamp counter (read-only)
0: Timestamp counter uses processor clock

Bit 3  **TXENA**: Hardware event packet forwarding enable
Enables forwarding of hardware event packets from the DWT unit to the trace port.
0: Disabled
1: Enabled

Bit 2  **SYNCENA**: Synchronization packet transmission enable
If a debugger sets this bit it must also configure the DWT_CTRL register SYNCTAP field in the DWT for the correct synchronization speed.
0: Disabled
1: Enabled

Bit 1  **TSENA**: Local timestamp generation enable
0: Disabled
1: Enabled

Bit 0  **ITMENA**: ITM enable
0: Disabled
1: Enabled

66.9.12 Cortex-M7 breakpoint unit (FPB)

The FPB allows hardware breakpoints to be set. It contains eight comparators which monitor the instruction fetch address and return a breakpoint instruction when a match is detected. The Cortex-M7 FPB does not support flash patch functionality.

66.9.13 Cortex-M7 FPB registers

FPB control register (M7_FPB_CTRL)

Address offset: 0x000
Reset value: 0x1000 0080

66.9.15  **Cortex-M7 embedded trace macrocell (ETM)**

The Cortex-M7 ETM is a CoreSight™ component closely coupled to the CPU. The ETM generates trace packets that allow the execution of the Cortex-M7 core to be traced. In the STM32H7, the ETM is configured for instruction trace only, so data accesses are not included in the trace information.

The ETM receives information from the CPU over the processor trace interface, including:
- The number of instructions executed in the same cycle
- Changes in program flow
- The current processor instruction state
- The memory address locations accessed by load and store instructions
- The type, direction and size of a transfer
- Condition code information
- Exception information
- Wait for interrupt state information

For more information, refer to the Arm® CoreSight™ ETM™-M7 technical reference manual [6].
### 66.9.16 Cortex-M7 ETM registers

#### ETM programming control register (M7_ETM_PRGCTL)

Address offset: 0x004  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>15</td>
<td>14</td>
<td>13</td>
<td>12</td>
<td>11</td>
<td>10</td>
<td>9</td>
<td>8</td>
<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **EN**: Trace program enable

- 0: Trace unit is disabled
- 1: Trace unit is enabled

#### ETM processor select control register (M7_ETM_PROCSSEL)

Address offset: 0x008  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>

</tr>
<tr>
<td>15</td>
<td>14</td>
<td>13</td>
<td>12</td>
<td>11</td>
<td>10</td>
<td>9</td>
<td>8</td>
<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **PROCSEL**: Processor select

This field has no effect since only the Cortex-M7 uses this ETM.

#### ETM status register (M7_ETM_STAT)

Address offset: 0x00C  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>15</td>
<td>14</td>
<td>13</td>
<td>12</td>
<td>11</td>
<td>10</td>
<td>9</td>
<td>8</td>
<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:1 Reserved, must be kept at reset value.
ETM trace configuration register (M7_ETM_CONFIG)

Address offset: 0x010
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:2</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 1</td>
<td>PMSTABLE: Programmers model stable</td>
</tr>
<tr>

<tr>
<td></td>
<td>0: Disabled</td>
</tr>
<tr>
<td></td>
<td>1: Enabled</td>
</tr>
</tbody>
</table>
ETM event control 0 register (M7_ETM_EVENTCTL0)

Only accepts writes when trace unit is disabled
Address offset: 0x020
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 3</th>
<th>BB: Branch broadcast mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0:</td>
<td>Disabled</td>
</tr>
<tr>
<td>1:</td>

</tr>
</thead>
</table>

### Register Layout

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE1</td>
<td>Resource type for event 1</td>
</tr>
<tr>
<td>SEL1[3:0]</td>
<td>Resource / Boolean combined resource pair, for event 1</td>
</tr>
<tr>
<td>TYPE0</td>
<td>Resource type for event 0</td>
</tr>
<tr>
<td>SEL0[3:0]</td>
<td>Resource / Boolean combined resource pair, for event 0</td>
</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **TYPE1**: Resource type for event 1
- 0: Single selected resource
- 1: Boolean combined resource pair

Bits 14:12 Reserved, must be kept at reset value.

Bits 11:8 **SEL1[3:0]**: Resource / Boolean combined resource pair, for event 1
- When TYPE1 is 0, selects a single selected resource from 0-15 defined by bits[3:0]
- When TYPE1 is 1, selects a Boolean combined resource pair from 0-7 defined by bits[2:0]

Bit 7 **TYPE0**: Resource type for event 0
- 0: Single selected resource
- 1: Boolean combined resource pair

Bits 6:4 Reserved, must be kept at reset value.

Bits 3:0 **SEL0[3:0]**: Resource / Boolean combined resource pair for event 0
- When TYPE0 is 0, selects a single selected resource from 0-15 defined by bits[3:0]
- When TYPE0 is 1, selects a Boolean combined resource pair from 0-7 defined by bits[2:0]
### ETM event control 1 register (M7_ETM_EVENTCTL1)

Only accepts writes when trace unit is disabled

Address offset: 0x024

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 31:13 Reserved, must be kept at reset value.

- **Bit 12 LPOVERRIDE**: Low power state behavior override
  - 0: Low power state normal behavior
  - 1: Entry to low power state does not affect resources and event trace generation

- **Bit 11 ATB**: ATB trigger enable
  - 0: Disabled
  - 1: Enabled

Bits 10:4 Reserved, must be kept at reset value.

- **Bits 3:0 INSTEN[3:0]**: Instruction trace event element enable
  - Each bit corresponds to an event:
    - 0bXXX0: Event 0 does not cause an event element
    - 0bXXX1: Event 0 causes an event element
    - 0bXX0X: Event 1 does not cause an event element
    - 0bXX1X: Event 1 causes an event element
    - 0bX0XX: Event 2 does not cause an event element
    - 0bX1XX: Event 2 causes an event element
    - 0b0XXX: Event 3 does not cause an event element
    - 0b1XXX: Event 3 causes an event element

### ETM stall control register (M7_ETMSTALLCTL)

Only accepts writes when trace unit is disabled

Address offset: 0x02C

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

- **DSTALL**: Debug stall event enable
  - 0: Disabled
  - 1: Enabled

- **ISTALL**: Instruction stall event enable
  - 0: Disabled
  - 1: Enabled

- **Level[1:0]**
Bits 31:10  Reserved, must be kept at reset value.

Bit 9  **DSTALL**: Stall processor based on data trace buffer space
   0: Do not stall processor
   1: Stall processor

Bit 8  **ISTALL**: Stall processor based on instruction trace buffer space
   0: Do not stall processor
   1: Stall processor

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:2  **LEVEL[1:0]**: Stalling threshold level
   A low level minimizes the amount of processor stalling, with a higher risk of FIFO overflow. A high level minimizes the risk of FIFO overflow but increases the amount of processor stalling.

Bits 1:0  Reserved, must be kept at reset value.

**ETM global timestamp control register (M7_ETM_TSCTL)**

Only accepts writes when trace unit is disabled

Address offset: 0x030

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>Bit 30</th>
<th>Bit 29</th>
<th>Bit 28</th>
<th>Bit 27</th>
<th>Bit 26</th>
<th>Bit 25</th>
<th>Bit 24</th>
<th>Bit 23</th>

</tr>
</tbody>
</table>

Bits 31:8  Reserved, must be kept at reset value.

Bit 7  **TYPE**: Resource type for time stamp insertion
   0: Single selected resource
   1: Boolean combined resource pair

Bits 6:4  Reserved, must be kept at reset value.

Bits 3:0  **SEL[3:0]**: Resource / Boolean combined resource pair
   When TYPE is 0, selects a single selected resource from 0-15 defined by bits[3:0]
   When TYPE is 1, selects a Boolean combined resource pair from 0-7 defined by bits[2:0]

**ETM synchronization period register (M7_ETM_SYNCP)**

Address offset: 0x034

Reset value: 0x0000 000A

<table>
<thead>
<tr>
<th>Bit 31</th>

Bits 31:20 Reserved, must be kept at reset value.

- **Bit 19 EXLEVEL_S3**: Trace disable, exception level 3
  - Disables tracing in the specified exception level in Secure state for exception level 3.
  - 0: Enable ViewInst in this exception level
  - 1: Disable ViewInst in this exception level

Bits 18:17 Reserved, must be kept at reset value.

- **Bit 16 EXLEVEL_S0**: Trace disable, exception level 0
  - Disables tracing in the specified exception level in Secure state for exception level 0.
  - 0: Enable ViewInst in this exception level
  - 1: Disable ViewInst in this exception level

Bits 15:12 Reserved, must be kept at reset value.

- **Bit 11 TRCERR**: Tracing of system error exception
  - Selects whether a system error exception must always be traced.
  - 0: System error exception is traced only if the instruction or exception immediately before the system error exception is traced
  - 1: System error exception is always traced regardless of the value of ViewInst

- **Bit 10 TRCRESET**: Tracing of reset exception
  - Selects whether a reset exception must always be traced.
  - 0: Reset exception is traced only if the instruction or exception immediately before the reset exception is traced
  - 1: Reset exception is always traced regardless of the value of ViewInst

- **Bit 9 SSSTATUS**: Current status of the start/stop logic
  - 0: Stop state
  - 1: Started state

- **Bit 8** Reserved, must be kept at reset value.
Bit 7 **TYPE**: Resource type  
0: Single selected resource  
1: Boolean combined resource pair

Bits 6:4 Reserved, must be kept at reset value.

Bits 3:0 **SEL[3:0]**: Resource / Boolean combined resource pair  
When TYPE is 0, selects a single selected resource from 0-15 defined by bits[3:0]  
When TYPE is 1, selects a Boolean combined resource pair from 0-7 defined by bits[2:0]

### ETM ViewInst start/stop control register (M7_ETM_VISSCTL)

Address offset: 0x088  
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   | STOP[7:0] |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   | rw rw rw rw |
| 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |   |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **STOP[7:0]**: Single address comparator selector to stop trace  
Defines the single address comparators to stop trace with the ViewInst Start/Stop control.
One bit is provided for each implemented single address comparator.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **START[7:0]**: Single address comparator selector to start trace  
Defines the single address comparators to start trace with the ViewInst Start/Stop control.
One bit is provided for each implemented single address comparator.

### ETM ViewInst start/stop processor comparator control register  
(M7_ETM_VIPCSSCTL)

Address offset: 0x08C  
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   | STOP[3:0] |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   | rw rw rw rw |
| 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |   |

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **START[3:0]**: Single address comparator selector to start trace  
Defines the single address comparators to start trace with the ViewInst Start/Stop control.
One bit is provided for each implemented single address comparator.
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:16  **STOP[3:0]**: Processor comparator input selector to stop trace
Selects which processor comparator inputs are in use with ViewInst start-stop control, for the purpose of stopping trace. One bit is provided for each processor comparator input.

Bits 15:4  Reserved, must be kept at reset value.

Bits 3:0  **START[3:0]**: Processor comparator input selector to start trace
Selects which processor comparator inputs are in use with ViewInst start-stop control, for the purpose of starting trace. One bit is provided for each processor comparator input.

**ETM counter reload value register (M7_ETM_CNTRLDV)**

67 Device electronic signature

The electronic signature is stored in the Flash memory area. It can be read using the JTAG/SWD or the CPU. It contains factory-programmed identification data that allow the user firmware or other external devices to automatically match its interface to the characteristics of the STM32H7Rx/7Sx microcontrollers.

67.1 Unique device ID register (96 bits)

The unique device identifier is ideally suited:
- for use as serial numbers (for example USB string serial numbers or other end applications)
- for use as security keys in order to increase the security of code in Flash memory while using and combining this unique ID with software cryptographic primitives and protocols before programming the internal Flash memory
- to activate secure boot processes, etc.

The 96-bit unique device identifier provides a reference number which is unique for any device and in any context. These bits can never be altered by the user.

The 96-bit unique device identifier can also be read in single bytes/half-words/words in different ways and then be concatenated using a custom algorithm.

**Graphics device package:**
0101: UFBGA144 SMPS GFX
0110: UFBGA169 SMPS GFX
1010: LQFP176 SMPS GFX
1011: UFBGA176+25 SMPS GFX
1100: TFBGA225 OCTO
1101: TFBGA225 HEXA

Bits 15:0 Reserved, must be kept at reset value.

The SBS clock should be enabled first in the RCC_APB4ENR register.
The STMicroelectronics group of companies (ST) places a high value on product security, which is why the ST product(s) identified in this documentation may be certified by various security certification bodies and/or may implement our own security measures as set forth herein. However, no level of security certification and/or built-in security measures can guarantee that ST products are resistant to all forms of attacks. As such, it is the responsibility of each of ST’s customers to determine if the level of security provided in an ST product meets the customer needs both in relation to the ST product alone, as well as when combined with other components and/or software for the customer end product or application. In particular, take note that:

- ST products may have been certified by one or more security certification bodies, such as Platform Security Architecture (www.psacertified.org) and/or Security Evaluation standard for IoT Platforms (www.trustcb.com). For details concerning whether the ST product(s) referenced herein have received security certification along with the level and current status of such certification, either visit the relevant certification standards website or go to the relevant product page on www.st.com for the most up to date information. As the status and/or level of security certification for an ST product can change from time to time, customers should re-check security certification status/level as needed. If an ST product is not shown to be certified under a particular security standard, customers should not assume it is certified.

- Certification bodies have the right to evaluate, grant and revoke security certification in relation to ST products. These certification bodies are therefore independently responsible for granting or revoking security certification for an ST product, and ST does not take any responsibility for mistakes, evaluations, assessments, testing, or other activity carried out by the certification body with respect to any ST product.

- Industry-based cryptographic algorithms (such as AES, DES, or MD5) and other open standard technologies which may be used in conjunction with an ST product are based on standards which were not developed by ST. ST does not take responsibility for any flaws in such cryptographic algorithms or open technologies or for any methods which have been or may be developed to bypass, decrypt or crack such algorithms or technologies.

- While robust security testing may be done, no level of certification can absolutely guarantee protections against all attacks, including, for example, against advanced attacks which have not been tested for, against new or unidentified forms of attack, or against any form of attack when using an ST product outside of its specification or intended use, or in conjunction with other components or software which are used by customer to create their end product or application. ST is not responsible for resistance against such attacks. As such, regardless of the incorporated security features and/or any information or support that may be provided by ST, each customer is solely responsible for determining if the level of attacks tested for meets their needs, both in relation to the ST product alone and when incorporated into a customer end product or application.

- All security features of ST products (inclusive of any hardware, software, documentation, and the like), including but not limited to any enhanced security features added by ST, are provided on an "AS IS" BASIS. AS SUCH, TO THE EXTENT PERMITTED BY APPLICABLE LAW, ST DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE, unless the applicable written and signed contract terms specifically provide otherwise.

|                |          | – Figure 33: $V_{CORE}$ voltage scaling versus system power modes  
|                |          | – Section 6.8.4: PWR control register 2 (PWR_CSR2)  
|                |          | – Section 10.3.16: High-speed low-voltage mode (HSLV)  
|                |          | – Figure 1004: APB-D CoreSight component topology |
## Updated:

- Read latency in Table 29: FLASH recommended read wait states and programming delays and Section 5.9.1: FLASH access control register (FLASH_ACR)
- IROT_SELECT value in Table 5.4.7: Description of security option bytes
- Section 5.9.22: FLASH RoT status register (FLASH_ROTSR)
- Section 67.1: Unique device ID register (96 bits)
- Section 67.2: Package data register

## Aligned capitalization:

- (S)VOS LOW -> (S)VOS low
- (S)VOS HIGH -> (S)VOS high
- STiROT -> STiRoT
